The engraving exhibits the method of self-application. The syringe can be very readily placed in position. The nozzle of the pipe rests against the upper wall of the auditory canal, and the tube is securely suspended by means of a perforated elastic curtain attached to the gutter. The new aural syringe will be found a great convenience in every-day practice, saving both time and trouble, and assisting in the efficient treatment of many common aural diseases and accidents. It is manufactured at a very moderate price by Messrs. Maw, Son, and Thompson.

## OBITUARY.

JAMES RUSSELL, M.D. LOND., F.R.C.P., J.P.

FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The annual meeting of this Corporation was held on the 5th instant, for the election of office-bearers. Dr. A. Fergus was re-elected President for the year, and Dr. H. Muirhead, Visitor. On the Board of Examiners Dr. Barlow, Lecturer on Physiology in the Royal Infirmary School, succeeded Dr. James Christie as Examiner in Physiology. The only other changes were the appointment of Dr. N. Carmichael and Dr. J. Dougall as Examiners on Public Health, *vice* Dr. Christie and Dr. Ebenezer Dunnean, who were ruled disqualified from continuing in office.

DR. JAMES RUSSELL, the well-known physician of Birmingham, died after a long illness on the 5th inst. Dr. Russell came of one of the oldest and best connected families in the Birmingham district, where his father long held a leading position as a medical practitioner. Born in 1818, he received his professional education at King's College, London, and took the degree of Doctor of Medicine at the London University in 1848. A few years later he became

a Member of the Royal College of Physicians of London, of which body he was elected a Fellow in 1867. Dr. Russell was for some years physician to the Birmingham General Dispensary, an institution which has had the services of many excellent physicians; in 1859 he was elected physician to the Birmingham General Hospital, discharging all the duties of that office with conspicuous ability and zeal until the end of last year, when he was elected consulting physician. Dr. Russell occupied the chair of all the local medical societies in succession. He took the deepest interest in the Birmingham Medical Institute from its foundation, and was chosen President in 1882. He published many excellent papers, but was chiefly known and esteemed as a clinical physician. On the opening of the present Session at the Queen's College, Birmingham, as we recently recorded, Mr. Augustus Clay stated that 109 past and present students had subscribed to a fund to present an address to Dr. Russell on his retirement from the position of a clinical teacher, which he had continued to hold for some years after he had resigned the Professorship of Medicine at Queen's College. Mr. Clay said that, though Dr. Russell's serious illness prevented the presentation of the testimonial, even privately, the subscribers hoped to do something to perpetuate the name of their most industrious and most kind teacher, towards whom they cherished a feeling which could only be expressed by the word love. Dr. Russell with great difficulty dictated an answer, in which he said that his association with the medical students had always been one of the chief enjoyments and satisfaction of his life. He had formed amongst them many valuable friends, and their kind feeling had been continuously shown to him. Dr. Russell was an excellent example of the provincial consultant. Highly cultured and thoroughly practical, he exercised a most beneficent influence both on his students and his patients, by all of whom he was most highly esteemed.

---

FREDERICK WILLIAM WARREN,  
M.B., M.A. UNIV. DUBL., F.R.C.S.I.

THE death from enteric fever, with albuminuria, of this young and well-known Dublin surgeon, occurred at his residence, 32, Harcourt Street, shortly before midnight on Sunday last, the 11th inst. Mr. Warren was only 33 years of age, and the news of his untimely death caused the greater number of his friends a pained surprise. A graduate in arts and medicine of the University of Dublin, Mr. Warren received his professional education and training at Steeven's Hospital and Medical College, where he was Cusack Medallist and Exhibitor in 1869-70 and 1870-71. In 1870 he won the first Clinical Prize in Surgery. A year later he took the Letters Testimonial of the Royal College of Surgeons in Ireland, proceeding to the Fellowship of that Corporation in 1877. In 1872, he became a Licentiate in Medicine and Midwifery of the King's and Queen's of Physicians, of which body he was enrolled a member in 1882. That he was destined to attain a good professional standing, had he survived, is sufficiently clear from the fact that he was surgeon to the Adelaide Hospital, Dublin. He also held the positions of Demonstrator of Anatomy in the School of Surgery of the Royal College of Surgeons, of Surgeon to the Elliott Home for Children, and of Medical Officer to the Dispensary at St. James' Gate, connected with Messrs. Guinness' world-renowned brewery. Mr. Warren was very popular amongst medical students, who flocked in numbers to his private classes. To the second volume of the *Irish Hospital Gazette* he contributed papers on "Diphtheria" and "Fracture of the Spine," and to the *Medical Press and Circular*, a communication on "The Toxicological and Therapeutical Effects of Carbolic Acid." He was a Fellow of the Academy of Medicine in Ireland, in the sectional meetings of which he often took an active part.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS.

A QUARTERLY meeting of the Council was held on Thursday, the 15th. A motion of condolence with the family of the late Mr. Gay was passed unanimously. In accordance with the recommendation of the Committee of Management of the two Colleges (to whom the question had been referred), it was resolved to inform Mr. Thomas More Madden, in reply to his communication, that the College saw no reason for altering the regulations by adding the Children's Hospital, Dublin, to the institutions at present recognised by them. Mr. Hutchinson was re-elected to the Court of Examiners. A letter was read from Sir James Paget, informing the Council of his readiness to sit for his bust. A report was submitted, approved, adopted, and directed to be presented to the meeting of the Fellows and Members of the College, to be held on the 29th instant, copies of which can be had on application to the Secretary. Mr. John Wood was elected Bradshaw Lecturer for next year. A letter was read, informing the Council that a sum of 1,000*l.* (subject to the life-interest of a daughter) had been left to the College, to be applied annually to the purposes of the Museum and the lectures connected with it. Mr. Hutchinson's motion, seconded by Sir James Paget, that a Committee be appointed to consider the practicability of adding a wing to the Museum of the College, to have for its especial (but not exclusive) object the display of casts, photographs, drawings, &c., illustrating the results of diseases and injury in the living subject. This was agreed to unanimously; Sir James Paget, Mr. Marshall, Mr. Lund, Sir Joseph Lister, Mr. Hulke, Mr. Durham, and Mr. Hutchinson to form the Committee.

The Council then adjourned.

### THE MONT DORE, BOURNEMOUTH.

THIS Institution, the foundation stone of which was laid by the King of Sweden some three or four years ago, is at last completed, and available for public use. Its prototype in the Auvergne has been known and frequented (with long intermissions) for centuries, the still existing ruins of the old Roman baths bearing testimony to the elaborate arrangements which the guests of former days appear to have held as essential to a proper enjoyment of the "cure." Unfortunately, the season at Mont Dore in the Auvergne is very short; moreover, the distance from England is considerable, and thus the advantages of the treatment pursued there can only be enjoyed by a minority of the invalids—rheumatic, gouty, asthmatic, phthisical—for whom it would seem nevertheless to be especially indicated. An attempt has therefore been made to bring the "Mont Dore Cure" over to this country, and Bournemouth has been selected as the place at which to establish it. Apart from the fact that there is some similarity in the climate of the two places, it is further thought that Bournemouth offers peculiar advantages of its own. It is built on sand and gravel, a fact, which keeps the place dry even in wet weather; charmingly situated on the sea, facing south and west, it is walled in on the north by rising ground and a wide belt of fir plantations, which, besides cutting off the cold winds, are supposed to exhale certain empyreumatic vapours possessing curative properties for all chest complaints. The mildness of the climate can be guessed from the abundance of evergreen shrubs, which fill the gardens by which the majority of houses are surrounded, and which form so striking a feature to visitors arriving in midwinter. The Mont Dore, or as some writers prefer it, Mont D'Or, as now completed, is not merely an hotel, but an establishment fitted with probably the most elaborate system of baths for medical

purposes to be found in this or any country. Neither expense nor ingenuity has been spared to make the arrangements perfect, and there can be little doubt that as soon as it becomes more widely known, visitors will prefer the new establishment, the advantages of which they can get in their own country, under their own medical men, and at any time of the year, without the need of a long, tedious and expensive journey across the channel, to the Mont Dore of Auvergne, its hot springs and mountains notwithstanding. The question of the mineral waters is to be solved by importing direct from the original sources, and heating artificially to the required point. For external purposes it seems very doubtful whether mineral water need be used at all; in the form of vapour the merest, if any, traces of the solid ingredients will be found; while for pulverising and drinking, of course the imported water, when heated, will be as effectual as if taken at the source. In the pulverisation rooms, which are one of the special features of the "cure," a series of differently shaped steam jets are at work, so that ears, eyes, or throats can be sprayed, and any number of patients can "take the cure" together. Those who are familiar with the antiseptic steam spray can form a very good idea how this part of the treatment is carried out; the thoroughness with which the water is pulverised depends on the fineness of the jets and the steam power employed. Nothing was said at our visit about the antiseptic treatment of chest disease; perhaps the medical advisers of the Mont Dore directors trust more to the vivifying influences of the "cure" than to any special mode of antiseptic treatment properly so called; in this they are probably right. It will be interesting to observe whether English invalids will be able to divest themselves of the idea that a foreign watering place is preferable to one in their own country. With cholera said to be still prevalent in South Europe, it must be agreeable to some invalids at least to know that so good an alternative can be enjoyed at Bournemouth; and it may be hoped that in due time, the fashion to patronize Bournemouth as a winter residence for its own sake, will set in with greater force, for the place enjoys certain natural advantages, which are not to be gainsaid and which are capable of great development. The new Mont Dore will serve as an additional attraction, and if carefully and economically conducted it may prove equally useful to the place, to its promoters and its visitors. The scale of charges is perhaps a little too high, except for better class patients. The directors would do well to revise it, with a view to attract patients in larger numbers, and so make its capabilities more rapidly and more widely known.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in Physiology only at a meeting of the Board of Examiners on the 8th inst., and when eligible will be admitted to the pass examination, viz. :—

Alfred E. Vaughan and Thomas A. Murray, Owens College, Manchester; D. W. Liebstein and W. S. Routledge, University College; Bruce Hamilton and Henry Hamilton, Bristol School of Medicine; John H. Clayton, John E. Foster, William M. Joyce and Matthew H. Vinrace, Birmingham; James E. Syme, Edgar N. Darwent and Thomas Walcott, University of Edinburgh; Walter Mitchell, Sheffield; Rhodes Hebblethwaite, Leeds School of Medicine; James Magauran, Dublin; Frenzt W. Guiselin and Francis a Brooks, St. Mary's Hospital; J. F. G. Alexandre, Bâle; Albert E. Tebb, G. W. A. Mitchell and Hubert Joslem, Guy's Hospital; Charles Mattei, Malta, and St. Thomas's Hospital; Frank Heasman, Sidney H. Badcock, and John More, St. Bartholomew's Hospital.

Passed in Anatomy and Physiology on the 9th inst. :—

Norman Allen, Harold H. Hawley and John Rannie Logan, Toronto; Samuel L. Melville, Liverpool; Robert N. Fraser, Kingston, Canada; James W. H. Steil, Glasgow; Ernest H. Gibbon, Newcastle; Horatio Edward Rawliugs, Birmingham; Kilham Roberts, Bristol School of Medicine; Alfred B. Jones, Middlesex Hospital; Frederick J. Nisbet, Guy's Hospital; Frank D. Bennett, St. Bartholomew's Hospital.

Passed in Anatomy only :—

Edward Foxton, Kingston, Canada; William H. Robinson, St. Thomas's Hospital; Frederic C. Wood, London Hospital; James H. Harrison, University College; H. J. Holman, Guy's Hospital.

Passed in Physiology only :—

Kenneth T. Stewart, Edinburgh University; Arthur J. Lambert, Leeds School of Medicine; George S. Pope, Frederick P. Moles

and Joseph F. Wright, Manchester; Frederick W. Walker, Edinburgh and Aberdeen Universities; John C. Dickinson and John P. De Buriatte, London Hospital; Alexander T. Harrison, Guy's Hospital.

Passed in Anatomy and Physiology on the 12th inst. :—  
Stephen Joseph Daly and Keneth McLaren, St. Bartholomew's Hospital; Christopher Robertson, St. Thomas' Hospital; Harold D. B. Castle, King's College; Theophilus W. Mead, St. George's Hospital; Robert H. Gilpin, Middlesex Hospital; George G. Borrett, London Hospital; J. M. C. Cole, Belfast; James Pearson and William Mitchell Cotton, University Hospital.

The following passed in Anatomy only :—

John Henry Austin, St. George's Hospital; Lewis St. John Reilly, London Hospital; Reginald Stilwell Freeland, Guy's Hospital; William Louis Abbott, Pennsylvania.

The following passed in Physiology only :—

Richard G. Pollock, Frederic G. Vicars, and A. L. Devcnish-Meares, Guy's Hospital; Martin A. Kirton, London Hospital; Stafford L. Archer, King's College; Charles H. Stevens, University College.

Passed on the 13th inst. in Anatomy only :—

Thomas A. Quirk, Melbourne University; Edmund Capper, Benjamin P. Johnson, Locke MacDona and T. Eyton-Jones, Liverpool; J. D. O'Sullivan, Dublin; John Fullard, Birmingham; J. W. Whitehead and Herbert Burland, Manchester; John Wilkins and William F. Fisher, London Hospital; Herbert L. Hudson, Sheffield; Arthur C. Elliman and John W. Emmet, Guy's Hospital; Frank Brightman and Charles H. Clayton, University College; Thomas S. P. Sparrow, King's College.

Passed in Physiology only :—

Alfred W. Waller and Henry B. Shepperd, St. Thomas's Hospital; Walter Watkins, Francis H. Lowe, and A. E. D. R. Peters, St. Bartholomew's Hospital; George Barton and F. B. H. Caudwell, Charing Cross Hospital; A. E. G. Roberts, St. Mary's Hospital; James D. Brown and O. W. Andrews, St. George's Hospital; William C. Burt, C. R. H. Buckley, George J. Cressy and Hugh F. Knyvett, Guy's Hospital; William W. Craig and Anthony Gorney, University College; George E. Price and Mark B. Dumaresq, London Hospital.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on Thursday, October 8th, 1885 :—

Edward Samuel Goody, M.R.C.S., 58, Kennington Road, S.E.

On the same day the following gentleman passed his examination in the science and practice of Medicine, Surgery and Midwifery, and received a certificate to practise, viz. :—

John Oddy Ward, Kippax, near Leeds.

The following gentlemen also on the same day passed their Primary Professional Examination :—

James George Burgess, Guy's Hospital; Henry Scarborough Cooper, Westminster Hospital; Henry Tottenham West, Belfast Hospital.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the usual Quarterly First Professional Examination, held on Monday, October 5, 1885, and following days, the undermentioned candidates were successful :—

Jean Helen Grant, London; Philip Lee, Monkstown, Co. Cork.

At the ordinary Monthly Examinations for the Licences of the College, held on Monday, October 5, and following days, the undermentioned candidates were successful :—

*For the Licence to Practice Medicine*—

Clarinda Boddy, London; Ambrose Birmingham, Ballinrobe, Co. Mayo; William E. Le Fanu Hearn, M.B. Melbourne Univ., Hamilton, Victoria, Australia; Gerard Irvine, Irvinetown.

*For the Licence to Practise Midwifery*—

Ambrose Birmingham; John Cuthbert, Bromsgrove, Worcestershire; Edward W. Gray, M.B. Univ. Dublin, Newry; William E. Le Fanu Hearn, M.B. Univ. Melbourne; Gerard Irvine; William J. R. Knight, M.D., A.U.I., Cookstown, Co. Tyrone; James Alexander Lindsay, M.D., R.U.I., Belfast; Edward L. Pooler, M.D., R.U.I., Newtownards.

The undermentioned Licenciate in Medicine, having complied with the by-laws relating to Membership, pursuant to the Supplemental Charter of December 12th, 1878, has been duly enrolled a Member of the College :—

Theophilus William Trend, Lic. Med. 1863, Raeberry Lodge, Southampton.

**ROYAL COLLEGE OF SURGEONS.**—The Library of the College will be closed on Tuesday, the 20th inst., for the purposes of the pass examination for the Membership.

**THE GRAEFÉ PRIZE.**—Shortly after the death of Professor von Graefe, a triennial prize was founded in his honour by Professor Welz to be given to the contributor of the best paper to the *Archiv für Ophthalmologie*. The judges, selected from the members of the Ophthalmological Society in Berlin, have awarded the prize for the past three years to Dr. Samuelson, of Cologne, for his paper on "Retrolubar Neuritis."

**SURGEON-GENERAL J. H. INNES, C.B.**, Honorary Surgeon to the Queen, has had bestowed upon him a distinguished service reward.

The vacant professorship of Ophthalmic Surgery in the University of Warsaw has been conferred upon Dr. Wolfring, extraordinary professor.

It has been decided that the memorial of the late Mr. R. B. Maekie, M.P., shall be an extension of the Wakefield Convalescent Home.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on the 13th instant, Sir W. R. E. Smart, K.C.B., M.D., Inspector General in the chair, the sum of 77*l.* was distributed among the several applicants.

The German Imperial Sanitary Board, which has been hitherto only a consultative body, is shortly to have its scope and functions greatly enlarged, all the medical and veterinary affairs of the Empire being placed under its authority. The Board is also to receive executive powers.

**SEAMEN'S HOSPITAL, GREENWICH.**—At the Quarterly General Court of the Governors of this Hospital, held on the 9th instant, the principal medical officer reported the hospital to be absolutely free from erysipelas and similar diseases, now that the drainage works were completed.

**THE JERVIS STREET HOSPITAL, DUBLIN.**—The new building will be opened for the reception of patients and clinical study on the 29th instant. The wards are on the ground floor and three storeys above. The basement provides accommodation for the dispensary apartments, for the medical men, corridor, waiting rooms, lavatories, &c.

**THE CITY OF DUBLIN HOSPITAL.**—The secretary has received a cheque for 120*l.*, the proceeds of an amateur performance lately given at the Queen's Theatre for the benefit of the hospital. He has also received 50 guineas from the Leicester Cricket Club, the proceeds of a match played in September last in aid of the funds of the hospital.

**THE ROYAL INFIRMARY, EDINBURGH.**—To utilize two (in which twelve beds each can be placed) of the four large rooms on the ground floor, at the south end of the four medical pavilions, hitherto unused, improvements are being made by which an addition of 24 beds will be available for the medical professors, without increasing the nursing staff. The estimated cost is about 400*l.*

**LONDON SCHOOL OF MEDICINE FOR WOMEN.**—Seventeen first year's students have entered this session, including one for anatomy only. The entrance scholarship, value 36*l.* has been awarded to Miss Annette M. Benson, and the John Byron Scholarship, value 25*l.* a year for four years, tenable at the discretion of the Executive Council, to Miss Gabrielle Breeze.

**SANITARY ASSURANCE ASSOCIATION.**—At the monthly meeting of the Council of this Association on Monday last, Sir Joseph Fayrer, K.C.S.I., F.R.S., in the chair, it was resolved on the motion of Mr. Mark H. Judge, A.R.I.B.A., seconded by Mr. Andrew Stirling, to arrange for another series of free lectures on sanitary subjects during the coming winter. Professor Roger Smith, F.R.I.B.A., will deliver one of the series.

**THE INCOME TAX.**—We desire to call the attention of the Medical Schools and all whom it may concern to a notice which appears in our advertisement pages, to the effect that all bodies corporate and unincorporate are required to pay a duty at the rate of 5 per cent. upon the annual value, income, or profits accruing to them from their real and personal property, and that, with a view to the assessment of the duty, all such bodies are bound,

under heavy penalties, to render returns, supported by full accounts, before the 1st December next, to the Secretary, Inland Revenue Department.

**MEDICAL SOCIETY OF LONDON.**—The Lettsomian Lectures will be delivered on January 4th and 18th and February 1st in the ensuing year by Mr. Jonathan Hutchinson, the subject being: "On some moot points in the Natural History of Syphilis." The annual Oration will be delivered on May 3rd by Dr. R. Douglas Powell. The subject of the Essay for the Fothergillian Gold Medal to be awarded in March, 1886, is "The Nature of the Fevers usually termed in this country Febricula, Simple, Continued, and Modified Typhoid"; for that to be awarded in the following year, "On the Methods and Results of Operative Treatment in Malignant Disease." Essays are to be sent to the Registrar, at the Society's House, on or before the 1st of November next preceding.

**SCHOLARSHIPS AT THE MEDICAL SCHOOLS.**—At St. Bartholomew's Hospital Medical College the open scholarships in science of 130*l.* for candidates under 25 years of age, have been awarded to Mr. J. Kerr, B.A., and Mr. Jones, B.A., both of St. John's College, Cambridge (equal); and that of 130*l.* for candidates under 20 years of age, to Mr. A. Stevens. The Jeaffreson Exhibition of 50*l.* has been awarded to Mr. Williamson. At University College, the Entrance Exhibition, of the value of 100*l.*, has been awarded to Mr. T. L. Pennell; that of the value of 60*l.* to Mr. J. B. Mitra; and that of the value of 40*l.* to Mr. J. J. Maenamara. The following have been awarded Open Scholarships in Natural Science at St. Thomas's Hospital:—Arthur Francis Stabb, scholarship, 100*l.*; Seymour Graves Toller, scholarship, 60*l.* C. R. Box, A. C. Lankester, T. A. Dukes, and M. C. Clutterbuck obtained the number of marks qualifying for a scholarship.

**LONDON TEMPERANCE HOSPITAL.**—A new wing attached to this hospital was formally opened last week by the Bishop of London. Four wards with a total of 70 beds have thus been added to the accommodation of the institution, making in the entire building 122 beds. The arrangements of the new wards and the dormitories for the nurses above them were highly approved of. Five hundred and eighty-four in-patients, and 2,000 out-patients passed through the hospital last year, and since its foundation—between eleven and twelve years ago—22,500 have availed themselves of its treatment. The necessity for the present extension is exemplified by the recent overcrowded condition of the hospital.

**ROYAL COLLEGE OF SURGEONS.**—We may remind our readers that a General Meeting of the Fellows and Members of the College will be held on Thursday afternoon, October 29th, at 3 p. m., to receive a Report of the Council. With a view to facilitate business, it is hoped that copies of any suggestions or recommendations which are to be brought forward by Fellows or Members expressive of their opinion on any of the matters comprised in the Report (a copy of which can now be had on application) will be furnished to the Secretary a few days previous to the Meeting.

**THE ELECTRIC LIGHT IN MEDICINE.**—At the conversation at Guy's Hospital the other evening, Messrs. Woodhouse and Rawson, to whom the whole of the electrical illumination had been entrusted, exhibited some incandescent lamps for laryngoscopic and dental purposes; the contrivance for increasing or diminishing the light was especially neat, this being effected by sliding a moveable ring up and down a coil of German silver wire wound spirally round the handle. The current for these and the other forms of lamps exhibited was obtained from a special form of Leclanché battery devised by the exhibitors. In addition to the above instruments for applying the electric light to surgical purposes were also shown by Messrs. Down, who had besides on view the latest novelties in the way of sphygmographs, ophthalmoscopes, &c., and various surgical instruments, including Gowan's new osteotome for division of the neck of the femur.

**THE UNIVERSITY OF EDINBURGH BUILDING FUNDS.**—At the last meeting of the Edinburgh Town Council a letter

was submitted from Professor Turner, the interim-convenor of the Building Committee of the University Buildings Extension, asking the Council's consideration of the appeal now being made for funds to complete the new educational buildings of the University. At the beginning of the year a sum of 15,000*l.* was still required. Mr. William M'Ewan subscribed then 5,000*l.*, and he had commanded this sum to be made available so soon as the remaining 10,000*l.* should have been subscribed. The sum of 7,000*l.* had since been subscribed, and there remained only 3,000*l.* yet to be obtained. He hoped that the Town Council, which had taken so practical an interest in the University, by subscribing 3,100*l.* to the original fund, would take this appeal into consideration. The Committee, it was added, had great hope that they would soon be able to close the subscription list for the educational buildings of the University. It was resolved to remit the letter to the Lord Provost's Committee for report.

**CHARITABLE BEQUESTS.**—Mr. Fletcher, late of Rosebaugh, has bequeathed 500*l.* to the Northern Infirmary, Inverness. Mr. Hugh Blayney, late of Dublin, has bequeathed to his executors 256 shares of the Bank of Ireland Stock, equal to 310*l.* each share, in trust to pay over the dividends or annual profits of same from time to time to the following, among other institutions:—The dividends of 10 shares to the St. Vincent's Hospital and Dispensary, St. Stephen's Green; also of 5 other shares to the Magdalen Asylum, Dominick Street, Dublin; also of 5 other shares to the St. Mary Magdalen Asylum, Donnybrook; also of 10 other shares to the Jervis Street Hospital; also of 20 other shares to the Mater Misericordiae Hospital; also of 5 other shares to the Deaf and Dumb Institution for Boys at Cabra; also of 5 other shares to the Incurable Hospital, Donnybrook; also of 5 other shares to the Buckingham Street Hospital, Dublin; also of 5 other shares to the Cork Street Hospital, Dublin; also of 5 other shares to the Coombe Lying-in Hospital; and a.l.o., of 5 other shares to Mereer's Hospital.

**POOR LAW MEDICAL OFFICERS' ASSOCIATION.**—At a meeting of the Council of this Association, held at their rooms, 3, Bolt Court, the subjoined resolution was unanimously adopted:—"That this Council having perused the correspondence relating to the epidemic of small-pox in Camberwell, regrets to find that two medical members of the Board have unjustifiably and on apparently insufficient grounds opposed the grant which was proposed to be given to the district medical officer for extra services in visiting and attending a great number of non-pauper cases of small-pox, more especially as at the same meeting a gratuity was granted to the relieving officers for the extra work they had performed in connection with such cases. And this Council further desires to express its recognition of the courteous and kind consideration exhibited by Dr. Massey in his advocacy of the just claims of such officers."

**HEREDITY AND INSANITY.**—Dr. Manning, the Inspector-General of the Insane in New South Wales, has lately investigated the family history in 21 families where two or more of the children were afflicted with mental weakness, the result of his labours being given in a short paper in the *Australasian Medical Gazette* for August. The 21 families yielded a total of 82 children, of whom 50, 29 males and 21 females, were imbecile or idiotic. In five of the families the parents were related, in two being first cousins, and in three brother and sister; in three families nothing was known of the parents, and in the rest it was ascertained that there was no blood relationship between them. In only one of the families could no insanity be traced amongst the relations of either parent; in three, no information could be obtained; whilst in the rest a strong family history could be made out in nearly all, and in five there was an insane inheritance on both sides. Dr. Manning concludes that in a large proportion of cases, idiocy is dependent upon hereditary influences, and that the marriage of those who are or have been insane, or in whose families insanity is known to exist, ought to be discouraged as much as possible. As regards consanguineous marriages, he agrees with Dr. Withington, whose paper was noticed in a recent number, that apart from inheritance they are not injurious.

**A NEW CODER ON THE AMERICAN DISSENSIONS.**—Dr. Jacobi, who has been removed from his official position in connection with the Washington Congress as one of the chief supporters of the New Code of Ethics, recently delivered an address as President of the New York Academy of Medicine, in which he spoke very gloomily of the prospects of the Congress. "It need not matter," he said, "how much may have, nay, has been done to mar the success of the next International Assembly, and to deprive us of the opportunity long looked forward to of greeting the giants of science, the celebrated teachers, the ingenious experimenters, and our literary or personal friends of Europe, on our own soil. For an International Congress will never convene under the roof of a house divided in itself, though the division may be the work of a few sacrilegious hands only. But this is a sad theme, deplored by everybody who feels, as both a personal grief and a public calamity, the humiliation which is involved in the hesitation on the part of the Congress to assemble in our country." On the relation of the Code Question to the present dissensions, he said: "The code question is dying a great deal more easily than the bloody shirt disappeared from the politics of the country. If it is puffed up as the pivot of the organization of the International Congress, everybody is perfectly aware that this is either a pretext or a grave mistake. I believe it is both. Europeans, who were not afraid of admitting laymen and homœopaths, expected to meet, if ever they should consent to cross the Atlantic for an International Congress, the American medical profession. No International Congress must be caught in domestic quarrels, or audaciously kidnapped by a society, or a party, or the faculty of a medical school. We are presenting a sad spectacle. In our first attempt at welcoming the medical world to our shores we have failed. The humiliation connected with this fact we have to submit to; to trace it to all its causes I can not undertake here. The least we can do is to admit it; if the task we hoped to accomplish was too much for us, let us try to prepare for the future by attending to those duties of our own which we can perform without hindrance or disturbance."

**THE MONTREAL EPIDEMIC AND VACCINATION.**—The present epidemic of small-pox is furnishing incidentally some evidence as to the utility of vaccination. From August 1st to September 14th, the total number of cases was close upon 1,000, and the number of deaths about 330. The very large majority of the victims were French Canadian Catholics. Thus, out of 128 cases occurring last week, all but five were Catholics, while of the total number of deaths, since August 1st, only 34 have been Protestants. It appears that the Canadian Catholics, on religious grounds, do not allow themselves to be vaccinated—hence the force of the epidemic is spent on them. No doubt uncleanly modes of life have also something to do with the excess.—*New York Medical Record*, September 19.

**ST. GILES' DISTRICT.**—The annual report of the Board of Works for this district, together with the report of Dr. Lovett, the Medical Officer of Health, for the year ending March 25th, 1885, has lately been published. After making the necessary corrections for the deaths of parishioners in public institutions outside the district boundaries, the total number of deaths was 1,220, equal to a death-rate of 26.1 per 1,000. The deaths were, however, very unequally distributed between the two portions of the district. Thus, in Bloomsbury the death-rate was 16, showing a decrease from last year's return, whilst in St. Giles' it was 31.7; in the northern part of this sub-district being 23 per 1,000, and in the southern, 38.9. This extraordinarily heavy death-rate is attributable partly to the fact that the workhouse is situated in this area, but more especially to the insanitary state of the Shelton Street area. This street has been for some years a source of great annoyance to the Medical Officer of Health; in 1877, in consequence of his representations, the whole of the north side was dealt with under Torrens' Act, and put into repair, but the houses were too old and the people too uncleanly and destructive in their habits for the improvements to last long, and very soon the houses were in as bad a condition as before. Ever since then Dr. Lovett has been trying to have them demolished, but thus far without success, the delay being due to the

inaction of the Metropolitan Board of Works and the authorities at the Home Office. The following facts in reference to this particular street are sufficiently startling, we should have supposed, to arouse even the official mind to realise that it is time something should be done. In 1884, the general death-rate was 56·8 per 1,000, the zymotic death-rate was 21·8, and the death-rate of children under 5 was 36·4. Ten years ago there were two other areas in the district which vied with this one in insanitary conditions; they have both, however, been done away with, and are now replaced by Peabody buildings. In one, the Great Wild Street area, the new buildings have been long enough erected to afford some evidence of the advantages of the alteration, and last year we find that there the death-rate was 22·6.

**CHLORAL AND OXIDIZING AGENTS.**—M. Cotton, who has been making researches on the chemical relations of chloral hydrate, finds that yellow oxide of mercury decomposes an aqueous solution of chloral, forming carbonic acid, carbonic oxide, and oxychloride of mercury. The red oxide acts similarly, but less energetically. Permanganate of potassium decomposes chloral, forming chloroform and peroxide of manganese, and disengaging oxygen, chlorine and carbonic acid. Chromic acid acts violently on crystals of chloral hydrate, forming carbonic acid and carbonic oxide. It does not decompose solutions of chloral unless heated. Chromic acid and permanganate of potassium do not act on chloroform, bromoform, or iodoform. Yellow oxide of mercury does not act on the two former substances, but decomposes iodoform with evolution of carbonic oxide and carbonic acid.

**THE MEDICAL PRESS GAGGED.**—A Russian journal of hygiene entitled *Health*, has just been suppressed by a tribunal consisting of several high officials, including the minister of education himself, and representatives of the ministry of justice, and the ministry of the interior. Curiously, too, the legal adviser of this triumvirate was the ecclesiastical lawyer of the Holy Synod, so that we may consider that not only law, justice, and education, but even religion itself was invoked in order to put away the accursed thing. We are not told whom our unfortunate contemporary had offended, or whose property was depreciated by its articles, but we dare say that the individual, whoever he may have been, was very thankful that he lived in a despotic country where inconvenient utterances could easily be stopped.

**THE EPIDEMIC OF TYPHOID FEVER IN TUNIS IN 1882.**—The French official report of the severe epidemic of typhoid fever, which occurred in the army and in Tunis in 1882, has only recently been published, and from it the *Union Médicale* (September 8) gathers the following facts. This disease was the second in frequency of those which attacked the expeditionary force, affections of the alimentary canal occupying the first place. Among the 20,000 men who constituted the corps, 2,400 fell victims to the disease, the young recruits especially suffering, so that of 4,200 cases of declared typhoid, 2,000 had not been more than seven months in the service. To the mischievous effects of this short period of service, the inordinate fatigues to which the troops were subjected have to be added. Chief clinical characters of the disease were the rapidity of its course, the frequency of adynamia, the predominance of intestinal lesions, the relative rarity of pulmonary localisations, and the frequency of sudden death. The fatal termination supervened so rapidly that in a sixth part of the deaths it is returned as sudden. This termination was in great part due to the bad ambulance accommodation which numbers declined to avail themselves of preferring to die in their clothes on the ground or on the litters. Among the most frequent complications towards the end of the epidemic was diphtheria.

**THE METROPOLITAN ASYLUMS BOARD.**—The usual meeting of this Board was held on Saturday last. The returns respecting small-pox in the metropolis showed that the epidemic which had long prevailed was steadily dying out. During the fortnight there had been received in all 36 cases, as against 75 in the previous fortnight. Of these five had been received in the South Eastern Asylum and

31 had been received on the hospital ships. During the fortnight six had died, 66 had been discharged, and 130 remained under treatment, of whom 129 were on the ships and one was in the South Eastern Asylum. The number left a fortnight ago under treatment was 155. Sir E. H. Currie stated that, the small-pox having now shown itself to be spent, the question arose whether the managers should proceed with the proposed buildings on the site at Darenth. He moved:—"That it should be referred to the General Purposes Committee to consider and report as to the nature, extent, disposition, and qualifications of the accommodation which, in the opinion of the committee, should be provided for the reception of small-pox patients, and that, pending the receipt of the report of the committee, the consideration of the plans for the proposed buildings at Darenth should be adjourned." Mr. Carr seconded the motion, which was agreed to. Sir Edmund Currie then brought under notice the report of the General Purposes Committee on a letter from the Local Government Board respecting the maintenance of wards in the urban asylums for the reception of small-pox cases. Sir Edmund pointed out that the managers had kept up such wards in two of the asylums, the Eastern and the South Eastern, and that while no patients had been received in the former, during the last fortnight only six had been received in the latter. The receptions in all during the fortnight only amounted to half the number which used to be received daily. Under these circumstances it was quite unnecessary, seeing the completeness of the arrangements, moreover, for taking the patients down to the ships, to keep up staffs at the several asylums in London. He moved that the following resolution be agreed to:—"That the Local Government Board be informed that the managers adhere to the opinion expressed in the report of the General Purposes Committee—namely, 'That it is not the desire of the managers in non-epidemic times to incur the very considerable expense which would necessarily follow the retention of a staff of officers for the reception and treatment in the five metropolitan fever hospitals of the comparatively few cases of small-pox which experience has shown will probably have to be treated, when the patients could all be more economically and quite as satisfactorily treated under one administration in the hospital ships at Long Reach; and that the managers have every reason to anticipate, from the return of the number of patients remaining under treatment in the hospitals of the Board and from the very few cases which are at present being removed daily to hospitals, that the present epidemic is virtually at an end. That the Local Government Board be urged to no longer withhold their sanction to the temporary closing of the small-pox isolation wards at the North Western, South Western, and Western Hospitals, keeping open those at the South Eastern and Eastern Hospitals.'" The motion was carried.

**THE SALE OF FOOD AND DRUGS ACT IN EDINBURGH.**—An important report on the analysis of food, for the quarter ending September, was recently submitted to the Edinburgh Town Council, by Mr. J. Falconer King, the city analyst. During the quarter he had received 15 samples for analysis—3 samples of butter, 4 samples of milk, 2 samples of condensed milk, 3 samples of whisky, 2 samples of water, and 1 sample of confections. Of the three samples of butter, one was found to be genuine as far as freedom from admixture with foreign fat was concerned. It contained, however, nearly 11 per cent. of water. The other two samples were most extensively adulterated, containing, indeed, little or no real butter, and being composed almost entirely of grease, salt and water. Of the four samples of milk, three proved to be genuine. The samples of condensed milk were both prepared from milk, which had evidently been much reduced in quality by having had the cream abstracted. The three samples of whisky were all genuine. The sample of confections might be classed as genuine, although it contained a small quantity of a metallic compound, added evidently as a colouring agency. The two samples of water were both impure. One was contaminated to such an extent by deleterious matter as to be quite unfit for use, and the other contained a distinct proportion of a soluble compound of lead. The report

also drew attention to the disadvantages under which they at present laboured in their attempts to stop the sale of adulterated food in the city. He was perfectly convinced that in Edinburgh at the present time a very large proportion of the food which was disposed of, especially to the poorer classes, was neither what it ought nor what it was represented to be; and in many cases where an attempt was made by the inspectors, who are unfortunately too well known to the sellers, to purchase samples of those adulterated materials in order to have them analysed, they were told that none of the articles which they happened to ask for was kept. Quite recently, a case of this kind occurred. A short time after hearing this, he sent a lad, poorly dressed, to one of these shops, and he was served at once when he asked for half-a-pound of butter. The material which was given him was found, on being analysed, to be adulterated so largely as to be hardly deserving of the name of butter. This being the state of matters, he was of opinion that, until some change was made in the mode of procuring samples, it would be impossible to stop the sale of much of the adulterated food which was at present sold in many parts of the city.

**A DUTCH OBSTETRIC CHARITY.**—The *Weekblad* publishes some interesting statistics of the Obstetric Charity at Gravenhage, which has now been nine years in existence. The confinements are as a rule attended by midwives; but in difficult cases the medical man in charge of the Charity is called in. During the whole 9 years 13,818 cases have been attended, the doctor being called in 1,253 of these; 949 operations were performed, resulting in 16 deaths of mothers and 142 of children. The number of cases during the past 12 months was 2,204, in 362 of which medical aid was sent for, operations being performed in 127 cases, one mother and 15 children dying. The forceps were used in 73 cases, all the mothers living and 68 of the children. There were 19 breech cases; all the mothers lived, but 4 children died. The foot presentations were 12 in number; one of the children was putrid. There were 5 cases of placenta prævia with no maternal deaths. There were 2 cases of triplets, in one of which a boy was born in the first cranial position, two girls following as footlings. Two placentas existed connected together. The children were very small, and all died within a week. There were no cases of puerperal convulsions.

### APPOINTMENTS.

- ANDERSON, JOSEPH, M.B. and C.M. Aber.—Senior House Surgeon to the Preston and County of Lancaster Royal Infirmary, *vice* C. J. Heath, M.R.C.S., L.S.A. Lond., resigned.
- APPLETON, HARRY, M.R.C.S., L.S.A.—Medical Officer to the Second Division of the Second District, Helston Union, *vice* Mr. G. Appleton, resigned.
- BARRON, ALEXANDER, M.B. Lond.—Curator of the Pathological Museum, University College, Liverpool, *vice* F. T. Paul, F.R.C.S., resigned; Assistant to the Professor of Pathology, University College, Liverpool, and Medical Tutor to the Royal Infirmary, Liverpool, *vice* E. Hyla Greves, M.D., resigned.
- COLLIER, JOSEPH, M.B., B.Sc. Lond., F.R.C.S. Eng.—Resident Surgical Officer to the Manchester Royal Infirmary, *vice* Mr. II. W. Pigeon, resigned.
- DAY, PERCY H., L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Stalmine District, Garstang Union, *vice* Dr. H. Barton, resigned.
- DAYMAN, BARNFIELD, L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the Third District, South Stoneham Union, *vice* Mr. Henry Dayman, deceased.
- DUNCAN, WILLIAM, L.R.C.S. Edin., L.M.—Medical Officer to the Nunney District, Frome Union, *vice* Mr. W. H. Wood, resigned.
- EMRYS-JONES, A., M.D. Edin., M.R.C.S. Eng.—Visiting Ophthalmic Surgeon to the Bolton Infirmary.
- FENNELL, THEODORE, M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Tabley District, Altrincham Union, *vice* Mr. W. H. Sutcliffe.
- HASELL, E. S., M.R.C.S. Eng., L.S.A.—House Surgeon to the Northern Branch of the Brighton, Hove, and Preston Dispensary.
- HEARNDEN, WALTER CARRINGTON, M.R.C.S. Eng., L.S.A.—Medical Officer to the Leatherhead District, Epsom Union, *vice* Mr. Allan MacLean, resigned.
- HOWARD, HERBERT, L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the Third District, Depwade Union, *vice* Mr. H. F. Howard, deceased.
- LANE, JOHN E., M.D. Qu. Univ. Ire.—Medical Officer to the Thames Ditton District, Kingston Union, *vice* Dr. Holdsworth, deceased.
- MAYNARD, FREDERICK, M.B. Durh., M.R.C.S., L.R.C.P. Lond.—Assistant House Surgeon to the Preston and County of Lancaster Royal Infirmary, *vice* W. F. Moore, promoted.
- MCCARTHUR, DUNCAN R., M.B. and C.M. Edin.—Medical Officer to the Workhouse and to the Minton District, Sturminster Union, *vice* Mr. J. Turgewell, resigned.

- MOORE, W. F., M.B. Durh., M.R.C.S.—Junior House Surgeon to the Preston and County of Lancaster Royal Infirmary, *vice* J. Anderson, promoted.
- NOBLE, JOHN, M.B., C.M. Edin.—House Surgeon to the Barnhill Hospital, Glasgow, *vice* Dr. Gibb, resigned.
- NUGENT, GUY, M.B.—Physician to the Richmond Hospital, Dublin, *vice* the late Dr. Benjamin McDowel.
- NUNN, JOHN R., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Peckham District, Alcester Union, *vice* Mr. J. W. Leacroft, resigned.
- PALMER, FRANCIS C., L.K. and Q.C.P. Irel., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Sapperton District, Cirencester Union, *vice* Dr. Cawthorne, resigned.
- POWELL, J. H., M.R.C.S., L.R.C.P.—House Surgeon to the Weston-super-Mare Hospital and Dispensary.
- RATTRAY, ALEXANDER, M.D. Edin., L.R.C.S. Edin., L.S.A. Lond.—Medical Officer to the Wymondham District, Melton Mowbray Union, *vice* Mr. R. Johnstone, resigned.
- ROGERS, WILLIAM F. C., M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Sithney District, Helston Union, *vice* Mr. E. Rundle, resigned.
- RUSSELL, JOHN H., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Cheshunt District, Edmonton Union, *vice* Mr. E. W. B. Garlike, resigned.

### VACANCIES.

- BURNLEY UNION.—Medical Officer to the Padiham District, in succession to Mr. John G. Booth, deceased. Area, 12,871 acres. Population 13,985. Salary, £45 per annum.
- CENTRAL LONDON OPHTHALMIC HOSPITAL, GRAYS INN ROAD, W.C.—Assistant Surgeon. (*For particulars, see Advertisement.*)
- DROITWICH UNION.—Medical Officer to the Hanbury District, in succession to Mr. R. Holyoake, resigned. Area, 10,204 acres. Population, 3,274. Salary, £85 per annum.
- HAVANT UNION.—Medical Officer to the Fourth District, in succession to Mr. P. Pope, resigned.
- MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.—Honorary Physician. Candidates must be Graduates in Medicine of a British University, or Members of the Royal College of Physicians and appear on the Medical Register. Applications, with copies of testimonials, to be sent to the "Chairman of the Board" not later than October 31st.
- NORTH LONDON HOSPITAL FOR CONSUMPTION, HAMPSTEAD, N.W.—Resident Medical Officer. Salary, together with board and rooms in the Hospital, £400 per annum. Candidates must possess a Medical and Surgical diploma. Applications, with testimonials to be sent to the Secretary, at the office, 216, Tottenham Court Road, W., not later than October 29th.
- OWENS COLLEGE, MANCHESTER.—Professorship of Physiology. Candidates to forward applications and testimonials to the Council of the College, under cover, to the Registrar, not later than Nov. 9th. Further particulars can be obtained on application to the Principal of the College.
- PARISHES OF TONGUE AND FARR, SUTHERLAND.—Medical Officers. (*For particulars, see Advertisement.*)
- THE GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, LONDON, N.—Surgeon. (*For particulars, see Advertisement.*)
- WOLFORD HOUSE HOSPITAL FOR THE INSANE, EXETER.—Assistant Medical Officer. Salary, £150, with board, lodging, and attendance. Candidates must be duly registered, and possess both a medical and surgical qualification, and not under 24 years of age. Applications, with not more than three recent testimonials, to be sent to Dr. Deas on or before October 26th.

### DEATHS.

- CLARKE, W. M., M.R.C.S., L.S.A., at 2, York Buildings, Clifton, Bristol, on October 2, aged 56.
- HAMILTON, WILLIAM, M.D., formerly of Marlton, co. Wicklow, Ireland, at Oakfield, Torquay, on October 4, aged 88.
- LAW, AUGUSTUS, M.R.C.S., at 14, Woburn Place, Russell Square, on October 10, aged 60.
- WILSON, DR. ROBERT, at Seabank, Aberdour, on October 4, aged 85.

### NOTES, QUERIES, AND REPLIES.

#### THE BRADLEY FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Will you kindly acknowledge the following additional subscriptions.

I remain, yours faithfully,

RICHARD JEFFREYS.

*Eastwood House, Chesterfield, October 14th, 1885.*  
The Proprietors of the *Provincial Medical Journal*, £5 5s.; Mr. Edward Cock, £2 2s.; Dr. W. H. Hooper, Dr. E. Cresswell Baber, each, £1 1s.; Anonymous, 5s.

#### CAPSICUM IN HÆMORRHOIDS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—The value of capsicum in hæmorrhagic diseases is noted in Section 1587:3 of the "Medical Digest," where Dr. Brock's "legacy," as published in the *British Medical Journal* in 1854, is given, *viz.*, five to ten grains of capsicum powder every ten minutes until post-partum hæmorrhage ceases.

I am, Sir, yours, &c.,

RICHARD NEALE, M.D. Lond.

THE BACILLUS OF BERI-BERI.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Is Dr. Wallace Taylor the discoverer of the beri-beri bacillus? In 1884, M. de Lacerda described the micro-organism found in this disease; whether Dr. Taylor claims a prior discovery I do not know.  
I am, Sir, yours, &c.,  
EDITOR "MEDICAL DIGEST."

J. F. de Alford.—We cannot give advice in private cases.

## THE HARVEIAN ORATION.

Delivered at the Royal College of Physicians of London, on October 19th, 1885.

By RICHARD QUAIN, M.D., F.R.C.P., F.R.S.

PRESIDENT AND GENTLEMEN, — It is known to the majority, or even to all, of those whom I have now the honour to address, that our great ancestor Harvey, when he conveyed by indenture his patrimonial estate to our College, made that conveyance subject to certain trusts. One of these trusts, Sir, had reference to the duty of to-day, which, at your request, I am about to endeavour to discharge.

Save for a few brief periods of intermission, this duty has been fulfilled annually since the year 1656, when the first Harveian Oration was delivered by Dr. Edward Emily. In the lengthy roll of those who have succeeded this first Harveian Orator we find the names of many Fellows who have been highly distinguished, not only in the annals of our College, but also in the still wider annals of English science and literature. To follow such eminent men, in the discussion of subjects on which little that is new can now remain to be said, is an undertaking from which I should naturally have recoiled. But, remembering,

Sir, that the request proceeded from you, the distinguished President of our College, once a fellow-student, always a friend, I felt that it was no longer open to me even to hesitate. I felt that I must adopt the words of the Controller Calonne, who, when asked by Queen Marie Antoinette to undertake a duty which her Majesty considered to be difficult, replied, "If it be only difficult, it is done: if it be impossible it shall be done." In the spirit which suggested this answer I am here; and I crave the indulgence of my hearers whilst I address myself to my task.

For more than twenty years I have listened with attention to successive Harveian Orations, and I have read with care those which have been published during the same period. I have scarcely known which most to admire: the patient research on which these orations have been founded, the philosophic spirit which has breathed through them, or the eloquent and impressive manner in which the conclusions of the authors have been laid before the College. Some of my predecessors have reminded us of Harvey's personal history and surroundings. By others we have been told what was known of the circulation of the blood before his time; and his method of research and his calm inductive reasoning have been admirably portrayed. By others, again, Harvey's claims to originality in relation to his great discovery have been fully set forth; and have been established with a certainty which can never be disturbed. In one of these brilliant discourses, his observations on genera-

tion found an able and fitting exponent. On another occasion his philosophy, more especially with reference to the doctrine of final causes, was most ably discussed. On another, the bearing of his discovery upon the improved knowledge of therapeutics, and the better practice of medicine which have resulted from it, was fully described; and the great philosopher was regarded in the light of a physician as well as in that of a physiologist; while we seem still to listen to the oration of last year, in which Harvey was represented as having anticipated some of the great discoveries which mark the present period. Reflecting on these admirable discourses, I felt that it would be impossible for me to retrace such familiar ground, otherwise than at the risk of reminding many of my audience how often they had already heard the same story, related in a more eloquent and a more impressive form.

Meditating, then, on the subject on which I should address you to-day, I remembered that I should have before me the portrait of our great predecessor, who might for a moment be assumed to animate the picture, and to be prepared to listen to what I had to say. And venturing then to ask myself what the founder of this Oration would most desire to hear, it seemed to me that he would say—as might be anticipated from a character so unassuming, so simple, so opposed to ostentation and display—"Of myself I have heard much: I appreciate the honour, the esteem, and the regard entertained for me by my successors. My work has accomplished all that I could have hoped for or desired. Tell me, then, if you can, something of the profession which I love so well."

Anxious to fulfil this unselfish and disinterested wish, and remembering that Harvey had assigned to the Harveian Orator the duty of encouraging his fellows to search out the secrets of nature, it occurred to me that there are two of these secrets which, though not strictly of the kind to which our benefactor's words were intended to apply, are yet of sufficient interest and importance to justify me in asking your attention to them for a brief time to-day.

The first of these secrets has reference to the past: Why is it that amongst a vast number of persons, alike in ancient and in modern times, medicine has not enjoyed that high estimate of its value, as an art and as a science, to which it is justly entitled? The other problem requires the exercise of the prophetic spirit; since I seek to ascertain whether we have any grounds for anticipating a more satisfactory future for our profession, either in the security of the foundations on which it is laid, or in the consequent appreciation of it by the public.

Why, then, is it that both in ancient and modern times medicine has been so often regarded with scepticism and want of confidence, and so often treated with satire, and even with contempt?

In seeking an answer to this question, we cannot be surprised that the scepticism as to the powers of the healing art should be rife, both within and without the profession, when we regard the nature of the problems with which we have to deal. The want of faith may be traced to two sources: one intrinsic, and due to the inherent complexity and difficulties of the subject; the other accidental, external, to be found amongst the people at large. In its scientific aspect, medicine possesses this peculiar difficulty and source of uncertainty: that the individuals or units, with which we have to deal, not only differ from each other, but also vary constantly, each one within itself. They are subject to endless influences from within and from without, mental or physical, inherited or acquired. This ceaseless change of circumstances, and the variations consequent upon it, complicate and con-

fuse the problems presented to the scientific physician, increase the labour of his investigations, and render his conclusions so far uncertain that only repeated verification can bring satisfaction to his mind. This source of difficulty is, however, so fully appreciated by those whom I now address, and by all indeed who are interested in the pursuit of science, that I do not propose to dwell upon it here, but rather to turn to what I have called the external causes, which, by affecting the feelings and judgment of the masses, have frequently thrown doubt and discredit upon our professional proceedings.

Evidence of the existence of such doubt, both in the past and in the present, is to be found in the judgments of men of science, not excluding indeed members of our own profession; in the sarcasms of dramatists and satirists, and still more in the daily action and behaviour of the sick, who, by submitting themselves to the treatment and by accepting the nostrums of charlatans and quacks, in the same spirit in which they would have recourse to our own aid, manifest the like esteem in which they hold us all.

I can best address myself to my argument by recalling to your memory some of the oft-quoted sentiments, which, in the half truths they have expressed, indicate the aspect in which our art has appeared to thoughtful minds.

Quot Themison ægros autumnno occiderit uno?

asks Juvenal satirically, in reference to the leading practitioner of his day—an expression which has been parodied in our own times by an eminent statesman who asked his friend and physician how many deer he had killed during his autumnal holiday; and, on being told a dozen or more, exclaimed, "I congratulate you: you could not have had more success amongst your patients!" Turning to our profession, we find Celsus asserting that "*optima medicina est non uti medicinâ.*" Even Hoffmann exclaimed "*Fuge medicos et medicamenta si vis esse salvus.*" Dr. Gregory half a century ago expressed a remarkable opinion, not more discouraging to his profession as a physician than damaging to his reputation as a prophet, when he said, "I think it more than possible that in fifty or a hundred years the business of physician will not be regarded even in England as either a learned or a liberal profession." Majendie once stated that "the doctor is often superfluous, sometimes mischievous, and occasionally fatal."

It was not likely we should escape from Shakspeare's criticism. "Trust not the physician," said Timon to the banditti; "his antidotes are poisons, and he slays more than you rob." The opinion entertained of our profession by Molière is too familiar to need repetition; whilst Voltaire tersely described our practice as "pouring drugs of which we know little into bodies of which we know less." The late Dr. Arnold wrote not so long ago: "The philosophy of medicine, I imagine, is almost at zero; our practice is empirical, and seems hardly more than a course of guessing more or less happy." I might easily extend this list, but there is probably no question more comprehensive and more damaging in its inference than that asked by the late Sir William Hamilton: "Has the *practice* of medicine made a single step since Hippocrates?" Embodying as it does the essence of adverse criticism, and coming from so high an authority, I nevertheless hope to succeed in showing how utterly unfounded is the suggestion which it embodies.

The tone of low esteem which runs throughout these quotations, often the reflex of current opinion, as well as of that of the individual, compels an attempt on our part to trace the causes to which it may be attributed. These, I think, may be considered as threefold in their character: first, the very course and progress of the

science and art of medicine itself from the earliest times to the present day; secondly, the amazing credulity of the mass of mankind; and thirdly, the obstinate and unreasoning incredulity of no inconsiderable minority.

In looking back on the history of our art, we may remember how it was believed to have emerged from the clouds, and how those who practised it were regarded as gods; how subsequently in the hands of Hippocrates the art first assumed the form of a science, and was by him and his immediate successors pursued on a line of careful observation, influenced by, but not entirely subjugated to, the prevailing philosophical speculations on the nature of things; how further, impeded at its origin, it became for centuries the prey of rival systems, which, based on *a priori* speculations, and founded on ignorance, were made to fit in with notions engendered by imperfect knowledge. The mere mention of some of these systems is sufficient to suggest the absurdities they propounded, and to justify the taunts and sneers of those who, even could they accept the doctrines set forth, were shaken in their faith when they witnessed rival sects strenuously contending each for its own infallibility. Galen strongly condemned the distinctions made by these sects as leading to interminable hypotheses and disputes; in which each individual supported his own theory to the disparagement of others, and to the great injury of medicine in general.

How, then, can we blame the critics who were bewildered by the rival factions of dogmatists, empirics, methodists, pneumatists, and eclectics, together with the many others in whose hands medicine was "reduced to a mere department of speculative philosophy, involved in futile disputations and in formulas based on no substantial facts," and who for six centuries practically monopolised the healing art? Through the dark ages, during which medicine was largely under Arabic influence, our science consisted for the most part of wordy commentaries on the writings of the ancients; and the practice, mainly confined to the priesthood, was regulated by the grossest superstition. Those were the days of the astrologer and miracle-worker, of cures by prayers, relics, and royal touch, and of the search for the elixir vitæ, the time when surgery was in the hands of barbers.

But it must not be forgotten that during this very period, when all science was at a standstill and when we can scarcely point to a single observation or discovery, the universities were founded, and in the hands of a few, in small and scattered schools, the light of investigation, although dimmed in the prevailing atmosphere of mysticism and hypothesis, had been kindled and was kept alive; notably at Salernum, where an attempt was made to substitute a scientific procedure for the generally prevalent superstitions. At Bologna, Padua, and other schools, anatomy, long discarded, was again beginning to be studied; and thus the revival of learning, and the foundation of the modern scientific method by Bacon, did not find our art absolutely unprepared to receive them. None the less, in Harvey's day the whole work had to be begun anew; the preceding centuries had been almost so much lost time; all that had been handed down from them in the shape of fact was of the most meagre character; dissection had fallen into disuse; without knowledge of structure there could be no physiology, still less any rational pathology and diagnosis; and all that existed of therapeutics was an empirical acquaintance with the efficacy of a certain number of drugs.

It was not long, however, before improvement reached us. In 1518 Linacre, who had studied at Salernum, returned to found our College by obtaining, through Wolsey's influence with Henry VIII., the

charter "whereby medicine was rescued from the tender mercies of the ecclesiastical profession."

The history of our profession from this time presents a record of ever-increasing additions to our knowledge, acquired by careful observation and experiment. Each division of our complex science received a fresh impetus, not a few becoming differentiated and distinct, and all pursuing for the next two centuries a path of uninterrupted progress. Anatomy, which Vesalius, Fallopius, Fabricius, and others had built up, reached, in the hands of their successors, a degree of precision only limited by the nature of the subject. Physiology, which can scarcely claim to have been a separate branch before Haller, was pursued with increasing energy by Hunter, Spallanzani, Hewson, and many others. To Sydenham, Baglivi, and notably Boerhaave, may be ascribed the merit of applying to medicine the method of observation which may be said to have been dormant since the days of Hippocrates. Morbid anatomy, which first took shape in the hands of Bonetus and was developed by the labours of Morgagni, more than sustained its position by the labours of the Hunters, of our illustrious Fellow, Mathew Baillie, and of many eminent French pathologists. Thus, then, did every branch of our science make progress. Unfortunately, however, incidental to this progress, often inseparable from it, and always detrimental to it, there has continued a tendency to system-making and speculating of the shallowest and most specious character. I am not concerned with the causes which occasioned the delusions hence arising, nor with the justification they might plead for their existence in times when superstition and credulity were rife: it is sufficient for my argument that they existed, and that they contributed, not without reason, to the low esteem in which the efforts of even the foremost of our profession were held. But, whilst the true science which budded forth with Hippocrates was stifled by the systems of his successors, its revival with Harvey and his contemporaries was too powerful to suffer the same fate; henceforth the vain imaginings ran their course side by side with the progress of scientific truth, frequently to its hindrance and injury, but still more frequently to be cast aside and forgotten.

The sources of the various superstitions which degraded our science, and which even still afford some ground for scepticism, are to be sought not only in the inherent tendency of the human mind to accept the marvellous and supernatural, to court deception, and to be pleased rather than otherwise with the result of its quest—"quandoquidem populus decipi vult, decipiatur"—but also in the admitted influence of the imagination over certain functions of the body. The simple and to us fairly intelligible occurrence of the occasional removal of pain by a concentration of the attention elsewhere, or by the substitution for it of some strong emotion, may account for much that, in the past no less than in the present, has become preposterous and absurd from the lengths to which it has been carried. With such material to work upon, it was and continues easy for designing charlatans, or mistaken zealots, to develop the most outrageous hypotheses and practices.

The revival of learning and the scientific method, whilst lighting up the path for the few, left the masses untouched; and the superstitions which we somewhat complacently refer to the dark ages remained unaffected by the results that accurate observation was producing. The practice of the healing art was not yet entirely removed from the hands of the priesthood; and the treatment of disease by supplications, by the laying on of hands, by the power of relics, shrines, and holy wells, found still its administrators and its dupes. The superstition of the curative virtues resident in sacred things was easily extended to objects intrinsically less reverend in their nature; and talismans of stone,

metal, or wood, engraved with cabalistic signs, or phylacteries, which were texts written on scraps of parchment, and, like amulets, intended to be worn on the person, were easily acquired adjuncts to the necessarily limited supply of saintly relics. And yet who shall say that a time which has produced clairvoyance, metallic tractors, and the "mind cure," is free to cast reproach at the deeds of these dark ages?

The whole so-called cabalistic sciences of astrology and alchemy, developed as they were by men of ability like Paracelsus, came to acquire a strength which they would scarcely have possessed if left alone to the ignorance of the people. John French, in a work on alchemy published in 1650 and supposed to have been among the last on the subject, thus enunciates the pretensions of his craft: "If men did but believe what this art could effect, and what variety of wonder there is in it, they would no longer be bound up to Galen or Aristotle, but would subscribe to be faithful to the principles of Hermes and Paracelsus."

Perhaps among the most curious of all the superstitions that have debased our profession is that of the royal gift of healing. Commencing with Edward the Confessor, the touch continued to be practised by our sovereigns, though with many exceptions, until the days of the first George. Nor was it limited to this country. France claims Clovis as the originator, and the ceremony was certainly performed by many of his successors. "In no reign," says Dr. Pettigrew, "did the practice prevail to such an extent as in that of Charles II., and it is not a little remarkable that more people died of scrofula, according to the bills of mortality, during this period than in any other." It may be further observed that surgeons did not disdain to recommend this treatment to their patients. It was at the instigation of Sir John Floyer, a physician of eminence, that Samuel Johnson was twice "touched" by Queen Anne; and, as Boswell remarked, evidently without success. This power has not been held to be limited to royalty: "Even today," wrote the late Dr. Meryon, "in Scotland the seventh male child in a family has the gift of curing the king's evil by touch."

The existence of these and a thousand other superstitions, the record of which excites alike our amusement and amazement, could not have been sustained for a moment except for the credulity of those on whom they were practised. "The kind of credulity," said Sir James Simpson, "which the public thus show daily in relation to medicine, they show in relation to no other practical art or science. Indeed, if a similar species of charlatany were attempted in relation to most other arts and sciences, the delusion would be at once detected, and the imposture duly announced; whilst, in medicine, the delusion would, on the other hand, probably make the propounder's fame and fortune, and in the course of years be forgotten." Truly we may say with Crabbe—

"This love of life, which in our nature rules,  
To vile imposture makes us dupes and fools."

So widespread and importunate were these errors that we find even our own College gravely testing men in their knowledge of astrology (1593-96), deputing members of our body to inspect bewitched people, and, summoning those who assumed the power of cure by touch, requiring them to exercise their skill in the presence of the College.

It is not to be forgotten that Harvey himself, following on the lines of Galen and Aristotle, adopted a view as to the nature of life which is a phase of the almost universal conception held in one form or another up to our own day. It appeared as the "animism" of Hoffmann and Stahl, who bequeathed to us as a consequence what is known as "expectant medicine."

Another development of the same idea is the theory of a vital principle, the "vitalism" of Haller and Barthez, from which even now we cannot be said to be entirely free.

Scarcely more than a century ago the medical world was divided by the contending schools of Cullen and Brown: the latter with his sthenic and asthenic diseases and tonic and depressant treatment, the former, in hot hostility, advocating the hypothesis that disease was the result of opposite conditions of spasm and debility. Soon after this appeared in France the doctrine of Broussais, who held that gastro-enteritis is the basis of pathology, and local depletion the proper remedy for fever. There is yet another system which cannot be passed over without reference, viz.—homœopathy, which teaches that disease consists of symptoms which are to be treated by remedial agents producing like symptoms, the potency of the medicaments increasing in proportion to their dilution.

The influence which these myths have had upon the healing art has been most varied. But certainly they have played a large part in occasioning the low regard in which practitioners of medicine have too often been held by the public. I cannot do better perhaps than quote the words of Dr. Percival, who said: "A list of all the follies which at different periods have been established as articles of faith in medicine would form the severest satire on the healing art."

But despite all these untoward influences, the progress, as I have reminded you, was sound so far as it went when we consider the disadvantages under which the workers pursued their investigations. Nevertheless, they came to a line, beyond which they made but slight advance, a line indistinct, perhaps, and not equally sharp and well-defined in every subject, but withal a line across which, without the intervention of some great change, they could never have passed. We may apply to this period the words that Bacon used in reference to science in general in a previous age: "Learning," he wrote, "is neither prosperous nor greatly advanced, and a way must be opened to the human understanding entirely distinct from that known to our predecessors, and different aids procured that the mind may exercise her power over the nature of things."

Looking back, as I can, to the manner in which the component parts of the medical curriculum were pursued, when I began my student life, and contrasting this manner with what goes on around me now, I cannot doubt, in the words of Bacon, that a new way has been opened—an *instauratio magna*. When I tell some of my young listeners that only forty-six years ago the late Sir Robert Carswell, the first pathologist of his day, whose drawings of morbid appearances remain a monument of accuracy and skill, never used a microscope in the course of his lectures, and that his only reference to microscopic appearances was to mention that pus consists of a clear fluid and globules, some idea may be formed of the change which has taken place.

And now during a few moments let me indicate to you the direction in which this change has been effected, seeking meanwhile if we may find therein any data which may help us to reply to my second question,—What are our hopes for the future? Clearly the direction was towards a better comprehension of the nature of life, and inferentially of disease; together with a more accurate knowledge of the body both in its structure and its functions. The halt to which observers had come was largely compelled by narrow methods of experiment; and it is particularly to improvement in the methods and instruments of research that much of our advance is to be attributed, as it is also from such improvement that still more is to be expected.

First, in respect to gross anatomy—the science of structure—little could be added to the knowledge

which has been continuously accumulated since the days I have previously referred to; but it was Bichat who in 1801, by his treatise on the minute anatomy of the tissues, opened up a new branch of enquiry which but for the microscope could not have existed, and for which the microscope has done what the reflecting telescope did for astronomy. It would not seem, however, that the work of himself and his followers had borne much practical fruit even in my early days. I have told you what was then the state of the microscope in reference to morbid anatomy. Its position in respect to healthy histology was scarcely better; and it is only since then that the impetus for investigation has arisen, and the application of this impetus to physiology. Prominent among the researches into structure was the recognition by Schwann and Schleiden of the so-called cell in all living tissues; a doctrine which has been subsequently extended to embrace the existence of protoplasmic forms generally. I need not more than mention the very considerable position, both as regards extent and accuracy, which histology has assumed within the past few years.

So long as the study of the phenomena of the living body was hampered by the dominant notion of a special vital principle, not amenable to the laws which govern inert matter, and which was to be investigated in ways other than those which were producing such grand results in the domain of chemistry and physics, the progress of physiology was likely to be slow and accidental. The turning point in the subject was undoubtedly its being brought into harmony with the principles which govern other experimental sciences, and being pursued along the same path. So far as the change can be attributed to one man, it is to Mayer that this credit must be given, for his work in 1845 on the relation of organic motion to the exchange of material. For some time from that date, no function of the body escaped investigation by a method of direct experiment of which a mistaken humanity and senseless clamour have since deprived us; always aided by the experiments which nature offers to the physiologist in the shape of disease, complicated though they be by conditions which render them more difficult of explanation.

From the chemical side physiology has received much assistance. Our knowledge of the composition of the blood and its derived secretions, though still leaving much to be desired, has done something towards unravelling the complex chemistry of the tissues. The chemistry of digestion and respiration, which a century, nay fifty years ago, was a jargon compounded of the residues of the Hippocratic notion of the four elements, and of alchemy interspersed with streaks of the new chemistry which was then arising, is now pursued on lines in harmony with those of every-day laboratory investigation. To mention but one practical result thence obtained, I would refer to the artificial digestive juices and prepared foods which are among the most valuable of our remedies. On the physical side are the study of the phenomena of muscular contractility, and the expression of the work done in such terms that it may be calculated with the same accuracy as the fuel value of a pound of coals; the study of the laws of osmosis which underlie all the physiology of absorption and nutrition: the conditions affecting and determining gaseous interchange which explain the process of respiration: the nature of elasticity and the important share it takes in the physics of the circulation: turn which way we will, we see now in our physiological laboratories—themselves the creation of the last twenty years—experimenter and instrument maker competing in a demand and supply of the apparatus by which such work as I have indicated has been rendered possible.

(To be continued.)

## ON THE CAUSATION OF PYREXIA.

BEING A PORTION OF THE ADDRESS DELIVERED AT THE OPENING OF THE SESSION OF THE MEDICAL SOCIETY OF LONDON.

By W. M. ORD, M.D., F.R.C.P.,

President of the Society, and Physician to St. Thomas's Hospital.

AFTER a brief allusion to the various Fellows of the Society who had passed away during the preceding year, Dr. Ord went on to say: When I pass from these relations, in which sorrow and pride are so intimately mingled, I feel that what I should say is not so clearly laid down for me. I will dare, therefore, to choose for myself, and say a few words to set you thinking, a few words touching a difficulty which occurs to me constantly in the study of disease. We all now use the clinical thermometer. We all, from day to day, see it indicating, in various cases, a heat of the body rising to various degrees above the average, with, as our experience tells us, indications increasing in gravity in some proportion to the ascent of the mercury. We know, again, that, for the most part, the rise of temperature coincides with the establishment of the process of fever. Now, this increased heat of the body in fever is to me a very constant stimulant of thought. When I ask people how it comes about, I am generally told that it is simply a matter of increase of combustion; that the oxidation processes of the body go on with undue vigour in fever; that the system is burning its candle at both ends, and that the two flames give more heat than one. When one looks at a patient who has passed through a febrile illness, one is ready to accept the explanation. He may have had no wasting discharge, hæmorrhage, or other obvious drain, yet there he lies bloodless and emaciated, to a degree which leads one readily to believe that on his bed of fever he has been consumed in all his tissues by an unseen fire.

But, for some years, my acceptance of this ready and most plausible way of accounting for the phenomenon has been hindered by an attentive consideration of an article on the Process of Fever, contributed by Dr. Burdon Sanderson to the Reports of the Medical Officer of the Privy Council, for the year 1875. The article contains an exhaustive notice of the best observations made, up to that time, with reference to heat-production in the body during pyrexia. Now, I am giving an address, and not reading a paper; I am, therefore, speaking to suggest a subject and line of thought, and not, as you will see afterwards, to go on to set before you conclusions which I hold that I can prove. I refrain from recapitulating the complex and very refined data upon which Dr. Burdon Sanderson sums up impressively. Suffice it to say that, after careful analysis of these data, he writes thus: "The general conclusion to which the preceding calculation leads us is a very important one, namely, that, although as compared with the heat-production of an individual on fever-diet, the heat-production of a febrile person is excessive, it is not by any means greater than the heat-production of health." There is, in fever, it must be admitted, increased exhalation of carbonic acid, increased excretion of urea, but, after calculation, they do not represent a source of heat sufficient to cause the increased temperature of the body. I have read the article again and again, I have referred to various authorities on the subject, and I am compelled to say that the increased combustion explanation, which satisfied me before, has no longer the same value. To what, then, as I felt obliged to lose faith in my first

belief, should I turn? Might, as some have argued, the increase of heat in the body be brought about by retention, by some state of the surface which would prevent the liberation of heat from the body and lead to accumulation within? The well conducted observations of Leyden and Liebermeister, tend to show that far from being retained, heat is discharged from the surface in larger quantities during fever than in health. And we all know that intense hyperpyrexia constantly co-exists with profuse sweating, involving the freest possible discharge of heat from the surface of the body, as in severe cases of acute rheumatism. If we are bound to deny the cogency of the two explanations we are impelled to find a new one. And in illustration of another possibility to which I would draw your attention, let me use an illustration.

Let us suppose that we place over a flame a metal basin containing water, and let the water come to the boil. Let us place a thermometer in the water. So long as there is water left, the thermometer never rises above 212° F., let the boiling be ever so fierce. The evaporation always compensates for the heat introduced. This is, in a way, a parallel to the marvellous heat regulation of the body, which maintains it at a fixed temperature whatever be the heat or cold of the surrounding air. The heat introduced from the flame is used up in turning water into steam, and raising the steam. Let oil be poured on to the surface of the water, and hinder the extrication of vapour. Heat is then also retained, and the temperature rises in the water, as it would in the system on the retention-hypothesis. On the other hand, let the water evaporate entirely. Then the metal basin becomes heated indefinitely, and the thermometer rises in proportion. The water had afforded to the heat the means of further usefulness in which it—to use an old term—became latent, or took another form of energy.

Now, what I am going to ask you to think about is this. Is it possible that the increased heat of fever may be brought about by the cessation of processes in which heat ought to be used up—either as motion, or chemical action, or other kind of energy; so that the process which may be represented by the boiling water ceasing to exist, like the water when boiled away, the heat generated for maintenance of the process overflows, and warms to excess the body, like the metal basin from which the water has evaporated? Is the increment of heat of body in fever due not only to combustion or other disintegrative process thereto allied, but also to the persistence, in the form of heat, of energy which should have taken another form? This appears to me in a high degree probable. Throughout the body, we recognise two processes ever going on: the building up of tissues on the one hand, their disintegration on the other. The disintegration of tissues is clearly attended by the liberation of heat. Their upbuilding presents itself to me as necessarily attended by the consumption or disappearance of heat, which assumes some other form of energy, kinetic or potential. There is here suggested to me the contrast between evaporation and condensation, between solution and crystallisation. You will ask me if I have any knowledge of experiments demonstrating the using up of heat in the tissue-formation of animal bodies. I have none. So far as I know, all the processes which have been examined have proved to be heat-evolving, even to the formation of peptones. Also, so far as I know, no processes of tissue-building have been investigated from this point of view, and it is difficult to see how, with our present means, any such process comes within the possibility of investigation. But if we have no direct evidence in this matter to help us, we may gain some help from a consideration of the chemical processes of fever. These comprehend, in the first place, an exaggeration

of the combustions of health. But they also comprehend changes which exactly reverse those of health, and indicate strongly that there is, first, a cessation of changes which should occur in health; and, secondly, a production of changes not occurring in health. The proportions of soda and potash which should be eliminated from the body in health are reversed in fever. The same holds of chlorides and phosphates. The potash and the phosphates are the associates of the highly organised principles; the chlorides and the soda of the introduced and further organised principles. On the view that there is, in fever, arrest or default of the building up of the tissues, we can imagine the retained chlorides and soda waiting with the organic substances on promotion, like salmon at the foot of a fall, till at the end of a fever they part with their associate organic matters, and pass them on to the elevating influence of the potash and phosphates. We can imagine the potash and phosphates during fever swept away as useless, because in the arrested ascending metabolism they have nothing wherewith to combine, and are, for the time, useless, fit only for the draught. It is, in fact, presented to me strongly that these chemical variations indicate the cessation, in various degrees, of that process of tissue-building which should, in health, use up heat, and which, ceasing in fever, leaves heat to run wild.

Thinking over such problems, and failing hitherto to find any possibility of experimental investigation of the using up of heat in ascending metabolisms of the body, I turned myself to the vegetable kingdom. In fruits we have, as it seems to me, two processes of meaning exactly opposed one to the other: the building up of the fruit, wherein we have the formation of cellulose, starch, &c., and the ripening, wherein we have the breaking down and the production of sugar. I determined to investigate fruits of rapid growth, and test their temperature as compared with that of the surrounding air. Before doing this, I consulted botanical books, and questioned great living botanists. But information was not forthcoming from either source. The kindness of a friend who has large hot-houses near London enabled me to make some experiments, which I venture to say have some importance in vegetable physiology, as well as in their relation to the question of pyrexia.

The cucumber was the fruit which I chose for my observations. It is a fruit which grows very rapidly, and a fruit in which the signs of ripening can be readily seen. It is grown in houses, at a fairly fixed temperature, and in an atmosphere of considerable moisture. Having chosen my growing cucumbers at a stage free from any fear of ripening, I had a glass bottle, with wide open mouth, filled with water, suspended by the side of each fruit, the bottle equalling the fruit as nearly as possible in size. After twenty-four hours or more I commenced observation. I used a delicate, pointed thermometer, lent to me by that skilful constructor, Mr. Hawksley. With this, I took, first the temperature of the air of the hot-house around the fruit; next the temperature of the water in the bottle; next the temperature of the cucumber at different points of its length. This was done by plunging the sharp end of the bulb containing the mercury to a fixed depth, marked by a line on the bulb. I took the temperature of the cucumber at various points in its length for a definite reason. Cucumbers begin to grow at the base or stalk end, and further growth is beyond this at the tip or flower-end. If any difference of temperature between the fruit and the air should be found, it might be argued to be due to evaporation if the difference were equal at all points; but, if the difference should vary at the several points tested, the influence of metabolism might be recognised.

On May 23rd, 1884, a very warm day, I examined a young growing cucumber thirteen inches long. The temperature of the house was 86°1' Fahr.; the temperature of the water of the bottle was 85°3' Fahr. The cucumber gave the following readings—At the stalk, 84°; two inches along, 85°; middle 85°; two inches from tip, 84°6': tip, 83°9'. The experiment was repeated with another cucumber on the same day and with similar cucumbers on other days. All the observations were to the same effect. I note one or two other observations. On June 7th, the weather being much cooler, and the air of the house being at 75°6' the water in the bottle was 76°9'. A ripe cucumber was found to be at 77°5' in the middle; a young cucumber, pendulous, 74°6' in the middle; a young cucumber, horizontal, 74°7' in the middle. On June 14th, the weather being again warm, the water stood at 86° in a bottle on one side, at 86°3' in a bottle on the opposite side of the cucumbers to be examined. A cucumber, nearly ripe, gave 84° close to stalk, 84°3' in the middle, 83°2' at the tip; a small, but evidently growing cucumber, 83°5' in the middle; a nearly ripe cucumber, cut the preceding day, and placed close to the others, 87° at all parts.

I trust that you will find in these observations, as they stand, something of interest. They show, at least, that the traditional coolness of the cucumber is not a mere creation of fancy; that the growing fruit is actually cooler than the medium in which it is growing. So far as these observations are concerned, a new fact has been established; but the observations are not numerous, and the inferences are not sure. I hope to extend the observations, to introduce many controlling experiments, and so to go on to safer inference. Nevertheless, arguing upon what we have before us, and upon parallel experiments made upon bananas, with which I will not now trouble you, we may acknowledge that the comparative coolness of the growing fruit may have been due to evaporation, and that the warmth of the separated fruit may have been due to the comparative cessation of evaporation. On the other hand, I may urge that the air of the hot-house was loaded with moisture, as is the case in properly managed houses of this kind, and that moisture was deposited in beads on the surface of the fruit. This, of course, is against the evaporation explanation. And, so far, I should urge that the difference in the temperature of the fruit at various points in its length is against evaporation. Further, it is in favour of the hypothesis of metamorphosis in metabolism, in that the temperature was most reduced where, according to all appearance, tissue-formation should be most rapidly proceeding. If time serve me during the coming year, I hope to institute experiments which shall eliminate the evaporation difficulty, and to investigate other fruits; but, so far as I have gone, I think that I am entitled to argue that there is indication that the metabolisms leading to formation of tissues from juices do actually use up heat.

Now, to apply what has been said to help us in understanding the causation of pyrexia and hyperpyrexia. Dr. Broadbent has written thus:—"If a theory of the febrile process is to be formed, it must be based upon a theory of the relation between the nervous system and the processes of nutrition and oxidation, and especially the latter." When I read this, I can read that my distinguished friend's thoughts go much with mine. I believe that, in the production of fever heat, there is a first factor of increased oxidation, or combustion, or disintegration, setting free heat. I cannot, however, find this sufficient to account for all the increase of heat observed in pyrexia, and still more in hyperpyrexia. The further increment I believe to be furnished by heat going astray in

default of correlative change in metabolism. And, like Dr. Broadbent, I am inclined to recognise in the nervous system the power, inciting, on the one hand, to disintegration, controlling, on the other, the nutritive functions. In the progress of febrile diseases, there is a manifest correspondence of deeper and deeper affections of the nervous system, with higher and higher degrees of temperature. As temperature rises, headache, excitement, insomnia are followed by delirium; on delirium follow various involuntary movements, and finally convulsions; to these succeeds coma. As death by coma approaches, the temperature rises rapidly, and, in many cases, is increased, or, for a time, maintained after death, when the oxidation processes dependent on the circulation of blood must have ceased. The coincidence up to death may be argued to be due to effects of increased heat of the body upon the nervous tissues, but this argument is strongly met by the difficulty of explaining the rise of temperature without invoking the aid of the nervous system. What I would suggest is that in all fever, slight or intense, there is superadded to the combustions which we recognise an influence of the nervous system, a trophic influence, arresting processes in which heat should be transformed; and that the increasing temperature of fever is determined by increase of this inhibitory influence. When death occurs, inhibition, a partial condition, must be replaced by annihilation, a complete condition; and at that stage, while we cannot allot any part to disintegration, we can claim that complete cessation of constructive metabolism must set absolutely free all heat previously generated.

All that I have been urging is, you will say, only theoretical. It is a new contemplation of things daily under our eyes. The practical objects of this Society justify me in going on to indicate how in some degree these speculations may bear upon treatment. We have lying ready to our hands a great armoury of drugs useful, in various ways, in the fight with pyrexia. Of these I will not now speak, not from want of respect, for I am conscious of the great value of many of them; but I wish to speak particularly of the usefulness of another remedy, also always ready to hand—baths—in the control of high fever, as its causation is here presented to us. I have for many years studied the use of baths in the treatment of diseases of various kinds, and have had personal experience of them in most of the important wells of Germany and France. My belief is that baths—large applications of fluids of various temperatures to large surfaces of the skin—come in as moderators; that their main beneficial use consists in attracting, so to speak, the attention of the nervous system, and drawing it off from certain pernicious paths upon which it has embarked. Some years ago, I was much struck with some remarks made at a meeting of one of the learned societies by Dr. Thudichum, in which he threw doubt upon the idea that the reduction of temperature in fever by cold baths was a purely physical phenomenon, dependent simply upon abstraction of heat. I had been using graduated baths in hyperpyrexia, placing the patient in water at 95° Fahr., and cooling the water very evenly down to 70° or 75° during half an hour. The result had been, in some cases, an abatement of temperature as large as 10°; and with this had come sleep, replacing insomnia; calm, replacing delirium; easy breathing, replacing panting. The change in the nervous state from excitement to tranquility had been as pronounced as the reduction of temperature. Soon afterwards, I made an experimental test of the power of such baths to reduce the temperature of a dead body to such an extent. I placed the body of a person dead the day before, after rigor mortis had ceased, in a bath heated to, and maintained at, 107° Fahr., until it was ascer-

tained by thermometer that it was heated through. Then I placed thermometers in the body, at various points and at various depths, taking care so to implant them that the water would have no access to their bulbs; and then I cooled the water to 95°; and, during a subsequent half-hour, cooled it gradually to 70°. The reduction of temperature in the superficial parts of the body was much less than that brought about by a bath, and the temperature in the deeper parts was scarcely affected. Even if the circulation had been going on, no lowering of temperature at all approaching a lowering of 6° could, I think, have been produced. It must be acknowledged that the experiment was incomplete, in that I did not maintain a circulation of warmed water in the blood-vessels; but, so far as it gave results, they were adverse to the simple physical theory.

In dealing with this question of baths, we must remember the enormous influence exerted upon the central nervous system by slight impressions made over a large peripheral distribution of nerves. A scald sufficient to produce but a slight vesication, when it involves the whole surface of the body, will kill. And I believe that the application to the whole surface of the body of water at a different temperature from that of the body acts in fever by exerting a reflex inhibitory influence upon the nervous system, leading to a relaxation of its trophic constraint. Of course, few remedies are simple in their action, and I should be prepared to admit the assistant influence of the lower temperature of the bath from the physical side. Anyway, in the treatment of hyperpyrexia, I know of nothing so trustworthy as the bath—cool, cold, or graduated. For my own part, I prefer the last, and have again and again seen it reduce temperature and save life, when quinine, salicin, salicylate, and other febrifuges had failed to arrest a steadily rising temperature already above 106° Fahr. And now my speculations are at an end. I have wished to say something that might give you food for thought, perhaps set some of you on the path of investigation, which I should myself like to follow more closely than circumstances are likely to permit. I cannot claim to have proven much, if indeed anything. I have not sought to do so. I have only sought, on a day when a new session opens, to suggest some new explanations of phenomena coming under our daily observation.

---

## SELECTIONS FROM TEN YEARS SURGICAL WORK.

By NELSON C. DOBSON, F.R.C.S.,

Surgeon to the Bristol General Hospital, Lecturer on Surgery at the Bristol Medical School.

HAVING recently completed ten years of surgical work it occurred to me, on looking over the list of operations I had done during that period, that I might, with advantage to myself, at least, if to no one else, select a certain number of them for classification and for remark.

I regret that various circumstances have combined to render the list somewhat incomplete; I find gaps in my note-book, extending occasionally over comparatively long periods, partly the result of forgetfulness in entering the cases, but chiefly because I have trusted (rather unwisely) to finding the records I required in the Hospital Reports,

### *Amputations and Excisions.*

With regard to amputations, I think I may say that the percentage of deaths is not less, perhaps, than that of most other operators, nor, on the other hand, is it greater than would be satisfactorily accounted for by the circumstances under which we are sometimes obliged to perform the amputation. By a reference to the accompanying table it will be seen that I have performed major amputations on thirty-six individuals. These are the only cases of which I have notes, but I know that I must have forgotten to enter some cases, especially belonging to the forearm, as I am certain that I have operated more frequently than is set forth in the table, but as I have no note of them I am compelled to omit them.

From the 36 persons, I have removed 39 limbs, that is, three of the patients have undergone double amputation. In these cases the second amputation followed the first, the moment the vessels in the first stump had been secured. One double amputation was thigh and opposite leg, another both legs, and the third both forearms. Out of the 36 patients submitted to amputation 8 have died at variable periods after the amputation. I do not look upon a statistical record of results as being of much value unless an account is given of the actual cause of death in cases which prove fatal. Of the eight deaths after amputation I find that three deaths followed amputation for disease, viz., two of the thigh and one of the leg; whilst five deaths occurred after amputation for injuries, viz., three of the thigh, one Syme's amputation, and one case in which I removed both fore-arms.

On enquiring more closely into the cause of death, I can only attribute death in two cases to what may be called preventible causes. One man, whose thigh I amputated, died of septicæmia, and another man died from the same cause after removal of his leg. The first case was for disease of the knee-joint, in which there was very considerable thickening, and necrosis of femur—the soft parts were converted from long-standing disease into dense fibrous tissue, within which the femoral artery retracted and was never properly secured. Acupressure was applied to the femoral instead of the ligature—severe secondary hæmorrhage occurred, and finally septic absorption; this was the first major operation I ever did. The second case was one of amputation of the leg for sarcoma in a feeble young man; both these cases occurred before I practised antiseptic surgery. The third death among the amputations for disease was in an old man who was suffering from senile gangrene, and whose thigh I amputated by the circular method; he lived 28 days after the operation, and died of exhaustion showing no repair in his stump. Out of the five deaths in primary amputations, two occurred after double amputation. In one of these cases I removed the thigh and opposite leg: the patient having been run over by a train in the evening, dragged himself to a place of comparative safety, and was exposed all night without any assistance; he had lost much blood, and was much exhausted on his admission at 7.30 next morning. The young woman from whom I removed both forearms for a railway smash, died really of an injury to her chest, the iron guard in the front of the engine having comminuted one of her ribs near the angle. She lived five or six days, and at the *post-mortem* a sharp piece of rib was found to have perforated her pleura, giving rise to some hæmothorax and finally empyema. There was also an injury to the shoulder which I diagnosed as being a fracture of the neck of the scapula; I could not very thoroughly examine this part on account of her other serious injuries, but the *post-mortem* showed only contusions and no fracture. One death following Syme's ampu-

tation is put down to typhoid fever, and unless I explained it might possibly be thought that this patient died really of septicæmia; it so happened that, although he was at work on the railway when he was run over, yet that he was unwell, and his wife and two children were at the time down with typhoid fever; and at his autopsy typhoid ulcers were found in the small intestines.

The remaining cases died from shock and loss of blood before admission. Thus it will be seen by this review that only one death really occurred from causes which might be considered to some extent within the surgeon's control; the deaths in the primary amputations were due to the severity of the accident, and I have no doubt I could have improved my statistics had I not given some of these patients the only chance that remained to them by amputating. I have invariably operated at once, rallying the patients as much as possible, but not waiting for the shock to pass off. I am certain that the best thing for such patients is to relieve them at once of the mangled limb if it is considered that the operation should be done at all, that is to say, in all cases except those which are absolutely hopeless, and where no good could be expected from amputation.

With a few exceptions in my early cases, all have been treated on strict Listerian principles; I used carbolised catgut ligatures. I have had two cases of secondary hæmorrhage, one in which I used acupuncture, and the other a very strumous man whose testicle I had previously removed for strumous disease. His stump had healed, but the union was soft, and when I opened it up, as I had to do for the secondary hæmorrhage on the eighteenth day, the tissues looked like pulpy and degenerating granulations. The hæmorrhage was from the femoral, which I re-secured, and he finally recovered; the former case died of septicæmia; otherwise I have had no trouble with hæmorrhage after the operation, and during the operation I restrain it by the elastic tourniquet.

In my thigh amputations I prefer a modified Carden, by which I mean a long anterior flap which I generally make from without inwards, and a short posterior flap made by transfixion; the anterior flap consisting of skin and subcutaneous tissue only. In amputating for senile gangrene I generally prefer the circular method. I have amputated three times for this disease with two recoveries and one death. The death occurred in a feeble old man a month after the operation from exhaustion; the flaps failed to unite, but there was no recurrence of the gangrene. In one of the cases which recovered the patient was apparently dying at the time of the amputation, with a very feeble pulse and muttering delirium; this condition was mainly caused by absorption of septic products from his gangrenous limb. Within 24 hours after the amputation he was conscious, and most of the delirium had disappeared. As I have described these cases at length (in a paper which I published in the second volume of the *British Medical Journal* for 1882), I do not now enlarge upon them. I have generally amputated at the lower third of the thigh in senile gangrene of the foot which is showing a tendency to spread. On two occasions in which senile gangrene of the toes has been spreading, I have amputated through the metatarsus with antiseptic precautions: one of these cases was successful after some gangrene of flap, and in the other case I amputated the lower third of thigh for a continuance of the disease, with a successful result. Of the three shoulder-joint amputations one was of no special interest; but two were exceedingly interesting, and similar cases. They were both cases of sarcoma of the biceps muscle; one occurred in a woman and the other in a man. In the first case there was no history of injury, in the second there was the history

of a blow on the part at which the disease first showed itself.

In the case of the woman the primary tumour was encapsuled, and was removed by an operation four-and-a-half months antecedent to the amputation; in the other case the tumour was not encapsuled, and amputation was the primary operation. In the woman the tumour was solitary, in the man there were two distinct tumours. In neither case was there any glandular or other secondary affection discoverable at the time of the amputation. One proved to be a round-celled sarcoma, and the other an alveolar sarcoma. Both these cases died after some months (the exact date of their deaths I do not know), but they both died in the same way with enormous local recurrence, notwithstanding that I dissected out both heads of the biceps in each case, and took care to be as wide as possible of the disease in fashioning the flaps.

Respecting amputations of the thigh I prefer, as I have said, Carden's method where possible, except in cases of senile gangrene, where I prefer the old circular.

Of amputations in the foot I prefer Syme's to any other form where the tarsus is involved. All my Syme's which have recovered have had most useful powers of progression. One, a mason, by the aid of an artificial foot, was able to mount ladders and to do ordinary masons' work without the loss of his foot being suspected by his employers; he kept his loss from their knowledge because he said they would expect him to work for less wages if they knew of it, and he did not see why he should do this, as he was quite as capable as his fellow-workmen. Another case, which I have not lost sight of, is also very successful. The patient holds the situation of a parlour-maid in a good household, and gets about with an artificial foot with scarcely a limp. I have never seen an excision of the ankle-joint that could compare with some of my Syme's in power of locomotion. In fact, one of my Syme's was in a case in which the ankle-joint had been excised some years before; her new joint breaking down necessitated the amputation; the patient can walk with more ease now than she could in the best days of her ankle-excision period.

I think it important in these cases to make a good fleshy stump. I do not carry my incision as far back across the heel as some surgeons do, and I am careful to keep quite close to the os calcis, especially on the outer side, as I dissect up the flap. Wyeth, of New York, says that the main blood supply to the flap is from the calcaneal branches of the external plantar. I agree with him that a fairly long heel-flap with these precautions is less likely to slough than a short one. I generally drain by perforating the thinnest part of the flap.

I have done two Chopart's, though I have only placed one in the table. They both did well; one of them I did ten years ago; he had a fractured pelvis as well. I see him now constantly, and he walks well. I am not, however, very partial to this operation, as I have twice seen pointing of the stump, and an incurable ulcer form over its face, necessitating a Syme's amputation; in one of these cases one of my colleagues did the Syme, and as the late Sir Wm. Fergusson had performed the Chopart, the pointing was not the fault of the operator. I have also myself operated for a like reason on a Chopart which had been done in Wales. And here I may remark that it constantly happens to the hospital surgeon that he is unable to keep his patients under observation for sufficiently long periods to allow him to accurately determine the relative values of various operations; thus, out of my comparatively small list of amputations, I have amputated

on three occasions in cases which, when they left the care of the surgeon they had originally been under, were certainly successful cases, viz. : one old excision of knee, one old excision of ankle, and one Chopart, and yet these cases did not stand the only test worth anything, namely, the test of time.

TABLE OF MAJOR AMPUTATIONS.

No.	Sex.	Age.	Amputation.	Disease or Injury.	Complications.	Result.	Cause of Death.	Date.
1	M.	55	Teale's lower third of thigh	Disease of knee-joint with necrosis of femur	Much fibroid thickening of soft parts; femoral artery could not be secured by a ligature, and acupressure was applied	Died ...	Secondary Hæmorrhage and exhaustion	
2	M.	15	Lower third of thigh	Pyæmic suppuration of knee joint	Acute necrosis of radius, with suppuration of elbow-joint	Recovered		
3	M.	—	Modified Teale's lower third of thigh	Disease of knee-joint	... ..	Recovered		
4	M.	7	Lower third of thigh	Disease of knee-joint	... ..	Recovered		
5	M.	18	Lower third of thigh	Railway smash ...	... ..	Recovered		
6	F.	6	Lower third of thigh	Disease of knee-joint	... ..	Recovered		
7	M.	6	Lower third of thigh	Laceration of leg ...	First amputated through knee-joint, flaps sloughed	Recovered		
8	M.	31	Lower third left thigh; lower third right leg	Railway smash; run over 9 o'clock in the evening, not found until 7.30 next morning	Very severe smash; long exposure	Died ...	Shock — Exposure — Hæmorrhage before admission	10½ hours.
9	M.	67	Lower third of thigh	Senile gangrene of foot	... ..	Died ...	Exhaustion and want of repair; no extension of gangrene	28 days.
10	F.	18	Through condyles...	Disease of knee-joint	... ..	Recovered		
11	F.	18	Through false joint of old excision of knee	Failure of excision of knee; knee excised in London	... ..	Recovered		
12	M.	62	Lower third of thigh	Senile gangrene of foot	Delirium, septicæmia	Recovered		
13	M.	30	Lower third of thigh	Disease of knee-joint	... ..	Recovered		
14	M.	7	Lower third of thigh	Disease of knee-joint	... ..	Recovered		
15	M.	14	Lower third of thigh	Railway smash ...	Brought from a distance; loss of blood	Died ...	Shock and hæmorrhage before admission	3½ hours.
16	M.	30	Lower third of thigh	Pyæmic suppuration in knee-joint, deep abscess in calf	Ineffectual attempt by captain of ship to open deep abscess in calf of leg	Recovered		
17	M.	54	Lower third of thigh	Dry gangrene of foot from occluded femoral	Occluded femoral artery at point of amputation	Recovered		
18	F.	67	Lower third of thigh	Malignant disease of tibia	... ..	Recovered		
19	M.	46	Lower third of thigh	Failure of excision of knee	Marked strumous condition; severe secondary hæmorrhage from femoral on 18th day	Recovered		
20	M.	44	Middle third ...	Severe railway smash	Much hæmorrhage before admission	Died ...	Shock and loss of blood	1½ hours.
21	F.	17	Shoulder-joint ...	Necrosis of humerus suppuration in elbow joint	... ..	Recovered		
22	F.	34	Shoulder-joint ...	Sarcoma of biceps ...	Sarcoma previously removed; return of growth	Recovered		
23	M.	41	Shoulder-joint ...	Sarcoma of biceps ...	Very large growth	Recovered		
24	M.	24	Upper third of leg	Sarcoma lower end of tibia	... ..	Died ...	Septicæmia	
25	M.	38	Upper third of leg six weeks after injury	Compound fracture	Cellulitis and sloughing of skin	Recovered		

TABLE OF MAJOR AMPUTATIONS—*continued.*

No.	Sex.	Age.	Amputation.	Disease or Injury.	Complications.	Result.	Cause of Death.	Date.
23	M.	22	Middle of both legs	Railway smash ...	... ..	Recovered		
27	M.	16	Middle of leg third day after injury	Railway smash of foot	Attempt to save limb; gangrene of foot	Recovered		
23	M.	32	Chopart ... ..	Railway smash ...	Fractured pelvis ...	Recovered		
29	M.	32	Syme ... ..	Railway smash ...	Typhoid fever ...	Died ...	Typhoid Fever	
30	M.	23	Syme ... ..	Disease of ankle-joint	... ..	Recovered		
31	M.	18	Syme ... ..	Disease of tarsus ...	... ..	Recovered		
32	M.	50	Syme ... ..	Intractable ulcer after a Chopart	... ..	Recovered		
33	M.	13	Syme ... ..	Smashed foot ...	... ..	Recovered		
34	M.	18	Middle of arm ...	Machinery smash ...	... ..	Recovered		
35	M.	7	Upper third of arm fourth day after injury	Smash of arm ...	... ..	Recovered		
33	F.	26	Both forearms ...	Railway smash ...	Fractured rib and empyema	Died ...	Fractured rib and empyema	7th day.

CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the Principles and Practice of Medicine and on Clinical Medicine.

LECTURE II.—CASE TAKING.

*The Family History.*

IN commencing the investigation of a case of illness, we must bear in mind that the signs and symptoms which the patient presents are the resultant of two sorts of influences, which, acting through the structural elements of his tissues, are manifested as the various functions of the body, whether healthy or diseased. These influences are those which are intrinsic, or are hereditarily transmitted, and those which are derived from the surrounding circumstances of existence, the atmosphere, temperature, food, clothing, &c. In endeavouring to accurately arrive at the condition in which an individual may be either in health or disease, and in attempting to ascertain the probable future course of his living, as in estimating the value of his life for insurance, or the progress and consequence of any malady he may be suffering from, it becomes of primary importance that the ancestral factor be enquired into as closely as possible; we therefore commence our investigation with the Family History of the patient.

SCHEME FOR CASE TAKING.

[If patient from age or nature of illness be unable to give an account, state source from which it is obtained.]

Name Age  
Date of admission Ward Bed

I. Family History.

Parents living, ages:

if dead, the cause in patient's own words and the

age at death; any blood relationship of parents previous to marriage.

Ages of parents at date of patient's birth.

Number and ages of brothers and sisters:

cause of death and age at, if any deceased.

If relatives (paternal and maternal) be generally long or short lived:

give ages of grandparents, uncles and aunts, if living, or at death.

Any malady prevailing in the family, especially

Gout, Rheumatism, Cancer, "Tumours," Scrofula, "Consumption," Heart Disease.

Bronchitis, "Asthma," "Spitting Blood."

Dropsy of Abdomen or whole Body.

Epilepsy, Insanity, Neuralgia, Paralysis of one side, or both legs.

Diabetes, "Bleeders," Obesity, Alcoholism.

Stone, Goitre, Fistula.

Imperfection of Sight, Hearing, Dentition.

Note members of family so suffering, age of first appearance of malady, and at death, if fatal.

Supplement by any confirmatory evidence, from medical attendant, death certificates, etc., that may be available.

I have here set down as completely as appears to me to be necessary, the various heads of enquiry into that portion of the evidence upon which the diagnosis will be based, which you are to ascertain by direct questioning, each question to include the words here employed. Thus:—Are your parents living? How old? How many brothers and sisters have you? How old are they? Have any of your family to your knowledge suffered from gout, epilepsy, &c.? Can you furnish any confirmation of the information required by reference to relations, records, former medical attendants, &c.? I do not say you will get all the information here asked for in every case, or in nearly every case. You will be fortunate if you obtain it in a few. But the nearer you can approach to it the more precise will be your knowledge, and the more valuable will be the result, both as contributing to the thorough understanding of your case and as a mental discipline for yourselves. The difficulty of obtaining this kind of evidence is very great: people either do not know or

have forgotten, or remembered but very incompletely, and it behoves you therefore to carefully qualify the answers given by such a phrase as "patient says," lest the bare statements encourage too much importance to be placed on them. You are entirely dependent for the evidence under this head upon what you are told—it may be correct, or it may not; but it is not of such a character as to be intrinsically impossible of precise acquirement, at least to a great extent, and this is what you should aim at, availing yourself for confirmation of the statements made by such help as cross-questioning or outside information may provide. With the exception of the age of the individual (which follows the name for purposes of convenience, and will be fully considered in the next section dealing with the "personal history"), all the points enumerated for investigation are concerned with the relationship existing between the subject of observation and his relatives; that is to say, with the share which the family, of which he is a member, may have had in determining his state of health. In a fair proportion of cases, you may reasonably expect to obtain some evidence of the life history of four generations: the adult who is before you, his children, his parents, and his grandparents; and if you obtain any history at all, it will most likely bear upon three of them. Sometimes details of family history, which are not of sufficient frequency of occurrence as to warrant enumeration in a scheme designed for general application, suggest themselves for enquiry during subsequent stages of examination, when you may insert the particulars obtained in this section of your record. By some it is recommended that this branch of the examination should be treated of after the patient's personal history and state have been ascertained, but I think it preferable to approach those sections of the subject with a knowledge, however imperfect, of the individual's inherent predisposition, before enquiring into the effects of those influences, for exposure to which he is more personally responsible.

"The two properties of organic being which determine and regulate the relation of the offspring to the progenitors, and which not only assign to individuals their position in the surrounding world, but also help them to attain it, are transmission or heredity, and adaptation. Heredity is the conservative, adaptation the progressive, principle. Yet all heredity is not directed to immutability, and many cases of adaptation involve morphological and physiological retrogression."<sup>1</sup> This, the language of a master, expresses to you briefly but completely the part which inheritance plays in determining the characteristics which a living being manifests. With the many theories which have been offered to explain how inheritance is effected, I am not now concerned. It is the facts alone that claim our attention here, that you may best understand what kind of information as well as its value that the family history of a patient furnishes you with. The general resemblance of offspring to parent is a matter of common knowledge. No one expects the seed of an oak tree to grow into anything else than an oak, or the egg of a hen to develop into other than a chick. The resemblance between the resulting oak and chicken may not, and probably will not, extend to absolute identity in every leaf and twig, or the marking on every individual feather, but sufficient resemblance is propagated to justify our recognising the offspring as of the same species as the ancestors. That the hereditary factor does much is self evident, though how much is at present open to dispute, and this for want of sufficient accurate evidence to determine. The general resemblance in configuration of a

child to its parent we accept as a fact of constant transmission and expect it with certainty; the frequent similarity of father and son we are not surprised at, and speak of it as "family resemblance"; but the manifestation of certain peculiarities of habit and manner that we frequently detect in parent and child, opens the question as to how far extrinsic circumstances may not have been concerned in fashioning them. In other words, whilst most of the structural and functional characters of the child are undoubtedly derived from or determined by the parent, the environment has some share in producing others; and the extent of that share is as yet unknown. In the departures from the assumed standard of a healthy person which we term diseases, the share which inheritance takes in bringing them about is especially uncertain, and requires much more precision of definition. But some of the conditions of the problem it is needful you should know.

Those abnormalities of structure which are apparent in an infant at birth, or very shortly after, are termed congenital, and may more properly be considered in the next section of our enquiry. Such defects as are included in the terms arrests of development and malformations, are herein comprised, as also the skin eruptions and other manifestations of congenital syphilis. But between these examples a considerable difference exists, for whilst the latter is most certainly an inheritance from one or both parents, the malformations and developmental imperfections may be, and usually are, due to harmful influences acting on the foetus, through the mother perhaps, but not derived from her, and which are as much the result of some adverse circumstances of the embryonic environment, as the exposure of an adult to some accidental injury is independent of heredity. Many imperfections are, however, transmitted, and cases of webbed fingers, cleft palate, malformed heart, brain, &c., have been known to occur in successive generations; whilst such minor abnormalities as the teeth being cut at birth, occasionally observed to recur in families, serve to connect well-marked diseased states across the boundary region with health.

Confining our attention to what may truly be called hereditary diseases, you will find the greatest difference of opinion exists between observers as to the extent to which they occur. On the one hand, a writer records his "strong impression that the majority of the phenomena of disease have a certain hereditariness of character";<sup>2</sup> and on the contrary, there are not wanting those who would throw doubts upon the almost universally admitted transmissibility of cancer. Surely, it may be urged, there ought not to be such a divergence in opinion among those enjoying equal opportunities of ascertaining the real state of the case. But there are many and grave difficulties which our imperfect knowledge cannot as yet bridge over. Towards making sure what is now uncertain, every well-recorded case that each of you can present will contribute, but you must be satisfied that your record is accurate and that you have taken every precaution to make it so. A fundamental difficulty as to enquiry is the variable meaning attached to the names of the diseases, not only by ourselves, but by the patients themselves, to whom much may be forgiven for a looseness of phraseology which we do not avoid. It is much better, therefore, to employ the words as used by the patient, not attempting to translate them into recognised pathological terms. For a patient to say her mother died of "tumours" does not give much information, but such as it is you have no right to substitute "cancer" for "tumours;" and "paralysis

<sup>1</sup> "The Doctrine of Descent and Darwinism," by Oscar Schmidt, 1875.

<sup>2</sup> "Induced Diseases of Modern Life," by B. W. Richardson, M.D., 1868.

of the brain" does not of necessity mean cerebral apoplexy. A little experience will soon help you to recognise the probable significance of some of the terms your patients use, though you may not build too confidently on your assumption. Another, and a great difficulty that prevents our obtaining accurate results, is the reluctance that many people have of disclosing what they very properly regard as family secrets. They may even wilfully conceal information bearing on any insanity, alcoholism, or even cancer that may have prevailed in their family, regarding the occurrence of such as reflections on their personal character. I need not tell you how sacredly you should respect the confidential knowledge you may obtain, guarding it by the most perfect anonymity. When your patient is assured of this, you may have many a glimpse disclosed that throws a valuable light on your investigation.

But besides these which I may call extrinsic difficulties in the way of obtaining perfectly accurate data on which you may conclude the existence or otherwise of any hereditary strain, there are many intrinsic difficulties which seriously complicate the problem. Foremost amongst them is the undoubted fact that many diseases do not breed true, that is, a large proportion of the children of parents who are the subjects of a certain malady suffer not from the same disease, but from some other which may or may not be apparently allied to it. This is particularly noticeable in the case of nervous diseases, concerning which I may say that many diseases of the central nervous system exhibit a singular proneness to hereditary transmission, a circumstance which suggests many interesting speculations. The various neuroses comprised in the terms insanity, epilepsy, paralysis, chorea, hysteria, neuralgia, hypochondriasis, and tendency to alcoholic excess, would appear to be propagated indifferently, at least to a very great extent. "Hypochondriasis," says Anstie, "is the almost inevitable inheritance of a certain percentage of the descendants<sup>3</sup> of any individual who may be strongly tainted with insanity." In rather less than one-third of his cases of epilepsy Dr. Reynolds<sup>4</sup> detected hereditary taint, not necessarily of epilepsy (for only 12 per cent. of such cases stated it to have occurred in the family), but of some nervous disorder. Dr. A. H. Bennett<sup>5</sup> also found in 41 per cent. of his cases of epilepsy a family history of the same disease and of some other allied neurosis. Such facts as these, which could only have been arrived at by careful observation, whilst they indicate the necessity for the most detailed enquiry in all cases, equally show how easily an erroneous estimate of the extent to which inheritance may prevail, unless the questioning be directed towards other than the actual disease the given patient may be suffering from. It is more than likely that extended observation may show a similar alliance among groups of diseases of other organs.

(To be continued.)

**CHARITABLE BEQUESTS.**—Mr. William Goldsmith, late of Parliament Street, has bequeathed 400*l.* each to the Westminster Dispensary, Rochester Row; Charing Cross Hospital, and the Hospital for Incurables, Clapham Road; 300*l.* each, to the Westminster Hospital, and the Deaf and Dumb Asylum, and 200*l.* to the London Fever Hospital. Mr. Robert Bownas Mackie, late M.P. for Wakefield, and of St. John's, Wakefield, has bequeathed 1,000*l.* each to the Wakefield Dispensary and Clayton Hospital, in aid of the endowment fund.

## APPOINTMENTS FOR THE WEEK.

*Friday, October 23 (this day).*

CLINICAL SOCIETY, 8.30 p.m.—Mr. Mayo Robson, "Two cases of Cholecystotomy," with remarks; Dr. Edward Seaton, "The Characteristic Symptoms of a Febrile epidemic illness at a School"; Dr. Samuel West, "A case of Idiopathic Purulent Peritonitis in a child of ten," with Autopsy; Mr. Walter Rivington, "Two cases of Ligature of the external Iliac Artery for Femoral Aneurysm."

*Monday, October 26.*

MEDICAL SOCIETY OF LONDON.—Dr. J. Milner Fothergill, "On a Presumptive Diagnosis of Gout"; Dr. Isambard Owen, "A case of Asymmetry."

*Tuesday, October 27.*

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Mr. Morratt Baker, and Mr. A. A. Bowlby, "Diffuse Lipoma"; Mr. Walter Rivington, "A Case of Ligature of the Left Common Carotid Artery Wounded by a Fish-bone which had penetrated the Pharynx."

*Wednesday, October 28.*

BRITISH GYNÆCOLOGICAL SOCIETY, 8.30 p.m.—Specimens will be shown. Dr. Heywood Smith, "Hernia of Ovary"; Mr. Lawson Tait, "Hernia of Ovary"; Dr. Imlach, "Treatment of Prolapsed Ovaries by Oöphorraphy."

HUNTERIAN SOCIETY, 8.30 p.m.—Mr. Clement Lucas, "On Inversion with Inflation in the cure of Intussusception," with a successful case; Dr. Stowers will exhibit a case of "Rare Disease of Nails," and one of "Erythematous Lupus"; Mr. Cotman will exhibit cases of "Dead Fingers."

*Thursday, October 29.*

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 3 p.m.—Annual Meeting of Fellows and Members to receive Report of Council.

## Medical Times and Gazette.

SATURDAY, OCTOBER 24, 1885.

WE would remind our readers that the annual meeting of Fellows and Members of the Royal College of Surgeons will be held on Thursday next, the 29th inst., when a report from the Council will be submitted. This report, which has been printed, comprises a record of the transactions of the Council during the collegiate year from July, 1884, to July, 1885, the returns of the results of the several college examinations, and a statement of the college receipts and expenditure during the same period. The substance of this document has already appeared in our columns in the periodical reports of the meetings of the Council. The returns of the results of the examinations show that of 113 candidates for the first Fellowship Examination 49 passed, and of 56 candidates for the second Fellowship 37 passed. At the Primary Membership Exami-

nation 1,191 candidates presented themselves in both Anatomy and Physiology, of whom 653 passed, and 254 were referred for three months in both subjects, while 144 were referred for the same period in physiology only, and 72 for the same period in anatomy only; the candidates referred for six months in both subjects numbered 56. At the Pass Examination there were 960 candidates, and 536 diplomas were granted. The total receipts of the College during the year were 23,801*l.*, and the expenditure 22,402*l.*, leaving a balance at the bankers of 3,464*l.* on Midsummer Day, 1885.

At the first meeting of the Pathological Society this session, held on Tuesday last, the crowded state of the room bore witness to the fact that this Society has lost none of its popularity. The President, on taking his seat, reminded the members that at some future meeting, the exact date of which will be settled by the Council, there will be an exhibition of specimens of intra-cranial tumour, especial regard being paid to their seat and nature. The new volume of the "Transactions" was laid upon the table, and will, it is hoped, be in the hands of members in the course of the next few weeks; judging from the cursory glimpse we were able to obtain of it, it appeared to be one of the biggest volumes that the Society has yet issued. There were a large number of exhibits, but nothing of any special interest, and there was so little discussion that a long programme was easily accomplished in the allotted time.

THE one-hundred-and-thirteenth session of the Medical Society of London was opened on Monday evening last by an address from the President, Dr. Ord, a part of which will be found elsewhere in this issue. As will be seen, Dr. Ord has been seeking in vegetable pathology for a solution of the mysteries of hyperpyrexia; how far he has succeeded can only be proved by lapse of time, and by further experimental observations in the same field. This much, however, can be said now, that we are more likely to find an answer to the problems of disordered function in the higher organisations if we first make ourselves thoroughly acquainted with the normal conditions in the lower forms in vegetable life. The new volume of the Society's "Transactions" will be distributed within a week or two, and will be found to maintain the high standard of its predecessors. The discussions on the various papers read, which have usually been published, will not be found in the present volume, and considering how imperfect they generally were, the omission cannot but be commended. We are pleased, nevertheless, to know that arrangements have been made for reporting the discussions more fully and more correctly, so that next year, in all probability, the volume will revert back to an improved re-issue of its original type.

THE first meeting of the Ophthalmological Society was held on Thursday se'nnight, and was well attended. The number of patients exhibited was large, and some of them were cases of unusual interest. The chief

paper was by Mr. Anderson Critchett, referring to a case of orbital cellulitis in which the very close connection which may subsist between orbital affections and dental irritation was once more made evident. Dr. McKeown, at somewhat undue length, detailed his operation for the treatment of cataract by the intracapsular injection of water. As none of those present appeared to have tried it, though brought to the notice of the profession some eighteen months ago, there was nothing but the author's experience as to it available; but as one of the speakers said, from a surgical point of view it seems a sound proceeding, and we shall expect before long to hear the results which it has met with in the hands of others.

THE Bowman Lecture of the Ophthalmological Society of the United Kingdom will be delivered at 9 p.m. on Friday, November 13th, by Dr. Hughlings Jackson, F.R.S., who has chosen for his subject "Ophthalmology and Diseases of the Nervous System."

THE decline in the progress of the cholera in Spain, which, at the date of our last issue, appeared to have been somewhat checked, has happily continued uninterruptedly since then, the daily tale of deaths having diminished from about one hundred to less than fifty. In the province of Palermo, too, there is a steady diminution in the mortality, the deaths now numbering some twenty a day. Professors Pettenkofer and Emmerich are reported to be at Palermo, having been sent there by the German Government to enquire into the causes of the cholera. The fact that the disinfection of letters coming from Sicily is no longer insisted upon by the authorities testifies that in their opinion, at any rate, the epidemic is nearly at an end. It appears that there is considerable doubt as to whether the International Sanitary Conference will re-assemble next month, as was agreed at the close of its session last May.

THE very influential meeting which was held at the Mansion House last Tuesday, for the purpose of promoting the objects of the National Association for supplying female medical aid to the women of India, augurs well for the ultimate success of that organisation. A fortnight ago we set forth the exact objects which the Association has in view, and we need add but little to what we then said. The main fact is that at the present time the women of India are almost, if not entirely, deprived of anything like skilled medical advice in the time of sickness, because prejudices which are the growth of centuries preclude them from seeing anyone of the male sex, and up to the present time the female doctors have been so few and far between as practically to afford no relief to this state of matters. Another chief fact is that it is essential that any lady doctor commencing practice in India amongst the women should have such an amount of money guaranteed to her as would, with her professional earnings, enable her to live in moderate comfort. The speakers at the meeting in question addressed themselves to both of these points, and we would only urge one point in addition to the remarks

then made, in favour of a good sum being guaranteed to those ladies who risk their lives in undertaking the arduous and responsible duties which they will take upon themselves. It is simply this: it is of the first importance that ladies engaged in the work should keep their health, and those who know the climate will agree that this often means that what we should regard as luxuries here, are in that climate necessities, which may not be dispensed with with impunity.

THE cold weather which we have lately experienced in London was fully maintained last week, when the mean temperature for the whole week was no less than 6° below the average of the past twenty years. The total number of deaths, 1,346, though exceeding the returns of the preceding six weeks, was 180 below the average; of the total deaths 550 occurred in children under five years of age. Of the zymotic diseases, measles had 28 victims, and whooping-cough 29, whilst scarlet-fever and diphtheria had 22 and 23 respectively. From small-pox there were no deaths, and we must go back nearly two years, viz., to November, 1883, to find a similar record. The deaths from diseases of the respiratory system amounted to 301, having just

that the work is making good progress, and that Messrs. Churchill have every expectation of issuing it to the subscribers early next year. The photographic reproduction has been very successful, so that many of the MS. passages come out more legibly than in the faded and time-worn original, a result which has not a little facilitated the labours of the transcriber.

IF M. Pasteur should succeed, as everyone but the antivivisectionists must hope that he will, in developing his scheme for the prevention of rabies by inoculation into a real working system, he will find plenty of scope for its utilisation in this country. Five and twenty years ago there would have been next to no demand for it, for from 1857 to 1863 the deaths from hydrophobia in England and Wales did not exceed an average of 3 *per annum*, and so low a mortality from hydrophobia implies a corresponding absence of rabies. But ever since 1864 the yearly deaths from hydrophobia have steadily advanced, and in 1877 they reached the alarming number of 79. The yearly numbers since then have been, in 1878, 50; in 1879, 35; in 1880, 29; in 1881, 34; in 1882, 28; and in 1883, the last year for which we have returns, 35. In the ten years, 1874-1883, 440 persons died in England and Wales of hydrophobia, viz., 365 males and 75 females. In London, during the same period, the deaths from this cause numbered 64—viz., 48 in males, and 16 in females. Of these 64 deaths, as many as 16 occurred in 1877, so that the year of greatest mortality in London corresponded with the year of greatest mortality in the country at large. We have at present, no means of knowing how fatal hydrophobia has been in the provinces, but if we may judge from the metropolitan mortality, 1885 is likely to enjoy the unenviable notoriety of beating the worst year yet on record, viz., 1877. In London, the record of 1877 has already been eclipsed, though the present year has still ten weeks to run. Seventeen deaths from hydrophobia have already been certified, and though the record of last week is happily a blank, we dare not hope that there will be no more deaths from hydrophobia this year.

IT is high time that some systematic measures were taken against the continuance of rabies. We cannot wait for M. Pasteur, whose device may take months and even years to put into working order. Science being unable to help us, we must fall back upon the Home Secretary and the police. The case is one which calls for strong measures, both for the sake of dog and human kind. There is such a strong prejudice in England against the compulsory muzzling of dogs when in the street that milder measures might perhaps be tried first. A notice should be issued at once that the police will capture and take to the dog's home all dogs found in the streets without a distinctive badge of ownership or a muzzle, and that such dogs will be at once destroyed. A few cases of hardship might occur under such an order which would not happen with universal muzzling, but dog-fanciers should remember that they have a responsibility to the community, who have a right to protect themselves against the risks of

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past twelve weeks.

doubled their number in a month. The healthiness of the metropolis is echoed in the provinces, where we find that the highest death-rates are those of Preston 27.0, and Manchester 24.0. Even Glasgow shares in this general state of well-being, and has a death-rate of only 20.5.

As our readers have been informed, Harvey's MS. Lectures will soon be published in facsimile of the author's handwriting, accompanied by an interleaved transcript in ordinary printer's type. We learn

a further increase in the prevalence of rabies. If the milder order failed, we should then be obliged to have recourse to muzzling, which Continental statistics show to be a sure and certain means of stopping rabies when thoroughly carried out.

THE return from University College Hospital, which had not reached us on the occasion of our last issue, shows an entry of 67 new medical students, and 69 for the Preliminary Scientific Examination of the University of London, a total of 136 in all. At King's College, as will be seen from Dr. Curnow's letter published in another column, the entries are not so unsatisfactory as appeared from our statement last week, the number which we then gave as representing the total entries really representing entries for the full curriculum, and not including 30 students who have entered for partial study. A corrected return from St. Mary's Hospital shows an entry of 17 for special courses, and 12 for preliminary scientific classes, in addition to the 52 full entries. We have as yet received intelligence of the new entries from only three of the provincial medical schools. At Cambridge, as many as 104 fresh men have already announced their intention of studying medicine, and more will probably do so after the publication of the October Previous Examination Pass-list. At Manchester, the total new entries number 94, or 13 more than last year. Of these, 54 have entered] for the full curriculum, 22 for preliminary scientific classes, and 13 for special subjects. At Leeds, the new entries for the full curriculum number 37, or 13 more than last year; there are also 4 students for special classes.

ACCORDING to no less competent an authority than the Rev. E. S. Roberts, late Senior Proctor of the University of Cambridge, the morals of the undergraduates have undergone a marked improvement within recent years. On lately resigning his office, which he had previously held eight years ago, Mr. Roberts said, "I desire to put it on record as matter of common observation, and I do so without fear of contradiction, that during the interval covered by the past eight years the gain to order, decency, and morality in every sense of the word has been immense." These eight years have seen the number of medical students increase from some fifty at most to over three hundred; and it is significant that the gloomy prophecies of some of the older members of the University—as to the ill-effect on the average of manners which would follow an influx of "medicals"—have been so agreeably falsified. The Cambridge "medical" has this advantage over many of his fellow-students, that he knows his aim and purpose in life, and that his numerous and stiff examinations enforce constant and persevering work. He is accordingly proving himself an elevating and an energising factor in college and university life.

DR. RUSSELL, the Medical Officer of Glasgow, is discovering how little honour a prophet has in his own country. The recent death of Mr. Kenneth Macleod

has left vacant the post of chief sanitary inspector. Under the old arrangement the medical officer and the chief inspector were each head in their respective departments, and one was not subordinate to the other. There was thus a risk of divided counsels. Naturally the opportunity of re-arranging the management, before a new inspector was appointed, was duly taken advantage of by the Committee on Health of the Town Council, and it was agreed "that in order to avoid divided responsibility in future the medical officer should be the head of the Sanitary Department, and should direct and superintend the work of the sanitary inspector, in the way and to the extent that he may think necessary in the interest of the health of the city." That seems a proper and a wise thing to do, but it did not commend itself to the Town Council, when the Committee's proposal came up for ratification, for they decided by 25 votes to 17 to continue the old method of management with its divided responsibility. But there was found a Councillor, a medical practitioner of the East End, to declare that he could bring forward proof that Dr. Russell had not performed his duties as he should have done, and that he was not able to accomplish the work which ought to be done by the Medical Officer of Health at Glasgow. This member of the profession may gain applause from the free and enlightened electors of the East End by petty attacks such as this, on highly placed and responsible officials, but he is singularly unfortunate in selecting one of the ablest and most widely known health officers of the country. If he chooses to enquire, he will find that those who are qualified to offer an opinion deem Glasgow fortunate in possessing Dr. Russell's services.

PROFESSOR CHARTERIS, of Glasgow University, has returned to his duties in connection with the Chair of Materia Medica and Therapeutics, after two years' absence owing to illness, and is apparently once more in vigorous health.

OUR Glasgow Correspondent writes:—The meeting held in Glasgow a short time back, to consider the financial position of the Western Infirmary, seems to have regarded the position from a very one-sided point of view. It was shown by the Treasurer that since 1881 the ordinary income has annually been insufficient to meet the expenditure. Last year the deficiency was over 5,200*l.*, and this year it promises to be 5,700*l.*, the deficit increasing though there has been no falling off in subscriptions and donations. The deficiency has hitherto been met from extraordinary income, but these sources are at present exhausted. After the Treasurer's statement had been read, the meeting proceeded to consider how the revenue could be increased to meet the expenditure. Now, when an ordinary individual finds year after year that his income persistently refuses to meet his expenditure, he usually concludes, if he is a wise man, that while it is desirable, if it be possible, to increase his income, it is absolutely necessary for him to curtail his expenditure. The diminution of expenditure was not once considered at the Infirmary meeting; it was

not even suggested that this was a possible method. It was stated that the demands on the Infirmary for accommodation were frequently greater than the managers were able to meet, and the meeting seems to have taken it for granted that, under these circumstances, diminution of expenditure was impossible. If, however, any one examines the report of the Infirmary for the past year (1884), he will see that of the total number of patients treated, numbering 25,816, only 3,777 were in-door patients, while 22,039 were out-door patients. Indeed, during 1884 there were 150 fewer in-door patients than during 1883, and yet the deficit in 1884 was much larger than that of 1883. Is it wrong to ascribe the increase in the deficit as due, at least to some extent, to the greater number of out-door patients, who in 1884 were over 3,000 in excess of their number in 1883? It is impossible from the report of the Infirmary to discover what is the expense of the out-door department. We venture, however, to think that a very considerable saving could be effected in it, and that here at least expenditure could be diminished with disadvantage to no one. Everyone who knows anything at all of dispensaries for out-door patients, is well aware that a very large number of persons are daily found in attendance who have no right to be there, who go to save the fee they are quite able, but unwilling to pay. If any one of the managers of the Glasgow Western Infirmary would take the trouble to attend the out-door dispensaries, one day's experience would probably be sufficient to convince him that money subscribed to help the sick poor is daily being expended on those who can pay for themselves, but who are quite willing to appropriate help meant for their penniless brethren. In the case of the out-door dispensaries it is absurd to say that the multitudes who throng them prove the need of their existence. In every large town there are thousands willing to take whatever they can get for nothing. The question is, Are they to continue to get for nothing what they can purchase for themselves? What we should like to point out to the Western Infirmary Managers is that they seem to have failed to consider the possibility of reducing their expenditure without interfering with the accommodation their house can afford to proper patients. We would suggest that they should consider the expense of their out-door department, which they seem entirely to have overlooked, and should determine whether they cannot arrest indiscriminate out-door relief. We venture to believe that if they did this, they would largely diminish their deficit without refusing help to a single needy person.

HER MAJESTY THE QUEEN has been graciously pleased to appoint Dr. William Moore, of 67, Fitzwilliam Square North, and Moore Lodge, Co. Antrim, to be one of Her Physicians in Ordinary in Ireland, in succession to the late Dr. Benjamin George MacDowel, Dr. Moore holds a foremost position in medical circles in Ireland, and his appointment has given satisfaction to his many friends. He was formerly King's Professor of Medicine in the School of Physic in Ireland,

and from St. Luke's Day, 1882, to the same date in 1884, he filled the Chair as President of the King and Queen's College of Physicians. He has made numerous valuable contributions to the literature of medicine and of medical science.

WE are glad to learn from a recent number of a Canadian journal, that the opposition to vaccination amongst the Roman Catholic population of Montreal and its environs has been strongly denounced by the priests, who have publicly assured their congregations that vaccination is the only known safeguard against small-pox, and strongly urged them to respect the laws of the health authorities.

It has been the fashion of late, to attribute the remarkable immunity from cholera enjoyed by the population of Rome, not only last year, but on each previous occasion, to the purity, *i.e.*, the freedom from faecal contamination of the water supplied by the four remaining aqueducts. To a certain extent this may be the explanation, but it should be remembered that there are a large number of wells public and private within the city. A few of these, Sallustian waters as they are called, rival those of the aqueducts in purity, and some, as those in the Via Garibaldi and the Piazza Rusticucci, are probably fed by some unseen communication with the Aqua Paola, and that in the palace of Prince Aldobrandini with the Acqua Felice, but the ordinary wells sunk into the ground water are very impure, so much so that Professor Cannizaro, the well-known chemist, in a report to the Sanitary Committee of the municipality, strongly urges their disuse. They are highly charged with nitrites and nitrates, chlorine and phosphoric acid, and yield a residue out of all proportion to their hardness. A comparison of the waters of two trasteverine wells with those of two within the city shows how the ground water of an area which has been inhabited by a dense population for 2,000 years is befouled. The residue of the former in the Porta pia and Villa Ludovisi was in parts per 100,000, 39 and 33, the hardness 25.1 and 21.5, the nitric acid 1.832 and 1.912, and the chlorine 1.207 and 1.388, while in the city wells in the Vigne Cancalani and Renazzi, the solids were 82 and 111, the hardness 66.5 and 81.3, the nitric acid 26.799 and 30.797 and the chlorine 14.058 and 14.004. The way in which the ground water gathers pollution in its course through the subsoil towards the river is well seen in a comparison of the residues of four wells taken successively in the direction of the underground current, *viz.*, 48, 57, 73, and 120, the hardness varying inappreciably. These facts are the more important and interesting since the waters are almost without exception limpid and pleasant and free from colour, odour or taste. Indeed, the only water that affords to the unaided senses evidence of pollution is that of the Argentina alla Marrana di S. Giorgio, which is redolent from the waste of the gas works. It too, alone, contains any appreciable amount (in this case a large one) of ammonia.

WE understand that after two protracted discussions at the Royal College of Physicians, at which it was generally recognised as a grievance that a degree of medicine should be almost inaccessible to the bulk of English practitioners, the following resolution was adopted:—"That it is desirable that persons examined by the Royal College of Physicians of London and the Royal College of Surgeons conjointly, and found duly qualified, either by the ordinary or by an additional examination, should have a degree in Medicine and Surgery conferred upon them." Of course we are aware that this is only a resolution, but it involves a principle, and we are glad that that principle has been formally accepted by the College of Physicians.

---

### THE HARVEIAN ORATION.

PLEASANT as are the feelings of the First-of-October orators when they have finally touched up and laid aside their Introductory Addresses, pleasanter far, it seems to us, if we may compare these small things with the greater affairs of Pall Mall, must be those of the Harveian Orator, however distinguished he may be, when he has sent his copy to the printer, and has only to look forward to the calm satisfaction of reciting it to his grave and sympathetic audience. Sympathetic, indeed, the audience of the Fellows will always be on these occasions when so good an opportunity is given and improved, for indulgence in an unselfish hour of self-gratulation; but such sympathy is no superfluous reward for the labour and anxiety which are the necessary lot of the speaker of the day. Dr. Quain is to be congratulated on having ably performed his arduous task in the production of the readable and fluent address which appears elsewhere in our columns, and if he has not quite solved the Horatian difficulty "*proprie communia dicere*," he has at least, while speaking of things familiar, spoken very well.

In the choice of his subject, Dr. Quain certainly availed himself boldly of the liberty of unlicensed interpretation, when even with his passing apology to the shade of the Pious Founder he proceeded to "search out the secrets of nature," by endeavouring to answer the questions why medicine has not enjoyed that high estimate of its value as an art and as a science to which it is justly entitled, and whether there be any grounds for anticipating a more satisfactory future. The licence which he thus took, was indeed "poetic," for these questions, besides being somewhat startlingly raised in this context, can scarcely be said to deal with "secrets" at all. To the first, none can be at much loss for an answer, though perhaps as to this, *quot homines, tot sententiæ*; and as to the latter, there is nothing hidden. But granting that on such an occasion it is but graceful for Dialectic to give way for once to her sister Rhetoric, we would merely enquire here whether Dr. Quain has given the best and fullest answer to the first question he propounds. He gives two answers to the question why scepticism as to the power of the healing art should be rife both within and without the profession. One source of

want of faith, he says, is intrinsic, and due to the inherent complexity and difficulties of the subject; the other is accidental, external, to be found amongst the people at large, not excluding men of science. In his treatment of these questions, Dr. Quain has not gone quite to the root of the matter; but has dealt rather with proximate than ultimate causes. It is quite true that the difficulty and complexity of medical science and art may cause the fainter-hearted among us to fall by the way and despair unduly of progress, regardless of the steps which are slowly but surely gained by scientific labour and research. There are many who, rightly realizing that the ideal of the most sanguine of our number is at least far off and probably impossible of attainment, are tempted in their weakness to cease toiling along their up-hill way when they see that there can be no advance by leaps and bounds. But the true scepticism which must be the companion of all enquiry is before all things a necessary factor of the scientific medical mind, and is due, as Dr. Quain says, to the inherent complexity of the subject. This is a fact which cannot be got over. It is the public attitude of the profession, which at least implicitly acknowledges this inherent and scientific scepticism, that really touches the question of the justice of the opinion formed by outsiders. The two elements in the undoubtedly false public estimate of the value of the medical art are very closely connected; they cannot be considered apart. We may at once admit with Dr. Quain, that one great cause of the classical doubt and discredit thrown upon professional proceedings is to be found in the annals of medicine of the pre-scientific period, when facts were always at hand to prove that the pretensions of physicians were in inverse proportion to their performances. The professed confidence of doctors in "the healing art," will never be greater in any scientific millennium than it has been in the darkest ages of superstition and quackery. Here, certainly, was a firm foundation laid for the incredulity of the incredulous during many years.

But when we come to consider the other "external" causes mentioned by the orator, namely, the amazing credulity of the mass of mankind, and the obstinate and unreasoning incredulity of no inconsiderable minority, it is by no means clear that these can be taken as ultimate facts in the present day, or as a satisfactory explanation of the results we deplore. The credulity of the public now is not to be wondered at in matters of medicine any more than in the past; it springs from the inalienable but often unexpressed conviction in the mind of even the educated that man, the lord of the universe, has a right to be well, and the love of life and health are so instinctive, the arrogance of the human being is still so great, that he will naturally cling to any hope offered him of prolonging the one and maintaining the other. What can many of the ignorant do but believe those who say most loudly that they can help him; and if the quack promises more than the scientific physician, small wonder that he gets a considerable following even now. But the number of these ignorant faithful is daily decreasing, and will diminish still further with a wider scientific and especially physiological education

The "incredulity, again, of no inconsiderable minority of the public," including some men of science, is but a complement of the credulity of the masses, and due indirectly to similar causes. While the latter believe that the medical art can do everything, and consequently put their faith in the omnipotent quack, the former, well aware that its scope is limited, and at the same time being ill-informed or misinformed of its real powers and progress, have a tendency to regard only its weakness and its failures, and to preach and profess a creed of medical nihilism. May it not be said that even in this later day, the attitude of the profession towards the public may have something to do with the sins of both faith and unfaith that are attacked in this oration. We still want more simplicity and down-rightness in dealing with our patients, and a little less mystery in medical matters would much diminish any force there may be in the accusation that our practice is not equal to our professions. We may hail with delight every improvement in our knowledge which leads to better treatment, but we need not be always singing pæans on our progress in this direction which, plainly stated to an outsider, must certainly appear but proportionately small. In telling the public that the sole *raison d'être* of the profession is to prevent and cure disease, we run a risk occasionally of being told we are unprofitable servants; but we strangely forget to congratulate even ourselves, and still more to inform the world, on the immensely greater strides that have been made in the knowledge which subserves prognosis. Hippocrates said that the best physician was he who could make the best prognosis, and the intelligent part of the public, whose sin is incredulity, is not so slow to appreciate this fact, and to give it its due value. There is, indeed, a very large proportion of intelligent people who well know how much more is possible now to the physician in this direction than in the not very distant past; and who keenly appreciate a careful opinion and forecast of an illness, though they are as well aware as the physician himself that perhaps but little can be done towards expediting the cure or delaying the fatal result. The feverish anxiety shown by some doctors and teachers of medicine to impress on the public and their pupils the omnipotence of what is called the Healing Art, and to warn them in vague and general terms against scepticism in medicine, is as dangerous in its way as the thoughtless remarks of others, that because we can do but little in proportion to what we desire we had better do nothing at all. Until teachers and practitioners of medicine are absolutely true to themselves, their pupils and their patients, there will always be a certain public which, on the one hand, reflects evil on the profession by overcredulity and patronage of the charlatan, and on the other hand, in a spirit of uncritical disbelief, refuses to trust to it at all. Let the scope and powers of the medical art be fairly and fully stated, and the curtain of mystery be finally lifted from before it, and we shall hear less and less with increasing education of the complaint of doctors that they are undervalued. Undervalued as a class they perhaps are, and many must deeply feel the inadequate estimate of their merits; but it is well to remember, with a view

to reform, that to some small extent at least the profession is itself to blame for the evils that all deplore.

---

#### THE GENERAL MEDICAL COUNCIL.

THE General Medical Council has been summoned for Tuesday, the 17th of November. We are well aware that the great majority of medical readers do not take much interest in the sayings and doings of this august body, an indifference which is much to be regretted, for were it otherwise the great waste of public money which is about to be perpetrated by what we regard as an utterly unnecessary meeting would no doubt be checked. The meeting has been forced on the President by the action of the Irish Branch Council, and we do not deny that it would have been difficult for him to refuse the repeated demand for an extra session; but having yielded, we trust that he will be more than ordinarily firm in keeping the members strictly to the business in hand, so that the session may be as speedily ended as possible. The pretexts on which the Irishmen have demanded this special session are three in number: (1) In reference to the matriculation examinations of the Queen's Colleges at Belfast, Cork, and Galway; (2) To remove the names from the Register of certain registered practitioners who have been convicted of various offences; and (3) To reconsider the regulations in regard to the place of elementary mechanics amongst the subjects of preliminary education. We trust that the last two will not be allowed to be discussed at the forthcoming session at all. The Council deliberately settled the place of mechanics last session, though warned of the result by Professor Haughton, and the proper course is for him to carry out his threat that the Dublin University students would not appear on the Students' Register, instead of wasting the time of the Council with any further discussion on a subject already worn threadbare. The second point presses even less for immediate decision; the case mainly referred to by the Irish Branch Council is that of a practitioner lately convicted and sentenced to ten years' penal servitude, and as he is at present safe enough in prison, there is no need to hasten the removal of his name from the Register, the object of which would be to prevent him from practising, an object much more effectually attained by the process of law now being carried out. As regards the other offenders also alluded to, we believe it is one of the unwritten laws of the Council that mere conviction in a court of law, even if followed by the cancelling of the offender's diploma, is not necessarily to be followed by the removal of his name from the Register. It must be remembered that this deprives a man of his calling in life, and is therefore virtually awarding an additional punishment to that inflicted by the law. There is, therefore, and we entirely approve the principle, no necessary sequence between conviction and removal from the Register, though no doubt in most cases the one very properly follows the other. When we come to deal with the first of the reasons for the forthcoming

session it is difficult to speak without indignation. At the tail end of a long session—on the eleventh day, in fact, of the sitting last May—on the motion of Professor Haughton, the report of the Preliminary Examinations Committee was adopted without discussion and almost without remark, and thus, merely on the strength of his statement that the examinations of the Queen's Colleges of Belfast, Cork, and Galway were superseded by those of the Royal University of Ireland, these three bodies were removed from the list of those whose preliminary examinations are recognised by the Council. The immediate effect of this was the delivery of strong protests from each of the bodies concerned, and the Executive Committee, finding that a blunder had been made, simply suspended the resolution until it could be further discussed by the Council. The Irish Branch Council are of opinion that it is necessary that the Council should be summoned to discuss this conduct of the Executive Committee. We feel confident that none but the Irishmen who will be paid to come over and argue the point will see the special urgency of the matter. The action of the Executive Committee simply left matters where they have been for many years past, and no injustice could possibly have accrued to anyone had they been allowed so to remain until next spring.

At the meeting of the Executive Committee which has been summoned for to-day (Friday), we believe the chief business will be the reconsideration of the standing orders regarding the removal of names from the Medical Register. The legal advisers of the Council are of opinion that the existing practice is right in principle and works satisfactorily, and they will therefore only advise slight modifications in detail. The statement that nearly twelve thousand copies of the British Pharmacopœia have been sold will, no doubt, be received with satisfaction, and it will not tend to make the Committee inclined to accede to the petition which hails from Liverpool to the effect that a copy of the new Pharmacopœia should be gratuitously presented to every registered practitioner.

---

#### DR. FERRÁN ON HIS TRIAL.

THE cholera which through the past summer has ravaged the southern and eastern provinces of Spain, though not yet extinct, has so far declined in extent and severity that there seems every reason to believe that, for this year at least, we shall not witness any recrudescence of the epidemic. The panic fear and the intense excitement natural to a southern people have at the same time subsided, and though Ferránists and anti-Ferránists still regard one another with feelings of suspicion, if not of antipathy, it is more possible now than it was some months ago to calmly review the evidence for and against the alleged efficacy of anti-cholera inoculation. In one of his admirable letters, the special correspondent of the *Times* gives an interesting account of his interviews with Dr. Ferrán himself, with Dr. Moliner, of the Madrid Commission, and with our countryman, Dr. Jelly, who has passed the whole of his professional career in Spain, as well as a very fair summary of the strongest, or apparently

the strongest, evidence on either side. Naturally the first question he put to Dr. Ferrán was whether he believed that one attack of cholera conferred any immunity against subsequent exposure to infection, as on that his whole theory and practice must stand or fall. Dr. Ferrán was positive on this point, but in this opinion he stands, we believe, alone. It is true that Lebert once advanced this view, but certainly the experience of Indian medical officers and of those who have had the widest acquaintance with cholera in Europe and America tends to the opposite conclusion.

The veteran Surgeon-General John Murray, in a letter to the *St. James's Gazette* of June 8th, stated that in Agra gaol between 1860 and 1865, out of an average strength of 2,364 prisoners, there were 1,196 cases of cholera, of which 63 were second and 5 were third attacks. Dr. Cameron, indeed, in his article in the *Nineteenth Century* of August last, endeavoured to prove from Dr. Murray's figures that the liability of the "cholerised" was twelve times less than that of the others. But Dr. Cameron's fallacious reasoning was fully exposed by Dr. Willoughby in the September number of that review; it arose from his treating the "average strength" of 2,364 prisoners as if it represented a permanent population instead of an ever-shifting one. It was, he said, as if Dr. Cameron "from an annual death-rate of 100 per cent. on the number of beds in a hospital, where the average time during which the patients remained under treatment was six weeks, had inferred that every case ended fatally instead of 1 in 9. What Dr. Murray's figures did prove was that of those who remained in gaol long enough to permit of a second attack, no fewer than 63 did so suffer," and "so far from a previous attack diminishing the danger of a subsequent one, while only 241 of the 1,060 primary cases (22·7 per cent.) died, 30 of the 83 secondary cases (47·5 per cent.) were fatal, a result which did not say much for the 'protection,' and contrasted strongly with the influence of vaccination on the mortality of small-pox." The United States Commissioners, in their report on the epidemic of 1873, say (p. 61): "Numerous instances are recorded of individuals who recovered from an attack of cholera to succumb to the disease at a later period of the same epidemic." Dr. Ferrán told the *Times* correspondent that when cholera broke out a second time in any place it was generally the new arrivals who suffered, and, in one instance, among a number of labourers, it only attacked those who had come from villages where there had been no cholera. Very well; no fact is better known than that different individuals are susceptible to a given infectious disease in different degrees—that when an epidemic dies out it is generally because the number of specially susceptible has been exhausted, the survivors escaping because they are less susceptible; but this is quite a different thing from immunity acquired by an attack, for new comers from a locality hitherto free are sure to include a large proportion of more susceptible individuals.

Dr. Ferrán, who formerly asserted that he had traced the life cycle of Koch's bacillus, appears to have considerably changed his views as to the nature of his cultivations. He now, we are informed, repudiates the suggestion of "attenuating" the virus

in the sense of modifying the development of the bacillus; he maintains that by boiling, or a process of self-exhaustion in closed tubes, the bacilli are exterminated, and that his "vaccine," free from all organisms, owes its virtue to a purely chemical product which he hopes may some day be isolated. He thinks that if injected into the intestine the results might be serious, and that the mildness of the symptoms following his inoculations is due to the choice of the subcutaneous connective tissue as the place of operation. But this is opposed to all analogous experience. This tissue presents, it is true, an unfavourable soil for the inoculation of tubercle bacilli, though Tscherning has recently reported a case in which accidental inoculation of the finger was followed by tubercular deposits extending as far as the axilla, though amputation of the finger and extirpation of the infected glands averted further trouble; but the subcutaneous tissue is well-known to be a most eligible site for the injection of chemical agents.

With Dr. Ferrán personally, the correspondent was very favourably impressed. "The worst," he writes, "that can be said against him by those who have not faith in his theories, is that he is the dupe of illusions conceived in ignorance, but acted on in good faith," and Dr. Ferrán expressed his readiness to put his practice to the test in India or elsewhere, believing that from Englishmen he would meet with fair and honourable treatment. But, when we come to the statistical evidence on either side, we encounter a mass of hard swearing which simply staggers us, and which we should not have expected except among Hindoos or Chinamen. On the one side we have reports by the score, stamped and sealed by alcaldes, judges, priests, and notaries, whose signatures are followed by those of the medical men and inhabitants of the various towns, declaring that so many of those who refused to be inoculated died of cholera, while all who underwent the operation escaped, or if they died did so within the five days which Dr. Ferrán asserts to be the incubation period, and that in no instance did serious consequences follow the inoculation. We may remark in passing that in the minds of most authorities there is great uncertainty as to this period. Niemeyer and Grüttner estimate it as from 36 hours to three days at the longest, and we are inclined to agree with them.

Such evidence as is adduced by Dr. Ferrán would, from any other civilised country, be irresistible; but Dr. Jelly, from long acquaintance with Spain and the Spaniards, attaches no importance whatever to this formidable array of figures. He considers that the ignorance of the rural population is such that the elaboration of any statistics is quite possible. He and Dr. Moliner, perhaps the ablest physician in Valencia, state that they have seen numerous instances of grave and even fatal septicæmia following Dr. Ferrán's own inoculations, and very many deaths from cholera at various periods subsequent to the operation. Indeed, Dr. Moliner, who believes in the specific nature of the bacillus, is inclined to the opinion that cholera may be thus induced and propagated. Several eminent Spanish medical men, who submitted themselves to inoculation, suffered from septic fever of a severe type, with a temperature of 105° F., and abscesses requiring

surgical treatment. Dr. Jelly, too, found at Alcira that the local doctors were incapable of correct diagnosis, while there is abundant proof that many deaths from cholera occurring among the inoculated have been certified as due to other causes.

But the most damaging revelations were those which followed the demand for the names and addresses of the persons whom Dr. Ferrán had inoculated in certain towns and villages. On comparing the lists produced with the registers of the deaths, it was found that numbers—in one village no fewer than twenty—were already dead and buried several days before the date on which they were stated to have been inoculated! No wonder, observes the correspondent, their deaths did not appear subsequently, and "it is an ominous fact that as yet no statistics are forthcoming from the villages where Dr. Ferrán inoculated the inhabitants under the control and in the presence of the Madrid Commission." It is idle to alledge that the Royal Commissioners were prejudiced, and came to their work with a foregone conclusion. When a cause had to be bolstered up by such barefaced forgery, it behoved men of high professional standing and official position to approach it with the most unsparing and sternest criticism. Their report, the only judicial investigation of the matter, is a crushing and unqualified condemnation of the entire theory and practice of Dr. Ferrán and his adherents.

---

## ABSTRACTS AND EXTRACTS.

---

COCAINE IN DISORDERS OF THE NERVOUS SYSTEM.—Dr. Jerome K. Bauduy, in a paper read before the American Neurological Association, said: "It has been well known for some time that the fluid extract of coca was a valuable remedy in the treatment of alcoholism and the opium habit, but it is not to be compared with the alkaloid cocaine in this regard. For a remedy of uncertain strength and action we have in cocaine one whose effects can be predicted with mathematical certainty. It not only replaces alcohol and morphine, but it generates a positive disgust for these agents. They can be withdrawn completely and at once without the slightest suffering or injury, and the cocaine itself may be gradually dispensed with, thus eventuating a perfect recovery. The only caution to be observed in these cases is to administer the drug hypodermically, and this by the hand of the physician himself. This I particularly insist upon. The drug should not be known to the patient, nor the amount of the alkaloid which is being given. If these precautions are not adopted there is great danger—nay, a certainty—that a cocaine habit will be formed, more disastrous in its results than alcoholism or morphinism. I have already referred to its uses in the obstinate vomiting of pregnancy and of hysteria, and would only add in this relation that there is nothing which relieves any of the ordinary manifestations of hysteria so rapidly and completely as a hypodermic injection of cocaine. The same effects may be expected from its use in cerebral and spinal anæmia, "spinal irritation," neurasthenia, and, in general, in all those cases where the brain and spinal cord do not properly perform their functions from want of proper blood-supply; in all these I believe cocaine will prove the remedy *par excellence*. I have tested its powers in the cold stage of intermittent fever, and have secured the happiest results. There is a return at once of a feeling of warmth, and the skin begins to act, thus bridging over both the cold and the hot stage of the fever. In pernicious cases I have no doubt it would prove of the greatest value. In-

deed, as the temperature is increased, both subjectively and objectively, at least 1° F., I have great expectations of its value in the algid stage of even such a disease as cholera. In chorea gravior, in convalescence from protracted illness of any kind, in blood-poisoning—in fine, in all cases where there is excessive tissue metamorphosis without corresponding constructive changes—I believe cocaine to be a most valuable remedy. Insanity, however, I believe furnishes the great therapeutic field for the useful administration of cocaine. Especially is this true of melancholia and hysterical and hypochondriacal insanity; in these especially there is a great future before it. The records of all asylums will show that melancholia is usually a long-continued and tedious disease to treat—one which most alienists naturally dread to encounter. The rapid relief and satisfactory therapeutical results which are observed in mania so frequently, the shortening of its duration, and the control of its more prominent manifestations, are not observed in the treatment of melancholia. Protracted mental depression with accompanying physical prostration are the constant conditions present. Anything which will alleviate this condition and shorten its duration is a boon to suffering humanity. I therefore urge upon the profession to fairly, extensively, and perseveringly test this drug and verify or disprove the wonderful results I profess to have secured in this direction. These effects are so wonderful that they must be witnessed in order to be believed.”—*New York Medical Record*.

ENTERIC FEVER IN CHILDREN.—During the latter half of 1884 and the first two months of 1885, a very considerable epidemic of typhoid fever appears to have passed over the town of Kiel, and from the fact that a large proportion of the patients attacked were young children, the record of the occurrence, supplied to the *Berliner Klinische Wochenschrift* by Dr. von Starck, presents several points worthy of note. One hundred and fifty-two cases in all are recorded, of which 100 are those of children under 15 years of age: 52 males and 48 females. The preponderance of children is accounted for by the frequency with which many members of one household were attacked in succession. In several families one child after another and finally the mother were infected in such a manner as to suggest that some special predisposition must have been present, although no possible cause could be traced other than the fact that many of the patients had been attacked with measles during a wide-spread epidemic in the previous year. Of the 100 children only 2 died. In one instance, perforation took place, the bowel being very extensively diseased; and in the other a neglected hæmorrhage, following close upon violent epistaxis, was the cause of death. The average duration of the disease was three weeks, although there were some cases which continued much longer. The course of the temperature presented many varieties. In some instances a high range was maintained throughout the whole illness, whilst in others the initial rise was followed by a steady and continuous diminution. The children appeared to bear even the higher degrees of fever very well, the mind in many cases remaining clear throughout, and only becoming affected in the worst cases during the third week. Enlargement and tenderness of the spleen was a prominent feature in many cases, but this did not appear to bear any definite relation to the severity of the disease. Pain in the right iliac region was but rarely noted. In almost every case a greater or less degree of bronchitis or broncho-pneumonia was present during some part of the attack. Only seven cases suffered any relapse, and of these only one proved serious. Castor oil was administered at the outset in all the cases, calomel also being employed in a few. Obstinate constipation was freely treated with oil, even into the third week of the disease. Antipyretic measures were employed as soon as the temperature rose to 39.5 C. (103 F.), generally in the form of cold packing or cold bathing at 66 to 76 degrees Fahrenheit, and by repeated doses of antipyrin. Several of the more severe cases resisted all these antipyretic measures for weeks. The children appeared to bear the treatment very well, and no deleterious effects followed either upon the cold bathing or upon the antipyrin. A certain proportion of the cases

were treated with naphthalin, in the form recommended by Professor Rossbach, but it could not be shown that the drug exercised any abortive effect upon the fever even when continued for a long period.

OZONE AS A CAUSE OF PNEUMONIA.—Dr. Daniel Draper, Director of the Central Park Meteorological Observatory, has issued a circular in which he presents a number of statistics, showing apparently some relation between the prevalence of ozone and that of pneumonia. He takes the figures from January to May inclusive, for 8 years. In 1878, there were 1,304 deaths from pneumonia, and the ozone percentage was 9.50 in 73 days. In 1882, the death-rate had increased to 2,056, and the ozone to 16.19 in 86 days. In 1884, the death-rate decreased to 1,603, and the ozone to 6.45 in 48 days. This year the death-rate increased to 2,308, as did the ozone to 13.26 in 87 days. The figures for 1882 and 1883 are not quite so convincing. In the former, the death-rate was 2,056, and in the latter 2,061. Yet in 1882 the ozone record was 16.19 for 86 days, and in 1883 it was 12.73 for 85 days. The death-rates were about equal, though there was a difference of nearly 25 per cent. in the ozone. Dr. Draper says, however, that he compared thousands of observations from the barometer, wet and dry thermometers, hygrometers, anemometers, and pluviometers with the mortuary statistics, and could find no continuous connection between these observations and the prevalence of pneumonia. It was only when “ozone was taken into consideration that there was found to be a very close connection between its observations and the death-rate of pneumonia.” It has been very positively established by numerous observants that pneumonia prevails most at seasons when there are sharp variations of temperature, as, for example, in the spring. We doubt very much whether a case can be made out for ozone.—*New York Medical Record*, September 10.

ANÆSTHETICS IN CHILDREN.—In a lecture delivered before the Philadelphia Obstetrical Society (*Philadelphia Medical Times*, July 25), Dr. De Forest Willard, surgeon to the Pennsylvania Hospital, observes: “In regard to anæsthesia, my experience is that great benefit is obtained by the use of ether when pain can thereby be prevented. In the first weeks of existence, I admit that a feeble vitality would contraindicate its use, although I have successfully administered it to a three days’ old infant. After the first or second month I see no reason why we should inflict pain on an infant, simply because we can control it by brute force. In the examination of fractures, great suffering is often inflicted by careless and frequent manipulation, &c.; unless the diagnosis is easy and positive, unconsciousness should be produced. No case of bone-injury should ever be passed by undetected, when ether will aid us to solve the question. . . . Should any symptom of ether-narcosis occur, it is so easy to depress the head of a child or to perform artificial respiration by acting on the ribs that serious accidents are infrequent. Subsequent vomiting is very common, but is not persistent, and is easily quieted by a small hypodermic of morphia, which ordinarily brings quiet sleep to the patient. If the child is feeble, I always allow milk up to within two or three hours of the operation, and administer wine or whiskey in water immediately before giving the anæsthetic. Milk with lime water and whiskey is usually retained within ten minutes after the first vomiting on rousing. In tedious excisions, not only should preliminary precautions be taken to secure against prostration by shock, but hot water bags should be ready for use, which, with hypodermics of brandy, may succeed in tiding over a temporary depression which would otherwise end in death. When the loss of blood has been great, especially in acute surgery, important assistance may be gained by transfusion, either of blood or of a warm saline injection.”

ATROPINE IN ACUTE CORYZA.—Dr. Solomon Cohen (*Philadelphia Medical Times*, August 8th) states that he can quite confirm the statement made by Dr. Gentilhomme (*Union Médicale*, September 4th, 1883), concerning the great efficacy of sulphate of atropine, even in bad cases of acute coryza, attended with fever, embarrassed respiration, &c. As the mode of administration he prefers a

solution of one grain to one ounce of water, the dose of which is usually four minims ( $\frac{1}{120}$  grain)—that is, when the discretion of the patient can be wholly relied upon in the use of a poisonous drug. In other cases he prefers granules or triturates of  $\frac{1}{120}$  grain, the directions for use being carefully written upon each. One of these is given on the first or second day of the attack, and is repeated in four hours if there be no dryness of the throat. The rule for the third dose is the same, the medicine being stopped if dryness of the throat or dilatation of the pupil occur. When the case is seen within the first twenty-four hours, two doses will often suffice for the complete control of the affection, although thick yellow mucus may be still secreted for about a week. Sometimes the same dose is required on the next day, of the necessity of which, watering of the eyes and stuffiness of the nose are signs; and in severe cases the remedy has to be pushed until dryness of the throat and dilatation of the pupil are produced. In some cases, seen too late for the atropine to be used, the salicylate of ammonium in doses of ten or fifteen grains, repeated every two hours, until tinnitus aurium is produced, has proved useful.

**PILOCARPIN IN ACUTE ALCOHOLISM.**—In an article in the *Philadelphia Medical News* (Sept. 19th), Dr. Josham relates some cases in which he had found pilocarpin in doses of a third of a grain exerted very decided effects in persons suffering from the effects of drink. "Its sobering properties," he says, "are remarkable." "After the sleep, the patient arouses perfectly rational and subdued, a consumption of no little importance, as all know who have to treat the victims of alcohol, since it renders them amenable to moral influences. The transformation wrought on the physical appearance is almost marvellous. The tense, red, bloated countenance, the bleared congested eyes, and general repulsive facial aspects pass away. The skin looks pale, clean, and soft, the features calm and easy, the eyes clear, or only with a slight yellowish fringe. Clothed in such an innocent guise, the subject of a recent debauch might easily deceive even an expert. There are three ways in which pilocarpin doubtless exercises a therapeutic influence in alcoholism: (1) By lowering cerebral blood pressure; (2) by eliminating alcohol; (3) by increasing the absorption of oxygen."

**SALICYLATE OF SODA OINTMENT.**—M. Pierre Vigier (*Gazette Hebdomadaire*, Sept. 11) observes that this poultice would be employed much more frequently than it is at present if the proper mode of preparing it were better known. When 10 grammes of this salt are simply incorporated with from 30 to 40 grammes of lard or vaseline, by rubbing up in a mortar it will be found to contain numerous little agglomerations of the salt which are very detrimental to its efficient application. In order to render it homogeneous and active it should be combined with about half its weight of distilled water, and M. Vigier recommends the following formula:—Lard 40 grammes, crystallized salicylate 16, and distilled water 5 grammes. The lard is to be well spread over the mortar by means of the pestle, and the salt, previously dissolved in the water, is then to be added little by little and rubbed up until complete incorporation is secured. This precaution of smearing the mortar with the lard before adding solutions of the salts to be incorporated is an excellent one; for, besides the facility and rapidity of execution which it secures, it obviates the necessity of adding almond oil, which would otherwise be often necessary, causing the double inconvenience of weakening the medicinal agent and rendering it more fluid.

**ADONIS VERNALIS.**—The action of the adonis vernalis was first studied by Bubnoff, who published some observations on its clinical uses in 1881. More recently, however, some further observations have been made, an account of which is given in the *Naples International Journal of Medical Sciences* by Dr. Gastano Traversa. The following are some of the more important conclusions at which he has arrived:—The drug increases and strengthens the contractions of the heart. It causes the cardiac sounds and especially systolic and presystolic murmurs to become more distinct. It diminishes the size of the heart. It usually slows the pulse. It increases the quantity of urine passed

from three or four hundred to two or three thousand cubic centimetres per diem, the specific gravity being diminished, also the total diurnal quantity of chlorides and urea. Albumen where it exists is diminished, likewise casts, except where actual disease of the kidneys exists. As the quantity of urine increases the weight of the body diminishes. Œdema also is diminished. The drug has also a considerable effect on various morbid conditions connected with the cardiac disease, as cyanosis, dyspnoea, palpitation and cough.

**TREATMENT OF HÆMORRHOIDS BY CHLORATE OF POTASH.**—In cases of severe hæmorrhoids no medicinal treatment is of avail, but in mild cases relief is often obtainable. In a very large proportion of such cases, chlorate of potash is much more efficient as a local application than are the more usually employed astringents. There is little doubt that in many cases the hæmorrhoids are really the expression of an inflamed mucous membrane, and the chlorate is then as efficient as it is in diseases of the inlet of the alimentary canal. Indeed, it is even more efficient because more prolonged contact is possible. Half-an-ounce to an ounce of the saturated solution of the chlorate, to which has been added from five to ten drops of laudanum, is to be thrown into the rectum morning and evening, and retained. Of course, the usual precautions in regard to keeping the bowels open are to be observed.—*Therapeutic Gazette*, July 15.

**QUININE IN THE TREATMENT OF PNEUMONIA.**—Dr. F. P. Atkinson holds that sooner or later quinine will supersede all other methods in the treatment of acute pneumonia, as it prevents the disease advancing beyond the end of the first stage, and rapidly causes resolution to take place, and it does away with the necessity for poulticing the chest, all that is necessary being to wrap the side affected in cotton wool. It may be given in two-grain doses every two, three or four hours to an adult, according to the case. Dr. Atkinson asks whether its curative action is due to the profuse perspiration it causes, or to its antiseptic properties or both, and whether it has any influence on the muscular coat of the arteries.—*The Practitioner*, October.

**ADENO-CARCINOMA TESTIS.**—A case in a boy aged 20 months is recorded in the *Centralblatt für Chirurgie*, No. 34 of the current year. It was noticed about three months before the child was brought under Dr. Schlegtendal's care in Hanover. The tumour was as large as a lemon; it was not transparent, nor did it fluctuate; and though of a firm consistence it slightly yielded to the pressure of the finger. The surface was smooth, and it was nowhere adherent to the superficial structures of the scrotum. The spermatic cord was normal, there was no testicular sensation. Castration was performed, and an iodoform dressing applied. Recovery took place rapidly. When discharged from the hospital the scrotum was quite free from tumour, the cord was normal, and there was no enlargement of the inguinal glands. On section the tumour was found to consist of a soft medullary substance, breaking down in the centre; at the upper portion the remains of the altered testis could be seen. Microscopic examination (made at the Pathological Institute at Göttingen) showed the growth to be an adeno-carcinoma. For about three months the child, who was kept under constant observation, remained well; then the spermatic cord began to indurate, and to become painful; infiltration of the penis came on, and later retention of urine. The secondary growths enlarged rapidly within the following two months, and the child died of general exhaustion about nine months after the disease had first manifested itself.

**THE SMALLNESS OF PARTS IN CHILDREN.**—First of all must the children's surgeon acquaint himself with the anatomy of the child. This is rarely done, as the ordinary dissections of adults during a college course give little idea of the size and position of the individual elements as seen in the infant. In consequence of ignorance upon this practical point, many grievous failures have occurred. After unusual opportunities for the study of both normal and abnormal tissues in the diminutive frame, I am still

frequently surprised to note the exceeding smallness of different organs and canals.—Dr. Millard, *Philadelphia Medical Times*, July 25.

**DISLOCATION OF THE CRYSTALLINE LENS.**—Dr. Dehenne, after narrating a case (*Union Médicale*, No. 92) of spontaneous luxation of the crystalline lens in a glaucomatous eye, for which he performed enucleation, lays down the following rules concerning surgical intervention:—(1) Extraction of a dislocated lens should be attempted only when it is luxated in front of the iris. (2) In no luxation posterior to the iris should it be undertaken. (3) If the patient do not suffer, all intervention should be abstained from. (4) If glaucomatous accidents appear, two circumstances have to be considered: (a) when all luminous perception is abolished, enucleation should be performed; (b) when the media and membranes remain intact, sclerotomy should be practised; and if the accidents reappear, the lens should be removed from the dangerous zone of the eye, and, as a last resource, enucleation performed.

**UNILATERAL PRURITUS IN HEMIPLEGIA.**—Professor Köbner, in a recent clinical lecture in Berlin, mentioned the case of a man of 36 with left hemiplegia, due to an embolism, following rheumatic cardiac disease, who complained of violent itching, both by day and by night, of the whole of the left or paralysed half of the body. No objective signs were to be seen, but the skin of the affected side did not perspire, and the temperature was lower than that of the sound side. This was the only case the Professor had seen of pruritus due to a pure neurosis uncomplicated by skin disease, diabetes, Bright's disease, &c. The treatment consisted in applying an ointment of equal parts of chloral hydrate and camphor rubbed up together and mixed with vaseline in the proportion of 1 of the mixture to 5 of vaseline. This answered well.—*Rundschau*.

## REPORTS OF SOCIETIES.

### PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, OCTOBER 21ST, 1885.

J. S. BRISTOWE, M.D., F.R.S., President, in the Chair.

#### *Sarcoma of Skull.*

DR. DICKINSON read notes of a case of this disease occurring in a boy aged 12. It began with tenderness of the scalp at the vertex and a lump appeared there, later on a swelling appeared on the right side of the head. Nine weeks before he came under observation, he lost sight of both eyes intermittently. When first seen there was exophthalmos with enlarged frontal veins and several lumps of soft consistence scattered over the scalp; there was another lump over the middle of the sternum. Mr. Frost had recognised a soft non-pulsating intraorbital growth on the left side. Vomiting, headache, absolute blindness, insomnia, irregular pulse, drowsiness, and delirium were the remaining symptoms. The head was greatly distorted from the tumours, and a fluctuating swelling was noted over the right tibia near the knee which was found to be suppurative. The growths were soft, livid, and beneath the pericranium, and filled the superior longitudinal sinus. There were no secondary deposits in the brain, but some were found in one lung.

Dr. NORMAN MOORE said that, in the last case shown to the Society, protrusion of the eye had been very marked, and actual sloughing had taken place. That case and one shown by Mr. Jessett were much younger, and in this respect the case shown by Dr. Dickinson was a little exceptional.

Mr. JESSETT referred to the absence of brain symptoms. In his own case of a large tumour pressing on brain, there had been no symptoms. He had seen the same thing in adults.

Mr. R. WILLIAMS asked whether the growth began in one place or in several.

Dr. DICKINSON said, in reply, that there were several separate points of growth.

#### *Bacilli from a Case of Rhino-Scleroma.*

Dr. J. F. PAYNE, referring to the case shewn by himself and Dr. Felix Semon, said that since then he had found bacilli which he had previously believed to be absent. M. Cornil had failed in the same patient, though afterwards he had succeeded. The bacilli were smaller than tubercle bacilli, and required soaking for a long time in a strong solution of methyl violet.

Dr. THIN asked whether the bacilli were in the cells or between them, or in the blood-vessels.

Dr. PAYNE had no doubt that in many places they were enclosed in cells.

#### *A Case of Pyloric Obstruction.*

Dr. HALE WHITE shewed this specimen taken from the body of a woman who died from pyloric obstruction. The gall bladder was full of gall-stones, and adherent to the pylorus, which was much thickened; the cystic and common ducts were normal. An opening was found at inner side of stomach at junction with duodenum, leading by a sinus into a sac the size of a large pea; this sac contained several minute gall-stones; the anterior end of gall bladder was adherent to the pylorus opposite the sac. Some gall-stones had ulcerated from the gall-bladder and formed a sac for themselves in the thick wall of the pylorus; subsequently the communication between the gall-bladder and sac became obliterated. The thickening of the pylorus was due to the irritation thus set up and was mostly fibrous. The gall-stones in the sac were very minute. The body was otherwise healthy. This cause of pyloric obstruction was probably unique.

Dr. NORMAN MOORE confirmed the rarity of this case. He mentioned two cases. One, a woman had vomiting soon followed by death. The common duct adhered to the duodenum, where a gall-stone had ulcerated through, and lay in the intestine; there had been no jaundice. In the second case, that of a man, aged 60, gall-stones had ulcerated into the liver, forming an abscess there; he had slight jaundice only late in the case.

The PRESIDENT mentioned the case of a woman who had had jaundice on and off for 20 years, and gall-stones. There was a nodular lump in caecal region; on being opened no pus was found, but for three months biliary gravel came away. The thickening caused much resemblance to malignant disease. The patient recovered.

#### *Cysticerci of the Brain.*

Dr. GULLIVER described this specimen. The patient, a woman, came under treatment for ascites due to cirrhosis of the liver. Epileptiform fits carried her off in twelve hours; she had just before complained of headache and stiffness of the neck. At the *post-mortem* the meninges were injected, a small cyst was found in the pons, and several in the grey matter of the convolutions, some also in the pia mater; their locality could not be determined. Cases of this sort were not uncommon, and this was more or less typical. The cysts might exist in the brain even for six years without any symptoms, or they might cause epilepsy or hæmorrhage.

Dr. HALE WHITE said that multiple hydatids of the brain were almost unknown.

Dr. WILKS thought this must be rare; he had seen one case, but never one of hydatids of the brain.

#### *Lympho-Sarcoma of Tonsil.*

Mr. BARKER showed drawings of this disease from sections of the right tonsil of a lady, aged 74. There was a history of rapid growth, but the patient appeared in excellent health. The growth shelled out easily and was encapsuled; some enlarged glands were previously removed from the neck. On section, the tumour was found to be a typical lympho-sarcoma. On the opposite side of base of tongue was a nodule which was also removed. In six weeks on opposite side of throat recurrence had taken place, the tonsil being enlarged and glands swollen. The operation was palliative only. This he supposed to be a rare

disease. Two cases had since occurred at University College Hospital. One was in an old man of 70. The glands were also enlarged. The patient had recovered after operation.

Mr. POLLARD showed a specimen of Sarcoma of Tonsil with microscopical sections. The patient, aged 72, was under Mr. Beck's care at University College Hospital, and had been ailing only three months with some difficulty in breathing. The patient had himself discovered the existence of a swelling of his right tonsil. When seen first the growth was the size of a large walnut, and caused some external swelling; breathing was markedly disturbed. The growth was moveable, and easily shelled out after the incision over it had been made; it was encapsulated. Microscopically, it was composed of small round cells closely packed in a homogenous matrix. In its fibrous capsule were bundles of transversely striated muscular fibres; similar bundles were found imbedded in the growth at some distance from the surface. It was worthy of note that, notwithstanding the infiltration of surrounding tissues, the mass was yet encapsulated.

Mr. BUTLIN said that operation in these cases was almost, if not quite hopeless. He had collected about twelve cases of this disease; it was not so very uncommon when cases came to be examined microscopically. These lympho-sarcomas of the tonsil were only portions of a disseminated disease, and not primary.

Dr. SEMON, in regard to the excessive rarity of these cases, believed both epithelioma and sarcoma of the tonsils were more common than was thought. He agreed as to the apparent hopelessness of operation.

Mr. GOLDING BIRD thought they were not so rare; he agreed as to the futility of operation.

Mr. R. WILLIAMS spoke to the same effect.

#### *Bladder and Rectum after Littré's Operation.*

Mr. MANSELL MOULLIN showed this specimen. He had been unable to find the rectum, and had opened the bowel in the groin. The child had recovered from the operation. A few days later feces came through the urethra; this was found to be due to an opening of the rectum into the prostatic urethra. There was no contraction of the bowel below the operation. The child died, worn out, from prolapse of the lower portion, as much as anything else.

Mr. PITTS asked as to the condition of the bladder and kidneys. In a case of his own, surgical kidneys had been found, and he had also seen this in another case.

Mr. MOULLIN said the kidneys were perfectly sound, and the fact that the child lived for six months was a proof of this.

#### *Broad Ligament Cysts above the Fallopian Tube.*

Mr. ALBAN DORAN exhibited a Fallopian tube and broad ligament which had been attached to a large multilocular ovarian cyst. Between the two layers of the broad ligament was an oval thin walled cyst half an inch in diameter. Under the broad ligament along its line of reflection over the Fallopian tube was a similar but smaller cyst. These two cysts were evidently identical in their origin, which was from the connective tissue in the broad ligament. Large thin-walled cysts were common below the tube, whilst above it they were practically unknown. There were very plain reasons why cysts above the tube did not grow large; the connective tissue beneath the broad ligament along the upper border of the tube was relatively dense and scanty, and the blood supply was limited; the reverse was the case below the tube. For similar reasons cysts under the serous coat of the small intestine remained small, whilst omental and mesenteric cysts often attained enormous proportions. There was little evidence that broad ligament cysts above the tube ever grew large, yet such might have been the case in some recorded cases of pelvic cysts with abnormal peritoneal relations. The unusual relation of the tube to the cyst would then be a source of confusion, and therefore of possible misinterpretation. The identity of broad ligament cysts above and below the tube was evident, and from this it followed that those below could not be invariably, if even as a rule, parovarian. He concluded by referring briefly to his remarks on a previous occasion on the non-parovarian origin of the thin-walled simple broad ligament cyst.

#### *Card Specimens.*

Dr. H. A. LEDIARD—(1) Primary Sarcoma of Femoral Gland in a young woman aged 26; (2) Intercondyloid Fracture of Femur.

Mr. C. B. LOCKWOOD—Heart with Band uniting Vena Cava Superior to Left Auricle. (Referred to Morbid Growths Committee.)

Dr. BRUCE—Pathological Specimens of Fine Sections of Entire Viscera.

Mr. J. H. MORGAN—Granuloma of Upper Lip following a Dog-bite, and growing to a Large Size in the course of a fortnight.

Mr. SHATTOCK—Congenital Absence of Fibula.

Mr. GOLDING BIRD—Aneurysm of Profunda Artery (recent specimen).

Dr. SAVAGE—Bladder from a Case of General Paralysis of Insane, Showing Thickening and containing Villous-like Fringes (the kidneys were "surgical").

### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, OCTOBER 15TH, 1885.

T. SYMPSON, F.R.C.S., Vice-President, in the Chair.

A COPY of the forthcoming volume of the Society's "Transactions" was laid upon the table.

Mr. LANG showed a case of Double Coloboma of the Right Upper Lid in a boy aged 12. One fissure was in the centre of the lid, and the other was one centimetre to its inner side. The piece of lid which intervened between the fissure contained normal lashes and Meibomian glands. The cornea had suffered somewhat before the patient was operated on. The closure of the fissures restored the lid almost to the normal condition.

Mr. R. BRUDENELL CARTER showed a case of Damage to the Optic Nerves after a railway collision. The accident happened ten years previously, and the condition then was the same as at present. There was amblyopia, with loss of accommodation, and decided diminution of vessels of the disc, especially of the arteries. Pallor of the surface of the disc was a noteworthy sign. The patient had lost colour sense. He possessed about one-fifth of normal vision when hypermetropia 7.2 D was corrected. He was a decorator, and could hardly distinguish different shades of colours. He also showed an instance of persistent remains of the hyaloid vessels, which have been described by another ophthalmologist as a morbid flocculus in the vitreous humour.

Mr. J. G. MACKINLAY showed a patient with Intense Pigmentation of the Cornea and Conjunctiva from a brown aniline dye. He was a man aged 44, who had been employed in aniline dye works for seven years, working ten hours and a half daily. The iris could only be seen with difficulty. The head and beard were dyed a red-brown, and the skin of face, neck, and hands of the same colour. There was no albuminuria. He could not name green, blue or black colours, but matched wools fairly well.

Mr. J. B. LAWFOORD read notes of some cases of Tuberculosis of the Choroid, and exhibited specimens of the bacillus tuberculosis in the nodules of the choroid. Four eyes had been examined, obtained from cases of general tuberculosis, and in all tubercular meningitis had been present. In three of the cases the bacilli were found in the choroidal tubercles, but in the fourth case careful and repeated examination failed to detect them, though in this case the rods were easily and abundantly discovered in the meninges about the chiasma. The specimens were prepared after the Weigert-Ehrlich and Gram methods, the latter being considered, on the whole, preferable.

Mr. SPENCER WATSON showed a case of Granular Lids and Rough Vascular Corneæ treated by peritomy, with only partially successful results. The patient was a female aged 22. The right eye was operated on in May, and the left in

July last. The improvement was but partial in both eyes, the corneæ having become some clearer and less vascular, but the palpebral mucous membrane remained as rough and granular as before the operations.

Mr. A. CRITCHETT thought that Mr. Watson had exaggerated the late Mr. G. Critchett's opinion, which was that in many cases peritomy sufficed without other treatment; in others it was necessary to treat the granulations after peritomy. If a considerable power of constitutional repair were present, then the tight cicatrix necessary for the complete cure would be formed, but this frequently failed to occur in strumous subjects. No doubt in some cases the treatment by jequirity was sufficient.

Mr. NETTLESHIP said that in his experience peritomy had in a certain proportion of cases given most brilliant results. In one case in which he had freely used jequirity, this treatment was followed by peritomy with a splendid result, the cornea being almost perfectly clear.

#### *Orbital Cellulitis.*

Mr. G. A. CRITCHETT read a paper referring to a case of this affection. The attack occurred in the spring of 1884, and the patient, a young lady aged 15, was transferred to him by Sir William Bowman. There was marked proptosis of the right eye, with considerable chemosis, accompanied by severe orbital and frontal pain; the pupil acted sluggishly, and the media were so hazy that no view of the fundus could be obtained. The temperature was 100°, and there had been a slight rigor. The patient was placed under an anæsthetic, and a free incision was made through the right upper lid into the orbit. There was a free escape of sero-sanguineous fluid, but no pus, nor could any tumour be felt. The deep-seated pain ceased, but the proptosis continued. Ten days later the sight of the left eye, which had hitherto been excellent, became affected, so that in the course of a few hours the patient could barely count fingers, while simultaneously there was a marked improvement in the vision of the right eye. In 36 hours the sight of the left eye was again normal, and the right eye had relapsed. These alternations continued at intervals of about four days during the next fortnight, when the proptosis of the right eye increased to an alarming extent, and after a consultation, at which Sir William Jenner, Sir William Bowman, and Mr. Hutchinson were present, it was decided that he should make fresh incisions into the orbital cavity without delay. At the operation it was found that a portion of the lacrimal gland had been forced downwards to the external canthus, and the incisions were followed by a considerable escape of serum, but no pus. From the date of the second operation the patient made a slow but steady recovery; but for some weeks the curious alternations in sight continued. At the present time she had entirely recovered the sight of both eyes. The cause of the attack was very obscure, and there was no specific history; but one very curious fact deserved notice: the teeth were almost devoid of enamel, and an experienced dentist stated that eleven of the second teeth were uncut. A few months back the right eye again became dim, but the sight rapidly cleared when a painful tooth was extracted.

Mr. NETTLESHIP asked if there had been any swelling of the left lids or any evidence of œdema of the orbit, to both of which questions Mr. Critchett replied in the negative.

Dr. McKEOWN mentioned a case of disturbance of vision that had come under his observation, in which one tooth was not cut. He also alluded to a case of impaired vision in which he had used pilocarpine, as he believed with the best results, but he afterwards learnt that the patient had cut a wisdom tooth just as she got better. He could see no reason why the irritation of a tooth should not produce inflammation.

#### *On the Intracapsular Injection of Water in the Extraction of Cataract.*

Dr. W. A. McKEOWN read this paper. His method consisted essentially in the substitution in the operation of extraction of a washing out of the cortex for the pressing, rubbing, and scooping out. His favourite method of

operating now was as follows. He made the small flap section of the cornea above with puncture and counter-puncture in the selero-corneal margin, and cutting out about half a line from the corneal margin. He always performed iridectomy. After lacerating the capsule freely and expelling the lens, if any cortex were left behind, he introduced the perfectly clean scoop syringe well within the capsule and injected gently distilled water of the temperature of about 100° F., making gentle motion at the same time with the scoop to facilitate removal. He had now used the scoop syringe in all thirty-nine times. In one case only was there irido-choroiditis, with complete closure of the pupil, but good perception of light. In another case there was most insidious iritis, beginning after the patient's discharge from the hospital and going on to closure of the pupil, but in this there was a good prospect from iridectomy. In the case of a syphilitic subject there was a severe iritis arrested by artificial leeching and mercurial inunction. In no case was there suppuration of the eye or of the cornea, and in no instance was there escape of vitreous from the use of the syringe. Even in two cases of traumatic cataract the syringe was used with advantage, notwithstanding the previous escape of vitreous. In a few cases some iritic adhesions formed, as was common in ordinary cataract operations, but caused no pain or diminution of vision. In twelve cases the cataracts were unripe, and in several the cortex was very sticky. In the last thirty cases he had had only one inflammation, and that was in the case of the syphilitic subject above referred to. There were two cautions to be observed. Firstly, after iridectomy, to get the blood out of the anterior chamber as quickly as possible; secondly, to be careful to introduce the scoop within the capsule. He did not believe in operating as against time, but there could be no doubt that the quicker the work could be done and the eye bandaged the better. He timed the duration of the last eleven operations from the introduction of the speculum to the application of the bandage. It varied from six to fifteen minutes, the average being about nine minutes. The operations were all done without chloroform, and some of the patients were restless. The conclusions which he thought he might draw from his own experience were (1) that the judicious injection of water within the capsule of the lens was innocuous; (2) that it was not liable to cause loss of vitreous; (3) that it was advantageous both in ripe and unripe cataracts; (4) that it shortened the average duration of cataract operations; and (5) that it was a most efficient means of clearing the wound.

Mr. McHARDY said that this operation appeared to present two sides first to ripen immature cataracts previous to removal, and second to facilitate the removal of cortex. His experience of Förster's operation of trituration of the cortex had been satisfactory, often in three or four days the cataract ripened and the patient was spared the long period of blindness, waiting after one eye had become blind until the second had become sufficiently blind to justify the operation. In extracting lenses after this method he had not experienced any unusual loss of vitreous; no doubt there was a little more risk of this in these cases, but it was compensated for by the being able to operate a great deal earlier and break down synechiæ. He was in favour of a preliminary iridectomy. Then he thought there would be some difficulty in introducing the instrument. In cases of sticky cortex he had always found it sufficient to let in a little aqueous humour and then churn it up by gently rubbing the lids, when the cortex was speedily rendered removable. He did not find that this occupied more than two minutes as a rule.

Mr. MACKINLAY wished to know if Dr. McKeown had used cocaine in any of his cases. He thought the risk of hæmorrhage was overcome by a preliminary iridectomy. The nozzle of the syringe appeared to him to be very rough, and therefore dangerous to use.

Mr. ANDERSON CRITCHETT observed that M. Panas irrigated the anterior chamber, but then the stream was produced for him by an assistant and all undue pressure was avoided.

Mr. FROST asked whether the operation had been tried in cases of lamellar cataract. He thought that where the cortex was clear, the operation would be valuable. It

seemed to him to be a sound surgical proceeding, and preferable to the use of the scoop, but he did not see that any time would be saved by it.

Dr. McKEOWN, in reply, said that cortex that came away in two minutes ought not in his opinion to be classified as troublesome. He had experienced no trouble on account of the roughness of the point of his syringe; care must be taken to get it behind some cortex—it must not be pressed against the cornea. He had no experience of the operation in lamellar cataract, but he thought it would be suitable for such cases. He now used cocaine in all his operations.

## OBSTETRICAL SOCIETY OF LONDON.

THURSDAY, OCTOBER 8TH, 1885.

J. B. POTTER, M.D., F.R.C.P., President, in the Chair.

THE following specimens were shown:—

### *Specimens.*

Mr. DORAN—Diseased Ovary.

Mr. GRÜN—Fœtus and Placenta from a case of Extra-Uterine Gestation.

### *On the Hypertrophy of Lupus of the Female Generative Organs.*

Dr. MATTHEWS DUNCAN read a paper on this subject. Hypertrophy, he said, was not an essential part of lupus. Extensive ulceration might occur without any hypertrophy. Hypertrophy rarely occurred without some ulceration. Ulceration and hypertrophy were to be regarded rather as alternative conditions than as concomitants. The hypertrophies might be minute or might approach those of elephantiasis. The destruction by ulceration in severe cases was greater than the growth by hypertrophy in severe cases. The hypertrophy affected the skin, the mucous membrane, the connective tissue, or the clitoris. The hypertrophy tended to be an outgrowth, not to grow deeply like a cancer. Hypertrophies were generally morbid in form and appearance, but might resemble healthy natural parts. The hypertrophy might affect the thigh and hip. A hypertrophied part might be ulcerated, and the ulceration might heal without the hypertrophy being destroyed. Hypertrophies were generally not sensitive unless inflamed; but some small hypertrophies, especially urethral caruncles, were often excessively sensitive and painful to touch. Hypertrophies might vary in degree of induration; they were liable to inflammation. Hypertrophied parts might have polypous hypertrophies growing from them. The colour might be red, brown, purple or white.

Mr. HUTCHINSON said that he rose in response to the President's invitation, although he had come rather to listen than to speak. He considered Dr. Matthews Duncan's paper a very valuable contribution to our clinical knowledge of a disease in which he had himself taken much interest. The narratives were clear and full, and the coloured drawings which illustrated the cases made them so complete as to give the members of the Society almost the advantage of having seen the patients. He might as well at once avow that a careful perusal of Dr. Duncan's paper (before the meeting), and an examination of the portraits, had led him to form an opinion somewhat different from that which the author had expressed. He felt it to be almost an impertinence to differ from one of Dr. Matthews Duncan's well-known clinical acumen, especially since he alone had actually examined the patients. He felt bound, however, in the interests of clinical accuracy, to question the diagnosis, and he did so with the more freedom because he well knew that there was no one more willing than Dr. Matthews Duncan to court the investigation of his facts. In the first place, he felt tolerably confident that all dermatologists would repudiate the name lupus, as inapplicable to the disease described; and in the next, he could not help a very strong suspicion that, in all the six patients whose cases had been just narrated, the

disease was remotely connected with syphilis. He expressed some surprise that Dr. Duncan had not attempted in any of the cases to show that syphilis was probably absent, and that he had indeed left it for the most part unmentioned. Having stated of the whole set of drawings that, so far as they went, he (Mr. Hutchinson) should have assumed that they were all representations of tertiary syphilis, unless that belief were entirely confuted by the case-narratives, he next proceeded to examine the latter, and he took each case *seriatim*, and showed that Dr. Duncan had recorded facts concerning all the women which were very suspicious. Thus, in one, it was acknowledged that there was a suspicion of syphilis; another had sores, discharge and a bubo a few years before, and so on; all were married women, and all were hospital patients of a class in which syphilis was very common. It must be remembered that the female genitals, when affected in tertiary syphilis, were liable to display some peculiar forms of morbid action. Chronic gonorrhœa very often complicated syphilis in women; and, as a consequence of the long continued irritation of discharges, the clitoris, nymphæ, and labia often became first œdematous and then hypertrophied. These were the conditions which Dr. Duncan's portraits showed. Although they were not all alike, most of them exhibited a combination of elephantoid hypertrophy, with ulceration and the formation of scars. There was, perhaps, nothing that deserved the name of elephantiasis, but there was an approach to it; and, for his part, he believed that the difference was only a matter of degree. In reference to lupus, Mr. Hutchinson stated that he did not believe he had seen true lupus, that is, such lupus as we are all familiar with on the face and other parts, on the vulva; and he thought it would be a great pity if these cases were placed on permanent record under that name. Not only did their local features differ widely from common lupus, but in not one of them was it recorded that lupus was coincidentally present on other parts of the body. In Dr. Duncan's former paper, he believed that one case had been recorded in which common lupus occurred on the patient's nose, and this was held to be important proof as to the nature of the disease of the vulva. In this instance, however, the narrative mentioned that there was perforation of the palate, a condition known to be infinitely rare in lupus, but very common in syphilis. He should be very much interested in what Dr. Duncan could say as to the exclusion of syphilis in his patients; whether, for instance, he had met with the disease under circumstances in which it was highly improbable that syphilis existed. Such improbability had not been made out, and he thought it had not even been attempted in the paper to which they had listened. As regards measures of treatment, he was entirely at one with Dr. Duncan, and warmly congratulated him on the success which had attended excision and free cauterisation of parts. He could not help thinking that a source of fallacy had existed here as regards syphilis, and that it had been assumed that diseases which were more successfully treated by local measures than internal specifics were probably not syphilitic. He had, however, if he might be permitted to express a personal opinion, long held that not a few of the tertiary manifestations of syphilis yielded much more readily to local cauterisation than they did to mercury or iodide of potassium. He felt compelled, therefore, to believe, at any rate until further negative evidence was produced, that Dr. Duncan's patients were the subjects of remote syphilitic taint, and that their local disease was partly due to it, and in part to local irritation. If the term "lupus" was to be used in connection with them at all, it ought certainly, he thought, to be used with the prefix "syphilitic."

Dr. PLAYFAIR said that he had been in the habit of describing cases like those figured by Dr. Duncan as elephantiasis. He had seen many cases in India, and some of these were very like Dr. Duncan's cases. For his own cases he had used free incision. In his opinion, Dr. Duncan had only given a new, and questionable, name to an old disease.

Dr. GALABIN asked as to the histology of the disease, especially in its relation to new growths. In a case of perforation of the body of the uterus by an ulceration, shown by Dr. Duncan some time back, he had found some

tendency to the characters of a new growth in the fact that in some parts the cells were joined by tailed processes. He had also regarded lupus of the vulva as a very rare disease. In cases similar to those shown by Dr. Duncan he had generally found some evidence of syphilis; they did not yield to anti-syphilitic remedies alone, but yielded to excision followed by such remedies.

Dr. THIN had found the microscopical appearances the same in all Dr. Duncan's cases. There was in all the cases more or less small-celled infiltration beneath the epithelium, and a number of blood-vessels ran straight to this part. There were no marked inflammatory changes in the fibrous tissue, which was found in all stages of development. The changes found in lupus vulgaris were absent, but so were also those of syphilitic gumma, as well as of cancer and elephantiasis. The appearances suggested a persistent form of irritation acting peripherally. M. Vidal, of Paris, informed him that in about one hundred and fifty cases of women affected with lupus vulgaris the region of the vulva had not been affected once. Professor Kaposi, of Vienna, bore the same witness. He believed that Dr. Duncan's cases formed a separate disease, separate, that was, from syphilis, lupus vulgaris, cancer and elephantiasis. He did not agree with Mr. Hutchinson, because, apart from the absence of syphilitic history, the appearances themselves differed from syphilis, compared with which the hypertrophy was out of all proportion to the ulceration, and the ulceration was not typically syphilitic in appearance. Still less could he agree with Dr. Playfair as to the cases being elephantiasis, which was well known to be due to obstruction of lymphatic vessels by *filaria sanguinis hominis*.

Dr. WEST believed that he was the first in this country to describe the disease 25 years ago in his lectures on the Diseases of Women. In none of his cases could either he or Sir James Paget discover any evidence of syphilis. Iodide of potassium in large doses produced no effect. For these reasons he differed from Mr. Hutchinson.

Dr. W. DUNCAN mentioned the case of a large growth in the vulva which he removed two years ago, and exhibited at this Society, when Dr. Matthews Duncan said he considered it a case of lupus. The patient had well-marked tertiary syphilis, and eighteen months after the operation a recurrence of the growth took place which disappeared under large doses of iodide of potassium and perchloride of mercury.

Dr. HORROCKS asked whether the author, in using the word lupus, meant lupus vulgaris or syphilitic lupus, or a different disease. He mentioned a case in which he had removed a large growth from the vulva which had resisted anti-syphilitic treatment. The wound had rapidly healed, and this seemed to him to be against its lupoid nature.

Dr. GANDY asked Dr. Matthews Duncan as to the presence or absence of secondary, syphilitic symptoms in any of his cases.

Dr. GERVIS asked Mr. Hutchinson whether he thought that hereditary syphilis could account for any of the lesions.

Dr. MATTHEWS DUNCAN, in reply, had observed this disease for more than 20 years, and had always done his best to exclude syphilis. Mr. Hutchinson relied on the general appearances, the frequency of child-bearing and vaginal discharges as evidences of syphilis. Now everyone at first held the same view, but many syphilologists and dermatologists and others, here and elsewhere, among whom Paget, West, Thin, Kaposi and Vidal were mentioned this evening, had satisfied themselves that the disease was not of syphilitic origin. The disease was not new, though little understood. There was a great literature of the subject. He could not himself entertain the notion of a syphilitic origin of a disease occurring in children, in virgins, in all classes of society, confined to the genital organs, and destitute of any evidence of primary, secondary or tertiary syphilis. The disease had an appearance and history quite distinct from that of tertiary syphilis. He could not allow that outward appearance, child-bearing and vaginal discharges were evidence of syphilis. Dr. Playfair had said that it was elephantiasis, but it bore no resemblance to that disease in outward characters, in its history, or histology. Mr. Hutchinson

had said that it was not lupus, and yet he held that it was a kind of syphilitic lupus. Dr. Duncan had taken care in a former paper and elsewhere to point out that the disease, however much it resembled lupus in some points, was not lupus vulgaris, a disease which neither he nor others more experienced in dermatology had ever seen on the vulva. He called the disease lupus because it had been called so before, and it was a much easier name than "esthiomène." He would soon lay a paper before the Society on the inflammations of this disease, and on its histology. He would only say now that the histology of Huguier, Paget and Thin lent no support to the theory of syphilis.

---

## SOCIETY OF MEDICAL OFFICERS OF HEALTH.

OCTOBER 16TH, 1885.

W. H. CORFIELD, M.D., President, in the Chair.

### *The History of House Sanitation.*

THE new President, Dr. CORFIELD, delivered his inaugural address on "The History of House Sanitation." The subject was, he said, one of the most important with which the Medical Officers of Health had to deal, and the more so from the growing interest that the public were beginning to take in it, and its bearing on the health of our rapidly increasing urban populations. House sanitation, in the wide sense of the word, would include many things for the discussion of which the brief time at the disposal of the lecturer would be obviously insufficient; he would therefore confine his remarks to a few of the most obvious, and foremost among these the removal of waste water and excreta. The cloacæ of ancient Rome, constructed 2,500 years ago by Tarquinius Priscus, were intended to carry away not the sewage properly so-called, but the surface waters, a purpose which the cloaca still fulfils. It was built of blocks of travertine, a volcanic rock, without cement, and was in fact intentionally pervious. Excreta were not formerly passed into sewers, but buried in pits dug in the ground, often down to the level of the ground water, which, in such cases, by constantly carrying away their contents, rendered the work of emptying them superfluous, but inevitably polluted the wells whence the population drew their water supply. Great as had been the ravages of war and of famine, those of pestilence were in the middle ages incomparably greater, and these were almost wholly due to the accumulation of filth in towns and the pollution of earth, air, and water. When this began to be realised cesspools were made water-tight and smaller, in order to facilitate the removal of their contents until reduced to a mere pail under the seat, as now used in several of our large manufacturing towns. The deodorising of the contents by means of earth washes had reached its perfection in the earth closet, but apart from the unsuitability of this system for large towns and the low manurial value of the deodorised, because as it were burned, product, Dr. Corfield could not approve any plan which retained the excreta on the premises an hour longer than was necessary. Whether intended so or not, the ancient cloacæ and modern brick drains soon became converted into sewers, partly because street washings were often as foul as sewage proper, and partly from the impossibility of preventing persons from passing into them the overflow of their cesspools, sink-wastes, &c. Indeed, even in ancient Rome and Pompeii they knew that a primitive form of water-closet and urinal discharged themselves into the cloacæ, and the laws prohibiting the practice in Old London were habitually evaded. Such pervious sewers could not fail to pollute the soil as much as the pervious cess-pool had before. Alexander Cumming, in 1775, and Joseph Bramah, in 1778, took out patents for water-closets with valves and traps and automatic flushings. Though rude, they were far better than the pan-closet which superseded them or the wretched conical hopper, both of which might now, after the lapse of a century, be found in perhaps the majority of houses. The syphon traps in Cumming's being found to

empty itself after a strong flush, was replaced by the odious D trap, the foul water in which could never be completely changed. In 1844 water-closets were becoming general, and the inconvenience of frequent emptying of cess-pools was felt to be so great that the connection of the soil pipe with the public sewer, hitherto prohibited, was first granted as a favour, and before long insisted on by the law. The President described and discussed the several modes of connecting the soil pipe with the drain, condemning the practice of closing the lower end of the former by a trap, and not approving that recommended by many authorities of direct continuation of the pipe as a ventilator for the public sewer, being himself in favour of complete disconnection and foot ventilation of the soil pipe, which would of course be carried up to and open on the roof. After a description of the methods of drain testing, and automatic flushing tanks, he concluded his address with a discussion of the arguments for and against the expediency of requiring from the lessor or vendor of a house an assurance or a certificate of its being in thorough sanitary condition. He considered that such certificates would too often be unsatisfactory and productive of litigation, and approved the decision of Parliament in restricting such provision to the case of dwellings for the labouring classes who had not the means of obtaining a sanitary inspection themselves.

## GENERAL CORRESPONDENCE.

### REFORM AT THE ROYAL COLLEGE OF SURGEONS.

[To the Editor of the Medical Times.]

SIR,—Permit us, as representing the Association of Members of the Royal College of Surgeons, to call the earnest attention of Members to the fact that the annual meeting of the Council, Members and Fellows will be held at the College, in Lincoln's Inn Fields, on Thursday next, the 29th instant, at 3 p.m., when the Council will present its Report. We desire especially to ask all Members of the College to be present at the meeting, and to support the resolutions which will be drawn up by the Committee of this Association, and which will be submitted on that occasion. This is a most serious time for the Members, and we would beg that they will muster in force at the College, and show that they take a deep interest in matters so vitally affecting their welfare. Our motto is "enfranchisement."

We are, Sir, yours, &c.,  
 ROBERT COLLUM  
 (Chairman of the Association),  
 WARWICK C. STEELE,  
 WM. ASHTON ELLIS,  
 Hon. Secs.

[To the Editor of the Medical Times.]

SIR,—The annual meeting of the College of Surgeons, extorted from the Council, is drawing near, and momentous are the issues at stake; it is therefore full time that all members should review their position past and present, and buckle on their armour for the fight. It is no imaginary evil of which they complain, but they have too long been left out in the cold, their only privilege, the right to use, at hours inconvenient to busy men, their own library and museum—when not usurped for other purposes. It is almost inconceivable that so large a body of men should so long have patiently put up with this treatment; but there are signs now of an awakening, and as a member of the Association of M.R.C.S., I am informed that letters from all parts of the kingdom are pouring in, expressing the determination of the members to assert their equitable rights, aye, and to get them. The demand for equality of franchise has been stigmatised by those interested in its refusal as *democratic*; but the allegation will not for one moment hold water, for the appeal is that of

men who have a distinct stake in the government of the Corporation. To be truly classed as democratic, it would have to be extended to the general body of medical students, or at any rate to those who have just so far identified themselves with the College in question as is implied in passing its primary examination. This no rational being would dream of asking, and this has not been asked. What we demand is the recognition of the right of the Members to share with the Fellows in the election of Members of Council. This is pressed in no spirit of opposition to, or jealousy of the Fellows, large numbers of whom have admitted the justice of our claims. But there are questions, prominent among which is the professional education of the medical practitioner, which bear far more intimately upon the interests of the Members than they do upon those of that "corps d'élite," the Fellows; and upon these questions it is but just that the Members should, by the mouth of their representatives, have an opportunity of expressing their views. To pre-suppose that the Members would be hasty and unintelligent in the choice of their mouth-piece is an unwarrantable hypothesis. Look at them in their ordinary business life; they have their own way to make in the world, and at every step in their daily path they are beset with problems quite as difficult to solve as those presented to their distinguished Fellow, whose hospital appointments will always cast sufficient lustre upon his name for his less prominent brethren, the Members, to send him a never-ceasing stream of clients, each armed with the golden tokens of esteem, so sparingly and uncertainly doled out to the family doctor. A few mistakes in diagnosis are easily overlooked by the charity and generosity of the general practitioner, who judges the consultant by the rule and not the exception. Not so with the Member; he has no brilliant reputation behind which to shelter himself, and often one blunder on his part will, in the eyes of his unreasoning and unstable body of patients, undermine the structure of confidence and of a practice it has taken him years to rear. For this reason we hold that the Member of the College is a man whose very profession requires the employment of a vast amount of judgment and discretion; and what he is in the habit of exercising all day long, there is little danger of his discarding when the business on hand is that of electing a Member to represent him on the Council of a College, whose name he holds it an honour to bear, but which conducts herself as though ashamed of her off-spring. We Members feel strongly that only by the voice of the Members and Licentiates of the English Colleges being heard in their Councils, can measures of true medical reform be inaugurated, the social relations of the profession with the laity advanced, and the abuses of these close corporations swept away. It is therefore a duty incumbent upon all who with their diplomas have earned the right to bear the significant name of MEMBERS to assemble in strength upon the 29th instant, and show the Council that they are in earnest. One word more, and that for the ear of the Council itself: it is not even yet too late for it unimpelled to grant the inevitable. Let it graciously acquit itself of the task, and the names of those who now form its august body will stand forth as a beacon of enlightenment to future generations of the followers of Æsculapius.

I am, Sir, yours, &c.,  
 A MEMBER.

### NOTIFICATION OF INFECTIOUS DISEASE.

[To the Editor of the Medical Times.]

SIR,—You state in your last issue that "the results of notification . . . in those towns . . . where it . . . has been adopted, places beyond the possibility of a doubt the great benefits which this system is capable of conferring upon the public health." Furthermore, "it is satisfactory to know that the system has been loyally carried out by the profession." As probably neither you nor I would desire to rediscuss a controversy which would overwhelm your

space and my leisure, I confine myself to entering my most earnest protest against the foregoing statements. Being fully conversant with the figures to which you refer, and with the system as a whole, I deny emphatically that compulsory notification by the physician has produced any public benefits. I deny that it is "loyally carried out by the profession." I assert that the system, as worked out in most towns, is *not* compulsory; that it is utilised only for cases which there is no motive to conceal; that, under it, multitudes of cases are notified as infective which are not so, and multitudes of infective cases are not notified at all; and that the statistics referred to prove rather that zymotic disease is more prevalent and more fatal in notification towns than in towns similarly situated in which compulsory notification does not exist, and more prevalent in notification towns to-day than before the notification system was thought of. I denounce the notification system as professing to be what it is not, as having been created to save sanitary officials trouble and expense, as having been thrust upon the public and the profession by sanitary enthusiasts without enquiry as to its efficiency and without asking their leave; and I hope that the influence of your journal will be given, not to bolster up the system, but to cause an exhaustive enquiry into its nature and results to be instituted.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB, F.R.C.S.I.

Dublin.

## THE MEDICAL ENTRIES AT KING'S COLLEGE.

[To the Editor of the Medical Times.]

SIR,—The number of *full* entries at King's College is 47, a larger number than last year, and the number of occasional students for science courses and special classes is 30. Our total entries are therefore also in excess of those (62) of last year. Will you kindly insert this, so that the erroneous impression in your last issue may be removed?

I am, Sir, yours, &c.,

JOHN CURNOW.

King's College, October 19th, 1885.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy only at a meeting of the Board of Examiners on the 14th inst., and when eligible will be admitted to the pass-examination, viz.:—

Henry E. Belcher, Herbert H. Browne, and George Ley, University College; Wilfred Sturges-Jones Guy's Hospital; Percival S. Harris, Alfred R. Nicholls, and Francis J. Brown, Middlesex Hospital; John Bate and Alfred L. Martyn, London Hospital; Charles W. Hopewell, King's College; H. Henry Folker, Charing Cross Hospital.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, October 15th, 1885:—

John Alexander Gillett, Brooke, Norwich; Arthur Meyrick Jones, M.R.C.S., Wellow Vicarage, Romsey, Hants; William Arthur John Nottingham, 2, Stavordale Road, Drayton Park, Southsea; John Acton Southern, M.R.C.S., 57, Daruley Road, E.; Albert William Webb, M.R.C.S., 11, Pyrland Road, Canonbury, N.

On the same day the following gentlemen passed their examination in the science and practice of Medicine, Surgery and Midwifery, and received certificates to practise, viz.:—

Morgan Ignatius Finnane, Wilton House, Shaftesbury Road; John Girling, Wyvenhoe Lodge, Colchester.

ROYAL UNIVERSITY OF IRELAND—AUTUMN EXAMINATIONS, 1885.—The examiners have recommended that the following candidates be adjudged to have passed the under-mentioned examinations respectively:—

*The degree of M.B.*—Upper Pass Division:—

Robert Abraham, Queen's College, Belfast; \*Jerome Barry, Queen's College, Cork; \*William G. Bigger, Queen's College, Belfast, and St. Thomas's Hospital, London; \*Andrew Buchanan, Queen's College, Belfast; \*Hugh A. Clarke, Liverpool School of Medicine; \*Henry A. Cummins, \*Wm. A. Fogerty, \*John F. Haines, Queen's College, Cork; James Shaw Lyttle, Queen's College, Belfast; \*Daniel M'Donnell, Catholic University School of Medicine; \*Ralph B. Mahon, Queen's College, Galway; Wm. R. Orr, \*John J. Redfern, Queen's College, Belfast; \*Benjamin Sumner, Royal Infirmary, Liverpool. Those marked thus (\*) will be admitted to take further examination for Honors.

Passed:—

Arther Stock, Queen's College, Galway, and Carmichael College; Wm. S. H. Briand, Queen's College, Cork; James Browne, Queen's College, Belfast; Alexander T. Drake, Carmichael College; Michael P. Dunlea, Queen's College, Cork; John F. Eagleton, Queen's College, Galway; John Flynn, Catholic University School of Medicine; Bernard Ford, Catholic University School of Medicine; Charles J. Humphries, Queen's College, Belfast; Francis J. Keys, Catholic University School of Medicine; Daniel T. Lane, Queen's College, Cork; Hugh A. Logan, Queen's College, Belfast; Charles J. Macdonald, Queen's College, Cork; David J. M'Kinney, John Menary, Queen's College, Belfast; Michael J. Moran, Catholic University School of Medicine; Samuel Moore, Queen's College, Belfast; Wm. H. Munro, Queen's Colleges, Galway and Belfast; John W. Oliver, Wm. R. Scott, Francis H. Sinclair, Queen's College, Belfast; Thomas D. Smyth, Queen's College, Belfast, and University of Edinburgh; Edward A. Spiller, Andrew S. Thompson, Queen's College, Belfast; Henry Walter, School of Physic, Trinity College, Dublin; Wm. A. Whitelegge, Queen's College, Cork.

*The Degree of M.A.O. (Magister Artis Obstetricæ)*—Examination.

W. S. H. Briand, Queen's College, Cork; Andrew Buchanan, Queen's College, Belfast; Henry A. Cummins, M. H. Curtin, M.D., Wm. A. Fogerty, Jno. F. Hames, Queen's College, Cork; Jas. S. Lyttle, Queen's College, Belfast; Dan. M'Donnell, Catholic University School of Medicine; John Menary, John J. Redfern, Wm. R. Scott, Andrew S. Thompson, Queen's College, Belfast; Wm. A. Whitelegge, Queen's College, Cork.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—Richard Dancer Purefoy, M.B. Univ. Dub., has been duly enrolled a Licentiate in Medicine and Midwifery of the College.

THE Museum of the Royal College of Surgeons will be closed on the 27th and 28th inst., for the purposes of the first examination of the Examining Board in England, and the Library will be closed on Monday, Tuesday, and Wednesday, the 26th, 27th, and 28th inst., at 4 o'clock, for the purposes of the pass examination (membership), for which examination 181 candidates have entered their names.

POPULAR MEDICAL LECTURES FOR YOUNG MEN.—We are requested to call attention to the series of five medical lectures which will be given on Tuesday evenings at 8 p.m., at Exeter Hall, in connection with the Young Men's Christian Association. The course will be opened on Tuesday next, by Mr. Cantlie, with a lecture on "Life in London," hygienically considered. On November 3rd, Sir Risdon Bennett will lecture on Food and Appetite, and the week following Sir Henry Pitman will speak on Rest and Food. Mr. Le Gros Clark and Dr. Alfred Carpenter will lecture on succeeding Tuesdays.

MEDICAL SCHOLARSHIPS.—*Middlesex Hospital Medical School*—The Entrance Science Scholarship of the value of £50 has been awarded to Mr. G. Watson; the Entrance Scholarship of £25 per annum, tenable for two years, to Mr. R. A. Earle; and the Entrance Scholarship of £20 per annum, tenable for two years, to Mr. F. A. Wagstaff. *St. George's Hospital Medical School*—The Entrance Scholarship of £125, open to the sons of medical men, has been awarded to Mr. James M'Enery, son of Dr. M'Enery, of Sherborne; there were no candidates for the two open scholarships of £50 each. *King's College*—The Sambrooke Exhibition of £60 has been awarded to Mr. Sandifer, and that of £40 to Mr. Cargill; the Warneford Scholarship of £25 per annum, tenable for three years, has been awarded to Mr. Soutter; and the Science Exhibitions given by the Clothworkers' Company have been awarded to Messrs. Hendrich and Paxon. *London Hospital Medical*

**College**—The Buxton Scholarship of the value of £30 has been awarded to Dr. Thomas Jones, and that of the value of £20 to Mr. Yarnold H. Mills.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—On Wednesday, October 14th, a Quarterly Court of the Directors of the above society was held, the President, Sir James Paget, F.R.S., in the chair. Two new members were elected; sixty-four widows, nine orphans and three orphans on the Copeland Fund sent in applications for relief, and it was resolved that a sum of 1,371*l.* be recommended for distribution at the next Court. The death of one widow was reported, who had been receiving grants since March, 1864, and the marriage of another was announced. For the last ten years or more the directors have been able to make a Christmas present to the widows and orphans on the funds—last year the gift was 5*l.* to each widow and 2*l.* to each orphan this year the funds in hand will not allow so large a sum to be expended, and it was resolved that the gift this year should be 2*l.* 10*s.* to each widow and 1*l.* to each orphan. A framed notice of the objects of the Society was shewn at the meeting, and it was determined that a copy should be sent to all the large Hospitals and Medical Societies within the limits of the society, with a request that the notice should be hung in some conspicuous place.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the annual stated meeting of the College, held on October 19th, 1885 (St. Luke's Day being on Sunday) the following officers were elected for the ensuing year:—President: Francis Richard Cruise, M.D. Univ. Dub. Vice-President: J. Magee Finny, Univ. Dub. Censors: J. Magee Finny, M.D.; Hawtrey Benson, M.D.; Francis J. B. Quinlan, M.D.; J. Rutherford Kirkpatrick, M.D. Additional Examiners: George F. Duffey, M.D.; Stephen M. MacSwiney, M.D.; Joseph M. Redmond; Arthur Wynne Foot, M.D.; John M. Purser, M.D.; Walter G. Smith, M.D. Registrar: John William Moore, M.D. Univ. Dub. Treasurer: Aquilla Smith, M.D. Univ. Dub. Examiners in Midwifery: Andrew John Horne; W. J. Smyly, M.D. Professor of Medical Jurisprudence: Robert Travers, M.D. Univ. Dub. Representative on the General Medical Council: Aquilla Smith, M.D. Univ. Dub. Agent to the Trust Estate: Charles Uniacke Townshend. Law Agents: Messrs. S. Gordon and Son. Librarian, on Sir Patrick Dun's foundation: Samuel W. Wilson. Extern Examiners for the Certificate in Sanitary Science: in *Law*, George Roberts Price, Barrister-at-Law; in *Engineering*, William Kaye Parry, M.A. Univ. Dub., Civil Engineer.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (ALBANY MEMORIAL), QUEEN SQUARE, BLOOMSBURY.**—A considerable portion of the new building recently opened by the Prince of Wales is now in occupation. In addition to more wards for free patients, others for persons able to contribute a guinea weekly will be made available at the end of the present month.

**MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.**—The secretary reports the receipt of 54*l.* 6*s.*, as the result of the bazaar held lately in the Bray Town Hall, in aid of the Convalescent Home. Also of 52*l.* 10*s.*, the proceeds of amateur theatricals held in the Queen's Theatre, on behalf of the funds of the hospital.

**THE NEW HOSPITAL AT STOCKHOLM.**—The town authorities have decided to erect a hospital for 250 patients on the site in Stadshagen, proposed by the Health Inspection Committee, and that a sum of 830,400 crowns should be obtained by means of a loan for this purpose.

**UNIVERSITY OF LEYDEN.**—At the University of Leyden, 157 students were enrolled by the Rector Magnificus on the 20th of September; of whom 13 entered for literature and philosophy, 45 for medicine, 5 for natural science, 5 for theology, and 89 for the law. An answer to the prize question asking for an experimental examination into the difference and agreement in the physiological effects of strychnine and curarine had been received. The prize was not awarded, but the answer was declared worthy of honourable mention, for some meritorious experiments contained in it.

**JUVENILE LABOUR IN PARIS.**—The official report of the inspectors, on the compliance with the law affecting the labour of children and girls under age, states that there were in Paris and the suburbs last year 127 breaches, against 152 in 1883. The indictments resulted in 72 convictions, mainly for employing children under 12 years of age, defective ventilation or warmth of the work-rooms, and for obstructing the inspectors on visiting the workshops. The decrease in the number of prosecutions favourably contrasts with that of the previous year, and we hope indicates a stricter regard to the requirements of the law.

**PRESENTATION AT FORT BLAIR.**—The residents at this station are about to present Mr. J. J. Peters, of the Bengal Medical Establishment, with a gold keyless half-chronometer watch, by J. W. Benson, as a token of their good wishes on his leaving the settlement.

**IN MEMORIAM.**—On Saturday, the Lord Mayor will unveil the painted window in the North-West London Hospital, in memory of Eliza and Eleanor Learmouth. These ladies, it may be remembered, both died during the epidemic of typhoid fever in the autumn of 1883, and in recognition of their self-sacrificing devotion, this window has been erected by subscription.

**SELLING METHYLATED SPIRITS AS A BEVERAGE—HEAVY FINES.**—A retailer of methylated spirits, in Glasgow, has been amerced in 20*l.* for each offence, for having sold half-a-gill of methylated spirits as a beverage, to two persons on the 9th August last.

**THE GRAEFE MEDAL AND PRIZE.**—It was determined by the Heidelberg Ophthalmological Society, soon after the death of Albrecht Von Graefe, to found, in honour of his memory, a gold medal to be awarded every ten years, for the most distinguished work done in ophthalmology. The first medal has just been unanimously decreed by the society to Professor Helmholtz, of the Berlin University. After Graefe's death, a prize was also founded by the late Professor Welz, of Würzburg, to be awarded every third year for articles appearing in the *Archiv für Ophthalmologie*, founded by Graefe, which the Ophthalmological Society deemed most deserving of it. As we stated last week, the fifth award has been made to Dr. Samuelson, of Cologne, the former prizes having been presented to Professor Leber, of Göttingen, to Dr. R. Weber, of Darmstadt, to Dr. Knies, of Zurich, and to Dr. von Güdden, of Munich.

**THE PARIS NIGHT SERVICE.**—Dr. Passant reports (*Gazette des Hôpitaux*, October 15th) that the number of night visits paid, during the quarter ending September 30th, amounted to 1,907, viz., 627 (33 per cent.) to males, 992 (52 per cent.) to females, and 288 (15 per cent.) to children under 3 years of age. The number of visits was less by 539 than those paid (2,446) during the same quarter of 1884.

**THE SUMMER OF 1885.**—In our own regions the summer of this year proved dry, but not hot, and the same has been observed in more northerly countries. In Ireland great cold prevailed, so that in July there was frost not only in the more elevated parts, but also along the coast, the pastures suffering greatly. On the western coast of Norway snow fell several times, and the harvest suffered much from night frosts, the cold being attributed to the enormous masses of ice floating from the Pole to the Gulf Stream. In Sweden, the unprecedented sight was witnessed of large numbers of migratory birds departing between the 16th and 18th of August.—*Revue Scientifique*, October 3.

**VILLAGE WATER SUPPLY.**—A question of importance in reference to the supply of water to several villages in the Sevenoaks Union, was considered at a meeting of the Sevenoaks Rural Sanitary Authority on the 15th instant. The Kent Water Company lately applied to the House of Lords for power to carry water into several parishes in the Sevenoaks Union. This was opposed by the Sevenoaks Rural Sanitary Authority, the Chairman promising at the time that that Authority would take action in the matter. The Committee of the House of Lords rejected the Bill, but came to no resolution. The Chairman now proposed that some scheme should be decided on to supply the

villages in question, which by a majority of two, ten for, and eight against, was carried. A committee was formed in accordance with that resolution. The chief cause against active measures being adopted to provide a supply of pure water to villages has been the expenditure it would involve. The usual supply from wells, more or less polluted by sewage drainage, is unfit for drinking purposes. The question so intimately affects the well-being of our rural population that the practical action just taken by the Sevenoaks Rural Sanitary Authority to carry out a pressing duty may be usefully noticed.

**THE INJURIOUS ACTION OF MAGNETS ON WATCHES.**—Dr. Luys, of the Charité Hospital, in a note addressed to the *Revue Scientifique* of October 10th, calls attention to the irremediable mischief which may be produced on watches which are worn on the person during the employment of powerful magnets. The possessor of a valuable chronometer which had gone with remarkably punctuality for nearly a year, while wearing it he had occasion to manipulate powerful magnets in relation to the sensibility of some hypnotised subjects. Shortly afterwards he found that his chronometer went badly, and not suspecting the cause he took it to the maker for the purpose of ascertaining this, and it was found that the various structures of the watch had become magnetised, and the maker enquired of the wearer whether he had not been in contact with some source of electrification or magnetism. He also exhibited its effect on the compass. The worst of it is that all attempts at remedying the defects have proved unavailing, the works of the watch having become to all appearance irretrievably deranged. This account evidently conveys an important caution to those engaged in the employment of powerful magnets.

**FRACTURE OF RIBS DURING COUGHING.**—M. Desnos related, at the Société Médicale des Hôpitaux (*Gazette des Hôpitaux*, October 13th), two examples of this occurrence. The first was that of a man, 30 years of age, who had been in the hospital from December 4th to January 22nd, for acute bronchitis, the subject of frequent and obstinate colds, with signs of pulmonary emphysema. Some days prior to his admission, he was seized with severe pain in the side, consequent upon fracture of the ninth rib while coughing. The other case was that of a man, 66 years of age, who had for years been subject to violent paroxysms of coughing. On one of these occasions, he fractured the eighth rib during the cough. Both cases did well under the use of a diachylon bantage. Comparing these cases with others which he has been able to collect, M. Desnos observed that the accident may also be produced, independent of external injury, by various other violent muscular exertions, as in sneezing, mounting a horse, the pains of labour, &c. Such fractures are of greater frequency during the second half of life than during the first, in women than in men in consequence of pregnancy, in the left than in the right side, and in the lower than the higher ribs.

**LIGHTING THE COUNTRY DOCTOR AT NIGHT.**—Dr. Ely, writing to the *Philadelphia Medical Reporter* for September 26th, observes that one of the difficulties attendant upon country practice is the arrangement of the light when driving on dark nights. As this is ordinarily managed, the light is just where it is not wanted, illuminating the horse's tail, and bringing out the brilliancy of the buggy, but casting a dark shadow just where light is wanted. He thus describes a remedy for this inconvenience, which, he says, is completely successful. "My light is a common tubular lanthorn, with a reflector and a spring for attachment to the dash. But in place of putting it on the dash, I slipped the spring over the middle of the breast collar, directly in front of the horse. Every part of the road in front of me was plainly seen, so that I could drive with as much confidence as in broad daylight. The conditions necessary for success are a level-headed horse with fair breadth of chest, and a shoulder strap attached to the check-hook to prevent the lanthorn sagging down between the horse's legs, when for any reason the traces slacken. It would be well to have a short strap sewed to the inside of the breast collar to slip the spring through, so as to prevent any lateral motion."

**LEGAL ESTIMATE OF MORAL INSANITY.**—Quoting from the *American Law Reporter*, the *Journal of Nervous and Mental Diseases* states: "We learn that the Supreme Court of Pennsylvania not only affirms the existence of moral insanity, but admits that it may, under certain circumstances, constitute a defence of crime. It says, 'Moral insanity is not sufficient to constitute a defence, unless it be shown that the propensities in question exist to such an extent as to subjugate the intellect, control the will, and render it impossible to do otherwise than yield thereto. No mere moral obliquity of perception will protect a person from punishment for his deliberate act. The jury should be satisfied with reference to the act in question that his own reason, conscience, and judgment were so entirely perverted as to render the commission thereof a seeming duty of overwhelming importance. While a slight departure from a well-balanced mind may be pronounced insanity in medical science, yet such a rule cannot be recognised in the administration of law, when a person is on trial for the commission of a high crime. The just and necessary protection of society requires the recognition of a rule which demands a greater degree of insanity to exempt from punishment.' This decision rests the issue of responsibility not upon knowledge, but upon power."

**CALCULI AFTER STRAWBERRIES.**—Dr. Pfitzner, of Stroppen, has remarked in two cases after the ingestion of large quantities of strawberries daily for ten years or more, the occurrence of a considerable amount of gravel in the urine, and in addition to that, minute round stones of a dirty yellow colour. In one case there was also hæmaturia and polyuria.

**AN AUSTRIAN STATISTICAL REPORT.**—A report has just been issued by the Central Commission of Statistics in Austria, dealing with the year 1882. The total number of practitioners consisted of 4,857 doctors of medicine, and 2,498 surgeons. (In the year 1873, there were only 3,349 doctors of medicine, and 3,323 surgeons.) The mean number of inhabitants to each practitioner was 3,011; this proportion varying in the different divisions of the Empire, being least in Trieste and greatest in Galicia, where there was only one practitioner for 7,000 people. In the towns the supply of practitioners was of course better, there being one to every 619 in Vienna, and to every 419 in Innsbruck. With regard to the distribution of medical men in relation to area, it varied from one practitioner to 0.8 of a square kilometre in Trieste, to one to 120.1 square kilometres in Bukowina. There were 1,274 pharmacists in the Empire, who were most plentiful in Trieste, and least so in Galicia and Bukowina. The death-rate for the whole Empire was 3.213 per cent., that for the different provinces being 4.102 in Bukowina, 3.769 in Galicia, 3.385 in Istria, 3.297 in Trieste, 3.225 in Lower Austria, 3.101 in Krain, 3.063 in Mähren, 3.002 in Görz and Gradiska, 2.944 in Bohemia, 2.810 in Upper Austria, 2.783 in the Tyrol, 2.769 in Carinthia, 2.744 in Styria, 2.718 in Vorarlberg, 2.688 in Salzburg, and 2.120 in Dalmatia.

**THE ADMINISTRATION OF MEDICINE.**—A mode of administering medicines which seems to be growing in use, and for which great accuracy is claimed, is that of compressing solid substances into capsules or into tablets by degrees of pressure varying from that of a hand machine to that of an hydraulic press. This method is based upon the fastidiousness of patients, which is indulged by the physician. Patients do not know that the conditions under which medicines do them most good are very limited, and physicians are either thoughtless, or they consider such matters of so little importance as to neglect them. When he does not order the compressed pills or tablets of the proprietary manufacturer, he will yet order the pharmacist to put such quantities of powders into capsules as require much compression to get them in, and will not stop to think that just in proportion to this compression will be the slowness of the solubility and disintegration of the mass. Suppose the capsule to dissolve promptly in the stomach before the mouthful of water with which it is swallowed be absorbed, the external surface of a hard mass is exposed for slow solubility, and the patient, instead of getting the

prompt effect of the calculated dose, is getting the continuous administration of doses so small as to be without effect, and in the meantime the mass is moving down the canal to points far below those to which the medicine is addressed.—*Squibb's Ephemericis*, No. 11.

**THE PROFESSION IN CANADA.**—"From the admirable address of Dr. Osler, delivered at the meeting of the Canadian Medical Association, we gather," the *Philadelphia Medical News*, September 26th, observes, "some interesting details with reference to the state of the profession in the Dominion. In certain directions it appears to have made satisfactory progress, and to have reached a very high degree of development. The question as to who should rule, the profession or the medical schools seems to have been settled at an early period, though not without a struggle. The boards elected from the practitioners in each province have now full control over all matters relating to medical education and licensing, and the teaching bodies must conform to their requirements. The system is thoroughly democratic, and seems to meet the serious problem of the profession, viz., the unrestricted competition between the schools. It matters little if the requirements for the degrees are easy, so long as those for the license to practise are rigid. It is well-known that in Germany the *Staats-examen* for admission to practise is more dreaded by the students than the examination for the doctor's degree. For the Commonwealth to permit a profession to regulate its own affairs, and to say what the conditions of it shall be, does not seem strange; the lawyers enjoy just such privileges. But in this country we have to deal with a profession jostled by a crowd of irregulars who claim equal rights, and who have often a controlling voice in the Legislatures, so that the difficulties in the way of uniform legislation are almost insuperable. Dr. Osler does not mention that in the province of Ontario the homœopaths have a certain number of representatives on the board, and that homœopathic candidates, though conforming in all respects to the full requirements, are examined in therapeutics and medicine by special examiners. We understand, however, that the effect of the strict regulations has been that on an average not more than one homœopath has presented himself annually at the Board. In the Province of Quebec there is, we believe, a special Homœopathic Board, which, as candidates are so few, is rarely, if ever, called together. That eleven schools of medicine are more than enough for a country like Canada, with a limited and scattered population, seems very evident, though the ratio to population is not so high as in the United States. The folly of so many schools becomes apparent when the financial basis is exposed. The true note is struck in urging the friends of higher medical education to assist in placing the schools in a position in which they will not be dependent entirely upon the fees of the students. Benefactions are coming at last in the direction of medical colleges; and the example set by the citizens of Montreal in subscribing for an endowment of the McGill Medical Faculty, and the munificent gift of Mr. Vanderbilt to the College of Physicians and Surgeons of New York, will not be without influence in other cities."

**DR. HUCHARD'S HÆMOSTATIC PILLS.**—R. Ergotine and Sulphate of Quinia aa 2 grammes; of Powder of Digitalis and Extract of Henbane aa 20 centigrammes. Divide into 20 pills. From 5 to 10 to be taken daily in different forms of hæmorrhage, as metrorrhagia, epistaxis, and hæmoptysis.—*Union Médicale*, October 13.

**DISGUISED THE TASTE OF BITTER AND NAUSEOUS SALINES.**—This is best done by iced water, a mouthful or two being swallowed before and after the dose, which is taken in a wine-glass full of iced water between these.—*Squibb's Ephemericis*.

**THYMOL IN THE BLOOD.**—Mairet, Pilatte and Combemale find that, when thymol is injected into the veins of dogs, the animal dies, if the dose exceeds 0.03 gramme per kilog. of body weight, or even with smaller doses if the dog is not in good health, many of the functions and organs being affected.

## APPOINTMENTS.

- ANNACKER, ERNEST, M.R.C.S., L.R.C.P. Lond.—Resident Medical Officer to St. Mary's Hospital, Manchester, *vice* F. Beunet, M.B. Lond., B.Sc., M.R.C.S., resigned.
- ANNES, F. R., M.R.C.S., L.R.C.P.—Resident Surgeon to the Seaman's Infirmary, Ramsgate, and Visiting Surgeon to the Ramsgate and St. Lawrence Royal Dispensary, *vice* G. H. Doudney, M.B., &c., resigned.
- BROWNE, EDGAR A.—Lecturer on Ophthalmology in University College, Liverpool, *vice* T. Shadford Walker, deceased.
- DUNN, LOUIS ALBERT, M.B., B.S. Lond., F.R.C.S. Eng., L.S.A. Lond.—Demonstrator of Anatomy at Guy's Hospital.
- GOODALL, JOHN HENRY, L.R.C.P. and S. Edin., L.S.A. Lond.—Medical Officer to the Bolsover District, Chesterfield Union, *vice* Mr. W. Wallace, resigned.
- HEHNER, OTTO, F.C.S.—Analyst for the County of Nottingham, *vice* Dr. E. B. Truman, resigned.
- ROBINSON, WILLIAM, M.D., M.B., and M.S. Durh., M.R.C.S. Eng.—Medical Officer to the Stanhope District, and to the Workhouse, Weardale Union, *vice* Dr. C. Arnison, resigned.
- SHARPIN, EDWARD COLBY, M.R.C.S. Eng., L.R.C.P. Edin.—Surgeon to the Bedford General Infirmary and Fever Hospital.
- SPACKMAN, HENRY ROBERT, L.R.C.P. and L.S.A. Lond., M.R.C.S. Eng.—Medical Officer to the Wombourn District, Seisdon Union, *vice* Dr. William Spackman, resigned.
- TARGETT, JAMES HENRY, M.B. Lond., M.R.C.S.—Surgical Registrar at Guy's Hospital, *vice* Dunn, resigned.

## VACANCIES.

- CENTRAL LONDON OPHTHALMIC HOSPITAL, GRAYS INN ROAD, W.C.—Assistant Surgeon. (*For particulars, see Advertisement.*)
- HASLINGDEN UNION.—Medical Officer to the Bacup District, in succession to Mr. John Snell, resigned. Salary, £90 per annum.
- HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN SQUARE, W.—Resident Medical Officer. (*For particulars, see Advertisement.*)
- MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.—Honorary Physician. Candidates must be Graduates in Medicine of a British University, or Members of the Royal College of Physicians and appear on the Medical Register. Applications, with copies of testimonials, to be sent to the "Chairman of the Board" not later than October 31st.
- NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, BLOOMSBURY.—House Physician. (*For particulars, see Advertisement.*)
- NORTH LONDON HOSPITAL FOR CONSUMPTION, HAMPSTEAD, N.W.—Resident Medical Officer. Salary, together with board and rooms in the Hospital, £400 per annum. Candidates must possess a Medical and Surgical diploma. Applications, with testimonials to be sent to the Secretary, at the office, 216, Tottenham Court Road, W., not later than October 29th.
- OWENS COLLEGE, MANCHESTER.—Professorship of Physiology. Candidates to forward applications and testimonials to the Council of the College, under cover, to the Registrar, not later than Nov. 9th. Further particulars can be obtained on application to the Principal of the College.
- PADDINGTON GREEN CHILDREN'S HOSPITAL.—House Surgeon. Salary, £80 per annum, with rooms. Applications to be sent to the Secretary by October 28th.
- PARISHES OF TONGUE AND FARR, SUTHERLAND.—Medical Officers. (*For particulars, see Advertisement.*)
- ST. MARY ABBOTTS, KENSINGTON, PARISH OF.—Medical Officer to the Third District and to the Workhouse, at Mary Place, in succession to Mr. Hubert W. Lilly, deceased. Salary, £150 per annum. Salary for Workhouse, £30 per annum.
- ST. OLAVE'S UNION.—Assistant Medical Officer and Dispenser at the Infirmary at Rotherhithe, in succession to Mr. W. Steer, resigned. Salary, £100 per annum.
- WONFORD HOUSE HOSPITAL FOR THE INSANE, EXETER.—Assistant Medical Officer. Salary, £150, with board, lodging, and attendance. Candidates must be duly registered, and possess both a medical and surgical qualification, and not under 24 years of age. Applications, with not more than three recent testimonials, to be sent to Dr. Deas on or before October 26th.

## DEATHS.

- BONE, WILLIAM, M.D., J.P., at Castlemaine, Victoria, on September 1st, in his 49th year.
- CUMMING, FREDERICK, Surgeon, Scots Guards, at Richmond Barracks, Dublin, on October 16th, aged 30.
- LILLY, HUBERT WALTER, M.R.C.S., at 18, Norland Square, Notting Hill, W., on October 13th, aged 45.

## NOTES, QUERIES, AND REPLIES.

### THE BRADLEY FUND.

Additional subscriptions:—Mr. E. H. Addenbrooke, £1 1s.; Mr. Jno. C. Creswell, 10s. 6d.  
The subscription list closes on Monday next, the 26th day of October.

## MILITARY AND NAVAL HOSPITALS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Will you allow me to call the attention of the medical authorities to the desirability of separating the consumptive patients, by keeping them in the most cheerful wards of the hospital by themselves, as it is often thought to be more or less an infectious complaint, especially to those who may be at all liable to consumption. I have even known enteric fever cases frequently in the same ward as the other patients; which certainly would not improve the state of the atmosphere; and also venereal diseases with surgical cases generally, which, to say the least of it, is disgusting. Would it not be better to *classify* the patients? It seems time that more attention should be given to this important point, which is a mere matter of the simplest possible arrangement.

I am, Sir, yours, &amp;c.,

M. C.

October 19th, 1885.

## COMMUNICATIONS RECEIVED—

Sir H. W. ACLAND, Oxford; Dr. DONALD MACALISTER, Cambridge; Dr. W. H. CORFIELD, London; Mr. H. N. DRAPER, Dublin; Mr. D. BRADE, Kendal; Dr. W. H. ALLCHIN, London; Dr. A. H. JACOB, Dublin; Dr. EWART, London; Dr. T. O. DUDFIELD, London; Dr. JOHN CURNOW, London; THE SECRETARY OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY, London; THE HON. SECRETARY OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, London; Mr. J. W. BENSON, London; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; THE SECRETARY OF THE OBSTETRICAL SOCIETY, London; Mr. F. E. LONGLEY, London; THE EDITOR OF THE "NATIONAL GUARDIAN," Glasgow; Mr. M. CHURCHILL, Bishops Waltham; Mr. J. W. HOOKER, Wimbledon; Dr. W. T. PARKER, Newport, R.I.; THE SECRETARY OF THE SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS, London; THE HON. SECRETARY OF THE HUNTERIAN SOCIETY, London; THE DEAN OF THE MEDICAL SCHOOL, OWENS COLLEGE, Manchester; THE DEAN OF THE MEDICAL SCHOOL, Leeds; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE SECRETARY OF THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, London; Mr. CHAS. E. CASSAL, London; THE HON. SECRETARY OF THE MEDICAL SOCIETY, London; THE EDITOR OF THE "VOLUNTEER SERVICE REVIEW AND MILITARY RECORD," London; OUR GLASGOW CORRESPONDENT; THE HON. SECRETARY OF THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS, London; Mr. G. P. FIELD, London; THE SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY, London; Mr. E. A. BROWNE, Liverpool; Mr. CHAS. UMNEY, London; THE HON. SECRETARY OF THE BRITISH GYNÆCOLOGICAL SOCIETY, London; Mr. RICHARD JEFFREYS, Chesterfield.

## BOOKS RECEIVED—

On the Interpretation of Pathogenetic States and Therapeutic Facts, by A. De Noé Walker, M.D.—Handbook of Diseases of the Skin, by H. V. Ziemssen, M.D.—Milk Analysis and Infant Feeding, by Arthur V. Meigs, M.D.—The Therapeutics of High Temperatures in Young Children, by W. P. Watson, A.M., M.D.—Supplement to History of Stamford Infirmary, by Dr. Newiman—Acne, by L. Duncan Bulkley, A.M., M.D.—Report on the Health, Sanitary Condition, &c., of Kensington, for the four weeks Sept. 13 to Oct. 10—The Will Power, by J. Milner Fothergill, M.D.—Transactions of the Willan Society of London, Vol. 1.

## PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Weekblad—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—The Hospital Gazette—Revue Médicale—Journal of the American Medical Association—The American Eagle—Revue des Sciences Médicales—Journal of Cutaneous and Venereal Diseases—Annales Medico-Chirurgicales—El Monitor Médico—The New Orleans Medical and Surgical Journal—The Detroit Lancet—Revue Médicale—The Liverpool Mercury, Oct. 17—The Journal of the British Dental Association—The Journal of Anatomy and Physiology—The Aesclepiad—The Westminster Review.

## HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.; Chelsea Hospital for Women, 2.30 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London' 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 2 p.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guys, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## THE HARVEIAN ORATION.

Delivered at the Royal College of Physicians of London, on October 19th, 1885.

By RICHARD QUAIN, M.D., F.R.C.P., F.R.S.

(Continued from page 563.)

To speak of the advance of physiology is to imply a progress in pathology, since the latter is but the application of the former under the conditions of disease. Mutually aiding each other as they have done, it was not until physiology was on a secure foundation that pathology could claim the title of rational. Although healthy structure came to be known, and the dependence upon it of function to be recognised, it was long before the same idea prevailed in respect to disease. It is the especial glory of Virchow's work on cellular pathology that he applied consistently to morbid structure and action the same principles which had already made considerable advance in regard to health.

Proceeding on such lines, lines that we feel assured are tending towards great truths, we find that in every branch into which pathology is artificially separated improvement is taking place. The causation of disease—ætiology—it is now known, must be sought in

disturbances of our environment, or in defective inherited tendencies. How immeasurable is the distance which separates the mental attitude of the enquirer of to-day, engaged in tracing the causation of an epidemic disease, from the mystics who bewildered themselves with the notions of malignant spirits and evil humours, or of those who still lose themselves in attempting to trace epidemic waves.

To illustrate especially the advance we have made in our knowledge of ætiology, I would select but one point, which is the practice of arresting the diffusion of disease by limiting the spread of contagion.

This practice was illustrated on a gigantic scale by the Rinderpest or Cattle Plague, which appeared in this country in 1865. Towards the end of June in that year a few bullocks, imported from Revel, bringing with them the infection of Cattle Plague, were sold in the Metropolitan Cattle Market. From this single centre the disease spread step by step throughout the country until it had established 25,000 foci of infection within the year. Then a remedy was applied: All traffic of cattle was stopped; all infected beasts were killed, and all healthy bovine animals with which they had come in contact. The pestilence was stayed, but not until 300,000 animals had died or been killed with a loss to the country, at a low estimate, of three millions sterling, and an indirect loss to the same amount. All this might have been spared if it had been possible for the authorities, by a better knowledge of the nature of the disease and of its remedy, to ex-

tinguish it at its single primary focus by the sacrifice of a small number of animals at the cost of a few pounds.

The system of preventive treatment which proved so successful in the case of these lower animals has, as far as may be, been employed in certain infectious diseases, such as cholera, scarlet fever, typhoid fever, and diphtheria. To isolate the sick and such persons as have been in relation with them, until the very end of the period of infection; to thoroughly disinfect the secretions and other products from the patient at the earliest possible moment; to properly dispose of the dead; to cut off from the public all sources of contaminated supply, whether of water, milk, or other kind of food—these are a few of the principal measures which the experience of a comparatively recent period has taught us to practice in contagious diseases with results so satisfactory as to encourage us in their further extension. We have rational grounds for the belief that if the spread of infection were restricted by law, this class of diseases would soon be effectually extinguished. The result of such measures in reference to cholera poison are particularly striking. Many of us remember the invasions of this country by cholera, and its fatal progress, in the years 1831, 1847, and 1854. When sanitary measures were yet in their infancy, the epidemic of 1866, though grave in certain districts, Swansea, for example, was rendered harmless in other places. From that period to the present there has been no serious outbreak of cholera in this country, although there have been infectious arrivals on our shores on several occasions, as in 1873 and 1884 at Southampton, Swansea, Liverpool, and in the Thames. This satisfactory result is entirely due to the efficient arrangements made by the proper authorities to limit the spread of the disease. In this matter they acted under, and carried out, the judicious counsel given by that wise administrator, Mr. Simon, when acting as medical adviser to the Privy Council and the Local Government Board. I need scarcely add that this teaching has not been lost upon Mr. Simon's former colleagues and able successors.

Nor would it be satisfactory for me to pass over the subject of vaccination, the procedure by which that dire disease small-pox can be prevented or greatly modified. "One fact is worth a shipload of arguments," and therefore it will be sufficient to say that Ireland, stated to be the best-vaccinated country in the world, is practically at this moment free from small-pox; that since 1874 not a single case of death from variola has occurred in the German army, which dwells in the midst of a population protected by compulsory re-vaccination; whilst, on the other hand, we see at this moment in the City of Montreal, unprotected by vaccination, a frightful mortality. It is painful to contemplate such a consequence of ignorance or neglect; but, as Mr. Simon said in his letter on vaccination to the President of the General Board of Health,—“it goes with the credulity which characterises the present age to be incredulous of proved truth. Alike in rejecting what is known and in believing what is preposterous, the rights of private foolishness assert themselves. It is but the same impotence of judgment which shrinks from embracing what is real and lavishes itself upon clouds of fiction.”

I feel, sir, that it would be almost impertinent in me to address such an audience as I see before me on the details of the improvements in our knowledge of pathology and the allied subjects, the diagnosis and treatment of disease. But when I recall the views quoted by me in an earlier portion of this address, as to the absence of progress in our science and the hopelessness of its future—when I recall that these opinions have been held, not only by men of science, but by many others, I feel it to be one of the duties

of the present occasion to indicate our real position in definite language, the echo of which may possibly be heard beyond these walls. It will, at least, reach the ears of some who will hear with satisfaction that the reproaches raised against us have no longer any foundation, and that the progress of our art and of our science has been greater during the last half century than during all the preceding centuries. Nay, more: that recent progress gives promise of still more rapid progress in the future. It is not necessary to recount an elaborate list of discoveries in support of this assertion. One may truly say that there is no organ, no structure, no function of the body in health or disease which has not received the stamp of improved knowledge during the period referred to.

In our knowledge of the structural changes which occur in disease, accuracy is now replacing with great strides the previous uncertainty and vagueness; and I feel it is due in this connection to refer to the good work of the Pathological Society of London, whose forty volumes of Transactions are a brilliant monument of labour and research, and a bright exemplar to future years. It is but justice to say, in memory of one long since dead, that the society was established in 1843 by the intelligent zeal of a member of our College, the late Dr. Edward Bentley, a name which will be remembered and honoured by those of his friends and colleagues who yet survive, although unheard of or forgotten by many who yet fully appreciate the value of the society which he was the chief means of establishing.

I need but remind you how extensive has become our knowledge within the past few years, of the facts of structure revealed by the microscope in connection with new growths, with regard not only to their distinctive characteristics, but also those which connect apparently diverse forms and indicate their relation to the tissues in which they occur. The structural lesions comprised in the term “degeneration” are now clearly recognised and defined, and, without pretending to a complete knowledge of these morbid conditions, that which we do know about them possesses a character of certainty and truth, dependent on the essentially correct method by which the facts have been determined.

Concurrently with the growth and diffusion of a scientific knowledge of the causation of disease, and of its structural manifestations, there has arisen a better understanding of morbid processes. The condition of inflammation, which has been recognised from the earliest times, and has probably given rise to more discussion than any other subject in pathology, is now regarded in a manner which, whilst it admittedly leaves much to be discovered, is at least in harmony with our knowledge of the functions of normal nutrition. The pathology of fever also, though not yet complete, may be said to have been scientifically studied during the last fifty years. The systematic use of the clinical thermometer, the application of chemical testing to the secretions, and the improvements in the methods of bedside investigation generally, have revealed to us a vast number of facts which were unknown to observers at the beginning of the century.

Another factor of the greatest importance, both in relation to normal function and to disease, is the direct influence exercised by the nervous system on the tissue metabolism. We have no clear knowledge how this influence is exercised, but the existence of some control is certain; and it is curious to notice how older notions of neural pathology recur in the more accurately defined conceptions of to-day. The comprehension of the part played by the blood in disease is also an advance which has been eminently fruitful in results, and which differs widely from the doctrine

that at one time attributed every malady to some vitiated condition of the circulating fluid.

But nothing will bring the conviction of recent progress more completely home to our minds than a brief retrospect of parasitic pathology during the last forty or fifty years. How great a step, though it looked but small at the time, was the discovery of the first vegetable parasite in the skin and hairs, by Gruby and others, about the year 1840! The notion of parasiticism as a cause of disease has clung to pathology in all ages; and the analogy between fermentation and the acute specific processes had long possessed the mind of every thoughtful physician. But we ought clearly to bear in mind, in justice to modern medicine, that the *Torula Cerevisiæ* itself was not discovered until 1835, by Schwann and others, and that it is only within the last few years that the presence and activity of an organism have been definitely connected with a specific febrile disease—I refer to the discovery of the spirillum of relapsing fever by Obermeier in 1873. A new era in pathology, whatever may be its result, has arisen within the last few years with the rise of bacteriology. Following their master, Koch, a host of highly trained and eager observers in Germany, France, England, and other countries, are now engaged in the study of the acute infective diseases; and by ever-improving methods striving to contribute something fresh to the great but still obscure and unsettled subject of the relation of these organisms to pathology. Fallacious no doubt as were some of the earlier conclusions on this subject, there seems to be no question that the study of bacteria and bacilli has greatly widened our views of the nature of disease, and that it promises to lead to practical results of the first importance in its prevention or modification as in the hands of Pasteur and others.

The value of all this progress has been greatly extended by the aid of that new line of scientific inquiry which has already done so much, and which promises still more—I mean *experimental pathology*. Of this subject Hunter laid the foundations a hundred years ago; but it was reserved for our own time to see the extension of his method on a large scale in this country to the subjects of fever and infection—to the study of artificially produced disease, which in the hands of Sanderson, Klein, Greenfield, and others, has been so materially promoted by the establishment of the Brown Institution.

Whilst pathology has been thus steadily progressing side by side with Physiology, Diagnosis, or Symptomatology, the science and art of Clinical Observation has proportionately profited by our improved knowledge of these subjects. The leading feature of modern diagnosis is the full adoption of methods and instruments of scientific exactness, which, through the aid they give to the senses, permit the diseased organs, as it were, to reveal their own condition. The stethoscope, introduced by Lænnec in 1819, was used by but a few at the commencement of the second quarter of this century; and I well remember how an eminent hospital physician whom I met in consultation little more than thirty years ago, characterised it as a dangerous instrument. The ophthalmoscope, invaluable in the detection of diseases of the eye, reveals to us also many morbid conditions of the brain and spinal cord, and even more general disease, such as is represented by albuminuria. The laryngoscope is of equal value in reference to the diagnosis of diseases of the throat and chest. Instruments are now in constant use which accurately measure and graphically record the condition and movements of the several organs—the sphygmograph and cardiograph; whilst even the number and value of the blood-globules are revealed to us by the

hæmacytometer and hæmoglobinometer. The general adoption of the clinical thermometer and of the electric battery has marked an era in medical diagnosis. The microscope has become indispensable to the medical practitioner; and even the spectroscope has some clinical uses. The chemistry of the secretions is now universally investigated, the routine examination of the urine having revealed to us a large number of interesting facts. On some of these I might dwell, did time allow me; but I can only refer in a word to the evidence which the examination of the urine furnishes of the remarkable relation which exists in a great number of instances, not only between the liver and glycosuria, but between the liver and azoturia and albuminuria. The subject is one of deep and general interest fully demanding investigation.

No advance has been more important than that of the differentiation of the several forms of fever—an advance to which you, Sir, have yourself so largely contributed. The increase of our knowledge of the symptomatology of diseases of the nervous system has been equally marked. In all directions we may note greater definiteness of knowledge and of diagnostic power. Many forms of disease, previously unknown, are now recognisable by the exercise of ordinary carefulness. In a word, it may be said that those only who lived in what may be called the pre-accurate period of medicine, and who are still engaged in practice, can appreciate the vast improvements which have been introduced in the course of a professional lifetime, in the art of the observation of disease, or can perceive how some of these are suggestive of still greater results in the future. In speaking of the progress of medicine I would of course be understood to include those departments which have been somewhat arbitrarily separated from it—surgery and gynaecology. But as special branches of the healing art their advancement has been so considerable as to demand for their full exposition some one more competent for the duty than I have any claim to be.

I now come to a most important part of my present enquiry: the practical application to *treatment* of the great advances which I have just recorded in the medical sciences. We must not forget, in our enthusiasm as scientific observers, that our very *raison d'être* as physicians is the prevention and cure of disease. With these two branches of practical medicine we are equally concerned: our College has ever been as distinguished for its influence in the one as in the other. As early as 1650, the Annals tell us that the College presented to the Lords of the Council a statement of "Annoyances" by way of preservation from the plague, very similar, indeed, to what the College might suggest at the present day.

With reference to the question how far our methods of treatment of disease have been improved, I fear I must expect to meet with a certain amount of scepticism. But this scepticism is not reasonable. During the last fifty years medicinal treatment has advanced in two directions—by the introduction of many new drugs of great importance, and by the conversion into rational remedies of a large number of substances which were previously employed in a purely empirical manner. These results have been greatly facilitated by the discovery of the alkaloids, the first of which was morphine in 1817. With these and other active principles the practical physician is able to determine with accuracy the value of drugs which possess definite physiological actions, and to apply them in a simple, uncomplicated form, especially by subcutaneous injections. Nay, more: the pharmacologist is no longer satisfied with the direct supply from nature; he is now busily engaged preparing synthetically a series of entirely new agents.

There are those who, seeing no progress in therapeutics, must have forgotten that some of the most efficient means for diminishing human pain and suffering, the whole class of anæsthetics, commencing with the application of ether in America in 1847, have been discovered within the last forty years. In this connection also I would mention the revival on scientific principles of the administration of nitrous oxide gas as an anæsthetic. Of still more recent introduction are chloral hydrate and cocaine; whilst nitrite of amyl and of sodium and nitro-glycerine are recognised as invaluable agents in the reduction of arterial tension. The proper use of the bromides is comparatively new; indeed, bromide of potassium was omitted from the London Pharmacopœia of 1851 as being a useless drug! At the present time we find the dominant idea in pathology, the doctrine of germs, pervading and influencing therapeutics also. Antiseptics, with which the name of Lister is inseparably associated, and antipyretics are being employed in treatment to an extent of which the last generation could not have dreamed, and with results of the greatest practical advantage. The introduction of the salicyl compounds in the treatment of rheumatism is still a comparatively recent event. Some of the new antipyretic drugs almost rival in power quinine and salicine themselves. Surely all this is improvement of the best kind. Let us pause for a moment and contemplate the condition and prospect of a surgical patient only fifty years ago. No anæsthetic to induce insensibility to pain; no antiseptics to promote healing of the wound; no chloral to procure sleep; no antipyretic in general use to control fever. With such instances before us, how unjust to say, with some, that medicinal therapeutics remain stationary!

Turning now to the prospect for the future, I may be allowed to add a few words on the means by which further therapeutical advance can best be secured. There are two lines of investigation which must be followed, namely, clinical observation and pharmacological research. We must not approach these enquiries with the question, now too often heard—Have you any faith in physic? but with minds free from prejudice and incredulity, and hopeful of results not inferior to those which have characterised recent investigations. It would be unbecoming in me to attempt to indicate in this assembly the manner in which clinical observation of the action of remedies should be conducted. Still, it seems to me that there are one or two points which greatly threaten in practice to interfere with the rational administration of remedies, and which I would desire to condemn, inasmuch as they tend seriously to retard our future. There has grown up a habit of prescribing ready-made physic, of using compounds which contain a variety of drugs, each having different properties—a practice in which there is a mental proclivity to regard the disease as suitable to the physic in hand rather than to take the trouble to find a remedy that is suitable to the disease. This system is unpractical, unscientific, and least calculated to promote a knowledge of the legitimate use of medicinal agents. In fact, the art of writing a rational prescription is in danger of becoming lost.

Closely connected with the practice here condemned is that which hastily repudiates remedies on the ground of their failing to fulfil the intentions with which they have been prescribed. A chapter might be written on this subject, which, however, I shall summarise by saying that when these incidents cross my path—as they do that of all of us—I am disposed to fear that my diagnosis and not the drug has been at fault.

Secondly, we must regard with jealousy what is

called the statistical method of enquiry—that method in which an aggregate of units is made to represent a single substantial fact. If these units differ among themselves, and if the recorders of these single facts are not quite certain of the uniformity of the facts with which they are dealing, the inference must be misleading. It was Morgagni who said that “facts must be weighed, not counted;” and there is nothing more certain than that, if this sage advice be not followed, the conclusions will be unsound. This is the danger to which what has been called “collective investigation” is liable. So long as the enquiry is confined to simple facts which the observers are not likely to mistake, it is probable that valuable results may be obtained. But so soon as the problems to be enquired into are such as demand a clear judgment and close reasoning for their solution, the capacity of the observers comes into play as an important qualifying consideration in estimating the value of the results that are formulated. And when the method is applied to obscure points difficult of verification, such, for example, as the hereditariness or the infectiousness of phthisis, the conclusions may easily be rendered mischievous and unworthy of confidence.

Having thus spoken briefly of clinical observation, the next method by which therapeutical science can be advanced is that of experimental pharmacology—the scientific investigation of the action of medicinal agents on healthy animals. These two modes of enquiry should be carried on simultaneously, each suggesting, and at the same time testing, the methods of research pursued by the other.

By the aid of pharmacology the circumstances of an experiment are greatly simplified; we can vary the conditions under which it is conducted, and thus trace the numerous influences which either assist or counteract the action of drugs, and which lead to variable and apparently conflicting results in man. By this means also we can determine which part of a complex mechanism, such as the nervous system, is affected by particular agents—whether, for example, the nervous centres, the nervous tracts, or the peripheral endings. And, again, it is only by experiments on animals that we can safely test the action and strength of new drugs, and the phenomena and morbid results produced by poisonous doses; whilst from such experiments we receive many fresh suggestions for the introduction or manufacture of allied products. In England, for the moment, we are compelled almost entirely to accept such results at second-hand, legislation interfering with this method of enquiry. We must revert to the liberty of action possessed by France, Germany, and other countries, or must send our enquirers to pursue science in places where they are free to do so without incurring legal penalties.

The results of investigations such as these, too often buried in elaborate monographs, may never reach the physician in a form to bring home their application to his mind and in his practice. How they might be made more popular and more available in our daily procedure is a question which should receive attention within these walls. Our College might do much for the encouragement of research in therapeutics, and we might require from the candidates for our licence a better knowledge of the subject. Fortunately we have means which might be made available for promoting the first of these objects in the funds derived from the Croonian Trust, recently increased in value. It is a grateful duty to remember the name of the founder, Lady Sadlier—a duty strictly in accord with the desire of Harvey that on these occasions our benefactors should be duly commemorated. Lady Sadlier in 1700 founded the Croonian Trust, a trust which established a lectureship remunerated by a yearly payment of 10%.

The property bequeathed to us has increased in value, and now affords the College an available income from this source of over 200*l.* a year. Harvey also desired that the Harveian Orator should exhort the Fellows and Members of the College to search and study out the secrets of nature by way of experiment. How could the Croonian fund, thus so much increased in value, be appropriated with more justice or with greater advantage than in promoting the scientific study of the treatment of disease—the very object for which our College exists?

Secondly, seeing the large number of individuals who, through receiving the Licence of this College, annually join the profession, it is quite within our power so to regulate the course of education and the examinations, as to bring the subject of therapeutics into that position in the curriculum in which it would receive the most practical and profitable consideration. And in mentioning the control thus obtained by the College over the medical profession, it is my pleasing duty to refer to those real benefactors who, in the year 1859, re-established the class of Licentiates, with a result which has enabled us, by the increase of our numbers, to assume that independent position to which the College is justly entitled, but which nevertheless it had not previously enjoyed.

But, Sir, whilst I have indicated to you, in this faint outline which alone time permits, the progress which our science and our art have made in every direction, my argument would be incomplete unless I produced some evidence that the improvement I have insisted on has been productive of substantial results. It is not only that we may claim to have substituted for blind groping along the pathways of knowledge a method based on reason and observation, in which we recognise the nature of our ignorance as well as the extent of our information; as exponents of a practical science, we are bound to show that our improvement is a real one. This, I think, may be done, even though it be briefly. The first object of medicine, as has been well said, is to prevent disease, and, failing that, to cure or relieve it; and the nearer we approach to these ends the more successful may our art claim to be. The evidence of disease displays itself in a statistical form in the rates of mortality and of sickness; and a reference to the pages of that masterpiece of vital statistics, the Registrar-General's annual reports, furnishes us with ample grounds on which to estimate the progressive value of preventive and remedial medicine in improving health and lengthening life, with the incidental national gain in labour and wealth therefrom.

During the forty-three years intervening between 1838, when registration began, and 1881, when the last census was taken, the population of England and Wales increased from upwards of fifteen millions to nearly twenty-six millions, and all evidences of improved health should be considered in reference to this total increase of population, as well as to such other influencing factors as the distribution in town and country, in respect to sex-and-age periods. Summarising the results of these statistics, we note that there has been a steady decline in the mean death-rate per 1,000 living, from 23.3 in 1838 to 19.6 in 1884. The decrease is still more strikingly shown if we compare the mean rate for the 37 years preceding 1875, when the Public Health Act became law, which was 22.3, with that for the succeeding eight years, when it fell to 20.3. Taking the mean death-rate for the 45 years from 1838 to 1883, as 22.0 per 1,000 living, the improvement within each of the past four years has been considerable: in 1881 it was 18.9; in 1882, 19.6; in 1883, 19.5; and in 1884, 19.6. This means that if the death-rate of the previous decade, which was 21.4, had been maintained, nearly 213,000 more persons

would have died during those four years in England and Wales than actually did die.

The decline in the rate of mortality has occurred at all ages except from 45 to 75 in males, and from 55 to 65 in females; the greatest improvement occurring in both sexes at ages below five years. Mr. Noel Humphreys, in an able paper on this subject, concludes that the effect of this decline in the death-rate is to raise the mean duration of life among males to the extent of two years, and among females to nearly 3½ years; and further that by far the larger proportion of the increased duration of life in England and Wales is lived at useful ages, and not in the dependent conditions of childhood and old age. More recently, Mr. Makuna points out that the diminution of mortality also means prolongation of life to maturity in most of the saved infants and children, and useful lives to some of them. And Dr. Longstaff considers that the tendency appears to be for useful working life to be increased, but for old age to be slowly shortened.

It is impossible for me here to consider in detail how the diminished mortality is distributed among the different diseases, and to assign to the two factors of that improvement, viz., better sanitation and better methods of treatment, their proper share in producing the result. But it is distinctly in those diseases which are caused by insanitary conditions, and which so far are preventible, that the greatest improvement has taken place. Following the main grouping of sickness adopted by the Registrar-General, there has been a decline from the mean rate for the decade 1871–80, during the years since 1880, in zymotic, parasitic, constitutional, developmental, and local disease. In dietetic diseases only has there been a slight increase. As regards special diseases, the diminished mortality has been most marked in the group of fevers (typhus, typhoid, and simple continued), and in phthisis. I cannot refrain from dwelling for a few moments on the truth of these results which concern the population generally in their special application to individual classes, and for that purpose I would select the army, though the same could be shown, I believe, in all other classes.

The general death-rate of the army at home for the decade 1870–79 was 56 per cent. below that before 1854, and the rate for 1880 was 62 per cent. below it. And, again, whilst in 1880 the death-rate per 1,000 living was 17.6, in 1881 it was 14; in 1882, 11.8; and in 1883 it fell to 9.8.

Professor McLean, speaking lately at Netley, said, in respect to the European part of the Indian Army, that the mortality in 1859–60 was about 79 per 1,000, whilst in 1882, the death-rate in all India, from all causes, was only 13.07 per 1,000. He further stated that he had known, in the "pre-sanitary age," dysentery kill 1 in 5 of those attacked; and in a regiment with an average strength of 1,098 there had been as many as 2,497 admissions into hospitals in a year, with 104 deaths, chiefly from dysentery and hepatic abscess, whilst in 1883, in the same part of India, out of 13,000 men only 3 out of 500 cases of dysentery proved fatal.

To speak of such a change and not to mention the name of Edmund Parkes, would be unjust alike to his memory, and to the fair claims of the profession which is itself honoured in calling him a member. We may say of him as Idomeneus, speaking of the wounded Machaon, said to Nestor,

Ἴητρος γὰρ ἀνὴρ πολλῶν ἀντάξιος ἄλλων—

or as Pope has rendered it,

A wise physician, skilled our wounds to heal,  
Is more than armies to the public weal.

The statistics from which conclusions may be drawn as to the amount of sickness that prevails are neces-

sarily imperfect, and any statement as to the decline of the sick-rate is difficult to prove. But the late Dr. William Farr considered that for every death there are two cases of severe sickness, and that the rates of mortality and sickness "within certain limits rise and fall together." And since it is considered that for every death there are twenty-five cases of illness mild and severe, a diminished death-rate means a lessened amount of illness. The full significance of these facts in their bearing on our national wealth and productive power, as well as on the individual well-being and capability for work, can scarcely be over-estimated; but these subjects lately received so complete an exposition at the hands of Sir James Paget, that I need not further allude to them here.

When we thus regard the rapid and marked progress which our art and our science have made during little more than half a century, I feel that we are most fully justified in believing that the progress in the future will be even more marked, and that with materials for investigation in abundance, with willing and able workers, and with our College aiding and guiding the work, there can be neither fear nor doubt for the continued advance of the Healing Art.

In an earlier portion of this address I mentioned those who have spoken in disparaging terms of our future. Let me now, on the other hand, refer to an opinion of greater interest and greater force, expressed recently by one of our most eminent statesmen, who said to me, and he repeated the observation on more than one occasion, "Your profession has a great future before it, and I believe that in one generation, or at most two, it will be far in advance of the other learned professions." This opinion is fully in accord with our recent progress. There is before us a great future, and it is the assurance of this which has led me to speak to you in so sanguine a spirit. I have done so in full reliance on the value of the results which will be accomplished by those who are engaged in this great work, on the spirit which moves them, and on the means which they must have at their disposal for investigation. I have spoken to you as a prophet; but let me add in conclusion one word of hope and of prayer: that at no distant period the Fellow of this College, having the privilege of occupying the position which I fill to-day, may be able to speak to you then no longer as a prophet but as an historian, recording the great work which had been accomplished, and the large share which our College had taken in its achievement.

---

## SELECTIONS FROM TEN YEARS SURGICAL WORK.

By NELSON C. DOBSON, F.R.C.S.,

Surgeon to the Bristol General Hospital, Lecturer on Surgery at the Bristol Medical School.

(Continued from page 569.)

*Excisions of larger joints.*—In this department of surgery, my cases have not been numerous. I have generally preferred in young subjects (and the demand for this kind of surgery has, in my experience, generally been in such subjects) a tolerable amount of patience and waiting, rather than a precipitate and early resort to operation. The total number of excisions of joints of which I have record is 14, viz., 3 of the hip, 6 of the knee, and 5 of the elbow. In elbow excisions one was only partial: it was for a

compound comminuted fracture in the elbow-joint, extending up the humerus two inches, so that it necessitated the removal of the lower third or very nearly of the humerus, the bones of the forearm were not fractured, and they were left as I was compelled to remove so much of the humerus, that I feared as it was that a useless arm would result, but as amputation was the only other resource, I gave the patient the chance, especially as he belonged to the class not obliged to obtain his living by manual labour. He recovered perfectly, but with a not very useful arm. This was the only case in which excision was practised for injury. All the excisions recovered from the operation, and with one exception, a knee in a very strumous man, aged 45, whose leg I was obliged to amputate, they were all successful in giving the patients very good limbs. One of the hip cases had had his opposite thigh amputated for disease of knee-joint; he had also a large liver which I took to be amyloid, but to my surprise, when I saw him a few years after the excision, he looked healthy and well, and his liver was nearly of the normal size. In my excisions of the knee, I have on three or four occasions used Esmarch tourniquet to restrain the bleeding, but though it is useful in giving one a good view of the parts, I do not consider it necessary, and as the after oozing is more than if it had not been used, and the cavity of the excision is apt to become filled with blood clot, notwithstanding the drainage tubes, I now prefer not using Esmarch at all in these cases. I always remove the patella, and latterly I have wired together the femur and tibia in two places, by drilling and using silver wire. It will be noticed that I have had no excision of wrist or ankle, though, in one case I removed the astragalus for compound fracture with dislocation of that bone, the result being quite satisfactory. I have also had one case of excision of the os calcis for disease in the calcaneo-astragaloid joint.

In the knee and elbow, I have several times incised the joint and scraped out the pulpy synovial membrane when this was the tissue only or chiefly involved.

In treating excisions of knee, I have used different forms of apparatus: Butcher's box, and various modifications of McIntyre's splints with plaster or wax bandages, but I am not quite satisfied with any of them; I aim at getting the wound well as quickly as possible under antiseptics, and then putting the limb up permanently in a Croft's plaster splint, which I use for various fractures and joint diseases, and which, I think, one of the most manageable and useful of all the permanent splints we possess.

*Tumours of the Female Breast.*—I find I have notes of 36 cases of tumour of the breast which I have removed by operation. Of these 36 cases, 27 were cancer of the breast, and 9 for various non-cancerous growths, viz., 1 sarcoma, 5 adenoma, 3 cystic disease.

These various tumours have necessitated excision of the entire breast in 29 cases. One of the cases which I have classified as a cystic tumour was really a cystic adenoma, and weighed more than one pound, the interior of the cysts being filled with firm grape-like clusters. The whole of the operations were successful in so far that every patient recovered completely from the operation, there being no death in any case. The patient with the sarcoma was a woman of 32 years of age, 4 months pregnant, and the tumour was fungating. I removed the breast, and about 18 months afterwards she came to me with a swelling in her abdomen, which I diagnosed to be a sarcoma of the ovary, and I made arrangements for her coming into the hospital to have this removed, but a few days before the time appointed for her admission, she was pushing along her child's cradle, when her thigh suddenly snapped; she was brought to the hospital,

when I found she had sarcoma of the femur, and she eventually died of this, combined with her abdominal disease.

Of the 27 cases in which I have removed the breast for cancer, I have not as a matter of routine cleared the axilla. I have, however, done so in five of the cases where I thought it necessary. I am not at present persuaded that the very extensive operation and *routine* clearing out of the axilla, as recommended by Dr. S. Gross and practised by Mr. Mitchell Banks and others, is wise or necessary. I do, however, now more freely excise than I formerly did, and frequently leave a gap so wide, that my incisions will not come together, but I generally endeavour by means of the button suture and careful planning of the incisions to make them do so. Mr. Banks' paper on the operative treatment of cancer of the breast has done good service to the cause of surgery by calling attention to the fact that surgeons have been more careful to secure primary union than to get well beyond the disease; but I am disposed to think, when I look at Mr. Bank's mortality table, that he may possibly be going too far in the other direction, and advocating an operation so severe, that even in his hands there has been a mortality from the operation of 6 out of 46 cases. If we turn to his table of "cases remaining free from two to ten years," I do not find anything that convinces me so strongly as to make me advise, as a matter of routine, the patient risking a 13 per cent. chance of death from the operation. I notice one case free for ten years, one for seven years, and eight for variable periods between two years and three years and eight months, the fifth best case being one in which the breast only was removed.

Now, my list is a small one, not much more than half as large as Mr. Bank's, I therefore have not the right to speak as positively as he does, but still it is large enough (certainly larger than falls to the lot of a good many surgeons), to have led me to some conclusions on the subject: the conclusion which I have arrived at being that not every case requires routine clearing of axilla, and that we must judge of the necessity for this in individual cases. I have been at considerable trouble to ascertain the condition of axilla in cases going on to a fatal termination, both where the breast has been removed, and where it has not; and I do not find it by any means universal that death is brought about by the axillary deposits, or that in more than a moderate percentage of cases have we the axilla so affected, that the patient suffers much pain or discomfort from this cause; it is true that œdema of arm and much pain are not uncommon, but I have noticed once or twice the same thing even when the axilla has been cleared. Formerly, I was not in favour of operating at all when I could feel the axillary glands enlarged, but even under these circumstances I now operate, when it seems to me there is a reasonable hope that the vessels or nerves are not involved in the mass.

Turning to my own cases, I am sorry that I have not been able to trace them all. I know as a matter of fact that many of them are dead, and if I do not know to the contrary, I have assumed that they are. Of the 27 cases, not one proved fatal from operation; 13 have died eventually, presumably from recurrence; 14, so far as I know, are alive, though one of them has a recurrence. One of the cases has been free for more than ten years. The original operation was done in September, 1874, the breast only being removed; there was recurrence in the cicatrix in February, 1875, which I also removed, and the patient was alive and well twelve months ago, and I should have heard had she been ill since.

One case is well (September, 1879), nearly six years, breast only removed; one case nearly five years—from

this patient I removed in 1882 (two years after I excised the breast) a tumour from the soft palate which proved to be a round-celled sarcoma. She has remained free from any obvious malignant disease since. The majority of the other cases have been done during the last two years.

All my cases have been seen by other surgeons, and of nearly all I have microscopic sections. I have not been able to establish the relative frequency with which the glands in the axilla, sub-clavicular region or mediastinum are affected. I have no doubt that the axillary glands are affected in much larger proportion than the others; still I do not believe they are universally affected, or that we have at present sufficient evidence to justify clearing the axilla in all cases. In three of my own cases remaining well after ten, six and five years respectively, the axilla was not cleared.

*Lithotomies.*—I have operated on twelve cases of stone in the bladder, all in males, and in all the cases I have performed the operation of lithotomy; nine of the cases have occurred in boys, that is, before the age of puberty, and three have occurred in men. In ten of the cases I did the lateral operation, and in two the median, viz., one boy and one man. There was one fatal case in the series, the boy on whom I did median lithotomy. This boy was about five years old, one of my earliest cases, and I did the median for him rather than the lateral, because it had been the custom for some of my older colleagues to prefer this operation to the lateral; this patient was removed from the hospital by his friends, and died about ten days after the operation; as I did not see him at the last, I do not know the actual cause of death, but there was no extravasation whilst he was under my notice. I have no doubt that in this case the urethra was completely torn across at the time of the operation. I made the usual incision, and whilst I was gradually dilating the urethra with my finger, something suddenly gave way, I have no doubt, as I just mentioned, that the urethra was torn quite across; however, having rather a small finger, I did not lose my hold of the urethra, and was able with a little care, to enter the bladder and remove the stone without difficulty, and in a very short time, so that none of the numerous by-standers were aware that anything unusual had occurred, or that the operation was not perfectly satisfactory to the operator. I had hoped that as I succeeded so readily in getting out the stone, that all would go well. The patient suffered more from shock at the time of the operation than I have been accustomed to see, but otherwise there appeared no reason why he should not recover. He died apparently, so far as I could see him, of exhaustion; there might have been some pelvic infiltration, but I did not especially notice this. Several years have passed since this operation, and I mention it now for the first time; had I not been quiet, and particularly careful in keeping in my finger, I doubt if I should ever have removed this stone. I am still at a loss to account for the fatal result in this case. I see no reason why he should have died from the tearing across of his urethra, seeing that there was a ready outflow for his urine through the perinæal wound; at any rate, cases in many respects analogous, such as rupture of the urethra from blows on the perinæum, recover frequently after opening the perinæum, and giving a ready exit for urine. I have long since ceased to practise median lithotomy in boys. All the other cases were successful, and with the exception of a man who had symptoms of stone complicated with perinæal abscess, and whose abscess I opened and removed the stone by median lithotomy, the lateral has been the operation both in boys and the remaining two men.

One of the boys was a puny, delicate child of 2½

when I first did lateral lithotomy for him, and when he was 5 years old I again did the lateral operation for him through the old cicatrix and removed a uric acid calculus, weighing 328 grains. This stone is the largest I could find recorded as having been removed at a second operation at so early an age. I carefully explored the bladder at the time of the first operation, and I am sure he had no second stone at that time, so that the case is interesting as giving us something like definite data as to the rate of growth of stones. I may say that in the interval of the two operations, I removed the boy's thumb and the index finger of the other hand for strumous disease; he was a perfect mine of surgery, but he has now grown into quite a respectable sized lad; he came to me only a few months ago with symptoms of bladder irritation, but I could find no stone. It will be seen that in the three men I did not perform in either of them Bigelow's operation, and for these reasons. The first case had perineal abscess, forming and I did the median; the second had had a stone removed from his bladder in India, and there was a large perineal sinus remaining, through which all his urine flowed—I did the lateral operation in this case and for a moment there was a very ugly rush of blood, probably from the prostatic veins in consequence of long irritation in this region; by keeping my finger for a moment in the incision the bleeding ceased and I rapidly extracted the stone; his perineal fistulae was much improved, but not cured. In the third case I was doubtful whether I should not do rapid lithotomy, but on carefully examining the patient with the sound I came to the conclusion that the stone was a very large one. I did lateral lithotomy, finding two flat faceted stones lying side by side and in close contact, weighing nearly 3 ozs., and as the patient made a speedy and perfect recovery I felt justified in my choice of operation.

*Strictures of the Urethra* have, of course, been constantly under treatment, and in such numbers that I have no notes of them. Not unfrequently the stricture has been associated with retention of urine, but I have always, with three exceptions, been able to relieve the patient sooner or later by the catheter. Of the three exceptions just spoken of in one instance I tapped the patient through the rectum; he wore the trocar for three days, when I was able to pass a catheter and he made a perfect recovery. In the other two cases I did perineal section without a guide; in one of these cases the patient's urethra was destroyed for a couple of inches, and it was necessary to establish a permanent opening in the perinæum over which the patient has perfect control. I am anxious that he should allow me to try to make him a new urethra now that the parts are so sound; he is an intelligent and educated man, but he expresses himself as being so much more comfortable than he has been for years that he prefers his present feminine method of micturition. When the stricture has been complicated with one or more perineal sinus which did not readily yield to a full-sized catheter I have always preferred Syme's external urethrotomy. I have only notes of five such cases, all of which did well, but I am certain that I have done this operation on several occasions of which I have no note. I have never had any serious trouble with these cases, or anything like urethral fever. When the stricture has not been complicated by either retention or perineal fistulae I have always succeeded in practically curing the patient by means either of gradual dilatation or by keeping in a catheter for a time. I have never had occasion to practise internal urethrotomy in any form except for strictures near the meatus; I have had several cases in which I should have judged this operation admissible, but hitherto I have been able to overcome my patient's difficulties without it by means of Lister's sounds. I

have a dislike, perhaps a prejudice, to the operation, as I think it not so free from danger as it is sometimes thought to be, and therefore I have avoided it. On one occasion, however, I felt I should be compelled to do internal urethrotomy, and made arrangements to do so, but on my telling the patient there was some slight risk he told me an eminent London surgeon, whom he had consulted, told him there was no risk. In consequence of this my patient went to London and was operated on by an equally eminent surgeon, and died in about forty-eight hours, and as the operation was done by one of the most skilful surgeons of the day there could be no doubt that, so far as the operation was concerned, there was no fault in its performance. Though I had no practical acquaintance with this operation I have always felt that there must be some considerable risk associated with it, when I have known patients actually die in a few hours from the mere passing of a catheter where there was no bleeding or evidence of laceration, and many times have I seen (and all surgeons must have had similar experience) severe rigors and serious symptoms follow catheterism, not in old prostatic cases only, but in young and middle aged men with stricture.

*Nephrotomy.*—I have had three examples in all of this operation; two of them occurred in my first ten years of hospital work and the other quite recently. I include this last case, which was fatal, on account of its importance. I intend giving, on another occasion, a more detailed account of these cases. I may say for the present that the first case occurred some years ago in a delicate man of about 40 years of age, and who had suffered from stricture of the urethra with perineal fistulae and who had undergone external urethrotomy a few years previously. The patient was passing pus in his urine, had high temperature, and a fluctuating tumour in his left loin; as the surgery of the kidney was not so well understood then as at the present day, the swelling was allowed to become superficial before it was opened. I opened it and drained it. I have no doubt that the pelvis and kidney itself was converted into one large abscess, and there was very little trace of true kidney structure; this man, who is since dead, lived for some years after the loin was opened.

In both the other cases I deliberately cut down upon and exposed the kidney; the abscess was situated in the pelvis of the kidney. In neither case was the kidney itself enlarged, though in the last case the kidney looked grey and unhealthy. In both these cases the incision was made directly through the kidney substance, and in both cases after the kidney had been exposed I inserted an aspirator needle through its substance to make sure that I could reach the pus before I incised the kidney.

The first of these cases was a man aged 33 sent to me from Devonshire; he had great pain in passing water and a constant desire to micturate, so that his bladder was examined for calculus, but none was found; there was a considerable quantity of pus in his urine. After a short time the right loin became fuller and more tender than natural; but the swelling, which indistinctly fluctuated, was more palpable on the front of abdomen just below the liver; the man was rapidly emaciating and losing strength. I cut down on the kidney through the loin and incised the substance of the kidney, and inserted my finger so as to explore the calyces and pelvis, but did not find at the moment as much pus as I expected. I inserted into the pelvis of the kidney, through the wound in kidney structure, an india-rubber drainage tube. Next day there was a considerable discharge of pus, and the dressings were soaked with urine; the urine passed by the urethra was violet coloured and contained some blood, the colour being mostly due to the local

effect of the carbolic dressing. The swelling in front disappeared, and after a very severe illness and tedious convalescence the patient recovered; but when he returned to Devonshire, some three months after the operation, there was still a small fistulous opening in his loin. This I believe has since healed.

The third case was that of a married woman, aged 35, who had been treated for some time in the country for painful bladder troubles; she was admitted into the hospital under one of my colleagues, when a swelling was discovered in the left loin. This swelling varied in sized from time to time. The patient was very weak and delicate; greatly reduced in flesh and strength by high temperatures ( $102^{\circ}$  to  $103^{\circ}$ ) and by passing water every half hour, with much pain. There was no doubt that the swelling was connected with the kidney and probably due to pus. I incised the kidney substance under chloroform with antiseptic precautions, let out the pus which was in the pelvis of the kidney, and after examining the interior of the pelvis with my finger inserted a drainage tube. The operation took place at 1.30 p.m., and occupied only a few minutes; at 4.30 she was taken with violent rigor, and at 5 o'clock her temperature was  $106.4$ . A dose of 15 grains of quinine was administered and her temperature fell to  $105^{\circ}$  at 6.30;  $104^{\circ}$  at 7.30;  $103^{\circ}$  at 8.30; rose to  $104^{\circ}$  at 10.30, and fell again to  $103.2$  at 12 p.m. When seen last thing by the house surgeon he thought her fairly comfortable, but she died at 5 a.m., about 16 hours after the operation. There was no loss of blood and no shock. The external wound was small. It was dressed antiseptically. The case, I think, is important because in these early days of kidney surgery it is not clearly established whether it is better to incise the kidney structure or open the pelvis directly. It is important because I could refer death only to that condition which occasionally manifests itself with rapidly fatal results after operations on the male urethra, and which we term urethral fever, in which a patient may die within twelve hours of an operation on the urethra, or it may be the mere passing of a catheter, and in which nothing is to be discovered *post-mortem*. But, so far as I know, nothing has yet been said, nor has any case been reported, in which similar symptoms have followed operations on the kidney itself. I do not consider death was due to shock in the ordinary sense of the word, for there was no decided shock at the operation. To me the death was as unexpected as it was disappointing, but I feel it to be of the highest importance that in comparatively novel operative procedures our fatal cases should be recorded in order that the dangers may be fairly appreciated, as I have a pretty strong feeling that the prevailing tendency is rather to under- than over-estimate the risks of some of our newer operations. In this case I could obtain no *post-mortem* examination.

In closing my list of operations on the urinary and generative organs I may say that I have several times amputated the penis and removed testicles, but of these operations I have nothing to remark. I have also, of course, had under my care a large number of cases of hydrocele of the tunica vaginalis. Many of these have simply been tapped as often as necessary; where I have attempted the radical cure I have injected iodine; occasionally this has failed. In one case of double hydrocele I failed in the first injection, but on a subsequent injection, a few weeks after the first attempt, a cure was effected which has been permanent. Twice I have slit up the scrotum after such failure and drained the hydrocele with antiseptic precautions, stitching the tunica vaginalis to the skin of the scrotum by a continuous suture with perfect success. Twice a hæmatocele has followed simple tapping among my cases; in one of these cases I tapped the hydrocele myself, in the other

I did not. In my own case (a somewhat feeble elderly man) the fluid was only blood-stained, but the sac supplicated; I laid it open to the bottom, but the patient died of septicæmia—an instance of the disastrous result that may sometimes follow so simple a proceeding as tapping a hydrocele. I have no doubt that there are many surgeons who must have had an experience similar to mine, but I do not call to mind a published fatal case.

Of the surgery of the *abdominal organs* I hope some day to have something to say; for the present I will only mention that with reference to strangulated hernia I have nothing special to say. I operate now with less employment of taxis than I used formerly to practise, and I am quite sure the change has been of benefit to the patients. I do not, as a rule, remove the sac, nor do I attempt the radical cure; what I may do in the future with respect to this point I am still uncertain.

Of *abdominal sections* I have had 17 instances, and with 3 exceptions these have all been for ovarian tumours. Of the three exceptions one was for malignant disease of the omentum; a second for acute intestinal obstruction, and a third for ruptured uterus during parturition with severe hæmorrhage into the abdominal cavity. All three of these cases proved fatal.

Of my ovarian cases, fourteen in number, three have proved fatal; these were some years ago. All my recent cases have recovered. For *diseases affecting the mouth and jaws* I have several times been called upon to operate. Among the most interesting of the operations I have ever performed in this region was a case in which I removed a large tumour from the soft palate of a healthy woman, aged 22. The tumour projected externally under the angle of the jaw; in the mouth there was a large uneven mass almost completely filling the pharynx, and extending from left to right: there was barely room for the finger to pass into the pharynx beyond. I removed this tumour, which was as large as a small orange, by an external incision over the portion which projected below the jaw, and inserting my finger through this incision I separated the tumour freely from its connections. I then made an incision through the soft palate over the tumour in the mouth, and repeating the same process with my finger separated the growth entirely from its connections, and delivered it through the mouth. From the large size of the tumour there was a difficulty in getting it through the mouth. There was very little bleeding and the patient made a perfect recovery. The tumour proved to be a fibro-adenoma. I have also removed a smaller tumour (about the size of a hazel-nut) from the soft palate of a patient whose breast I had previously excised for scirrhus. This growth proved to be a small-celled sarcoma, but the patient still remains well, though four or five years have elapsed since the operation.

Of operations on the jaws I may mention three cases, in one of which I removed simultaneously the greater part of both superior maxillæ. This was for malignant disease which had so far advanced when I saw the patient that the palate processes were considerably softened by the disease. The orbital plates were not removed. The disease returned in the base of the skull, and the patient died some months after the operation. This case was reported upon by Mr. Wagstaffe, and I believed published in the *Pathological Society's "Transactions."* I must mention another case (though it does not come within my first ten years' work), in which I have quite recently removed the left superior maxilla for malignant disease. The case was instructive, as it had been under my observation for a long time (more than twelve months), during which period I was under the impression that the

patient was suffering from a chronic abscess in the antrum. She complained of severe neuralgic pain in the face, and an occasional discharge from the left nostril. There was, until quite late in the case, no swelling of face or in the nasal cavity. Thinking it was an abscess in the antrum I drained it and kept it open, there being a pretty free discharge of pus; and at one time I removed a piece of necrosed bone from her alveolus. I noticed some swelling of the front of the face, and thought the palate process rather softer than natural; just at this time I lost sight of her for six weeks. When I next saw her I found the growth originally in the antrum had burst its bonds both anteriorly and posteriorly as well as in the nasal fossa, and, of course, there was now no doubt as to its nature, and as it appeared fairly localised with no glandular swelling and no prominence of eyeball, I removed the superior maxilla. I then found that it extended right across the nasal fossa, had nearly destroyed the palate processes, extended far back into the base of the skull, and was altogether more extensive than I had anticipated. I scraped suspicious portions which remained with the spoon, and applied chloride of zinc freely. I expected a good deal of hæmorrhage and therefore, as a preliminary, I introduced a tube through the cricothyroid membrane—this simple proceeding immensely facilitated the subsequent steps of the operation; as I was able to securely plug the pharynx by sponges, no blood got into the trachea, and there was no interruption to the chloroform, the patient being perfectly still and unconscious throughout, absolutely free from the unpleasantnesses which usually belong to operations on a large scale about the mouth.

I have once removed half of the lower jaw from the symphysis to condyle for dentigerous cyst. The case was published in the St. Thomas's Hospital Reports. My dental colleague, Mr. Parsons, fitted her with an admirable substitute. It is now ten years since the operation, and when I saw this patient a few weeks ago I found she needed no artificial jaw, that the parts had so consolidated that she masticates perfectly, and so complete was repair that some of my pupils who looked into her mouth could not at first ascertain what operation she had undergone.

I have had but few operations on the tongue. From my own small experience of these operations, and from what I have seen in the practice of others, I prefer to use the ecraseur when large portions are to be removed. I have used either knife or scissors when only the anterior part of the tongue was affected. In one case where I removed the whole of the tongue as far back as possible, the patient remained free for six months, and then had a most painful recurrence of which he died. In this case I made a vertical incision in the median line beneath the jaw, and through this I carried the ecraseur into the mouth by means of a large curved needle, keeping close to the upper border of the hyoid bone. I then divided the femur and adjoining parts freely with scissors, drew the tongue well forward, and passing a stout curved needle through the extreme base of the skull, slipped the ecraseur chain over this, and thus readily removed, without hæmorrhage, the whole of the tongue. In this particular case the man had had syphilis, and the epithelial tumour situated in the middle of his tongue looked like a gumma, and several surgeons who saw him thought so; but a small piece clipped off prior to operation showed it to be a typical epithelioma, which the sequel of the case only too fully proved. I mention this fact because I have an idea that in the tongue particularly syphilitic affections are not unfrequently followed by malignant disease.

There are two classes of operations which have not come under my observation, viz., the ligation of large arteries in their continuity, and the operation for un-

united fractures. As I have before stated, only two cases of secondary hæmorrhage occurred after amputation, and in both these instances I secured the bleeding vessel (the femoral artery) in the stump. I have had no case of primary hæmorrhage which I could not secure in the orthodox way; and of the surgical aneurysms I have had three cases, viz., two of the popliteal, and one of the femoral, all of which I cured by digital compression. I have a strong feeling that with proper precautions and careful attention to detail, that in large hospitals the occasion ought seldom to arise where it is necessary to ligature an artery in its continuity for aneurysms affecting the limbs.

It is perhaps not quite correct to say that I have not operated for ununited fracture, as I have done so on two occasions, one in which both bones of the forearm were operated on by simple resection, and one case of ununited fracture of the humerus which I resected and wired. I should rather have said I have never had a case of ununited fracture that had been under my care from beginning to end; this is perhaps a piece of good fortune, as a very large number of fractures have come under my notice. I am, of course; speaking of the long bones, and exclude fractures of the neck of the thigh bone. In one recent fracture of the patella I cut down and wired the fragments with perfect success.

I have had a large number of operations which it would be difficult to classify; tumours of various kinds I have constantly removed, but especially does it seem to me that I have been called upon to remove sarcomas in greater numbers than any other class of tumours. The point that has most frequently struck me about these sarcomatous tumours is their difference of behaviour after operation. I have removed sarcomas which have recurred locally so often that on two or three occasions the patient has given it up in despair, and died simply of the local disease, whilst other tumours apparently similar in microscopical character have not recurred locally, but have diffused themselves in every region and tissue of the body; especially was this the case in one instance in which I removed a large sarcoma from the groin which had apparently commenced in a lymphatic gland. This patient was literally from the crown of his head to the sole of his foot covered with sarcomatous tumours; and every internal organ except his brain was studded with similar growths.

I do not in the foregoing account pretend to have given a summary of all the operations I have performed, but only of the classes which I have mentioned so far as my notes would enable me. I do not know that my list of operations is larger than that of my colleagues in the same period. I think it will fairly show the large amount of material that a provincial hospital of 150 beds may provide. In bringing to a close this record of my surgical experiences I am conscious that it is open to the criticism of being crude and unconventional, but I believe that in this form it is more likely to be read than a mere statistical account, and certainly I have found it easier to put together my facts in this way, and also to insert my somewhat casual observations on the various points that have occurred to me.

UNIVERSITY COLLEGE, LONDON.—The following awards have been made:—Medical Entrance Exhibitions: 100*l.*, Mr. T. L. Pennell; 60*l.*, S. B. Mitra; 40*l.*, Mr. J. J. Macnamara. Andrews Entrance Prizes of 20*l.* each: for Science, Mr. C. F. T. Blyth; for English and other languages, Mr. Arthur Vaughan. Gilchrist Entrance Engineering Scholarship (35*l.* for two years), Mr. R. J. Durley.

## CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD  
AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the  
Principles and Practice of Medicine and on Clinical Medicine.

## LECTURE III.—CASE TAKING.

*The Family History*—(concluded).

ANOTHER source of difficulty, both in estimating the exact share ancestral influence has in determining the occurrence of a malady in a given patient, and in judging of the inherent liability to disease in an apparently sound person, is to be found in the undoubted effect that one morbid constitutional state may have either in favouring or in preventing the occurrences of another in the same individual. This idea of harmony or antagonism between diseases has come down to us from very early times, and, indeed, is almost to be looked upon as being quite in accordance with the older notions of the entity of disease. When maladies were so regarded, it was not far-fetched to assume that the "morbid spirits" dwelt some in harmony and some at war in the bodies of their hosts. But, be that as it may, the idea has prevailed, and claims attention now; and, without attempting an explanation of so obscure a subject, there would seem to be good reason to believe—at least so far as figures at present show—that apparently very different diseases mutually predispose to each other, or, at all events, their coincidence is so frequent as to suggest some relationship. Thus a form of scrofula has been described as of frequent occurrence in the children of paralytic, epileptic, and insane parents. And "it is certain," says Dr. Maudsley, "that there are very intimate relations between phthisis and insanity; one-fourth of the deaths in asylums are caused by phthisis, and Dr. Clouston, who found that there is hereditary predisposition in 7 per cent. more of the cases of insanity with tubercle than of the insane generally, has described a certain form of insanity as phthisical insanity."<sup>1</sup> Dr. Bennett, among his cases of epilepsy, found 12 per cent. of those who gave a history of hereditary disorder mentioned phthisis. Rokitansky, in his celebrated "Pathological Anatomy," the chief authority thirty years ago, and a storehouse of facts and information, refers, under the head of Tubercle, to various diatheses which are favourable or antagonistic to the occurrence of that new growth. Some of the statements have since been confirmed by the extended observations of recent workers, others have not stood the same test. Thus it was shown by him that tubercle and carcinoma rarely, if ever, occurred together; cancer was very occasionally observed to follow tubercle, and with even much less frequency did tubercle succeed cancer. I am not aware of any *a priori* reasoning that would have led to formulating such conclusions; they were the result of careful observation, and by pursuing the same course they have been verified. To this question of the antagonism of diseases I shall refer again when speaking to you of the previous illnesses of the individual; here I am only concerned to show the relationship of the diseases which run in families.

And yet another circumstance which complicates the

influence of heredity is the liability that some diseases seem to have to skip a generation, or to appear in the progeny whose immediate ancestors have been free from any appreciable manifestation of the same. The subject of atavism (*atavus*, a grandfather) is one of the most perplexing problems that is offered to the biologist: his researches into it extend among plants as well as animals; in health and in disease; and, as may readily be supposed, it affords the ground for the enunciation of most diverse opinions. That many structural peculiarities, and even many traits of character and likeness, appear in the members of one generation, whose immediate progenitors have not possessed them, but which have a striking resemblance, often the very closest, to what may have occurred in some preceding generation, is a matter of common knowledge. The records of the breeders of domestic animals furnish ample proof of "reversion," or of "throwing back" as it is termed. The facts are undisputed: it is the interpretation that is to be put upon them that is in doubt; whether or not there is any law of relationship, or that each reappearance of a characteristic is to be regarded as determined by the immediate environment, with little or no influence of inheritance, is the question for solution. Those who adopt the latter view regard it as inconsistent with the essential notion of heredity that the offspring should differ from the parent, as is the case when a disease skips a generation; and that the difficulties of admitting that inheritance is in any way responsible become insuperable when it is attempted to assert its causal influence at a distance of several generations, as I shall presently give you illustrations of. Further it is urged, if a morbid taint is capable of remaining in abeyance through one or more successive generations, to appear no one knows why or when, that, in place of pointing to exceptionally degenerate races, we should fail to find a single family that might claim to be healthy. In short, the doctrine of atavism and latency takes too little heed of the effects of such outside circumstances bearing directly upon the individual, such as training, example, and imitation.<sup>2</sup> I could select for illustration no more notorious instance of reversion in disease than is offered by gout, yet note what Dr. Garrod<sup>3</sup> says on this very subject, admitting that "more than half the gouty subjects can distinctly trace their ailment to hereditary taint," and acknowledging "that there are often apparent grounds" for the notion that the disease tends to skip a generation; he regards such as an "erroneous idea," and would prefer to explain its non-appearance in the child of a gouty parent, whose offspring in turn may suffer by the precautions taken "to keep the disease at bay."

Turning to those who concede to atavism the fullest share in the predisposition to disease, I would refer to the writings of Mr. Sedgwick,<sup>4</sup> who has paid special attention to this subject, and has collected the records of many cases, particularly of colour-blindness, hæmophilia, pseudo-hypertrophia, muscular paralysis, &c., from which I would select the following as a well-marked illustration of the phenomena we are considering; incidentally also showing how the defect appeared only in the males, being transmitted only by the females of the family.

The record extends over four generations:—

- (1) Great-grandfather, colour-blind; great-grandmother, normal.
- (2) They had five daughters, all normal.
- (3) These five daughters had among them twenty-

<sup>2</sup> Heredity. *British and Foreign Medico-Chirurgical Review*, July, 1875.

<sup>3</sup> "Reynolds' System," Vol. i, 1866.

<sup>4</sup> *British and Foreign Medico-Chirurgical Review*, 1863, Vols. i. and ii. *British Medical Journal*, 1882, Vol. ii.

<sup>1</sup> "The Physiology and Pathology of Mind," 1868.

six children, of whom six were males, all colour-blind, the remaining twenty females being normal.

(4) One of the twenty females had two colour-blind sons.

Another had three colour-blind sons, and one son and one daughter both normal.

A third had two colour-blind sons, and one son and one daughter both normal.

This is but one example of very many that I could give you, drawn from the most varied diseases. It is surely more reasonable to see in such a case the working of some law than to regard the remarkable regularity of alternation as the accidental result of surrounding circumstances. "And if the influence of atavism in the hereditary transmission of disease can be maintained for four, five, or seven generations, it would be illogical to assign it any limits; and, moreover, when there is also limitation by sex the evidence is then very strongly in favour of the extended, but undiluted, influence of atavism." (Sedgwick.)

So far I have referred to transmission in the direct line, but there is reason to believe that a child may present in his appearance or constitution traits derived, not from his own father, but from a former husband of his mother. This form of indirect atavism is well known to appear in animals in the form of characteristics which are not to be mistaken.

It is extremely difficult for me to indicate to you what is to be learned from these facts without referring very briefly to the theoretic side of the subject. What is it we understand that is transmitted? To this question I cannot pretend to give you a complete answer, but, as showing you the way in which we are inclined to reply, would prefer to quote from Sir James Paget, whose remarks on this subject in his lecture on "Surgical Pathology" (1870), and, still more, in a paper on "Constitutional Diseases," published in his collected clinical lectures and essays (1879), should be read by you all. Speaking of cancer, he says, "what is transmitted is not cancer or cancerous material, but a tendency to the production of those conditions which will finally manifest themselves in a cancerous growth. . . . Though we cannot assume the passage of a cancerous material, we cannot, on the other hand, understand the transmission of a tendency or disposition to any event independently of all material conditions, therefore the germ or semen of a cancerous parent is in some conditions different from that from a parent who is not cancerous, if, in the course of years, cancers are to be formed out of the substance which the germ in its development or subsequent changes will appropriate." What is here spoken of in respect to cancer is applicable to other diseases which may be shown to be transmissible, as well as to the structural and functional characteristics of health. No attempt, you will see, is made to define what the tendency is, it is merely the expression used to describe the *direction* taken by the series of changes which constitute life; the expression, in short, to denote the guiding principle which has determined two *apparently* identical ova developing, the one into a dog, the other into a cat. The importance to us here in trying to understand the intimate nature of heredity is to recognise the undoubted fact that the tendency transmitted is not of necessity so potent as to withstand the influence of conditions subsequently brought to bear on it. I do not, of course, mean that we can so arrange as to make the ovum of a cat develop into a dog; the characteristics of a species are not to be upset in one generation. But there are tendencies of a less specific character which are certainly capable of modification, and which should be taken advantage of in dealing with disease. Every stock or horse breeder knows that by inbreeding he can improve and develop the points of the animal that he desires,

and morbid strains may be equally diluted or reinforced by suitable marriage, at least within very considerable limits. The records of consanguineous marriages clearly show the intensification of diseases when the taint exists in the family, and that in proportion to the nearness of the blood-relationship of the parents. Hence the importance of enquiry on this point, as showing the character and strength of your patient's predisposition. It has been urged with good ground that diseases which are detrimental factors of evolution, so far as the species is concerned, tend to die out after a few generations: that the fittest, *i.e.*, healthiest, alone tend to survive. Syphilis, for instance, is rarely, if ever, transmitted beyond the third generation, and then perhaps in the third or fourth appearing as scrofula, or, as some have thought, as rickets. But it is easy to see that this natural tendency to disappearance might be averted by the inter-marriage of the representatives of two syphilitic families.

Notwithstanding all these difficulties connected with obtaining a perfectly correct estimate of the nature and value of the ancestral influences which tend to make our knowledge of the subject uncertain, sufficient evidence, of a more or less perfect character, does exist to render it in the highest degree probable, if not quite certain in some cases, that the diseases I have enumerated in the scheme recur with sufficient frequency in successive generations as to justify the assumption of some hereditary cause. It may be that as our knowledge progresses the list will have to be extended; or it may be that careful records will show that some at present considered hereditary diseases are entirely due to the operation of causes acting subsequent to birth and quite independent of ancestry; though I am bound to tell you that accumulating knowledge does not point in that direction. The question is one that entirely depends for its settlement on accurate statistics, which have been happily defined as "facts admitting of numerical notation." There would be no advantage in my repeating to you a table of the proportions in which a family history of transmission has been ascertained in the various diseases above mentioned; the figures are admittedly inexact, and are only sufficient to show the probability of hereditary influence, which further information must refute or confirm. Sufficient, as example, I have already referred to in the course of my remarks. But there is one reference that I have not included in the scheme, to which I should wish to direct your attention. It is, in brief, to enquire for and record any minor ailments, those not finding a place in our standard nosologies, which may have prevailed in the family. It is impossible to enumerate them: the list would mainly consist in the mention of the most varied and often disconnected symptoms, but which, taken together, might materially assist in your arriving at a truer conception of the constitution of your patient; and, conversely, might contribute to formulate the characteristics of such constitution.

But, besides the investigation into what diseases may have prevailed in the family of your patient, you will observe there is the question as to whether the family have been especially long-lived or short-lived. The value of the information obtained on this head in estimating the health power of the subject of your study is considerable. "It is now generally," says Ribot,<sup>5</sup> "admitted that longevity depends far less on race, climate, profession, mode of life, or food, than on hereditary transmission." Centenarians are found in all countries, and among all classes of people. Dr. Lucas, in his work on heredity,<sup>6</sup> in reference to the

<sup>5</sup> Heredity: a psychological study of its phenomena, laws, causes, and consequences, from the French of Th. Ribot, 1875.

<sup>6</sup> "Traité physiologique et philosophique de l'Hérédité naturelle": P. Lucas, 1847.

same, pointed out that "the average of life plainly depends on locality, hygiene, and civilisation; but individual longevity is entirely exempt from these conditions. Everything tends to show that long life is the result of an internal principle of vitality which privileged individuals receive at their birth. It is so deeply impressed in their nature as to make itself apparent in every part of their organisation." That certain families are long-lived, as are others, perhaps fewer in number, short-lived, is notorious. Professor Humphry,<sup>7</sup> in the course of his investigations into the records of 500 persons above 80 years of age, says "the greater proportion were reported to be of long-lived families"; and further points out the curious fact that there was a considerable frequency of occurrence of phthisis in such families. It is also, I think, very common to find that aged persons have suffered very little from illness during their lives, have been, in short, healthy beyond the average. Advanced age, therefore, as Professor Humphry says, expresses the transmission of "an inborn, inherent, quality of endurance, of steady, persistent, nutritive force, which includes reparative force and resistance to disturbing agencies, and a good proportion or balance between the several organs." I know of no collected records of "short-lived families, but, as one of many scattered examples, I might mention Turgot, who died at the age of 53, fully expecting he should not exceed 59 years, the limit which but few of his family had passed.

Corresponding to this liability to death at about the same age prevailing in a family is the liability to attacks of illness at about the same age, which would indicate to you the need for stating the ages of the patient's relatives when attacked or at death, as set forth in your scheme. Many curious illustrations could be given of this, and you will be frequently hearing your patients express their convictions that they will not live beyond such and such age, because others of their family did not, and you may not altogether disregard their warnings. Sir Henry Holland<sup>8</sup> mentions the case of three brothers who were attacked with hemiplegia at about the same age; and of three sisters in another family, who all died at about 24 years of age from cerebral disease. Esquirol records the case of a father, son, and grandson, all becoming insane at the age of 50. The age, therefore, at which disease has occurred in relations signifies much in forming your opinion of the individual. The age also of the parents at the birth of the individual often influences the health of the offspring. Occasionally one sees the youngest child of a family, between whom and the next older is an interval of many years, and whose parents at his birth are one or both well advanced in life, of a sickly, puny constitution, reared with difficulty, and showing throughout his life an enfeebled health; and this although his brothers and sisters and parents themselves may be remarkably sound. The occurrence of this condition in the offspring of the aged is too frequent to prevent one recognising a causal relationship between the degenerated tissues of the parent and the deteriorated vitality of the child.

Thus, then, you will see that the enquiry into the family history of the patient is one of considerable extent and also of much difficulty. Nevertheless, you should aim at obtaining as complete and accurate an account as possible, since every item of it may bear upon the case before you. The total result of your investigations should give you some idea of the inherent predispositions towards health or disease of your patient, which will materially assist you in ascertaining the exact nature of his malady and contribute not a little towards forming that opinion on the probable

course and termination of the illness which you will be called upon to make. The importance of this line of enquiry has lately received emphatic exposition at the hands of Mr. Francis Galton, who, as a step towards improved knowledge on the subject, has drawn up and published a "Life History Album," wherein are to be recorded with much else the details of family medical history.

One word as to the method of keeping your record. On this matter each one may with advantage adopt his own plan, but I would advise that any scheme you may pursue should be as graphic as you can make it. You should appeal in your written account to the eye as well as to the ear, that the full bearing and relationship of the facts you have collected may be appreciated. How much more completely and easily does a temperature chart represent the progress of a fever than the same data arranged in columns of figures. To this end I would recommend your arranging the details as far as possible in the form of genealogical tables, a very convenient form for which was published by Dr. G. Leslie in the "Transactions" of the Medico-Chirurgical Society of Edinburgh for 1882. The desirability of keeping the various statements on separate lines and under distinct headings, as well as the judicious use of abbreviations, are trifling, but none the less useful, points which will suggest themselves to you as considerably facilitating future reference.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

---

### ROYAL FREE HOSPITAL.

---

#### A CASE OF IDIOPATHIC TETANUS.

By SAMUEL WEST, M.D., F.R.C.P.,

Physician to the Hospital, &c.

---

MICHAEL M., aged 46, a carpenter, was admitted into the Royal Free Hospital on July 2nd, 1884, with symptoms of tetanus. He gave the following history: He is a married man with five children, all healthy, but not living with his wife. He had enjoyed good health, except from an ulcer on his leg, the result of a blow, and which had remained unhealed for many months. For this he was admitted into the Kensington Infirmary, and after several weeks was discharged cured about three weeks ago. Since then he has had no work to do, and has been drinking much and eating little, and has been exposed a good deal to the recent heat. The bowels have not been relieved for a week. For the last three or four days he has been unwell, having lost his appetite, feeling languid and tired, and sleeping little. Two days ago, he first noticed a sense of stiffness about his neck and lower jaw. This gradually increased up to to-day, when it became so marked that he was unable to open his mouth, or bend his neck. At the same time he found that he could not walk properly, and that he had some difficulty in swallowing, and he suffered much from severe general headache.

In the out-patient room he looked ill, and had an expression of pain and anxiety. His jaws were clenched so that the teeth could only just be separated. The head was slightly drawn back, and the muscles at the back of the head and neck were rigid, as were also

<sup>7</sup> "On old age and the changes incidental to it." Annual oration at the Medical Society of London, by Prof. G. M. Humphry, 1885.

<sup>8</sup> "Medical Notes and Reflections," 1840.

his sterno-mastoids on both sides. He could hardly stand, and could only walk with difficulty and assistance. Any movement increased the spasms in the already rigid muscles, and produced similar spasm in the muscles of the trunk and thighs, so that the patient was bent backwards, and seemed as if he would fall unless supported. The spasms were not violent, and only of short duration, but they appeared to recur at intervals of a few minutes. The patient complained, besides the headache, of pain in all the joints, and the face and neck, and to a less degree the trunk, especially its upper part, were bathed in perspiration. The mind was perfectly clear, and the patient gave this history and described his sensations and condition very intelligently.

On examination in the wards an hour later, the following note was taken:—The patient is lying upon the back with the head thrown back. The face is congested and slightly blue. He is perspiring freely from all parts of the body, but most over the most affected parts, viz., the head and neck. The lower jaw is locked, but except during one of the paroxysms, can be moved a little so as to separate the teeth far enough for the tip of the tongue to be protruded. The tongue appears furred, the head is drawn forcibly backwards by the contraction of the muscles of the neck, and it is almost impossible for the patient to sit up, for any movement produces spasmodic contraction of the muscles of the back and thigh. During a paroxysm the arms as far as the elbow, and the legs as far as the knees become rigid, but the rest of his limbs remain flaccid. Patella tendon reflex is normal. Liquids are swallowed without apparent difficulty, but chewing is of course impossible. The pupils react normally. The respirations are 24, the pulse 96, regular, and of full volume. The temperature is not raised above normal. The heart is acting strongly and regularly; there is no murmur, and the sounds are good. Some rhonchus is present at the bases of the lungs. The abdomen is not rigid, and the respirations are easy. Upon the left leg was the large scar of an old ulcer, which was perfectly healed. The patient had suffered in no way from it since its healing, and had felt no peculiar sensation in it lately.

At 7 p.m. an enema of soap and water and castor oil was administered; the bowels were freely opened afterwards with the passing of many scybala.

*Midnight.*—The patient is much worse in every way. He has suffered great pain in paroxysms during the evening. The pain commences in the epigastrium, and spreads thence to all parts of the body. The paroxysms of rigidity are more severe, but of the same character and distribution, and attended by such severe pain that the patient cannot help screaming out. There was no delirium, and the temperature was still normal.

July 3rd. — At 2 a.m. the enema was repeated, but without effect. He then had 30 grains of hydrate of chloral, and half a drop of croton oil. He had passed no water since admission, but the bladder was not distended. The diet consisted of beef tea and milk, and was taken without difficulty. Swallowing produced no spasm or discomfort.

11.30 a.m. — The patient remained in the same condition during the night, and hardly slept at all; the attacks are now more frequent and more violent, and recur every few minutes; they are the same in character, but the abdominal muscles are now hard and rigid, and partake in the spasms. The temperature has risen to 102.2°, and the pulse to 130. It is regular, but rather hard. He has had only snatches of sleep, for a few minutes at a time, during the morning.

At 12 noon the water was drawn off by a soft catheter; this produced no spasm and gave great relief.

Seventeen ounces were withdrawn, specific gravity 1.020; acid, no albumen and no sugar.

2 p.m.—Enema repeated and a drop of croton oil again administered, but without effect. The perspirations are profuse. The patient is taking 10 grains of chloral hydrate, and 10 grains of bromide of potassium every two hours.

6 p.m.—The medicine has relieved the patient much. The spasms occur now at interval of eight to ten minutes instead of three or four, with short snatches of sleep for five or six minutes between the paroxysms. Temperature 101.6°. Pulse 130 regular.

At 8 p.m. a third dose of the medicine was given, and half a minute afterwards he was seized with what appeared to be a sudden spasm of the respiratory muscles. The breathing stopped suddenly, the patient became almost black in the face and quite unconscious; the pupils dilated widely, and did not react to light, and the pulse became slow. All other spasm ceased, the lower jaw relaxed and dropped, so that the mouth fell wide open and the muscles of the arms, legs, and abdomen became lax. There was no struggling, or sound of air entering the chest. He lay in this condition for two or three minutes as it seemed, and then suddenly took a deep inspiration, and continued to breathe. The blueness disappeared, the pupils contracted and reacted to light, and the pulse became more rapid, and in five minutes he became suddenly once more conscious. A few seconds later he was attacked by a most violent spasm of the muscles previously affected, so that he screamed with agony and became bathed again in perspiration.

At 11 p.m. he had another respiratory spasm of the same kind, having, in the interval, been in much the same condition as before, sleeping restlessly until roused by the spasm. The temperature was now 105.5°, and the patient was sponged, but half an hour later it had risen again to 104.8. The medicine was not repeated after 8 p.m.

July 4th.—At 2 a.m. the third attack of respiratory spasm seized him, and he never breathed again; though the heart continued to beat some minutes after the respiration had stopped.

The *post-mortem* examination was made twelve hours after death. The body was muscular and well-nourished. Rigor mortis absent. The lungs were extremely congested, the heart hypertrophied, chiefly its left ventricle. The kidneys granular, and the cortex slightly narrowed. The granules were fine, and the lesion not very far advanced. The brain and spinal cord were removed and put aside to harden, the former in spirit, and the latter in 2 per cent. of bichromate of potash solution. On macroscopic examination of the brain, the veins were congested, and the substance felt soft. On the under surface of the left hemisphere were several spots of meat-jelly-looking substance in the meshes of the pia mater, but apparently continuous with the brain substance beneath. The largest of the spots was situated over the inner two-thirds of the orbital surface of the frontal lobe; the others were much smaller in size, half an inch in diameter, and scattered chiefly over the inferior temporal convolutions. On the right side, the only spot of this kind was upon the orbital lobe; the same position, but not so extensive, reaching only from the horizontal fissure over the olfactory region. The spinal cord was soft on section, the grey substance appeared pinker than natural, and the white matter, especially in the immediate neighbourhood of the grey substance, had a semi-transparent greyish appearance. Microscopical examination of the cord was incomplete, but so far as it went, revealed no change.

The case calls for no special comment. It was a well-marked instance of idiopathic tetanus. The most

interesting clinical feature it presented was the remarkable way in which the spasm suddenly disappeared during the respiratory attacks from all the muscles of the jaws and limbs, which until the attack came on were fixed and rigid, and again became so as the respiratory attack passed off.

## APPOINTMENTS FOR THE WEEK.

### *Monday, November 2.*

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, 40, Leicester Square, 8 p.m.—Papers by Mr. J. H. Balkwill, of Plymouth, on "A Method of Mounting Porcelain Crowns on Pulpless Molar Stumps; and Mr. W. Hern, on "A Method of Treatment of Pulpless Teeth." Casual Communications by Messrs. S. J. Hutcheson; C. W. Dunn; Storer-Bennett; A. S. Underwood; and Exhibition of Ward's Non-Thermal Lamp.

MEDICAL SOCIETY OF LONDON.—Dr. Gowers will introduce a discussion on "The Clinical Value of the Deep Reflexes."

ROYAL INSTITUTION, 5 p.m.—General Monthly Meeting.

### *Tuesday, November 3.*

UNIVERSITY OF LONDON, Burlington Gardens, 5 p.m.—Adjourned Extraordinary Meeting of Convocation to consider the Proposed Scheme for the Re-organisation of the University.

PATHOLOGICAL SOCIETY, 8.30 p.m.—Dr. Sainsbury, "Tumour from the Base of the Brain containing Skin"; Mr. Sheild, "Cancer of the Bladder"; Mr. Barker, "Epidermal Cyst of Finger"; Mr. MacCarthy, (1) "Carcinoma of the Kidney"; (2) "Necrosis of the Patella" (Card); Dr. Norman Moore, "Chronic Endocarditis"; Mr. E. H. Fenwick, "Extra-Peritoneal Rupture of Bladder"; Dr. Percy Kidd, "Obstruction of the Coronary Arteries"; Dr. Lediard, "Black Tongue" (Card); Dr. Savill, "Heart from a case of Chorea (Card); Dr. Port, "A case of Leprosy (Living Specimen); Sir W. MacCormac, "Epithelioma of the Clitoris" (Card); Mr. Larder, "Cancer of Oesophagus (Card); Mr. Davies-Colley, (1) "Tendinous Slough from the Abdominal Muscles" (Card); (2) "Annular Slough of Mucous Membrane of Rectum" (Card); Dr. Goodhart, for Mr. Anderson, "Large Aneurysm of Internal Carotid within the Skull"; Dr. Hale White, "Tubercle of Dura Mater and Vertebrae."

### *Wednesday, November 4.*

OBSTETRICAL SOCIETY OF LONDON, 8 p.m.—Specimens will be shown. Papers: Dr. Herman, "On the Suppuration of Pelvic Dermoid Cysts"; Mr. S. D. Hine, "Case of Obstructed Labour in which Spontaneous Version followed an unsuccessful Attempt to deliver with the Crotchet after Craniotomy."

### *Thursday, November 5.*

WILLAN SOCIETY OF LONDON, 8 p.m., at St. John's Hospital for Diseases of Skin, Leicester Square, W.—President's Address. Dr. Harries, "Cases of Lupus treated by Paracitides"; Mr. Startin will show a Case of Diffuse Scleroderma.

### *Friday, November 6.*

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, 8 p.m.—Mr. H. Percy Dunn, "A Collection of Specimens of Sarcoma and Carcinoma from Patients who have died in the West London Hospital during the last Fifteen Months"; Dr. C. Wells, "Specimen of Cancer of Colon"; Dr. Savill, "Microscopic Specimens of Cancer"; Mr. C. B. Keetley, "Case of Gritti's Amputation"; Dr. Alderson, Paper "On the Aetiology of Cancer chiefly as to Local and Mental Causes"; Mr. H. Percy Dunn, "On the Theory of Cancerous Inheritance."

# Medical Times and Gazette.

SATURDAY, OCTOBER 31, 1885.

OUR Paris correspondent writes:—M. Pasteur has communicated to the Academy of Medicine and the Academy of Sciences the results of his latest experiments upon the prophylaxis and cure of rabies, together with the account of a case observed in the human subject. M. Pasteur now adopts the following method. A rabbit is inoculated with a fragment of the spinal cord of a mad dog. The animal is affected with hydrophobia in the space of about one fortnight. A portion of its spinal cord is employed to inoculate a second rabbit, which also contracts the disease, but more rapidly; the spinal cord of this second rabbit serves to inoculate a third, and so on. It is observed that at each step of this process the intensity of the disease becomes greater, and the period of incubation shorter. When the spinal cord of these animals, which have died of hydrophobia, is suspended in a perfectly dry tube, its virulence diminishes by degrees, and at last disappears. A collection of these spinal cords, some of them entirely stale and powerless, others more fresh and active, others again quite fresh and extremely active, are always kept in readiness. To render a dog insusceptible of rabies, he is first inoculated with the stale and powerless specimens, then with fresher and more active ones, and lastly with the most powerful of all, when he becomes quite proof against the inoculation of rabies. Lately, a young boy, nine years of age, Joseph Meister, was brought by his friends to M. Pasteur's laboratory. He had been most severely lacerated by a mad dog, having fourteen bites in different parts of his body. M. Pasteur, in presence of the almost absolute certainty of death, inoculated the child according to his system; the first inoculation was made with a spinal cord 15 days old on the 6th of July, 60 hours after the child had been bitten. Similar inoculations with virus of constantly increasing intensity were made up to the 16th of July, when the spinal cord employed was quite fresh. The child, having up to the present time, four months after the accident, exhibited no symptoms of hydrophobia, is considered as radically cured by M. Pasteur, and he has already recommenced the same method of treatment upon a young shepherd, who in defending other boys was cruelly bitten by a mad dog, which he killed upon the spot. The results of this new experiment will be communicated by M. Pasteur in due time to the Academy. With respect to the first patient, it must be remembered—(1) That sixty per cent. of people bitten by mad dogs do not contract hydrophobia. (2) That the incubation of the disease is sometimes extremely long (cases have been known to occur two years after the bite). The experiment is not therefore absolutely conclusive, although it marks a great progress in the history of the disease and justifies in some measure the enthusiastic applause with which the communication was received.

Two interesting papers were read and discussed at the opening meeting of the Royal Medical and Chirurgical Society on Tuesday last. That by Messrs. Baker and Bowlby on "Diffuse Diploma" was illustrated by a series of admirable drawings as well as by some remarkable living specimens of the disease, which excited much attention. Mr. Rivington's paper dealt with a very serious and fatal injury due to so trivial an accident as swallowing a fish-bone. It had penetrated the pharynx, and subsequently the carotid artery. The difficulties of the diagnosis, the modes of treatment, as well as the lessons which may be learnt from an analysis of all the hitherto published cases, made a very interesting and instructive paper; one of these lessons may be thus formulated:—The rapid course, after hæmorrhage has once come on, and the usually fatal nature of the lesion, suggest early and radical interference with a view to rescue the patient from impending death. A second lesson was the danger which attends the common mode of treating such cases by the indiscriminate passing of the probang. Owing to slight indisposition, Dr. Johnson, the President, was unable to be present; Mr. Berkeley Hill, one of the Vice-Presidents, ably presided in his place, and welcomed the Fellows back at the termination of the long vacation. The new volume of "Transactions" was presented, and will shortly be distributed.

A YEAR ago the Clinical Society, under the tutelage of Sir Andrew Clarke, renounced refreshments after their meetings as unphysiological, or perhaps we ought to say that their Council did all this for them; at the meeting on Friday last, by a very large majority, it was decided to revert to the ancient and unphysiological custom, and accordingly, in future, tea and coffee will be served after the meetings. Mr. Mayo Robson, this weighty matter having been settled, read an excellent paper on two cases of cholecystotomy which have been attended with the best results; indeed, the gall-bladder would seem to be quite as tolerant of surgical interference, as the other viscera have one by one proved themselves to be when the question has been put to a practical issue. Dr. Seaton's paper on the symptoms of a febrile epidemic at a school was the model of a clinical study, and it is no fault of his that he was not able to give more particulars in regard to the *post-mortem* appearances; but that he was describing a distinct and specific disease no one who was present could have the smallest doubt. Dr. J. H. Bridges, of the Local Government Board, added greatly to the interest of the narrative by his account of the insanitary state of the school in regard to the disposal of fæcal excrement, and we can assure those members of the Society who were dissuaded by the rain from attending the meeting that they missed hearing a paper of unusual interest.

THE officers of the Glasgow Pathological and Clinical Society are arranging for another discussion during the new session, similar to that held more than a year ago on Albuminuria. The subject is to be *Tumours*. Whether this subject will call forth the

same interest as its predecessor remains to be seen, but it ought to draw out the surgeons as Albuminuria did the physicians.

THE Session of the Medical Schools of Glasgow was opened on Tuesday last by the usual introductory addresses. Professor Bower opened the session at the University, and Dr. Wallace Anderson and Dr. James Morton at the Royal Infirmary and Anderson's College respectively. Professor Bower's address was an able and practical defence of the position of Botany in the medical curriculum. He referred at length to the difficulty that has arisen in Glasgow regarding the Royal Botanic Institution. The Institution is in debt to the Corporation to the extent of nearly 50,000*l.*, and under an agreement the Corporation is entitled to call up the bonds as soon as principal and interest reach 50,000*l.* That sum being almost reached, the Corporation has given notice of its intention to exercise its rights. As pointed out by Professor Bower, the town has thus an opportunity of acquiring a garden fully equipped with plant, houses, &c., and with a rare collection of plants, which it could not only maintain as a pleasure-ground, but, by little additional expense, make of the utmost usefulness to science and of great benefit to the University. The trouble is that the gardens are situated in Hillhead, which is beyond the municipal boundary of Glasgow, although in unbroken continuity with it. There are, of course, multitudes who will cry out against the ratepayers maintaining pleasure grounds for those who refuse to come into the town and help to bear its burdens. Apparently, the Town Council is desirous of using the leverage which its power over the gardens gives it for compelling the Hillhead people to consent to annexation. For if the ground of the Botanic Gardens were to be let off for building purposes the amenity of the district would be largely destroyed. Professor Bower's address comes as a timely and vigorous reminder of other than merely commercial interests. The University is deeply interested in the question, for, in return for a subscription of 2,000*l.* given in 1817 by the University, the Professor of Botany was to have a lecture-room in the garden, and every facility for himself and his pupils for the study of Botany. Since the removal of the gardens to Hillhead these conditions have not been fulfilled, and if the gardens were to be broken up the Professor would be deprived of almost his only source of material for teaching and practical purposes.

ON Monday, October 26th, the session of 1885-86 was inaugurated in the School of Surgery of the Royal College of Surgeons in Ireland by an address from Mr. Edward Hamilton, one of the Professors of Surgery in the School. Sir Charles A. Cameron, President of the College, occupied the Chair, and there was a very large attendance of members of the profession and of students. Professor Hamilton chose as his theme the subject of the medical profession in Ireland. Speaking of the attractions of the medical profession, he said that the public services opened a wide field for employment, and he was glad their college had done much to bring about needful reforms in the military

department of the public service. But the profession could not now offer the princely incomes realised by their forefathers. Neither could it attract followers to its standard by the hopes of State honours, dignity, or titles. The State encouragement and rewards doled out to Medicine bore no adequate proportion to the benefits which she conferred on humanity. The successful general, the poet, the painter, and the actor had honours and titles showered upon them, and deservedly so; but what could the arts which they represented offer to mankind when compared with the healing of the sick, or the still nobler and disinterested services of the prevention of disease, the staying the plague, the maintenance of public health, and the prolongation of human life? Such benefits were apt to be unrecognised and unrequited because the work was unseen. The profession in Ireland had suffered this injustice in a special degree, and it was no exorbitant demand to ask that the honours which were conferred on distinguished members of the profession in Dublin should not be permitted to lapse because those who held them had ceased from their labours in the sleep of death. The session was opened at St. Vincent's Hospital, Dublin, on Tuesday, October 27th, when Mr. Cox, one of the physicians to the hospital, delivered an introductory address.

THE first sitting of the Commission appointed to enquire into the working of the Dublin hospitals was held on Saturday, October 24th, in the Privy Council Chamber, Dublin Castle. The Commissioners present were—Sir Rowland Blennerhassett, Bart. (presiding); Sir Richard Martin, Bart.; Mr. Richard Owen Armstrong, J.P.; Mr. Arbutnot H. Holmes; Mr. Charles A. Kennedy, J.P.; and Mr. Thomas Maxwell Hutton, J.P. Dr. Thomas Myles, Secretary to the Commission, was in attendance. The witnesses examined were Mr. Thomas Hughes, Registrar of the House of Industry Government Hospitals, Mr. William Stokes, Vice-President, and Professor of Surgery of the Royal College of Surgeons in Ireland, and Senior Surgeon of the House of Industry Hospitals, and Dr. William Thomson, another of the surgeons to the same institution. Both these surgeons admitted that the nursing in the Government hospitals was at present unsatisfactory, that there was no trained superintendent of nurses, owing to the vested interest enjoyed by the present matron, who had not received any special training in the modern sense of the term; and that there was deficient provision for night nursing. They were not opposed to amalgamation, say with Steevens' Hospital. Mr. Stokes considered that the Hardwicke Fever Hospital—one of the House of Industry group—was certainly required as a fever hospital for the north side of Dublin, while Dr. Thomson spoke of the fever accommodation likely to be provided by the Mater Misericordiae Hospital as probably sufficient together with Cork Street Fever Hospital. The feature of the day's proceedings was the very unfriendly cross-examination to which Mr. Charles Kennedy subjected both witnesses in reference to the Government grant of 7,600*l.* per annum enjoyed by the House of Industry hospitals. On Monday, the 26th, Dr. Samuel Gordon, one of the physicians to the House of Industry hos-

pitals, was examined. He expressed his entire satisfaction with the existing nursing arrangements in the Hardwicke Fever Hospital, and so laid the staff of the hospitals open to a suspicion of divergence of opinion on a point of vital importance. The other witnesses examined were Mr. Benjamin Mullen, the Superintendent and Paymaster of the hospitals; Mr. James Wilson Hughes, the Secretary and Accountant; Mr. Charles Cobbe, D.L., and Mr. Charles E. Martin, two of the lay governors of the hospitals. The enquiry was then adjourned to Saturday, the 31st instant.

MR. JOSEPH FRANCIS O'CARROLL, Demonstrator of Anatomy in the Catholic University Medical College, Dublin, has been appointed Assistant Physician to the House of Industry Hospitals in succession to Mr. Guy Percival L'Estrange Nugent, recently elected Physician to the Hospitals. Mr. O'Carroll became a Licentiate of the King and Queen's College of Physicians and of the Royal College of Surgeons in Ireland in 1881, and two years later he took the degrees of M.B. and M.Ch. in the Royal University of Ireland. He is spoken of as a well-read physician and an able teacher.

THE deaths of 1,458 persons were registered in London last week. This shows an increase of more than 100 above the return of the previous week, but the deaths were, nevertheless, considerably below the corrected average for the corresponding week of the preceding ten years. The increased mortality of last

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past thirteen weeks.

week was restricted to those over twenty years of age, and would seem to have been pretty equally divided between diseases of the respiratory and circulatory systems. The so-called zymotic diseases caused rather

fewer deaths than in the preceding week, the most noteworthy facts being that there were only 18 deaths from scarlet fever, the average number being 72, and that for the second week in succession there were no deaths from small-pox. There were 50 deaths from violence, and 108 inquest cases, including 2 deaths from hydrophobia; making a total of 12 deaths from this disease since the middle of July. Only 5.6 hours sunshine out of a possible total of 72 hours were registered during the week, the mean temperature of which was 5.1° below the average. The average mortality of the 28 large towns was 18.5, while the highest death-rate was 23.2 at Bolton. The death-rate in Dublin was 23.8, whilst in Glasgow it was only 20.6.

CONSIDERABLE discontent has been created among the young men who enter the competitive examination for the "Internat," or house-surgeony to the Paris hospitals, by the rumour that an unfair indiscretion has been committed. The subject drawn for the written composition was "Morbid Anatomy and Symptoms of Asiatic Cholera." This question had been proposed by Dr. Gougenheim, one of the examiners. But in the course of the day it was asserted that Dr. Gougenheim had previously informed his pupils of the subject which he intended to propose, thereby giving them an unfair advantage over other competitors. An angry controversy took place, in which Dr. Gougenheim and his *interne*, M. Kolin, alternately shifted the responsibility to each other's shoulders. In fine, the proceedings were annulled, a new jury drawn, and the proceedings recommenced. Any scandal of this kind very rarely occurs now in the French competitive examinations, although in former days some ugly tricks are said to have been played. In the present case it would seem that information very imprudently given by Dr. Gougenheim to some parties not concerned in the *concours* was by them very improperly communicated to others, and thus became the property of some candidates, to the prejudice of their rivals. It must be hoped that similar indiscretions, which would lay the axe to the very root of the present liberal system of promotion, will not be heard of again for a long time. Another novel feature of the present *concours* is the presence of two female candidates, Miss Edwards and Mlle. Klumpke, the first an Englishwoman, the second a Russian. Both these ladies were very unfavourably received by their masculine competitors. It remains to be seen whether their merit will justify the favour extended to them.

THOSE of our English readers who have followed with painful interest the course of the struggle now in process in America with regard to the Washington Medical Congress of 1887 will be amused to hear that the new executive committee of the Congress have resolved that their actions "*are final, not being subject to revision, amendment, or alteration by either the Committee of Arrangements or the American Medical Association.*" The astuteness of that resolution is as remarkable as the irony of it is delicious. If the original committee had only been wise enough, before the event,

to have adopted such a decision, there would have been none of the dissensions which have so terribly distracted the American profession. The resolution is at once a slap in the face to the American Medical Association and a sneer at the original committee of eight, as if to say, "Why, what idiots you were, not to have thought of this!" And yet it is at the same time a score to the original committee and its supporters in that it is a justification of their action in resenting the interference of the Association with their decisions. Meanwhile we hear affairs are *in statu quo*. The resignation of Dr. Dalton, the chairman of the Physiological section, which has happened since we last wrote on the subject, leaves the organisation of the Congress without a single really scientific representative if we except the Flints and Dr. N. S. Davis. If the meeting is held, the sections of Anatomy, Physiology, and Pathology will not be attended by any of the American workers in those fields. There is, we fear, little hope now of an arrangement. All the prominent American men of science have withdrawn, and will not return unless very considerable concessions are made, of which there appears no hope. The *Berliner Klinische Wochenschrift* this week roundly states that hardly a single "medical personage" will be found to undertake the voyage from Germany for the privilege of sitting under the presidency of Dr. Shoemaker. It makes, however, a strong appeal to the American Medical Association to approach the subject in a more wise and generous spirit when its next Spring assembly takes place, and to re-arrange its propositions [in such a manner that the services of the leaders who were nominated in the first instance may still be made available. In the absence of such a re-arrangement, our Berlin contemporary expresses a decided opinion, which we can heartily endorse, that the Congress of 1887 will be foredoomed to dismal failure. The whole thing is a bad business. It is an awkward position, for it must be remembered that the Washington Congress will have to make arrangements for the succeeding meeting. Suppose Dr. Shoemaker and his friends decide that the Congress of 1890 shall be held in Texas!

A CELEBRATION of more than common medical interest is being held during the present week in Berlin, in honour of the 25th anniversary of the foundation of the Berlin Medical Society. It may safely be prophesied that the proceedings will sooner or later relapse into festivity of a less dignified sort, but no exception can be taken to the strictly business-like programme for the day. An address from the President, Professor Virchow, is followed by an historical retrospect by Dr. Fraenkel; a paper on Extirpation of the Kidney, by Dr. von Bergmann; Laryngoscopy and Diagnosis, by the newly appointed Clinical Professor, C. Gerhardt, and a pharmacological paper by Herr Liebreich. After such a day's work the resources of the Kaiserhof are likely to be taxed to their utmost limit when the inevitable adjournment to that celebrated hostelry takes place. Might not the London medical societies occasionally make an opportunity for a little informal junketing of this sort? It is not given to every President to inspire his constituents with the geniality

and brilliancy of a Virchow, but the *esprit de corps* of any of the scientific gatherings would lose nothing if it were to be occasionally stimulated by influences more penetrating than those of the light mental and bodily refreshments which enliven the *conversazioni* of the present day.

THE 58th meeting of the German Society of Naturalists and Physicians, which took place at Strasburg last month, seems to have been only moderately successful. About 1,500 members attended, but the number of prominent men of science was very limited, and the work done in the various sections does not appear to have been very remarkable. We shall notice some of the papers read at a future opportunity. The people of Strasburg took no part in the proceedings of the Congress; and the new and elaborate buildings of the new university, which now surpass anything of the kind even in Germany (although, as yet, they have attracted but a very limited number of pupils), formed the chief object of attraction for the visitors. The next meeting is to be held at Berlin, with Professors Virchow and Hoffmann as the directors.

THE stream of "foreign doctors" in search of clinical experience outside their own schools would seem to have turned with great force in the direction of Berlin. Following the example set by their *confrères* in Vienna, the Privat-Dozenten in the northern capital have organized series of classes which, after a successful run during the holiday season, are now so sought after as to warrant their continuance during the winter session. The new series will be commenced on November 2nd, and names are directed to be sent to Dr. Anders, Dorotheen-Strasse 57. Amongst the courses as at present arranged are demonstrations by Professor Eulenburg on "Electro-Diagnosis and Electro-Therapeutics"; by Dr. Lassar on "Skin Diseases," and by Dr. Lublinsky on "Diseases of the Nose, Pharynx, and Larynx."

A CAUCUS of prominent graduates of the London University, presided over by Mr. Philip Magnus, was held on Wednesday week for the purpose of discussing the course of action which should be taken at the meeting of Convocation on Tuesday next, when the scheme for the reorganisation of the University will be again discussed. As a result of these deliberations a letter has been addressed to the Members of Convocation, signed by Mr. Magnus, who, it may be mentioned, was a member of the Committee which prepared the scheme of reform. The Members are advised to receive Lord Justice Fry's scheme, and then to refer it back for further consideration to the Special Committee, reinforced by the addition of twenty fresh members. The Caucus thinks the scheme itself open to the following objections:—(1) It proposes to transfer to a number of new and untried bodies, not necessarily consisting of Graduates of the University, the functions hitherto exercised by Convocation. (2) The bodies proposed to be constituted include Teachers of Institutions which differ widely in their objects, and

some of which have no reasonable claim to University rank. (3) In the proposed constitution of the Senate the representation of Convocation (instead of being increased in accordance with the repeatedly affirmed wishes of Convocation) would be diminished from *one* in *four*, as now, to *one* in *five*. (4) On the other hand, the proposed representation of the Faculties on the Senate would give an undue and preponderating influence to teachers, which, considering the views held by certain representative teachers, would tend to the lowering of the standard of the examinations. (5) The arbitrary restriction of the area of the University would exclude from participation in its work the London Graduate Teachers of such Provincial Colleges as are now associated with the University by their curriculum of studies. (6) Except as regards the establishment of Boards of Studies, the scheme contains no indication of the means of effecting other University reforms, the importance of which the Graduates in Convocation have already affirmed. We fully sympathize with Mr. Magnus and his friends in their objection to Lord Justice Fry's scheme as it stands; but their practical proposals are absurd. The Special Committee of forty, which was commissioned to draw up the scheme, was far too large for practical usefulness, and to increase it to sixty would be equivalent to laying the scheme on the shelf. Perhaps that is what the graduates led by Mr. Magnus want; but, if so, good-bye for many a long year to all attempt to get the University out of its ruts.

A BRISTOL correspondent informs us that a special department of ophthalmic surgery has recently been instituted in connection with the Royal Infirmary in that city and placed under the charge of Mr. Richardson Cross, who has resigned the general surgeoncy to the Infirmary and will henceforward devote himself exclusively to eye work.

It does not appear whether the ladies who compose the Women's Peace and Arbitration Association are blessed with families of model behaviour, amongst whom, for example, corporal punishment is as utterly unnecessary as we may presume it is unknown. But it would be at least interesting to less gifted mortals to learn upon what course of physical training they rely for keeping young people in order, and whether they find the inculcation of moral precepts sufficient to that end. The deputation from this laudably intentioned Association, which waited upon the London School Board last week to protest against the institution of military drill and the proposed formation and training of cadet rifle corps in connection with the Board Schools, owes the unenlightened world at large something in the way of a substantial explanation of its tenets. The maintenance of discipline in schools is a problem which taxes all who are dealing practically with the great subject of school hygiene; and no one who has had any experience of its working can doubt the efficacy of regular military drill, properly carried out, in inculcating the habit of ready obedience to orders, to say nothing of its great and immediate physical advantages. The regular games

of school children more fortunately situated, with their strict rules and general encouragement of English fair-play, have a similar tendency. But such advantages are not possible to all Board School children, many of whom lack strength, or energy, and even elbow-room, for thoroughly enjoying regular and invigorating open-air pastimes. For such as these drill is a real blessing to both soul and body. Is it a light thing, we might ask, amid a system which tends to force the mental precocity of the juvenile population, to be asked to throw aside a ready and attractive method of bodily training which, at the same time, encourages those moral qualities which are so necessary to law-abiding citizens, and by which alone the peace of human society is secured? And if a proportion of the lads thus trained do eventually join the army, such a process is by no means the *frequens et facilis descensus* which the lady arbitrators seem to imagine; is not this better, both for themselves and for their comrades, than that they should be recruited from the list of broken workmen and pot-house loiterers? There is a voice, yet echoing from Khartoum, which answers such a question in no uncertain terms. We do not, indeed, expect much result from the action of the deputation; and it may be said to have got its answer when the subject was referred to the Works and School Management Committee, for it is only your raw theorist who ignores the immense moral value of proper physical training; but the educational engine against which it was specially directed has such just claims to public recognition and support that those who assail it are bound to justify their attacks.

It is stated that the Commissioners of Sewers are beginning to view with serious anxiety the difficulty which they find in letting the sets of rooms in their new block of artisans' model buildings in Whitechapel. The site and buildings, which contain 239 sets of chambers or flats, have cost 200,000*l.* It has been finished for nearly a year, and only half the building is occupied. A further analysis of the reported facts goes far to explain this result and to lessen the first feeling of surprise. While tenements consisting of only a single room have been eagerly taken in all parts of the building, the unlet portion is nearly all on the third and fourth stories; and the same rent, it is said, is demanded for rooms at these levels as for those of the more eligible floors below. After all, the British workman is not peculiar in wishing to get the most for his money, and in expecting a reduction for rooms which involve more trouble and higher stairs. Physical disadvantages of this sort have not escaped even the seaside lodging-house keeper.

DID Asiatic cholera exist in India before the great epidemic of 1817? This is a question which has been often put, and has not by any means received the same reply. Macpherson and Macnamara have expressed themselves in no vague manner in support of this view, whilst Annerley speaks with equal confidence in an opposite sense. Dr. J. Semmelink, after a prolonged residence in the Dutch settlements in the East as chief medical officer of the army belonging to his

government, has published a critical enquiry on this subject, in which he sides with Annerley. None of the recorded outbreaks from the time of the Hindoo writers before the Christian era, down to the year 1817, in his opinion afford conclusive evidence that the disease was true Asiatic cholera; they are instances, he believes, of cholera nostras, bilious cholera, dysentery or colic. He further arrives at the opinion that cholera nostras may, under unfavourable conditions, become converted into Asiatic cholera, and he thinks that it was owing to its having originated in this way, that the Egyptian outbreak in 1883 did not make its way into Europe, and he surmises that Koch's comma bacillus will be found to be present in cases of cholera nostras. When this has taken place, no doubt his views will receive strong confirmation.

THE epidemic of hydrophobia—for we can call it nothing else—which is now prevailing in our midst demands the immediate attention of the authorities at the Home Office. The two cases which have come under the notice of Dr. Danford Thomas, the Coroner for Central Middlesex, this week, bring up the total number to 21 for the metropolis alone during the present year. German experience shows that rabies can be entirely stamped out by the enforced use of the muzzle, and what has been done in one country successfully can be done in our own with equally good results if the same measures be as rigorously pursued.

AT the Ordinary Meeting of the Fellows of the Royal College of Physicians, held on the 29th instant, eight members of the profession who had passed the examinations by the Censors' Board were admitted Members of the College, and the License of the College was granted to 34 candidates who had satisfied its Examiners of their fitness to practise; while 12 others passed, and will receive the License when they have obtained a surgical qualification. A communication was received from Sir Joseph Fayrer on the Sanitary Conference held at Rome. The thanks of the College were awarded to Sir J. Fayrer, and the document will be laid on the table of the reading-room. The audited accounts of the College for the year ending September 29th were laid before the College and passed. The financial condition of the College is highly satisfactory. A report was received from the Committee of Management of the Examining Board in England, and was adopted. Dr. W. Overend Priestley was appointed an Examiner in Midwifery to the College, and Mr. W. Marrant Baker an Examiner in Surgery. The following resolution, "That it be referred to the Council to consider the possibility and expediency of this College taking a more active share than heretofore in the guidance of medical education, and in furthering every measure calculated to promote the interests of the profession and the public weal," was submitted to the College and passed. It was announced that the President had nominated Dr. Birkett and Dr. J. W. Ogle as Vice-Presidents for the ensuing year, and Dr. W. H. Stone as the Lumleian

Lecturer, Dr. Latham as the Croonian Lecturer, and Dr. Seymour Sharkey as the Gulstonian Lecturer for 1886.

---

### THE MEETING AT THE COLLEGE OF SURGEONS.

ON Thursday afternoon, at three o'clock, the President and Council of the Royal College of Surgeons had the pleasure of receiving the Fellows and Members in the theatre of the Institution; of hearing in dignified, or what was meant to be dignified, silence a few home truths, not always conceived or expressed in the best taste; and finally of seeing passed literally over their heads by overwhelming majorities resolutions which pledged the meeting to fight for the representation of the Members upon the Council, which demanded a more general participation of Fellows and Members in directing the policy of the College, so that no changes in its constitution or by-laws should be made without their consent, and which finally called for a further meeting of Fellows and Members at no distant date to receive the views and decision of the Council upon the points in debate. The discussion on the main resolution was most ably opened, and closed in a reply of admirable tact and humour, by Mr. Sampson Gamgee. Most of the other speeches were hardly worthy of the occasion, and some of the remarks made were unworthy of any serious occasion, but ample reparation for any faults of taste was made by Mr. Gamgee in his reply, and abundantly endorsed by the meeting. It was perhaps to be regretted that none of the Members of the Council availed themselves of the opportunity ostentatiously given them of defending their policy of excluding Members from a share in the administration of the College. But we may console ourselves with the reflection that the Council itself is so divided on the point that no one could claim to speak authoritatively on its behalf, except its official representative, the President, and he distinctly gave it to be known that he could only speak for himself individually. The feeling was very general, and was expressed by more than one of the speakers, that the Secretary of the College, and the Secretary alone, was the person from whom we might expect the most valid defence of the Council's policy. It is a pity, nevertheless, that the arguments for that policy—and we fully admit that there are strong arguments on that side—were not put forward, so that they might be answered by the advocates of reform. The strongest argument that we know against the extension of suffrage demanded is that with such an unwieldy and widely separated body of men as those whom it is proposed to enfranchise the power of directing their votes and their action is only too likely to fall into the hands of professional medical politicians, of whose good taste and ability in affairs we had not the best possible foretaste at Thursday's meeting. It may be admitted that recently the Association of the Members has conducted its policy with fair judgment and with a sufficient feeling of responsibility, and in securing the services of Mr. Sampson Gamgee it showed its sense of

the necessity of a wise and moderate advocacy of its requirements. But if the Association is to play that important and successful part in the direction of the action of the Members which at present seems marked out for it, it is in the highest degree incumbent on it to secure officers of tried experience in the management of affairs and of men. The services of its present President have been great, and, indeed, but for his zeal and enthusiasm, it is doubtful whether the Association could ever have attained the strength which it showed on Thursday last, but the time has come for a change, and if Mr. Gamgee can be induced to take the official headship of the Association, we are sure that the Members will gladly place themselves under his able guidance.

---

### THE PHYSICIANS' DECISION.

ON Thursday week the Fellows of the Royal College of Physicians of London agreed, by a large majority, "That it is desirable that persons (a word of common gender, be it noted) examined by the Royal College of Physicians of London and the Royal College of Surgeons of England conjointly, and found duly qualified either by the ordinary or by an additional examination, should have a degree in medicine and surgery conferred upon them." The passing of that resolution means that the London teachers have scored a point of considerable magnitude in their up-hill struggle against the Edinburgh School. The victory, it is true, may turn out a barren one, for the acceptance of a principle is a very different thing from the inauguration of a practice, and the London teachers may yet find themselves robbed of the fruits of victory, especially if the ripening is retarded, as may well happen, until the reign in Pall Mall of a less masterful President. Still, that the Fellows as a body should have shown themselves willing to accept an innovation to which the feeling of very many individual Fellows, some of them hospital teachers, is mostly strongly opposed, furnishes remarkable evidence of the telling force of the open arguments and hidden motives which are pushing on so modest and conservative a body as the College of Physicians to enter into rivalry with the Universities. Those who have followed our occasional outpourings on the subject will know how cordially we sympathise with the London medical teachers in their present difficulties, and how heartily we wish them well in their efforts to obtain an accessible degree for their students. There is nothing ignoble in their desire to place the London hospitals on the same level, as regards attractiveness to the student, with the Edinburgh School, though this, which is the efficient motive of the present agitation, was decorously disguised in the discussion in Pall Mall. The interests of the teachers, pecuniary and otherwise, are no doubt involved in the question, and from that point of view the agitation is, of course, a more or less selfish one. But the interests of English students are involved much more largely, and we can well understand Fellows of the College, independent of any teaching hospital and its emoluments, going heart and soul with the teachers in their

endeavour to procure for the London student the same prospect of obtaining a degree that the Edinburgh and Newcastle student enjoys. It is, moreover, to the manifest interest of the public at large that English medical students should receive their clinical training at those schools where the available material and the teaching experience which depends on abundance of material are at their best. The teachers, then, though fighting justifiably enough for their own hand, are also fighting for the benefit of the English student and the English public, and, as this becomes increasingly evident to the profession at large, we shall find, as we have already prophesied, that the opposition to their demands will steadily abate.

The repugnance of many, whose opinions we sincerely respect, to the new course which the College of Physicians meditates entering upon, is founded on traditional beliefs, natural enough in the graduates of our older Universities. The idea that a degree in Medicine should only be conferred on evidence of learning and culture by a University representing the whole field of learning and culture is, in itself, no doubt an excellent one; but it has this disadvantage, that it is out of date. Circumstances are against it. For, on the one hand, degrees are daily given by nearly all our Universities which represent so small an amount of culture as to be hardly worth taking into consideration; while, on the other hand, so far are the Universities from being, as they once were, the only seats of learning or sources of culture, that many of the greatest thinkers of the present century have never lived at a University at all. An age whose culture men like Mill, Buckle, Grote, Herbert Spencer, Huxley, and in our own profession many of the best minds, have been able to mould without ever having nestled at the breast of any *Alma Mater* cannot be expected to cherish a very superstitious reverence for the name or the methods of a University. Moreover, in one of the most important faculties, that of Law, men receive their training as well as their *imprimatur* from bodies which have no connection with other faculties or with the general pursuit of culture. There is, in fact, no reason that will hold water why a single faculty should not stand alone, and give its degrees altogether independently of the influence or interference of the professors of other branches of learning. And, if so, no one will deny that the Colleges of Physicians and Surgeons are intrinsically worthy of taking such a duty upon them, and making themselves in the general recognition what they already are in fact, the repositories of the highest medical culture. Another point on which we would insist is that the curriculum at present required of medical students is far more worthy of the name of a liberal education, and far more efficient as a means of culture, than the small amount of classical or mathematical learning demanded of the University pass-man. Compare the average country squire, with his Oxford or Cambridge B.A., and the average country doctor, with his M.R.C.S., L.R.C.P., and it would not be difficult to decide which were the more worthy to bear the honoured stamp of a liberal training.

One of the main arguments used at the College of Physicians against this new proposal was that, if

carried out, the Edinburgh and Dublin colleges would claim and probably receive the same right to give degrees, and the main object of the reform would thereby be lost, our students still being tempted to Edinburgh by the greater cheapness of its new degree. We agree with Dr. Moxon that such an argument ought to have no weight with the London College of Physicians. Besides, students do not go to Edinburgh now to get the cheaper diplomas of the Scottish colleges; they go to get a degree from the University, or, if they go to the colleges, it is that the diplomas are easier to get, not that they are cheaper. Under present circumstances no English student will content himself with Edinburgh licences if he can get London ones; and, if ever the Scottish colleges should obtain the degree-giving power, they would still be sought only for their easier examinations, and not for their cheaper degrees. The right of the Edinburgh colleges to grant degrees might no doubt injure the Edinburgh University, but that is no concern of the London colleges. Moreover, it is, after all, extremely doubtful whether any Government would give that right to the Edinburgh colleges. Their claim to it would rest on very much weaker grounds than that of the English colleges. Edinburgh has already a University which gives an accessible medical degree. London, on the other hand, has a University which prides itself on not giving an accessible degree. Edinburgh already gives degrees to a large percentage of her students; London to an extremely small one. The argument is a *bogus* one, got up by those who are afraid of the effect which the institution of an accessible degree in London would have upon the Edinburgh School and University. If that effect were not intended to be considerable, if it was not deliberately meant to bring back to London the students who have been tempted away to Edinburgh by its accidental advantages, the present agitation would not be worth supporting. But if it should prove as successful as we all wish it, the movement would improve rather than damage the Edinburgh Medical School, which, by all accounts, is at present in a state of plethora, and would gain greatly in healthy efficiency by the depletion from its crowded wards and class-rooms of a considerable proportion of its present students.

#### RABIES.

THE world is startled this week by the announcement that the celebrated Frenchman, M. Pasteur, has fulfilled the promise held out at the Copenhagen Congress, and discovered a cure for hydrophobia; and indeed the world at large has cause for unbounded gratitude to any scientific observer who shall accomplish this end. Infection with rabies is too a surely fatal and terrible disease as yet, and if the statement which Pasteur made amid acclamations to the Paris Academy of Medicine on Tuesday night is fully borne out by subsequent results, this celebrated *savant* will have the proud consciousness of having more than anyone else contributed to the demolition of one of the most obstinate barriers ever placed by Nature against Science. The statement amounts to this, that

Pasteur has succeeded in curing rabies in the human species. Though the microbe of rabies has not yet been identified, the virus is undoubtedly microbic. If by any of the devices known to bacteriologists a modified form of this microbe can be obtained, which upon inoculation into an animal shall produce a mild variety of the disease, and yet be protective against further infection, the object is accomplished, and rabies is a thing of the past. This is what Pasteur claims to have done. By inoculating rabbits from the spinal cord of a rabid dog and cultivating through successive generations from the rabbit, Pasteur has obtained a number of cultivations of successively increasing virulence and shortened incubation period; and by keeping the spinal cords of these rabbits in perfectly dry tubes for varying periods he is able to obtain a virus attenuated [to any desired degree. On July 6th a boy named Joseph Meister was sent to his laboratory, having been bitten by an undoubtedly rabid dog in no fewer than fourteen places. Sixty hours after the bites, Pasteur first inoculated him. The inoculations were repeated twice a day for a fortnight with virus of successively increasing strength. Now, after a period of between three and four months, the boy, who when first seen by Dr. Vulpian and Professor Granger was doomed to die, is declared by Pasteur to be out of danger. Pasteur has another patient under similar treatment whom he is confident of curing.

However inclined one may be to jubilation, it is not wise to indulge in extravagant laudation yet. The method must be tried and criticised rigorously. The extravagant hopes raised by reports of cholera vaccination were not fulfilled, and, though Pasteur's cautious procedure differs *toto cælo* from the rash behaviour of Ferrán, we must not whistle before we are out of the wood. It must be remembered that the incubation period of true rabies is very variable. Though the average appears to be two to three months, in two cases out of twenty-five collected by us it was respectively thirteen and fourteen months. A very remarkable case was narrated by Colin of two soldiers bitten by a rabid dog. One died of rabies on the forty-third day, and the other exactly five years after. The period of incubation of cat-bite appears to be very short, in one case being only one month and in another six weeks. It will be interesting to watch the boy Joseph Meister. The infecting medium of rabies is probably the saliva. In 1879 Galtier injected the saliva of a mad dog into the veins of eight sheep. A form of rabies resulted which, though not fatal, was protective against further infection. Galtier clearly foreshadowed Pasteur's work. There is undoubtedly some difference in the action of the salivary secretion, for in some experiments conducted by Raynaud in 1880, in which he injected under the skin of two healthy rabbits fragments of an excised submaxillary gland (taken from a rabbit dead of rabies), the one died on the fifth, the other on the sixth day, of true rabies; but, on the other hand, Paul Bert (C.R. 95-1253) concluded that the salivary liquids never communicate rabies, but that the mucus from the respiratory tract of a rabid dog is always infective. Saliva that has been filtered seems to have lost its virulent power, but the

infection remains in the residue on the filter. Rabic virus will, according to Galtier, preserve its virulence after suspension in water for forty-eight hours. Pasteur himself stated in 1882 that the nervous system is the chief seat of development of the virus, and he made a very important communication to the Academy of Sciences upon his experiments, the recent work of his being the natural outcome of his former researches. According to Pasteur, the virus taken from the brain and spinal cord is invariably fatal, and a rabic brain can be kept virulent for three weeks at a temperature of 12° C. When the poison is injected into the arachnoid cavity the incubation period is much shortened. Pasteur thought then that he had discovered a microbe, the true rabic microbe, but he subsequently withdrew this opinion. The differences observed in the length of the period of incubation may probably be due to the manner of entry of the virus into the system. If it enters by the lymphatics, it probably becomes located in the nearest lymphatic glands, there to await some favourable opportunity for developing in all its intensity. There is apparently much modification in the virulence of the poison when it enters the blood directly, and there is some evidence to show that it produces a non-fatal form of rabies with a shortened incubation period. The blood of men suffering with rabies has been injected into rabbits by Raynaud with negative results, the saliva of the same patient being, however, fully virulent. In one of Lussaux's experiments the injection of the blood of a rabid dog into a healthy dog caused no symptoms. It is probable that the transmission of the disease is less virulent from dog to dog, and cat to cat, than from dog or cat to man. From our present knowledge of microbes in disease we may infer that the rabic virus is microbic, and Pasteur's recent researches are a brilliant development of this theory. The acclamations which greeted Pasteur's announcement on Tuesday night will not fail to be re-echoed on this side of the Channel, but we shall temper our admiration of the brilliancy of the researches with the scientific soberness which regards no research or result as perfect which is not confirmed by experience and time. But even the most obstinate scientific sceptic must hope that Pasteur is on the right track for the complete eradication of the disease.

---

#### DR. ORD ON THE CAUSATION OF PYREXIA.

THE very suggestive and philosophical address of Dr. Ord at the Medical Society, which appeared in our last issue, is eminently worthy of the closest attention of both physiologists and practical physicians. Dealing as it does with one of the most important and at the same time most difficult questions of pathology, namely, the nature and causation of increased body temperature in fever, it is marked throughout by caution and clearness, and is an admirable example of the true use of the scientific imagination checked by experiment. In common with many attentive and thoughtful observers of the phenomena

of pyrexia, or heightened body-temperature, at the bedside, Dr. Ord confesses himself dissatisfied with the generally accepted hypothesis of increased combustion as competent<sup>5</sup> to cover all the facts, and quotes the comprehensive report of Dr. Burdon Sanderson on this subject as tending to show that the increased excretion of carbonic acid and urea in fever cases does not represent a sufficient source of heat to cause the increased temperature of the body. The hypothesis put forward by Dr. Ord as supplementary to the received theory is that in fever the increased heat may be brought about partly by the cessation of processes in which heat ought to be used up, or, in other words, rendered latent; that, besides increased combustion in fever, there may be a persistence, in the form of heat, of energy which should normally take another form. And the process by which such heat is rendered latent Dr. Ord suggests to be the building up of the tissues in the healthy subject; just as their disintegration,<sup>6</sup> as is well known, is attended by the liberation of heat. That arrest of tissue-building takes place in fever is probable *a priori*, and Dr. Ord illustrates this by quoting the chemical facts observed by analysis of the urine in fever, which shows an increase of potash and phosphates, and a decrease of the soda and chlorides which are the associates of the more highly organized principles.

The experiments devised by Dr. Ord to check or confirm this hypothesis are worthy of the greatest attention, and we hope will be repeated and extended both by himself and others. Seeking for evidence as to whether heat is used up in the process of tissue-building, Dr. Ord turned to the vegetable kingdom, and commenced a series of experiments on growing cucumbers, the details of which our readers may gather from the published lecture. The result of these experiments, as far as they went, was to show that the growing fruit was actually cooler than its surrounding medium, and that the temperature was most reduced where tissue formation was probably proceeding most rapidly. This is clearly the line which experiment should take in the question, and all will look forward with interest and even hope to the further prosecution of this enquiry.

From the clinical side, the important question at once arises in this context: what is the cause of the cessation of the up-building process and the consequent rise of temperature in fever? And the answer given by Dr. Ord is that it is probably to be found in some inhibitory influence of the nervous system by which an arrest may take place of the processes by which heat is transformed. It must be admitted that whenever pathologists seek to explain a chain of events by some primary functional disorder of the nervous system they enter a kind of cloud-land, but nevertheless increasing knowledge seems to show that it is in that cloud-land that many secrets are hidden which further investigation may reveal. And at this point it must be remembered that there are many instances of heightened and lowered temperature known to clinical observation which seem to be undeniably connected with causes acting chiefly on the nervous system, and much concurrent light may be thrown on Dr. Ord's investigations by a careful study

of such cases. It is, perhaps, especially in the child that clinical observations may be of aid in contributing to elucidate this important physiological enquiry: for there we have the two factors in relief of an impressionable nervous system and rapid growth or tissue-building. There are certain facts observable in early life, and in some conditions of disease and recovery therefrom, which seem at first sight to favour the hypothesis so ably and yet so tentatively put forward by Dr. Ord; but, without going further at present into the physical or the clinical aspects of this interesting problem, it must be said that the lecturer is to be warmly congratulated both on the matter and the manner of his address, and that we hope, before long, to hear or read something more by him on the subject.

## REVIEWS AND NOTICES OF BOOKS.

### HEALTH RESORTS.<sup>1</sup>

MUCH has been done of recent years to give a scientific character to climatological and balneological therapeutics, but the subject is one that does not easily lend itself to exact treatment. It is still, like most other departments of the healing art, in the empiric stage, and, even more than in their case, its development is hindered by the untrustworthy assertions of enthusiastic or interested observers. The reading of report after report of the marvellous cures worked by this or that health resort, prepared for foreign consumption by the local physician, is enough to drive the reader into an attitude of more than wholesome scepticism. Yet there can be no doubt that cures *are* worked at health resorts which cannot be worked at home; that Homburg succeeds where Cavendish Square has failed, that Aix cures what has non-plussed Savile Row, and Davos now and then saves one whom all Brompton has doomed. If it were only that in many cases it has ejected the drug cure, and replaced the internal administration of alien vegetables and minerals by a simple change of nature's environment and the use of more or less harmless water, thus working on the lines of the old Hippocratic maxim *νόσων φύσις ἡτρώει*—if only for this, the fashion of health-resorting would be worthy of cordial support from the philosophical physician. But, besides this, it must be admitted that in a certain proportion of cases the advantages of a course of treatment at a health resort are positive as well as negative. It not merely removes unfavourable conditions, and substitutes a healthy, regulated life for an unhealthy, unregulated one, but it exerts on the patient a positive benefit, as tangible as a cure by specifics. The number of such cases is small, however, compared with that of the patients who seek a health resort every summer because there alone they can find the resolution to live a natural, healthy life. The sending of such cases to a health resort is about as scientific as administering a periodical emetic for gluttony, or giving brandy and opium for the sleeplessness of overwork. A life, healthily regulated as a matter of habit, and not by summer spurts, is what the physician ought to encourage, and his success in this duty is not greatly encouraged by the Spa fashion.

In England the average practitioner knows very little about the treatment of disease by climate and health resorts, and indeed the subject is one of such complexity, owing to the multitude of unclassifiable facts, that it is always likely to be left largely in the hands of experts. In

<sup>1</sup> Climate and Health Resorts, by J. BURNEY YEO, M.D. New Edition. London: Chapman and Hall, 1885.

Health Resorts at Home and Abroad, by M. CHARTERIS, M.D. London: J. and A. Churchill, 1885.

Dryness; Dryness and Elevation the most Important Elements in the Climatic Treatment of Phthisis, by CHARLES DENISON, A.M., M.D. Chicago: Rand, McNally, and Co., 1885.

the first two of the books before us an attempt is made to give the medical reader some reliable information on the various health resorts at home and abroad. Dr. Yeo does more, in attempting to lay down the scientific principles on which the choice of a health resort should rest. This is much more feasible in the case of the climatic health resorts than in that of the spas and baths, for the use of which no general principles can be laid down. The two classes of health resort, indeed, represent two entirely different subjects, which are only treated together for the sake of convenience. Dr. Yeo has made the former of the two especially his own, and he writes about it with the enthusiasm and eloquence that come of full knowledge and trust. His treatment of the spas and baths is less satisfactory, though he gives a very fair account of the qualities of the different medicinal springs and the virtues attributed to them. There is no doubt, however, that climatology is a much more interesting subject than balneology, for it involves and depends on the study of those great laws of wind and weather,—climatic physiology, so to say,—which have exerted an irresistible fascination on some of the greatest of physicians from the earliest times, and our knowledge of which is now being gradually reduced into some order. Dr. Yeo gives an excellent summary of this knowledge, and in his subsequent remarks on individual climates applies it in a very interesting manner. His studies of the Engadine and the Western Riviera occupy a large portion of the volume and render it especially useful to the practitioner.

Dr. Denison's *brochure* deals with the same problems as those with which Dr. Yeo mainly concerns himself, viz., the climatic treatment of disease, especially of phthisis. It gives some very interesting statistics with regard to the climatic characters of different regions of the United States, illustrated by several excellent maps showing their relative cloudiness and humidity at different seasons of the year. The outcome of Dr. Denison's paper is that the high and dry air of Colorado is much more suitable to phthisical patients than warm, moist climates. The book, however, is more valuable as a study of weather than as a therapeutic essay.

The little volume which Dr. Charteris has been able to produce as the result of an enforced absence from work, now happily at an end, forms an excellent guide to the better known health resorts, most of which are described at some length. The author does not attempt, any more than Dr. Yeo does, to lay down general rules as to the use of baths and spas, but his remarks on the subject are sensible and to the point. The book is further rendered valuable to the wandering physician, and to the home-staying physician to whom patients from time to time bring foreign prescriptions, by a comparative summary of the Austro-German and British Pharmacopœias. The reproduction of Dr. Steinsehneider's map of European health resorts adds immensely to the value of the book. We would strongly recommend Dr. Yeo, in future editions of his work, to follow Dr. Charteris' example, and to give, besides, hyetographical and other maps illustrating his earlier chapters.

*Elements of Pharmacy, Materia Medica, and Therapeutics*; by WILLIAM WHITLA, M.D. Third edition. London: Renshaw, 1885. Pp. 618.—This third edition of Dr. Whitla's well-known students' text-book is in many respects an advance on the last issue, which was noticed in these columns nearly two years ago. The order of arrangement of the different parts of the book has been altered, as the author explains in the preface, to facilitate its rapid transit through the press; the chief change in this respect is that the sections on the administration of medicines and on prescription writing are now placed quite early in the book, before the detailed consideration of the pharmacopœial preparations and of their therapeutic actions; there is a certain sense of fitness in this arrangement—it reminds the student, before it is inconveniently late, that knowledge of Latin adjectives, verbs, prepositions, &c., requires to be kept up; it also furnishes an early explanation of the various terms employed so commonly to indicate by a single word the general therapeutic action of a drug. A change which we do not welcome so warmly is the omission of the more important tests for

the various official remedies; the result being that we are presented with over twenty pages of chemical equations of an uninviting aspect. For the rest, the book has been very carefully revised to bring it into complete accordance with the new British Pharmacopœia; the new articles and preparations are marked with asterisks, and very numerous paragraphs respecting them have been introduced into the therapeutic section. As in the last edition, Dr. Whitla devotes some space to "Non-official Remedies," this section forming an interesting commentary on the things that have been left undone by the Pharmacopœia Committee. Special praise is due to the author for the care bestowed upon the parts dealing with extemporaneous pharmacy; these are full of practical hints, calculated to be alike serviceable to the prescriber and the dispenser. Valuable as an alphabetical arrangement may be for a book of reference, we still deplore the entire absence of a botanical classification of drugs obtained from the vegetable kingdom; a few pages of equations might well have been spared to make room for this, and the usefulness of the book for examination purposes would have been thereby largely increased. Viewed as a whole, the essential characteristics of the book are conciseness and lucidity—characteristics which we need scarcely say will render it a most acceptable addition to other works on materia medica.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 23RD, 1885.

W. MORRANT BAKER, F.R.C.S., Vice-President, in the Chair.

#### *Two cases of Cholecystotomy.*

MR. MAYO ROBSON, who described these cases, said that, after the interesting paper by Mr. Lawson Tait, on the Surgical Treatment of Gall-stones, in the *Lancet* of August 29th and September 5th, 1885, with the reports of his cases previously published, and after the paper by Musser and Keen in the *American Journal of Medical Sciences*, in which thirty-five cases of cholecystotomy are reported (of which ten were fatal), the record of his two successful cases would seem to be almost unnecessary if the subject were not still *sub judice*, and did not present many interesting physiological and pathological questions not yet settled, and which every case fully reported might do something to elucidate. But his apology must be a paragraph taken from Sir Spencer Wells' work, "Uterine and other Abdominal Tumours," 1885, p. 203, where he says: "What we need is further experience and an accurate record of all cases." In the first case Mr. Robson was consulted in June, 1884, by Mrs. B., æt. 33, on account of a tumour the size of a hen's egg, which caused dragging pain and uneasiness, but there had never been any jaundice. It was then diagnosed as a distended gall-bladder, but consent to operate was not obtained until June 21st, 1885, when, the tumour having greatly increased in size, with augmentation of the discomfort, cholecystotomy was performed, and eight faceted gall-stones were removed from the cystic duct. They varied from the size of a pea to that of a large bean, and were of a dark brown colour. The gall-bladder contained nearly half a pint of clear watery fluid, which was removed by an aspirator before the cyst was opened. Peritonæum was then sutured to peritonæum, and mucous membrane to skin, and the rest of the wound was closed by catgut sutures, a drainage-tube being inserted into the gall-bladder. Recovery was uninterrupted, union occurring by first intention, and the patient being able to go for a drive on the seventeenth day. A minute fistula remained in September, just capable of admitting a small probe. It discharged a little thin mucus, but gave no inconvenience. The patient was feeling well in every respect, having gained in strength and weight.

The second case was that of a German governess, æt. 22, who was admitted into the Leeds Infirmary, under the care of Dr. Churton, in February, 1885. There was vomiting after all food, a history of prolonged constipation, and a tumour in the position of the hepatic flexure of the colon, the size of which was unaffected by many large enemata; the vomiting continued. It being then suspected that the tumour was a distended gall-bladder, the patient was transferred to Mr. Robson, who performed cholecystotomy, removing numerous small white calculi and eight ounces of clear fluid. The steps of the operation were exactly the same as in the first case, and in both the finger was passed inside the peritonæum, along the cystic duct, in order to be sure that no calculi were left to cause a block in the passage. After the operation the vomiting absolutely ceased, and recovery was uninterrupted, the pulse and temperature being normal throughout, and the wound healing by first intention. The fistula discharged a clear mucous fluid for a time, but on September 5th had completely closed. It, however, re-opened in October, and discharged the same kind of fluid again, the patient experiencing no discomfort or pain, and feeling absolutely well in every respect. He remarked that the cases resembled one another in being both examples of multiple gall-stones causing, or else simply co-existing with, a persistent block in the cystic duct; and in neither case was there any existing jaundice, or previous history of such; but, whilst the diagnosis in one was perfectly clear, in the other, although the nature of the disease was suspected, a distinct diagnosis was not made until the abdomen was opened. Whilst in Mrs. B——'s case the symptoms were chiefly dragging pains and loss of flesh; in the other, persistent vomiting and constipation were principally complained of. In the operations, which were performed antiseptically, pains were taken to stitch peritonæum to peritonæum, and mucous membrane to skin, great care being exercised in protecting the peritoneal cavity from the intrusion of any of the contents of the tumour. In the after progress the discharge of clear fluid free from bile, and the length of time elapsing in the second case before the fistula closed, soon, however, to reopen (the fistula in the first case never having closed), indicated that the cystic duct remained blocked in both, but, there being no jaundice and no illness, the common ducts were evidently patent; moreover, since the finger introduced into the peritonæum and passed along the cystic duct failed to discover any perceptible enlargement, and a probe passed as far as it would go failed to feel any hard body, the only conclusion he could come to was that in these cases there was organic stricture of the ductus cysticus. He raised the question—Is there organic stricture of the cystic duct in both cases, or is the obstruction due to other concretions which careful probing and intra-peritoneal digital exploration failed to discover? If he thought there were calculi causing obstruction, he would not hesitate to advise laparotomy as a preliminary to choledolithotomy, but if there were stricture, which he believed, then he would hesitate to advise another operation, since, if the stricture were dilated, contraction would be likely to recur, again giving rise to a tumour requiring further treatment. Another question arose—Would cholelythectomy have been in these cases a better operation? Sir Spencer Wells seemed rather to incline to this extreme measure in preference to cholecystotomy, but in the record of published cases the mortality was so great that, unless he saw a better way of doing it, he should certainly hesitate to recommend it. However, if he ever had to perform cholelythectomy, he should, if possible, completely draw out the gall-bladder, bringing the duct into the wound just as Mr. Thornton did the ureter in abdominal nephrectomy, this being more likely to prevent the entrance of foreign matter into the peritonæum. If he had thought that dilatation would have done any good, he would have passed in bougies from the outside through the fistula; but this he felt would have been attended with risk, as it would be very easy to push a bougie through the thin wall of the duct, and such a proceeding would, he feared, lead to fatal results. He had put the case plainly to his patients, who were both well, and felt very little inconvenience from the slight discharge; they preferred it to running any risk. Mr. Robson remarked on the clinical importance of the fluid, which, he thought, might possibly be mistaken for hydatid fluid in an explora-

tory puncture. He thought that the secretion had some antiseptic property, since the apertures of the fistulæ were always so clean, and a dressing of cotton-wool saturated with the fluid and remaining in contact with the body for a week remained sweet and odourless; this had been confirmed by his colleague Prof. de Burgh Birch, who had also found it to contain a milk-curdling ferment and another ferment having a marked diastatic action on starch; further experiments were, however, being made in order to verify these observations. He remarked that in the *Lancet* for September 5th, 1885, page 424, Mr. Tait said: "In cases where patients suffer from numerous gall-stones, the gall-bladder is never distended," and again on the same page, "when we operate, therefore, in cases of small numerous gall-stones, we find them lying in bile, the gall-bladder to a large extent contriving to perform its functions," the cases he had just reported must, therefore, come under an entirely different category, as they apparently differed from any of Mr. Tait's; for the gall-bladders were distended and were evidently not performing their functions, and there were numerous small calculi which were not bathed in bile. He had another case at present under observation, in a middle-aged gentleman of temperate habits, which he thought resembled the cases referred to in the paragraph quoted, in whom, after repeated attacks and "spasms" usually coming on in the night, and unaccompanied by jaundice, he found a tumour in the right lumbar region, about the size of a swan's egg, which persisted for several weeks and then disappeared after an attack of pain lasting about three hours. He reported himself to Mr. Robson about a month ago, when there was no trace of the tumour, and there had been no repetition of the pain. He had no doubt that this patient was the subject of multiple small gall-stones, which, in passing, occasionally obstructed the cystic duct. He had explained the nature of his case to him, and, should the duct again become obstructed, or the pain recur, he would advise cholecystotomy, as he felt sure that it was a perfectly safe operation if carefully performed; which, whilst offering the probability of a radical cure, saved an immense amount of suffering and no little danger. He believed that there were many cases of frequently recurring biliary colic without the presence of a tumour, where cholecystotomy would in future be adopted as a relief to suffering, and as a preventive of the many dangers of exhaustion, biliary toxæmia, rupture, suppuration, and ulceration into neighbouring cavities. In conclusion, he could not help feeling that the surgical treatment of gall-stones opened up a comparatively new field in abdominal surgery, which, unlike many surgical triumphs, was at the same time safe and efficient.

Mr. SYMONDS said that there were two chief points to be considered in reference to such cases. One was whether it was better to completely excise the gall-bladder; it had been said that this added an extra risk to the dangers of the operation because it was never possible to be certain that every stone had been removed, one might remain in the duct at a point below the seat of operation. The other point had reference to suture of the gall-bladder, and he thought that in cases of undilated gall-bladder it would be difficult to suture it to the abdominal wall. In one case of gall-stones in a small gall-bladder, where he had been consulted, he did not operate, owing to this difficulty. In such cases extirpation had been performed, but the operation was attended with a very large mortality. It would be a question whether it was better to aspirate and probe for gall-stones or to open the abdomen at once; the dangers of hæmorrhage and local peritonitis were very great, and in cases of very bad jaundice the latter proceeding would be preferable.

Dr. B. O'CONNOR asked whether in either case there had been any difficulty in digestion or any change in the appearance of the fæces.

Mr. MORRANT BAKER had been much interested in the report of these cases, and, so far as he was aware, the observation as to the antiseptic properties of the secretion from the gall-bladder was entirely new.

Mr. ROBSON, in reply, said that there was no difficulty in finding the gall-bladder in those cases in which, though not dilated, it contained gall-stones. So far the results of suturing the opening in the gall-bladder and returning it into the abdomen had been unfavourable. He held that

there was far more risk in introducing a needle through the abdominal wall and then probing the gall-bladder than in performing laparotomy and inserting the fingers into the peritonæum. He had seen fatal hæmorrhage in a case where jaundice was present, the bile apparently having some toxic effect on the walls of the blood vessels. As to the health of his patients, one had declared that she was better than she had been for years, and the other one had gained a stone in weight since the operation. The absence of the fluid secreted by the gall-bladder did not seem to have any appreciable effect on the general health.

*The Characteristic Symptoms of a Febrile Epidemic of Illness at a School.*

Dr. EDWARD SEATON commenced by explaining that it was through the kindness of his friend Dr. Bridges, of H.M. Local Government Board, that he had lately had the opportunity of clinically studying an epidemic illness which had occurred this summer at a Roman Catholic school, or orphanage, in the country near London. The disease had been strictly confined to the school, there having been no illness in the few cottages and houses in the immediate vicinity. The disease had commenced in an epidemic form in June, and since then there had been 157 cases and 7 deaths. The cases were more severe during the earlier part of the epidemic, and there had been distinct second attacks—not relapses—in at least five cases. In one of these the interval between the attacks had been as long as sixty-six days. The group of symptoms characteristic of illness was as follows:—Suddenness of attack without any premonitory symptoms. Attack commencing with rigors and severe frontal headache, followed in a few hours by pyrexia, vomiting (often very severe) without diarrhœa, the acute stage being further marked by scantiness of urine and almost complete absence of chlorides. Rapid development of the crisis, the fatal cases terminating in twenty-four hours, and (in the uncomplicated cases) defervescence occurring in two or three days in slight cases, and in four or five days in severe cases. A sudden fall of temperature, the fall being generally simultaneous with the appearance of an herpetic eruption on the upper lip, and perspiration, but no marked sweating. Ear-ache frequently occurring towards the end of the fever, and sometimes being followed by otorrhœa. Absence of any other local pains, except those due to the straining of the muscles in vomiting. Duration of illness short, not exceeding four or five days, unless complicated with pneumonia. It was the grouping of these symptoms which chiefly claimed attention, for although out of the whole number of attacks twenty-six per cent. were judged, by the height of the fever, comparatively slight, there was observed in all of them a striking uniformity in the main features of the disease. Dr. Seaton then proceeded to discuss the symptoms in detail, first describing the following typical cases from his own notes and those of Mr. Joseph Williams, F.R.C.S., of Brentford, who had the medical charge of the cases. "M. R., æt. 13, brought to infirmary at 2.45 p.m., September 3rd. Was observed joining in a boisterous game in the playground at 11 o'clock in the morning. On admission, face pallid, aspect distressed, respirations 40 in the minute, shivered violently. Held his hand to his forehead, and moaned with pain. On being put to bed, his temperature was found to be 103.4°, at 5 p.m. it was 104.0°, and at 10 p.m. 105.2°. Rigors continued during the night, but not so severe; vomited frequently, and was delirious. September 4th, 10 a.m.—Face flushed, conjunctivæ suffused, breath heavy and offensive, but not ammoniacal, tongue dry, and coated with yellow fur, temperature 104.2°, pulse 120. Tenderness over the epigastric region from straining of the muscles. Skin moist, headache continuous, though less severe. September 4th, 5 p.m.—Symptoms about same. Temperature 104.0°, urine of previous twenty-four hours measured and examined—quantity, seven ounces, highly coloured, deposit of lithates, chlorides as low as .17 per cent. September 5th and 6th.—Pyrexia and other symptoms continued. On the morning of September 7th crisis found to have taken place. In the morning the boy woke up with a very moist skin, temperature 98°. An herpetic eruption had appeared the day before on the upper lip, and was

spreading round the left corner of the mouth. Complained of ear-ache, but otherwise free from discomfort. Next day was out of bed, and in the course of two or three more days, a week from the commencement of illness, was well enough to go into the convalescent room." The above was an account of a typical non-fatal case. He would supplement it by giving a fatal case, which he took from Mr. Williams's notes. "W. M., æt. 13, brought to infirmary on July 2nd, at 9 a.m., with severe rigors and pain in head, and with temperature 101°. Throughout the day rigors very severe, and vomiting of bilious matters incessant. Towards evening recorded symptoms were temperature 106°, respirations 60. Pulse imperceptible. Feet blue and cold. Skin congested and purple. Much pain in head and stomach. He gradually became comatose, and died at 9 p.m., just twelve hours after the onset of illness." *Sudden onset.*—In many instances boys were seized with the headache, vomiting, &c., whilst at play or out for a walk with the master. In some cases they got up quite well in the morning, and were seized whilst at morning chapel. *Frontal headache.*—In all cases this was a prominent symptom. This symptom as well as delirium was, generally speaking, proportionate to the height of the fever. *Pyrexia.*—Remarkably rapid rise of temperature was a constant feature. He had classified the cases according to temperature into "slight" (highest recorded temperature 101° or under), "severe" (highest recorded temperature up to 103°), "very severe" (highest recorded temperature from 103° to 106°). The slight cases were 27 per cent., the severe 21 per cent., and the very severe 52 per cent. of the whole number. In the vast majority of cases the fall of temperature was as marked and sudden as the rise, but in a few pneumonia supervened, and caused comparatively long illness. *Diminution of chlorides in the urine.*—The amount of chlorides had been estimated in fourteen cases by M. Otto Hehner and himself, and the proportions per cent. were as follows:—(1) .256, (2) .274, (3) .043, (4) .333, (5) .466, (6) .278, (7) .466, (8) .366, (9) .592, (10) .170, (11) .190, (12) .354, (13) .190, (14) .310. In no case was the proportion as much as .6 per cent. In No. 3 it was as low as .043 per cent. This was in the case of a boy, æt. 10, who suffered with a moderately severe typical attack. The amount of urine secreted during the summit of the fever, when the chlorides were estimated, was as much as 25 ounces. Very soon after defervescence they reappeared in normal proportion. *Herpetic eruption.*—This was present in almost all cases classified as "severe" or "very severe." Of 28 cases occurring in September, he had a note of this symptom more or less marked in 20, that is 71 per cent. Of the remaining eight, three were slight ephemeral cases, in which the illness lasted only 24 or 48 hours, and in which the highest recorded temperature was under 101°. The eruption was generally thrown out under the alæ of the nose, in some cases, not always the most severe, subsequently extending round the corners of the mouth, and giving the lower part of the face a swollen and sore appearance. Occasionally it appeared first at the corner of the mouth. It usually appeared on the third or fourth day of illness. *Otorrhœa.*—In a considerable proportion of the cases classed as severe and very severe there was ear-ache, more or less intense, which was sometimes followed by a muco-purulent discharge from the ear, and subsequently by a lichenous eruption about the lobe of the ear, due to irritation. In none of the cases was complaint made of sore throat, but in many cases there was noted an inflammatory condition of the nasal passages, accompanied by an acrid secretion. Dr. Urban Pritchard, who had kindly examined one of the cases in which deafness followed otorrhœa, thought that the ear-ache was due to extension of the inflammatory condition of the naso-pharyngeal passages along the Eustachian tube, affecting the middle ear and leading in some cases to pus formation, the intense pain which occurred being suddenly relieved by rupture of the tympanum and escape of matter. *The duration of illness—Occurrence of Pneumonia.*—The classification of illness by the terms slight, severe, and very severe, taken from the temperature charts, was borne out by the duration of illness, which, speaking generally, was short or long in proportion to the height of the pyrexia. Thus, excluding the severe fatal cases (six of which proved fatal

within 24 hours of the onset), the temperature rarely exceeded 101° in cases where the illness lasted only two or three days. In the cases which lasted four or five days the temperature ranged from 101° to 105°. The short attacks (two or three days) were in the proportion of 40 per cent. of the whole number, the attacks of four or five days in duration were in the proportion of 49 per cent., in the fatal cases in the proportion of 4·5 per cent., and in addition there were 10 cases of long illness which in proportion to the whole were 6·4 per cent. Of the long illnesses one was due to peritonitis, six were due to pneumonia, and in the remaining three no complication was recorded, though in these the lungs might have been affected; indeed, Dr. Bridges was of opinion that many of the short illnesses were accompanied by an abortive attack of pneumonia, and this view was borne out by the condition of the lungs observed in the fatal case in which a *post-mortem* was made. In the cases where the symptoms of pneumonia were observed, the prolonged illness with pyrexia was accompanied by dulness of one or both bases, tubular breathing, quickened respirations, but no rusty expectoration. The average duration of illness in these prolonged cases was fifteen days, the limits being eleven and twenty-six days. *Post-mortem appearances.*—In only one of the six fatal cases was a *post-mortem* examination made. In this case Dr. Bridges noted distinct and marked congestion of the lower third of each lung, and patches of congestion in that part of the small intestine which alone was examined (the four or five feet next to the œcum), and also small patches of a similar kind in the gastric mucous membrane. Dr. Seaton then proceeded to discuss points in the ætiology of the disease which it was impossible to consider apart from its clinical characters. He formulated then three questions:—Is the disease specific? Is it contagious? What is its incubation period? (1) As to its being specific, he thought there could be no doubt that it was so. Murchison, in his classical work on the continued fevers of Great Britain, quoted Tweedie, who said that “all cases of febricula were mild cases of typhus, or relapsing fever, and did not think that a new nosological term should be introduced merely to accommodate such cases.” But, added Murchison, “I am satisfied that short cases of fever, independent of any specific poison, are occasionally met with in this country.” It was difficult to understand the meaning of this passage, and it would be interesting to know whether Murchison would have classed ague among the diseases independent of any specific poison. (2) As to the question of contagiousness, he desired to speak with caution, but the evidence as far as it went tended to show that it was not contagious. He explained the various reasons which led Dr. Bridges and himself to that conclusion. (3) As to the question of incubation period, he had been singularly unfortunate in his endeavours to obtain evidence on this point, though he had made careful enquiries among new arrivals and departures. There was as yet only one case which threw any light on the question. It was that of a boy who left the school for a week, and who was taken ill about twenty-four hours after his return. The entire absence of premonitory symptoms, and the suddenness of attack, made it probable that the period was short. He concluded the paper with some important facts as to age incidence, which he showed by means of a table of statistics. None of the adults, including masters, nurses, and attendants, about twenty in number, had been attacked, though, if they had suffered equally with the rest of the school population, at least four would have succumbed to the disease. The table showed that the incidence was much heavier on the older than the younger boys, that is, the boys over ten years of age suffered much more than the boys under ten. The incidence was heaviest of all on boys between thirteen and fourteen years old; forty-six boys out of eighty-three at this age, or fifty-five per cent., being attacked.

Dr. J. H. BRIDGES, having been invited by the Chairman to speak, said that it was during the earlier part of the epidemic chiefly that the cases had come under his personal cognisance, and, whilst entirely agreeing with the clinical description given by Dr. Seaton, he should himself be disposed to lay more stress on the pneumonia as a symptom. He believed that a very slight degree of this had been

present in a very much larger proportion of cases than had been supposed. On enquiry, he had learned that in May a considerable number of cases of pneumonia had occurred in the school, which, however, had not been regarded as in any way connected with the epidemic, and in June there had likewise been an unusual number of cases of catarrh. He strongly suspected that a slight lung congestion had been present in a great many of the cases. Turning to the ætiology of the outbreak, he said that the hygienic surroundings of the school had been unsatisfactory for years. The school stood on about six acres of land, and extreme difficulty had been experienced in dealing with the sewage. The earth-closet system had been in use almost exclusively for the past twenty years, and the amount of space available for the disposal of the excrement of this large school was entirely insufficient, only amounting to an acre and a half; the ground was therefore charged, and overcharged, with faecal matter. Four years ago there had been some similar cases, and in consequence of the rapidly fatal termination in one case an inquest had been held, when the insanitary condition of certain closets was set down as the cause of the outbreak. These were removed, and improvement followed, no cases having occurred since that time till the present epidemic. The disease, he considered, was one of soil exhalation. The water supply was no doubt extremely polluted, but the symptoms bore no relation to the diarrhoeic or typhoid group of symptoms usually found in cases of water pollution. He did not regard this as a truly contagious disease. As to the question of age incidence, he suggested that the older boys were more employed in the garden than the younger ones, who played near the buildings and so were less exposed to emanations from the soil. The immunity of the fifty boys in the infirmary was, he thought, very significant; he found that a large number of these were attacked after their return to the school; the soil of the play-ground attached to the Infirmary was not so likely to be polluted as the other ground, which would explain their freedom until their return to the school. As to the meteorological aspect, the epidemic was mainly from June to September, though fresh cases were still occasionally occurring. This had been a period of unusual dryness, the rainfall only being a fourth of the normal; the temperature had exceedingly little to do with it, as July was the hottest month, whilst the greatest number of cases had been in September.

Dr. STEPHEN MACKENZIE read a letter from Dr. Stevenson, relating to the previous epidemic in 1879, to which allusion had been made when, at the request of the Home Secretary, he had made a careful analysis of the contents of the alimentary canal in three cases, and had been unable to detect any poison, either mineral or vegetable; Mr. Thomas Bond, who had made the *post-mortem* examinations, had attributed the deaths to asthenia, due probably to sewer gas.

Dr. B. O'CONNOR referred to some cases he had seen in a girls' school, with similar symptoms.

Mr. R. W. PARKER asked whether there had been any other *post-mortem* examinations, and, if so, whether anything constant had been found; he thought there ought to have been, as the symptoms were so very constant. He asked if any change in the earth-closet system had been lately made, and whether there was any possibility of antecedent contamination with excreta from diphtheria or typhoid fever cases.

Dr. SEATON, in reply, said that in the *post-mortem* which was made there was found hypostatic congestion of the lungs, and congestion of the last five feet of the ileum, and of the gastric mucous membrane. He had enquired very closely but had been unable to ascertain any history of other, defined fever prior to the epidemic.

VICTORIA UNIVERSITY.—The first intermediate M.B. examination since the affiliation of University College, Liverpool, with the Victoria University has just taken place. The following have passed from University College: 1st Division—Buchanan, R. J. M.; Collins, A. W.; Livsey, W. E. 2nd Division—Corkhill, J. G. G.; Cunningham, John; Shannon, J. W.

ROYAL MEDICAL AND CHIRURGICAL  
SOCIETY.

TUESDAY, OCTOBER 27TH, 1885.

BERKELEY HILL, F.R.C.S., Vice-President, in the Chair.

*Diffuse Lipoma.*

MR. MORRANT BAKER and MR. BOWLBY contributed a paper on this subject. The term Diffuse Lipoma was applied by the authors to certain cases in which there is a great increase of the subcutaneous fat, without any distinct boundary or capsule, such as is usual in the more common forms of lipoma. These growths are usually symmetrical, and are most common behind the ears, over the mastoid processes (not extending above the superior curved line of the occipital bone in the nape of the neck), and in the sub-maxillary regions. The same tendency to the development of fat is in many of the cases observed also in the arms and fore-arms, the scrotum, and the abdominal wall. The authors had observed and recorded thirteen cases, and referred to others already published. A point to which attention was directed is the fact that these fatty masses are prone to develop in the regions occupied by lymphatic glands. Whether these latter are ever involved in the growth the writers are not in a position to state. All the cases hitherto observed have been males, the ages varying from twenty-nine to sixty-three years, the majority of the patients being from thirty-five to forty-five years of age at the time the tumour commenced to grow. None of the patients were exceptionally stout men. Some of them had been healthy and strong, others had suffered from phthisis, albuminuria, and other wasting diseases. All the swellings observed appeared to have a similar structure, being composed simply of adipose tissue. With regard to the anatomical position of the swellings, the writers gave reasons for believing that they were situated in the subcutaneous cellular tissue. The manner in which the growths were limited in the various regions in which found was discussed. The development of these tumours was said to be somewhat rapid. The rate of growth, however, varied much in individual cases. Another noticeable fact was that in some instances the swelling varied in size from time to time. Of this fact several of the patients were very certain, and in some cases the authors were able to verify this statement. Whether the tumours ever entirely disappeared in the absence of any wasting disease could not be affirmed with certainty. The only circumstance which seemed to give any clue to a cause (so far as the writers have been able to observe) was the fact that, with one or two possible exceptions, the patients have been hard drinkers. Beyond the discomfort produced by the deformity, no symptoms specially referable to the fatty tumours had been observed. Internal remedies had apparently little or no effect. In one or two cases, however, the administration of arsenic with steel seemed slightly beneficial. In accordance with Brodie's suggestion, the writers had tried the effect of liq. potassæ, but had not hitherto found it beneficial in reducing the size of the growths. They had administered the above-mentioned drugs, as well as iodide of potassium and mercury, in several cases for some months.

Dr. CREIGHTON, after hearing these cases, was reminded of a case of infiltrating swelling extending from ear to ear beneath the skin, but of scirrhus hardness. It occurred to him whether this might have been fat which had undergone a sclerotic or semi-cartilaginous change.

Mr. MORRIS thought the case referred to by Dr. Creighton was not quite of the same nature as the cases described in the paper, for the skin as well as the subcutaneous tissue was involved. In another case, one of cancer of the tongue, there was a quantity of fat among which the infiltrated lymphatic glands were found. This began to inflame, and subsequently suppurated, a quantity of very foetid discharge coming away. Mention was also made of a subaponeurotic lipoma on the scalp.

Mr. BUTLIN had treated two such cases, and one of these was a young woman who had the swelling over the parotid,

extending down the neck. After several months' treatment by liq. potassæ she appeared to improve.

Mr. DAVIES-COLLEY also referred to a female, one of two cases on which he had operated.

Mr. JESSETT was well acquainted with a gentleman suffering from this condition; he was, and always had been, an abstainer.

Mr. BAKER briefly replied; he was chiefly interested to learn that the condition occurred in females.

*A Case of Ligature of the Left Common Carotid Artery, wounded by a Fish-Bone which had penetrated the Pharynx.*

Mr. RIVINGTON related the case of R. B., æt. 9, who was admitted into the London Hospital, under the care of Dr. Sutton, on November 14th, 1882. Six days previously he had swallowed a plaice-bone. At the hospital a probang was passed, and he was sent home; not being relieved, he came back to the hospital and was taken in. His symptoms were pyrexia, stiffness of the neck, œdema of the upper eyelids, profuse salivation, and a small tender lump on the left side, opposite the cricoid cartilage. Pulse 120, temperature 101.3°, respiration 22. He could not swallow solid food, and was very drowsy. He had two attacks of hæmorrhage from the mouth on the 17th, and profuse hæmorrhage on the 19th. Being sent for, and diagnosing wound of left carotid from penetration of the fish-bone, he cut down and tied the artery above and below the seat of injury. The operation was difficult, owing especially to inflammatory adhesions and uniform staining of all structures, including nerves and blood-vessels, with effused blood. The pneumogastric was adherent to the artery for about two inches, and, being in front of the artery and undistinguishable, was necessarily included in the ligature. The fish-bone was found in the centre of a clot. The patient lived ten days after the operation, dying from abscess of the brain on the left side, which had probably commenced to form before the operation. Remarks were made on the salient features of the case, and on the mischief which was often wrought by the incautious passage of bougies and probangs in these cases. In an appendix the author gave an abstract of forty-four cases of wounds of blood-vessels by foreign bodies introduced through the mouth. These included wounds of the following vessels—thoracic aorta 22, carotids 12, abnormal right subclavian 1, pulmonary artery 1, azygos vein 1, heart and right coronary vein 1, vena cava 3, inferior thyroid 3. Comparison of these cases with one another, and his own case, suggested a variety of considerations, the most important being some which bore upon diagnosis and treatment. For diagnosis there were the history of a foreign body having been swallowed; persistence of pain referred to one spot; dysphagia, especially inability to swallow solids; ptyalism; failure of the foreign body to pass *per anum* or from the mouth; recurring expectorations or vomitings of blood; passage of blood by stool, and fainting fits. In the neck there would be local evidences of inflammation, swelling, and tenderness. For treatment, improved illumination of the pharynx and œsophagus and extraction of the foreign body with forceps, regulation of diet, exhibition of demulcents, and the cautious use of the expanding probang. In some cases the question of œsophagotomy might have to be considered; in all cases, as life was soon endangered by the occurrence of hæmorrhage, prompt surgical assistance became imperative.

Mr. MORRANT BAKER referred to the injuries sometimes inflicted by tobacco-pipes. Mr. Hilton's dictum was that they were caused by the sudden contact of two persons, one coming out of, and the other going into, a public-house. He related the case of a man who applied at the hospital on account of tonsillitis, no mention being made that a pipe-stem had been rammed into it until several days later. The pipe was found; suppuration and hæmorrhage occurred, which proved fatal; the carotid artery was found to have been injured.

A visitor (whose name we did not catch) related the case of a soldier. After repeated trials with the probang, a ragged piece of bone was brought up, and a good recovery ensued; this would seem to show that the use of probangs

was not always so dangerous as the author of the paper had endeavoured to show.

Mr. BOWLBY referred to a specimen in the museum of St. Bartholomew's Hospital, showing a fish-bone which had been forced into the aorta by a probang.

Mr. RIVINGTON, in reply, said that both Mr. Baker's and Mr. Bowlby's cases would be found referred to in his paper.

The Society then adjourned.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, OCTOBER 15TH, 1885.

T. MORTON, M.D., President, in the Chair.

### *Case of Iodic Purpura.*

Mr. A. Q. SILCOCK related the case of a woman who was admitted into St. Mary's Hospital on account of proptosis. Although no history of syphilis could be obtained, iodide of potassium was prescribed in 10-grain doses three times a day. After a lapse of 13 days, the dose was increased to 15 grains; 7 days later, a purpuric eruption appeared, most marked on the legs. Arsenic was then prescribed in combination with the iodide: the rash disappeared after 3 days. The arsenic having been discontinued, the spots recurred in an aggravated form. Five minims of liq. arsenicalis were again added, and this was followed in 6 or 7 days by a disappearance of the eruption and by general improvement. Arsenic was omitted two days after the disappearance of the rash, the latter again returning after ten days, accompanied with malaise and some catarrh. After this, the patient lost courage and ceased to take her medicine regularly. A few months later, the iodide was again prescribed, and once more slight purpuric spots appeared after a few days, when the drug was finally omitted, the case being regarded as one of exostosis or of ossifying chondroma. In his remarks Mr. Silcock rejected the view that the effect was due to increased diaporesis, such as is said to follow the intravenous injection of salines. Arsenic was prescribed in the hope that it might possess the same specific influence which attaches to its administration in bromide eruptions. He believed that it was frequently prescribed conjointly with iodide of potassium, especially at the Lock Hospital.

Dr. CHARLES RENNER expressed doubt as to any antagonism between the drugs, and suggested that the case was one of idiosyncrasy.

Mr. MALCOLM MORRIS alluded to the rarity of recorded cases of iodic purpura. The exceptional case published by Dr. Mackenzie deserved mention, the child having died from purpura after a single dose of  $2\frac{1}{2}$  grains. Even in the rash of bromide arsenic after a time lost its beneficial effect. The paper was of great value as demonstrating that purpura was not a disease, but a symptom.

Dr. LEES considered the case one of idiosyncrasy—in cases of meningitis he had administered to children large doses of iodide (3 grains every 3 hours) for weeks and months without any toxic effects. Children were more exposed to the rash of bromide, adults to that of iodide of potassium.

### *Pyosalpinx.*

A specimen of pyosalpinx was exhibited by Mr. A. Q. SILCOCK. The patient was supposed to have caught cold during menstruation. The symptoms were indeterminate, consisting of pain in the abdomen and discharge of pus from the rectum.

The PRESIDENT, Dr. J. PHILLIPS, and Dr. LEES referred to cases from their experience.

Dr. M. HANDFIELD JONES remarked on the occasional absence of all symptoms. Vaginal examination could seldom avail, for the physical signs would naturally vary with the amount of distension and matting. Prolapse of the ovaries, complicated by retro-uterine peritonitis, might simulate disease of the tubes. He had treated a case of 15 months' standing, in which, beyond some abdominal distensions, pyosalpinx had occasioned no discomfort.

### *The Treatment of Chorea.*

Dr. W. B. CHEADLE, after referring to the failure of innumerable specifics, and to the scepticism too widely engendered therefrom, declared his own belief in the value of medicinal treatment. Speaking from the careful notes of 160 cases observed during a period of 8 years, he stated that the average duration of the disease under treatment had been 5 weeks (extremes being 10 weeks and 4 days), whereas cases without treatment might extend from 11 to 52 weeks, or indefinitely. The author had tried various methods, including rest and expectancy, with results sometimes beneficial, but never completely successful. In arsenic he had at last found an agent which did succeed. Todd, as long as 40 years ago, had recognized its power, so had Babington and Begbie; but dread of the poison had checked their use of the remedy. He gave some striking cases of rapid improvement under the influence of ordinary doses of liq. arsenicalis with small doses of Tr. Ferri perchlor. A comparison of long series of cases treated without arsenic and with arsenic respectively gave for the former an average duration of 40 days, for the latter, of 29 days; and this difference was increased when the last 58 cases were compared with 58 consecutive cases in the former series, the average duration under arsenic being only 24 days. Arsenic was in every case well borne, exerting a remarkable result repeatedly observed by the author, but not hitherto described by others, viz., a bronzing of the skin analogous to that observed in Addison's disease. The staining was most marked in the flexures, did not affect the face, and ultimately disappeared. In one case, however, it had become permanent, but would probably vanish in time. The pigment deposited was not metallic as in discolouration by silver, but resembled the pigmentation due to chronic congestion. In conclusion, whilst advocating arsenic in chorea, the author did not wish to depreciate the value of other therapeutic agents which should be employed concurrently.

Dr. CLEVELAND called attention to the fact that iron in small doses had had a share in the results obtained by Dr. Cheadle.

Mr. MALCOLM MORRIS enquired whether the pigmentation described might not have been the result of the disease rather than of the remedy. Dermatologists were, however, beginning to think that the discolouration observed after the cure of patches of psoriasis might have been caused by the prolonged use of arsenic.

Dr. CULVER JAMES had found arsenic of little value in mild cases, although decidedly beneficial in severe attacks.

Dr. EWART and Dr. DE WATTEVILLE had administered large doses of arsenic in the chorea of children, without any toxic effects; the latter had combined with the drug large doses of bismuth.

Dr. LEES was in favour of arsenic, and had checked the value of the remedy by watching the effect of its interruption.

## LIVERPOOL MEDICAL INSTITUTION.

THURSDAY, OCTOBER 22ND, 1885.

Dr. GEE, President in the Chair.

### *Pathological Specimens.*

Dr. ALEXANDER exhibited a kidney that had become converted into a thin-walled irregular cyst owing to obstruction of the ureter two inches below the hilus by a primary carcinomatous tumour of the retro-peritoneal glands. The opposite kidney was cirrhotic, and the patient, who was seen just four days before death, died from symptoms of delirium passing into those of coma.

Dr. GREVES showed several interesting specimens of typhoid, tubercular, and syphilitic ulcerations of the intestines.

Dr. IMLACH showed a renal cyst containing calculi removed from a woman, from whom he had thought of removing the kidney. As digitalis and acetate of potash

did not increase the flow of urine, and as the flow was intermittent and had once stopped for some time, he believed the opposite kidney to be useless. Suppression of urine, however, set in, and death rapidly occurred before anything was done, except the drawing off by aspiration of 2½ quarts of ammoniacal urine; one kidney was cystic, and the opposite completely atrophied and useless.

Dr. IMLACH showed an extra-uterine foetation where the foetus was found in the peritonæal cavity, and where the death of the mother was produced by the rupture of the extra-uterine cyst. He also showed the uterus of a woman who had died in child-birth, after cephalotripsy, where the obstacle to parturition was a hard dermoid cyst that lay immovable behind the uterus.

Mr. BICKERTON related the case of a cataract he had successfully removed from a lunatic. The use of cocaine in ophthalmic surgery was well illustrated in this case.

Dr. BURTON reported a case of removal of the uterine appendages for myoma, where the tumour had now become reduced to five-sixths the size it was at the time of the operation. The myoma was a soft one. In commenting upon this case, Dr. Imlach said the result was more favourable than he could report in any of his cases. In his, no result was apparent for some months, and the menses appeared as usual. Many seemed failures, but twelve months after they turned out successes. The soft fleshy fibroids were least successful.

#### *Operations for Hernia.*

Mr. RUSHTON PARKER read a paper, entitled "Remarks on Hernia, based on seventy-four Operations," and showed some cases of the radical cure of umbilical hernia, by ligature of the neck of the sac, that were very satisfactory. Out of thirty-three operations on unstrangulated hernia, four deaths had occurred, viz., one out of seven umbilical hernias, one out of four femoral hernias, and two out of twenty-two inguinal hernias. In strangulated cases he performed the same operation, that is, he ligatured the neck of the sac, but never attempted to bring the sides of the ring or opening together. In this respect he differed from all the subsequent speakers, who without exception insisted on the advisability or the necessity in all cases of bringing the pillars of the ring or the sides of the opening together. Mr. Parker reported only about six recurrences in thirty-nine inguinal cases, a very favourable issue of his method. Many of his cases healed by granulation and cicatrisation, and it was held by some of the speakers that the adhesion of the pillars of the opening actually took place by this means in his cases, and that, had they healed by the first intention, the result would not have been so good.

In the discussion, which was a very lively one, Drs. Alexander, Barr, Campbell, Hamilton, Pughe, and Steele took part.

## SPECIAL CORRESPONDENCE.

---

### INDIA.

(From Our Bombay Correspondent.)

*Demand of Army Medical Officers for Military Rank—  
Medical Officers and Appointments in Presidency Towns—  
A Hospital for Women and Children in Bombay—  
Steamers Carrying Explosive Oils—Pension Rules for  
the Indian Medical Service.*

October 9th.

AN agitation has been started in the columns of a medical contemporary by gentlemen belonging to the Medical Staff of Her Majesty's Army, evincing, it would seem, a sort of hankering after military rank, or, in other words, after the titles Captains, Majors, Lieutenant-Colonels, &c., thereby becoming more militarized. This morbid craving for the acquisition of military rank appears, I regret to notice, to be fast spreading among members of the service in this country who, in general, would appear to forget or ignore the fact that they belong to the noble profession of

medicine, and that it is their calling to heal or cure wounds, and by no means to inflict them. It is a truth beyond cavil that those who are sincerely devoted to their profession would never dream of professing or affixing to their names a bogus rank, and it is to be hoped that the medical press generally will discountenance any such proposal as that mentioned above, which cannot but have the effect of lowering the profession in the eyes of the outside public.

A short time back the subject of hospital appointments in presidency towns in India was attracting public attention. Then the question turned on the pivot whether these should be, as had hitherto been the case, filled by members of the Indian Medical Service or held by those not in the service. That these appointments are, as a right, reserved to the service is quite correct, and it would certainly be a breach of faith if they were to be bestowed or outsiders. But the question still remains to be settled how the claims of members of the service should severally receive attention. We know that in London, and in provincial towns especially with a medical school, all candidates for surgical appointments have to be Fellows of the Royal College of Surgeons of England, and those for medical (including obstetric) appointments have to be Members of the Royal College of Physicians of London. These diplomas of F.R.C.S. and M.R.C.P. are considered, respectively, as an ample guarantee of a man's fitness for the office of surgeon and teacher on surgical subjects, and of physician and teacher on medical subjects. In India, there is often great heart-burning produced by the manner in which such posts are awarded. Likes and dislikes, interest and influence, all come into play, and so justice is often not fairly meted to those who are struggling for an academical career, or for that of a consulting surgeon or consulting physician. Could it not be arranged that all the more important hospital and professorial appointments should be reserved for members of the Indian Medical Service who possess the higher diplomas? Some such rule for Indian medical appointments could not fail to act as an encouragement to men to take the highest diplomas in surgery and medicine. Seniority and interest ought to have nothing to do with the matter. The gentlemen who possess these respective qualifications should be posted, and if too many should possess the requisite qualification, then seniority and other circumstances bearing upon their claims might be taken into account. Some such innovation would tend to raise these appointments, which offer wide fields for original research, in the estimation alike of the profession and of the public.

At the recent Bombay University Examination for the first professional examination for the licence (L. M.), out of 50 candidates who presented themselves, 18 were declared to have passed, 4 in the first class and the rest in the second.

The Bombay Town Council had before them the other day a resolution of Government thanking a native donor for his public-spirited offer of one lakh of rupees towards the cost of building an infirmary for the treatment of diseases of women and children, at which at the same time clinical instruction might be given to the students of the Grant Medical College. The cost of the building is estimated at 2,45,000 rupees. The Government, it appears, were to furnish the balance of one lakh and a half; but they regret that it is, at present, impossible for them to provide this sum. The Government, however, are prepared to meet a portion of the total expenditure by making a grant hereafter if the contributions from other sources can be increased, and the Government are also willing to bear the cost of the establishment. The donor was asked whether his family had any objection to the Municipality contributing towards the cost of the proposed new hospital, if invited and willing to do so. He replied that his family had no objection to the Municipality contributing, on condition that it would not in the future claim any share in the management of the hospital, which, it is wished, should be exclusively under the Government. And, if so, what sum the Municipality were prepared to contribute? It was proposed that the Municipality should contribute a lakh of rupees towards the building-fund of the hospital, the amount so required to be raised by a

temporary enhancement in the consolidated rates. The motion, however, was lost on a division, the proposer and seconder being alone in favour of it.

I have to call attention to the great danger of passenger-steamers carrying such combustible or rather explosive substances as kerosine oil when over-proof. This has recently been detected to be the case in the case of the steamer *Kaiser-i-Hind*, in which 150 drums of kerosine oil, which had been brought by that vessel, were condemned by the analyst. The Government, I learn, have directed that the commander of the vessel be prosecuted under the Petroleum Act.

New pension rules for the Indian Medical Service are, I understand, anxiously looked forward to, and it is earnestly hoped that they will be more favourable, both as regards retiring allowances, and for furlough and leave to reckon for service towards pension, than those now in vogue. It is believed that the subject is now under the consideration of Her Majesty's Secretary of State for India and the Government of India, and that references are being exchanged between the India Office in London and Simla. Indian medical officers are eagerly awaiting the promulgation of the new rules, which at the same time, they hope, will improve their furlough pay. If the Government intend that the service should be raised in the estimation of the profession, and be sought after, this important matter of pension and furlough pay should receive the prompt attention and liberal consideration it deserves. The Indian Medical Service, in days gone by, was the first service in the world. There were men in it who proved themselves to be luminaries of the highest order. The time-honoured Indian Medical Service deserves well of the Government, and I trust these sentiments will be echoed by some of your powerful daily contemporaries, so that the young and able statesman who is at the head of the India Office will take the matter up and do justice to Her Majesty's Indian medical officers.

## GENERAL CORRESPONDENCE.

### THE PREVENTION OF RABIES AND HYDROPHOBIA.

[To the Editor of the Medical Times.]

SIR,—The alarming prevalence of hydrophobia, and the unusually large number of deaths from that disease which have occurred in the course of the last few months in the metropolis alone, has begun to direct general attention to the subject, and people are asking that preventive measures should be more rigorously enforced, or that other and more efficient ones should be sought out.

This is undoubtedly a country much be-dogged; and no small proportion of the dogs which swarm in and about our large centres of population are homeless and ownerless. Another large class are practically friendless, their nominal owners—after the novelty of possession has worn off—leaving them to all intents uncared for and unwatched. It is mainly from these, the lower strata of his kind, that the mad dog is recruited; they are the classes most exposed to infection; and in them the earlier symptoms of the disease are, from the very circumstances of their case, almost certain to be overlooked.

To put the matter in another way, it may safely be asserted that the number of dogs now at large is greatly in excess of the number of current dog-licenses. And it would seem that a more stringent application of the law should act as an important prophylactic against rabies. If every apparently ownerless dog were straightway seized and, after some interval allowed for the appearance of a possible claimant, destroyed; and if every person owning a dog for pleasure were compelled to take out a license forthwith, on penalty of his pet's becoming liable to seizure and destruction, we should quickly see a marked diminution of the vagrant curs which are threatening to become in many

quarters something more terrible than a mere nuisance. For the effective carrying out of such provisions two things are requisite: an incentive to greater zeal amongst the police, and the adoption of some method by which they could ascertain at once and with certainty whether the owner of any dog coming under their notice had taken out the necessary certificate or not. The first of these could be met by a system of "head-money"—a small payment being made for each dog justifiably seized. Should the dog be claimed, this would be added to the amount of the ransom required from the owner; but, in any case, it would be far more than made good by the increase in revenue derived from a strictly collected dog-tax. The second requirement would be met by issuing with each annual dog-license a simple metal badge, legibly stamped with the date of the year of issue, to be visibly attached by a collar to the neck of each animal above six months old. Any dog found outside a private dwelling-house without such a badge should be liable to immediate seizure by the police. On the back of each license might be printed a brief synopsis of the earlier symptoms of rabies, and simple rules for the immediate treatment of dog-bites. With each yearly renewal of the license a fresh badge would be issued: and no badge would be obtainable on the plea of loss or breakage without the simultaneous purchase of another license. To those—as, *e.g.*, shepherds—who are allowed to keep a certain number of dogs without payment—a corresponding number of badges would be granted every year on application. But the principle would be—no dog in public without his badge bearing the date of the current year; and the dog of any owner violating such a provision would be liable to seizure "on sight." A similar combination of badge and license has been found to work well at the Cape, where hydrophobia is unknown. I do not believe that such an extension of the present Dog Licensing Act would be found to work otherwise than well. It would go far, amongst other advantages, to lessen the necessity for the use of muzzles, which are in too many cases cruel, and perhaps otherwise injurious in their effects; while we are convinced that it would do much to both lessen the frequency of rabies and to render extinct the class of useless dogs which are peculiarly liable to suffer from and apt to propagate this most dangerous evil. The provisions of such a measure would not entail upon each dog-owner anything like the amount of trouble now involved in stamping one letter a month. By adopting such reasonable precautions, the public might not only feel justified in anticipating something of that aid which is proverbially accorded to those who help themselves, but they would await with greater equanimity the evolution of that fuller measure of defence which a perfected "protective inoculation" may haply afford us in the not distant future.

I am, Sir, yours, &c.,  
CANTAB.

## AURAL SYRINGES.

[To the Editor of the Medical Times.]

SIR,—The "New Aural Syringe," described by Dr. Ward Cousins in your number of October 17th, resembles in principle the "Simplex Ear Irrigator" which I designed with the object of avoiding the difficulties, inconvenience, and discomforts that attend the use of the ordinary syringe. It was made for me a few years ago by Messrs. Arnold, who exhibited it at the following annual meeting of the British Medical Association. It consists essentially of a cup embracing the lower part of the ear and held in place by the usual head spring. The hollow stem of the cup is continued into a length of rubber tubing by which the effluent fluid is conducted to any convenient receptacle. From this stem springs a flexible metal arm which carries the adjustable injecting nozzle of celluloid. Fluid is propelled through rubber tubing to the nozzle by an ordinary enema syringe, a "hand ball," a Simplex syringe (the least fatiguing of all), or by simple siphonage from a vessel of water placed on a shelf or bracket above the level of the

patient's head. The patient may hold his head in any position most comfortable to him, or change its position from time to time, since there is no necessity for keeping the head inclined. The instrument is adapted for self-application; and, if siphonage is used, not even one hand is required for its manipulation.

I am, Sir, yours, &c.,  
C. E. SHELLY.

Hertford, October 22<sup>nd</sup>.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS.

A MEETING of the Fellows and Members was held at the College on Thursday last, the 29th inst., at which a report from the Council, or, more correctly speaking, a record of their transactions during the preceding collegiate year, was presented and discussed. After a few words of welcome from the President, Mr. SAMSON GAMGEE proposed the first resolution: "That, the Council of the Royal College of Surgeons not having accepted the principle that Members as well as Fellows should take part in the election of the Council, steps be at once taken to memorialise Parliament and the Crown, so as to secure, in the interest of the public and the profession, the right to representation in the administration of the affairs of the College for its 16,500 legally qualified Members." He said that, though the College was composed of two classes, Fellows and Members, they formed but a single corporate body with common interests. The line of action which this Association was adopting was not in any way opposed to the interests of the College, for it was essentially constructive and not destructive. He asked if it was right that the management of the College should be solely in the hands of the minority. Contrasting Fellows and Members together, the numerical difference was enormous, 1,100 as against 16,500. It was a fundamental principle that taxation and representation should go hand in hand. If the balance-sheet of the College were examined, it would be seen what an enormous proportion of the total funds came from members, and how small a sum the Fellows contributed. The work of the Council was very largely administrative; could it be argued that a young man, who obtained his Fellowship at the minimum age, was *ipso facto* better qualified to take part in College affairs than members of 10, 20, or 30 years' standing, who had honourably practised their profession, had held offices of trust, and received marks of public approval. About 90 per cent. of all surgeons in the Army and mercantile service were Members of the College. Were not these men in responsible positions; was the College, by excluding them, to publish abroad that they were unfit to take even so small a part in College management as voting for Members of the Council? A new Medical Bill, he thought, would doubtless soon be introduced; what its provisions would be, he could not say, though he ventured to predict that the Bill itself would be framed on the principle of general representation. Dr. COLLUM seconded the resolution. Mr. JOSEPH ROGERS spoke in favour of it. His remarks were chiefly retrospective; the Council, he said, had not studied the interest of its Members in the past, and he had no confidence that they would do so in the future. Dr. GOODING supported the motion. Many Members of the College, he said, held in addition degrees at one or other of the Universities. They obtained honours in social as well as in professional circles; he failed to see on what grounds the Council could withhold the privilege claimed by the Members. After speeches from Mr. George Brown and others, and a few words of reply from Mr. Gamgee, who deprecated raking up the past, the motion was put, and carried by an overwhelming majority. Mr. NELSON HARDY tried to bring forward the multiplicity of medical schools, but the meeting declined to hear him. Mr. PAUL SWAIN then moved "That in the opinion of this meeting no alteration in the constitution or in the relations of the College, or in any of its by-laws or ordinances, shall

be effected without the consent of the Fellows and Members convened to discuss such alterations." He adverted to the somewhat irregular proceeding of the Council in not having formally proposed that the Report be accepted previous to its being discussed, thus depriving the Members of making any suggestions or alterations. It was in itself another instance of how the Body Corporate of the College were disregarded by the Council. The great alteration which the Council had recently made with regard to the license without the consent, almost without the knowledge, of either Fellows or Members. The whole scheme was conceived and carried out in a panic. This being carried, it became necessary to provide a site on which to erect suitable buildings for examination purposes, which would involve the Council in an expenditure of between 2,000*l.* and 3,000*l.* per annum, besides the cost of the buildings. However wise such a course might be, it would have been well to take counsel of the Fellows and Members before agreeing to the scheme. Dr. DANFORD THOMAS seconded the resolution, which was unanimously carried without further discussion. Mr. PARKER YOUNG then proposed (and Mr. GEORGE BROWN seconded) that the meeting be adjourned until the 19th of November, in order to give the Council time to consider and report to them on the resolutions which had just been passed. After consultation with the secretary and (it was supposed) the legal advisers of the Council, the President declared that he could not put the resolution. The by-laws not permitting it, Mr. Tweedy said that, if that were so, it was in accordance with a by-law which had been specially framed to exclude both Fellows and Members, and prevent them from holding meetings on their own account. After considerable discussion and the exhibition of some feeling, the President accepted a show of hands as a requisition to the Council that another meeting should be held. He promised that this should take place without any unnecessary delay. Mr. Hawkins proposed a vote of thanks to the President for his conduct in the Chair, which was seconded by Dr. Collum, and carried by acclamation.

THE third Hospital Sunday was observed at Brighton on Sunday last.

ON Friday, the 23rd inst., the Lord Mayor, M.P., entertained the Senate of the University of London, of which he is a member, and several other distinguished guests, at dinner at the Mansion House.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At the annual meeting of this College, held on Wednesday week, Dr. Douglas Argyll Robertson was unanimously elected President for the ensuing year.

LUMBAR NEPHRECTOMY.—Mr. Clement Lucas operated on October 20th, in Guy's Hospital, upon a woman, *æt.* 35, who had been tapped for hydronephrosis in May of this year. The organ was exposed by the "oblique-crucial" incision employed by Mr. Lucas, and removed without injury to the peritonæum. The patient's temperature during the week following the operation did not reach 100° at any hour, and she is in a fair way to recovery.

ABERDEEN UNIVERSITY.—The winter session of the Faculty of Medicine commenced at Marischal College on the 21st inst. There was a large muster of students, and in most of the classes the Professors delivered introductory addresses. A course of lectures has been arranged under the Combe Trust by Professor Stirling, on the subject of the physiology of food, digestion, respiration, and ventilation.

MANCHESTER PATHOLOGICAL SOCIETY.—The following office-bearers were elected at the annual meeting on the 14th inst.:—President, H. Ashby, M.D.; Vice-Presidents, J. Dreschfield, M.D., A. W. Stocks, Esq.; Treasurer, Judson S. Bury, M.D.; Secretary, A. H. Young, M.B.; Committee, J. Dixon Mann, M.D., J. Broadbent, Esq., A. H. Griffith, M.B., H. R. Hutton, M.D., H. G. Brooke, M.B., T. C. Railton, M.D.

SMALL-POX AND FEVER IN THE METROPOLIS.—The returns read at the meeting of the Metropolitan Asylums

Board on Saturday showed that the small-pox epidemic was evidently dying out with rapidity, inasmuch as only 25 fresh cases had been received in the fortnight, 44 had been discharged, and there remained only 106 patients under the care of the officers, one being in the south-east (Dptford) asylum, and the others in the hospital ships. The numbers showed a decrease of 24 upon those of a fortnight ago. With regard to fever, the like favourable account could not be given, for there were 298 scarlet fever cases in the urban asylums, 35 cases of enteric fever, and 11 other cases of fever—in all, 344, as against 275 a fortnight ago.

**MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.**—The winter session of 1885-86 will be inaugurated on Monday next, November 2nd, when an introductory address will be delivered in the theatre of the institution at 10 a.m. by Dr. Arthur Wynne Foot, the senior physician of the hospital. In the evening a dinner for the re-union of old students and the governors of the hospital will take place at seven o'clock in the Shelbourne Hotel, St. Stephen's Green, Dublin. Arthur Wynne Foot, Esq., M.D., F.K.Q.C.P., Senior Physician to the Hospital, will preside. The Honorary Secretaries are Professor Rawdon Macnamara, Dr. John William Moore, Mr. William J. Hepburn, and Mr. Charles M. Scott, and the Honorary Treasurer is Mr. Lambert Hepenstal Ormsby. One or two guests may be invited by each governor or old student who wishes to dine on the occasion of what is now an established annual reunion.

**THE PAUPER LUNATIC ASYLUM FOR MIDDLESEX.**—The report of the Justices' Committee appointed to provide an additional asylum for pauper lunatics of the county state that they have selected the Birch Hall Estate, Theydon Bois, Essex, for which they had entered into a provisional contract for 12,750*l.*, and the requisite steps for obtaining the sanction of the Home Secretary have been ordered to be taken.

### DEATHS.

GARLAND, HENRY, L.R.C.P., L.S.A., formerly of Walworth, at Herne Bay, on October 14th, aged 63.  
MASON, DR. GEORGE, Inspector-General R.N., at Burgoyne Villa, Nelson Road, Southsea, on October 20th, aged 58.  
RICHARDSON, HENRY, Fleet Surgeon R.N., at Castle Terrace, Berwick-on-Tweed, on October 25th, aged 68.  
SMYTH, ARTHUR VEREKER, Staff Surgeon R.N., at Bexley Heath, Kent, on October 13th, aged 37.

### NOTES, QUERIES, AND REPLIES.

#### THE BRADLEY FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—I feel I should be very remiss in forwarding what I believe will be the last list of subscriptions, without, at the same time, thanking you for your kindness in having assisted in so good and popular a movement, not only by throwing open your columns, but also by your able advocacy. Several friends, who have taken a keen interest in the matter, think there should be a public presentation, and, as Sheffield is the nearest large town to the village of Brimington, where Dr. Bradley practised his profession, that it should take place there; consequently it has been decided that the money subscribed, together with an address, shall be given publicly. Every subscriber will receive intimation of the date and place of presentation. Also, if you would kindly allow me to publish it in the pages of the *Medical Times*, you would add very materially to the aid you have already given.

I remain, yours faithfully,

RICHARD JEFFREYS.

Eastwood House, Chesterfield, October 28th, 1885.

Dr. Ewing Whittle, £3 3*s.*; Medicus, £1; Dr. C. R. Illingworth, Dr. John Ringwood, each 10*s.* 6*d.*

#### MEDICAL EDUCATION IN SPAIN.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Will any of your numerous subscribers be good enough to give me some information regarding the present state of Medical Education in Spain? Or, failing that, would anyone kindly tell me where to apply for such information? Trusting I am not occupying too much of your valuable space,—

I am, Sir, yours, &c.,

CHAS. HARVEY

Edinburgh University, October 27th, 1885.

## LECTURES ON THE PRINCIPLES OF THE PRACTICE OF MEDICINE.

By W. H. SPENCER, M.A., M.D. Cantab., F.L.S.,  
Senior Physician to the Bristol Royal Infirmary, Lecturer on  
Medicine and on Pathology at the Bristol Medical School.

### LECTURE I.

*The Scope of Medicine as a department of Knowledge.—  
Health and Disease.*

IN the study of any department of knowledge we must begin by specifying the subject we propose to investigate. We must mark off the field of our investigations, and separate it clearly from other departments of knowledge. The subject of chemistry may be specified as being the combinations of matter to form new substances and the decompositions of matter into constituent substances. The manner both of union and separation is not known to any other department of nature, and is therefore special to chemistry. The subject of biology may be specified as being the phenomena relating to living things (animals and plants). In the study of biology it is necessary to subdivide the department; each subdivision, however, has its special subject. Thus, we have the branch of knowledge called anatomy, and another branch called physiology. The subject of the former is specified as being the

VOL. II. 1885. No. 1845.

form or structure of living things: of the latter the activities of living structure.

The subjects of these and of such-like departments of knowledge are cultivated and studied for the sake of gaining knowledge of Nature, and without intention to put the knowledge to any special use. Albeit the knowledge gained within any of these departments is *available* for use in the investigation of the subject of any other department of knowledge, or for other purposes. Thus, biology avails itself largely in its own investigations of the knowledge gained by chemistry. So, also, chemistry avails itself of the knowledge gained by physics. On the other hand, the knowledge gained by physics and by chemistry may be used in a different way; it may be used to explain and improve processes in various arts and manufactures: and when knowledge is used in this way, it is said to be *applied*. Here we have a *practical application* of the knowledge proper to any department of nature.

The subjects of some departments of knowledge are cultivated and studied *from the first* with a view to practical uses—for use in a *corresponding art, and in that art only*.

In such departments study and investigation are undertaken with a view to the attaining certain ends and the effecting certain purposes. Knowledge is not only sought within the department, it is borrowed from other departments—indeed, from *any* available source, even the whole field of Nature. This collected knowledge is arranged and brought to bear upon the end

and purposes proper to the department and to its corresponding art. Such collections of knowledge are called *practical sciences*. Each practical science is marked off, and its subject is specified by the statement of the end and purposes proper to that practical science.

Medicine, in the widest acceptance of the term, is a practical science with a corresponding art. It cultivates, selects, and adjusts knowledge with a view solely to the practical use of it in the corresponding art; and the subject of medicine is specified by the statement of the end and purposes for which the knowledge is collected and acquired. The *science* of medicine includes the knowledge that is to be used in attaining the end in view. The *art* of medicine selects and takes so much of this knowledge as it can make use of in effecting its purposes, with the same end in view, and converts the selected knowledge into practical rules and precepts or maxims of practice.

What, then, is the end, and what are the purposes of medicine? The end or ultimate aim of all the knowledge that medicine does or can include is—health.

But, *what* is health? Almost everybody can say that he knows what health is. In common speech health is talked about as if it were a very well-defined thing, and a thing well understood. And no doubt it has a meaning, and can be understood, and is even intelligible as being the end of medicine, in the common and popular sense. But in the popular view, and with the popular experience, the meaning of health, both in itself for what it is and as being the end to which practical medicine works, is understood only in a loose and limited way. And the popular and limited view cannot give us clear and correct ideas about the end and purposes of medicine; it cannot make plain to us the scope of medicine as a department of knowledge; it cannot define *what has to be studied and investigated* as being the subject of the practical science medicine. Health, moreover, is indefinable.

Nevertheless, the popular view is founded upon a principle—the law of relativity of knowledge; and the common forms of speech declare the principle and conform to it. To express the fact of health, the possession of health and its abiding presence—in other words, the phenomenon health itself—one man will say that he has never known what it is to have a day's *illness*; another, meaning the same thing, will say that he has never had *even* a headache. The presence of health is affirmed by stating the absence of something else—in the one case, illness; in the other case, something which is represented by headache. Directly we begin to speak about health we find that, in order to be understood, we must speak about, or at least imply, a state of things that is *not* health; this other state of things comes into our minds as part and parcel of our notion of health. Indeed, we can form no conception of the state called health apart from another state which is opposed to it, as being a variation from it, a differing and contrasted state of things. This other state of things is the state called disease.

Our conception of *heat* depends upon experience of change from one temperature to another, provided the temperatures are wide enough apart, and the transition is abrupt enough, to create a distinct contrast; similarly for our notions of the property called *hard*. Once gained, this experience of change and contrast makes us to *know* the meaning of heat, or of hard, and enables us to understand what may be said about them. It is the same with regard to health. Experience of disease is needed to give us a notion of the meaning of health. This experience makes us to *know* the meaning of health, and enables us to understand what may be said about it.

The names used to express these opposed yet co-

related states—health and disease—have nothing in common; they are arbitrary names, used merely to distinguish the members of a couple—a couple whose members are mutually co-operative to the understanding of either of them. One name has no meaning, nor can it be explained without reference to the other; one member cannot be understood without experience of the other.

But although the meaning of one name and the understanding of the state expressed by it depend on the association of that name and state with the other name and state, we can fix our attention more upon one name and state than upon the other. We can speak of one state, and investigate it as a distinct phenomenon or set of facts, without *direct* reference to the other state.

The phenomena of the state health on the one hand, and of the state disease on the other hand, are ultimate facts of experience. Health is a positive state, a real experience. And to know and understand health, the state which is negative to it, viz., disease, must be experienced in some form or other. The state health is known only through and by means of positive experience of this other state. Each state is as real and as much a matter of positive experience as the other, although the terms positive and negative may be applied to them when we wish to designate them in particular relations. Let us illustrate this.

Suppose a person to have been always in a state of health, never to have experienced or seen in others any, even the slightest, form of disease. The experience of health would be positive to that person. Yet, to that person, health would have no meaning; it would be unintelligible to him, and he could neither describe nor explain it. Now, let such a healthy one catch small-pox, and go through the regular stages of that disease. The experience of the negative of his former state would teach the meaning of health, and the new experience—an experience of disease positive enough in itself—would be intelligible only by contrast with the former state, and this former state now becomes the negative of disease. Again, suppose a child who has been weakly and ill and suffering almost from its birth. That child's experience will be positive and an experience of disease, yet unintelligible as a state of disease until the child compares himself with strong and healthy children. By contrast of himself with these other children he learns to know their state, health, as the negative of his own experience, and he forms a true conception of his own positive state, disease, by contrast with its negative, health. Or, let the weakly child be made well; he would then experience in himself positively the state which before was negative, and whose meaning he had already learned in part.

In the couple, health—disease, disease seems in a special way to be the positive term and health naturally the negative term. Disease would seem to be, to our small-pox patient, naturally the positive and health the proper negative in his two experiences; and generally, this will seem to be the natural relationship of the terms of the couple, health—disease. This apparent natural relationship of the terms depends on the fact that whilst the one—health—brings pleasure, content, and sense of the happiness of living, the other—disease—brings pain, disquiet, and distress. Naturally, disease is the more prominent member of the couple; we prefer health, and seek it; disease is the destroyer of health. Although, to speak strictly, each member of the couple is as real in the positive place as it is in the negative place, yet the peculiar nature of the experiences denoted by the couple gives to disease a better title to the positive place than it gives to health.

A limited experience of a few examples of disease will give a meaning to health. Most people have had some experience of disease, in themselves or from observation of others. But the extent to which we can *know* the meaning of health, and can understand it as specifying the *whole* subject of medicine, depends upon the extent of our knowledge of disease. The more diseases we know, the wider becomes our conception of the state called health. Professor Bain's happy illustration of this point must be quoted in his own words:—

"Health to a rustic means the absence of a certain number of familiar diseases, catarrh, rheumatism, dyspepsia, measles, &c.; to a hospital nurse, it has a still wider meaning; to an institutional writer on medicine it means the exclusion of upwards of a thousand diseases."<sup>1</sup> Our knowledge of health as the end of medicine widens with and is at any given time co-extensive with our knowledge of disease. The complete conception of health would be gained if we could say in any particular case that all *possible* forms of disease were absent; at the present time our conception of health is comprised in the statement that all *known* forms of disease are absent.

Wherefore, the meaning of health as being the end of medicine is defined by our knowledge of disease. And our notions and knowledge of health, both in itself for what it is, and as being the end of medicine, are at the present time co-extensive with and limited to our present knowledge of disease.

A small experience of disease acquaints us with the fact that its presence is at all times, and in any form, undesirable; that it is often dangerous and sometimes fatal. Such an experience, coupled with the agreeable character of health, leads to the desire to preserve and maintain health—and this means, to get rid of disease. Hence the *purposes* to which the knowledge included in medicine is destined; and hence the *means* by which it is sought, by exercise of the art, to effect the purposes.

The *end* of medicine is health. What of the *purposes* of medicine?

Medicine proposes ends subordinate to the chief end which defines it as a practical science—purposes, let us call these subordinate ends. The science has an end, the art has purposes.

It is one of the purposes of medicine to hinder the operation of any causes that are known to endanger or destroy health; it is another purpose to effect complete restoration to health when the state of health may have been interfered with or destroyed; or again, in cases where complete restoration is impossible, it may be the purpose to effect the nearest possible approach to the state of health. And this is to say as much as that medicine purposes to prevent disease, or to cure disease, or to alleviate disease.

The end of medicine, then, is health; the purposes of medicine are the various subordinate ends proposed in dealing with disease, actively and by practice. By this statement, now intelligible to us, we have specified the subject of medicine as a practical science with a corresponding art.

It follows that our ability to attain the end and effect the purposes of medicine must depend upon our knowledge of disease. Our study and investigation in the department of knowledge, medicine, becomes therefore a study and investigation of disease, with a view to the practical end, health.

Let us now attend to that member of the couple, health—disease, called disease. Let us try to give clear ideas of what has to be studied and investigated; and thereby a clearer view of the other member of the couple, viz., health.

## CLINICAL LECTURES

### ADDRESSED TO STUDENTS ON THE METHOD AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the Principles and Practice of Medicine and on Clinical Medicine.

#### LECTURE IV.—CASE TAKING.

##### *The Personal History.*

HAVING obtained all the information that you can in respect to the family history of your patient and thereby furnished yourself with some knowledge of the predispositions which he may have, whether to health and long life or to certain special maladies, the next step is to ascertain how far these inherited tendencies may have been strengthened or weakened in his person; or what fresh liabilities the subject of your examination may have contracted himself. How far, in short, the circumstances of his individual existence have contributed to favour a continuance of health, or, if he be ill, to induce his present malady. A reference to the subjoined list of headings for enquiry, which make up the personal history of the individual, will show that for some of the circumstances he may be regarded as distinctly responsible, such, for instance, as to quantity and quality of his food, alcoholic excess, insufficient clothing, &c. Other circumstances, on the contrary, are essentials of his being, such as age and sex. Since the state of health, whether good or bad, of an individual at any given time is the resultant of the hereditary tendencies which he intrinsically possesses, and of the external influences which may be brought to bear on him, it follows that enquiry into what the extent and character of these influences may be should succeed to the knowledge obtained of ancestrally derived traits.

#### II. Personal History [distinct from present illness].

- |  |     |
|--|-----|
| Age  | Sex |
| Single, married (age at marriage), widow; number and ages of children; miscarriages.   |     |
| Place of birth; subsequent places of abode (town, country, abroad).  |     |
| Occupation; how long followed.   |     |
| Food (sufficient in quantity and quality); drink (beer, wine, spirits, tea; quantity); habitual use of other stimulants or sedatives (opium, chloral); smoking (extent of).  |     |
| Clothing (sufficiency; as to wearing flannel).   |     |
| Exercise (amount and character of; athletics); amusements.   |     |
| Overwork (mental and bodily); anxiety. Over-lactation.   |     |
| Temperament (nervous or excitable, sanguine, bilious, phlegmatic, lymphatic, melancholic).   |     |
| Idiosyncrasies (as to food, drugs, etc.).  |     |
| General state of health.   |     |
| Appetite (good, indifferent, bad, capricious).   |     |
| Bowels (regularity of).  |     |
| Sleep (amount, soundness).   |     |
| Age at commencement of menstruation; regularity of.  |     |
| Previous diseases or accidents, their dates of occurrence and duration. Especially note occurrence of minor ailments to which patient may be subject, <i>e.g.</i> , repeated colds or sore throats, frequent headaches, cutaneous eruptions. |     |

<sup>1</sup> Bain's Logic. Vol. i., p. 61.

tions, epistaxis, or discharges of any kind. And specifically state whether patient has or has not suffered from Gout, Rheumatism or Rheumatic Fever, Scarlet Fever, Typhoid Fever, Measles, Whooping Cough, Hæmoptysis, Syphilis.

Previous attacks of present illness, if any, with dates of, and duration of, occurrence.

*Age.*—In what way does a knowledge of the age of the individual assist in forming a judgment as to his probability of healthy life, or, if ailing, how does it contribute to the formation of a diagnosis? This is the question before us, and, to answer it, we must have some preliminary knowledge as to what is the duration of human life. One of the gifts of every living thing's inheritance is the tendency to death. And as living may be said to be the resistance to this tendency, which slowly and surely gains ascendancy and triumphs, so disease may be considered as intervals in which this tendency has the opportunity of asserting itself before that time which general experience has led us to expect that life should end. Just in proportion to the severity of an illness is the sufferer's nearness to death, and equally, the older he grows, the closer he approaches the same fate. The common lot which will one day befall each one has occasional opportunities of happening, so to say, before its time. What then is the time at which it may be expected? The average expectation of life of every male child born in England is reckoned at 39·91 years, and of every female at 41·85 years. This, which may be called the average longevity of the race, is obtained by dividing the total duration of life (from an hour to a century) of all born within a given period by the number of those born. The calculation is based on the census returns for 1841 and 1851 for England and Wales, together with the register of deaths for the 17 years from 1838 to 1854, and was made by the late Dr. William Farr, and published in 1864 in the "English Life Table." This expected duration of life obviously falls short of what is very frequently reached, but the low figure is due to the great mortality in infant life, which keeps down the average. Any improvement in the death rate will tend necessarily to raise this average, and the more recent censuses and registers of deaths distinctly show an improvement and have justified Mr. Noel Humphrys in concluding that "the decline in the death rate, measured by the life table method, is to raise the mean duration of life among males from 39·9 years to 41·9 years, that is, about two years, and among females from 41·9 to 45·3, an increase of nearly three-and-a-half years." In the same way the expectation of life at every year of age is computed, forming a table upon which are based many of the calculations connected with life insurance. Thus a male who has attained the age of twenty years may, according to this table, expect to live another 39·48 years, that is until about 59½. As I have said, a table, constructed on the same principle, but upon the more recent data, would give a higher rate of expectation at almost all ages.<sup>2</sup>

Turning to those lives which exceed the average duration, we are led to ask what may be the extreme limit of existence, the potential or possible longevity, the "lease of life" of the individual. That people may

live beyond a hundred years is now recognised as a fact, although some caution is required in accepting the statement in every case; the sources of error in record and in recollection being so frequent. In the Registrar General's report for 1883, out of 522,997 deaths in England and Wales, 63 were reputed to be centenarians (13 males and 50 females), and of these one, a male, reached 107 years, 2 males and 1 female attained 106 years, and 2 males and 2 females died aged 105 years.

Age.	Male.	Female.	Age.	Male.	Female.	Age.	Male.	Female.
0	39·91	41·85	35	29·40	30·59	70	8·45	9·02
1	46·65	47·31	36	28·73	29·94	71	8·03	8·57

23	37·46	38·33	58	14·68	15·55	93	2·41	2·55
24	36·79	37·68	59	14·10	14·94	94	2·29	2·42
25	36·12	37·04	60	13·53	14·34	95	2·17	2·29
26	35·44	36·39	61	12·96	13·75	96	2·06	2·17
27	34·77	35·75	62	12·41	13·17	97	1·95	2·06
28	34·10	35·10	63	11·87	12·60	98	1·85	1·96
29	33·43	34·46	64	11·34	12·05	99	1·76	1·86
30	32·76	33·81	65	10·82	11·51	100	1·68	1·76
31	32·09	33·17	66	10·32	10·98			
32	31·42	32·53	67	9·83	10·47			
33	30·74	31·88	68	9·36	9·97			
34	30·07	31·23	69	8·90	9·48			

The lifetime of an individual is divided into certain periods which successively merge, one into another, and which in the main are characterised by distinct and recognisable structural conditions and functional manifestations both of health and disease. These periods are three in number—the stage of development or evolution, the stage of maturity, and the period of decline or dissolution, or, as it has been conveniently termed, involution. Each of these periods may for convenience be further subdivided, but the distinctive characters of these lesser stages are subordinate to those essential differences which markedly distinguish from one another the three main periods, the leading features of which you will do well to keep before you.

The period of development extends from the impregnation of the ovum to the complete growth of the body and differentiation of its component tissues, and comprises the stages of (1) *fœtal life*; (2) *infancy*, from birth to the time of the first dentition; (3) *childhood*, from the appearance of the milk teeth to the cutting of the first of the permanent set, that is from the end of the first year to the seventh year; (4) *boyhood* or *girlhood*, which extends from this time up to puberty at about 14 or 15 years of age; (5) *adolescence*, which denotes the interval from puberty to complete development at about 24 or 25 years.

The duration of mature life is not so easy to define, owing to the variability in time of its further limit, or, in other words, the different ages at which different

<sup>1</sup> *Journal of the Statistical Society*, June, 1883.

<sup>2</sup> I should say that this table is not the one actually used by the greater number of Life Insurance Companies, who more commonly employ one of those computed on the results of their own experience, such as that of the 17 offices published in 1843, or the table of the Institute of Actuaries published in 1869. Based as these are upon a select class of the population, reputed to be healthy, and rarely including lives before the age of 20, the "expectation of life" at each age is somewhat higher than that in Dr. Farr's table, which includes all the populations at all ages, and which better serves to illustrate my present purpose.

people commence to decline. By some maturity is regarded as corresponding to the period during which the reproductive power persists, but this offers a great contrast in the sexes; for, whereas the capability of child-bearing usually ceases in women at about the age of 45, the procreative power usually remains in men for many years later. For our purposes, considering, as we are, the influence of age on the incidence of disease, I think we may speak of maturity as lasting from 25 to about 55 years of age, a date which corresponds to the climacteric in men, as that of women occurs about ten years earlier.

The period of decline is rarely marked off by any sharply distinguishing feature from that which has preceded it. Slowly and gradually the individual fails in his powers; the physical properties of his tissues, their flexibility, rigidity, and especially the important qualities of permeability and elasticity, become progressively impaired; the vital activity of the protoplasmic elements of his organs, their contractility, nutritive and metabolic power, and capability of multiplication, slowly deteriorate, and, with the obvious structural changes comprised in the term degeneration, the individual becomes functionally less capable. Differing from the days of maturity, in which the formative and reparative powers of the body successfully held their own against the inherent death tendency, and for a period of 25 or 30 years the individual remaining in about the same condition, the same powers, when decline commences, gradually fail; and, though occasionally we meet with cases of exceptionally good health, in which for a few years the individual remains tolerably stationary in his vitality, the majority slowly deteriorate from year to year; and, though it may be difficult exactly to define when old age commences, it may be convenient to consider that senility is fully established at the age of 80.

The most superficial comparison of these three main age periods cannot fail to suggest the important distinctions they present as regards the health powers of the individual and the varying liability they offer for the production of disease, and for the course of a disease when once established. Thus it is that, due to the very altered conditions of environment of the infant, the adult, and the old man, no less than to difference in power of the inherent tendencies at these ages, very different diseases are induced; a wholly distinct rate of mortality prevails; and even the same diseases at these different periods run most distinctive courses and call for most diverse prognoses. Especially is this seen in those minor ailments and sicknesses to which no special name can be easily applied, and which are seen so much more frequently outside the walls of a hospital than in the wards, where for the most part well marked cases of disease are met with.

The influence of age *per se*, on the occurrence and progress of disease, may be said to be exerted in virtue of the variable environment which it determines for the individual and the degree of power of the inherent death tendency associated with it. In a healthy person, who lives to the age of 80, this tendency is obviously stronger at 60 than when he was 20, and it is this fact, expressed in figures, which constitutes the table of expectation of life. Either of these factors may predominate favourably or unfavourably; thus the natural tendency towards a long life that an individual may inherit is counteracted, and illness or death follows the living in unsuitable or unhealthy surroundings; or, on the contrary, exceptional care in the selection of the environment may avert for a time the inherent liability to death which, unless so guarded against, would have asserted itself before. That age itself, with all that it may be thus said to imply, does exert a most distinct influence both in causing disease and determining mortality will be evident from the

following table, extracted from the 46th Report of the Registrar General for 1883:—

DEATH RATES OF MALES and FEMALES per 1,000 living at 12 age periods from 1881-1883, compared to Average of 1838-1883.

YEARS.	MALES.		FEMALES.	
	1881-83	1838-83	1881-83	1838-83
All Ages ...	20.5	23.0	18.3	21.0
0 ...	59.4	70.8	50.4	60.9
5 ...	6.1	8.1	5.8	7.8
10 ...	3.2	4.5	3.3	4.7
15 ...	4.6	6.3	4.3	6.8
20 ...	6.1	8.5	6.0	8.0
25 ..	8.3	9.6	8.0	9.6
35 ...	12.9	13.1	11.0	12.2
45 ...	19.4	18.9	15.2	15.6
55 ...	34.0	32.8	28.0	28.0
65 ...	68.0	67.5	58.7	59.8
75 ...	143.9	147.8	128.4	134.5
85 and above	292.3	313.9	266.4	288.8

This table shows the death-rate from all causes at twelve successive age periods, and, besides demonstrating how considerably the rate varies with the age, it indicates the period of life at which fewest deaths occur, viz., 10 to 15 years, to which minimum the rate slowly falls from birth and subsequently rises, at first gradually, but afterwards more rapidly, to the end of life. The difference in rate in the two sexes is also apparent, and by comparing the average rate for the three years 1881-2-3 with the average for the 45 years 1838-83 the improvement in the death-rate, *i.e.*, the diminished mortality which has taken place in males at all ages, except from 45 to 75, and in females at all ages, is evident.

(To be continued.)

## ANÆSTHETICS AT SOUAKIN.

By J. EDWARD SQUIRE, M.D. Lond., M.R.C.P.,  
Lately Senior Medical Officer at Souakin to the National Aid Society.

AMONG my medical observations made at Souakin, some notes on the employment of anæsthetics come first in point of time, and may be of sufficient interest to merit publication.

I arrived at Souakin as one of the medical officers of the National Aid Society whilst the first skirmish with the Arabs at Hasheen was in progress, and Surgeon-General Barnett, the Principal Medical Officer to the Force, was good enough to attach me at once to the Base Hospital at H Redoubt. Here I was at first posted as assistant in one of the divisions, and subsequently had charge of the second division, consisting of 80 beds, which I retained till the hospital was closed at the end of the campaign. For a time, whilst numerous encounters with the enemy gave a prominence to surgical work in the hospital, some previous experience in the subject led to my appointment as chloroformist, and I was relieved from ward duty in order that my services might be available for every operation. One tent in the hospital camp was specially reserved as an operating tent, and this, under the direction of the Field-Surgeon (Surgeon-Major Tobin, late Assistant Professor of Military Surgery at Netley), was most conveniently arranged. There was a good operating table of suitable height, and, as far as convenience was concerned, we were not far behind a London hospital.

Both chloroform and ether were available, but the condition of the patients made me decide to use ether

aloue, as less likely to depress the heart than chloroform. The ether used was Savory and Moore's Anæsthetic Ether of specific gravity 0.720, which kept well as long as the cork was not drawn. When once opened the stopper was continually lifted by the vaporization of the ether, and much was lost if the bottle was not quickly used. The inhaler I used was Ormsby's, which is most simple and convenient.

The patients to whom anæsthetics had to be administered were, of course, those wounded in our engagements with the enemy, and from the nature of the climate and the exertion which they had had to undergo, they were always much pulled down before receiving the wound. A long march, or perhaps a few days in the open in a zariba with no shelter, scanty food and very little sleep, followed by the fatigue and excitement of fighting, do not constitute a good preparation for a surgical operation; and in many cases the men had to be operated on after a long and trying ride of five or six miles in a dhooli with short allowance of food and water. As a result many of our patients came on to the table with weak and sometimes almost imperceptible pulse; and in the few cases in which operations were performed directly after the receipt of the injury, shock—sometimes very severe—was added to the debility of the patient, and still further diminished the strength of the pulse. In addition to these causes of debility in the patients, the temperature of our operating tent was always comparatively high. Taking all these points into consideration, it seemed unwise to use chloroform, which might depress the heart, while ether, from its stimulant action, appeared to be exactly what was required. I was, however, surprised at the extremely satisfactory effect of the administration of ether. The pulse quickly gained in strength, and the improvement was maintained in all cases as long as the anæsthetic was administered. In the case of a marine whose leg was smashed by being run over by the train just outside the hospital camp, and who was brought straight to the hospital, the shock was most marked, and the pulse at the wrist almost imperceptible. It was, in fact, doubted whether he could survive long enough to have the limb amputated. In order to spare him the pain of moving him on to the operating table, I gave him ether while he was lying on the stretcher on which he had been brought in. His pulse improved almost immediately, and it remained fairly good throughout the operation, which lasted about an hour.

Most of the men took the ether well; some few struggled against it at first, but soon became quiet on the anæsthetic being pushed. Three or four patients had hiccough towards the close of a somewhat lengthy operation, but this quickly passed off on allowing the patient a few inspirations of air and lowering the head or drawing up the chin. By taking care that the patients had no food for some time before taking the ether, we had very little vomiting either during or after the operation.

In some cases I found, what I have noticed at home, and what must have occurred to most administrators of anæsthetics, that patients who took the anæsthetic badly and required a long time to get under, remained in an unsatisfactory state of incomplete relaxation of the muscles during the chief part of the operation, but when the inhaler was removed to allow of return to consciousness, the anæsthesia became more intense, the pupils getting small, almost to the vanishing point, and the patient was put to bed in a condition which would have pleased everyone concerned if it had occurred early in the operation. These patients always slept soundly for a time, and came round quietly and with no disagreeable consequences.

Only in one case was I obliged to use chloroform, the

spasm caused by the ether being so marked that the patient could not take it. In this case, after producing partial anæsthesia with chloroform, I substituted ether for the rest of the time. In giving ether in this hot climate, I observed that a longer time was required before the patient became fully under the influence of the anæsthetic. Probably from the rarefaction of the ether vapour by the high temperature, the equivalent of ether taken by the patient at each inspiration is less than would be the case in a moderate temperature, and the number of inspirations required before an effect is produced would thus be greater than in a cooler climate. For a similar reason, the inhaler must be carefully fitted to the face to prevent escape of the vapour. At first I began the administration by using the inhaler so that a certain proportion of air was allowed to enter along with the ether at each inspiration, but I soon found that it was better to allow the ether to be inhaled without any extraneous air.

The phenomena noticed during the progress of the inhalation and their order were the same as usual. The perspiration which occurs under the influence of the ether was very marked, all the conditions being such as would favour dilatation of the superficial capillaries. In each case I noticed nystagmus and marked contraction of the pupil when the patient was fully under the influence of the ether, and during the administration the pulse first quickened and then became slower, and increased in fulness, while the respiration at first quickened and then became slow, and blowing or stertorous. I noticed also that the conjunctival reflex was abolished before complete relaxation of the muscles had occurred; and in some cases the sense of pain was completely annulled while talking and struggling still persisted. In such cases too, the conjunctival reflex had disappeared at this stage, showing that what were apparently voluntary movements were purely unconscious.

---

#### CASE OF MELÆNA IN A NEWLY-BORN FEMALE CHILD—RECOVERY.

By HARRY V. WALKER.

Mrs. L. was confined with her fifth child early on the morning of Friday, October 9th, 1885. The labour was a very easy one, occupying little more than an hour. The child was large, to all appearances healthy and strong, and passed meconium soon after birth. Forty-eight hours after this the bowels again acted, and on removing the napkins the nurse found a quantity of blood mixed with the motion. When seen soon after this (10 a.m., Sunday, October 11th), the hæmorrhage had ceased. It recurred, however, at 11.30 a.m., and at 3 p.m. on the same day; also at 4 p.m., when the child seemed to be in pain and suffering from tenesmus. Black stringy clots were coming away *per anum* freely, together with an oozing of a "tarry" consistence. The child was white and feeble, the gums and lips very pale, nose and forehead quite cold, and it was evident that unless the hæmorrhage soon ceased death must result. A warm dilute solution of perchloride of iron was injected into the rectum, and two or three minims of the perchloride in a teaspoonful of water given by the mouth. In addition, a mixture of ext. ergot. lig. ℥ v, in glycerine and water, was ordered every hour if necessary, and small quantities of Mellin's food to be given frequently. Directly after the injection the child appeared to revive and the bleeding gradually stopped; the

infant was ordered to be kept moderately warm, in the horizontal position, and moved as little as possible. On Monday morning, October 12th, it was found that the child had passed no blood during the night, and had slept well; the ergot, therefore, had only been given three times. There was slight jaundice; nothing noticed about the abdomen; no spots of any kind. A mixture of ext. ergot. lig. ℞ v, tr. camph. co. ℞ ij, and potass. iod. gr.  $\frac{1}{2}$ , in glycerine and water, was ordered every three hours.

On Tuesday morning, October 13th, it was stated that the hæmorrhage had appeared once or twice the day before in small quantities, and a good deal of pale urine had been passed. According to the nurse the child looked "as yellow as a guinea" this morning, early. Wednesday, October 14th.—No bleeding since Monday, October 12th; child has passed no motion since October 11th. Half a drachm of ol. ricini to be given, and repeated in two hours if necessary. Infant takes the breast and Mellin's food alternately. Saturday, October 17th.—The bowels acted three times after the second dose of the oil on October 14th, and a little hæmorrhage followed. The child is much stronger and takes its food well. Saturday, October 24th.—No appearance of hæmorrhage since October 14th. When seen on this date, the child was doing well.

There is a history of phthisis on the mother's side. The fourth child died of marasmus when a few months old; the other children are markedly strumous in appearance. It is uncertain whether the father, who is a deaf-mute, has had syphilis or not. It seems probable that there was some hæmorrhage into the stomach, as the child was seized with vomiting a few hours after its birth, but only a little glairy mucus was expelled. This was repeated from time to time until Sunday, October 11th, when melæna appeared. No blood was vomited at any time. None of the other children have suffered from melæna or hæmatemesis. Under the circumstances it is impossible, with any degree of certainty, to assign a cause for the hæmorrhage in this case.

EVELINA HOSPITAL FOR SICK CHILDREN.

---

CASE OF VESICAL CALCULUS IN A FEMALE  
CHILD—OPERATION—CURE.

(Under the care of Mr. CLEMENT LUCAS.)

We are indebted to Mr. CARPENTER, the Registrar, for the following Report.

---

H. L., a female, aged ten, was admitted into the Evelina Hospital on September 23rd, 1883, suffering from very severe pain on micturition, so great that she would scream for five minutes at a time when passing water. There was also hesitation at the commencement of micturition, and sometimes interruption during the act.

The history of the case was as follows:—Two years ago, in 1883, she told her parents that she had swallowed a pin, but she was not seen to swallow it, they only had the child's word for it. Fifteen months later the pin was passed in the water. It

was a long pin with a black-beaded head, and when seen was encrusted with phosphates. She has always suffered from pain on micturition since. The case was sent to the hospital from the country by Dr. Farr, of Andover, on the suspicion of stone, but she had not been sounded.

On admission she was placed under chloroform and sounded, when a stone was felt.

On September 30th, the patient, having been given chloroform, was placed in the lithotomy position. A three-bladed female urethral dilator was passed into the urethra, and, the stone being felt, the passage was rapidly dilated to the extent of admitting the finger. A large stone was easily detected. Lithotomy forceps were then inserted and the stone seized, but it crumbled during seizure, and was extracted piecemeal. During the operation the bladder was syringed out with a 1 in 40 solution of carbolic acid, and also again at the conclusion of the operation. On examining the stone it was found to be composed of phosphates, there was no nucleus, and the pieces weighed 140 grains.

Three hours after the operation the patient called for the chamber utensil, having held her water from the time of the operation. There was great pain on micturition, and a considerable quantity of blood was passed mixed with the urine. No inconvenience followed. An enema was given in the morning before the operation, and a normal motion followed.

October 1st.—She slept well, took plenty of milk, complained during the night of great pain on micturition, and passed much blood in the urine. This morning, has taken a little solid food, and plenty of milk. She passed water freely during the day, slightly discoloured with blood, and complained of slight pain on micturition. Her bowels were open once slightly during the night, and twice during the day, the motions being normal. Temperature 98·2°.

2nd.—She slept well and passed water freely during the night, only slightly discoloured, but complained still of great pain on micturition. During the day she passed water, discolouration slight, pain slight. Bowels open once slightly during the night, and twice slightly in the day-time, motions normal. Temperature 98·2°.

3rd.—She slept well, and passed water once during the night, slightly discoloured, pain slight. Takes food well. Passed plenty of water with but little pain. Bowels open once slightly during the night, motion normal. No motion during the day. Temperature 98·3°.

4th.—The patient slept well and passed water once during the night, discolouration slight, and slight pain. She takes food well. She micturates freely and without pain. Bowels open once, motion slight, but normal. Enema given, but was unsuccessful, and the rectum had to be cleared out. Temperature 99·1°.

8th.—Continuing to go on satisfactorily; the patient to-day got up.

14th.—Since the last note patient has gone on remarkably well, the further progress of the case calling for no detailed account. She leaves the hospital to-day cured.

*Remarks by Mr. LUCAS.*—The lodgment of a calculus in the female bladder is an infrequent event, and the retention of a stone in the bladder of a female child extremely rare. So far as I can ascertain, this is the only case that has occurred at the Evelina Hospital since its foundation in 1869. We must attribute the formation of the calculus to the introduction of a foreign body into the bladder, and to the subsequent cystitis in this way produced. The child's explanation of having swallowed the pin is, of course, to be regarded with the scepticism one always extends to the remarks of those who speak in fear of the truth. No doubt

the pin was introduced into the urethra, and its discharge, when coated with phosphates, is a proof of the irritation it excited. Probably some part of the coating became separated from the pin during the efforts which led to its expulsion, and became the centre of the calculus extracted. The absence of any nucleus of oxalate of lime or uric acid points very strongly to the probability of the calculus having taken origin in mechanical cystitis, produced by the foreign body. It is not a little remarkable that after the enormous size to which this child's urethra was dilated no incontinence whatever followed. The child held her water for three hours after the operation and then called for a utensil, and subsequently passed her water normally.

## APPOINTMENTS FOR THE WEEK.

*Friday, November 6 (this day).*

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, 8 p.m.—Mr. H. Percy Dunn, "A Collection of Specimens of Sarcoma and Carcinoma from Patients who have died in the West London Hospital during the last Fifteen Months"; Dr. C. Wells, "Specimen of Cancer of Colon"; Dr. Savill, "Microscopic Specimens of Cancer"; Mr. C. B. Keetley, "Case of Gritti's Amputation"; Dr. Alderson, "On the Ætiology of Cancer chiefly as to Local and Mental Causes"; Mr. H. Percy Dunn, "On the Theory of Cancerous Inheritance."

INSTITUTE OF CHEMISTRY, at Burlington House, 4 p.m.—To celebrate the Incorporation of the Institute by Royal Charter. Address by the President, Professor Odling, F.R.S.

*Monday, November 9.*

MEDICAL SOCIETY.—Clinical evening. Living specimens at 8 p.m. Dr. T. D. Savill, "Case of Myxœdema in the Male"; Mr. E. H. Fenwick, "Case of Extensive Varicosity of Abdominal Veins"; Dr. C. E. Beevor, "Cases of Athetosis"; Mr. John H. Morgan, "Case of Abdominal Tumour in a Boy"; Dr. J. K. Fowler, "Case of Bullet Wound of Thorax."

*Tuesday, November 10.*

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 p.m.—Dr. Stevenson Thomson, "Scarlatinal Albuminuria and the Pre-albuminuric Stage studied by frequent Testing"; Mr. Arthur Barker, "On some Points regarding the Distribution of the Bacillus Anthracis in the Human Skin in Malignant Pustule."

ANTHROPOLOGICAL INSTITUTE, at 3, Hanover Square, W., 8 p.m.—Mrs. Bryant, D.Sc., "Experiments on Testing the Characters of School Children"; Mr. Joseph Jacobs, "A Comparative Estimate of Jewish Ability."

*Wednesday, November 11.*

EPIDEMIOLOGICAL SOCIETY, 8 p.m.—The President, Dr. Walter Dickson, will deliver an Inaugural Address on "Recent Epidemics at Home and Abroad."

PHARMACEUTICAL SOCIETY, 8 p.m.—Mr. Charles Umney, "On the New British Pharmacopœia."

ROYAL MICROSCOPICAL SOCIETY, 8 p.m.—Mr. W. B. Turner, "On some new or rare Desmids"; Dr. E. Giltay, "On the Amplifying Power of a Lens or Objective"; Mr. F. Crisp, "Limits of Resolution in the Microscope"; Dr. E. Crookshank, "Microbiological Technique."

BRITISH GYNÆCOLOGICAL SOCIETY, 8.30 p.m.—Specimens by Mr. Lawson Tait and others. Dr. Imlach, "Treatment of Prolapsed Ovaries by Oöphorraphy"; Dr. R. T. Smith, "Fissure of the Cervix."

*Thursday, November 12.*

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 8.30 p.m. Living specimens at 8 p.m.—Dr. Sharkey, "A Case of Locomotor Ataxia with Ophthalmoplegia Externa and Interna"; Mr. Lang, "Pemphigus of Conjunctiva"; Mr. Snell, "Foreign Bodies in the Back Parts of the Eye, with Preservation of Sight"; Mr. Jessop, "On a Case exhibiting Definite Movements of the Pupils in association with the Extrinsic Movements of the Eye"; Mr. Nettleship, "Note on Gelatine Discs of Cocaine"; Dr. Samuel West, "Case of Double Optic Neuritis after a Fall; Perfect Vision throughout; Recovery"; Mr. Higgens, "Neuro-paralytic Ophthalmia."

*Friday, November 13.*

CLINICAL SOCIETY, 8.30 p.m.—Dr. S. West, "A Case of Idiopathic Purulent Peritonitis in a Child of Ten, with Autopsy"; Mr. Rivington, "Two Cases of Ligature of the external Iliac Artery for Femoral Aneurysm"; Dr. Dyce Duckworth, "A Case of Nitric Acid Poisoning"; Mr. Barwell, "A Case of Gastrostomy." Living specimens: Dr. Kingston Fowler, "A Case of Pseudo-hypertrophic Paralysis in an Adult"; Mr. Bernard Roth, "A Case of Severe Lateral Curvature of the Spine"; Dr. Crocker, "A Case of General Discolouration"; Dr. Colcott Fox, "A Case of Pigmentary Disorder"; Mr. John Morgan, (1) "A Case of Gastrostomy," (2) "An unusual Form of Spina Bifida"; Mr. Clutton, (1) "Cervical Spina Bifida undergoing Spontaneous Cure," (2) "Tubercular Ulceration of Palate"; Mr. Walsham, "A Case of Acute Spreading Obliterative Arteritis."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Special Meeting, 9 p.m. The Bowman Lecture, by Dr. Hughlings Jackson, F.R.S.

# Medical Times and Gazette.

SATURDAY, NOVEMBER 7, 1885.

LAST Monday's sitting of the Medical Society was devoted by special arrangement to a discussion on the clinical significance of the deep reflexes, the subject being introduced in an admirable manner by Dr. Gowers. After some preliminary remarks on the nature of the tendon reflexes, he proceeded to express his conviction that the knee-jerk is always present in some degree in health; its absence he considers a most valuable sign of early locomotor ataxy, but its absence must be proved by a rigorous and careful examination. The loss of the knee-jerk in diphtheritic paralysis and pseudo-hypertrophic paralysis was also mentioned; indeed, in the latter disease Dr. Gowers regards it as a diagnostic point of very great importance. Ankle clonus he regarded as a very valuable sign of organic disease. Two fallacies, he pointed out, require to be guarded against in these examinations; the first is that the knee-jerk, though really absent, may be simulated by an excess of superficial reflex action, and the other, that in hysterical contracture a clonus is often obtained that is spurious, being due to a voluntary contraction of the muscles of the calf. Dr. Gowers then went on to speak of the real nature of the so-called functional diseases of the nervous system, pointing out with much force that nutritional diseases would be a much better and more correct name for them. Dr. Hughlings

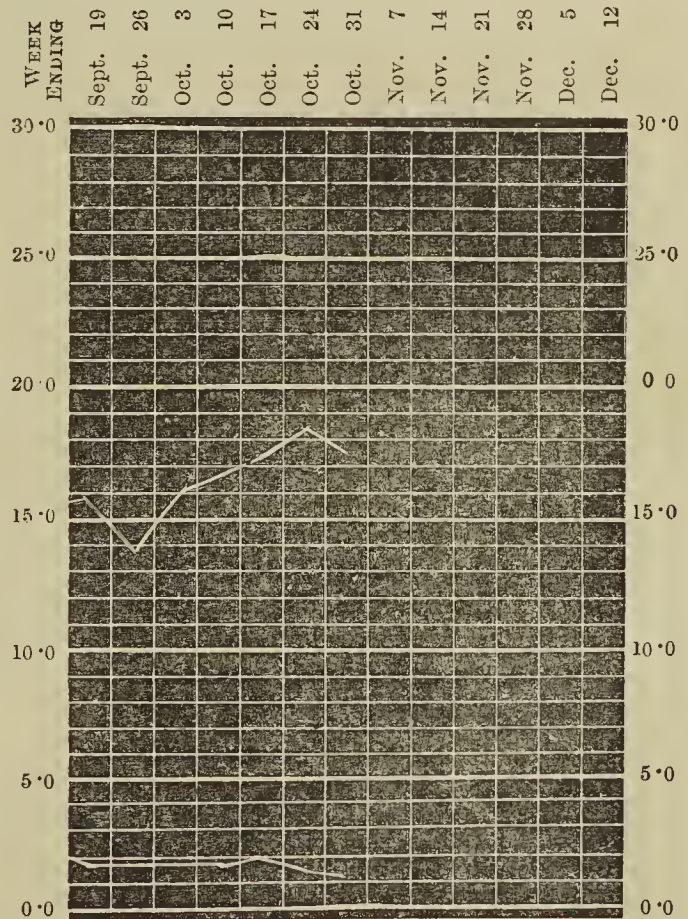

Jackson and Dr. Buzzard both agreed in the main with the views expressed by Dr. Gowers, and Dr. Althaus briefly alluded to one or two conditions which he thought ought to have been included in the paper. The totally unexpected collapse of the debate, through the unwillingness on the part of anyone to propose an adjournment, spoilt an excellent and instructive discussion, and seemed hardly courteous on the part of the Fellows towards the opener of the debate.

THE specimen which attracted most interest at the meeting of the Pathological Society on Tuesday last was one of spontaneous rupture of the bladder, brought by Mr. Hurry Fenwick. The patient from whom the specimen was taken had been a professional cornet-player, and had been seized, whilst playing, with severe abdominal pain, and no doubt at this moment the rupture took place, the contents of the bladder escaping into the pelvis; here they formed for themselves an extra-peritonæal sac, and for a time all went well; in fact, at the end of three weeks the patient seemed convalescent, but then this sac ruptured into the peritonæum, speedily setting up a fatal peritonitis. Mr. Fenwick offered alternative hypotheses to account for the disease which rendered the rupture possible, one of which, viz., that of the giving way of one or more tunicary herniæ, seems, especially after the remarks made by Mr. Arbuthnot Lane, a competent and likely explanation. Mr. Anderson showed an unusually large intracranial aneurysm, probably the largest on record; the case was peculiar in the fact that the symptoms were by no means always present. Dr. Norman Moore brought a very interesting specimen of endocarditis associated with atheroma of the aorta, but with no valvular disease, a condition which appears to be very rare, and which he thought might have been the result of syphilis. Many other specimens of interest were shown, to which we cannot here refer, notably a card specimen of black tongue, sent by Dr. Lediard, of Carlisle. We ought not, however, to omit to mention the admirable demonstration which Dr. Sainsbury's case elicited from Mr. J. B. Sutton on the mode of production of certain teratological tumours.

It is a matter for congratulation that the police authorities of the metropolis have decided to enforce with the utmost strictness the enactment which provides for the seizure and detention of stray and ownerless dogs. In certain of the London districts it is officially notified that such measures will be rigidly carried out "for a space of 60 days"; and all owners of dogs are earnestly admonished to permit free access to plenty of pure drinking-water. This is certainly a move in the right direction, and excellent so far as it goes. The fault, and it is a serious one, lies in the fact that it does not go far enough to ensure dealing comprehensively with the matter. It is all very well to enforce muzzling and to snap up stray dogs within a district where the appearance of some rabid cur has started something like a panic. But mad dogs are specially given to wander, and preventive measures which do not recognise this fact, and the

essentially sporadic character which an outbreak of hydrophobia is thus apt to assume, may indeed prove of some selfish value by their local effect, but are little better than a delusion as regards promptly and completely stamping out the mischief traceable to many different and widely separated foci. A fitful system of muzzling, intermittently adopted by various local authorities in accordance with their own supposed sufferings or immunity, without regard to any common plan of action, is necessarily doomed to failure. Whatever measures are taken must not only be good of their kind, but they must be carried out to the letter throughout the length and breadth of the land if we are to do what we all profess to be anxious to have done,—namely, stamp out rabies with the minimum expenditure of time, trouble, pain, and life. It seems that a system of combined badge and license, similar to that advocated by one of our correspondents last week, is in force in Holland, with, it is stated, satisfactory results.

THE low death-rate which obtained in London throughout the third quarter of the year is being maintained in the present one, the average for the past four weeks being 17.5 as compared with 19.6 for the corresponding period of the preceding ten years. Last week there were 1,366 deaths in London, 244 below the average, and of these only 111 were attributed to the zymotic diseases. Of the latter whooping cough alone exacted more than its average number

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past seven weeks.

of victims, counting 36 as compared with 31 last week. Measles caused 23 deaths, and scarlet fever and diphtheria 10 a-piece. From diseases of the respiratory system there were 358 deaths, showing a trifling increase over last week's record. The mean tempera-

ture was 44°, and 4·2° below the average for the week. The general health of the principal towns remains satisfactory, and there was nowhere any special fatality from any of the infectious diseases. In Glasgow and Dublin the general death-rates were 27·4 and 25·6, both returns being considerably higher than those for any of the chief provincial towns in England.

WE have on several occasions drawn attention to the controversy between the staff and the lay governors of the Aberdeen Royal Infirmary, and our readers will remember that one of the chief points in dispute had regard to the sanitary state of the hospital. In consequence of the publicity which had been given to them, and the serious nature of the charges of Dr. Angus Fraser and the rest of the staff, a committee of enquiry was at length appointed, and their report has just been received and adopted by the Board. The state of affairs disclosed would be literally incredible, did it come from any less official source. The water-closets, so says the Report, are altogether unsuitable for the interior of any inhabited building; the troughs, in several instances when inspected, were found to be full, it being apparently the usual practice for a man to go round once a day and lift the plug; the water-closets, it is to be noticed, open directly on a passage communicating with the wards. The waste pipes of these troughs are not trapped at all. The baths are described as dirty and repulsive, being placed in dingy closets; the waste pipes from these and from the basins, and the overflow pipes from the cisterns, all communicate directly with the soil pipes. The drains were found to be defective, especially at their junction with the pipes. The Report concludes with the terse statement that the whole sanitary arrangements and appliances are wrong in principle and defective in workmanship, than which no more sweeping condemnation could well have been made. The Board have had the wisdom to see that it would be futile any longer to deny the necessity for alteration, and have given instructions for plans of the necessary sanitary alterations to be drawn up. We regard the appointment of Miss Lumsden as Lady Superintendent as another proof that the Board have at last realised the truth about the numerous complaints as to the inefficiency of the nursing, and we are satisfied that the appointment of so experienced a lady is a sufficient guarantee that the nursing will be conducted in a very different manner in the future from that which we have lately had reason to condemn and regret.

OUR Glasgow correspondent writes: The Liberal Committee of the General Council of Glasgow University have decided not to offer at this time any opposition to the return of the present sitting member, Dr. James A. Campbell. It is understood that this decision has been dictated by various considerations. Dr. Campbell has proved a hard-working member, and qualified, in a way few candidates would be, to represent the interests of the Universities, so that his services were specially valuable at a time when legislation was being proposed for these institutions. It was therefore felt that the Committee could only oppose

Dr. Campbell with success if a medical candidate of eminence were obtained or a politician of the first rank. Even if such a one were secured, there would be great risk at present of his chances being marred, as Mr. Erichsen's have been in Edinburgh, by the disestablishment difficulty. It seems, however, as if the Conservative member were threatened by opposition of a novel kind. He was asked to receive a deputation from the University Council Association, who desired to urge upon him the necessity of reform in the teaching and management of the Scottish Universities, and he consented. The meeting took place in the St. Enoch Station Hotel, Glasgow, on Thursday of last week. The spokesmen of the Association were Mr. R. Vasy Campbell, Advocate; Dr. D. C. McVail, Rev. J. W. King, and Mr. W. R. Herkless. These gentlemen placed a bold programme of reform before Dr. Campbell, one of the chief proposals being that the administration of the University as a whole should be taken out of the hands of the Senate and placed in the hands of an enlarged University court, in which the Council should be more fully represented. Dr. Campbell, in his reply, declined to commit himself to any particular proposal, but expressed his approval of the proposals of the late University Commission, and desired to see a new Commission appointed which would make enquiry into such questions as those which had been raised, and would also have executive powers. This is all the deputation got out of Dr. Campbell. It is impossible to suppose that they ever expected more, and equally impossible to suppose that they would be satisfied with it, or at least that the leading spirits of the Association would be satisfied with it. So, at a subsequent meeting whose proceedings were not reported, dissatisfaction was expressed with Dr. Campbell's reply, the chief expression of this feeling also devolving upon Mr. Vasy Campbell; and then, by some other speaker, the suggestion was thrown out that Dr. Campbell should be opposed by the Association, in short, that the Association should run a candidate of their own. It appears that the meeting did not fasten upon the idea with any avidity, and that, indeed, its sympathies were so evidently with subsequent speakers, who took occasion to object to the Association being made a political engine, that the idea was allowed to drop, and the meeting thereupon broke up. Whether, therefore, Dr. Campbell is to be returned unopposed, remains to be seen. The energetic reformers who rule the Council Association may make another effort to run a candidate, and probably Mr. Vasy Campbell would not object to fight still more vigorously for the principles he has of late shown so keen a desire to advocate.

THE Winter Session of the Edinburgh University was opened on the 27th ult. by an address from the Principal, Sir William Muir, who drew attention to the great advance in the number of their students. In 1833-4 1,754 students matriculated; in 1884-5 they had 3,338, so that in the half-century the numbers had nearly doubled. Moreover, these increasing numbers were drawn from all grades of the people and from every quarter of the nation and its dependencies. In a subsequent portion of his address Sir W. Muir

suggested the foundation of halls and hostels for the residence of students. In the evening the students held a torch-light procession in honour of their new Principal. On the 28th the various classes were opened by addresses from the Professors. Dr. Grainger Stewart, in the Practice of Physic class, devoted his remarks to Oertel's views with regard to the treatment of heart disease by dry diet and hill-climbing. It had always been admitted, he said, that the heart muscle, like others, might be improved in its tone by exertion. Scottish physicians were recommending exercise on the level, and particularly such exercise as golf afforded; but, if Oertel's views should be confirmed, instead of sending their patients to St. Andrew's or Machrihanish, they might have to send them to Ben Ledi or Ben Nevis. The superior advantages claimed for hill-climbing must, however, be carefully investigated. The treatment was manifestly well suited for certain cases of heart disease, but it would be useless and even hazardous in many others, such as those in which the fibre was degenerated or the valves recently or seriously affected. In such cases great caution must be exercised with regard to effort, and rest in bed had been proved to be of importance. In the Physiology class Dr. Rutherford dealt with bodily motion and its results, concluding with the assertion that either we must adopt the theory that the intelligence resulted from the motions of molecular mechanisms, or that in all animals which gave signs of intelligence there was a mind super-added to matter, which used the mechanism of nerve cells to make itself manifest. Comparative physiology pointed to the former conclusion as the more probable. But, should that view come to be adopted, mental philosophy would be as ever a study of the highest moment, and moral philosophy and practical religion would be none the less essential as aids to human progress. In opening his class, Professor Fraser said that the traditionary method of instruction in *Materia Medica* could no longer be adhered to, because by general consent its many departments had been separated into two groups, and the re-arrangement had demanded a great expansion of educational appliances and accommodation. With reference to the subject of pharmacology, he thought it was now time that in Great Britain they should be up and doing something. They had been trusting very much to their friends in Germany and in France for fresh acquisitions in pharmacology, and that was a reproach which ought not to be allowed to continue. Professor Chiene, in his address to the Surgery class, dwelt on the necessity of preserving the individuality of the student. Dealing with the question why it was that so many students migrated north into Scotland, he said he could not help comparing their migration with the migration of birds. Ornithologists agreed that birds migrated from one place to another to get food, and he believed that the main factor at work in students coming to Edinburgh was that they got mental food. The great danger, as he had already warned them, was the danger of over-feeding; he wanted them to pick up for themselves rather than to be fed. In the Anatomy class Professor Turner spoke of the organism and its constituent organs, and in the

class of Pathology Professor Greenfield dealt with the question of taking notes and the copyright of the Professor in his lectures.

CONSIDERABLE interest attached to the opening of the Winter Session in the School of Physic in Ireland on Monday, the 2nd inst., as the occasion was chosen to inaugurate the new anatomical theatre of the school in the presence of the Lord Lieutenant. The opening address was delivered by Dr. D. J. Cunningham, Professor of Anatomy in the University of Dublin. The Anatomical Theatre is in direct communication with the dissecting room and other anatomical apartments. Its construction was commenced in July of the present year, and has been completed in a period of less than three months. The theatre is not what would be regarded as a spacious building, but its accommodation has been well developed. It is constructed after the model of the Edinburgh Anatomical Theatre, but is regarded as a decided improvement on that structure. The seats are arranged in a half ellipse, horseshoe fashion, and will accommodate 300 students, a desk on the floor centre of the ellipse being provided for the professor, with demonstrating plates of ground glass in front of the class. His Excellency was received on his arrival by the Provost of Trinity College, and upon entering the new Anatomical Theatre the assembled students cheered him loudly. By some strange chance or oversight no formal invitation to be present at the opening ceremony was sent officially to the President and Fellows of the King and Queen's College of Physicians, who exercise a joint control over the School of Physic with the Provost and Senior Fellows of Trinity College.

THE Winter Session of the Meath Hospital and County Dublin Infirmary was inaugurated on Monday, November 2nd, with an introductory lecture by Dr. Arthur Wynne Foot, the senior physician of the hospital. There was a large attendance. Dr. Cruise, President of the College of Physicians, presided. The address, which was a singularly able one, and had for its theme Clinical Instruction and Clinical Observation, appears at length in the *Dublin Journal of Medical Science* for November, and will well repay perusal. In the evening the third annual dinner of the Governors and old students of the Hospital took place at the Shelbourne Hotel. Dr. Foot presided, and the company, which included several guests, numbered fifty-seven. The *menu* card was a unique specimen of art, giving, as it did, a picture of the Meath Hospital, vignettes of Graves, Crampton, Stokes, Macnamara, Porter, and Smyly, with the dates of their appointment and resignation, and also a map of the world, representing geographically the ills that flesh is heir to, with the hospital motto—"Quæ regio in terris nostri non plena laboris."

THE Dublin Hospitals Commission continued their sittings on Saturday, October 31st, and Monday and Tuesday, November 2nd and 3rd. On Monday the case of Dr. Steevens' Hospital was proceeded with, the evidence as regards the House of Industry Hospital having been closed on Saturday. The Secretary sub-

mitted the answers sent in to the queries issued by the Commission, which stated that the hospital, founded in 1720 by proceeds of land bequeathed by Dr. Richard Steevens, is now governed by a board of Governors—twelve elected and nine *ex officio*. There is an annual grant from Parliament of 1,300*l.* given, and a continuance thereof claimed on the ground that at the request of the Government certain accommodation had been provided and services rendered in the institution as to the medical care of the constabulary and of patients suffering from specified disease. The hospital was utilised for purposes of medical education, but the average number of students on the books receiving instruction during the past three years was only 6·3. The number of intern patients treated in the hospital during the twelve months ended the 31st of March, 1885, was 1,376, while 2,054 accident cases had been attended to, and 9,622 dispensary cases. On an average there were nineteen beds under the control of each visiting physician and surgeon daily. Cases of infectious disease were received from the Constabulary. The total annual income was returned at 6,734*l.* 5*s.* 7*d.*; 1,196*l.* 10*s.* 2*d.* for pay patients, 2,630*l.* 0*s.* 1*d.* from rents of houses and lands, 284*l.* 0*s.* 7*d.*, interest, dividends, &c.; 182*l.* 4*s.* 2*d.* from the hospital; and the expenditure was in excess of income by 1,638*l.* 8*s.* 1*d.* The average daily number of beds occupied throughout the year was but 94, the average annual cost per bed, as compared with 51*l.* 14*s.* 11*d.* in the House of Industry hospitals, was 67*l.* 7*s.* 5½*d.* Dr. Thomas W. Grimshaw, the Registrar-General for Ireland, and a consulting physician of the hospital, and Mr. Edward Hamilton, one of the visiting surgeons to the hospital, were the witnesses examined on Monday. On Tuesday the Commission examined witnesses on behalf of the Meath Hospital, which receives a Government grant of 600*l.* a year.

OUR Paris correspondent writes:—The academical discussion which was expected to take place between M. Pasteur and his opponents fell through altogether; the illustrious champion of inoculation not having appeared in the field, his chief adversary, M. Colin d'Alfort, declined addressing the Academy. In the meantime a number of more or less authenticated cases of hydrophobia flock to the laboratory of the Rue d'Ulm, and if M. Pasteur had the *commercial* spirit of a Dr. Ferrán he might easily start a flourishing practice. At the Congress of French Veterinarians, where M. Pasteur was hailed with loud applause, some doubts were expressed as to the condition of the dog by whom the young boy, Joseph Meister, was bitten. It was observed that the mere fact of finding bits of wood and straw in the animal's stomach after death was not a sufficient proof of rabies, and that, the animal having been immediately killed, no means were left of ascertaining the progress and evolution of the case. On the other hand, the young shepherd who was placed under treatment by M. Pasteur, is reported cured. The validity of these cures must, of course, be left to the test of time. But a wide and promising field is now thrown open to the activity of Continental physiologists in which they will not

be troubled by English competitors, thanks to Miss Cobbe and the Anti-vivisection Act.

THE trial of Dr. Estachy has just come to a conclusion. It will be remembered by the readers of the *Medical Times* that this gentleman, who enjoyed a flourishing practice in a town in the south of France, was disturbed by the appearance of a rival practitioner, Dr. Tournatoire. Intense jealousy soon arose between them. One day Mme. Tournatoire received from an unknown hand a parcel of game. She partook of it, together with her servant. Both soon exhibited severe symptoms of poisoning by belladonna, but ultimately recovered. The remaining birds, on being examined, were found to contain a large quantity of atropine. The parcel was traced to Dr. Estachy, who, when called before the judicial authorities, made a full confession, but pretended to consider the whole affair a practical joke. The Court has just sentenced the doctor to eight years' imprisonment with hard labour, and has degraded him from the Legion of Honour, of which he was an unworthy member. So much for the consequences of a *practical joke*.

THE Medical Society of Berlin has just celebrated in business-like fashion the twenty-fifth anniversary of its foundation. Although we may hesitate before assigning to it the very foremost place among scientific societies, it has nevertheless every title to the respect of the profession in other countries than its own for the sterling character of its work and the untarnished purity of its reputation. Formed under the guidance of Albrecht von Graefe by the amalgamation of two medical societies of Berlin, it has already been the scene of some epoch-making discoveries and of many notable discussions. The speech delivered by its President at the festive gathering last week was worthy of the occasion. Professor Virchow occupies a position in the medical world which is almost unique and in the lesser world of his own immediate surroundings he is an object of well-nigh reverential worship, standing, in point of intellectual vigour and historical association, on a level with the late Prime Minister of England. His words, although addressed to a local and very sympathetic audience, have a value which may be appreciated in medical society all the world over.

It is not long since the advantages of specialism in medicine were brought somewhat prominently before the public in London in the pages of a well-known magazine, and one of the most powerful arguments which could be brought to bear in support of the opposite view was this: that the younger and more enthusiastic workers in medical science, having all the facts before them, deliberately select the broad roads of general medicine and surgery in preference to the narrow and possibly devious paths which lead to the pecuniary success of the specialist. To all the workers in the wider and more laborious field the words of Professor Virchow will be welcome, in which he cordially supports the view that the separation of the science even into such wide divisions as those of medicine and surgery is not so conducive to its real

advancement as the union of all its divisions into one comprehensive whole. "No specialty," he says, "can really flourish which cuts itself entirely off from the great body of the science." He condemns as the highest flight of folly and mischief the establishment of schools for the study of special subjects without regard to the requirements of general medicine. For the medical societies he rightly claims a large share of credit that so many of them are always tending to unite the diverging lines of medical study and practice by bringing together all branches of the science for discussion by practitioners of every variety of opinion.

WITH unsparing tongue Professor Virchow expounded the differences between the written and unwritten codes of medical ethics. The lamentable example afforded by the recent proceedings in the United States, whereby the next meeting of the International Congress is jeopardised, has shown that the most elaborate code will not serve to instil self-respect into the minds of those to whom it appeals, or to keep in check the overwhelming desire for notoriety by which the less scrupulous members of an honourable profession are too often actuated. In the medical profession no written code of ethics should be necessary; "it should be borne in the bosom of every good practical doctor, and if, by chance, he should transgress it, the example and influence of his fellows will suffice to set him on the right path again." With pardonable pride Professor Virchow claimed for the profession in Germany that its own good sense and no elaborate code of restrictions had sufficed to keep the ranks clear of all who might disgrace them, and had raised Medicine from the grade of a "craft," as it is described in the statutes, to the more honourable position of a free art, neither dependent upon State support nor hampered by Imperial supervision.

It is now several months since a correspondent of one of the medical journals detailed his experience of the value of pigeons as messengers in country practice. It was his habit to start upon his rounds accompanied by a basket containing a number of "homing" birds. Upon leaving the house of any patient for whom some speedy attention was desirable, a scrap of thin paper bearing the necessary message or prescription was folded and attached to a pigeon's leg, and the bird was then set at liberty. The missive was detached as soon as the aerial postman reached the doctor's house, and the medicine at once made up and despatched. The Editor of the *Field* suggests the further elaboration of this system. In the course of an interesting article on the subject he cites an instance in which pigeons are in the habit of thus carrying the morning newspaper, in sections, to their owner, who lives at a distance of some five miles from his post-town. A page of the *Telegraph*, for instance, is folded into a longitudinal strip and rolled tightly into a cylinder, which, suspended round the bird's neck, hangs in front of its breast. One of these packages was found to weigh no less than three-quarters of an ounce; and

it would, of course, be quite feasible thus to rapidly despatch small quantities of potent remedies with tolerable certainty and safety. The scheme is, no doubt, a "pretty" one; the practical hindrance to its general adoption lies in the fact that, like most other arrangements, it can only work so long as it is always in working order, and that few people will undertake the trouble of purchasing, keeping, and training carrier pigeons in order that one may be available as a messenger in the event of a dozen pills or a few minims of a concentrated fluid being required in a hurry. It is also urged that, by the time a system of this kind could have been generally adopted throughout the country, the need for it will have passed away; that, in short, London, Birmingham, Liverpool, and Manchester will have run together into one vast wilderness of bricks and mortar, through which pedestrians will speed on patent electro-rubber boot-soles over corrugated steel pavements. It is possible that something may be made of Mr. Tegetmeier's suggestion before this consummation comes upon us. But meanwhile it is probable that the ordinary special messenger will continue to be employed whenever conveyance by the overburdened rural postman is deemed a too tardy means of transit.

A CORRESPONDENT sends in the following:—It has frequently been urged by leaders of the profession, such as Sir James Paget and others, that the hospital schools would do well to cease to attempt to impart instruction in pure science, such as Physics, Chemistry, and Biology, and should leave this to the special colleges of science. That the medical students of London are of their own accord acting in this direction is evident from the fact that, out of 159 successful candidates at the Preliminary Scientific Examination of last July, 52 came from the Faculty of Science of University College, Gower Street. The next largest number (a long way behind) is 16 from St. Bartholomew's—whilst Guy's, St. Thomas's, and King's passed 11 each. It further appears that the total number of candidates who entered their names as having prepared for this examination at University College was 63. Thus only one-fifth of the University College candidates failed. Of the total number of candidates from all localities as many as one-half failed. These facts are worthy of serious consideration. They certainly tend to prove that the examination is not so difficult a one as some persons represent it to be. Candidates who take the trouble to prepare for the examination at a properly organised school of scientific instruction have no difficulty in passing. The failures at the examination are not due to the fact that the test is too severe or of too high a standard, but simply to the fact that the candidates who fail have not been through a course of preparation equal in efficiency to that offered at University College. Very naturally the managers of our London schools are afraid that the student who studies his preliminary science at University College will stay on there to carry out his medical studies. The entries in the Medical Faculty of the college abundantly prove that this is a groundless fear. The students of the Faculty of Science of University College do *not* exhibit any

preference for University College Hospital. Of the 52 successful candidates of last July, only 12 have entered the Medical Faculty of the College. The Metropolitan Schools generally might, quite fearlessly and without detriment to their entries, make use of the Faculty of Science of University College and issue admissions to the science courses there as part of their own composition ticket.

THE current number of the *Revue de Chirurgie* contains notes by Dr. Kirmisson, of Paris, on a "Voyage chirurgical à Londres," from which we extract the following:—After relating his impressions, as acquired in a variety of hospitals, he concludes a very flattering account by stating some general conclusions at which he has arrived. He was most struck, first at the Samaritan Hospital, "with the marvellous cleanliness of the wards, the happy arrangement of the operating table and of the instruments, and the silent and attentive assistants. These details were at first thought to be special to this hospital, but subsequently he found "that this exquisite cleanliness and this good organization were absolutely general" throughout the London hospitals. "The wards have a smiling aspect; here and there are flowers; engravings on the walls; a singing bird in its cage. These appearances remind the patients of home rather than of a hospital ward. There are no disagreeable smells, no dirty objects about; all the articles of furniture, all the utensils required by the surgeons, the very floors even, are perfectly clean." The operating theatres were even more striking still. "It was with sadness, after having seen all these details, which to-day have so great an importance in the practice of surgery, that I returned home, and felt the condition of real inferiority in which the Paris hospitals now stand." The *personnel* of the wards is not deficient in number only, but much more so in training; the wards are all overcrowded; for each one, in addition to the ordinary beds, has provisional beds—*brancards*—so that, instead of 30 or 40 patients, they contain not infrequently 50, or even more; while the *personnel* is not increased in the same proportion. Thus it comes that, although "torrents of carbolic acid and mountains of gauze are used," antiseptic surgery, as practised by Lister, is unknown in Paris. "Hospital surgeons cannot be blamed for such a condition of things; but it is for them to enlighten the administration, and to say, 'the antiseptic method has revolutionised surgery; the old order of things which obtains in the hospitals no longer meets the requirements of modern surgery—reforms are necessary, they are urgent.'" Dr. Kirmisson concludes his paper with a series of recommendations. We can, from personal knowledge of the Paris hospitals, quite endorse his plea for a radical change in their administration. It is to be hoped that such praise as this will not lead our London hospital administrators to the belief that they have arrived at perfection, but that it will rather give them the courage to proceed in a course which has not been entirely free from opposition.

A NEW method of treating lupus has recently been suggested by Professor C. Gerhardt, of Berlin, which may be said to be a direct outcome of the discovery of the bacillus of tubercle. Hitherto it has always been thought essential to use destructive measures in dealing with the disease, and whether by cauterization or by direct scraping out of the affected tissue the main object has always been the same. But of late years the presence of the tubercle bacillus in the lupoid patches has been constantly recognised, although in very small number. As many as twenty and thirty specimens have been examined by Professor Koch before the bacilli have been seen. Taking this fact into consideration with the extremely slow progress of some cases of lupus, Professor Gerhardt is led to the belief that while the bacillus is at work as a principal factor in the disease, some other element must be present which prevents the bacillus from spreading and multiplying with the rapidity which characterises it elsewhere. He finds in the superficial situation of lupus and its consequent exposure to cold, the deterrent influence which hinders the spread of the micro-organism. Acting upon this view, he has adopted a form of treatment whereby the influence of cold, by means of small ice bags, can be constantly exercised upon the diseased surface, and he records some cases (*Deutsche Medicinische Wochenschrift*, No. 41) which would seem by their results to justify the line of treatment, if not to prove the theory upon which it is founded. The advantages claimed for the method are these: that the disease is checked in the same or even a shorter time than by the ordinary means, and without any destruction of surrounding tissues, and that the activity of the tubercle bacilli is checked, if not altogether destroyed. To what extent the good results hitherto obtained will be permanent has, however, yet to be proved by the test of time.

IN his half-yearly report for the term ending June 30th, Dr. Collingridge, the Port Medical Officer, speaks at some length on the matter of the rag trade. As our readers are doubtless well aware, on the news of an outbreak of cholera the Local Government Board issues an edict forbidding the importation of rags from the infected district, such prohibition lasting until further notice unless any definite time is stated. Dr. Collingridge points out the great injustice that is done by this action to an important trade, and moreover he shows that it really defeats its own object, as the consequence is that a large portion of the rags thus condemned are kept in waiting until such time as they are again permitted to be landed, when they can be brought in without let or hindrance, and with just as much risk to the public at large as before. A standing rule that all rags previous to being landed were to be subjected to the action of a sufficient heat to destroy all germs, would at once remove the injustice at present made on one industry, and would afford a permanent security against the introduction of disease by this channel. The number of vessels inspected during the half-year was somewhat less than usual, not from any lack of activity on

the part of the officers, but partly owing to the depressed state of the shipping trade and partly to the unsatisfactory condition of the steam launch at the disposal of the Authority. The number of vessels ordered to be cleansed was actually larger than on previous occasions, and this was due not so much to any carelessness on the part of the masters of vessels, as to the increased power which a better definition of its functions has enabled the Authority to wield. Dr. Collingridge and his inspectors have been as zealous as ever in dealing with outbreaks of infectious disease, of which there were but few, and which in no instance, thanks to their vigilance, were allowed to spread. The amount of unsound meat condemned was smaller than on some previous occasions, but in March one ship, which had met with bad weather, was found to have a large consignment of meat in a putrid state; the whole cargo, amounting to 30 tons, was condemned and destroyed. Dr. Collingridge finds that sanitas oil is the most satisfactory material for the treatment of diseased meat; it adheres closely to the meat, gradually soaking in, and its flavour is such that there is no likelihood of any one attempting to eat meat, to which it has been applied; as it mixes with common oil without any detriment to its properties, a small quantity goes a long way, and it is therefore a cheap article to use for the purpose.

THE rural sanitary district of Glanford Brigg having been for some time the seat of a serious epidemic of diphtheria, the Local Government Board instituted an enquiry through the medium of Dr. Astley Gresswell, whose report<sup>1</sup> is now before us. The district in question is divided into two groups for the purposes of this report, viz., (1) The ironstone villages, of which the most important are Bromby, Frodingham, Scunthorpe, Crosby, and Ashby; and (2) the villages of Horkstow and Worlaby. The epidemic in the ironstone villages had lasted about sixteen months, in which time 388 persons had been attacked, and 51 had died. Of the total number 121 were over 20 years of age, and of these only 2 died. For the rest there were 120 boys attacked, with 18 deaths, and 147 girls with 31 deaths. The disease was clearly introduced from without in the beginning of 1884, and was, in many instances at any rate, communicated by personal contact, the habits and customs of the villagers being peculiarly suited to facilitate the progress of disease in this way. The cottages inhabited by the villagers were found, almost without exception, to be destitute of any means of ventilation. The privy accommodation mostly consisted of ash-pits, which were, in many instances, so large and so difficult to get at that thorough cleansing of them was impossible. The sewerage was by means of non-ventilated clay-jointed pipes. The water supply was deficient in quantity and bad in quality. Milk was reported to be very scarce, and both the National School at Frodingham and the Board School at Ashby

were very ill-ventilated. The outbreaks at Horkstow and Worlaby afford additional evidence of the way in which school attendance contributes to the spread of this type of infectious disease. The introduction of the disease into the former village from without was clearly made out, but the mode of origin in the case of Worlaby could not be satisfactorily determined. In every instance closure of the school proved a speedy and effective means of bringing the epidemic to an end.

THOUGH it is not more than three or four years since the Municipal Laboratory for the Analysis of Food was opened in Paris, it has for some time been largely utilised by the public. Two kinds of examinations are made of articles submitted by private persons: the so-called qualitative, which, however, is often practically a quantitative one, but in which the article is simply referred in the certificate to one of four classes, viz., good, passable, bad, but not injurious, or bad and injurious. For this no charge is made. In the quantitative examination the proportions are stated numerically, and a fee varying from five to fifty francs is demanded. For the greater convenience of the public, the articles may be left at any police station, whence they are collected daily by a police van and taken to the laboratory. Each parcel must bear the name and address of the vendor, and, if found "bad," an "expert inspector" is immediately dispatched to inspect the stock of similar articles and to obtain samples for further analysis, with all the legal formalities necessary for their identification in court. Should they be condemned, a prosecution is undertaken by the municipal authorities, but the name of the original purchaser is not divulged. Whatever may be the result of the action taken by the authorities, the effect of the first certificate, condemning the article as "bad," naturally leads to a withdrawal of his custom by the purchaser, and the fraudulent tradesman thus suffers a pecuniary loss often far exceeding any fines imposed by the court. All articles sent to the laboratory are received by an official who enters in a book the particulars of the purchase and hands to the applicant a counterfoil, telling him when to call for the result. The samples are then numbered, and sent into the laboratory without any indication of their source. Such articles as admit of it, wines especially, are first submitted to experts accustomed to judge of their quality by taste, smell, and appearance, before being handed over to the chemists for analysis. Though these men are generally competent to undertake any kind of work, they devote themselves specially to single departments, as the analysis of wines, milk, fat and oils, &c., or to microscopic work. This regulation is found to effect a great saving of time, and to facilitate the operations of the office, while ensuring the greatest accuracy.

THERE is a little consolation to be got by London Medical Teachers out of a study of the returns of new entries at the Provincial Schools. At Cambridge, which to the London teachers of primary subjects is

<sup>1</sup> This report may be obtained from Knight and Co., 90, Fleet Street; Shaw and Sons, Fetter Lane; Hadden, Best and Co., West Harding Street, Fetter Lane; and P. S. King and Son, Canada Building, King Street, S.W.

the most formidable as to the clinical teachers it is the least formidable, of provincial rivals, the entry has slightly fallen off from 111 last year to 104 this year. At Manchester there is a decrease of 13 in the number of students who have entered for the full curriculum, viz., 54 this year as against 67 last year. But 40 students have entered for special courses, and a large proportion of these will, no doubt, figure among the full entries next year. At Birmingham the total entry is 28, about the same as last year. But at Leeds and Bristol there has been a striking increase, the former recording 37 full entries as compared with 24 last year, and the latter having 31 total entries against 20 in 1884. We have as yet received no returns from Oxford, Newcastle, and Sheffield.

---

### THE RECONSTRUCTION OF LONDON UNIVERSITY.

LONDON University Convocation met on Tuesday, and resolved by 120 votes against 76 not to proceed with Lord Justice Fry's scheme as it stands. The majority were in favour of sending it back for reconsideration and amendment to an enlarged special committee of fifty members, including as many of the original committee as were again willing to serve. As Lord Justice Fry, however, with several of his colleagues declined to have anything more to do with the scheme, the meeting was adjourned until December 8th, when we may take it for granted that another committee will be appointed to amend the proposals at present before the House. We regret the vote, for, much as we dislike certain effects of the scheme, we believe it would have been easy for Convocation to suggest such amendments in it as would have made it acceptable to the majority of the graduates; whereas we have little hope that a new Committee, containing as it must so many representatives of divergent interests, will be able to agree upon any scheme for the reorganisation of the University which will really contain the elements of a vital reform. The longer the question is debated, the more irreconcilable do the ideals of the opposed parties appear. The ideal sketched by Professor Michael Foster, in his admirable speech on Tuesday, of a University governed solely by those who are engaged in University work, is not one that commends itself to Convocation groundlings, whose ideal University is one in which they would be mainly supreme. No doubt Professor Foster's contention that teaching is the true office of a University, and examining only a very subordinate function, is a hard word to the thick-and-thin adherents of a University which has gained what reputation it has solely through its success in passing and plucking the pupils of other institutions. But, as we saw on Tuesday, and as we shall see more clearly when the division list appears, it is the view which has the support of the best minds in Convocation, as it had the support of the best speeches and the most telling arguments. The difficulty is to reconcile the two views, as they must be reconciled if any scheme is to be proposed which will be acceptable to

the body of graduates. We have all along contended that Lord Justice Fry's scheme gives too little influence to Convocation in the affairs of the University. It is true, as maintained by its supporters, that the scheme professes to leave the privileges and powers of Convocation untouched, but it is impossible to deny that in reality it limits those powers very materially. Convocation is still to retain the privilege of making representations to the Senate, and the effect of those representations might be supposed to be increased by the fact that the representatives of Convocation on the Senate would, under the scheme, hold office during good behaviour, and not, as at present, for as long as they choose. But when side by side with Convocation there are called into being other bodies, with not only the right, but the duty, to advise the Senate, it is impossible to maintain that this particular privilege of Convocation remains untouched. Suppose the Boards of Studies advise the Senate to a course distinctly opposed to that recommended by Convocation, is it likely that the recommendations of the latter will have as much weight with the Governing Body as they have now, when they proceed from the only authoritative voice that can make itself heard? We think, for reasons we have repeatedly expressed, that the failure to give Convocation a larger share of representation on the Senate and the Boards of Studies constitutes the main defect of the scheme of the Special Committee, but the defect is one that could readily have been remedied if Convocation had only condescended to pass a resolution to that effect, and we regret that the scheme is likely to be referred to a new Committee, to the loss of many precious months in the settlement of a question which everyone admits to be of pressing moment. We fear that the new scheme, when it comes before Convocation—if ever it does come—will be found to be a mere tinkering reform, instead of the large and able measure of reconstruction which almost every one admits Lord Justice Fry's scheme to be.

The best friend of Convocation cannot pretend that it showed to advantage on Tuesday last. It was at loggerheads with one of its own resolutions, and yet was ruled not to have the power of rescinding that resolution. Some months ago it approved certain specified objects of the Association for Promoting a Teaching University in London, and appointed a Special Committee to promote the carrying of those objects into effect "by this University." A scheme is submitted to it which does propose to carry those objects into effect, and Convocation practically decides that it has changed its mind, that it does not approve those objects, and therefore will not look at the scheme. Really there is some excuse for the action of the Sub-Committee in whittling down the powers of a body which can show such inconsistency and ineptitude. Then, by a very unfortunate, and to our thinking faulty, ruling of its chairman, Convocation very nearly had to accept the unwieldy Committee of fifty proposed by Mr. Magnus, and could not even discuss a proposal which seemed to meet with very general approval, that a smaller Committee—one of fifteen members was mentioned—should be appointed. Altogether the discussion, though relieved by some:

forcible speeches such as those of Mr. McDowall, Dr. Michael Foster, and Professor Tilden, of Birmingham, was not one that Convocation can look back upon with any particular complacency.

### REFORM AT THE ROYAL COLLEGE OF SURGEONS.

AFTER the crowded meeting at the College of Surgeons on Thursday week it may, we think, be taken as a foregone conclusion that the right of voting in the elections to the Council will be conceded to the Members without long delay. If the Council had been still obstinately bent on refusing the demands of the Members, it is inconceivable that they should not have taken the excellent opportunity then afforded them of defending their policy; and, even assuming that their sense of dignity forbade them individually to meet the arguments of the speakers, it would not surely have been difficult for them to have put their case into the hands of some junior Fellow, like the one whose letter we publish in another column. As it was, the conspiracy of silence seems to have extended even to the half dozen juniors who alone voted against Mr. Gamgee's resolution, and judgment went practically by default. By their action the Council appear to have placed themselves in this dilemma. Either they intend to grant the Members' demands, in which case the meeting of Thursday was a mere solemn farce. Or they intend, neither to grant them, nor to show good reason why they should not be granted, and in that case their treatment of the Members was, to say the least, not very respectful. The explanation of the conduct of the Council is, we presume, to be found in intestine differences on the question, and if, as we suspect, some of its members have been waiting to see which way the wind blows, we may hope that Thursday's meeting, at which no prominent Fellow of the College supported the Council either by word of mouth or vote of hand, will give that body the necessary impetus in the direction of reform. If not, the Councillors will have to prepare themselves for a succession of such meetings, each more enthusiastic and determined than the last, a prospect which, we imagine, not the most obstinate of them cares to contemplate. It is not for us to complain of the tactics by which the party that we sympathize with has gained such a striking success; but we may point out that if the Council, instead of foisting their old minutes on the meeting as their Report, had drawn up a document for the occasion, stating in temperate language the reasons for their refusal to admit the Members to the franchise, and had commissioned two of their body to propose and second it, they would have had their opponents at a certain disadvantage. An amendment would still have been carried, of course, by an overwhelming majority, but the Council would have had the satisfaction of knowing that their procedure had been conducted on the lines usual at public meetings, while such a course would at the same time have encouraged those who approve of their action to give expression to the belief that is in them. It might even have tempted "A Junior Fellow" to an utterance of his view

of the case, and so have deprived us of the privilege of becoming the channel of its publication. But even that we could have borne if it had given more interest to Thursday's contest in making it less of a walk-over.

It is easy to gain a cheap victory over opponents by stating their weakest arguments in one's own words, and then proceeding to demolish them. This, it is evident, is the plan adopted by "A Junior Fellow" in his letter to us. No one can be more conscious than the more sensible of the Members how feeble and futile, not to say how ungenerous, were some of the speeches in support of Mr. Gamgee's resolution, but in cases where speech has been long bottled and wired in there will always be a certain amount of gas to get rid of before the real wine of sound argument flows. Dr. Joseph Rogers' denunciation of the sins of past Councils was far wide of the question before the meeting, but, if his complaint is worth quoting at all, it is worth quoting correctly. He condemned a previous Council, not for persuading the Government to require that all poor law officers should take the membership of the College, which in itself was no doubt a very excellent requisition, but for getting the rule made retrospective and so forcing medical officers who had spent half their lives in the service of Government to pay the College a fee and pass a sham examination. If the facts are as Dr. Rogers stated, and he was himself an eye-witness of them, we may safely say that no Corporation ever perpetrated a more unseemly piece of jobbery. But these things happened more than forty years ago, the men who took part in them are long dead, and may well be left in oblivion. But the College still works and lives on the bad principle of using the monopoly which the State has given it in order to mulct each successful candidate for its membership of a large sum, in excess of the net cost of the diploma, for the support of its library and museum. No doubt the library and museum are excellent institutions to support, and every Member may make use of them to the top of his bent, but the least that the College can be fairly expected to grant in return for the forced contributions of its Members is to admit them to a place in the Corporation and to give them a share in its administration. "A Junior Fellow" tells us that the College is a corporation of surgeons and not of general practitioners. If so, then let the surgeons bear the cost of supporting it. We readily admit that in purely surgical questions the opinion of the Fellows, even of that very large proportion of them who are, admittedly or not, general practitioners, is worth more than that of the Members. But the questions on which the Members desire to have a voice are not surgical questions, are not even questions as to surgical merits; they are mainly questions as to the character of rival candidates for the Councillorship and large questions of administrative policy, and on such points we make bold to say that the varied experience of 16,723 Members forms the better basis for a sound opinion than that of the 1,153 Fellows, in spite of the fact that some half of them have undergone the rigorous and not altogether trustworthy examinations for that grade. The simple fact underlying the whole matter

is that, in spite of its successes, the College is in a bad administrative groove, and that the Fellows who wish to get it out of that groove have not proved strong enough to overcome those Fellows whose interest it is to keep it in it. Mr. Timothy Holmes saw this, but found circumstances too strong for him, and, if we read his action aright, gave up the certain prospect of the highest honour open to a surgeon because he was too conscientious to identify himself with a system which he condemned. The Fellows, even the strongest of them, have failed to reform the administration of the College, and it is now for the Members, with the weight that comes of numbers and disinterestedness, to lift it out of its ruts and raise it on to a higher level of usefulness, efficiency, and repute.

### MILK ANALYSIS AND MILK TESTING.

CONCLUSIONS as to the extent to which milk has been diluted, deprived of its cream, or otherwise tampered with, based on inferential evidence, however satisfactory to the analyst, are not at present admissible in courts of law, where, if he be not called on to produce them, he is expected to have actually seen, handled, and weighed the several solids contained in the particular sample. Inferences from specific gravity and other physical properties are not unreasonably looked on with suspicion, and things are preferred to phenomena. But, without disputing the wisdom of these demands in the event of proceedings being taken against the vendor, it may safely be affirmed that no efficient control can be exercised over an entire trade, or adulteration be so frequently detected as to cease to be profitable, by any process involving so much time and trouble as to be applicable to perhaps one churn only in several thousands. The objections to any estimate of the quality of a milk based on specific gravity alone are obvious when it is remembered that this is the resultant of two opposite factors, the presence of casein and sugar tending to raise the density above, and of fat to bring it below, that of milk. Cream is of such uncertain composition, and its apparent quantity is so dependent on the rapidity with which it is made to rise, that cremometers are almost absolutely valueless.

Lactoscopes, as Donné's and Feser's, the indications of which depend on the degree of opacity given to a thin layer of milk, and the lactobutyrometer of Marchand, since improved by Tollens and Schmidt, are indeed fairly accurate so far as they go, the readings of Feser's lactoscope rarely varying more than .1 and never than .5 from the result of actual analysis, and the lactobutyrometer seldom differing more than one or two hundredths per cent. They, however, have regard to one only of the constituents of the milk, and have not hitherto found much favour in this country. In Germany, on the contrary, where dairy farming is conducted on more scientific principles, and where a wider control is exerted over the milk markets than has been attempted here, endeavours have for some time been made by Fleischmann and others to discover a relation between the specific gravity and the percentage of fat and other solids. After long series of comparative observations conducted on these lines and by the ordinary gravimetric or analytical process, it has been found that firstly—given the specific gravity and the percentage of fat,—that of the total solids, and therefore of the solids not fat, may be calculated; and secondly—given the specific gravity

and the total solids—the fat, and therefore the solids not fat, may be likewise found.

Fleischmann's formulæ are—

$$I; t = f \times 1.173 + 2.71 \left(100 - \frac{100}{s}\right),$$

$$II; f = t \times .852 - 2.31 \left(100 - \frac{100}{s}\right),$$

where  $t$  = percentage of total solids,

$f$  = " " fat,

$s$  = sp. gr. (water = 1).

The specific gravity is calculated for a temperature of 15° C., or 60° F., and therefore requires a correction for other temperatures which is easily ascertained from a table. Dr. Vieth, of the Aylesbury Dairy Company, found in a series of 65 comparative experiments that the difference between the fat calculated by Formula I. and the fat extracted averaged .01 per cent., or was absolutely nil, and it very rarely exceeded .1. So long as the quality of the milk is above the standard agreed on, no further examination is necessary, but if, on account of the low figure obtained for either the total solids or the fat, proceedings, legal or other, seem expedient, the extraction of the fat becomes imperative. Here there is reason to believe that the processes commonly adopted, at any rate in past years, by the majority of English analysts are defective. Some dry the milk in the evaporating basin until it ceases to lose weight, others follow Wanklyn in evaporating for three hours only; in the former case the mass becomes so hard that the complete extraction of the fat is impossible, in the latter a part of the water is apt to remain, and in either the percentage of fat is inevitably underestimated. There is in this country a groundless prejudice against adding an inert material to the milk. Dr. Vieth prefers plaster of Paris, adding 20 or 30 grains of this to 10 of milk. The dried mixture he transfers to a cartridge of filtering paper which is dropped into a Soxhlet's fat extractor and treated for a couple of hours. The total solids are best estimated by complete desiccation of a given weight of milk, as usually practised. The estimation of the fat by means of Soxhlet's areometer gives very accurate results, but when great precision is not required, or, more correctly speaking, when no serious consequences are involved, the lactobutyrometer offers the readier method.

Mr. Adams, of Maidstone, has suggested the employment of reels of stout porous paper for taking up the milk and the exhaustion of the fat therefrom in a Soxhlet's apparatus, without any evaporation. Curiously enough, this method always gives results a trifle higher than any other, even when they have been conducted so carefully that no loss is found on summing up the constituent solids. In some cases it was found that the paper itself contained a trace of fat, but the same excess was noticed when the paper had been completely freed therefrom. The explanation has yet to be found: one suggestion is that the fat is oxidised in some way, thus gaining in weight, but it has not yet been proved to differ in properties or composition from ordinary milk fat. If this question can be satisfactorily settled, Adams' practice presents several advantages over any method involving evaporation to dryness.

UNIVERSITY OF CAMBRIDGE. — The examinations for medical and surgical degrees during the present term will commence on the following dates:—First examination and second examination for M.B. degree, on Thursday, December 3rd; third examination for M.B. degree, Part I., on Tuesday, December 8th; third examination for M.B. degree, Part II., Wednesday, December 9th; for the degree of Bachelor of Surgery, on Saturday, December 12th; for the degree of Master of Surgery, Friday, December 11th.

## REVIEWS AND NOTICES OF BOOKS.

*Contributions to the Surgical Treatment of Tumours of the Abdomen.* PART I.—*Hysterectomy for Fibrous Tumours of the Uterus*; by THOMAS KEITH, M.D. Edinburgh: Oliver and Boyd, 1885, pp. 104.—The operation which forms the subject of the present essay is still on its trial, and it may be some time before it becomes thoroughly naturalised in abdominal surgery. There are few men more competent than Dr. Keith to express an opinion upon it. Let us, therefore, see what he has to say. "The natural history of the ordinary uterine fibroid is different from that of other tumours. As a rule, it has only a limited life; other tumours go on, and vex or kill, according to their nature or place in the body. A stone in the bladder, if it be not taken away, is there for ever, and as it grows it torments more; but, to the woman with a fibroid uterus, who has passed the best of her years in weariness and pain, middle age brings relief, and old age may be spent in peace." This quotation may be taken as Dr. Keith's argument against hysterectomy, except in certain cases; chiefly because of the high mortality attending the operation at the present time. Of 359 operations—all the recorded cases up to March, 1884—227 recovered, and 132 died, a "greater mortality than one out of every three operated upon." He goes on to say that "had this frightful mortality been the result of operations done for the extreme cases of uterine fibroids, where the sufferings were great and life had become a useless burden, there might be some excuse for it; but many of these operations were done in cases of small tumours that were giving little trouble, or of peritonæal outgrowths that were giving still less. . . . So far as hysterectomy has thus gone, it has done more harm than good, and it would have been better that it had never been. . . . If these be the best results that surgery can give, then, the sooner this operation is laid aside, the better." The cases in which, with our present knowledge, hysterectomy may be reasonably advised are: (1) in very large rapidly growing tumours of all kinds in young women; (2) in all cases of real fibrous cystic tumour, if they can be removed, also in all cases of suppurating tumours; (3) in most of the cases of the soft œdematous fibrous tumour; (4) in cases of large bleeding fibroids of any age, provided the patients are not approaching 50 years of age, and provided their lives are rendered practically useless; (5) in certain cases of tumours surrounded by free fluid, the result of peritonitis, provided that the fluid shows a tendency to re-accumulate after two or three punctures. Dr. Keith admits that the sum of misery in such cases, both to patients and friends, "is something simply incalculable." Fortunately, he tells us, for those afflicted with uterine fibroids, a prospect of relief has lately opened out to them by the safer operation of removing the ovaries; this will diminish the number of cases for hysterectomy, though it will not altogether supersede it. For the success of this latter operation, it seems almost essential that it should be undertaken while the tumours are small; the ovaries will be easily reached at such a stage, whereas, later on, one or both may not be removable even if they can be reached. This essay, which concludes with some remarks on the operation, and includes a detailed account of all the cases Dr. Keith has operated upon, should be read with great care by everyone who practises in this department of surgery. With one or two reservations, we should endorse all Dr. Keith's views. Even should the mortality be greatly reduced by the development of the technical methods of operating, hysterectomy is an operation which should never be advised or undertaken except for cases unsuited to the less severe treatment by oöphorectomy.

*Contributions to Pathology and the Practice of Medicine*; by J. R. WARDELL, M.D. London: H. K. Lewis, 1885.—This is not a formal or systematic treatise on medicine or any one branch of it, but a collection of papers on various diseases and points of medical practice. Most of the articles have seen the light before, and many

of them are widely and deservedly known. The article on relapsing fever remains, as it was at the time of its publication, the best monograph on the subject, containing a good historical review of the disease as well as a minute study of more than a thousand cases during the epidemic in Edinburgh of 1843-44. Next to this we would place the article on pleuritis, serous and purulent effusions, as one which bears evidence of the keen discrimination of the author in his more mature years. The papers on diseases of the spleen and pancreas, on enteralgia and on peritonitis are well known to all readers of Reynolds' System of Medicine, and fully warrant the confidence that was shown when he was selected to write those articles. The first article in the volume will be even more widely known, having appeared in Quain's Dictionary of Medicine; it deals with hypertrophy of the heart in a most exhaustive manner. There are also short papers on ulcer and cancer of the bowels, and on ulcer and cancer of the stomach, on enteritis and typhoid fever. Aneurysms of the subclavian artery, of the heart, and of the abdominal aorta, have also come in for a share of attention, whilst the papers on chorea, tubercular meningitis, tumours of the brain, and on syphilitic hemiplegia, evince the interest which he took in diseases of the nervous system. There are also miscellaneous papers on scurvy, puerperal convulsions, spasm of the glottis, croup and tæniæ, whilst those on infanticide, suspected poisoning, and on poisoning by laudanum, sulphuric acid and Burnett's fluid, show that his interest in his profession was both wide and deep. In the concluding chapter he briefly reviews the present state of medicine. One cannot put this book down without a feeling of sincere regret that its author has not been spared to see the full fruits of his labours, for his death took place just at the moment when he had completed the revision of his book, and it was ready to be issued to the public. On every page it bears the stamp of being the work of a man of large experience, and one who used that experience well.

*A complete Pronouncing Medical Dictionary*; by JOSEPH THOMAS, M.D., LL.D. Philadelphia: J. B. Lippincott Company, 1886. We may hope that there is less crying need for this special dictionary among English students and practitioners of medicine than, according to the author's preface, there would appear to be in America. The main specialty of the book is that it assumes the reader to be entirely innocent of Latin, and still more of Greek, and it is intended for the multitudes of young men who in the United States commence the study of medicine without any previous acquaintance with the dead languages. Thus the derivation and pronunciation of the different words are given with especial fulness, the student even being assisted to a real Parisian accent in the case of such French synonyms as it has been found necessary to give; while at the end of the volume, in the form of an appendix, we have a concise Latin accidence, in which words like *vena* and *ligamentum* serve the function so uncomplainingly performed by *mensa*, *regnum*, &c., in the days of one's youth. The dictionary also goes somewhat, though perhaps not unwisely, out of its way to give under *Pathogenesis* a long and very good article on the germ theory of disease by Dr. Longstreth. As for the dictionary itself, as far as we have tested it, it appears both accurate and complete, but one does not find out a dictionary's defects until one goes to it in difficulties, and then all of them are apt to fail one. We have not yet had an opportunity of putting the present publication to this test; but we can, nevertheless, recommend it as a sufficiently safe guide under all ordinary circumstances.

*Illustrated Lectures on Ambulance Work*; by Dr. LAWTON ROBERTS. London: H. K. Lewis, 1885, pp. 171.—These lectures were originally delivered to ambulance classes held in connection with the Wynnstay Colliery, the new British Ironworks, and the Plastkynaston Colliery. Dr. Roberts could hardly have had an audience more likely to appreciate his lectures, or one to whom such lectures would be more useful, than "the colliers, furnace-men, fitters, carpenters, blacksmiths, puddlers, brickmakers," and other representatives of the working population for

whose especial benefit they were prepared, and we are not surprised that he should have been requested to print them. We will hope that these men, who showed "remarkable aptitude in the pursuit of their ambulance studies," now that they have the means will continue to shew this aptitude, and thoroughly master all the details these lectures contain. The ignorance of the general public on all matters pertaining to medicine and surgery is quite remarkable, and it is not improbable unless ambulance classes are more thoroughly grounded than is possible in the course of five lectures, that their little knowledge many often lead to more harm than good, for good intentions are no protection against meddling fingers. Among populations where accidents and surgical injuries are common, information of *what to do* and *what not to do* must be of very great service, and may often be the means of saving life.

*A Physician's Pharmacopœia*; by J. BAILY. London: J. & A. Churchill, 1885.—This is a useful little collection of formulæ, a fair proportion of which are original. Many of the prescriptions reflect, as is quite natural, the besetting sin of the general practitioner, love of polypharmacy; but that is not the author's fault, who, as a pharmacist, is only concerned to discover and make known the best way of combining the drugs which the doctor has incontinently ordered to be thrown together. With one object of Mr. Baily's pharmacopœia we fully sympathize, viz., the discouragement of the use of secret nostrums, but we fear that some more far-reaching measure is required for this purpose than the publication of a small red volume by a country chemist.

*Milk Analysis and Infant Feeding*; by ARTHUR V. MEIGS, M.D. Philadelphia: P. Blakiston, Son, & Co., 1885. This little volume consists of a reproduction, with slight amendments, of papers read before certain learned societies in Philadelphia, on some of which we commented in terms of high approbation more than a year ago. We are very glad to see them brought out in a separate form, as they are thus rendered more accessible, and they deal with a subject which all must admit to be of the first importance. A bibliography of the subject is appended, which undoubtedly adds to the value and completeness of the work.

## ABSTRACTS AND EXTRACTS.

**CASES OF LIGHTNING STROKE.**—In the *Australasian Medical Gazette* for August, Dr. Edward Jenkins describes the effects of lightning stroke on three men who took refuge in a brickshed during a thunderstorm. The roof of the shed was of galvanised iron, but there was a slit two inches wide along the top, which admitted the rain. At the moment when the flash of lightning came they were crouching together in the centre near one of the supports; they were all three knocked over by the flash, but the man who had been in the centre with his back close to the post, though stunned for the moment, soon recovered, and felt no further ill effects. The others were both taken to Prince Alfred's Hospital; one of them was insensible on his arrival and much collapsed, with dilated pupils and a very weak pulse; soon after he was taken with convulsions which lasted about twenty minutes, and the same evening he was again convulsed. He was still insensible next morning, but later on he complained of headache, though he remained drowsy and stupid all day; after this he rapidly improved, he never had any pain, but complained of numbness and tingling all over; there was no paralysis, sensation was normal, and the reflexes were natural. There was a wound on the back of his head from which some dead bone was removed after a time; in about nine weeks he left the hospital quite well. The third man was able to give some account of himself when he reached the hospital, and had a clear recollection of everything that happened up to the

time of the flash; he also had a wound on the back of his head; his pupils were natural, and his pulse regular; his temperature was 101°. For the first few days there seemed to be nothing but the scalp wound wrong with him, but when he got up on the fifth day his gait showed decided incoordination. Next day the following points were noted: he was somewhat febrile and complained of headache, the incoordination was as before; the patella reflex was much increased, but the skin reflexes were normal; there was no paralysis, and sensation was perfectly acute everywhere; there was no deafness or alteration of smell, the discs were healthy and sight good; the electrical reactions were natural, and there was no loss of control over the sphincters. The incoordination and exaggeration of the patella reflex persisted at the time the paper was written, but it was noted that the man's memory was unimpaired.

**MÈNIÈRE'S DISEASE.**—There are two kinds of giddiness associated with ear affection, according to Dr. Pierce (*Medical Chronicle*, October), one in which the patient feels his body impelled in different directions with a distinct tendency, more or less marked, to fall to the ground; and the other in which unsteadiness of the body is produced by the sensation to the patient of extraneous objects appearing to move about in certain defined planes and assume abnormal positions. The majority of cases of so-called Mènière's diseases are in reality, according to him, only cases of labyrinthine vertigo. In true Mènière's disease there is not any antecedent ear affection, the attack is sudden, severe, and may never recur, it is nearly always limited to one ear, although the deafness is extreme and permanent. The tinnitus aurium and giddiness diminish or cease after a time, and the external and middle ears show no sign of disease. In labyrinthine vertigo, on the other hand, there is frequently a history of some previous ear trouble with more or less deafness. The attacks are less sudden but more frequent than in true Mènière's disease; in both there is no loss of consciousness, but the hearing after labyrinthine vertigo may be unaffected or only slightly injured, or previous deafness may be considerably increased; the giddiness of labyrinthine vertigo is rarely so severe as in Mènière's disease, although more chronic and liable to intermittent exacerbation. An attack of labyrinthine vertigo is often preceded by slight staggering or nausea for a day or so. In true Mènière's disease the treatment during the attack should consist of rest in the recumbent position, restricted diet, cold to the head and sinapisms to the calves and epigastrium. The after-treatment at present is particularly unsatisfactory, bromide and iodide of potassium and quinine have all been recommended, but do not appear to exert much effect, and Dr. Pierce hopes for more from the continuous current than from any other line. In labyrinthine vertigo careful attention should be paid to the general health; local treatment either by means of the Politzer bag, catheter, or by stimulating inhalations will generally be indicated and found useful; where there is much tinnitus, leeches in front of the ear give relief, and large doses of the bromides, tincture of gelsemium, hydrastis, and valerianate of zinc have been found efficacious.

**TERMINATIONS OF HEPATIC ABSCESSSES.**—A Peruvian physician describing the various forms and results of hepatic abscesses, gives the case of a man of 60, who had been for some months coughing up great quantities of bilious pus from an abscess which had perforated the diaphragm. A second abscess formed on the liver, more to the right, which was opened, and a considerable quantity of pus drawn off. No communication existed between the two cavities; however, the first abscess decreased gradually, and ultimately the expectoration became quite free from pus. The wound made into the second abscess became inflamed and ulcerated, and torrents of pus poured forth during coughing; a drainage tube was inserted, but the patient succumbed from extreme marasmus and constant diarrhœa. A short time before death a true periostitis attacked the eighth and ninth ribs. In another case, where there was abscess of the concavity of the liver, and aspiration was performed with injection of iodine, a temporary cure resulted, and the man went back to his work, but had

no skilled attendance where he was, and returned to hospital in a worse state than before, the two aspiration punctures having become gangrenous, and, as was feared from the odour of the secretion which exuded from them, the liver itself was in the same state. This was really the case, and the patient shortly afterwards died. These cases support the opinion of the physician who gives them that the prognosis is much more serious when abscesses attack the lower than the upper border of the liver, and when perforation occurs into the intestine than into the lungs.—*El Monitor Médico*.

**NITROUS OXIDE IN LABOUR.**—In a communication made by Dr. Doederlein, assistant in Professor Zweifel's obstetric clinic in Erlangen, to the recent (58th) assembly of scientists and physicians at Strasburg, a detailed description is given of the method employed by him for manufacturing and purifying nitrous oxide and oxygen for the purpose of administration as a mixture in the proportion of 4 to 1 to patients in labour. He has made a large number of observations, and confirms the statement of Klikowitsch, of St. Petersburg, that though the inhalation of the mixed gases may be continued for a considerable time, not only is there no danger of arresting the action of the heart, but the contractions of the uterus, though unfelt by the patient, suffer no diminution in their intensity, so that labour is not liable to be prolonged as it is when chloroform is given. The author finds it quite unnecessary to erect a strong chamber where the pressure of the atmosphere can be increased, as was recommended by Paul Bert in a paper published in the "Comptes Rendus, 1878," in which some experiments on dogs were described. According to Dr. Doederlein, patients under the influence of the mixed gases keep their colour, and show no trace of a cyanotic state. They are, too, not completely unconscious, though they feel no pain. They sometimes cry out, but when questioned afterwards, say they have had a pleasant dream.

**FRACTURE OF THE STERNUM.**—A man about fifty years of age and of intemperate habits, whilst somewhat under the influence of drink, fell through a dilapidated gallery twenty feet down to the pavement. He was examined about six hours after the accident. There were simple fractures of the ninth and tenth ribs of right side posteriorly to axillary line. There was also a prominent deformity situated just below the junction of the upper and middle pieces of the sternum, about an inch and a half in length; the movements of the chest in respiration caused distinct bony crepitation and a gliding movement to be felt over this deformity. This proved to be a fracture of the sternum, in which the lower fragment was overlapping the upper to the extent of an inch or more. The left anterior chest wall was emphysematous from the clavicle down to about the sixth rib, and from the left sternal margin to the axillary line. There was percussion dulness over dependent portion of left lung; the heart sounds were distant and a metallic tinkling could be heard over front of left lung. Evidently, here existed a wound of the pleura, caused by the jagged end of the upper fragments penetrating the thorax, with a resultant hæmorrhage into pleural cavity and escape of air into areolar tissue of chest wall. The condition of shock was profound, the temperature falling to 96°, breathing very shallow, and the radial pulses could not be felt at the wrists; stupor was well marked, although when aroused he would answer questions intelligently. Owing to fracture of ribs, no efforts were made to approximate the fractured ends of the sternum, but as soon as reaction from shock occurred, a bag containing two pounds of sand was placed over site of fracture, and continuous pressure kept up for ten days. His recovery was complete.—*New Orleans Medical and Surgical Journal*, October.

**SPRAINS OF THE ELBOW IN CHILDREN.**—Among other papers of much interest in the August number of the *Annals of Surgery*, edited by Mr. Keetley, is one by Mr. Hutchinson, Junior, "On certain Obscure Sprains of the Elbow occurring in Young Children." Commencing with an excellent survey of the literature of the subject, the author passes in review the various theories which have

been adduced in explanation of the lesion. Not satisfied with these explanations, he made a series of experiments on the dead body, and found that the orbicular ligament of the radius had slipped up, with or without rupture of the sub-orbicular membrane. For reduction, Mr. Hutchinson advises flexion of the elbow and pronation of the hand, when the ligament again slips down into its right place. The accident only occurs in children not more than six years old, and seems almost invariably to be produced by raising them sharply or dragging them by the arm, the hand being in a condition of supination. The accident is not uncommon; and, if not recognised, the displacement may remain unremedied. Mr. Hutchinson is to be congratulated on being the first to settle the exact nature of the lesion by experimental enquiry and dissection.

**EXTIRPATION OF THE GALL BLADDER.**—In the course of a long discussion at the Royal Academy of Medicine in Belgium, on the subject of excision of the gall bladder, M. Gluge expressed his opinion that after removal of the gall bladder there need be no further fear of calculi forming in the liver, and he mentioned a case which he had seen in consultation ten years ago, where an abscess in the abdomen was opened, and discharged not only pus and bile, but a biliary calculus which had evidently caused ulceration and perforation of the gall bladder. The patient was cured, and had no return of the symptoms.—*Le Scalpel*.

**THE FORMATION OF RHINOLITHS.**—It is said that some forty cases of rhinoliths are recorded in literature, most of them having formed round some foreign body as a nucleus. Professor Störck of Vienna has, however, had a case where no foreign body could be detected, but, as the whole was composed of phosphate and carbonate of lime, he thought it possible that a fragment of bone might originally have existed and acted as nucleus. Dr. Ottokar Chiari exhibited at a recent session of the Vienna Medical Society a rhinolith he had extracted from the right nostril of a young lady, and which had blocked it up for some ten years. The chemical composition of the body was, as in Störck's case, phosphate and carbonate of lime, but here a definite nucleus existed in the form of a metallic button. The patient had no recollection of its introduction and supposed she must have put it up the nose when she was a child.—*Wiener Medicinisches Blatt*.

---

## REPORTS OF SOCIETIES.

### PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 3RD, 1885.

J. S. BRISTOWE, M.D., F.R.S., President, in the Chair.

#### *Tumour at base of Brain.*

DR. SAINSBURY showed this specimen, of which he could give no history. The tumour looked like a pendulous fibroma. Microscopically the matrix was fibro-cellular invested by a dermis with papillary layer, epidermis, rete Malpighii, and horny layer; no hair follicles or sweat glands were seen. He suggested that the tumour was developed from the anterior lobe of the pituitary body.

Mr. J. BLAND SUTTON remarked that teratomata were tumours of considerable interest inasmuch as they occurred with especial frequency in the neighbourhood of obsolete canals, particularly those which brought the three blastodermic layers, epiblast, hypoblast, and mesoblast, into direct communication in the embryonic condition of mammals. A good example of the kind of canal referred to was seen in the canal which pierced the floor of the pituitary fossa, whereby in early foetal life the infundibulum, foregut, and buccal involution came into contact. At the caudal end of the notochord the central canal of the spinal cord communicated with the alimentary canal

by means of the neurenteric passage; in this way the three layers came into direct relation. The post-anal gut in its relation to sacral cystic tumours, supposed to be derived from Luschka's gland, afforded another instance. The branchial clefts were also examples of obliteration of disused passages between hypoblast internally and epiblast externally. In this way the occurrence of teeth imbedded in cysts attached to the petrous portion of the temporal bone of horses might be explained, the tympanum being in reality a modified branchial arch. With regard to ovarian and testicular tumours, there was good evidence to show that during their development they came into relationship with regions where the germinal layers split, and where transformations occurred likely to produce similar events such as might be demonstrated at the base of the skull, sacral region, branchial arches, and elsewhere. A paper of his having reference to the sacral teratomata would, he hoped, shortly appear.

Dr. HALE WHITE thought Mr. Sutton's explanation was probably the correct one, and it was applicable to a case he had himself shown during the previous session.

Mr. BUTLIN had been much interested in Mr. Sutton's remarks in reference to the development of the testicle which was always supposed to take place from the epiblast. If Mr. Sutton's view was correct, the occurrence of carcinomatous tumours was much more easy to understand.

#### *Cancer of Bladder.*

Mr. MARMADUKE SHEILD exhibited a bladder infiltrated by soft cancer, which also formed irregular nodular projections covered with calcareous deposit; the ureters were obstructed by the growth, and much dilated and thinned. The patient, a man aged 58, under the care of Mr. Timothy Holmes, had undergone amputation of the penis for epithelioma in 1866. He remained well until 1883, when micturition became difficult; in August 1884 the orifice, which had contracted, was dilated. He at that time suffered also from vesical irritability and hæmorrhage, and in October was re-admitted with extravasation of urine into the scrotum; the urine contained much pus, blood, and débris of new growth; there was marked cachexia, great pain, and œdema of the left leg. Death ensued in a few days. Secondary growth was found in the iliac, sacral and lumbar glands, and in the liver; the pelvic growths were chiefly on the left side and had compressed the left iliac vein. The pelvis of the kidneys were dilated. In the left iliac fossa was an abscess which contained foul pus and disintegrating tissue; it reached as high as the kidney and was in part bounded (in front) by the colon, and appeared to have originated in a sloughy mass of growth about the iliac glands. Under the microscope the growth presented a well-marked stroma containing large spheroidal multinucleated cells. It was rare to find the bladder the seat of primary cancer, nearly all the cases had occurred in the male. He referred to the absence of villous growths, and expressed the opinion that the affection of the penis, which had been amputated nearly 18 years earlier, could have had no direct relation to the disease of the bladder, which he attributed to the irritation of the mucous membrane caused by changes in the urine consequent upon difficulty of expulsion. In conclusion, he observed that the comparative frequency with which abscess formed in connection with malignant disease within the abdomen might be accounted for by the rapidity of the growth, leading to necrosis, and by the proximity of the intestine.

Mr. BRUCE CLARKE had exhibited a similar case of a pyæmic nature, due to catheterisation, but he agreed that in Mr. Shield's case the cancer was primary in the bladder.

Mr. DAVIES COLLEY asked whether the catheter was frequently passed. In these cases he believed the cancer was often directly due to the irritation produced by the catheter. He mentioned a case in point where cancer of the bladder occurred 30 years after urethrotomy. He had shown a case before the Society where cancer of the bladder owned such a cause following the removal of a calculus from the bladder.

The PRESIDENT mentioned the case of a gentleman who had had hæmorrhage from the bladder for 18 years; after death sarcoma of bladder and kidneys was found;

this could not have existed so long. He might have had a villous growth. There had been frequent catheterisation.

Mr. SHIELD, in reply, did not regard this as a case of pyæmia. He was not certain whether the catheter had been frequently used or not. He believed not.

#### *Cyst of Finger.*

Mr. BARKER showed drawings of this affection. The tumours in these cases were usually small, on the palmar aspect of the phalanx, cystic, and with a dermal lining; the contents closely resembled sebaceous material. In his own case, on section through the wall, there was seen an outer layer of fibrous tissue, the ovoid cells gradually becoming smaller, leading to a horny mass; there were no true papillæ, and no traces of follicles. In each case there appeared to have been an injury. If they had a traumatic origin, he considered they ought to be more frequent.

#### *Carcinoma of the Kidney.*

Mr. J. HUTCHINSON, Jun., showed this specimen for Mr. McCarthy. The man had pain in the left groin and lumbar region. The urine contained blood, albumen, and casts of fibrine. The kidney was removed, and he recovered from the operation, but died three months later, probably from heart affection. The tumour appeared to have arisen from the pelvis of the kidney; it was a carcinoma, part of which had become fatty.

#### *Chronic Endocarditis.*

Dr. NORMAN MOORE showed two cases illustrating the changes in the endocardium relating to similar changes in the aorta. Case 1.—A heart weighing 25 ounces, from a man aged 42, who died suddenly. The heart was hypertrophied, but the valves were not thickened, and there were no growths upon them. The aorta was highly atheromatous, and above the valves there was a small aneurysmal bulging. Below the valves both walls of the left ventricle showed complete opacity and great thickening of the endocardium. It presented a uniform white glistening surface, and section showed that inflammatory tissue had been formed in the deeper layers of the endocardium; the most superficial layers were regularly stratified and normal. Beneath them was a zone of irregularly arranged connective tissue dipping into the muscular substance. The nearest part of the muscular tissue showed some granular degeneration of the fibres. A similar thickening existed over a smaller area of the right ventricle. The auricles were normal. The pericardium was slightly thickened, the kidneys were healthy. The hypertrophy appeared to be due to the obstruction to the cardiac movements caused by the thickened endocardium. There was no history or evidence of rheumatism, but syphilis seemed to be the probable cause. Case 2.—The heart of a man aged 54, who died after many attacks of angina pectoris. The aortic arch contained many calcareous plates, the valves were healthy, but below them was a thickened patch on the septum of the ventricles. It originated in a degeneration spreading from the attachment of the mitral valve, probably due to strain. This form of thickening was always confined to the septum.

Dr. GOODHART agreed as to the extreme rarity of this disease. He had only seen one case. The escape of the mitral valve in this specimen was very remarkable.

The PRESIDENT recalled a similar case, which he fancied was syphilitic.

Dr. ANGEL MONEY thought that some developmental considerations might explain it.

#### *Extra-Peritoneal Rupture of the Bladder.*

Mr. E. H. FENWICK showed this specimen, taken from a cornet-player, aged 42. The symptoms came on suddenly when he was playing, with extreme abdominal pain. He passed large quantities of blood and water. He vomited freely. When seen, there was dulness over the lower part of the abdomen. There was marked cystitis, and air was passed per penem. For three weeks he improved and seemed convalescent, but then was seized with abdominal pain and died in a few days from peritonitis. On opening

the abdomen in the lower part, there was found a large extra-peritonæal sac, formed originally by a sudden egress of the contents of the bladder; this contained purulent urine: its walls were sloughing. It had two openings, one leading into the peritonæum and quite recent, the other led into the bladder and was older. From the bladder side the opening was rounded and about the size of a two-shilling piece. The surrounding mucous membrane showed tunicary herniæ and also an altered condition of the veins, with clotting. There was a stricture of the bulbo-membranous portion of the urethra, admitting a No. 12 catheter. There was both recent and old peritonitis. What was the cause of the ulceration? Herniated protrusions and subsequent giving way might have caused it, or was it due to a change in the venous system of the bladder? The length of time the man lived after the rupture, viz., 26 days, was noteworthy, being the second longest on record for spontaneous rupture.

Mr. SHEILD mentioned a case of a small perforation of a bladder which was much thickened and fasciculated, forming a lot of softened pouches.

Mr. W. A. LANE believed the tunicary herniæ were not uncommon on the upper surface of the bladder, they had no muscular covering, and would easily yield. They were almost constant where there was any obstruction, e.g., from stricture or prostatic disease.

Mr. FENWICK said that he had omitted to draw attention to one point, viz., the complete control which the patient retained over his bladder up to the day of his death.

#### *Obstruction of the Coronary Arteries.*

Dr. PERCY KIDD showed this specimen, taken from a man, æt. 46, with emphysema, cardiac dilatation and hypertrophy and granular kidney. The symptoms during life were, extremely irregular and weak pulse and great shortness of breath. Spasmodic attacks of dyspnoea took place the last fortnight of his life. At the autopsy the heart was much hypertrophied and dilated, the muscular tissue appeared quite healthy, and there was no disease of the valves beyond slight thickening. The right coronary artery was completely blocked by recent adherent thrombus throughout its course. The left coronary artery was greatly obstructed at one point by calcareous atheromatous change, and one of its transverse branches was completely calcified. The openings of the coronary arteries in the aorta were quite free. Arch of aorta dilated, but only slightly atheromatous. The rest of the aorta and its branches were extremely atheromatous. The pulmonary artery was also somewhat atheromatous. Kidneys granular, but of good size. Infarcts in kidney and spleen. Liver, nutmeg. Lungs slightly emphysematous and contained infarcts. Vessels of the brain highly atheromatous. Brain itself healthy.

#### *Aneurysm of the Internal Carotid within the Skull.*

Mr. ANDERSON showed the specimen, taken from a man, aged 55, who suffered from attacks of headache and right-sided fits. There was no loss of consciousness; the right side was slightly weaker after the fit. Optic neuritis was present, the right pupil being the larger. He died, after an attack of a few hours of coma, with right hemiplegia. The tumour was found in the left middle fossa, lying on the dura mater; it was almost filled with laminated clot, had a well-defined capsule, and communicated with a large artery. It was an unusually large aneurysm. It was thought to arise from the middle cerebral artery.

Dr. GOODHART mentioned a specimen in the College of Surgeons, almost as large, presented by Mr. Jonathan Hutchinson, who had diagnosed the condition during life from hearing a murmur through the skull.

The PRESIDENT alluded to a case that had been shown by Dr. Brinton, who had written a report upon the subject.

#### *Tubercular Growth of the Dura Mater, with Affection of the Subjacent Vertebra.*

Dr. HALE WHITE showed specimens of a yellowish hard mass which lay outside the dura mater behind the bodies of the upper dorsal vertebrae. It was somewhat irregular

on the surface, and grew out through one of the adjacent spinal foramina around the spinal nerves. There was no sign of any breaking down, and the inner surface of the dura mater was free. The spinal cord was considerably pressed upon. The vertebra subjacent showed erosions on its surface. On section it was not soft, except in the centre, but very white. Microscopically, there was a delicate reticulum with many small and giant cells; caseous masses were scattered throughout. The growth had nowhere penetrated the dura mater so as to affect either the cord or nerves; the latter had undergone some atrophy, and the former was considerably pressed upon. The inter-vertebral discs were slightly affected. The patient had phthisis and paraplegic symptoms. No bacilli could be found in the growth, which was very dense. The disease was probably tubercular, but possibly syphilitic.

#### *Card Specimens.*

Dr. LEDIARD—Black Tongue.

Dr. SAVILL—Heart from a Case of Chorea.

Sir W. MACCORMAC—Epithelioma of the Clitoris.

Mr. DAVIES COLLEY—(1) Sloughing Muscle and Tendon; (2) Annular Slough of the Mucous Membrane of the Rectum.

Mr. MCCARTHY—Necrosis of the Patella.

Mr. BRYANT—Mesenteric Retro-Peritonæal Myxolipoma.

### MEDICAL SOCIETY OF LONDON.

MONDAY, NOV. 2ND, 1885.

W. M. ORD, M.D., F.R.C.P., President, in the Chair.

#### *The Clinical Significance of the Deep Reflexes.*

Dr. GOWERS opened the discussion; he gave a brief outline of what he believed to be the mechanism by which the symptoms commonly known as "tendon-reflex phenomena" were produced. It was only by understanding the mechanism of their production that their relation to other symptoms could be comprehended, and the phenomena used in the diagnosis of cases that did not conform to regular types. Tension on a muscle stimulated the afferent nerve-fibres (which end in the interstitial tissue); and this stimulation so influenced the centres in the spinal cord, as to induce in the muscular fibres a state of slight contraction, probably the same condition as physiological "tone." In this state, local mechanical stimulation caused a sudden brief contraction. A sudden increase of tension was one form of mechanical stimulation, and a tap on the tendon acted by suddenly increasing the tension. If increased tension was maintained, the muscle, relaxing from the first contraction, was excited to another, and so a clonus occurred. The contraction was local; the irritability was reflex, and, as it was excited by tension, it was convenient to speak of it as "myotatic irritability," or the irritability of extended muscle. The muscle-reflex centres overacted in consequence of a loss of the normal control, which was probably exerted by structures in the grey matter of the cord at the same level, structures in which the lateral fibres ended. It was pointed out that this hypothesis enabled many conditions otherwise inexplicable to be understood, such as the condition of these phenomena in ether and in chloroform-narcosis, and after epileptic fits. The facts seemed to show that this hypothetical controlling structure was more susceptible to the action of poisons than was the muscle-reflex centre itself. Dr. Gowers passed next to the questions in practical diagnosis that especially invited discussion; he first considered locomotor ataxy. Without denying that the knee-jerk might occasionally be absent in health, he believed that most alleged instances of such absence (including some he himself described several years ago) were due to imperfect observation, and that its absence was of great significance as an indication of commencing tabes, even though other symptoms were extremely slight. On the other hand, the presence of the knee-jerk did not

exclude true tabes. He had watched its disappearance after other symptoms of the disease were distinct. A peculiar difficulty in determining the absence of the knee-jerk in this disease was next mentioned. When there was excess of superficial reflex action, a true reflex action might stimulate the knee-jerk, although this was really lost; the distinction being that, while some attempts to obtain it failed, others might cause a contraction now in the extensors, now in the flexors, now in the muscles of the other leg, and that a prick on the skin had precisely the same effect in these cases. The loss of the knee-jerk in diphtheritic paralysis was mentioned as of great significance, diagnostic and pathological, and the important observations of Bernhardt, that the loss might follow diphtheria when there was no paralysis, showed that the influence of this disease on the nervous system was more frequent than obtrusive palsy suggested. The loss might cause an erroneous diagnosis of tabes, if it coincided with inco-ordination. In pseudo-hypertrophic paralysis, the diminution and ultimate loss was probably due to the morbid process occupying the interstitial tissue in which the afferent nerves of muscle ended. It was of great diagnostic importance, as a distinction from the disease with which pseudo-hypertrophic paralysis was most likely to be confounded, slight congenital spastic paraplegia, in which the knee-jerk was always increased. After alluding to the conditions met with in intracranial disease, Dr. Gowers passed to the question of greatest difficulty, the state of these phenomena in functional diseases, especially in "hysterical paraplegia." Certain facts might, he said, be stated with confidence. (1) In many cases, the myotatic irritability was perfectly normal. (2) In others, there was distinct, though slight, excess, insufficient to give a true clonus. (3) In hysterical contracture, and depending on it, there might be a clonus like that which occurred in health in standing on "tiptoe." (4) A "spurious foot-clonus" was common, depending on a voluntary contraction in the calf-muscles, pressing down the foot, and varying in degree from time to time, the clonus varying with it. This was very characteristic, and was a most important diagnostic sign of hysterical paraplegia. While not denying the possibility, in hysterical paraplegia, of a true uniform clonus, such as occurred in spastic paraplegia, Dr. Gowers expressed the opinion that, to say the least, it was so rare that it did not materially lessen the value of this sign of organic disease. He believed, and cited cases in support of his opinion, that some of the cases from which the inference had been drawn, that a true clonus was frequent in hysterical palsy, were cases of organic disease. More than a mere diagnosis was required as evidence. It must not be forgotten that true spastic paraplegia might be recovered from. He did not assert this of lateral sclerosis; he believed that spastic paraplegia might depend on disease of the structures in the grey matter in which the lateral fibres end, intermediate between the lateral fibres and the muscle-centres. If, as he assumed, there were controlling structures, the symptoms of their disease would be identical with those of disease of the lateral columns. A subject that arose out of the last topic, and had an important relation to the subject under discussion was the wisdom of the current wide use of the term "functional disease." He maintained that in many cases and maladies so described there must be a change, and a considerable change, in the nutrition of the nerve-elements, springing, it might be, out of functional derangement, but always maintaining and increasing that derangement. The changes in nutrition that the microscope could detect were simply colossal considered as alterations of molecular nutrition. Many, perhaps most, so-called functional diseases were far better thought of and spoken of as nutritional diseases. In cases of hysterical paraplegia, in which a persistent change in myotatic irritability, however slight in degree, was found, there must be a change in the nutrition of the spinal cord, on which so persistent an objective symptom depended. A case had been recorded by Charcot that seemed to prove, as clearly as a single case could prove, that a paraplegia, at first purely hysterical, might pass into structural disease—lateral sclerosis. The transition must have been by changes in nutrition, such as Dr. Gowers believed were, in slight degree, common in

these cases. While function depended on nutrition, nutrition equally depended on function. The question was to what degree such secondary change in nutrition might go. The view that even structural disease often had this origin had been urged a few years ago in a very thoughtful paper by Dr. Donkin. It was not suggested that there should be a departure from the present lines of practical diagnosis, but only that we should strive to gain more accurate conceptions of the conditions that underlay them. In conclusion, Dr. Gowers said that the explanation of these symptoms, and of their use in diagnosis, that he had given, might seem complex, but he was convinced that their nature was complex, and that the evidence they give often required much care rightly to interpret. In the progress of science first impressions of simplicity had often to give place to a conviction of complexity, and they had to wait until fuller knowledge could reveal the alternate simplicity of order and of law.

Dr. HUGHLINGS JACKSON thought the paper a masterly contribution to a very important subject, combining, in a manner to be envied, the practical and the scientific. He thought Dr. Gowers had no need to apologise for the elaborate way in which he had dealt with a very complex subject; but, on the contrary, that he was to be congratulated on having dealt faithfully with the many different details of it, and their intricate relations. It was laziness which led to simplifying a really complex subject by the easy process of ignoring its complexity. Industry did not consist in doing something all day long, but in facing, as Dr. Gowers had done, the full complexity of problems taken up. He agreed with Dr. Gowers in thinking that there were cases of tabes dorsalis in which the knee-jerks were present. It was quite certain that a man might be perfectly paraplegic for many months, twelve for example, with extreme rigidity of the legs, and yet recover, at any rate with the qualification Dr. Gowers had made; this remark did not apply to so-called protopathic spastic paraplegia. He had suggested that increased knee-jerk and foot-clonus, in cases of hemiplegia from destructive cerebral lesion, were owing to loss of cerebral control. Passing over some cases in which these super-positive phenomena were present for a while at the onset, the objection which had naturally been urged to his hypothesis was that the super-positive symptoms mentioned came on late—"waited" for the establishment of lateral sclerosis. The current doctrine was that the "descending" process which destroyed the fibres, next coming to the anterior horns, produced in their cells the diametrically opposite functional state of exaltation. He did not believe that the increased excitability of the anterior horns, or, to use Dr. Gowers's expression, muscle-centres, was owing to pathological change, but that it was the result of permitted hyper-physiological activity. By borrowing Dr. Gowers's hypothesis of local spinal inhibitory centres, he thought his view of "loss of control" was still tenable. Following Dr. Gowers, and thereby acknowledging great indebtedness for any value his modified hypothesis might have, he would say that the "descending" pathological process destroyed the local inhibitory centres, leaving the "muscle centres" intact, but yet, from loss of control, in increased functional activity. The current hypothesis would not account for increased knee-jerk and foot-clonus in some cases of post-epileptiform paralysis. He next mentioned some facts from a case he had recorded: a convulsion, beginning in the left foot, affecting the left leg chiefly, and followed by temporary paralysis, chiefly of the leg, with exaggerated knee-jerk and foot-clonus. In this case, following Todd and Robertson, he believed that the paralysis was owing to exhaustion among other parts of fibres of the lateral column. Dutil had adopted the same hypothesis in a very important contribution to our knowledge of post-epileptiform paralysis. Once more taking up Dr. Gowers's hypothesis, he thought that, not only were the fibres in the lateral column exhausted in the case mentioned, but also the local inhibitory centres; in consequence the muscle centre was "let go." Westphal and Dr. Gowers had both pointed out that, after some epileptic fits, there was very transitory loss of the knee-jerk. In these cases the presumption was that the exhaustion was greater in range, involving not only the local inhibitory centres, but the muscle centres also. Dr. Gowers

suggested that, in his case of loss of the knee-jerk after an epileptic fit, the lumbar nuclei were exhausted. He referred in this connection to some valuable researches by Dr. Beevor, who had in many cases found ankle clonus and increased knee-jerk after epileptic fits. The cortical discharges both in epileptiform and epileptic fits varied greatly in degree, as the varying degree of the paroxysms produced by them showed; the after-exhaustion would vary in range correspondingly. He thought the condition of the deep "reflexes" after epileptic fits a matter of very serious importance in the analysis of the wide symptomatology of epilepsy. Foot-clonus after epileptic fits was, he thought, an illustration of the principle of "loss of control" stated many years ago by the late Dr. Anstie. It was, he thought, a phenomenon of the same order as passage of fæces after a slight fit of epilepsy, and of the same order as post-epileptic mania.

Dr. BUZZARD, after expressing his high sense of the value of the paper which had just been read by Dr. Gowers, went on to speak of the necessity for great care in the methods of testing for the knee-jerk; the best method known to him was that recently introduced by Jendrassik, who required his patients to hook the fingers of one hand in those of the other and then to pull steadily apart, and, whilst the attention was concentrated on this struggle, the tendon should be struck. Sometimes one method failed when another would succeed; he preferred always to use a percussion hammer. The absence of the knee-jerk was always, he believed, pathological. There were several affections of the spinal cord in which it was absent, and this fact did not serve to help in diagnosing between these several conditions, but it did serve to diagnose between disease of the spinal cord and of the brain. The knee-jerk was absent in that form of multiple neuritis which followed diphtheria, but it was not always absent when the paralytic symptoms first appeared, and it might be absent after diphtheria without any paralysis supervening; it did not return until long after the paralysis had passed off. He had never seen the knee-jerk regained after tabes dorsalis, and cases where this was said to have occurred had in his experience always turned out to be cases of multiple neuritis. An excessive knee-jerk signified that the inhibitory influence of the nervous centres was no longer being normally excited. It was most marked in compression of the cord as in Pott's disease, though when the disease was low down it was possible that the knee-jerk might be absent altogether. True ankle clonus always suggested organic disease, but it was no proof of it.

Dr. ALTHAUS regretted that no mention had been made of the light reflex, which he held ought to be considered as a deep reflex. He had examined a large number of cases of tabes, and in 60 per cent. found the Argyll Robertson symptom present; it was one of the earliest signs and was a very important one. He would also include tetany with especial reference to Trousseau's symptom, viz., the inducing a spasm by compression of the artery; percussion of the muscles and tendons too caused spasm. In the case of exaggerated reflexes he recognised three types, cerebral, spinal, and muscular, according to the seat of the disease; these three types were easy to recognise, and he found such a division of great practical use in diagnosis.

At this point, it being past ten o'clock, a proposal to prolong the meeting for half an hour was negatived, and, as no one moved the adjournment of the debate, the proceedings came to an end, Dr. Gowers stating that he had no reply to make.

---

WEST LONDON MEDICO-CHIRURGICAL  
SOCIETY.

OCTOBER 2ND, 1885.

W. B. HEMMING, M.R.C.S., President, in the Chair.

*President's Address.*

THE PRESIDENT, in opening the session of the society, in the course of his address thanked the members for conferring upon him the honour of election to be their

President for the year. He, however, felt that a great responsibility had been thrust upon him, more especially when he remembered the able manner with which the duties of the chair had been discharged by his predecessors in office. A new position was, to every man of some nervousness, a source of embarrassment. He trusted that the prestige of the society would not suffer any deterioration during his year of office. The success of the session depended largely upon the individual exertions of the members and upon the character of the discussions. He concluded by reminding the members of the continued prosperity of the society, and he hoped that such prosperity would always be a distinguishing feature of the West London Medico-Chirurgical Society.

*A Case of Stricture of the Small Intestine.*

Dr. CLIPPINGDALE read a case of stricture of the small intestine, the stricture being due to scirrhus infiltration by which the calibre of the bowel was lessened by about three-fourths of its normal size. The patient was a gentleman aged 65. He was stout and strong; had always been a free liver. He was not careful in deglutition. Swallowing a fish bone or a fruit stone would seem to have been a less serious matter to him than to most people. This fact was mentioned because it was just possible that the disease from which he died had been caused by irritation produced by some indigestible matter which had become lodged in the intestinal canal close to the ileo-cæcal valve, the spot at which the disease was situated. The symptoms exhibited by the patient were mainly:—vomiting, constipation, flatulence, and restlessness. Pain was not complained of, nor tenderness. There were neither wasting nor cachexia, and nothing could be detected by repeated and careful examination. The vomited matter consisted merely of food, which was partially or wholly undigested; it was never stercoraceous. Bile was occasionally present. The absence of stercoraceous vomiting could be accounted for by supposing that the food on passing through the pylorus set up peristaltic action of the bowel, which continued until it was checked and reversed by the stricture. Thus, the stricture being high up, the food was ejected before it had time to decompose. Dr. Habershon saw the case twice with the author, but its occult nature baffled even that keen observer. At the *post-mortem* a thin layer of scirrhus infiltration involving the muscular and sub-mucous coats of the intestine for about one inch was found. About three-fourths of the circumference of the wall was diseased. The calibre of the bowel was diminished so as to admit only the tip of the index finger. As the patient was stout, and the affected bowel covered by rolls of inflated intestine, it was apparent that the disease could not have been felt through the abdominal parietes. The peculiarities of the case were—(1) That it ran its course in a somewhat short time, the patient dying at the end of six weeks. (2) That there were no symptoms indicating the nature of the constriction. (3) The rarity of such a growth in such a place, the small intestines being the seat of primary cancer in not more than 5 in every, 100 cases of cancer of the bowels.

Mr. PATMORE enquired as to the amount of injection which had been thrown into the rectum.

Dr. TRAVERS asked if there was much enlargement of the colon, and what was the condition of the ileo-cæcal valve.

Dr. THUDICHUM did not gather from the account that there had been no loss of lumen. In the course of his practice he had not found that with regard to cancerous strictures the lumen was always destroyed. He asked whether the disease had been localised. How was it that operative treatment had not been discussed? If the disease was not large it should have been treated surgically.

Mr. EDWARDS agreed with Dr. Thudichum. How was operative treatment not thought of? The symptoms pointed to a case of internal hernia. Abdominal section in his opinion should have been performed, and the disease excised. Operative interference might have prolonged life.

The PRESIDENT observed that the case presented several points of interest, and if the disease had been localised he

agreed in thinking that abdominal section should have been performed.

Dr. CLIPPINGDALE, in reply, remarked that half a pint of salad oil and afterwards a pint and a-half of soap and water were thrown up the rectum through a tube 18 inches long. The stricture did not occlude the bowel, but diminished its calibre sufficiently to prevent the passage of food. There was nothing to be felt through the abdominal wall. Dr. Habershon thought that the case might be one of twist of the gut.

*Pathological Specimens.*

Mr. H. PERCY DUNN showed the following:—(1) The Liver of a Child of Eight, showing an Extensive Rupture of the Right Lobe; (2) A Right Kidney, in the Pelvis of which a Large Calculus is impacted; (3) Sarcoma of the Heart; (4) A Uterus, showing several Nodular Growths of Scirrhus in its Substance.

---

## GENERAL CORRESPONDENCE.

---

### REFORM AT THE ROYAL COLLEGE OF SURGEONS.

[To the Editor of the Medical Times.]

SIR,—The crowded state of the meeting at the College of Surgeons on the 29th October proves that at last the Members have shaken off their lethargy, and are busying themselves with their prospective share in the administration of the affairs of the College. Eighteen months ago it seemed a hopeless task to induce so large a number of medical men to take care for their own professional interests; “*mais nous avons changé tout cela.*” And we say “*nous*” advisedly, for it has been the unceasing toil of this Association, from its foundation the day after the meeting at the College in March last year, to convince the profession that it was only for want of a rallying point that the Members had so long suffered their wrongs in silence. The result is that, whereas at the meeting in 1884 the lecture theatre of the College was but thinly tenanted by some eighty medical men, on the 29th ultimo it absolutely overflowed, and numbers of men had reluctantly to turn their steps from a hall which was too full to hold them. This in itself should be a sufficient reply to the reference in the article in your last week’s issue to “*lack of organisation.*” We maintain that to have drawn so many busy practitioners together is a proof of organisation almost more than could be expected in so young an Association as ours. The doubtful blessings of the Caucus are not to be looked for in an organism evolving out of chaos. That at such a memorable meeting there should have been a certain flavour of asperity in some of the speeches is regretted by none more than by the Association of Members itself; but it cannot hold itself responsible for the individual utterances of irresponsible Members. Let it neither be forgotten that the uncompromising refusal of the Council, as embodied in its Report, to accede to the demands of the Members, the withholding of all grounds for that refusal, and finally the closing of the College library on that very day, betrayed a distrust of the Members calculated to recall to those present the corporate shortcomings of Councils of years gone by. The Association would now wish to assure the Council that any words used by individuals on that day, which were not in accordance with the rules of courtesy, have pained itself, and to beg that the excitement of a coming, though then still uncertain, triumph be held accountable for the same. It would also shelter itself behind the precedent of Mr. Gladstone in the “*Hands off, Austria!*” incident, who claimed the allowance due to a “*position of greater freedom and less responsibility.*” That meeting, by entirely altering the outlook through its glorious assertion of the principle of enfranchisement within the very walls of the

College, has placed the Members now in a position of great responsibility, not held by them before the vote, and they will show by their moderation their worthiness to maintain it. The brilliant address of Mr. Sampson Gamgee, who held the brief of the Association, should be taken as evidence that, while conscious of their strength, the Members will use it with discretion. We would still crave a fraction of your valuable space, in which to recall to Members who have not yet joined the Association the fact that its work cannot be properly carried on without the expenditure of a certain amount of money. Hitherto extra demands, such as that contingent upon issuing circulars to remind Members of the meeting at the College, have fallen almost entirely upon the pockets of the Central Committee; but that body feels that it is now time to call upon fresh Members of the College to acknowledge the work done by joining the Association and remitting to the Hon. Secs. the trifling annual subscription of 5s. Printers are long-suffering creditors, but even they like at last to see their names written across a penny postage stamp; and when the minority has worked for the good of the majority it develops a not unnatural desire that it should not be too much out of pocket by the transaction.

We are, Sir, yours, &c.,

WARWICK C. STEELE,  
WM. ASHTON ELLIS,

Hon. Secs.

Association M.R.C.S.

*Western Dispensary, Westminster.*

[WE have looked in vain through our last week’s article for the reference to “*lack of organisation,*” of which complaint is made in the above letter.—ED. M. T.]

[To the Editor of the Medical Times.]

SIR,—As one present at the meeting of the Fellows and Members of the Royal College of Surgeons, I should feel grateful if you could spare space for a few remarks on the present state of affairs. The position taken up by the Members seems to be that the College does nothing for them, that they have paid more money into its coffers than the Fellows, and therefore they demand “*the College Franchise.*” Various arguments were used in support of this demand. First, in an able speech of socialistic tendency, we are asked as brothers to admit the Members, this request, as is the case with most socialistic ones, being coupled with the threat that, if we do not comply with the demand, we have only annihilation to expect. The demand is supported by comparison with the franchise in general, and by the arguments that a wider base and consequent increased strength and importance would be given to the College; that by the present system many influential and important men (even K.C.B.s, C.B.s, and V.C.s) are excluded; that the members have provided in the past, and do still provide, the greater part of the income of the College; and lastly, that the change would be for the good of Fellows, Members, and the general public. Another speaker dealt principally with the “*misdeeds*” of the College in having advised the Government to require a surgical qualification from the poor law medical officers; a third considered the expenditure on administration and the museum excessive; a fourth based his opinion on the need of extension of the franchise on the refusal of the Council to institute wholesale legal proceedings against sinning Members; two other gentlemen confined their energies to asserting the scientific equality of the two grades; while the principal cause of complaint to all seems to be the amount paid to the examiners. What then is the position of the Fellows? At the time the present Charter was granted a certain number of Fellows were elected free, while any Member prior to the year 1843 was given the privilege of becoming a Fellow on satisfying certain requirements and paying a fee of 10*l.* Since then any Member has been free to proceed to the Fellowship by passing a stringent, but perfectly fair, examination, certainly not of too high a class for anyone intending to practise as a surgeon. The body of Fellows thus elected have the privilege of electing the President and Council, hence, of

governing the College, and these are the rights the Members demand. I will attempt to answer some of the more prominent arguments advanced by the Members; some matters of detail, such as the expense of the examinations, do not seem to affect materially the general principle. As to the question of brotherhood, the Fellows own it, not only with the Members, but with all legally qualified medical practitioners; but that renders them no more willing to surrender their legal rights than the actual tie of brotherhood renders an elder son willing to divide the paternal estate. The comparison to the extension of the franchise in general, which finds so much favour, is an inapt one, because to obtain a parliamentary vote certain money qualifications, unfortunately still out of the power of many of our fellow countrymen, are necessary, while in the case of the College Fellowship any Member can gain the right to vote by an examination, an examination moreover, the value of which in the eyes of the Members is light, since they deny any scientific distinction between the two grades. The widening of the base of the College by the extension of the electorate is a specious argument, but one which in our case falls to the ground; the College of Surgeons is not a body representative of the profession, but of its surgical section; the number of Members is only an evidence of its efforts to keep up a good standard of surgical knowledge among general practitioners. The Members would wish to convert the College of Surgeons into a highly endowed British Medical Association, and two bodies of this nature would seem hardly desirable. As to the inclusion of K.C.B.s, C.B.s, and V.C.s in the electorate, no members of the profession can be more proud of such distinctions gained by the Members than the Fellows and Council, but the College is not a coterie of distinguished men, but a College of Surgeons, and surgical claims alone are of importance in its managers. The remarks made by one speaker as to the use of the museum and library are a valuable hint as to the probable policy of the Members, should the College be given over into their hands. The vast majority of the Fellows, not only Juniors, but those at present representing the College as its Council, have spent time and labour in acquiring by examination the rights they possess, a procedure open to every Member, and till now no adequate reason has been advanced why they should resign them voluntarily or in answer to unjustifiable demands. As the first test to Members who are raising the present outcry, I would ask, Why did you take up the Membership of the College of Surgeons? The simple answer seems to be, because it is the most useful and respectable of the ordinary surgical qualifications, and confers on its holder an unimpeachable respectability as a practitioner. Now, who is responsible for the high position the qualification has taken; the answer to be returned is—the Council of the College for the time being, by reason of their efforts to keep up the standard of the examinations, and thereby the efficiency of those who go into practice as Members. Then, Sir, the Council, under the present system of election, is the body which has given the holders of the diploma of Member the advantage of practising as high-class medical men, and this, I contend, is a sufficient answer to those who say that the College has done nothing for its Members but “take their money and kick them out.” As to the privileges of the use of the library and museum, I will say nothing, since the seconder of the motion led us to infer that the Members consider them of small value.

I am, Sir, yours, &c.,  
A JUNIOR FELLOW.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual calendar has just been published by the Council of the College. From it we make the following analysis, which we think will be interesting not only to the Fellows and Members of the College, but to the profession generally, and indeed to the public, who will learn from it

that there is no scarcity of doctors to look after their health, seeing that there is a small army of no less than 17,876 Fellows and Members on the roll of this one institution, being an increase of 201 over the number of last year. Beginning with the Fellows of the College, we find there are 1,153, including 635 who have obtained the honour after undergoing the severe examination; there are five who have been elected as Members of twenty years' standing under Section 5 of the Charter XV. Vict.; and three *ad eundem* Fellows, viz., two from the Irish and one from the Scottish College. There are 16,723 Members; 957 Licentiates in Midwifery, the examination for this distinction having been suspended for the last ten years. The Licentiates in Dental Surgery remain at 553. The examiners in Elementary Anatomy and Elementary Physiology, appointed in conjunction with the Royal College of Physicians under the scheme for an Examining Board in England, are elected annually. The examiners in Elementary Anatomy have held eleven meetings, and the examiners in Elementary Physiology two meetings, during the past year; 365 candidates presented themselves, of whom 308 passed in both subjects; 34 passed in Elementary Anatomy, 14 passed in Elementary Physiology, 9 were referred in both subjects, 14 referred in Elementary Anatomy, and 34 referred in Elementary Physiology. The fees received from candidates for this examination amount to 1,916*l.* 5*s.*, the examiners receiving in fees 274*l.* 10*s.* The examiners in Anatomy and Physiology appointed in conjunction with the Royal College of Physicians, under the scheme for an Examining Board in England, are elected annually. They have conducted the Primary Examinations for the Diploma of Member under the old regulations, as well as the second examination of the Examining Board, and have held during the year forty meetings. 1,271 candidates presented themselves, of whom 665 passed in both subjects, 135 passed in Anatomy, 93 passed in Physiology; 311 were referred in both subjects; 119 were referred in Anatomy and 176 were referred in Physiology. The fees received from the candidates for this examination amounted to 5,803*l.* 7*s.* The examiners received in fees 3,329*l.* 5*s.* The Board of Examiners in Anatomy and Physiology for the Diploma of Fellow consists of nine Members annually elected by the Council from the Fellows of the College, and has held during the past collegiate year seven meetings. 113 candidates presented themselves, of whom 49 passed and 64 were referred. The fees received for this examination amounted to 766*l.* 10*s.*, the Board receiving in fees 477*l.* The Court of Examiners consists of ten Members elected by the Council from the Fellows of the College, all of whom, however, are Members of the Council, except Dr. Humphry, Mr. John Langton, and Mr. T. Pickering Pick. During the past year the Court has held two meetings for the Fellowship and fifty-three meetings for the Pass Examination for the Membership; at the former there were 56 candidates, 37 of whom passed, 19 being referred for twelve months. For the Membership there were 960 candidates: 350 obtained their diplomas; 213 passed in Surgery only; 77 were referred for three months, 295 referred for six months, 16 referred for nine months, and 9 for one year. The fees paid by the candidates amounted to 12,033*l.* 10*s.*, the fees paid to the Court of Examiners amounted to 5,634*l.* 6*s.* The Board of Examiners in Dental Surgery has held two meetings for the examination of 24 candidates, 17 of whom obtained their diplomas; the fees paid by them amounted to 178*l.* 10*s.*, of which the Board received 71*l.* 8*s.* The income of the College from all sources during the past year amounted to 25,866*l.* 13*s.* 9*d.*, derived principally, as already shown, from fees paid by candidates for the Diplomas of the College, viz., 20,698*l.* 2*s.* Rents from chambers adjoining the College produce 1,455*l.* 17*s.* Dividends on Stock, 1,237*l.* 11*s.* 4*d.* From Members of the Council and Court of Examiners, on their election, 126*l.* The expenditure for the year amounted to 22,402*l.* 9*s.* 1*d.*, the largest item being in fees paid to Members of the Court and Boards of Examiners, viz., 9,785*l.* 19*s.* The next largest amount appears in Salaries, Wages, and Pensions for the officers and servants of the College in the three departments: Library, Museum, and Office, viz., 4,464*l.* 11*s.* 3*d.*, Taxes, Rates, Diploma Stamps, and Insurance absorbing the large sum of 1,618*l.* 3*s.* 2*d.*

Under miscellaneous items and extraordinary expenditure 856*l.* 5*s.* 11*d.* appears as having been expended. There appears the respectable balance at the bankers' of 3,464*l.* 4*s.* 8*d.* The Metropolitan hospitals are represented on the Council by Messrs. W. S. Savory, F.R.S., President; Sir James Paget, Bart.; H. Power, Vice-President; and T. Smith, of St. Bartholomew's. King's College by Mr. J. Wood, F.R.S., Vice-President, and Sir J. Lister, Bart. Guy's by Messrs. J. C. Forster, T. Bryant, and A. E. Durham. University College by Messrs. John Marshall, F.R.S., C. Heath, and M. B. Hill. The London by Mr. J. Hutchinson, F.R.S. The Middlesex by Messrs. J. W. Hulke, F.R.S., and G. Lawson. St. Thomas's by Sir W. MacCormac, Messrs. J. Croft and S. Jones; and Westminster by Mr. C. N. Macnamara.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following were admitted Members on October 29th, 1885:—

Robert Boxall, M.D. Brussels, 60, Gower Street, W.C.  
Michael Colman Collins, M.D. Queen's University, Nottingham.  
Archibald Edward Garrod, M.B. Oxford, 10, Harley Street, W.  
Samuel Herbert Habershon, M.B. Cambridge, 70, Brook St, W.  
Jogendra Nath Mitra, India.  
Lauriston Elgie Shaw, M.D. London, 3, Newton Grove, W.  
John Hinks Vinrace, M.B. London, Birmingham.  
Dawson Williams, M.D. London, 4, Oxford and Cambridge Mansions, N.W.

On the same day the following were admitted Licentiate:—

Alexander Louis Achard, Charles Kingley Ackland, George Frederick Aldous, Horace Bascom, Lancelot Bathurst, Edmund Frederick Bindloss, James Andrew Blair, James Allen Bratton, Lewis Brown, Arthur William Burrell, Frederick William Burton, John Archibald Cones, Isaac Rising Cory, Arthur Holdsworth Davis, Reginald Samuel Orme Dudfield, Frederick William Emery, Charles Ewart, Merwanjee Nourojee Gandevia, Henry Willoughby Gardner, Charles Gayford, Ernest Ormond Gilkes, Albert Edward Godfrey, Richard Park Griffin, Percy Oswald Ward Hailey, Ralph Hodgson, John Douglas Hughes, Spencer Hurlbutt, Frederic Joseph Knowles, Maurice Koettlitz, James Pirie Martin, Walter Francis Moore, Frank Edward Nichol, Arthur Wesley Ogle, Frederick Arthur Thomas O'Meara, Richard Jeffreys Owen, Ernest Willmer Phillips, George Richard Mackintosh Pollard, William Edmund St. Michael Raw, Henry Albert Reed, Lionel Pierrepont Shadbolt, John Turville Smith, John Acton Southern, Benjamin Sumner, Charles Henry Taylor, David Thomas, George Henry Warren Thomas, Charles Henry Wade, Robert Nasmyth Arnold Wallinger, William George Weaver, Albert William Webb, Percy Charles Edward d'Erf Wheeler, David James Gibb Wishart, Robert Wallace Wright, Edward Herbert Young.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 22nd ultimo, viz:—

Richard Andrews, L.S.A., New Malden, St. Thomas's Hospital; Frederick John Jaynes, L.S.A., Wornington Grange, Middlesex Hospital; Edward Herbert Young, L.S.A., St. John Street, Stamford, University College; Robert Briggs Wild, L.S.A., Wethington, Thomas Walmsley Heywood, L.K.Q.C.P.I. Southport, Herbert Strange Hall, Leigh, Lanc., and Frederick Edge, Manchester, Royal Infirmary, Manchester; Edward Phillips, L.R.C.P. Edin., Birmingham, General Hospital, Birmingham; Francis Henry Mead, M.D. Durham, Taunton, Newcastle and St. George's Hospital; Robert Chambers Owen, L.K.Q.C.P.I., Liverpool, Liverpool Royal Infirmary; Oscar James McCully, M.D. McGill, Montreal, McGill College, Montreal; John MacGregor, L.R.C.P. Edin., Edinburgh University; Alfred Reuben Aubrey, M.B. Durham, Salisbury, Newcastle, and Bristol; George Forden, L.S.A. York, Leeds General Infirmary; James Matthew Robson, M.B. Durham, North Shields, Newcastle-on-Tyne Infirmary; Michael Alcock Ottley, L.K.Q.C.P.I. Sheffield, Durham and Sheffield General Infirmary.

Three candidates were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members.

Seven candidates were referred for 6 months and one for 9 months.

Admitted Members on the 23rd ultimo:—

Alfred George Francis, L.S.A. Southchurch, Essex, and George Frederick Aldous, L.S.A. Petersfield, St. Bartholomew's Hospital; Wilberforce Thompson, L.S.A., Bardsey near Leeds, and George Henry Oliver, L.S.A. Doncaster, Leeds General Infirmary; Edmund Taylor Milner, L.S.A. Manchester, and Alfred Alexander Mumford, L.S.A. Manchester, Manchester Royal Infirmary; Charles Jenner Parsons, L.S.A. Godalming, University College Hospital; Herbert Edward Rayner, L.R.C.P. Lond., Colchester, London Hospital; Frederic Charles Larkin, L.S.A. Everton, and William Arthur Martin, L.R.C.P. Edin., Crail, M.B., Royal Infirmary, Liverpool; Ernest Farr, L.S.A. Hammersmith, Charing Cross Hospital; George McNair, West Dulwich, King's College Hospital; Arthur Deaker Owen, L.S.A. Totnes, Devon, Birmingham and London Hospital; Upendra

Krishna Dutt, L.S.A. Leicester, St. Mary's Hospital; Sorabji Manekji Kaka, L.M. and S. Bombay, Whitehall Gardens, Bombay.

Two candidates were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members.

Three candidates were referred for 3 months and eight for 6 months.

Admitted on the 26th ultimo:—

Robert Aston Bostock, L.S.A., Onslow Gardens, S.W., Ralph Hodgson, L.R.C.P. Lond., Lewisham, S.E., Arthur Holdsworth Davis, L.R.C.P. Lond., Doughty Street, W.C., Reginald Samuel Ormer Dudfield, L.R.C.P. Lond., Upper Phillimore Street, W., Augustus Charles Dove, South Kensington, Robert David Barber, Nottingham, Arthur Lucas Morgan, Swansea, Harold Cecil Halsted, Arundel, Benjamin James Inniss, Barbados, West Indies, St. Bartholomew's Hospital; Charles Henry Wade, L.R.C.P. Lond., Upper Norwood, S.E., London Hospital; Charles John Holtom, L.S.A. Stoke-upon-Trent, University College Hospital; Francis William Jollye, L.S.A. Donington, King's College Hospital; William George Holloway, St. John's, S.E., and Ernest Henry Richmond Watts, Buckingham Palace Road, Cambridge and St. George's Hospital; Charles James Glasson, Clifton, Bristol, Bristol General Infirmary; Henry Octavius Preston, Cambridge, Petrus Johannes de Nyssen, Portsdown Road, W., and Leonard Remfry, Nightingale Lane, St. George's Hospital; Hugh Vallance, Red Hill, and Frederick William Farr, Kennington Road, Guy's Hospital; George Brooke French, Edinburgh, Edinburgh University; Henry Pope, York, Leeds General Infirmary; Edward Lawrence Fox, Plympton, Cambridge and St. Bartholomew's Hospital.

Admitted on the 27th ultimo:—

Arthur Charles Edward Parr, L.S.A. Cardiff, James Allen Bratton, L.R.C.P. Lond., Victoria Road, W., and Frederick Arthur Thomas O'Meara, L.R.C.P. Lond., West Dulwich, King's College Hospital; William Scott Tebb, L.S.A., Albert Road, N.W., Cambridge and St. Thomas's Hospital; Alfred William Hunton, L.R.C.P. Lond., and John William Rigby, Chorley, Manchester Royal Infirmary; Charles Ewart, L.R.C.P. Lond., Curzon Street, W., St. George's Hospital; Frederick Wm. Emery, L.R.C.P. Lond., Birmingham, Birmingham General Hospital; Charles Hamilton Conolly, Wood Green, Clayton, Campbell Harris, Craven Road, Henry Willoughby Gardner, L.R.C.P. Lond., Birkenhead, St. Bartholomew's Hospital; Robert Major Brown, Tulse Hill, Cambridge and St. Bartholomew's Hospital; Edwin Cooper Perry, Temple, E.C., Cambridge University, Joseph Henry Collymore, West Brompton, Guy's Hospital; Percy Priestley, Sheffield, Sheffield and St. Thomas's Hospital.

Five candidates were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members.

Five candidates were referred for 3 months and seven for 6 months.

Admitted on the 28th ultimo:—

Frederick William Morison, Hampstead; Thomas Harry Frederick Clarkson, Southsea; John Collier Barker, Montague Square; William Benjamin Lauria, Holford Square, and Herbert Elwin Harris, Binham, St. Bartholomew's Hospital; Ernest Aston Otho Travers, Sutton, Surrey, London Hospital; Edward Kendrick Macartney, Sundur, Madras, University College; Ernest Maberly, Bath, Birmingham General Hospital; Thomas Frederick Barton Palmer, Peterborough, Guy's Hospital; Alexander Whyte, Eytoun Road, S.W., Newcastle and St. George's Hospital; Charles Edward Stewart Flemming, Freshford, Bath, Bristol General Infirmary; William Arbuthnot Alexander Cheves, Devonport, King's College Hospital.

Four candidates were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members. 2 candidates were referred for three months, 12 for six months, and 3 for one year.

Admitted on the 30th ultimo:—

Albert William Webb, L.R.C.P. Lond., Canonbury, Arthur Meyrick Jones, L.S.A., Romsey, Ernest Augustus Farr, L.R.C.P. Lond., Andover, and Hugh Jones Roberts, L.S.A., Penygroes, Guy's Hospital; Francis Murray Haig, L.S.A., North Street, S.W., and Edward Samuel Goody, L.S.A., Devonshire Terrace, W., St. Thomas's Hospital; Oliver R. A. Julian, L.S.A., Plymouth, and Edward John Nixon, L.R.C.P. Lond., Cape of Good Hope, St. Bartholomew's Hospital; Robert William Hazell, L.S.A., Cape Town, and William E. St. Michael Raw, L.S.A., Stoke Newington, London Hospital; John Lynes, L.S.A., Kennington Park Road, Charing Cross Hospital; Cornelius Frederick Glinn, L.S.A., Devonport, St. George's Hospital.

Five candidates were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College.

One candidate was referred for 3 months, nine for 6 months, one for 9 months, and one for 12 months.

Admitted on the 2nd instant:—

Edmond Walter Emtage, L.S.A., Liverpool Road, N., University College Hospital; Frank Edward Nichol, L.R.C.P. Lond., Kensington, Percy Charles Edward d'Erf Wheeler, L.R.C.P. Lond., Camberwell, John Stuart Hutton, L.R.C.P. Lond., Forest Hill, S.E., and Otto Fraser Frohwein, L.R.C.P. Lond., Portsmouth,

St. Thomas's Hospital; Arthur William Burrell, L.R.C.P. Lond., Clarence Square, Gosport, London Hospital; Henry Ernest Hill Smith, L.S.A., Wimpole Street, King's College Hospital; Frederick Greasley Armson, L.S.A., Burton-on-Trent, Middlesex Hospital; Hubert H. Du Boulay, George Street, W., Guy's Hospital; Henry Dudeney Halliday, Hamilton Gardens, N.W., St. Bartholomew's Hospital.

Seven candidates were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College.

Two candidates were referred for 3 months and eight for 6 months.

Admitted on the 3rd instant:—

Charles Edward Liesching, Elm Park Road, S.W., St. George's Hospital; John Frederick Bate, L.S.A., Merton, University College Hospital; William Henry Johnson, L.S.A., Commercial Road, E., and Edward Osborne Fountain, L.S.A., Hillingdon, St. Bartholomew's Hospital.

Four candidates were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College.

One candidate was referred for 3 months and four for 6 months.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, October 22nd, 1885:—

Raheem Buksh, M.R.C.S., Poplar Hospital; Albert Green, M.R.C.S.; Guy's Hospital; Francis Murray Haig, M.R.C.S., North Street, Westminster; John Melhuish, 5, Crossfield Road, Belsize Park, Leslie Powne, Granville House, Swindon.

At the recent examinations for the Prizes in *Materia Medica* and Pharmaceutical Chemistry, prizes were awarded to the following gentlemen:—

1st, Henry Edward Skyrme, Student of the London Hospital; 2nd, Frederic William Edridge Green, Student of St. Bartholomew's Hospital, the Silver Medal and Books.

On Thursday, October 29th, 1885:—

Henry Ernest Hill Smith, M.R.C.S., 82, Wimpole Street, W.

On the same day—

Edward Osborne Fountain, Hillingdon, near Uxbridge; Stuart Oliver, The Trellis, Bickley, Kent,

passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery.

**ROYAL UNIVERSITY OF IRELAND AUTUMNAL EXAMINATIONS, 1885.**—The Examiners recommend that the following be adjudged to have passed the examination for the degree of Master of Surgery:—

Robert Abraham, Queen's College, Belfast, Jerome Barry, Queen's College, Cork; William J. Bigger, Queen's College, Belfast, and St. Thomas's Hospital, London; William S. H. Briand, Queen's College, Cork; Frederic James Burns, M.D., James R. Burrows, M.D., Queen's College, Belfast; Hugh A. Clarke, Liverpool School of Medicine; Henry A. Cummins, Michael P. Dunlea, William A. Fogerty, George H. Foott, M.D., John F. Haines, Daniel Hennessy, M.D., Queen's College, Cork; Michael Jennings, M.D., Queen's College, Galway; Francis J. Keyes, Catholic University School of Medicine; William J. R. Knight, M.D., Queen's College, Belfast; John E. Lane, M.D., Queen's College, Cork; William John Loughrey, M.D., James Shaw Lyttle, Queen's College, Belfast; Daniel M'Donnell, Catholic University School of Medicine; Charles J. Macdonald, Queen's College, Cork; Ralph B. Mahon, Queen's College, Galway; William H. Munro, Queen's College, Galway and Belfast; James Joseph Nagle, M.D., Queen's College, Cork; John J. Redfern, William R. Scott, Queen's College, Belfast; Francis H. Sinclair, Queen's College, Belfast, and Trinity College, Dublin; Frederic C. Sinclair, M.D., Ledwich School of Medicine; Thomas D. Smyth, Queen's College, Belfast, and University of Edinburgh; Edward A. Spiller, Queen's College, Belfast; Benjamin Sumner, Royal Infirmary, Liverpool; Henry Walter, School of Physic, Dublin; William A. Whitelegge, Queen's College, Cork; Samuel Wilson, M.D., Queen's College, Belfast.

**ROYAL UNIVERSITY OF IRELAND.**—At a meeting of the Senate of this University, held on Wednesday, Oct. 28th, 1885, the following resolutions were adopted:—(1) That a special diploma be awarded to each candidate who may satisfy the examiners at the examination for the Stewart Scholarship for proficiency in the treatment of mental diseases. (2) That application be made to the Lord Lieutenant for approval of the following additions to the list of recognised medical institutions:—The Glasgow Royal Asylum for the Insane, Hanwell Lunatic Asylum, Birmingham Lunatic Asylum, the Cork Union Hospital. (3) That attendance at either theoretical or practical midwifery ought not to be commenced until after the passing

of the second examination in medicine, and that no certificate of such attendance shall henceforth be received where the attendance may appear to have taken place subsequent to the close of the year 1885, but prior to the passing of the second examination in medicine.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—The President and Council held a special meeting on the 22nd inst., pursuant to the provisions of the Supplemental Charter, to elect an examiner to examine candidates for the Letters Testimonial and Fellowship, in room of the late Dr. Benjamin G. M'Dowel, when Mr. John Barton, 26, Upper Merrion Street, Dublin, was elected. Mr. Barton is a Doctor of Medicine of the University of Dublin and a Fellow of the Royal College of Surgeons in Ireland. He is also a demonstrator of Anatomy and a private teacher in the School of Physic in Ireland, Trinity College, Dublin. The Council also held a special meeting on the 22nd inst. for the election of Dental Examiners, when the following gentlemen were elected, viz.—Edward S. O'Grady, Henry G. Croly, Henry G. Sherlock, Daniel Corbett, jun., Robert Hazelton, and Arthur W. W. Baker.

**EDINBURGH ROYAL INFIRMARY.**—Plans have been prepared by Mr. Sydney Mitchell, architect, for the erection of an Observation Hospital at the Edinburgh Infirmary, on a site between the medical and surgical departments, at the back of the boiler house. Into this building there will be removed persons who may be suspected of suffering from infectious disease, and in the event of such suspicion turning out well founded the patients will be sent to the City Hospital for treatment; otherwise, they will be brought back to their respective wards in the Infirmary. The structure is intended to be of brick, plastered inside with cement, the corners of the wards being rounded off so as to prevent the lodgment of dust. The accommodation consists of two wards containing four beds, and two wards containing two beds, two being for males and two for females. Between the male and female wards, in the centre, is a nurses' sitting-room and bed-room. Behind the building is a passage, part of it simply a covered way, and part with walls on both sides. At the back of this passage is a small wing with a flat roof, which contains an additional nurse's room, kitchen, bath-room, &c. The hospital will be raised 18 inches clear from the ground, being supported to that height by narrow brick piers, so that the air may pass freely under it. The heating will be by steam pipes, and four æolus water spray extract ventilators are to be fixed in the roof. The building, though quite plain, with its hipped roof, overhanging eaves, and crow-stepped dormers, will present a pleasing aspect. The cost of the whole work is expected to be rather less than 1,000*l*.

**RE-ORGANISATION OF ABERDEEN ROYAL INFIRMARY.**—A few months ago, Dr. Angus Fraser, one of the Infirmary staff, called public attention to the deplorable state the Aberdeen Royal Infirmary was in, not only in regard to sanitary arrangements, which are very defective, but also the nursing and general management. A special committee of managers was formed under the presidency of Dr. Struthers, to draw up a scheme of re-organisation. The committee unanimously resolved that, under the control of the committee of management, the working of the Infirmary should be placed in the hands of (1) a general superintendent and secretary, (2) a lady superintendent. The committee have been assisted in their work by Dr. James B. Russell, Medical Officer of Health of Glasgow, and Dr. Simpson, Medical Officer of Health of Aberdeen. Dr. Russell and Dr. Simpson lately inspected the Infirmary, and have condemned as a whole the present arrangements as regards sanitary condition, accommodation for nurses, washing, laundry, and cooking. In regard to the treatment of contagious diseases, Dr. Russell stated that infectious diseases could not be safely provided for in a general hospital; they are also of opinion that the plans of extension on the ground at disposal are not such as to meet with approval on sanitary principles. The committee are in favour of a new infirmary on a new site; in the meantime the present defects, sanitary and otherwise, are

to be remedied in the old building. We sincerely trust that a new building on a new site, and essentially within easy distance of the Medical School, will soon be erected, and that it will be a credit to the city, and to the University with which its name is so closely allied.

**VOTES TO THE DUBLIN HOSPITALS.**—At a special meeting of the Corporation of Dublin, held on Monday, October 26th, Mr. Winstanley moved the adoption of the following grants to the various city hospitals, amounting in the aggregate to 4,800*l.* Jervis Street Hospital, 300*l.*; Mercer's Hospital, 300*l.*; the City of Dublin Hospital, 300*l.*; St. Vincent's Hospital, 400*l.*; the Meath Hospital, 300*l.*; the Mater Misericordiæ Hospital, 500*l.*; Sir Patriek Dun's Hospital, 300*l.*; the maternity department of same, 50*l.*; Dr. Stevens's Hospital, 150*l.*; Cork Street Hospital, 300*l.*; the Rotunda Lying-in Hospital, 250*l.*; the Coombe Lying-in Hospital, 500*l.*; the Hospital for Incurables, 300*l.*; the Hospice for the Sick and Dying, Harold's Cross, 200*l.*; the Treasurer of St. Mark's Ophthalmic Hospital, 150*l.*; the National Eye and Ear Infirmary, Molesworth Street, 100*l.*; the Children's Hospital, Upper Temple Street, 200*l.*; the Dublin Orthopædic Hospital, Brunswick Street, 100*l.*; and the National Orthopædic Hospital of Ireland, 7, Adelaide Road, 100*l.* Sir William Carroll seconded the motion, which was adopted.

**ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.**—The directors of this hospital have appointed Dr. James Haig Ferguson and Dr. S. H. Puekle, both of the Maternity Hospital, to be resident physicians in this hospital for a period of six months. The directors have also established lectures on the diseases of children to the students attending the extra-mural classes, and have appointed Dr. Underhill and Dr. Playfair to be the lecturers.

**THE MEDICAL DEFENCE ASSOCIATION.**—A meeting of the Council of the Medical Defence Association was held at the offices of the Association, 60, Chandos Street, Covent Garden, on the 23rd inst., Dr. Richardson, F.R.S., in the chair. Several new members were nominated and duly elected. Complaints were received as to unqualified practice from Leicester, Landport, and other places, and the solicitors were instructed to investigate the cases with a view to prosecution. A letter was read from Dr. David R. Pearson, of Kensington, suggesting that the usefulness of the Association might be considerably extended by affording assistance to medical men who are threatened with litigation, or against whom charges of malpractice or other grave accusations have been made for the purpose of extortion. The President said it had struck him recently that the Association might do a vast amount of good in the direction suggested by Dr. Pearson. Medical men often submitted to gross imposition and extortion from fear, and the conviction of their inability to get the best legal assistance except at a ruinous cost, when they would, if supported by their professional brethren, be encouraged to face their difficulties and come out of the trial satisfactorily. The Edwards, Haffenden, and Bradley cases showed the necessity for such assistance. These cases might have had less unhappy terminations, had sound advice and kindly sympathy and help been within reach in the hour of trial. The Hon. Sec., Mr. George Brown, pointed out that the suggested extension of the operations could only be carried out by altering the by-laws of the Association, which must be done at a general meeting of the members, and it was resolved to convene a special general meeting at an early date for the purpose of altering the by-laws so as to extend the powers of the Council.

**APOTHECARIES' SOCIETY.**—The Botanic Garden of the Society, at Chelsea, continues to be useful, as it has been for the past two hundred years (during most of which time, indeed, it stood alone as an institution for the study of Botany from the living plants), in affording the means of instruction for medical students. During the present year the number of visitors, mostly students, who have been admitted is 2,784, of which number 1,200 were males and 1,584 females; the former consisting chiefly of young men in training for the different branches of the medical profession, and the latter in great part of young persons training for teachers in public schools. The Society gives

annually a Gold Medal and also a Silver Medal, in both classes of students, to those who pass the most creditable examinations.

**THE ST. JOHN AMBULANCE ASSOCIATION.**—The practical utility of this Association has been so thoroughly established, that its increasing extension, as shown by the annual report just issued by the formation of many new centres and classes, both at home and the colonies, is very satisfactory. During the year 10,123 certificates and nearly 3,000 medallions have been awarded, of which 5,342 certificates have been bestowed on male classes, 3,417 on female "first aid" classes, and 1,364 on "nursing" classes. About 90,000 certificates altogether have been awarded by the Association. Interesting details are given of important cases of "first aid," rendered by certified pupils, and attested by surgeons. An appeal is made for funds to carry on and enlarge the work of the Association. Her Majesty the Queen has sent a second donation of 25*l.*, and the Duke of Connaught and Princess Beatrice have accepted the presidency of two of the London districts.

**HOSPITAL SATURDAY FUND.**—At the meeting of the Board of Delegates on Saturday, it was stated that the workshop collection, doubtless owing to the widespread depression in trade, had not realised the expectations of the delegates so far as the amount hitherto received was concerned. The street collection having, however, this year been nearly double what it was in 1884, to a considerable extent supplied the deficiency in the workshop collection, and from both sources, as well as by means of special donations, 11,000*l.* would, there was reason to believe, represent the aggregate collection of the year. Life governors were appointed from among the delegates to the following hospitals:—Charing Cross, East London, Royal Free, Poplar, Royal National, National for the Deformed, North West London, and Royal South London Ophthalmic.

**THE SHAFTESBURY NATIONAL MEMORIAL.**—A general approval will, no doubt, be accorded to the resolutions adopted at a meeting of the committee, held at the Mansion House last week, that, in addition to the erection of two statues to the memory of the late Earl, a National Convalescent Home for Poor Children (bearing Lord Shaftesbury's name) should be established.

**THE POISONED RIVER.**—Dr. S. Gibbon, Medical Officer of Health, has reported to the Holborn Board of Works, that during the past fortnight, three lads of the Central Shoeblock Brigade, on Saffron Hill, had died of typhoid fever, supposed, with good reason, to have been contracted by them in bathing in the river Lea, at Clapton. Soon after bathing they were taken ill with the disease, which is generally caused by drinking water. They were treated in St. Bartholomew's Hospital, where they all three died.

**THE DUNOON DISTRICT COTTAGE HOSPITAL.**—This hospital was formerly opened on the 24th ultimo. It owes its existence to Dr. Dennistoun, of Dunoon. It is situated in the rear of the town, and provides accommodation for six patients. About 600*l.* has been expended on the building and furnishing.

**DR. ROBERT McDONNELL, F.R.S.**, the well-known Dublin surgeon, has been placed on the Royal Commission appointed to enquire into the condition of the blind.

**PROFESSOR VON LANGENBECK** is suffering from so serious an affection of the eyes that it is feared he must submit to a critical operation within the next few days.

**MR. ERICHSEN ON THE PROPOSED MEDICAL DEGREE FOR LONDON STUDENTS.**—Mr. Erichsen has addressed a letter to the Secretary of his Edinburgh Committee, in which he states, in reference to the proposed scheme giving to the Colleges of Surgeons and of Physicians of London the power to confer medical degrees, "that not only would the proposed scheme not have my support, but that I should feel it to be my duty, on general professional as well as on academic grounds, to oppose that or any other scheme which would tend to lower the value of the medical degree. The degree of M.D. would not only be materially depreciated in value, but would in my opinion be completely extinguished as a mark of professional distinction in public

estimation, if every student who passed the ordinary qualifying examination of the two corporations had a degree conferred upon him. A title common to all would be an honour to none."

**PROF. VERNEUIL ON THE VULGAR VIEW OF SURGERY.**—Prof. Verneuil addressed the French Association for the Advancement of Science, at Grenoble, on the subject of the vulgar prejudice existing against the admission of medicine as a science rather than as one of the arts. He remarked that his protest against this prejudice was to some extent unnecessary in the case of his present audience, since five out of their fourteen presidents had been doctors. He pointed out the absurdity existing in the assertion which many people make, that they believe in surgery but not in medicine, since the former is a positive science, the latter a conjectural one, that surgery makes progress every day, but that medicine has made no advance since the days of Hippocrates. Notwithstanding these confident assertions, the very people who make them constantly refuse to follow the advice given them by a surgeon, and take in preference that of a doctor, even of a chemist, or a herbalist, who will undertake to effect a cure without an operation. A second prejudice exists against the methods employed in surgery, the surgeon being compared by some ignorant people to a butcher. It is sufficient to pass through a ward to which all are admitted indifferently to be convinced that a large number of patients are cured without losing a drop of blood or a millimètre of flesh, some by aid of internal medicaments, others by the employment of what is termed minor surgery, namely, a series of manual acts which take nothing from the integrity of the organs. Under this heading may be classed the topical applications applied to bruises, superficial burns, circumscribed inflammations, &c.; for the severer inflammations leeches, cupping, flying blisters, &c.; but the greatest regenerators are absolute repose, the position of the limbs, and perfect immobility of the affected part. Then again, in fractures and articular affections, much manual labour is needed, but not a drop of blood is lost. Prof. Verneuil added that he felt in a position to assert that out of a hundred patients who might consult a surgeon, scarcely a quarter rather, only a fifth or a sixth were submitted to a true operation. Against a very serious imputation Prof. Verneuil entered a vehement protest, namely, that surgeons often operated from the love of operating. He remarked that he could fill many pages with tales told him of unnecessary operations or of those with fatal consequences. His opinion is that the essence of the whole matter may be summed up in these words, "Irrational confidence in surgery, and injurious and unjust suspicions of the surgeon."

**IS FERRÁNISM DEAD?**—Ferránism would seem to be very nearly played out in Spain; a significant sign is that the *Sección Ferraniana* which a prominent Spanish medical periodical has contained for some months past has been suddenly discontinued, the last number containing not a word on the subject, to which all the eloquence at the editor's command seemed to have been somewhat exclusively devoted since a little before the commencement of the so-called "suspicious disease" which has since unhappily carried off, it is said, 120,000 Spaniards.

**CLINICAL TEACHING IN MOSCOW.**—A recent university statute having declared several of the special hospitals of Moscow to be suitable for clinical instruction, advantage has been taken of the valuable field of study which they supply, and various members of their respective staffs have announced the opening of courses, e.g., Dr. Kusmin will lecture on Surgery in the hospital attached to the Foundling Institution, Dr. Solovieff on Gynæcology in the Pavloff Hospital, and Drs. Roth and Minor on mental diseases and nervous diseases in the Staro Yekaterina Hospital.

**THE SPREAD OF SYPHILIS BY FOUNDLINGS.**—A very serious matter for the health of Moscow has been brought into notice by the observations of one of the parochial medical officers, and confirmed by those of his *confrères*, viz., the fact that syphilis is being constantly and secretly disseminated amongst the population by the infant waifs who are put out as narse children by the Moscow Foundling Institution. Many of these are syphilitic, and they com-

municate the disease to their foster-mothers, hard chancres being found on the nipples. The women thus syphilize their own children, their husbands, and even their neighbours' infants, whom they frequently take care of temporarily. The attention of the managers of the Foundling Institution has been called to this, and it is to be hoped that they will do their utmost to put a stop to it at once.

**NEPHROLITHOTOMY AFTER NEPHRECTOMY.**—Mr. Clement Lucas operated on a unique case in Guy's Hospital on October 29th. A woman upon whom he had performed nephrectomy about four months ago, for complete destruction of the left kidney, by large calculi and hydronephrosis, and who had made a rapid and perfect recovery, was suddenly seized with great pain in the region of the other kidney, followed by vomiting, headache, and suppression of urine. The symptoms commenced early on Sunday morning, October 25th, from which time not a drop of water was passed. Her medical attendant, Mr. Atkins, of Lutton, recognising the gravity of her symptoms, put himself in communication with Mr. Lucas, and it was found possible to remove the patient to London on Wednesday, October 27th. It was still thought advisable to try the effect of flushing the kidney by diuretics for another twenty-four hours before operating. These had no effect, and the symptoms having become much more serious, there being signs of sinking accompanied by much drowsiness, Mr. Lucas cut down on the remaining kidney and removed a conical calculus measuring seven-eighths of an inch by half an inch, tapering to three-eighths. Total suppression of urine had lasted 102 hours. Free drainage of urine immediately took place through the wound, and vomiting and headache at once ceased. Five days after the operation she was doing well and feeling comfortable. Mr. Lucas's case of nephrectomy performed on October 20th healed without suppuration or fever. She sat up for the first time on the eighth day, and is now convalescent.

**BREACH OF MEDICAL ETIQUETTE IN BELGIUM.**—The *Lyon Médical* (October 18th) quotes an instance from a Belgian journal, showing that breaches of medical etiquette of a slanderous character are there sharply dealt with. It seems that a Dr. Quinet, a village practitioner, was called 6th December to a girl who had injured her thigh, and for whom he prescribed 20 grammes of mercurial ointment in frictions and half a gramme of calomel as a purgative. After three visits another doctor was called in. On the 2nd January the child died, and a young doctor, who had been recommended to her, declared that her death was due to mercurial poisoning. The *post-mortem* did not exhibit any change due to mercury, as was certified by the three doctors present. Regarding the charge as libellous, Dr. Quinet laid the case before the Medical Association of Charleroi, and brought an action against his accuser. The Association, after hearing the particulars, unanimously resolved upon the expulsion of the doctor in question, while the tribunal of Charleroi found a verdict for 4,000 francs damages in favour of Dr. Quinet, which was confirmed on appeal to the court of Brussels.

**THE BEARD IN THE FRENCH ARMY.**—The French newspapers announce that the present Minister of War is favourable to granting a wish which has long prevailed in the French Army, that of wearing the beard, and to this end has issued circulars to the generals of the army requesting their opinions on the subject. It is greatly feared in the army that their replies will be unfavourable, seeing that most of the generals are men in years and are wedded to prevalent routine. The *feuilletoniste* of the *Union Médicale* is very favourable to the measure, not only on account of its reasonableness and economy (for the cost of shaving an entire army is considerable), but also on a sanitary ground, which, in a service that loses so many men from phthisis, is deserving of notice. The beard, he observes, would exert great protective influence among those who have to employ their voices much, either in instruction or command. The comparative freedom of the sappers with their fine beards from phthisis is also adduced as an additional argument for a change which, although

strongly desired in the army, is scarcely expected to be granted.

**LADY DUFFERIN'S FUND.**—Branches of this fund have been started in the Punjab and British Burmah, under the auspices of Sir Charles Aitchison and Mr. Bernard. Sir Rivers Thompson has issued a circular in his province, and intends to call a meeting to inaugurate a branch in Bengal. Lady Dufferin has sent the Lord Mayor a letter of thanks for his exertions on behalf of the fund, which she hopes "will not only be the means of bringing medical relief to many suffering women, but will also open out a career to the native women, and will tend to improve the general female education throughout the country." "I think also," Lady Dufferin continues, "that numbers of English lady doctors will find employment in India, as I am in hopes that posts will multiply here very much more quickly than we can find native women ready to fill them, and, in fact, the most sanguine of us know that it will be many years before the medical schools here can be expected to supply candidates for the larger appointments. I enclose your lordship a copy of a letter I have received from the high priest of a Hindoo temple, as it may interest friends of the movement to know that its *bonâ fide* character is understood here, and that the guardians of the national customs of the country recognise the fact that alleviating the sufferings of the native woman, improving her education, giving her a possible career, and at the same time respecting all her prejudices, is the sole object of our present endeavours."

**WATER AS A FATTENER.**—It has been observed that water is fattening; that those who drink large quantities have a tendency to fulness and rotundity. That there is considerable truth in this observation, we have had occasion recently to establish. While we should say that excessive imbibition of very cold (iced) water (especially when one is hot) is not to be commended, yet we have reason to believe that the *unlimited use of pure spring water*, at its natural temperature, is not only very conducive to health, but has an actual tendency to favour a fulness and soundness of body. Whether this is the result of a better action on the part of the digestive, assimilative, and depurative functions, owing to the internal cleanliness or flushing of the human sewers produced by large quantities of water, or whether water has some specific action in producing this fulness, we do not know, neither does it signify, since observation confirms as a fact that the free use of water does have this effect.—*Philadelphia Medical Reporter*, October 3rd.

**ILLEGIBLE PRESCRIPTIONS.**—The *Western Druggist* lifts up its voice against what it calls the "abominable chirography" of many physicians. It adds, "A physician who cannot or will not write a clear legible hand should be debarred from practice, or at least be required to have in constant attendance a capable penman. A department of penmanship is the crying need of the hour in our medical colleges. There is very little practical difference between bad prescription-writing and downright malpractice."

**A VETERAN PROFESSOR OF ANATOMY.**—The Nestor of physicians in this country is probably Dr. Neyron, the Professor of Anatomy at Notre Dame University, Indiana. He is 94 years of age, and was a surgeon in Napoleon's army during the Russian campaign and Waterloo. After the Restoration he became a Catholic priest, and was an early missionary in the north-west. Few men of seventy are so strong and active, and he is still able to conduct his classes.—*Philadelphia Medical News*.

**REDISPENSING OF PRESCRIPTIONS.**—The Society of Legal Medicine, after prolonged deliberation, has arrived at the following resolutions:—(1) When a physician prescribes any substance capable of producing poisonous effects, he should write out in full the dose and the mode of employment; and should indicate on the prescription how many times the *pharmacien* may renew the preparation. (2) The *pharmacien*, every time he makes it up, should attach to the prescription his seal and its number and the date of sending the medicine. (3) Solutions intended for hypodermic injections should never be renewed without a fresh prescription.—*Lyon Médical*, September 6th.

**GERMAN MEDICAL STUDENTS IN THE SUMMER SESSION OF 1885.**—The numbers were in the various Universities as follow:—Vienna, 2,307; Munich, 1,129; Berlin, 1,072; Dorpat, 809; Würzburg, 784; Leipzig, 662; Freiburg, 474; Greifswald, 457; Breslau, 397; Gratz, 371; Halle, 316; Bonn, 311; Heidelberg, 265; Königsberg, 251; Marburg, 267; Tübingen, 242; Kiel, 227; Strassburg, 222; Erlangen, 219; Göttingen, 204; Jena, 204; Zurich, 204; Bern, 186; Giessen, 159; Basel, 104; Rostock, 92.—*Berliner Klinische Wochenschrift*, October 5th.

**CREMATION OF DISSECTING-ROOM REMAINS.**—The Paris Municipal Council has just sanctioned the erection of a crematory in Père Lachaise, for the purpose of incinerating the remains of the bodies employed at the various dissecting-rooms, &c. The expense of the erection will be 250,000 francs, and it will comprise three of the Gorini ovens. The cremation of an entire body in an hour-and-a-half or two hours will require from 100 to 150 kilogrammes of faggots and some kilos of coal, and will cost 15 francs. The duration of the cremation will be eight hours daily, during which time 12 bodies may be burned in the three ovens, *i.e.*, 4,300 per annum.—*Lyon Médical*, October 6th.

**INFECTION THROUGH MILK.**—Several people have been attacked by "nervous fever" on an estate in the neighbourhood of Råå, in Skane, Sweden. Cases of the same disease have now occurred in Helsingborg, precisely in the parts supplied by milk from the infected neighbourhood, whence it is conjectured that the disease in both instances arose from the milk.

**IN CONSEQUENCE** of the epidemic of scarlet fever at Leyden, the Minister of Marine has ordered that youths under 16, who have been taken from the different counting-houses to enlist for the sea, shall not be sent to the School of Navigation there, but shall be sent on board training ships.

**PROCURING ABORTION IN LIVERPOOL.**—Ethens de Tomonzie, or the "Black Doctor," as he is popularly known in Liverpool, has been remanded at the Police Court, on a charge of procuring abortion on a hotel maid-servant who died after the operation. This gentleman practises on the strength of a midwifery certificate obtained at some London hospital, and a British Burmah qualification, about which no one seems to know anything definite. It will be remembered that the prisoner has already undergone a term of imprisonment for signing vaccination certificates without a legal qualification.

**PROPOSED COTTAGE HOSPITAL FOR WEST HAM, STRATFORD.**—The Lord Mayor presided at a meeting of the inhabitants of this district, on Tuesday, in support of the proposal to erect a Cottage Hospital for West Ham and the neighbourhood, when the following resolution was adopted: "That this meeting of the inhabitants of West Ham and neighbourhood, feeling convinced of the urgent necessity for the immediate establishment of a Cottage Hospital for the treatment of cases of accident, hereby pledges itself financially and otherwise to give its hearty support to the movement now inaugurated." The Lord Mayor announced that at the last meeting of the Corporation 50 guineas was voted in aid of the proposed hospital.

**EUTHANASIA.**—The editor of the *New York Medical Record*, September 19th, states that the opinion formulated by a member of the Birmingham Speculative Society that in all cases of hopeless and painful illness it should be the recognised duty of the medical attendant, whenever so desired by the patient, to put an end to suffering by a quick and easy death—every possible means being put into force to prevent any possible abuse of such duty—was submitted to the consideration of several leading New York physicians. "All agreed to the soundness and humanity of the views stated, but no one cared to express a frank opinion as to how they should govern daily conduct. It is claimed that such a principle in no wise contravenes the laws regarding the sanctity of human life. Any man who sacrifices his life, say its advocates, to save another from lingering pain, is always reckoned a hero. Why should he not do the same for himself? In his own case

the motive is, of course, lower. It may be styled a form of selfishness. The mere act, however, is regarded as justifiable in both cases. The opinions of those consulted were unanimous in regard to the serious risks incurred in the adoption of any such principle. Its rigid enforcement would not allow for possible error in diagnosis. In cases of carcinoma and phthisis no room for such doubt would exist. But there are many cases where no such thing would be thought of by the attendant unless his own affirmative should be sustained by the result of a consultation. This argues a much more advanced state of professional opinion than obtains at the present time. Patients supposed to be *in extremis* have often recovered. The patient himself might not be in that state of mind wherein he could rightly judge concerning euthanasia, though it might possibly be indicated in his own particular case. Its enforcement would have to be under legal restraint. The farther settlement of the question depends upon the growth of public opinion. We cannot hasten it. For the present the guide of each man must be his own conscience."

**CLASSIFYING MILK ACCORDING TO ITS QUALITY.**—The Middlesex Magistrates' Committee for the Adulterations Acts have reported that with respect to the adulteration of milk they did not concur in the suggestion that milk should be classified according to its quality. They were of opinion that it was desirable that all milk sold as food should be required to contain a *minimum* percentage of nutritive solids, of which a certain proportion should consist of butter-fat. The Court held at the Sessions House, Clerkenwell last week agreed with this opinion, and moreover a motion was carried that, as Sunday was the great day in the week for the sale of adulterated milk, by which the poorer classes were thus defrauded, the Inspectors under the Food and Drugs Acts were directed to procure samples on Sundays for analysis. As an article of food, it is of obvious importance that milk should contain certainly a *minimum* quantity of butter-fat, or the impoverishment of it, with the view of its sale at low prices (always an attraction to the poor customer), would go on to an extent far in excess of that hitherto known, and the article, as to its nutritive contents, become all but valueless.

WITH the beginning of the medical year in Vienna, a batch of extraordinary Professors have as usual been nominated. Dr. von Reuss, who since the death of Professor von Jäger has conducted the second Ophthalmic Clinic, becomes Extraordinary Professor for Ophthalmology, Dr. Oser for Internal Medicine, and Dr. Urbanschtsch for Otolaryngology. The name of Dr. Weichselbaum has been recommended for similar honours in the department of Pathological Anatomy and Histology.

DR. NAPOLEON CYBULSKI has been appointed Professor of Physiology in the University of Cracow.

THE post of Medizinalrath for the City of Berlin is to be of the annual value of 10,000 marks (500*l.*), and is to be thrown open to candidates.

## APPOINTMENTS.

BASSET, W., L.R.C.P. Lond., M.R.C.S.—House Surgeon to the Newport (Mon.) Infirmary and Dispensary.  
BLAKER, T. FREDERICK J., M.R.C.S., L.S.A.—Honorary Surgeon to the Northumberland Branch of the Brighton, Hove, and Preston Dispensary.  
BRADSHAW, THOMAS R., B.A., M.D. Univ. Dub., M.R.C.S.—House Physician to the Liverpool Northern Hospital, *vice* F. Johnston, M.B., C.M., promoted.  
CARLESS, ALBERT, M.R.C.S., L.S.A.—House Surgeon to King's College Hospital, *vice* Harries, retired.  
COX, ALFRED HAROLD, L.S.A.—Assistant House Physician to King's College Hospital, *vice* Lewis, retired.  
CROFT, EDWARD OCTAVIUS, M.R.C.S., L.R.C.P.—Resident Obstetric Officer to the General Infirmary at Leeds.  
CROSS, FRANCIS RICHARDSON, M.B. Lond. F.R.C.S. Eng.—Ophthalmic Surgeon to the Bristol Royal Infirmary.  
DALY, JOSEPH H., L.R.C.S. Irel., L.R.C.P. Lond.—Medical Officer to the Third District, Abingdon Union, *vice* Mr. M. S. Todd, resigned.  
DICKSON, JOHN DUNBAR, M.D. Qu. Univ., Irel., M.Ch. and L.R.C.S.I.—Medical Officer to the Bisham District, Cookham Union, *vice* Mr. G. R. Robson, resigned.

DUMMERE, HOWARD HOWSE, M.R.C.S. Eng., L.R.C.P. and L.S.A. Lond.—Medical Officer to the Fifth District, Ecclesall Bierlow Union, *vice* Dr. De Wolfe, resigned.  
FETHERSTONHAUGH, ROBERT T., L.R.C.P. Lond., M.R.C.S. Eng.—House Physician to the Hospital for Women, Soho Square, W., *vice* C. Couper Cripps, M.B., M.S. Durham, resigned.  
FULCHER, GEORGE FREDERICK, M.B. and C.M. Edin.—Medical Officer to the Chingford District, Epping Union, *vice* Dr. F. C. Cory.  
HANDFIELD-JONES, MONTAGU, M.B. Lond., M.R.C.P.—Physician-Accoucheur in Charge of Out-patients to St. Mary's Hospital.  
HARRIES, JOHN FRAIL, M.R.C.S.—Ophthalmic Clinical Assistant to King's College Hospital, *vice* Gray, retired.  
HARRIS, JAMES C., L.R.C.P. Edin., L.R.C.S. Edin.—Medical Officer to the Aveley District, Orsett Union, *vice* Mr. M. J. De Brent, resigned.  
HEWKLEY, FRANK, M.R.C.S. Eng., L.S.A. Lond.—Resident Medical Officer to the St. Pancras and Northern Dispensary, *vice* Arthur Rea Edwards, M.R.C.S. Eng., L.R.C.P. Lond., resigned.  
HOUSTON, FRANCIS T., M.D., M.C.L., to be Surgeon to the Adelaide Hospital, Peter Street.  
HUGHES, EDGAR ALFRED, M.R.C.S., L.R.C.P., L.S.A.—House Surgeon to King's College Hospital, *vice* Priestley, retired.  
JACK, ROBERT M., M.B., C.M. Aberd.—Medical Officer to the school at Padgate, Warrington Union, *vice* Mr. C. N. Spinks, resigned.  
JACOMB-HOOD, CHARLES JOHN, M.R.C.S., L.S.A.—Assistant House Accoucheur to King's College Hospital, *vice* Childe, retired.  
LEWIS, PERCY GEORGE, L.S.A.—Physician's Assistant to King's College Hospital, *vice* East, retired.  
LEWELLYN, DAVID WILLIAM HENRY, L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the Eighth District, Tonbridge Union, *vice* Mr. E. J. Hutchings, resigned.  
LUCY, REGINALD H., M.B., C.M. Edin.—Receiving-room Officer to the London Hospital, *vice* F. Tratman, M.R.C.S.  
MACLAGAN, CHARLES GEORGE, M.B., C.M. Edin.—Medical Officer to the Workhouse, Berwick-on-Tweed Union, *vice* Dr. Thomas Fraser, resigned.  
MASON, DAVID JAMES, M.B., C.M. Edin., L.R.C.P. and S.E.—Resident Medical Officer to the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.  
NUNN, JOHN ROBERT, M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Stock and Bradley District, Droitwich Union, *vice* Mr. J. W. Leacroft, resigned.  
O'CARROLL, JOSEPH FRANCIS, M.B., M.Ch.R.U.I., L.K.Q.C.P.I., L.R.C.S.I.—Assistant-Physician to the House of Industry Hospitals.  
PENNY, FRANCIS, M.R.C.S., L.S.A.—Physician Accoucheur's Assistant to King's College Hospital, *vice* Hughes, retired.  
RICHMOND, SYLVESTER, M.D. Edin., M.R.C.S. Lond.—Medical Officer to the Fourth District, Dartford Union, *vice* Mr. C. H. C. Huddart, resigned.  
SHARPIN, EDWARD COLBY, L.R.C.P. Ed., M.R.C.S.—Surgeon to the Bedford General Infirmary and Fever Hospital.  
SMITH, ERNEST HENRY, M.R.C.S., L.S.A.—House Surgeon to King's College Hospital, *vice* Jaffree, retired.  
SOUTHCOMBE, ARTHUR GEORGE, L.R.C.P. Lond.—Medical Officer to the Long Preston District, Settle Union, *vice* Dr. Lazenby, deceased.  
SYMONS, MARK JOHNSTONE, M.D., M.S. Edin.—Honorary Ophthalmic Surgeon to the Adelaide Hospital, Dublin.  
THOROWGOOD, JOHN C., M.D., F.R.C.P.—Consulting Physician to the West London Hospital, Hammersmith, W.  
WHITE, DANIEL, M.D., M.S. Irel.—Medical Officer to the Ireby District, Wigton Union, *vice* Dr. T. R. Denham, deceased.

## VACANCIES.

BOROUGH OF WAKEFIELD.—Mr. Alfred Henry Allen, re-appointed Analyst for the Borough. Remuneration by fees.  
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.—Surgeon. Candidates must be Fellows of the Royal College of Surgeons of England. Applications, with testimonials, to be sent to the Secretary, at the office, 24, Finsbury Circus, E.C., on or before November 11th.  
DEWSBURY UNION.—Medical Officer to the Thornhill District, in succession to Mr. C. W. G. Burrows, resigned. Area, 3,497 acres. Population, 8,843. Salary, £20 per annum.  
HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN SQUARE, W.—Resident Medical Officer. (*For particulars, see Advertisement.*)  
OWEN'S COLLEGE, MANCHESTER.—Professorship of Physiology. Candidates to forward applications and testimonials to the Council of the College, under cover, to the Registrar, not later than Nov. 6th. Further particulars can be obtained on application to the Principal of the College.  
ST. LEONARD, SHOREDITCH.—Assistant Medical Officer to the Workhouse and Infirmary, in succession to Mr. D. Lloyd, resigned.  
STONE UNION.—Medical Officer to the Ecclesall District, in succession to Dr. J. W. Hopkins, resigned. Area, 15,354 acres. Population, 3,781. Salary, £25 per annum.  
WESTERN GENERAL DISPENSARY, MARYLEBONE ROAD.—Honorary Surgeon Oculist. Candidates must be fully qualified. Applications, with testimonials, to be sent to the Secretary, at the Dispensary, on or before Saturday, November 7th. The candidates must attend the Board on Monday, November 9th, at 9 p.m.

## DEATHS.

BILLING, HENRY JAMES, M.D.—At 51, Oxford Gardens, London, W., on October 28th, aged 43.  
BULL, HENRY GRAVES, M.D. and J.P.—At Hereford, on October 31st, aged 67.  
STEVENSON, WILLIAM, M.D., late of the Bengal Medical Service.—At Crieff, N.B., on October 29th, in his 86th year.  
WHARTON, HENRY SAMUEL, M.R.C.S., L.S.A.—At Clopton House, Gosport, Hants, on October 31st, aged 63.

## NOTES, QUERIES, AND REPLIES.

## THE BRADLEY FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

The following additional Subscriptions have been received:--  
Dr. L. Nugent MacDermott, £1; Mr. J. Roche Lynch, 10s.

## COMMUNICATIONS RECEIVED--

## CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the Principles and Practice of Medicine and on Clinical Medicine.

LECTURE V.—CASE TAKING.

*Personal History.*

*Age—(continued).*

HAVING shown the direct effect that age has in determining the rate of mortality, we must now consider any influence it may have upon disease.<sup>1</sup> To a certain extent this may be expressed in figures, although not nearly with the same accuracy that we formulate the death-rate.

The following table from Villermé (*Annales*

<sup>1</sup> The relationship of the rate of mortality to the sick rate or morbidity is one of considerable practical interest and moment. It has been estimated by the late Dr. Farr (Supplement to the 35th Annual Report of the Registrar-General, 1875), that for every death two men on an average are constantly suffering from disabling illness; and further, that sickness is so related to the mortality that both within certain limits rise and fall together. Moreover, it is computed that for every death there are 25 cases of illness of every degree of mildness.

*d'Hygiène publique*, 1829) indicates the amount of sickness that may be expected at the different ages from 20 to 70 for a male of the working class; the sickness being understood to be such as incapacitates from work.

At	20	years expect	4	days sickness yearly.
„	20 to 30	„	5 or 6	„
„	45	„	7	„
„	50	„	9 or 10	„
„	55	„	12 or 13	„
„	60	„	16	„
„	65	„	31	„
„	70	„	74	„

Very similar results to these have been obtained by Mr. Sutton, the Actuary to the Registry of Friendly Societies, from the investigation of between three and four hundred thousand members of the Manchester Unity of Odd Fellows, and were quoted by Sir James Paget, in his address on the National Value of Public Health, June 17th, 1884. Such tables are, however, only approximately correct, since the social status and occupation very considerably influence the calculation. Speaking generally, however, the probability of becoming sick is greatest in the first week of life, and though diminishing after the sixth week, remains considerable until the end of the first year, when it decreases until the seventh or eighth. From this minimum it increases to the 18th year, when it again slowly falls till the 24th to the 30th year, from which time the liability increases to the end of life.

Since then the data at our disposal would clearly

seem to indicate that each age is accompanied by a definite amount of illness as it is with a specific rate of death, it becomes necessary to ascertain as far as possible the conditions which regulate this coincidence.

The sequence of anatomical conditions and physiological manifestations which constitute the life of the individual is divisible, as we have seen, into three main age periods; this grouping being based rather upon the special characteristics of the body at successive times, than upon a mere arbitrary division into months and years; since although in the majority of cases these definite characters do coincide with certain ages, their appearance may be anticipated or postponed; for just as certain infantile or childish peculiarities may persist beyond the age of their usual duration, so cases are not unknown of death at early manhood with all the appearances of senile decay. Such a conception of the nature of age is sufficient to suggest the influence it must have upon the course of disease. For as ages are distinguished by specific structural and functional peculiarities—those, in short, by which we distinguish a child from an adult, or youth from old age—so must the perversions of those conditions, *i.e.*, disease, differ at different periods. The changes which progressively occur in the constitution of the organism of themselves must determine an increased liability to illness, and thence, what may be perfectly in accordance with health at one period of life, may be distinctly morbid at another. Thus, the degenerative changes which may be looked upon as the normal accompaniments of senility are very certainly to be regarded as unhealthy when occurring in youth or early manhood.

Although, however, we speak of the phenomena of life as progressively changing from birth to death, the progress itself is scarcely at a uniform and steady rate, it is marked rather by alterations at tolerably definite periods, the intervals being distinguished by a more or less gradual inclination to these changes. Such, for instance, are the times of dentition, of puberty, and of "change of life," and, as might be expected, distinctly pronounced maladies characterise these seasons, induced by the structural changes associated therewith, just as other diseases more commonly occur in the intervals. "At these seasons, disease is either invited or thrown off or diverted in new directions."<sup>2</sup> It was the appreciation of this fact that led the ancient physicians to attach so much importance to critical days and climacteric years, reckoned on a septenary or lunar scale, and even so lately as Cullen, the doctrine of critical days found favour. Thus, at multiples of seven or nine years changes in the health of the body were anticipated, and at 63 "the grand climacteric," as it was termed, the individual was regarded as especially liable to untoward influences. At the present day, disregarding almost entirely the idea of critical days, we have mainly confined the use of the word climacteric, which is derived from a Greek word *κλιμακτηρ* signifying a step, to the "change of life" in women and the date of commencing decline in men.

The influence of age, acting through the environment which it determines and the degree of death tendency which it confers, is manifested in the actual occurrence of disease in its phenomena, its progress, and its termination. There are certain maladies which are only possible at particular ages, the anatomical conditions on which they depend are only existent at certain times, and as the evolution, maturation and involution of the body proceeds, the liability to disease may occur or be arrested. Or again, the signs and symptoms of one and the same malady, so far as the initial lesion is concerned, offer a marked contrast at different age periods, sufficiently to

necessitate a special study of the illnesses of children and old age in contrast to what may, for purposes of convenience only, be regarded as the standard presented by adult life. Further the prognosis in the majority of cases will be largely dependent on the age of the patient, whether in respect to the obvious differences in anatomical structure, the degree of vitality, or such idiosyncrasies of disease as are seen in the direct variation of the mortality of typhus fever with the age.

A brief record of the predispositions to disease at various age periods, will serve to illustrate more clearly the foregoing remarks.

The period of evolution, with all the stages comprised therein, especially exemplifies the influence that the two component factors of age may exert in causing or modifying diseases. From conception to maturity the individual exhibits a gradual transition from absolute dependency on its surroundings to the completest freedom that is enjoyed at any time. The influence of the foetal and infantile environment upon the individual's well-being is most considerable. Many of the congenital malformations and diseases are directly attributable to conditions of intra-uterine life; whilst the gradual diminution that is taking place in infant mortality and sickness, testifies to the very distinct effect that the circumstances of life have in the production of disease, as well as to the essentially preventible character of most of these causes. The responsibility for exposure to such harmful conditions is clearly not to be ascribed to the sufferers in their early days, but as the child grows older and becomes more and more dependent on himself, it is shifted to his shoulders.

But as there is probably no period of life in which the extrinsic causes of disease are so numerous and active as in infancy and childhood, so is there no time at which the susceptibility of the body to these causes is so keen. The tissues at this stage contain the largest amount of living material, and proportioned to it exhibit the maximum of vitality, as represented in its assimilative and formative aspects; from which result the growth and development. The quickened pulse and inspiration, the higher temperature, and the exaggerated sensibility of the nervous system, all show the activity of life at this period; whilst the physical properties of the tissues, their greater softness, flexibility, and permeability to fluids, are equally characteristic. It is not difficult to see how such circumstances of themselves confer a special liability to disease apart from the predominant effect of the environment, and determine a maximum of sickness and mortality in the early days of life, when existence is "but a series of efforts towards establishing a regularity of procedure."<sup>3</sup> This very activity of the tissues, and this greater delicacy of construction, carry with them a facility of disturbance beyond what is met with at later periods. Hence it is that very slight causes, such as would pass unnoticed in the adult, are apt in the child to produce illness even of a serious character. The violent change of the environment which occurs at birth, and the subsequent exposure of the air-passages and alimentary canal to very variable and too often improper ingesta, determines a special predominance of disease in those organs during early life. The anatomical features of size and connection with other parts, which the as yet improperly developed organs present, permit a difference in the character of disease, and affect considerably their ultimate course. Thus the extremely small size of the glottis in infancy and childhood causes, on the slightest swelling of the adjacent mucous membrane, a dangerous risk of suffocation, and whilst such is a common occurrence of

<sup>2</sup> Southey. Lectures on Personal Hygiene, *Lancet*, 1879.

<sup>3</sup> Considérations générales sur les âges, par Dr. F. Estève, 1859.

these ages, it is of comparative rarity in adult life. Lesions of the valves of the growing heart are of a different import to the future of the child from the same damages when occurring for the first time in a full-sized organ. But distinctive as many of these conditions are of the developing period of life, the most characteristic feature which disease offers at this time is the extreme readiness with which the body generally responds to stimuli which may be very limited in the area of their application. A slight bronchitis, for example, may give rise in the child to a group of symptoms such as convulsions, considerable fever, perhaps diarrhoea, by which the essential signs of the local ailment are obscured. The entire organism shares to the fullest in the affection of one part, leaving the specific malady less prominent in its manifestations than is usually the case in the adult. The facility with which diffusion takes place through the tissues, together with the activity of the circulation, favour alike serous effusions, especially at mucous surfaces (as seen in the frequency of diarrhoea) and absorption from the same. This has been suggested, though inconclusively, as the explanation for the greater frequency with which specific fevers occur in childhood and youth, their contagia being then more readily absorbed. Whatever the explanation, the fact remains that these diseases notably prevail at these periods, being rarer and almost unknown as age advances. These characteristics of the period of development, so far as they affect the production and cause of disease, become less and less marked as maturity is approached. Before that time, however, the stage of puberty is passed through, and the reproductive capability is established. This calling into activity of a special set of organs entails upon them a liability to disease which had not previously existed, and is furthermore accompanied by a reaction on the part of the body generally, which in the case of the female is frequently associated with definite illness.

---

## LECTURES ON THE PRINCIPLES OF THE PRACTICE OF MEDICINE.

By W. H. SPENCER, M.A., M.D. Cantab., F.L.S.,

Senior Physician to the Bristol Royal Infirmary, Lecturer on Medicine and on Pathology at the Bristol Medical School.

### LECTURE II.

#### *Disease and Diseases.*

WE have a vast array of information concerning disease. Taking the whole of what is commonly held to be knowledge about disease, and deducting from it much that is mere matter of opinion or conjecture, much that is unproven, still we have a vast array of knowledge of disease that is sound and true beyond doubt or question. Already the pace at which knowledge has been accumulated by the science of Medicine has far outrun the powers of the corresponding art to adapt the knowledge to practical use. And still fresh knowledge comes.

Naturally many attempts have been made to condense this knowledge, and by condensing it in scientific form to arrive at a definition of disease; the attempt has been made to analyse the complex phenomena of disease into constituent and simpler phenomena; and, even, it has been suggested that a little more knowledge may, in the hands of some

genius, discover the first principle of disease in the shape of a simple and universal law.

Of disease as a fact, a phenomenon, there can be no definition; disease cannot be separated from the special appearances whereby it becomes known to us. Disease is indefinable in the same sense and for the same reason that health is indefinable. Nor can we analyse disease into constituents. We do know enough about disease to tell us that the suggestion of a first principle and a universal law for disease comes from the region of fancy and poetical license.

We must build up a true conception of disease by accumulation of facts from examples of disease, and by piecing together the multitudinous bits of knowledge that accumulate upon us so fast—taking care to receive only those bits of knowledge that have been confirmed as true.

Nevertheless it is possible to generalise from our array of information and particulars about disease. It is possible to give a generalised account of disease (and therefore a corresponding generalised account of health) from the knowledge we have already gained; from the knowledge gained by study within the practical science and from outside sources—notably from Physiology, Physics and Chemistry.

Wherefore, discarding all idea of a definition of disease, all idea of analysis of disease, and the suggestion of a first principle lying at the root of the matter, we will proceed to give an account of disease (and its co-relative health) in accord with our actual knowledge, and no more than our actual knowledge, of the facts and circumstances of the case.

Now for our account of Disease, and its co-relative, Health.

At the outset of our enquiry as to the *end* of Medicine we learned that we had to do with matters of *experience*. Let it be well understood that we have nothing to do with any *abstract* notions; we have to do only with experiences and matters of fact. First, then—the word disease stands for matters of fact, for facts actually observed and verified, together with the best explanations of the facts we can give at the present time. Disease can *never* be at any time anything but all the true facts of a certain sort, and the best explanations of them, clearly made out up to that time. The men who come after us a century hence will be able to give better explanations of some of our facts than we can give; they will have many more facts than we possess, and explanations of them as good as can be given at the time. But these men, too, will have to tell the student to cease asking for a definition of disease or for some essential fact of disease or even for the nature of disease; they also must bid him take what facts and what explanations he can get, and then hand on his stock to those that come after him—as Disease.

Next, the word disease stands for facts belonging to the matter and the energy which together make up the body and its life. The facts of disease are not supernatural nor mysterious in any sort of way; they are solid, material experiences. The facts of disease are experiences gained in the same way as the facts or experiences of physics and chemistry, and botany and physiology are gained—by observation and experiment and verification, and by reasoning out the relations of the facts.

All the facts open to our observation and discovery in the living body may be set out in three groups. There are, first, facts about the nature and composition of the matter of which the body is made up. Secondly, there are facts about the mode of arrangement of the matter, and the forms arising out of this arrangement. Thirdly, there are facts about the motion and activities of the matter: the changes which the matter is continually undergoing—whether these be visible actions

or the invisible changes that characterise the inner life of the body. If we look closely at all the things we know about any living body, regarded as an individual living organism, we shall find that all the known things range themselves in one or other of these three classes. Now this applies to the living organism, both in a state of health and in a state of disease.

The facts of disease, then, are facts relating to the nature or composition, and to the form or structure, and to the motions or activities of the matter of which the body as a whole and in its various parts is made up.

But these facts are the same sort of facts that the chemist and the anatomist and the physiologist are dealing with when investigating the living body in a state of health. To find out what especial marks and what distinguishing characters pertain to the facts of disease we must go a step further.

We have already seen that the state of disease is a state opposed to and a variation from the state of health. The facts of disease must still relate to composition, and structure, and activities; but they must relate to an altered or varied state of things as to composition, and structure, and activities. The chemist and the anatomist and the physiologist must still busy themselves with facts of composition, and structure, and activities, when pushing their enquiries into the domain of disease: but, now, the enquiry pertains to alterations and variations. It is the old order of facts, but now studied in new situations; the same elements, the same matter, the same motions, but now in new circumstances and with new results.

Alteration implies difference. If we speak of disease as an altered state of things we imply that some state of things has existed which has suffered alteration; we imply that there has been a variation from a *status quo ante*; or that there has been a deviation from a course of things which otherwise would have gone on and persisted in some *known* direction. Indeed, strictly speaking, we imply that we *do know* what is the composition and the structure, and what are the activities of the body and its various parts when alteration has not yet been made, when disease has not yet come upon it.

The question then arises—What is this state of things that is altered; what is this persistent course? It will not do to say that it is the normal or natural or usual state of things as to the body or its parts. To say this would be to state in an abstract and indefinite form what we want to explain and define. Nevertheless, with the knowledge at our disposal, we may gain a conception of important points of *difference* between the facts and state of health and the facts and state of disease.

Let us turn to a chapter in elementary physiology. It is the chief business of the physiologist to enquire into the working or activities of the body and of all its various parts. These activities are the changes which occur to the matter of the body in connection with the absorption and evolution of energy. We represent the material of the body as made up of minute particles that cannot be separated into smaller particles or into anything different to themselves—the *atoms* of carbon, hydrogen, oxygen, &c. These minute particles are aggregated into the larger *molecules*, such as the molecules of sugar, fat, albumen, &c., and still more complex groups. This matter is built up into definite shapes. We call the arrangement or position of the molecules with reference to each other the structure of the body. Here, again, we see complexity of structure arrived at by aggregation of simple elements. In the brain this aggregation of simple elements reaches a complexity which probably, is not paralleled in nature. Everywhere in the living body

its matter is in a state of ceaseless, more or less active, motion and change. There are the visible motions connected with muscular action, and with the circulation and transport of matter in the liquid form—mechanical in their nature. And there are the motions connected with the aggregation of matter and its interaction and its disintegration—mechanico-chemical and molecular in their nature. These motions represent energy in its various forms: the storing up of energy, or its absorption; the giving out of energy, or its evolution. There is a constant stream of matter into the body in the form of food, carrying with it energy—or, the capacity of doing work; and there is a constant stream of matter out of the body in the form of the comparatively simple and more or less de-energised matters we excrete. The meeting-point of these streams is in the tissues of the various organs and parts of the body. The matters composing both the in-going and the out-going streams undergo a continuous and orderly series of changes, chemical and physical. At the meeting-point changes also occur, changes of a more intricate and subtle kind. These changes consist in an interaction between the matter which is definitely shaped and in its place as formed tissue and the liquid matter which is brought up to it and bathes it—the changes proper to nutrition.

All these changes conspire to produce *definite results*. And the result as to any part of the body is the *maintenance* of the composition and structure and activities of the part; or, as to particular parts, this result together with some special result—like the production of a secretion, or muscular motion, or nerve-currents. Now Physiology seeks to make out all about the changes and the results, and something more—the conditions under which the changes will produce always the same definite results. In making out the various and complex changes that go on in the body, Physiology takes it for granted, not only that the same changes are required to bring about the same definite results, but that the course of nature as to the working of the body never alters; it looks upon and investigates the succession of changes as to any definite result, as existing and going on under conditions which persist and recur, altering only within certain narrow limits—such a limit as might be allowed for wear and tear, or the gradual failure due to friction. And Physiology finds that the changes occurring under such conditions tend to maintain the composition and the structure and the activities of the body and its parts always in the same state—*i.e.*, tend to maintain the body always in good working order. This, then, is the physiological state—the state of health; changes determined and occurring in orderly relations of co-existence and succession; these changes determining new relations and changes: all conspiring to produce definite results. And the grand total of the results is the maintenance of such a composition and structure, and such activities *as shall provide for the recurrence of the phenomena over and over again in orderly cycles*. Physiology finds that the life, the normal or healthy life, of any part of the body is a cycle of events; it determines how the cycle is kept a cycle.

But what if conditions arise that cause the cycle to break, anywhere and at any time; conditions under which the changes do not bring about the same regularly recurring definite results, but some other result, whether affecting composition or structure or activity, or all of these? Then we pass to the state of Disease: and we pass out of Physiology into Pathology. Pathology determines the conditions under which the physiological life-cycle of any part of the body is or can be broken, and under which the changes, instead of recurring in the physiological cyclic order, go on in a straight line or a zigzag or any deviation

from the form of a circle we please—conditions that produce different changes and different results to those realised under physiological conditions. Pathology is concerned with the changes and the results that come out of this altered state of things, with the altered composition, and the altered structure, and the altered activities. And it is to these we must give the name *Disease*.

All the pathological facts that we can make out as to any particular state of disease, *e.g.*, the series of facts connected with embolism of a small artery of the brain, the softening of brain tissue, and the functional changes; or the series of facts connected with erysipelas of the skin would be perfectly real and could be correctly described if there was no such thing as Physiology at all. There are the facts; they are open to observation and to verification and they can be set forth as facts relating to the composition and the structure and the activity of the matter composing the living body. Without Physiology, however, we should never be able to explain or understand what Pathology had made out and described. Physiology comes in and gives us facts with which to compare pathological facts. And by placing the one order of facts alongside the other order of facts, and comparing them, we are able to explain and understand the breaking of the physiological cycle, the advent of pathological change, and the nature and results of the changes.

We are very far from suggesting that Physiology has as yet made out all the circumstances and conditions under which the integrity of the body and its parts is maintained, and the changes proper to this or that organ or part are made to recur perpetually in the same order and with the same results. We can say, however, that those unaltering and constantly recurring facts which Physiology has as yet made out are, as far as they go, our standard, whereby we estimate pathological facts and learn to know these facts as alterations in conditions and in changes and in results, which give a meaning to the correlative terms Health and Disease, normal and morbid change. And, until the time when Physiology may be complete Pathology must be incomplete. There can be no hard and fast line of demarcation between health and disease—between physiological and pathological changes. The physiological state of things is but a state of mobile equilibrium; the transition from that state of things to a state of disease must be often and necessarily a series of oscillations, now tending to a return to the physiological balance, and again tending to a definite pathological result. The body or organ which can readily adapt itself to variations in conditions, which, so to speak, is expert at living, will keep its balance more easily and run into a state of disease less easily than the body or organ which is stamped from birth with an incapacity for adaptation. We have constantly to refer to the physiological standards before we decide whether we have or have not to do with facts of disease. We may be physiologists purely, but we cannot be pathologists unless we are also physiologists.

The appearances whereby disease becomes known to us, the accumulated facts wherein we find our conception of disease, are apprehended by us in collective form, as concourses or collocations of facts. It is a matter of experience that the facts of disease come before us in batches or groups, and as groups of colligated facts. A certain series of disease-appearances reappears in different persons, or it may be at different times in the same person; the series as it reappears presents the same or similar circumstances of onset and the same or similar characters and order of succession and relations as to the phenomena. Again a certain series of morbid phenomena is observed to be connected with some particular

organ or tissue, as the stomach or the liver or the heart or a serous membrane; and the same or a similar series of phenomena reappears in the same organ or tissue in different persons or in the same person; or, again, a series of morbid appearances—morbid, because not physiological—may be observed to belong to the function of some organ or the functions of some co-related organs, to wit, the several functions connected with the organs of digestion, and to reappear in connection with the same functions in different persons or it may be in the same person. And, anon, a different series—differing in the circumstances of onset, in the characters of the phenomena, in the order of their succession and their relations, or in some of these—is observed to reappear and to recur in like manner. Wherefore, according to this experience, we mark off the facts of disease into groups; and we call the groups *diseases*; and we give a name to each group, by which to distinguish it.

This assemblage of the facts of disease in groups is no arbitrary and artificial arrangement. It is a natural classification of the facts of disease. Not only do we recognize the same groups when they reappear by obvious superficial appearances common to the groups; not only do we separate groups from one another according to obvious differences in the superficial appearances. Penetrating beyond what is obvious and on the surface, we find that each grouping, although a record of a multitude of very complex phenomena, yet shows a characteristic common to all the groupings, that of association of all its phenomena in collective order. Every group is a record of changes in the physiological order of things as to the body generally (in so-called "General Diseases") or as to some organ or part (in so-called "Local Diseases"); a record of co-existences and sequences among the changes; a record of interdependence of the changes and relationship of facts to each other and to outlying facts; a record of cause and effect, near and remote. Herein we find an intelligible objective meaning of the term, *a disease*. A disease can only become known to us by observation of its marks or characters; one disease is identified with another by community of characters; one disease is distinguished from another by differences in their characters. Amongst the agreeing or differing marks or characters we must include the mode of connection of the characters, their order and relations.

• When we have made out and set down in their due order of sequence and relationship, and in detail, all the available facts of the record for any particular grouping, then we can say that we know that disease, and our statement of the facts of the record would be a definition of that disease.

Now Pathology seeks to define in this sense the natural groupings of the facts of disease and to set its due limits to each group. Nor has Pathology, as yet, made progress to a complete definition and limitation of the natural record for those groupings or diseases whose existence we already recognise. The discovery of the facts, still more, of *all* the facts belonging to any grouping, and the placing them in their true order of sequence and relationship, is a difficult work and a work of time; though pathologists are ever busy at the work.

In making out the record of facts and constructing a definition of any particular disease, we cannot go beyond our experience of actual examples of that particular disease; and the examples known to us may be few or many. The examples, moreover, come to us for the most part piecemeal. Rarely, if ever, does a disease begin and work through to its end, completing the full record of its facts in one and the same example and before the same observer. Rarely, if ever, does a disease disclose itself here or there in its progress, as

it recurs, by facts of the same degree; so that, as we observe it here or there in its course, it may seem that we have to do with a separate grouping, so marked are the variations in the modes of the same disease. And, further, the examples of disease known to us are liable to be associated with such circumstances as (what we call) the *constitution* of the patient, or his *temperament*, or his *diathesis*. These terms indicate realities and, for the most part, physiological variations in structure or in modes of activity within the limits of health—natural weaknesses at points in the cycle of life-changes, or permanent tendencies, or degrees of expertness at living as we have designated it. All these things have to be taken into account in our estimate of the examples of particular diseases. Wherefore, our best definitions of diseases are provisional and incomplete; and every definition of a disease must be held to be faithful only to the great mass of examples of that disease. Nevertheless, the separation and definition of diseases has reached a degree of completeness which puts great power in the hands of medical men to the understanding of a great part of most known diseases and to the cure of them or the alleviation of their ills.

To give a definition of any disease, we must enumerate and describe and set forth in their due order of sequence and relationship, and in detail, all the facts that have as yet been made out for the particular grouping; and this from observation of examples of the grouping. Further, we may, very properly, connect the phenomena with their antecedents or causes; we may advance explanations of the phenomena by assimilating facts with other facts or by means of some theory or hypothesis; we may set out all we know about the consequences, early and late, of the phenomena. Information about such things gives material help in distinguishing and defining diseases; it is necessary to a proper understanding of diseases; it may be, and is often, necessary to an enlightened treatment of a disease. But neither the causes, nor the explanations, nor the issues are *the disease*; nor do these belong to the definition of it. These have their value and their place in our accounts of diseases; but they are predications, not definitions, and as predications they must be separately set forth and separately discussed. *The disease* is our record of its phenomena and their relationships—what belongs to the definition.

And if, when we had marked off the facts of disease, into groups and had named the groups, we should arrange the groups themselves in some order—if we should add to distinction and nomenclature a classification of diseases, we should get what is called a *Nosology*. The grounds and methods of such a classification are many and various, and in the making of nosologies this or that basis and method has been adopted according to the purpose held in view. A nosological classification is always an arbitrary and artificial arrangement. Such a classification of diseases is adopted merely for our own convenience or for some other special purpose. It may be for a statistical registration of diseases—and this with a view to register the causes of death, or the prevalence of diseases in various places, or for any such like end; or such a classification of diseases may be made in order to facilitate our study and our treatment of disease. An arrangement of diseases according to their seats, an anatomical arrangement, is a useful and generally adopted arrangement for the purposes of practical medicine.

Thus, then, we have tried to give a clear and accurate account of what is meant by the term *Disease*, and by the term *Diseases*. We must not forget that although medicine is a science it has a corresponding art. It has been said already that we have a vast

array of knowledge about disease, and this knowledge of disease comes chiefly through our knowledge about diseases. It becomes, therefore, of vast importance that our knowledge about disease and diseases should be arranged and set forth in an order adapted to the strict requirements of science and to the needs of the practitioner. To this topic we propose next to devote our attention.

## REMARKS UPON INJURIES TO THE EPIPHYSES.<sup>1</sup>

By EDMUND OWEN, F.R.C.S.

THOUGH the subject of the development of the bones may appear a matter of uninteresting detail to the student, the importance of it is apt to be forcibly brought home to him soon after entering on practice.

It is in the layer of cartilage between the end of the shaft and the epiphysis that the growth of the bone, as regards length, takes place. In the neighbourhood of this layer physiological activity is great, whilst the adjoining strata of new bone are delicate and soft. A slight injury may suffice to “unglue” the epiphysis, and it is for this reason that dislocation in childhood is rarely met with; violence expends itself more readily in detaching the epiphysis than in displacing the articular surface.

Without entering into tedious detail, and with the view of simplifying the matter, one may call to mind the fact that the special nutrient arteries of the long bones take the course in their respective bones *towards the elbow and away from the knee*. Now, the epiphysis towards which the nutrient artery runs is invariably the first to join the shaft, therefore the elbow-ends of the humerus and radius<sup>2</sup> are attached early, whilst the knee-ends of the femur and tibia are attached late. Thus it is evident that in the growth of the arm the integrity of the elbow epiphyses will be of secondary importance to those near the shoulder and wrist; whilst, in the lower limb, the knee-ends of the femur and tibia are of chief concern. In the case of excision of the knee-joint, then, it is of extreme importance to respect the integrity of the junction cartilages of the femur and tibia. Removal of these plates of cartilage is certain to entail serious dwarfing of the limb.

At the sacrifice, perhaps, of absolute accuracy to convenience, one may say that the epiphysis towards which the nutrient artery is running is ossified to the shaft soon after puberty, whilst the other epiphysis delays its attachment until about the twentieth year, that is *until growth is completed*.

When a young subject has had a fall, has been run over, or knocked down, a methodical examination of the epiphyses should, so far as is practicable, be undertaken, and, if a joint be found so swollen or tender that a satisfactory conclusion cannot be arrived at, chloroform should be administered and all doubt cleared up. (It must be remembered, too, that the discovery of a fracture in the shaft of the bone is not evidence that the distant epiphyses are unaffected.)

Though in the case of separation the plane of the fracture may have deviated from the junction-cartilage, and passed in certain spots through the adjacent bone tissue, still definite crepitus is hardly to

<sup>1</sup> Abstract of Clinical Lecture delivered at St. Mary's Hospital October 30th, 1885.

<sup>2</sup> The upper epiphysis of the ulna is merely a thin cap over the top of the olecranon.

be elicited. A peculiar "mortary" sensation may, however, very likely be detected. Should the evidence of separation be considered equivocal, no rude search for crepitus should be undertaken. Such violence would increase the local disturbance and invite disastrous complications. But even when extreme gentleness has attended the examination, and the treatment has been conducted with all efficiency, the result may prove disappointing or calamitous.

The complications which may supervene are abscess at the site of fracture, with or without suppurative inflammation of the joint. The epiphysis may be cast off as a sequestrum, and may eventually require extraction. Convulsions or rigors may mark the onset of an attack of pyæmia. From local excitation, ossification of the end to the shaft may take place, with, of course, serious interference with the development of the limb. The neighbouring joint may be left stiff or deformed. It is well that the possibility of such contingencies be duly recognised, and that the parents be made to understand that the lesion is a serious one; that the breakage is through a region in which the growth of the bone is concerned, and that the injury is close against, even if it do not implicate, the joint. On the other hand, it is a consolation to know that these injuries generally do well, that the detached end is quickly cemented on again, and without permanent deformity, and that the stiffness of the joint soon disappears with massage and methodical movement.

As a rule, the joint should not be confined longer than three weeks.

---

## ON THE THERAPEUTIC VALUE OF BLOOD-LETTING.

By JAMES ROBINSON, M.D. Brux., M.R.C.S. Eng.

THE value of blood-letting as a therapeutic agent under appropriate pathological conditions being so slightly appreciated, I am induced to record my individual experience of the beneficial results of its practice, in the hope that its efficacy in the treatment of certain forms of disease may be more generally acknowledged, and that it may obtain that place in modern therapeutics to which it is fairly entitled; at the same time I lay no claim to originality in suggestion either in method or application.

In former times, its value being overrated, and its practice indiscriminate, venesection was often productive of more harm than good. Fostered by irrational empiricism, use degenerated into abuse, undue laudation of its value was followed by condemnation, and finally by almost total exclusion from the list of therapeutic agents. Whilst it is true our forefathers bled too frequently, it is equally true we bleed too seldom, a judicious abstraction of blood often contributing to the comfort and well-being of many individuals, not obtainable by any other procedure, and, in many diseases, tending to avert an otherwise certain fatal termination. Instead of retaining its practice under appropriate conditions, the wheat and the tares have been destroyed together, and a most valuable and powerful means for good is so infrequently adopted as practically to amount to its rejection from the list of remedial agents. This is to me very remarkable, as the pathological conditions demanding the practice of venesection are so indicative of the means of relief, and the results so immediate and satisfactory, and may be attributed, partly to that natural

revulsion of feeling which popular abuse always engenders, partly to the absence from the clinic of those cases peculiarly adapted to this method of treatment, and partly to the student mind not being directed to the special study of its application in the treatment of disease modified by change of type, locality, and constitutional peculiarity. The general symptomatic indications necessitating venesection may be thus broadly stated: an overloaded vascular system, as in general plethora, and hyperæmia of certain viscera, whether of primary or secondary origin, so intense as to seriously embarrass the action of the heart, and sometimes even to threaten its complete failure. Under such conditions a timely bleeding is always and immediately followed by relief, a fatal termination is frequently averted, and the disease is so modified as to make its subsequent progress towards recovery easier and more certain.

The question as to the quantity of blood to be taken must be left to the discrimination of the operator, who ought to be guided upon this point by the impression produced upon the symptoms, and by the effect upon the heart as indicated in the character of the pulse. It will be noted that in some of my cases the quantity usually considered to be sufficient is much exceeded, but in no case have I found any evil results to ensue from the abstraction of such an amount as the symptoms evidently demanded for their amelioration. The notes here appended are selected as being typical of those diseases in which I have found venesection to have been remarkably beneficial.

Female, age 45 years.—Flushings of the face and hot sweats, noises in the ears, constant headache, and occasional bleeding from the nose. Pulse full and labouring. Superficial veins full and distinct. Catamenia entirely ceased two years ago, since which time these symptoms have been more or less present. The recognised remedies failing, I bled to syncope with decided relief to all the symptoms, which was maintained for six months, when the operation was repeated, similar good effects resulting. It is now twelve months since the last operation, and she now enjoys fair health, being troubled only occasionally by severe headache.

Male, 12 years.—Acute pneumonia. Sudden attack of dyspnoea on the third day, quickly followed by orthopnoea, short and persistent cough, difficult expectoration of sputa streaked with blood, great mental excitement, with fear of suffocation. Imperative demands for relief. 23 ounces of blood removed from the arm. The breathing became easier at once, and the boy was quite comfortable and peacefully sleeping in half an hour. Subsequent progress uninterrupted and final recovery complete.

Male, 61 years.—Has suffered from shortness of breath on going upstairs or in ascending a hill occasionally from oppression and palpitation of the heart and tightness across the chest. Been gradually declining in strength for the past twelve months. Heart's action irregular, impulse feeble and area enlarged; first sound weak, no murmur. Slight arcus senilis. Appetite fair and tongue clean. These symptoms were relieved by treatment, and all was progressing favourably, when, after going upstairs to bed, he was suddenly attacked with urgent dyspnoea, short and dry cough, with little expectoration. I found him sitting in a chair, being unable to lie down, bathed in cold perspiration, pallid, and almost pulseless. Respiration slow and shallow, and performed with difficulty. Various means for relief were tried during the space of four hours with no success, when I abstracted 25 ounces of blood from the arm. The pulse at the wrist began to improve when about one half this quantity had been taken, and with it the breathing grew easier, becoming comparatively free when the

full quantity here stated had flowed. In half an hour I left him composing himself to sleep, having been able to retire to bed. On the following day the cough was quite easy, the expectoration free and mixed with blood. All went well for exactly two months, when I was hastily summoned, similar symptoms having returned during the night after a dull, heavy, and damp day, during which the breathing had been difficult and cough troublesome. Two hours were allowed to elapse before recourse to venesection, during which time other remedies were used, when 20 ounces of blood were taken from the arm, which at once ameliorated the distress, and he was sound asleep an hour afterwards. During this last attack he became paralysed on the right half of the body. Subsequent progress much slower than after previous attack, and, in addition, there was mental disturbance and delirium, with other symptoms usually following embolism of a cerebral artery. These slowly passed away, and he was able to get about with comparative ease, the paralysis gradually disappeared, and the general health improved until he was able to take a walk with comfort and enjoyment at a moderate pace. He enjoyed fair health for exactly two months to a day, when for the third time he suffered from similar symptoms to those previously noted. He demanded to be bled at once, with which demand I complied, abstracting 25 ounces of blood from the arm. The relief expected came at once, and I was able to leave him quite composed in three-quarters of an hour. Subsequent progress satisfactory. It is now four months since the last attack, and he is at the present time in fair health, being able to take a walk of a couple of miles at a moderate pace with comfort and enjoyment.

Male, 20 years.—Tall, strong and well-developed, intelligent and active. Been the subject of epilepsy for six years. Fits occur in rapid succession with an interval of a month or five weeks. They come on after violent exertion, visiting public amusements or entertainments, and similar mental excitants, and frequently without aura. Bromide of potassium in large doses had been taken for over twelve months with only slight relief of the trouble. Venesection was performed to the extent of two pints, which caused fainting. No seizures for three months, when he returned for a repetition of the bleeding, which secured a respite for five months; when, after witnessing a foot-ball match in which he had a peculiar interest, the fits returned. The same evening two pints of blood were removed from the arm. Large doses of bromide were then ordered to be taken twice a day, and he has been now free from the epileptic attacks for eleven months.

Male, 40 years.—Stout, of low stature, short thick neck, large posterior development of the skull, round head, nervous temperament. Complains of constant headache, weight at back of head, deafness, loss of appetite, and occasional attacks of vertigo. Pulse irregular and small. Pupils dilated. Treated with purgatives, cold to the head, &c., for some time without relief. Venesection to 35 ounces, causing slight nausea and drowsiness. Next day felt considerably relieved from all the symptoms, and subsequently for three months he continued to take saline purgatives with potassium bromide, and applied cold to the head each morning by means of a shower bath, at the end of which time he returned to his employment. At the expiration of three months he was again bled, the old symptoms having come on after a night's carousal. One pint of blood removed with decided benefit. At present under treatment.

Male, 35 years.—Medium height, very stout, and of florid complexion. Complains of severe headache, dimness of sight, specks before the eyes, noises in the ears, and fulness in the head. Pulse small, hard and

wiry. Venesection to syncope was performed, and next day he returned to business quite free from his former troubles. Returned in nine months with similar symptoms. Bleeding again performed to syncope. This patient has since been bled on two occasions, with an interval of six and twelve months respectively, each time with entire removal of the head troubles.

Female, 38 years, married.—Low stature, stout, and of florid complexion. Has had five children. Menstruation profuse and regular. In the interval she suffers from fulness in the head, facial neuralgia, headache, weight upon top of the head, vertigo, flatulence and constipation. Purgatives, cold to the head, and free exercise prescribed without decided amelioration of the symptoms. Venesection was afterwards performed, and 38 ounces of blood were removed. By subsequent attention to the bowels and under proper general regimen the cure was complete.

Female, 34 years.—Confined a week previously of a male child at full time, after which she went on favourably until found by a neighbour, who had been acting as nurse, in strong convulsions. An hour previously she was apparently quite comfortable. I saw her two hours subsequently, when I was informed "the fits had never been off her" during the whole time. I immediately abstracted 20 ounces of blood from the arm, the fits ceased, and deep sleep followed, lasting several hours. Subsequent progress satisfactory. It is now two-and-a-half years since the events just narrated, and recently, I am informed, she has been again confined without any untoward circumstances supervening, and is now in good health.

Male, 50 years.—Tall and powerful. After a drinking bout, lasting for a week, was seized with epileptiform convulsions, which came on at 8 a.m., lasting until 2.30 p.m. without intermission of more than five minutes. I abstracted 30 ounces of blood from the arm, after which the fits did not return, and he slept soundly for eight hours. He returned to work in two days. This man, nine months afterwards, again had a long drinking spree, when it was followed by delirium tremens for two days, and finally by the convulsions as before. Immediately upon visiting him, I opened a vein in the arm, and took two pints of blood. During the time the blood was flowing he had a severe convulsion, after which he became quiet; his breathing, which previously was stertorous, then became easy, and after the operation was completed he fell asleep, awaking in 12 hours. Recovered perfectly in a week, and was able to resume work.

Female, 38 years.—Medium height, always enjoyed good health. Eight months advanced in pregnancy. Suddenly seized with convulsions, which came on every quarter of an hour. Perfect insensibility in the interval of the fits. No mitigation of the symptoms following the hypodermic injection of half-a-grain of morphia, I decided to bleed from the arm. I took 30 ounces of blood, after which the convulsions did not return. Two hours subsequently she was delivered, without assistance, of a dead fœtus. Subsequent progress slow, but finally complete recovery.

Male, 18 years.—Having been out of employment for several weeks, and after fruitless efforts to obtain any, he became depressed in spirits and his appetite fell off. He complained of occasional pain in the head, but of no other symptom. He went to bed earlier than usual, and two hours afterwards was found delirious; this state soon increased, and it was with the greatest difficulty that he could be restrained and kept in bed. This condition of matters went on until morning, when I saw him. He was then wildly delirious, the pulse was small, hard, and frequent. I injected half-a-grain of morphia hypodermically, which in a few minutes produced quiet and, subse-

quently, sleep, from which he awoke in about twelve hours quite as wild as before. I again injected the morphia, which produced sleep for eight hours, when there was a return to the previous condition. As it was impossible to restrain him, I injected quarter-of-a-grain of morphia, and as soon as he became quiet I bled him from the arm to the extent of twenty ounces. He continued to sleep until next day, in time about twenty-four hours, when upon awaking he asked for something to drink. He had no recollection of anything after getting into bed three days previously, and was unable to give any account of the commencing symptoms of his illness. His subsequent progress was rapid, and complete recovery ensued.

Male.—An Irishman, a haymaker, during the summer of 1882, came into my surgery, and requested to be bled. He complained of severe pain on the left side of the chest, and stated that in his country bleeding was generally adopted for similar symptoms, and that previously to his leaving home a fellow-workman "was bled for the same complaint, and was cured thereby." I examined the chest and found well-marked signs of pleurisy. As nothing but bleeding would satisfy him, I complied with his request, and relieved him of nearly a pint of blood. He felt no inconvenience whatever, and departed doubtful as to my having taken a sufficient quantity. Two days afterwards he returned, bared his arm, and requested me to repeat the operation, as the former one had failed to "cure the pain." I now abstracted 30 ounces, which caused a little squeamishness and the appearance of a few beads of sweat upon his brow. After a short rest he departed, and I heard nothing more of him for a week, when I accidentally met him. Upon enquiry, I was informed the last bleeding had cured him "entirely," and he felt quite well.

In conclusion, I will offer a few hints, derived from experience, as to the method of procedure, which, though of apparently small consequence in themselves, are of real value, and contribute largely to the success or otherwise of the operation, often preventing discomfort to the patient and discomfiture of the operator. Place the arm in the position it shall remain during the operation. Fix the vein by pressure of the thumb upon it, and take especial care not to stretch the skin so that, on removing the thumb, a valvular opening be left, which obstructs the flow of blood and defeats the object in view. Put on the fillet only so tight as to obstruct the flow of blood through the veins, but not that through the deeper arteries. Always use a particularly sharp and clean lancet. In order to arrest the flow of blood, place the thumb firmly upon the distal side of the incision, remove the fillet, wash the arm whilst the thumb is in position; then place a fourfold piece of lint upon the cut, put on a narrow bandage, or the fillet, in the figure-of-eight fashion, with one turn only above the elbow and two or three round the arm, taking care that the pressure shall be below the incision, the turn above the elbow serving only to keep the whole in position.

---

THE MEDICAL STAFF OF THE AUSTRIAN ARMY.—Some changes are proposed in the medical department of the Austrian army, which will have the effect of increasing the numbers in all the ranks except the lowest or that of second-class regimental surgeons, which is to be diminished by 37. Studentships of the values of 500 florins and 300 florins, to the number of 135, are to be established for aspirants to the military medical service, the funds for these being to a great extent met by the suppression of the special military medical course of instruction.—*Wiener Medicinisches Blatt.*

By F. KNIGHT, M.B. Lond., House Surgeon.

CASE I.—SARCOMA OF OS INNOMINATUM—SECONDARY  
DEPOSITS IN LUNGS AND KIDNEYS.

ANDREW C., a boy thirteen years old, was admitted on January 19th, 1885, complaining of pain in the left hip. He stated that six weeks previously he had fallen on the pavement and struck his left hip, but he felt no bad effects from this until three weeks afterwards, when he was seized with pain in this part; afterwards a lump appeared, and this has continued to increase in size ever since. Before the fall he had always enjoyed good health. There is no history of malignant disease in any member of the boy's family.

On admission, he was pale, considerably wasted, and had an expression of suffering. On the left os innominatum, two inches below the centre of the iliac crest, was a hard lump about the size of a hen's egg, not red or tender, and evidently connected with the bone. Temperature, 99° (morning), 101° (evening).

On January 31st an aspirating needle was introduced, but nothing came through except a few drops of blood.

The tumour rapidly increased in size, and on February 10th was noted as occupying the whole of the dorsum ilii. The boy continued to emaciate.

By March 9th the tumour had grown to such an extent that it formed a large hard mass in the left lumbar and inguinal regions, reaching down below Poupart's ligament and up as far as the margin of the thorax. On this date also numerous loud friction sounds were heard over the base of the left lung; these sounds were considered to be probably due to secondary deposits; there was no dulness. He complained of slight cough. A poultice was applied and he was allowed a small dose of morphia whenever the pain was severe. He now complained of severe pain of a neuralgic nature down the left leg, and this leg became very swollen and œdematous.

On March 11th a small hard lump was observed just outside the margin of the left orbit; for four weeks before this both eyelids on the left side had been much swollen.

He died exhausted on March 26th.

During his residence in the hospital his nose bled frequently, nearly every day. The temperature was uniformly raised, varying from 99° to 101°, and occasionally exceeding 103°. During the last few weeks he was unable to pass his urine, and a catheter had to be used regularly.

At the *post-mortem* examination it was found that the tumour was growing from the iliac bone, extending outwards beneath the gluteal muscles, inwards beneath the psoas and iliacus muscles as far as the middle line, upwards beneath the left lower ribs, and downwards over the pelvis and into the upper portion of the left thigh, where it was giving rise to pressure on the femoral vein and crural nerve. By removing the left os innominatum with the sacrum and upper part of

left femur the whole tumour was got away; it weighed eight pounds four ounces. On section, the growth appeared whitish, firm, and yielded a juice on scraping; the portion nearest the bone had a gritty feel. The whole of the front of the spinal column was covered with numerous masses of new growth; there were also several deposits in the ribs on both sides. Both pleuræ were almost universally adherent, and were studded all over with small secondary deposits. There was one small deposit in each kidney. The secondary deposits had the same characters as the primary growth.

Microscopical examination showed that the tumour and the secondary growths were all composed of small round cells; some of the gritty portion, after being decalcified, showed a growth of cartilage in it, so that at this part true ossification was taking place.

**CASE II.—PERIOSTEAL SARCOMA OF FEMUR—SECONDARY DEPOSITS IN KIDNEY SKIN AND MESENTERY.**

ALEXANDER H., age 21 years, formerly a seaman, was admitted on May 16th, 1885, for swelling of the right leg.

His history was as follows. When three years old, he fell and struck his knee on the edge of a spittoon. Next morning the knee was swollen and painful, and he was laid up for three months by it. There is now a small scar over the front of the right patella. He had no further trouble with the knee till three years ago, that is, in the middle of 1882, when it again became painful; the pain continued for four months, when the knee began to swell, and it has continued to enlarge ever since. In March, 1884, he noticed that the foot became swollen while he was walking about, but went down again when he rested. In April, 1884, he was in Bombay, and the leg becoming worse, he went into a hospital where he was treated first for synovitis and afterwards for periostitis. In July he returned to England, and was admitted into the Southern Hospital on July 14th. At this time he was rather thin, but in fair general health. All that could be made out was that there was considerable thickening of the lower half of the right femur; he had scarcely any pain, and there was no œdema of the leg while in bed.

He remained in the hospital till September 7th, when he left to attend to some private affairs. During his stay rest and anti-syphilitic remedies were perseveringly tried, but with no effect.

He returned to the hospital on May 16th of this year. His condition was then much changed for the worse. He was very weak, pale, and emaciated. The right leg was enlarged to twice the size of the left, chiefly due to œdema. In the skin were eight tumours, seven in different parts of the thigh, and one below the knee over the calf. Each was about the size of a small orange, and looked just like an acute abscess about to burst, but was quite solid. The one in the calf was beginning to ulcerate on the surface, and on the evening after admission it began to bleed. The blood poured out from several different spots in a steady stream, just like water from a watering-can. It was stopped by firm pressure, but every time the pressure was removed the blood poured out, so that it was subsequently dressed only every three days, and the dressings changed as speedily as possible.

He remained in much the same condition, but growing weaker every day, till his death on June 28th.

Autopsy 30 hours after death. Right leg enormously enlarged, most of the swelling caused by œdema. The tumours in the skin were found not to extend deeper than the subcutaneous fat. The periosteum of the femur was invaded by a solid growth and was in parts more than an inch in thickness; it could be readily peeled away from the subjacent bone, which appeared to be quite healthy. The knee-joint was not affected. There was a small nodule of new growth in the right

kidney, and the upper half of the ureter was surrounded by a cylindrical mass of it about  $\frac{3}{4}$ -inch in diameter, but the canal of the ureter was pervious. The mesentery contained a mass of enlarged glands which weighed nine ounces. There was also a nodule in the lower end of the right rectus abdominis, about the size of a walnut.

Microscopical examination of the primary growth in the periosteum and of the secondary deposits showed that they were all composed of large round cells.

**APPOINTMENTS FOR THE WEEK.**

*Friday, November 13 (this day).*

CLINICAL SOCIETY, 8.30 p.m.—Dr. S. West, "A Case of Idiopathic Purulent Peritonitis in a Child of Ten, with Autopsy"; Mr. Rivington, "Two Cases of Ligature of the external Iliac Artery for Femoral Aneurysm"; Dr. Dyce Duckworth, "A Case of Nitric Acid Poisoning"; Mr. Barwell, "A Case of Gastrostomy." Living specimens: Dr. Kingston Fowler, "A Case of Pseudo-hypertrophic Paralysis in an Adult"; Mr. Bernard Roth, "A Case of Severe Lateral Curvature of the Spine"; Dr. Crocker, "A Case of General Discolouration"; Dr. Colecott Fox, "A Case of Pigmentary Disorder"; Mr. John Morgan, (1) "A Case of Gastrostomy," (2) "An unusual Form of Spina Bifida"; Mr. Clutton, (1) "Cervical Spina Bifida undergoing Spontaneous Cure," (2) "Tubercular Ulceration of Palate"; Mr. Walsham, "A Case of Acute Spreading Obliterative Arteritis."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Special Meeting, 9 p.m. The Bowman Lecture, by Dr. Hughlings Jackson, F.R.S. The subject of the lecture is "Ophthalmology and Diseases of the Nervous System."

*Monday, November 16.*

MEDICAL SOCIETY, 8.30 p.m.—Dr. Colecott Fox and Dr. Heneage Gibbes, "Specimens of Bromide of Potassium Eruption"; Mr. Clinton, T. Dent, and Mr. W. C. Bull, "Central Necrosis, occurring in Children."

*Tuesday, November 17.*

PATHOLOGICAL SOCIETY, 8.30 p.m.—Mr. Eve, "Two Cases of Sarcoma of the Tongue"; Dr. Chaffey, "Hæmorrhage into Grey Matter of Spinal Cord"; Mr. Sutton, "Cysts in the Reproductive Organs of Animals"; Dr. Hale White, (1) "Fatty and Cirrhotic Liver"; (2) (for Dr. Beavan Rake) "Specimen of Leprosy" (Card); Mr. Lockwood, "Casts and Dissected Specimens of Contracted Fingers"; Dr. Norman Moore, "Cases of Gout"; Mr. Shattock, "Iridescent Calculi"; Dr. Gulliver, "Stricture of Small Intestine"; Mr. D'Arcy Power, (1) "Two Cases of Osteitis Deformans," (2) "Quiet Necrosis of Femur" (Card); Mr. Larder, "Cancer of Oesophagus" (Card); Dr. Hadden, "Right-sided Ulcerative Endocarditis" (Card); Mr. Fenwick, "Miliary Tubercle of Bladder" (Card).

MEDICO-PSYCHOLOGICAL ASSOCIATION, Bethlem Hospital, St. George's Road, S.E., 4 p.m.—Dr. Conolly Norman, "On Some Points in Irish Lunacy Law"; Dr. Hack Tuke, "On a Recent Visit to Gheel"; Dr. Savage, "On some Hæmorrhages in General Paralysis."

STATISTICAL SOCIETY, at Royal School of Mines, 7.45 p.m.—President, Sir Rawson W. Rawson, K.C.M.G., C.B., on "International Statistics, illustrated by Vital Statistics of Europe and of some of the United States of America."

*Wednesday, November 18.*

THE HOSPITALS ASSOCIATION, 1, Adam Street, Adelphi, W.C., 8 p.m.—Dr. J. C. Steele, on "Cholera and the Hospitals."

*Friday, November 20.*

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Adam Street, Adelphi, 8.30 p.m.—Dr. Heron, on "Koch's Cholera Organism," with demonstrations.

# Medical Times and Gazette.

SATURDAY, NOVEMBER 14, 1885.

At the Royal Medical and Chirurgical Society on Tuesday last, the President, Dr. George Johnson, on taking the chair, alluded to the death of Dr. W. B. Carpenter, one of the Honorary Fellows of the Society. He was in the act of taking a hot-air bath, when the bed-clothes caught fire, inflicted severe burns on him, in consequence of which, and of the shock, he died within a few hours. The evening was devoted to the reading and discussion of an interesting paper on "Scarlatinal Albuminuria and the Pre-Albuminuric Stage," by Dr. Stevenson Thomson, late Resident Physician in the Glasgow Fever Hospital. Although the number of cases, 180, was comparatively small, yet the frequency and care with which the urine was tested, and the delicacy of the more modern tests which were used, render the observations of great value and bring out the unsuspected fact that both albumen and hæmoglobin are present in the so-called "pre-albuminuric" stage. The great importance of this fact was borne out by subsequent speakers, notably Dr. George Johnson, Dr. West, and Dr. Dickinson. Dr. Thomson elected to read his own paper, but his strong Glasgow accent and not over-clear enunciation rather detracted from the value which is supposed to be gained when an author acts as his own mouthpiece. Owing to the unfavourable weather probably, there was but a very small meeting. As will be seen by reference to the discussion in another part of our columns, some very interesting and novel views were expressed. Albuminuria was regarded by the elder speakers as part and parcel of the original disease, whereas Mr. Fowler, one of the Resident Medical Officers of the Fever Hospital, Liverpool Road, thought it was a complication which treatment could and did ward off in a considerable proportion of cases. Many medical men have been brought up to regard albuminuria as the result of exposure to cold during desquamation; now, Dr. Dickinson seems to think that there is no connection between the one and the other, and that albuminuria does not arise from cold; he advocated keeping patients in bed for three weeks, while Mr. Fowler thought that such a practice, by weakening the patients, predisposed to kidney mischief, and that with good food and a well-ventilated ward patients need not keep their bed so long. This was especially the case with children, who could not be kept covered up and warm in bed all this time. Dr. West, on the other hand, advocated the practice, and thought there must be something of truth in the popular belief. Dr. Dickinson rather leaned to the belief that the old plan of rubbing the body with fat substances during the desquamative stages did more harm than good by closing up the pores of the skin. A most important lesson is conveyed by the discussion, viz., the value of frequent and long continued testing of the urine with the best and most approved methods and drugs with a view to determine absolutely, not only the appearance, but also the disappearance of blood and albumen from the urine of patients who have had scarlet fever.

By the death of W. B. Carpenter, on Tuesday last, one who has occupied a foremost place in scientific progress for well-nigh half a century has passed from among us. Best known to the denizens of the metropolis, perhaps, as the Registrar of the University of London, Dr. Carpenter's name is familiar to all who have studied Physiology during the last forty years, and until quite recently his well-known volume on Human Physiology was almost without a rival. During the long period of twenty-two years that he held office at Burlington House, Dr. Carpenter found time to make numerous communications to the Royal Society; his papers on the Foraminifera, which will be found in the Philosophical Transactions of that body, are probably the best known of these. But more important still were his reports on the results of the "Challenger" expedition, in which, doubtless, he would have been more than willing to have taken a very active part, had his other duties permitted so prolonged an absence from home. In his earlier days Carpenter wrote a treatise on the microscope and its revelations, which at once attained a wide and deserved popularity, and for many years he edited the *British and Foreign Medico-Chirurgical Review* with marked ability and success. As one of the pioneers of modern physiology, Dr. Carpenter has made his mark and left a name that will be held in reverence for many generations to come.

THE Academy of Medicine in Ireland have elected as Honorary Fellows the undermentioned leaders in medical science:—Sir William Jenner, Bart., M.D., F.R.S., as representing Medicine; Mr. Jonathan Hutchinson, F.R.S., Surgery; Professor Emmett, of New York, Gynæcology; Mr. John Simon, C.B., State Medicine; Professor Ludwig, of Leipsic, Physiology; and Professor von Recklinghausen, of Strassburg, Pathology. It has been resolved that medical officers of the army and navy, as well as registered medical practitioners residing at a greater distance than fifteen miles from Dublin, shall in future be eligible to become Fellows of the Academy on payment of the entrance fee and an annual subscription of one guinea.

THE honoured name of Virchow, politician and pathologist, archæologist and ethnologist, is in Germany a name to conjure with. He now adorns the Upper House, as he formerly did the Prussian House of Commons, with his eloquence, geniality, and varied knowledge, and during the past Session he vigorously supported the Bill introduced with a view to prohibit the further practice of ovination as a protection against sheep-pox, on the ground that, whatever benefit might accrue to the individual sheep, it kept the disease alive and infection active among the ovine population. Forthwith, Dr. Oidtman, editor of the *Impfzwanggegner*, the organ of the antivaccinationists, claims him as an ally, and, substituting the term vaccination, so much abused of late, for ovination, proceeds to argue that Parliament has stultified itself by passing one Act for the enforcement of vaccination of children, and another prohibiting vaccination of sheep. But surely Dr. Oidtman must know that the inoculation of small-pox and vaccination are quite distinct, and that the

legislatures of most countries, when rendering the latter compulsory, have declared the former illegal for precisely the same reasons as those which have led the German Parliament to forbid ovination. Inoculation, whether of man or of sheep, with his own pox, though as a rule it gives the individual a remarkably mild form of the disease, can never stamp it out. It cannot but serve to perpetuate it, and may destroy more lives indirectly than it saves directly. Vaccination in the true sense of the word, if practised as a preventive of sheep-pox, will be found illusive for this simple reason. Cow-pox has been experimentally shown again and again to be nothing else than small-pox profoundly modified by its passage through the body of the cow, where it has lost its infectious nature and been transformed into a local affection. It is in virtue of its descent from small-pox that it protects against small-pox, but sheep-pox and small-pox are two distinct and independent diseases, neither of which can exert any influence over the other. If any effectual and safe means of conferring immunity on sheep is to be found, it must be on the same lines as vaccination, that is, by the inoculation of some *other* animal, found to be susceptible, with sheep-pox, and the subsequent employment of the virus thus modified.

WE have heard a great deal during the last fortnight of M. Pasteur and his ingenious device for protecting dogs from rabies, but as yet no one has spoken up for those indispensable allies of his, the rabbits. It is particularly hard on these innocent rodents that, having had good reason from time immemorial to regard the dog's bite as one of their most dreaded destinies, they should now be called upon to lay down their lives in order to protect the dogs themselves from the evil consequences of that self-same bite. The anti-vivisectionists will tell us that, by countenancing this one more wanton injustice, science has thrown away the last shred of a claim to their regard. And, indeed, when we come to consider what the practical working of M. Pasteur's expedient would involve, it does seem, to say the least, a little startling. We do not know how many dogs a single rabbit's brain and spinal cord, when used with the strictest economy, would suffice to inoculate. But put it at fifty—a very liberal estimate considering the size of the rabbit's central nervous system—and it is evident that many a hecatomb of rabbits must be devoted to a painful death, in order to supply protective material for the immense canine population of this country. That M. Pasteur should have dreamt of proposing to initiate his experiment in England, the only State whose paternal sympathies are efficiently extended to the lower animals, shows that his scientific enthusiasm has led him to forget the local difficulties, moral and material, of his proposal. In choosing us as the first recipients of his favour, we will give M. Pasteur credit for being actuated by other considerations than that which proverbially determines the choice of a subject for experiment. We are an island, and dogs are one of those articles that we manufacture with sufficient success to render any large importation of them (and, therefore, of their diseases) unnecessary. Australia and New Zealand have rabbits, but no rabies, and

the same is more or less true of Ireland. There is rabies in Mauritius, and M. Pasteur must regret the circumstances that severed it from the French connection, which would otherwise have perhaps made it a convenient locality for his purpose. But Mauritius is too small, and possibly too warm, for the successful trial of an experiment intended to convince this world of unscientific and scientific sceptics. Malta, Hong Kong, the West Indies, and Ceylon are open to the same objection, while the Hebrides, the Azores, and St. Helena are put out of court by the not unsatisfactory circumstance that they have hitherto been free from rabies. So every consideration points to England as the one country in which the experiment can be carried out with the least fear of vitiating circumstances. We have only to keep a sharp eye on our canine imports, and M. Pasteur will no doubt undertake to eradicate rabies from our kennels and with it the much-dreaded hydrophobia.

As practical men, however, we would ask to be allowed to pause awhile before submitting to an experiment which, if it did nothing else, would certainly increase the cost of the poor man's rabbit pie. We should like first to give a fair trial to those old time-honoured expedients by which determined Governments and sensible subjects have before now succeeded in staying the plague of rabies. M. Pasteur proposes to render the dogs tooth harmless. Well, we too, without any magic, can render the teeth of every dog harmless—by putting them behind a wire guard. The authorities could tomorrow, if they would, place every mad dog, actual and potential, as much beyond the power of harming us as if they had them all in a ring fence. And if they went to the work with a will they could, in a year or two, make rabies as extinct in England as the sweating-sickness and the black-death. They take care that in factories all dangerous machinery should be protected by a wire fencing, and yet, in the open streets, they leave that most dangerous machinery, the mad dog's jaw, unguarded. Proper caution will keep one safe from the risks of whirling wheels and leather bands, but no amount of caution will keep one's calves from the rabid dog when he has taken into his head to run a-muck. The instructions which have been given to the police to look more carefully after stray dogs may do something to limit the spread of rabies; but if, as we believe, there are many owned pet-dogs still amongst us with the seeds of the disease in them, such precautions are ludicrously insufficient. The muzzle is the sole expedient that will meet the present emergency. If we are to stop this epidemic of hydrophobia at its source, if the dog-owners are to save the lives of their threatened pets, we must exact, and they must submit to, the universal muzzling of all town dogs, when in the streets, for a period to be determined upon by the veterinary advisers of the authorities.

THE death-rate in London last week rose again, as will be seen from our chart, from 17.5 to 18.9, a higher point than any that has been reached during the past three months, but the total number of deaths, viz., 1483, is nevertheless considerably below the average. Measles proved fatal in 41 instances, 35 of the victims being

under the age of 5 years. Whooping cough carried off 29 children, all under 5 years of age, and there were 16 deaths from diphtheria and 15 from scarlet fever. The deaths from diseases of the respiratory system and from

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eight weeks.

phthisis showed an increase, the former amounting to 394, the latter to 188. There was one death from hydrophobia, that of a child aged 8, making a total of 21 deaths in London this year. There were 13 deaths from measles in Liverpool, 8 in Newcastle, and 7 in Manchester; and 11 deaths from scarlet fever in Glasgow. The highest death rates in the chief provincial towns were 28.9 in Bolton and 27.1 in Manchester.

THOSE who have followed our weekly notices of the public health in London will be quite prepared to hear that during the third quarter of the present year the death-rate for England and Wales was 16.5, or 2.1 below the average of the corresponding previous ten years. In other words, 26,000 persons survived the three months who would have died during them according to the average computation. In London the death-rate was 18.2 as compared with 19.4 in the other twenty-seven great towns. There were 114,042 deaths in all, of which 2,668 were from measles, 2,646 from whooping cough, 1,263 from scarlet fever, 912 from diphtheria, and 361 from small-pox; the three latter figures being considerably lower than for the same period last year. The total number of uncertified deaths was 3,774; in London the percentage of uncertified deaths was 0.9, whilst in the rest of England and Wales it was 3.8; in Wales alone it was 8.1. In England the proportion ranged from 6.5 in Durham to 0.0 per cent. in Rutland. The average prices of beef, mutton, and coal were lower than in any quarter during the last two years.

THE quarterly return of the Irish Registrar-General does not show so marked a fall in the general death-rate for Ireland; in fact, it does not show any fall at all, being 15.0 per 1,000, as compared with 14.9 last year. It has been said on more than one occasion in these columns that Ireland is the best vaccinated country, and the statistics before us would certainly bear out the statement, for we find that there were only two deaths from small-pox, and that 27,203 persons were vaccinated, and 63 reported as insusceptible to vaccination, whilst the operation was postponed in one per cent. of the children. From measles there was a great falling off in the mortality as compared with the earlier part of the year, 185 deaths only having occurred; scarlet fever caused 228 deaths; the deaths from whooping cough, 281, likewise show a considerable diminution on recent returns. Diphtheria caused 59 deaths, and hydrophobia is credited with two victims. The reports from the various district registrars do not contain any information of special interest.

THE Glasgow Philosophical Society held its first meeting for the session on the 4th instant, when Dr. Cameron, M.P., discoursed on Ferrán's Anti-cholera Inoculation. Dr. Cameron professed merely to present statistics of some eleven thousand inoculations and their results, and to make out a case for enquiry, but his paper was really an argument in favour of Ferrán. Consequently it was severely criticised by several of the medical members of the Society, some of whom refused to see in Ferrán anything but an impostor. In his reply, Dr. Cameron showed himself rather in the light of a prejudiced partisan than an impartial enquirer. The Society, however, agreed that a searching enquiry into the reliability of the statistics was most desirable.

THE junior medical classes of Glasgow University have this session reached a higher number in respect of attendance than has ever before been attained. The junior Anatomy class contains close upon 180 students, and the senior over 160. The Physiology class contains over 160. Though these large numbers render still more urgent the demand for increased accommodation for the medical departments of the University, the work is going forward quietly and thoroughly, unaffected by the pressure for space.

THE Dublin Hospitals Commission heard evidence on Tuesday and Saturday last week in the Privy Council Chamber, Dublin Castle. On Tuesday evidence was tendered on behalf of the Meath Hospital. The Secretary submitted the replies to queries forwarded by the Commission, from which it appeared that the hospital was founded in March, 1753, and constituted, by Act of Parliament, County Dublin Infirmary in 1774. It is administered by a board of 21 directors, meeting monthly, and three forming a quorum. There is an annual grant of 600*l.*, given originally in 1826, for the maintenance of 36 beds for fever patients. The staff consists of 2 physicians, 6 surgeons (visiting), 1 surgeon and apothecary, and 2 pupils (resident), with a corps of nurses under a trained lady superintendent. For the year ended

31st March, 1885, the number of cases treated were 1,037 intern, 2,439 extern accident, and 7,773 extern dispensary cases, the average number of beds in daily use being 83.24. The total income was 5,246*l.* 19*s.* 10*d.*, including, besides the Government grant, 423*l.* from the Hospital Sunday Fund, 2,518*l.* from subscriptions and donations, 120*l.* from rents of houses and lands, and 371*l.* from dividends and interest. The expenditure amounted to 5,430*l.* 11*s.* 9*d.*, the gross average annual cost per head was 50*l.* 6*s.* 7½*d.*, the average annual cost per bed for establishment 25*l.* 18*s.* 6½*d.*, for management 6*l.* 4*s.* 4*d.*, and for the maintenance of the patient 18*l.* 3*s.* 0¾*d.* The witnesses examined on behalf of the Meath Hospital were Mr. William MacComas, a member of the standing committee, and Sir George H. Porter, Surgeon to the Queen in Ireland, Mr. Lambert H. Ormsby, and Mr. W. J. Hepburn, surgeons to the hospital.

IN the replies to the queries submitted to the Governors of Mercer's Hospital, it was stated that the Institution was founded in 1734 by Miss Mary Mercer. It was governed by a Board of Governors elected by ballot. The hospital accounts were audited at the end of every financial year by a Managing Committee. The hospital did not receive any annual Government grant, but the infirmary attached to the hospital received a Parliamentary grant of 43*l.* 12*s.* 9*d.* The average daily number of students attending the hospital during the last three years was 50. The total number of beds in the hospital was 97. Accident cases were admitted without any recommendation; other cases by order. In the past twelve months 5,328 accident cases were received. Cases of contagious fever had been treated in the hospital; but such cases had obtained admission by accident, and when discovered were unfit to be transferred.

MR. FREDERICK ALCOCK NIXON and Mr. Edward Stamer O'Grady gave some singularly conflicting evidence as to the hospital, the nursing arrangements, and the Ledwich School of Medicine. On Monday, the 9th inst., the very unpleasant evidence relative to Mercer's Hospital was concluded, and Mr. Sydenham Chandlee, resident medical officer, Mr. Abraham Shackleton and Sir John Barrington, governors, were examined on behalf of Cork Street Fever Hospital, Dublin.

OUR Belfast correspondent writes: The winter session of the Belfast School of Medicine was opened on Saturday last by an introductory lecture from Dr. J. W. Browne, the Senior Surgeon of the Belfast Royal Hospital. Since the recent legislative measures connected with the disestablishment and extinction of the late Queen's University, there has been a considerable falling off in the number of students attending the classes of the Belfast Queen's College, and there at last appears to be every reason to hope that the diminution has reached its lowest point, and that a steady increase upon the last four sessions will be the experience of the teachers in all the departments in connection with the medical part of the school. It is difficult to determine exactly the number of men who will be in actual attendance until some

time after the session has really commenced, owing to peculiarities in the arrangements for entering and registering, but there is evidence that the present session promises better than its immediate predecessors. At no time in the history of the school has it attained such a high state of efficiency, but, as we pointed out upon previous occasions, there can be no solid and substantial improvement in the condition of University education in Ireland until the unsettling influences of the recent fruitless legislation are either forgotten or replaced by a more just and thorough enactment.

It is said that several members of the New York Yacht Club propose to employ flasks of mercury this summer as ballast. The swaying of the fluid is expected to increase the speed of the craft. We trust that care will be taken with regard to breakage and leakage, for there have been such accidents which were followed by the salivation of the whole crew! Only a very carefully and scientifically selected body of mariners could be expected to derive any benefit from such a mishap, and we hope it may be guarded against in the case of ocean cruisers.

THE twenty-third volume of the "Jahrbuch für Kinderheilkunde" contains two communications on the subject of the treatment of rickets by means of phosphorus, the one by Carl Hochsinger and the other by Griebisch. Both of these observers relate the results of an extended series of investigations, although the former presents statistics ranging over a much wider field than the latter. Comparing these results, however, whether reduced to percentages or considered individually, or in groups, the reader cannot fail to be struck with the very marked divergence from one another which they present. The symptoms of rickets and the physical signs with which they are associated are well known and easily recognisable, and whatever the influence of this or that "diathesis" may be upon individual cases, the features of the disease are as clearly defined as those of any other malady to which children are subject. Nor is there much ambiguity in the pathology of the disease, although a variety of ingenious theories have been from time to time propounded to account for the onset and initial stages of the well-known changes. It cannot therefore be assumed that so great a discrepancy in the results of therapeutic treatment can be due to error in the choice of cases. The fact, however, remains that one observer obtained good results in all but 12 cases, out of a total of 487, whilst another records an almost equal balance of success and failure in a total of 41 cases. Whether in the general progress of the disease or in the prominence of one or other of the special physical signs and symptoms this inequality remains the same.

It is hardly to be wondered at that the one author is as positive in his praise of phosphorus as a specific, as the other is negative in his belief in it as a practical remedy. Differences of opinion upon this point however, have frequently found expression in the columns of the medical journals, and in the "Transactions" of the societies, and much has been said in praise or blame of the drug, but it has not yet been made sufficiently clear that success has been due to the

phosphorus alone. In one of the present series of cases a somewhat important fact is stated in parenthesis, to which a little more prominence might well have been given. The phosphorus, we are told, was administered in the form of an emulsion with cod-liver oil, in all those cases of which so many proved satisfactory. The accuracy of therapeutic observation is sometimes spoken of by sceptical critics in a tone of undisguised contempt, and complaint is often made that such a tone is unwarranted and unfair. But the complaint is not justified. The publication of successful cases claiming to prove the efficacy of individual drugs will never deserve the rank and style of scientific work so long as the writers continue to suppress other points in the history of their cases, which may have a bearing upon the final result. What value can possibly be attached to the vaunted action of a new drug when it is found that the exciting cause of the malady has been at the same time removed? A rickety child placed in good hygienic surroundings, properly fed and supplied with cod-liver oil, is, in the great majority of cases, enabled to overcome his rachitic tendencies. Does phosphorus enable him to overcome them more rapidly? It either does or it does not. The elaborate statements in the two papers which we have quoted afford no satisfactory answer to the question.

ANOTHER instance of the spread of diphtheria by personal intercourse is afforded by the history of the outbreak in the Whixley sub-district in Yorkshire, as told by Mr. R. D. R. Sweeting in his report to the Local Government Board. The cases chiefly occurred in the two parishes of Whixley and Green Hamerton; the disease making its appearance in the latter village first. Diphtheria broke out in Green Hamerton at the end of 1883, and as is so often the case from the fact of the investigation taking place long after the occurrence of the cases, it was impossible to trace the mode of origin in the first case. It began, however, in two contiguous houses, in which, out of thirteen occupants, eleven were attacked, and four died; as the daughter of one occupant was acting as servant to the other, there was very free inter-communication between the two houses, and it was this daughter who was the first attacked. Two other families were attacked in the village, presumably owing to personal communication, and then the disease began to show itself in Whixley, where it remained endemic for a year. A son of one of the above-mentioned families was attending school at Whixley all the time his throat was bad, and it is therefore a reasonable assumption to suppose that he may have been the means of introducing the disease. As usual, the school played a very prominent part in the spread of the disease; when a fresh family was attacked, it was always the attendant at school who was first seized, and during the periods of school closure many families with school attendants escaped the disease. Moreover, it was found that the infant school was insufficiently ventilated, and that underneath the latrines there was a large cesspool which had not been cleaned out for years. The total number of cases in Whixley was 51 with 10 deaths, of these 32 were between the ages of 3 and 15, of

whom 7 died, whilst 5 were under 3, with one death. Several instances were noticed of second attacks, and children who had previously had croup were taken with it, whilst those who were subject to quinsy appeared to be especially liable.

---

#### THE ARMSTRONG CASE.

THE condemnation of Mr. Stead and his coadjutors forms, we may hope, the final incident in one of the most pitiable histories of modern times. Those who, like ourselves, were from the first sceptical as to the accuracy of the allegations of the *Pall Mall Gazette*, and thoroughly opposed to their publication in so sensational a form, have now, at any rate, the satisfaction of knowing that their attitude was fully justified, though at the same time we have melancholy reason to believe that the objectionable romance concocted by Mr. Stead, by working on foul imaginations, has given a fresh impetus to the commission of the very crimes which it was intended to suppress. Mr. Stead may be allowed the barren credit of having proved that it is possible to abduct and narcotize a helpless child without interference from the police, but he has also proved that his own wholesale incriminations rested on no sufficient foundation, for with all the money and expert help at his disposal he could not lay his hands on one of the young girls with whom he professed that the market was so well stocked. For us however, the sad interest of the case lies in the fact that it has involved the reputation of our own body. Of Dr. Heywood Smith we wish to say as little as we possibly can. We cannot excuse or in any way extenuate his conduct. That we leave to contemporaries who swallowed Mr. Stead's stories whole and condoned his offence. Neither would we write a word which would add to the distress which Dr. Heywood Smith has brought upon himself. The profession resented, with one voice, we believe, the imputation cast upon it by Mr. Stead that there were men in it who were willing for gain to prostitute their art, in order to serve the base ends of the debauchee. Mr. Stead has not been able to substantiate his assertion in a single instance. All he has shown is that the study of medicine is not always successful in teaching the necessity of avoiding hasty and unfounded inference, and of keeping a due restraint on emotion. That both Dr. Heywood Smith and Mr. Stead acted with good motives we have not the slightest doubt. But, in doing as they did, they set at nought one of the fundamental laws of morality, and in asking us to hold them guiltless they are seeking to revive the Jesuit ethics, which we thought had long ago received their final condemnation and quietus from the unanimous voice of civilized men.

#### THE RESULT OF THE HOMERTON HOSPITAL ENQUIRY.

At the meeting of the Metropolitan Asylums Board, on Saturday, the decisions arrived at by the Local Government Board as a result of the recent enquiry into the management of the Homerton Hospitals were

made known. The Committee are severely censured for putting so much trust in their late chairman, and the Board of Managers are censured for failing to exercise a due supervision over the committee. Mr. Hodges, the chairman, and Mr. Bashford, the steward, having resigned, and Mr. Freethy, the clerk to the committee, having absconded, no notice is taken of their part in the irregularities, and it would appear that in the opinion of the Board nothing has been proved against any of the lay officials which would justify more than grave censure. We think it will be generally admitted that that is a very impotent conclusion to an enquiry which extended over several weeks, and which seemed to have elicited evidence of something beyond mere carelessness and extravagance.

But the most unsatisfactory part of the action of the Local Government Board is their decision with regard to Dr. Collie, the medical superintendent of the hospitals. The Managers of the Asylums Board suddenly suspended Dr. Collie from his office in the early part of the year without giving him an opportunity of meeting the charges brought against him, and now, after keeping him in enforced and unremunerated idleness for eight months, the Local Government Board refuse to remove his suspension. In the letter in which this decision is communicated to Dr. Collie the Board state that "they are satisfied that nothing elicited at the enquiry can be regarded as in any way reflecting on your integrity in connection with the financial business of the managers, and they are prepared fully to admit that your duties, so far as they were strictly of a medical character, were performed with zeal and efficiency." So that the decision of the Board solely rests on Dr. Collie's failure "to exercise that due supervision over the expenditure of the hospital which it fell specially within your province as medical superintendent to bestow." But, as Dr. Collie showed in his defence, such a responsibility could not fairly attach to him, for all estimates and contracts were decided upon by the Committee entirely without his knowledge, and it is wanton injustice on the part of the Local Government Board to saddle him with irregularities for which the Committee, and the Committee alone, were really responsible. That there were some grave irregularities in regard to the diet sheets of one week, irregularities which have never yet been explained, Dr. Collie fully admits, but all the charge that can be brought against him on this score is that he did not amidst epidemic pressure do certain clerical work which he ought never to have been required to do, and which it was impossible for him to do without neglecting the more important work which the Committee kept heaping upon him. During the period in which the chief irregularities occurred Dr. Collie was in charge of three hospitals, one of which was five miles distant from Homerton. And all the time small-pox cases were pouring in at the rate of fifty and more a day, and these had to be carefully sorted, some being sent to the ships and others retained. Besides this, Dr. Collie was responsible for an average of 230 fever cases, and he was also engaged by the managers in inspecting sites and buildings for cholera. That under these circumstances, when the managers had had the help of Dr. Collie's unstinted

efforts in their contest with a serious epidemic, they should have turned round and suspended him, and the Central Board should have allowed his suspension, for neglecting duties for part of which the Homerton Committee were responsible, and the rest of which ought not to have been thrown upon him, shows how little a public official can rely upon the gratitude of a Board.

The whole case opens a question of principle, which ought to be settled by the Local Government Board once for all before other medical officers suffer in the same way as Dr. Collie. The medical superintendent of a large public institution has quite enough work to do in conscientiously performing his medical duties, and he ought not to be asked to undertake responsibility for details of management which properly appertain to the lay officials. It may flatter a medical officer's pride to feel that he is the head "boss" of an establishment, but no medical man who respects himself and his profession should consent to undertake work outside his own special province. It is this very principle, this thoroughly bad principle, which ruins the medical efficiency of so many superintendents of lunatic asylums and converts them into mere stewards and factors; and the medical officers in other departments of public work should take every care that their own efficiency is not exposed to the same deteriorating influences. What makes it the harder in Dr. Collie's case is that he has all along repudiated the responsibility thus thrust upon him, so that he has, in effect, been punished for neglecting the duties of other people. It is still in the power of the managers of the Asylums Board to do tardy justice to Dr. Collie, and to reinstate him in the office which he filled for so many years. They cannot possibly find anyone more competent for the post from a medical point of view, and Dr. Collie would probably not complain if they at the same time relieved him of the small clerical duties which ought never to be required of a man of his calibre.

---

#### THE CONTROL OF SPEECH.

THE discovery of a physiological justification for profanity is consistent with the tendencies of many modern thinkers, if it do not accurately represent the outcome of the best modern thought. America is a country in which conclusions are quickly reached, and her citizens are clever in justifying, by their conclusions, the methods by which they were achieved. Just now her moralists are engaged in reprobating the employment of that strong language in which they state their countrymen are too much given to indulge; and—combining warning with the revelation of a better way—are engaged in pointing out to their readers how one bad habit may be broken by the cultivation of another good one. "The man who reasons with himself," they tell us, "never swears"; and if men would only stop to reason they would soon cease to be profane. To which the *New York Herald* retorts, on behalf of the admittedly numerous class whose rectitude of speech has been impugned, that a man never can or will stop to reason upon occasions which provoke to

expletive ejaculation. The verbal explosion is inevitably begotten of "an automatic action of the vocal cords, whenever the proper conditions prevail." This is an explanation which the moralist also would admit, give him but leave to substitute "improper" for "proper" in the statement. And the physiologist, reasoning in the abstract—*quâ* physiologist, and without regard to the moral and merely human aspect of the question—must admit its truth, put either way. He is driven back on the essential axiom that all educational results—good or bad—are founded upon reflex action; upon the fact that any action, or complex combination of actions, at first voluntary, becomes, by frequent repetition, involuntary and purely automatic. So that just as the sensation of hunger provokes the thought of food, and just as the mastication of food provokes a flow of saliva, so—as the inevitable outcome of a previous training which was not the less thorough and continuous because now more than half forgotten—will the sudden incidence of joy, anger, grief, or pain, provoke the utterance of an oath.

Both the moralist and the physiologist, however, are at one in seeing, in the general growth and extension of this habit, evidences of mental and physical degeneracy. Every cause produces an equivalence of effect. The doctrines of the Continuity of Forces, and of the Conversion and the Dissipation of Energy, are as true for the human economy as for the Universe of which man forms a part. The force of every nervous shock is either straightway "switched," by reflex action into some other channel of kinetic energy, or it must be opposed by a special combination of mental breaks and buffers, thus to be more slowly absorbed and finally dissipated in a lower form. There can be no question as to which is, usually, the more immediately expensive process. The body which is free to move receives a blow lightly, transmitting the impact into motion under the influence of which it becomes merely passive; but, if fixed, it suffers the penalties of both action and reaction. People "bear pain well" for different reasons in different cases. One man, from natural bluntness or acquired hebetude of nerve-susceptibility to sensation; another, from superior practice or strength of nervous break-power, which enables him to repress the natural and kinetic reflex manifestations, neutralizing one form of nervous energy by meeting it with another called forth for the occasion. In the latter case, the expenditure of nerve-force is much greater; greater even than in the case of him who, "bearing pain badly," allows the energy which it evokes to be spent, actively, in the muscular expressions of cry or movement.

Though the incidence of sudden pain is here taken as an example, a similar explanation holds for the effects of any stimulus, pleasureable or the reverse. And it should be observed that, while the exercise of "control" under such circumstances is, in the first instance, brought about only by the careful and painstaking application of nervous energy through the Will, yet this process may become by training and repetition a reflex surely and accurately evoked by any repetition of the exciting cause under the influence of which it was first called forth. The break, in fact,

becomes, by practice, more or less "automatic" in application and in action; and, under such circumstances involves much less mental wear and tear. On the other hand, those who, in popular language, bear pain "badly"—who scream loudly and kick forcibly under slight distress—often suffer less physical damage in consequence. The French surgeon had, in general terms, good warrant for his statement that those whose cries were loudest while under the knife, suffered less in the way of shock and general nervous damage than those whose silent fortitude was a measure of their efforts to suppress the natural signs of agony. So, then, it may be claimed that outcry is the normal safety-valve of the human as of the "dumb" animal in pain; and that articulate outcry, by switching this suddenly incident force into at least two channels of escape at once, evolving speech as well as sound—giving the mind something to do and something to translate and understand, as well as exercising the body—is doubly effective in the same direction. Yet we have seen how, in this as in other cases, the unbridled repetition of such acts, leading to overgrowth in the sensitiveness and activity of merely automatic reflex centres, runs to a riotous excess which outgrows all control. On the other hand, the careful practice of the control-power not only suppresses, and indeed anticipates, such outbursts of reflex activity, but, by educated repetition, becomes to a great extent automatic, and itself a reflex act. Herein lies the benefit and the reward of that studied evolution of the controlling centres of the nervous system which marks the highest type of civilised humanity. Others may attain to it in part, like the Red Indian, silent under torture at the stake. But it is the man with the well-balanced brain who commands the well-balanced mind; and from the lips of such a man profane speech is not lightly moved to flow. In proportion as brain-power decays, or as its culture is neglected, so is its control-power visibly impaired; the once calmly courteous reasoner grows irritable and impatient; the half-educated boor's only retort to pain and blame is an oath or a blow. Sudden and overwhelming pain or anger may provoke a man, physically and mentally strong, under conditions to which he is unused or which he has not taught himself to face, to some blindly articulate expression of the reflected shock. But the man who swears habitually—at anything, at everything, at nothing—moved thereto by simple contact with external impressions of every degree and kind, has, by a steady course of training, reduced himself physiologically to the level of a pithed frog. Such a state of cerebral degradation is most likely to prevail under the conditions which make human life fast and feverish, and when the energies of the higher centres are early exhausted by continuous working at high pressure and with forced draught. Under such circumstances the jaded palate craves the stimulus of spice and bitter; and the worn mind loses its appreciation for all but the sharpest phrases. Body and mind are in a state of unstable equilibrium. Life is a business of touch-and-go. It is no good sign of health for an individual or for a nation when the vocabulary is loaded with explosives, and speech is set by a hair-trigger.

## ESSAYS ON MEDICAL CLASSICS.

### XIII.—HUXHAM.

JOHN HUXHAM came of an old Devonshire family and was born, probably, at Totnes, about the year 1692. Having from his youth a predilection for medicine, he went to study at Leyden—then among the chief universities of Europe, and the home of Boerhaave,—where he became one of the most distinguished graduates. On returning to England, he settled down to practise at Plymouth, and there he spent the rest of his life, immersed in professional work and slowly amassing wealth. He carried on, however, with perseverance, numerous scientific investigations connected with medicine. For thirty years he carefully recorded observations on the weather and seasons in his locality, and on the concomitant phenomena of epidemics and cases of disease,—observations subsequently published in three volumes, the last after his death, by his son. He was elected a Fellow of the Royal Society at an early age, and contributed several papers on Pathology and Morbid Anatomy to the *Philosophical Transactions*. Huxham was an accomplished Latin scholar, and a continuous and eager student of the ancient medical authors—especially Hippocrates. His principal work is the “Treatise on Fevers,” which, published in 1739, passed through several editions, and was speedily translated into French, German, and Portuguese. A smaller treatise of a similar nature, on the “Malignant Ulcerous Sore Throat,” was appended to it. He also wrote “Observations on the Medical and Chemical Properties of Antimony”; an account of an epidemic of the Devonshire colic; a method for preserving the health of seamen on long cruises; as well as the “Observationes de Aere et Morbis Epidemicis,” above referred to. The last-named work was written in Latin, so as to appeal directly to the learned of all countries; it was afterwards translated, and published amongst his collected works after his death, which took place in 1768.

Huxham’s doctrines and practice were alike determined by his faith in those of the Ancients. The more carefully he observed, and the more attentively he reflected on his observations, the more closely he found them in accordance with those of the old masters. He says, “All the regular and judicious practice has been consonant to the Hippocratic doctrine.” He claims that he writes with the advantage of a long and large experience, that he has used the utmost care and diligence, and that his motives are the honest ones of a sincere well-wisher to the profession; but he admits that he very frequently supported his doctrine and practice by the authority of the Ancients—especially Hippocrates, who was of great use to him in the course of his studies and practice, and whose works he recommends young physicians to read and re-read. “But, ye young novices in physie, approach nearer to the fountain head, and drink freely, and you will from thence perceive how sagacious and diligent the Ancients were. A man will make a much better physician for so doing; for Hippocrates studied Nature

with the greatest care and assiduity. The Ancients gave the picture and naked truth of things, which is infinitely more beautiful than the affected daubings and flourishes of a modern luxuriant imagination.”

Thus zealously striving to copy the Father of Physic, he could not but walk in the footsteps of Sydenham, to whom indeed he was a worthy successor, and to whom he frequently refers as a master. But, while fully recognising the remarkable penetration and usual correctness of Sydenham’s judgment, he often criticises and improves upon his practice. Like Sydenham, he studied disease carefully and independently; he says, “Each particular disease in every individual patient is to be considered by the attending physician, not according to the nomenclature, but according to the nature, causes, and symptoms of the particular disease in that particular person, and measures should be taken accordingly. Nothing certainly more mischievous ever crept into Medicine than imposing on all diseases general names, and attempting to cure them by a kind of general medicine.” He carefully watched the progress and tendency of the malady, noticing the means by which Nature restored health, and all the modes of treatment by which benefit or harm was produced. Finding out which was the most natural and favourable type of the disease, he tried so to modify each unusual form as to bring it towards the normal standard, and so encourage it to run a favourable course. He says, quoting Hippocrates, “Whoever knows the nature of a disease knows the method of cure”; accordingly he gives but few formulæ for prescriptions, for “when a physician knows whether stimulants, anodynes, relaxants or restringents, attenuants or incrassants, are indicated, he can be at no loss to serve himself of proper drugs. He should select a few of the most effectual for his use of each sort, and stick to them, and not run into the monstrous farrago which some are so proud of. By doing so, he will soon be acquainted with their real virtues or effects. . . . But, after all, it is not this or that medicine that will cure a disease, unless prudently made use of; this is the Arcanum. In good hands a valuable drug will certainly do great things.” “The timid, low, insipid practice of some is almost as dangerous as the bold unwarranted empiricism of others. Time and opportunity, never to be regained, are often lost by the former, whilst the latter, by a bold rush, sends you off the stage in a moment.” He differs also from his great predecessor, Sydenham, in adding to his simple descriptions of disease fuller explanations of their pathology, based chiefly on the ideas of physiology contained in the mighty system of his old master, Boerhaave.

The “Essay on Fevers” is designed principally to show how the various species depend on different constitutions of the blood, &c. Beginning with an account of the chief structures of the body in health, and the slight deviations consistent therewith, he points out that due tenacity, with proper flexibility, of the solids is the happy medium of their condition; too great firmness, though it may give a greater vigour, or too great laxity, predisposing to disease. At the same time the blood should be of moderate thickness and density; if too dense, it may provide strength and

heat, and therewith a readiness for activity, but is a source of danger, for it shows a tendency to violent fever: on the other hand, too loose a texture of the humours causes a general state of inertia and indigestion, in which no function is adequately performed, and which may result in a very low and intractable form of fever. A third and still more dangerous state of the blood is a "dissolved and putrid state," generally betokening a scorbutic or other cachectic condition. This form gives rise to malignant, putrid, and pestilential fevers, which are of extreme virulence. By the aid of these distinctions he arrives at his classification of fevers: the first two, corresponding pretty closely to what have since been known as sthenic and asthenic, he denominates inflammatory and "slow nervous" fevers; to these is added the malignant kind. His division was not made for the sake of any logical subtlety, but for the really important end of adapting the right treatment to every case. Sydenham, who had to combat the alexipharmac school of Morton and others, looked on nearly every case of fever as inflammatory, and used depletion; his system came to be the most prevalent, though many practitioners still had few resources beyond the ready and indiscriminate use of alexipharmac cordials. Too many of Huxham's colleagues seem to have combined the methods in the worst way, bleeding freely when they should have given wine, and administering stimulants when depletives were called for. It is Huxham's merit that he saw pretty distinctly, and insisted upon, the indications for each class of remedies, so that each could be applied in appropriate cases with the best effect and without confusion. He saw that bleeding was the most effectual mode of combating inflammatory fevers, "the heat of which exalts the salts and sulphurs of the blood, and increases the acrimony and putrescent state of the humours," that, the longer it was neglected, the more viscid and acrimonious the blood became, and the less likely was it to be of use. He also insists on the fact that in pleurisies and pneumonia, for example, an oppressed pulse at the onset is an especial sign for bleeding, instead of the reverse, to restore due circulation. In pneumonia he goes so far as to say that bleeding is necessary in all cases in some degree and at some time, and when well executed is quite curative. On the other hand, in slow nervous fevers (which he claimed to have been the first to describe, and of which the symptoms are mostly nervous and ataxic, and the duration often three weeks or more), bleeding, if permissible at all, is so only in small measure and at the very outset. Bleeding may, or may not, be necessary in malignant fevers, according to the violence of the febrile agitation, but it is always contra-indicated when the blood is loose and dissolved and the patient is more languid after the operation. When it cannot be borne, and yet the state of excitement demands lowering measures, an emetic is of the greatest service. In conditions of prostration (*lax habits with poor blood*) he would give alcohol freely. He had a strong prejudice against ammonia, "the volatile alcalious salts such as ladies smell to," though he would not banish it from the *Pharmacopœia*, believing that it destroyed the crisis of the blood during life—he narrates at

length a fatal case of habitual use of ammonia—just as it keeps it fluid after removal. He says these salts were too often given in putrid petechial fevers, aggravating the acrimonious and broken state of the blood, and the diminished tone of the fibres characteristic of such cases. Still it is necessary in many cases to use warm medicines and raise the fever: "every kind of fever is a struggle of nature to relieve herself from something oppressive"; "behold, then, a cure for this evil without the fatigue of medicines: mix only a little generous red wine with some diluting liquors, and, being taught by experiment, you will be surprised at such mighty effects arising from such a small quantity." In all protracted fevers such wine is "a most noble natural subastringent cordial, and perhaps Art can scarcely supply a better." He paid great regard to the dietetic part of medicine, which is "not so much studied as it deserves; it is the more natural way of cure, though less pompous, indeed, than alexipharmac boluses, febrifuge draughts, and cordial juleps." Thus slow nervous fevers are to be cured by "mild cordial stimulants, diet, and medicine, which directly counteract the debility of the fibres and faulty lentor of the humours." Quoting Pringle, and Galen long before, he draws a distinction between the peculiar biting and tingling heat, "the sensation of which remains in the finger after removal," sometimes met with, and the ordinary pyrexia of fever, and ascribes it to "the abundant acrid salts and sulphurs in the blood and its intestine motion," thereby denoting malignancy.

Just as there are several species of common continued fever, according to the state of the constitution, and the way it is affected, so there are corresponding kinds of small-pox, each requiring its appropriate line of treatment. He approves of inoculation as a preventive and advances the suggestion that, as the quality of the small-pox depends much on the constitutional state, a peculiar disposition of the latter might be induced so as to prevent infection, or ensure an attack being mild. In inflammatory cases he would bleed, but in low depressed cases would give sack and saffron, and sometimes large quantities of wine. He points out the indications for emetics, opiates, &c., in maturing the pocks, and does not neglect to urge the importance of changing the linen and opening the windows towards the close of the complaint. At that period also he would purge "to prevent boils, indurated glands, foul ulcers, carious bones, rotten lungs or hectic." His treatise on Pleurisy and Peripneumonia is good, illustrating his treatment of typical inflammatory fevers; he notes the important fact that a severe rigor almost always betokens a severe attack.

The "Malignant Ulcerous Sore Throat," which is the subject of a separate essay, was a rare disease,—apparently a severe form of scarlet fever with a diphtheritic sore throat—which occurred as an epidemic around Plymouth in 1751 and the following years, and was very fatal, especially to children. It was first accurately described by Fothergill in 1748, but had been met with before in Spain and Italy at the beginning of the 17th century, and was probably identical with a form known to the Ancients. Its

symptoms were highly malignant in character, almost as much so as the Plague; bleeding was not well tolerated, but clysters and emetics were sometimes found to do good.

The "Medical and Chemical Observations on Antimony" is a curious tract, describing the best mode of making a reliable preparation of the mineral for therapeutical purposes, and the uses to which it might be put. It is interesting to learn that "200 years ago physicians prescribing antimony were expelled from the faculty; now it has become the Catholicon." He says, "I laboured formerly with all my power and diligence to get some useful medicine from antimony; I tried almost all the processes of the chemists and alchemists, not only as to the preparations, but likewise by exhibiting them to various patients; but I must solemnly affirm I never found any one of them to be better, safer, or more effectual than the common, simple, antimonial wine. In the smallest doses it can pass through and scour even the very smallest tubuli of the whole human frame, but, from the great tenuity of the particles, cannot lacerate the blood vessels." Hence its value as an attenuant and deobstruent. This "Vinum benedictum" was composed of 1 ounce of glass of antimony infused in 24 ounces of Madeira wine. "Crude antimony consists of much sulphur and more reguline metallic parts"; the latter the active principle, owing its properties to the "spiculine or needle-like form of the particles." It is useful in obstinate rheumatism, cold, scorbutic affections, most cutaneous diseases, asthma, leuco-phlegmatic and icteric diseases, old stubborn headache, vertigo, epilepsy, and mania. In acute diseases also, especially slow fevers, low irregular intermittents, catarrhal fevers, peripneumonia notha, and even peri-pneumonia after due evacuations, &c.

From the opportunities thrust upon him, Huxham paid much attention to scurvy; many a ship's crew he saw with health destroyed by this disease. He ascribes it to an "alkalescent acrimony" of the blood, due to bad food, bad water and air, and states that it is best cured by vegetable and mineral acids; therefore he recommends that all ships should be provided with sound generous cyder, vinegar, and lemon-juice. While recommending cyder for scurvy, he traced the ill effects of its excessive consumption in producing an extensive and severe epidemic of Devonshire colic in 1724. Nearly every family of the lower classes had it, sometimes six or seven persons in the same house.

Those who greatly admire laborious and protracted scientific observations, recorded after the fashion of the modern Meteorological Society, will do well to look through Huxham's daily notes on the "Air and Epidemic Diseases" between the years 1727 and 1757. Following the example of Hippocrates and Sydenham in his firm belief in the great influence of climate, season, and weather in determining the constitution of the body and the characters of disease, he recorded indefatigably the temperature and moisture of the air, the wind, and rain at Plymouth every day, at the same time remarking the prevalent diseases. In this form he has left us abundant clinical records, which exhibit his mode of dealing with all manner of complaints, and formed the basis of his more important treatises.

This brief outline of what Huxham has left to us will be sufficient to show that his claim to remembrance is based on unmistakably great merits and solid work, and that he did not owe his success and fame to the attributes possessed by some whom he thus contemptuously describes: "To be the favourite of some great man (or what is rather better, of some great woman); to be the tool or fool of a party with a splendid equipage and no small share of assurance: these are the qualifications which finish the doctor, to the reproach of the profession and the danger of society."

N. H.

## REVIEWS AND NOTICES OF BOOKS.

### SMALL-POX AND VACCINATION IN ENGLAND.<sup>1</sup>

NINETEEN vaccinated persons to one unvaccinated. Such is the general composition of the population of England deduced from a comparison of the reported vaccinations with the number of births, deducting therefrom the number of deaths of infants during the year; and this proportion of vaccinated to unvaccinated should always be borne in mind when the total deaths from small-pox in each class are compared, confirmed as it was by the vaccination censuses carried out at St. Pancras and West Ham. Yet since the memorable year 1871, when the deaths from small-pox in London, numbered 2,420 per million inhabitants, there have been no fewer than three or four occasions on which they were numerous enough to deserve to be considered as epidemics, viz., 1877-8, in which they were 710 and 390 per million; 1881, when they were 620; and last year, 1884, with 313; the mean annual rate of the past ten years having been 240. Or if we compare the deaths from small-pox with those from all causes, we find the rate of the former to 1,000 of the latter to have been in 1871, 98; in 1877, 33; in 1878, 17; in 1881, 29; and in 1884, 15; the mean proportion for the last ten years having been 11. This latter mode of computation is not altogether so satisfactory as the former, but it is the only one we can employ when drawing comparisons between the present mortality and that of periods antecedent to the census when the actual number of deaths was recorded, but the population was not accurately known.

In an appendix to his Report, Dr. Buchanan gives the table presented by Dr. Lettsom to a Committee of the House of Commons in 1802, and another recently compiled in like manner from the "bills of mortality" as well as one taken from the Registrar-General's reports, which together show the deaths from all causes, and from small-pox, the number of the latter to 1,000 of the former, in each year, with some unavoidable omissions, from 1667 to 1831, and since 1838 also the death-rate from small-pox per 1,000 persons living. From 1667 to 1686, and 1701 to 1722, the mean annual number of deaths from small-pox to 1,000 deaths from all causes was 72; in eight years it was over 100; and once only did it fall below 10, that year intervening between two of over 100. In the next seventy years, or 1731 to 1800 inclusive, the period during which inoculation of small-pox was more or less practical, the mean ratio was 90 per 1,000

<sup>1</sup> Fourteenth Annual Report of the Local Government Board, 1884-85. Supplement containing the Report of the Medical Officer for 1884.

from all causes, while it never once sank below 10: it reached 100 or more in 28 years, at one time (1762-5) maintaining this height for four consecutive years, and in 1796 attaining the appalling figure of 184 or 1 death from small-pox to  $4\frac{1}{2}$  from all other causes put together. Between 1801 and 1831, it fell gradually but steadily with the spread of vaccination, never reaching 100, and averaging 45 or half what it was in the inoculation period, and five-eighths of what it had been in still earlier years. From 1838 to 1884, the mean has been under 16 or one-fifth of what it was in the last century; in 23 years it has been under 10, and in two years actually under one: these were 1874-5. From 1847-53, while vaccination was still optional, the deaths from small-pox per million living throughout England and Wales were 305. From 1854-71, when it was obligatory but not efficiently enforced, it was 223, and from 1872 to 1880 with stricter compulsion 156. To the allegation that this steady falling off in the mortality from small-pox is really due to improved sanitation, it is easy to show that though the death-rate from all other causes, many of them as diarrhoea, enteric fever, phthisis, &c., more immediately dependent on insanitary surroundings, has been appreciable, it has been incomparably less marked, or to put it numerically, if we take the deaths from small-pox and those from all other causes in the period 1847-53 (that of optional vaccination) at 100 each, we find that in 1872-80 (the period of efficient compulsion) the small-pox deaths sank to 51, and the others only to 93.

The death-rate from small-pox for children under five years of age was during the three periods of optional, obligatory, and enforced vaccination, 1,617, 817, and 323 per million living respectively. This mode of approaching the question, viz., taking the relative mortality during the period in question at different ages brings into prominence the remarkable fact that while the mortality from small-pox at all ages has greatly diminished, and that in childhood is remarkably less than formerly, the death-rate from this disease compared with that from other diseases or per million living has risen among adults. If we go still further back, that is to say, into the last century, we shall find that small-pox was almost exclusively a disease of childhood, its adult victims being very nearly confined to those whose affluent circumstances had enabled their parents to shield them from infection when young. Thus, from Dr. Haygarth's report, we learn that in 1774 out of 546 deaths in the city of Chester, 203 were from small-pox, 180 being those of children under 5 and the remaining 22 under 10 years of age. In Kilmarnock between 1728 and 1764, there were 622 deaths from small-pox, of which 586 were under 5, and only four, of 20 years or over, unless some of the nine whose age was not stated were adults. The same distribution as regards age appears in Casper Neumann's Breslau tables for the years 1682-91. The explanation is obvious. Nearly everyone (in Chester 13 out of 14 of the population) had small-pox, as nearly everyone now has measles, on the first exposure to infection, but those who survived (in Chester 5 in  $6\frac{1}{2}$ ) acquired thereby almost absolute immunity, though too often blind or deaf and always more or less disfigured. Now-a-days vaccination protects us during early life to a great extent, but after puberty this acquired immunity, feebler than that conferred by small-pox itself, becomes progressively feebler, and the susceptibility to the infection of small-pox increases *pari passu*, so that the greatest mortality occurs among unvaccinated infants, and among adults over 20 years of age. In Paris where, as throughout France, vaccination is less efficiently performed, this increased incidence of small-pox, both absolute and relative, among adults is more marked than it is here. It is this transference

of the mortality from childhood to later life that furnishes so strong an argument in favour of revaccination which has accordingly been made compulsory in Germany by the law of 1874, on all children before leaving school, *i.e.*, at 13 years of age. The consequences of this new regulation are shown in the extraordinary reduction amounting almost to extinction of small-pox in the Empire, the mortality in the great towns having fallen from over 90 to 1.4 per 100,000 of the population. Of course, there is still a large residuum of persons who left school ten years ago who have not been revaccinated, but they enjoy the benefit indirectly in the fact of lessened exposure to infection; for the immunity conferred by a single vaccination being but partial, and to a certain degree terminable, the presence of small-pox in a community, and therefore the presence of a number of unvaccinated and consequently specially susceptible individuals, constitutes a standing danger even to the vaccinated.

In 1884 out of every 1,000 deaths from small-pox occurring among unvaccinated persons no fewer than 612 were those of children under ten, while of the same number among the vaccinated, who are twenty times as numerous, 86 only were under that age. Again, in the epidemic of 1884-5, of every 1,000 deaths from small-pox, 248 were those of children under 10 years; but though the vaccinated are probably twenty times—Dr. Buchanan for argument's sake says ten times—as numerous as the unvaccinated, the latter contributed 235, and the former 13, and once more 92 were those of London-born infants under one year, and of these 91 had not been vaccinated.

As regards the alleged deaths from small-pox among vaccinated children, or rather the deaths of children alleged to have been vaccinated, it is most important to bear in mind that there is a vast amount of imperfect vaccination abroad. Many private practitioners are surprisingly deficient in manipulative skill, and some so wanting in principle that they are found willing to yield to the prejudices of parents so far as to make but one or two small insertions. This sham vaccination, against which Dr. Buchanan vigorously protests, keeps the disease alive and brings discredit on vaccination itself. It is a remarkable fact that on a former occasion Dr. Buchanan found that of 125 children under ten dying of small-pox after "vaccination" in only one had the operation been performed by a public vaccinator! As to the dangers incident to vaccination, 14 cases were reported to the Board and investigated by the medical officers. One was a genuine instance of careless vaccination by a private practitioner resulting in undue irritation in the arms of several children. One of alleged syphilitic affection was found to have been a vaccination from the calf, and the remainder were owing to parental mismanagement, as dressing with cobbler's wax and brown paper, &c. These were all the allegations of injury among 750,000 vaccinations. It is true that the Registrar-General's returns show 55 deaths alleged to be owing to vaccinations or its results. Most of these, if correctly reported, were cases of erysipelas caused by insanitary surroundings, filthy vaccination shields saturated with the discharges of a succession of wearers, dressing with "oils," &c. But even if all the certificates be accepted as trustworthy they merely indicate the necessity for greater care and cleanliness, and no more support the outcry against vaccination itself than, as Dr. Buchanan humorously remarks, do the 974 cases of children suffocated by bed-clothes call for the disuse of all coverings at night. In conclusion, Dr. Buchanan very properly suggests that if vaccination is not to be in future compulsory in the sense of the infliction of penalties for neglect, "the Act should be so further altered as to mark by law the sense of the community that a parent will have committed an offence, whose

*child dies of small-pox without having been vaccinated while in the legal custody of its parents. Such parents will have failed to give the security that the law provides for their helpless children, and will be in the same position as if they had failed to provide their children with any other security important to their lives."*

*Lectures on Dietetics and Dyspepsia; by WILLIAM ROBERTS, M.D., F.R.S. London: Smith, Elder & Co., 1885.* In this admirable series of lectures Dr. Roberts investigates the effects of what we may call ordinary articles of diet, viz.: alcoholic drinks, tea and coffee, on the digestive processes. The separate stages of salivary, peptic and pancreatic digestion are considered one by one. A 5 per cent. solution of proof spirit, brandy, or whisky does not perceptibly interfere with salivary digestion; nor does a 10 or even a 20 per cent. solution of proof spirit exercise any material influence, but a 10 per cent. solution of brandy or whisky retards salivary digestion in a most remarkable manner, and brandy produces a more powerful effect in this respect than whisky; a 20 per cent. solution of brandy and a 40 per cent. solution of whisky altogether arrest the action of the saliva. The difference between these and proof spirit appears to be due to the ethereal bodies and volatile oils that they contain, and the more powerful effect of brandy is owing to its containing tannin. Both the stronger and the lighter wines exhibit a powerful inhibitory effect on salivary digestion, which is shown to be due to the acids contained in them. The practical outcome of this enquiry is that spirits as used dietetically promote digestion by calling forth an increased flow of saliva, but when taken in excess they altogether arrest its flow. In regard to peptic digestion less than 10 per cent. of proof spirit, brandy, or whisky, produced practically no effect; in a higher proportion a marked inhibitory effect was rapidly produced. Port and sherry, especially the latter, were found to produce a retarding effect quite out of proportion to the quantity of alcohol they contained, and the same holds good of the lighter wines, though champagne only produced these effects when used in considerable doses—a small percentage of it, indeed, seemed to increase peptic digestion; malt liquors were also found to retard the process to a degree quite disproportionate to the quantity of alcohol contained in them, and the effect was more marked when they were "flat" than when well "up." Effervescent table-waters only retarded digestion when used in very high degree of concentration. The result of all this is that wine and spirits used dietetically facilitate digestion by acting as a stimulant to the secretion of gastric juice. Tea and coffee exercise a marked effect in arresting salivary digestion, the former being much the more powerful in this respect; the length of time the tea is infused does not affect this at all, as after only two minutes the retarding effect was fully produced, the only way in which this retarding effect can be avoided being either to use a very weak solution of tea or to add some carbonate of soda; it (the retarding effect) is due to the tannin in tea and caffen-tannic acid in coffee. In regard to peptic digestion tea and coffee exert an equal retarding effect, but, inasmuch as the latter is usually taken in much stronger proportions than the former, it follows that practically coffee retards digestion more than tea. Common salt has little or no effect on salivary digestion, but has a considerable retarding power over peptic digestion. Having thus shown that the food accessories in every-day use with us one and all tend to retard digestion, Dr. Roberts sets to work to supply the explanation of this apparent anomaly. The elaborate manipulation and preparation which our food undergoes in the various cooking processes to which it is subjected render it not only more digestible, but more capable of being thoroughly exhausted of its nutritive properties, and it is to obviate the risk that our food when in this highly digestible state will pass too quickly and wastefully into the blood, and thence into the excretory organs, that we take these various precautions to retard digestion; in short, we damp our digestive fires in order to ensure the economical use of our food. Other matters of almost equal interest and importance are

touched upon in these lectures in relation to the effects of beef-tea on digestion, and the symptoms and treatment of acid dyspepsia; but we have said enough to show how full of interest they are, and we are deeply grateful to Dr. Roberts for having published them.

*Bad Drains, and How to Test Them; by R. HARRIS REEVES. London: E. and F. N. Spon, 1885.*—The aim of this little book is not very evident, unless it be to call the attention of the public to the author's invention of an apparatus termed by him a detector. He has found by experiment that if a section of a drain containing 300 cubic feet of air be shut off at each end by traps, the introduction of one cubic foot of water exerts a compressing power on the air sufficient to force the 2-inch water seal of a common trap, a result which is easily shown by the detector when put in communication with such a section. The chapter contains also many illustrations of prevalent defects in house drainage, with which we are all familiar. In the next chapter we are favoured with the author's views on sewer ventilation, some of which are at variance with those generally entertained, rightly or wrongly, and some are to say the least suggestive. He is strongly opposed to gratings in the roadways and to using the soil pipe as a ventilating shaft; and he hints at, rather than describes, his own peculiar system, which has, we believe, been carried out successfully at Sandown. The last chapter, on the origin and transmission of zymotic disease, would better have been left unwritten. Taking advantage of the evolutionary hypothesis held by many pathologists, that pathogenic micro-organisms may be developed from others, and thus a disease as enteric or diphtheria, afterwards propagated by contagion, be now and then originated in putrescent feci, he denies contagion altogether, ignores incubation periods, denounces the best established experiences of medical science as mere theory, and propounds his own assumptions as rational explanations of the origin of disease without even taking the trouble to give any evidence or proof.

*The Essentials of Materia Medica and Therapeutics; by ALFRED BARING GARROD, M.D., F.R.S. Eleventh edition, revised and edited by Nestor Tirard, M.D. London: Longmans, Green, & Co., 1885.*—This work, which has now reached its eleventh edition, and contains the work of three successive holders of the Chair of Materia Medica at King's College, is so well known to the profession that it may be dismissed in a few words. Those with whom the book is an old favourite will be glad to find that, in spite of the numerous additions to the materia medica, and the large promises made by enthusiastic pharmacologists, the book retains its old form, and with it the practical common-sense view of therapeutics which had hitherto favourably distinguished it. The valuable portions added by the late Dr. Baxter have been retained, and the new editor, Dr. Tirard, has given very clear and concise accounts of the newer drugs. Much space has been economised by a rearrangement of type, and the new edition is not 30 pp. longer than the fourth edition. One new and not unimportant fact, which we have seen for the first time in this work, is that alkaline solutions impair the efficacy of Indian hemp. In the fourth edition, it was recommended that the drug should be prescribed with aromatic spirit of ammonia in order to keep it in solution.

*The Vegetable Materia Medica of Western India; by W. DYMCK, Surgeon-Major, &c. Bombay: Education Society's Press, 1885, Second Edition, Part I.*—This little work is the outcome of a long and intimate acquaintance with the indigenous drugs of the Bombay Presidency, and of a careful study of several Mahometan works and of Mr. G. Watt's excellent catalogue of the Economic Products of India, while in the identification of plants growing in the Concan, the author has had the assistance of Messrs. Gray and Sakaram Arjun. The arrangement of the matter is botanical rather than therapeutic. Mr. Dymock, in describing each drug, gives its technical terms, and the vernacular equivalents, after which he deals with

its history, uses, &c., the latter of which we regret to notice he treats almost exclusively from the empirical standpoint, without troubling himself with physiological actions. He next gives a botanical description, after which the microscopic structure, the chemical composition, and lastly, the commercial uses are described. It is disappointing in these days to find a work of this kind ignoring so completely the modern scientific standpoint. Still, to the pharmacist and manufacturing druggist, there is much in Mr. Dymock's work that will prove of interest and usefulness.

## ABSTRACTS AND EXTRACTS.

**INFLAMMATION OF THE ATTIC OF THE TYMPANUM.**—Inflammation of the middle ear is subject to certain limitations due to its anatomical construction, especially of its osseous boundaries, and that arising in the attic is, owing to its sequestration, usually of much more significance than the form which begins in the atrium. In the October issue of *The American Journal of the Medical Sciences*, Dr. Samuel Sexton calls attention to this form of disease, which has not, it is believed, hitherto received the attention its importance demands; indeed, in its early stage, it is likely to escape observation altogether if examination of the ear be limited, as it very often is, to an inspection of the membrana tympani only, since this membrane may not, at any stage of inflammation of the attic, be greatly or at all affected. Inflammation of the atticus tympanicus is considered under two forms, acute and chronic. The symptoms and course of the disease are described. In the treatment Dr. Sexton relies upon minute doses of mercury in inflammation of mucous surfaces until purulency threatens, when the calx sulphurata is indicated. Pain and vascular excitement may be controlled by aconite, belladonna, pulsatilla, gelsemium, and other remedies. In certain cases much relief may be obtained, or even a cure may result, by removing secretions from the attic through the Eustachian tube. In the local treatment, where there is simply redness of the membrana flaccida, due to acute catarrhal inflammation, a regressive course is soon established in many cases and any local interference is inadvisable. Where there is periostitis of the canal, incisions often do harm, but where catarrh advances to the purulent stage the symptoms may become more urgent and the employment of the knife be demanded. Vent to secretions in the attic may be assured in some cases by introducing the myringotome through the upper edge of the membrana tympani and behind the long process of the incus. The danger of wounding the chorda tympani nerve is considerable in this operation and incurrence of the risk would only be justifiable when symptoms were urgent. Where inflammation has extended to the antrum, either from without, in consequence of caries due to periostitis externa, or along the petro-mastoid canal from the tympanum, the surgical aspect of the case may become paramount. From his own experience an extension of the diseased process from the attic is a common occurrence and usually calls for no special interference. But in neglected and otherwise unfavourable cases drainage must be secured, whether we have to deal with middle ear disease or any of its complications. Ineffectual operative procedures here needlessly torture the patient without accomplishing the end in view; an operation for the relief of pachymeningitis might thus be tantamount to trephining because of the pains of middle ear disease, a procedure which at best would not probably liberate the products of inflammation of the dura, even if any were present. Dr. Sexton cannot, therefore, from this point of view, regard trephining the mastoid as other than a means of drainage, not likely to affect the course of pachymeningitis or cerebral abscess. Dr. Sexton thinks that we may often avail ourselves of the tendency manifested by the pent-up products of inflammation to escape through the posterior wall of the external auditory canal by perforating the posterior edge of the thin auditory plate just above where it joins the tympanic plate. This operation

opens up immediate communication with the attic and petro-mastoid canal. In a large number of instances the same object is attained by perforating the membrana flaccida as previously recommended. Efforts must not be omitted in these cases to re-establish drainage from the attic down into the atrium, nor should it be forgotten that a communication with the Eustachian tube very frequently remains in these cases. In the local treatment of chronic cases where sinuses remain, after the removal of polypi or other products, salicylic acid has been attended with the best results, bringing about a dry desquamative condition, which is often the best issue to be hoped for.

**DIURETICS.**—From an interesting article by Dr. Reichard in the *Philadelphia Medical Times*, August 22nd, we extract the following observations. "Diuretics may be divided into two great classes; those in which the chief effect is an increase in the amount of urinary water, and those in which there is a decided increase in the urinary solids. The first act principally by raising the blood-pressure; the latter have a selective affinity for the renal epithelium, causing a secretion of solids and, in a less degree, of fluids. In the first class stands the digitalis group. In the second are the alkalies and most of the class of drugs known as urino-genital, of which buchu stands first as a diuretic. In the first class digitalis stands easily at the head, and of all its preparations the *infusion* is the diuretic *par excellence*. This seems to have some special action on the kidney, and with no other preparation of the remedy, given even in equivalent doses, have I been able to procure the same amount of diuresis. The pulse may show the specific effect of the drug, and still the diuretic effect will not be produced to the same extent. Much has been said about the cumulative effect of digitalis, but in my own use of it I have never had any bad results further than disordering the stomach. This it is sure to do if pushed strongly and continued for a week. But when a diuretic is ordered because of either dropsy or retained substances in the blood, and there is a rapid, weak pulse, the infusion will act like a charm for a few days. After being given in decided doses (say a tablespoonful every four hours) for a few days, it can be reduced either in the size or number of the doses, so that there will not be much danger of gastric disturbance. Sometimes, however, we are forced to abandon the use of the drug until the tongue cleans and the stomach regains its normal tone." Dr. Reichard refers to a case of extensive œdema due to cardiac dilatation, in which he obtained most satisfactory results by intermitting digitalis and giving convallaria. The latter had no appreciable diuretic action, yet as a cardiac tonic it sustained the heart until the digitalis could be renewed. Having in all cases found digitalis and convallaria satisfactory, he has made no trial of caffeine. Nor has he tried, among the second class of diuretics, the lithium carbonate, having confined himself to the potash salts, which break up readily in the blood, increasing its alkalinity, while the carbonic acid is given off. Through this increased alkalinity, the amount of urates deposited on cooling is diminished. All these alkalies, especially the acetate, increase the amount of urinary water as well as solids, and in choosing one of them it is rather a matter of personal preference. The only thing to avoid is giving a soda salt, as the insoluble urate of sodium will be formed, and harin will result where good was expected. "Buchu is the type of diuretics the activity of which depends on a volatile oil. It is indicated when a diuretic is wanted, pure and simple, with no reference to the heart. In any case of idiopathic renal insufficiency it is the drug to be given; or if from any cause the amount of urinary water is to be increased without affecting the blood-pressure. Cases of lithæmia all do better if buchu be added to the alkali. A plan which I have often used with much satisfaction is to give about 20 grains of bitartrate of potassium with an ounce of infusion of buchu in a cup of cold water every three hours. Under its use I have seen nervous, depressed, neuralgic women brighten and clear up physically and mentally. After being literally "washed out," they have in a number of cases expressed the greatest satisfaction. In ordinary routine work it may not always be possible to say just in what cases buchu and an alkali

will do good. The effect, however, will soon show whether the diagnosis be right or wrong. As they are mostly sub-acute or chronic cases, one has a chance of making the trial of several diuretics."

**CHLORATE OF POTASSIUM, ITS USES AND DANGERS.**—The *Therapeutic Gazette* for October, alluding to a case of poisoning by the chlorate when used as a gargle, reported by Dr. Wilkie of Berlin, makes some observations on the cautions which should be observed. The case in question was quite an exceptional one, as the patient used the enormous quantity of 4 lbs. of the chlorate between the 9th of July and 8th of August. A considerable portion of this was probably swallowed. At all events, both the symptoms and the *post-mortem* appearances were those which attend poisoning by this drug. In most of the reported cases of poisoning in the adult, the dose has been more than half an ounce, while a dram has proved fatal to an infant a year old. "The kidneys are profoundly affected in these cases, their tubules being full of brownish casts, and their epithelial structure evincing nephritis. The effect which the drug has upon the kidneys makes its *internal use* especially dangerous in cases of diphtheria and scarlet-fever; and we have no doubt that its too free employment has added very seriously to the mortality of these diseases. It certainly has no direct effect upon them, and is of no value whatever in their treatment, save only for the slight effect which it has upon the sore throat; and, if given at all, it should be administered with great caution and only in very small doses. The *local* use of the drug has been conceived to be harmless. In ordinary sore throat, used three or four times a day as an ingredient in a gargle, the drug is an efficient one, and the small quantity that will be swallowed may be of service. It should be remembered that it is very freely eliminated by the salivary glands, so that, when taken internally, the parts about the mouth and throat are continually bathed in its dilute solution. It is in this way, by a perpetual local effect, that it is useful in the ulcerated stomachs of children. When, however, as in a bad case of diphtheria or scarlet-fever, the whole mucous membrane is covered by thick exudate, it is to our mind absurd to think that the chlorate is of appreciable value. Remedies of more distinct power and more ability to destroy or make their way through the membrane are to be employed. They should be applied with a swab by the physician himself. We do not think that the experience of Dr. Wilkie should prevent the habitual use of the chlorate in mild cases of angina: but it should give us caution in any attempt to make a very powerful local impression by a very frequent use of it as a gargle in severe cases."

**ASPIRATION OF THE AORTA.**—This sounds at first rather a bold, not to say unjustifiable procedure, but after reading the account of the case in question, we are bound to say that any criticism to the latter effect is uncalled for. The case is reported in the *Bristol Medico-Chirurgical Journal* for September, by Mr. J. Dacre, and is as follows: A laborer, aged 40, was brought to the Infirmary suffering from extreme dyspnoea and cyanosis. He had no enlargement of the superficial veins in the neck or arms, the heart sounds were inaudible, nor could the impulse be felt, the breathing was slow, shallow, and gasping, and the conjunctivæ were insensitive. Under these circumstances it was decided to try and relieve the heart by tapping the right auricle. A medium-sized needle was accordingly inserted in the fourth intercostal space on the right side, close to the sternum, and when in the chest, the point was turned sharply inwards under the sternum, and pushed on for an inch and a half, when it was felt to be in a cavity, but there was no impulse. On removing the needle, black blood flowed freely through the canula, and the heart's action was so far restored as to communicate an impulse to the syringe; when 16 ounces had been drawn off, there was a very fair pulse at the wrist; in five minutes 30 ounces had been withdrawn, and the operation was then stopped; no hæmorrhage took place through the puncture. The lividity was much diminished, he became conscious, breathed more readily, and was able to speak. A few minutes later he became very restless and his pulse failed; this, however, was relieved by the hypodermic injection of ether, and for the next few hours he went on fairly well.

Six hours after the operation, his condition having again become very serious, he was tapped a second time, the needle being inserted at the same spot, and in the same manner as before; 16 ounces of venous blood were removed, and for a few minutes the pulse revived. He then became more restless than ever, complaining of feeling very hot, and in spite of stimulation he gradually sank, and died in about forty minutes from the time of the second operation. At the *post-mortem* it was found that the needle had passed immediately above the right auricular appendix, and had pierced the anterior surface of the aorta, about a quarter of an inch above one of the semilunar valves. The author concludes his paper with some remarks on the advisability of cardiacentesis, and observes that the auricle would have been reached in this case if the needle had been passed in directly backwards.

**TREATMENT OF ACUTE GONORRHOEA.**—Surgeon-Major Lawrie, writing in the *Indian Medical Gazette* for October, furnishes a short abstract of a lecture on Gonorrhœa, in order to bring into prominent notice a mode of treating it which he has found most prompt and effectual. Proceeding on the admission that the disease is due to a micrococcus, which is readily destroyed by weak solutions of corrosive sublimate, and that local inflammation may be prevented or arrested by frequent small doses of tartar emetic, he relates a case as a specimen of the manner in which he has found these means operate. When called to the patient, he found him suffering from fever, profuse discharge of pus, and a highly inflamed penis, the inguinal glands being enlarged and tender, the perinæum very uneasy, micturition exquisitely painful, and sleep prevented by chordee. Two leeches were ordered to the penis, and two to each groin, and fifteen minims of vin. antimon. were given every two hours. An urethral injection, as hot as could be borne, consisting of one part of corrosive sublimate to 15,000 of water, was given every hour. In less than 48 hours all the most distressing symptoms were relieved and calm sleep obtained. The treatment was continued for a week, the strength of the injection being gradually increased to 1 in 5,000, and the antimony given at longer intervals. He was then ordered to apply both means only three times a day, and in another fortnight was quite well. A month afterwards the passage of a catheter showed that the urethra was in quite a normal condition. Surgeon-Major Lawrie contrasts this result with those obtained by the old means of treatment, after months or years of treatment. "In short," he says, "corrosive sublimate and antimony may be regarded as little less than specifics; and I find it difficult to avoid overstepping the limits of moderate language in advocating their use. It only remains to add that urethral injections ought always to be used hot. Apart from their beneficial action, their effects are so soothing and grateful to the patient that he at once acquires confidence in you, without which it is useless to expect that he will carry out your orders with implicit obedience."

**HYSTERICAL PARAPLEGIA.**—In a clinical lecture on some forms of myelitis, Dr. Charles K. Mills alluded to the points of differential diagnosis between subacute or chronic myelitis and hysterical paraplegia. After narrating a typical instance of the latter, he observed that a history of frequent attacks of paralysis, in connection with other hysterical symptoms, though very suggestive, was not positive evidence. The patellar reflex was often exaggerated and rarely lost in hysteria, whilst it was usually lost in poliomyelitis. Electro-muscular contractility was often normal in hysterical paralysis, though sometimes slightly diminished quantitatively to both faradism and galvanism. There were no reactions of degeneration in hysterical paralysis; the cutaneous plantar reflex would be impaired, but there were no bedsores and no nail-markings. True muscular atrophy was wanting, though the limbs might be wasted from disuse. The temperature of the affected limbs was usually good; there was no blueness or redness, and the intestines and bladder were unaffected. In poliomyelitis the disease came on with diarrhœa and fever, and vomiting and pain were often present.—*Medical News*, August 22.

**THE CAUSES OF LOCOMOTOR ATAXY.**—Under this title M. Belugou has recently published a careful study of 32 cases of this disease with especial reference to its ætiology in *Le Progrès Médical* (Nos. 35, 36). As regards syphilis about which so much has lately been written, he finds that in 18 of his cases there was no evidence of its existence. He admits that it may often play an important predisposing part, but it does not create locomotor ataxy. It may, by the lesions which it produces in the cerebral nervous system, give rise to a symptomatic motor ataxia, and it is precisely in such cases that the mixed treatment appears to produce the best results. Some nervous inheritance he found present in 13 of his cases, and he concludes that this occupies a marked place in the ætiology of locomotor ataxy and is almost of equal importance with syphilis. Rheumatic antecedents were present in 7 of his cases, and although this has been ignored by some writers, yet he considers that rheumatism constitutes an important and definite factor in the causation of the disease. Functional abuses in one form or another were present in all his cases; venereal excesses or masturbation being the most common (21 cases); in five cases excessive tobacco smoking was held to have played a part; in other cases mental over-strain in the hard struggle for existence seemed to have been a cause. Mostly some combination of these causes will, he says, be found, such as an hereditary tendency with some form of functional abuse or a syphilitic or rheumatic diathesis.

**AN UNUSUAL CAUSE OF COMPLETE AMAUROSIS.**—It is generally supposed that, though ordinary or simple anæmia may certainly cause some defect in vision, it is incapable of producing complete amaurosis. That it can, however, do so in rare instances is shown by a case occurring in the Berlin Polyclinic which is reported in the *Berliner Klinische Wochenschrift*. A young woman of anæmic and badly-nourished appearance, who suffered from spasmodic gastric pain, after complaining for a short time of defective sight, had suddenly become blind two days before being seen. The papillæ on both sides were found to be swollen and the optic nerves slightly red and dull-looking, the veins being distended and tortuous. The patient's blood presented the usual microscopic characters of anæmia, the corpuscles being club-shaped, pear-shaped, &c. The number of white corpuscles was slightly increased, but the appearances of the amaurosis of essential anæmia—white papillæ, bright red veins, streaks of blood, &c., were absent, so the prognosis was hopeful. The patient was kept in bed on good food, and was ordered iodide of iron. The pains in the stomach soon disappeared, and the blood soon regained its normal condition, the eyes at the same time becoming capable of vision, with normal ophthalmoscopic appearances.

**HIGH TEMPERATURE IN AN INFANT.**—Dr. Seibert recently reported to the New York Society of German Physicians the case of an infant, four months old, which he had treated for gastritis, and which for eighteen consecutive days had almost uninterruptedly a temperature of over 106° F. The infant recovered.—*Boston Medical Journal*, October 1st.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 10TH, 1885.

Dr. GEORGE JOHNSON, F.R.S., President, in the Chair.

*Scarlatinal Albuminuria and the "Pre-albuminuric Stage," studied by frequent testing.*

Dr. STEVENSON THOMSON, late Assistant Resident Physician, City of Glasgow Fever Hospital, read a paper on this subject, giving the results of the examination of the urine of 180 cases of scarlet fever. Special attention was devoted to the first appearance of blood and albumen for

the purpose of investigating the exact condition of the urine in the so-called "pre-albuminuric stage." The subject was considered under the five following heads:—  
I. *Period of occurrence of scarlatinal albuminuria.* In this section the cases investigated were divided into two classes: (1) Cases of "initial albuminuria" occurring during the first eight days of the fever, while the symptoms were still acute. (2) Cases of "late albuminuria" occurring at any subsequent period when the more acute symptoms were subsiding or had already disappeared. This classification was confessedly arbitrary, yet might be found of some practical value. II. *Its frequency.*—On account of the limited number of cases examined, the results of the investigations upon this point were not, in themselves, of any great importance; but the frequency of mild and evanescent attacks of nephritis in scarlet fever was brought out very distinctly, as would be seen from the tables appended to the paper. The evidence seemed to favour the view that *nephritis is a feature of scarlet fever almost as essential as the rash or sore throat.* III. *The relations which blood and albumen bear to each other in the urine of scarlatinal nephritis* were of importance mainly in bringing out the fact that the so-called "pre-albuminuric stage" is a condition which is of somewhat infrequent occurrence, and in demonstrating the existence of what might be called a "post-albuminuric stage," in which the urine had characters very similar to that of the "pre-albuminuric stage." IV. *"Pre-albuminuric stage,"* so called. In this section the views brought forward differed considerably from those generally accepted, for the presence of albumen as well as of hæmoglobin in this stage was demonstrated. The same was found to be the case in the "post-albuminuric stage." The presence of blood-corpuscles and of casts in both stages was also shown. V. In this section *treatment* was briefly touched upon.

The PRESIDENT, in proposing a vote of thanks to the author of the paper, said that the Society was under obligations to Dr. Thomson, who had come all the way from Glasgow to read this paper. Its publication would have good results, as showing the value of the frequent and systematic examination of the urine in scarlet fever. The severe cases of chronic Bright's disease, which so frequently came under observation in an incurable stage, would be less frequent if Dr. Thomson's example were followed. He related how he had recently seen a young man who believed himself in perfect health until his sight began to fail, and who, on consulting an oculist, was found to have albuminuric retinitis. On examination, he was found to have extensive and incurable kidney mischief, which dated from an attack of scarlet fever very many years previously. As to picric acid as a test, he still thought it the most delicate and the most reliable. He did not think it produced any precipitate in normal urine which could be mistaken for albumen.

Dr. WEST congratulated himself on having listened to so excellent and suggestive a paper at one of the first meetings of the Society at which he had been able to be present since his permanent return to practise altogether in town. He congratulated the Society on the advances made in this department of practice, and on the greater accuracy of the methods of examining the urine which had come into practice "since you, Mr. President, and I were young." The paper seemed quite to establish the fact that albuminuria is part and parcel of the disease, just as is the rash or sore throat. The great differences which were reported in the percentage of albumen in different epidemics, ranging from 4 to 80 per cent., doubtless depended on varying degrees of accuracy in making the observations. Dr. West thought there might be something of truth in the supposed effect of cold on the skin in checking secretions and interfering with the circulation. He referred to the period of onset of the albuminuria, and also to the unfavourable prognosis which a large quantity of albumen in urine of a low specific gravity led to.

Dr. W. H. DICKINSON joined his thanks to those of previous speakers; he was at one with the author on almost all points. As regarded picric acid, it was no doubt a most valuable test, and would not only discover albumen when present, but, he thought, also sometimes when it was not present. The mercuric iodide was a still more delicate

test. On the whole, he thought "our good old friend, nitric acid" was still the most ready, valuable, and reliable test we had. He agreed with Dr. West that the albuminuria is part of the disease and not the effect of merely catching cold. Contrary to the views of some authors, he thought there was often less proportionate albuminuria in the severe forms than in some milder cases. He did not think that desquamation bore so very directly on albuminuria as was generally believed. The most persistent cases of Bright's disease were those which commenced in cases where there was no dropsy and nothing to suggest albuminuria. Would the present more delicate tests have detected albuminuria? Lastly, he would just express his own opinion that the plan often practised of inuncting certain substances, and so stopping the pores of the skin, was not a good practice, or one so free from harm as usually taught.

Dr. JOSHUA EDWARDS said that, reference having been made to the concentration of the urine in order to detect albumen, he could remind the Society of a paper which had appeared in one of the recent numbers of the *Berliner Klinische Wochenschrift*, in which the author stated that albumen could be discovered in any urine, provided it were concentrated; the test used was the ferro-cyanide of potassium.

Dr. DOUGLAS POWELL would like to have heard something about the surroundings of the patients, the temperature of the wards, as to whether they kept their beds and how long, and as to their clothing. He was inclined to think that if cases could be classified on these lines some useful information could be obtained; he could not believe that the poison attacked the throat in some cases, the skin in others, and the kidneys in others; the asserted differences in the percentage of albuminuria much depend on other causes than this.

Mr. FOWLER had enjoyed considerable opportunities at the Fever Hospital during the past four years of testing the urine in fever cases. He had found its appearance most frequently towards the middle or end of the third week, and chiefly in those cases where the temperature had been high. Excluding very slight cases, and those in which it might be traced to the administration of drugs, albuminuria had occurred only in 14 per cent. of the cases. The treatment of scarlet fever should be directed to prevent albuminuria; and, seeing that its occurrence could be prevented, he did not agree that albuminuria was any essential part of the disease. As to the effect of weather, they had found, when the weather was cold and the ventilation could be well effected, albuminuria was less common than when, the weather being warm and stagnant, efficient ventilation could not be secured. He did not approve of the usual three weeks in bed; it tended to weaken patients and to predispose to albuminuria, whereas, when well fed and kept in the ward, albuminuria occurred less frequently; this applied especially to children, who could not be kept still and covered up if they were in bed.

In reply to Dr. WEST—

Mr. FOWLER said he did not think that age made any difference as regards the incidence of albuminuria.

Dr. THOMSON briefly replied.

The Society then adjourned.

## SOCIETY OF PHYSICIANS OF VIENNA.

FRIDAY, OCTOBER 16TH, 1885.

Professor ARLT, President, in the Chair.

### *A New Form of Cutaneous Tuberculosis.*

DR. RIEHL, late Assistant of Professor Kaposi, read a communication on a new form of tuberculosis of the skin. He first mentioned the different skin affections which had been recognised as of a tuberculous nature, as the sub-acute miliary form, which had been first observed by Jarisch, and which had generally been accepted as truly tubercular; besides lupus and serofuloderma, which were not unanimously admitted to be tubercular in origin, though

tubercle-bacilli had been found in them. Dr. Riehl wished to bring under notice a fourth form of tuberculosis of the skin, which he had the opportunity of observing in Professor Kaposi's clinic, and which had not been described before. The disease consisted in the presence of round *plaques* of a warty character, and sometimes resembling "ichthyosis hystrix"; in other places they had the appearance of horny warts, and in others a more inflammatory character. Each plaque was surrounded by a bright red halo which disappeared under the pressure of the finger, and was not infiltrated, it being only slightly, if at all, raised above the level of the surrounding skin. After some days the plaques presented very superficial pustules, which soon burst and became covered with crusts which in course of time fell off. The skin, which had before been smooth, became wrinkled and uneven, and from five to six weeks later presented papillary excrescences covered with horny substance. At the same time he observed a discharge of pus, either from pustules or from points which could not be microscopically distinguished. Sometimes he also observed an acute inflammation of the *plaques*; they became red and painful to touch, and after few days the inflammation disappeared. Some weeks after the development of the papillary excrescences, the process began a retrogressive metamorphosis. The discharge of pus ceased, the masses of epidermis became quite cornified, the papillomata increased in size, and the *plaques* assumed the appearance of horny warts or of the papillary excrescences which are met with in "ichthyosis hystrix." The patches often remained in this stage for some months; the excrescences disappeared gradually, the spots became flatter, and finally the horny masses fell off, and there remained a small white cicatrix. Dr. Riehl had observed this affection hitherto only on the hands and the forearms, in fifteen cases. The *plaques* were to be seen most commonly on the back of the hand and the extensor aspect of the arm; much more rarely on the flexor aspect and the palm of the hand. The patients affected with this disease were all healthy, robust adults, the youngest being 19 years of age, the oldest 45. None of them had any other symptoms of tuberculosis or of serofula. A male patient with tuberculosis of the skin had died in Professor Schrötter's wards from chronic kidney disease, and no trace of tubercle had been found in his organs; a second case died outside the hospital from carcinoma of the tongue. Of his 15 cases three occurred in women, all of them cooks; the rest were males. Dr. Riehl regarded it as peculiar that he had only met with this affection in individuals who had to do with animals, living and dead. Six of the male patients were butchers, three coachmen, and the rest had other occupations which involved continued intercourse with animals. The affection was an excessively chronic one; none of the cases observed had lasted less than two years, in one case the affection had lasted even for fifteen years. The course of the relapses was still slower than that of the primary efflorescence.

The histological examination had been made in conjunction with Dr. Paltauf, assistant to Professor Kundrat. The chief alterations occurred in the superficial layer of the cutis, especially in the "stratum vasculosum subpapillare." This was nearly absent, the abundance of vessels usually met with in this situation being replaced by infiltration centres consisting of granulation tissue and representing isolated nodules containing granulation cells in their periphery, and epithelioid and giant cells of variable size with many nuclei in the centre. Most presented caseous change in the centre and this continued quite diffusely into the exterior layers. Besides this infiltration the *plaques* also presented the appearances of chronic inflammation, not only in the superficial layers of the cutis, but also in the subcutaneous tissue. The disease could be distinguished from "lupus" by the fact that in its case the infiltration occurred in the superficial layer of the cutis, whereas in "lupus" the infiltration was found in the deeper layers of the cutis and in the subcutaneous tissue. Further the papillomata were only met with in lupus after ulceration had taken place, whereas in the present affection there was never any ulceration. Again, a lupus nodule never suppurated, whereas this was often the case with the nodules of this new disease, and in this they underwent a

tubercular process. In addition, there were also differences in the shape of the tubercles, the giant cells, and in the character of the inflammation. The histological diagnosis was "tuberculosis of the skin" on account of the giant cell tubercles, with the central caseous degeneration and the presence of tubercle bacilli. He had examined several cases for micro-organisms and found in each of them tubercle bacilli and a certain variety of cocci. The bacilli were more numerous than in "lupus" and were contained either in epithelioid or giant cells sometimes; they were also found in granulation cells. The cocci were to be found at any point where there was acute inflammation, and always near the epidermis. Dr. Riehl remarked that no affection had been described which would correspond to this disease. Leloir had described a similar affection, which was also confined to coachmen, butchers, &c., and in which there were also giant cells and granulation tissue. He called that disease form "Périfolliculite suppurée et conglomérée en placard," and hence it might be assumed to have been a primary affection around the follicles, to which Dr. Riehl's affection had no relation. The course of the affection in Leloir's case was also different; in the first case the disease reached its maximum in eight days and disappeared in 14 days more. Leloir did not seek for tubercle bacilli. The only affection which resembled Dr. Riehl's disease was the corpse wart (*Leichen-Warze*) found in *post-mortem* room attendants, anatomists, &c. No distinct description of these growths was to be found in the manuals of dermatology and surgery. Neumann, however, had paid some attention to them, and quoted a case in which C. Heitzmann had observed an infiltration of the papillary stratum and granulation tissue, with proliferation of the epidermis. Cornil classed the "corpse wart" among the forms of tuberculosis, and Besnier quoted two cases to prove that the affection was the starting point of a general tuberculosis of which the patients had died later on. But this was not absolutely certain, as both individuals came of families affected with tuberculosis. Cornil had declared that the presence of the tubercle bacillus in the corpse wart had not hitherto been proved. Dr. Riehl and Dr. Paltauf had examined only a single "corpse tubercle," the bearer of which was Dr. Kolisko, assistant to Professor Kundrat. They found here giant cells situated in inflamed tissue, besides papillomata with horny masses, tubercle bacilli, and the above-mentioned cocci, which proved to be "Staphylococcus aureus et albus." Some time ago Dr. Karp had, independently of Dr. Riehl, found tubercle bacilli in corpse warts. As to the ætiology of this disease, it was probably due to the direct inoculation of the tubercle, as the patients were otherwise healthy and they had to handle substances which might possibly contain the tubercular poison. It was difficult to say why no general infection occurred in such cases, but different authors had stated that the cutis was an unfavourable soil for the propagation of tuberculosis, whereas the subcutaneous tissue was very favourable for it. In inoculating animals, nodules in the subcutaneous tissue were very easily produced, but never in the cutis itself. Our experience of the inoculation of tubercle in man was not extensive. There had recently appeared a work by Verchère, who collected all the published cases in which corpse tubercle was also present. Czerny had published a remarkable case in which the servant of a tuberculous physician introduced a small quantity of his saliva under her skin by breaking a spittle, and who afterwards became affected with an inflammation of the tendon sheaths and suppuration of the glands, which proved on examination to be tuberculous. As in many other affections, the clinical diagnosis could not be made from a single symptom or stage of the disease; it would be difficult to decide in the stage of cornified warts whether the case was one of the disease in question, or of ichthyosis hystrix. But the cases observed presented many stages which greatly facilitated the diagnosis. The prognosis, according to present clinical knowledge, was not unfavourable, as there never occurred any general infection; but it could not be denied that this might possibly sometimes occur. The affection passed off spontaneously, though slowly; though relapses occurred. If the disease was treated, the prognosis was still more favourable. Dr. Riehl at first

applied macerating agents, *e.g.*, a 10 per cent. salicylic soap-plaster, under which the crusts became softer and the *plaques* became flatter, but no recovery resulted. Later on he scraped the *plaques* with the sharp spoon, and applied an iodoform dressing; the cases which had been treated in this way recovered completely. Dr. Riehl recommended the galvano-cautery or the actual cautery, as the danger of propagating the affection to other parts was thereby avoided. Dr. Riehl proposed for this disease the name of "Tuberculosis verrucosa cutis."

The paper was illustrated by numerous specimens, including the hand of the patient who died in Professor Schrötter's wards, as well as specimens illustrating the histology and bacteriology of the disease.

---

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, NOVEMBER 5TH, 1885.

T. MORTON, M.D., President, in the Chair.

---

### *Case of Hemiplegia, with Paralysis of Third Nerve on the same side.*

DR. SIDNEY PHILLIPS exhibited a man, æt. 37, who had contracted syphilis seven years ago, and who, in addition to occasional headache, had had three epileptiform seizures within the last twelve months. In August last the right third nerve became paralyzed, and a few days later also the right limbs and the right facial muscles. Iodide of potassium (in doses of 25 grains in combination with drachm-doses of liq. hydr. perchlor.) cured the patient of his hemiplegia, but produced only a very slight improvement of the ptosis. Whilst under treatment, the patient had two attacks of painless conjunctivitis of the right eye, which temporarily aggravated the ptosis. Dr. Phillips considered that in this case the lesion was double, the hemiplegia being due to disease in the left side of the brain, whilst the right third nerve was implicated at the base of the skull. The conjunctivitis was probably due to pressure on the ophthalmic vein.

### *The Treatment of Lacrimal Fistula.*

Mr. JULER showed two cases of chronic ulceration of the face, resulting from lacrimal fistula. The treatment, which had been most successful, had consisted (1) in removal of the obstruction, (2) in complete removal of the thickened tissue. A Volkmann's seop was used for scraping the ulcerated surface, and skin grafts had led to rapid healing without any noticeable scarring or contraction of the skin.

### *Passage of large Gall-stones; Recovery.*

Dr. W. F. CLEVELAND read notes of a patient, æt. 80, who, after a severe biliary colic twenty years ago and a second attack eight years later, had become the subject of very frequent and very troublesome jaundice. Gall-stones had been searched for in vain; nevertheless, confident in their presence, Dr. Cleveland prescribed a brisk saline aperient which brought away several large gall-stones. The patient did well.

### *Death from Impaction of a very large Gall-stone in the Ileum.*

This communication was made by the PRESIDENT on behalf of Dr. F. Hill. The stone, which was of very large size, completely blocked the bowel. The patient, æt. 90, died within three days.

### *An unusual case of Empyema.*

Dr. W. H. BLENKINSOP described the case of a man, æt. 60, of healthy descent, but subject to rheumatic gout, who had suffered from an old ulceration above the left clavicle, which refused to heal. Under the influence of cold weather, the left apex became the seat of friction and of dulness on percussion, and two weeks later the presence of pus in the pleura was inferred from the bulging of the

three upper intercostal spaces, and from the general symptoms. A teacupful of pus was removed from the chest, and the sinus was probed and found to take the direction of the chest cavity, passing along the posterior surface of the scalenus anticus. The patient did not improve; caries of the sternum led to falling inwards of the end of the clavicle and to pressure upon the trachea, and the patient died. The autopsy showed disorganisation of the left upper lobe, limited empyema of the upper third of the left pleural cavity, and free communication between the empyema and the wound in the neck.

*Cancer of the Pleura and Effusion in a case of Latent Carcinoma of the Spine.*

Dr. EWART gave an account of the clinical history and of the *post-mortem* examination of the subject of this communication, a marble polisher, *æt.* 59. Pleural effusion was diagnosed from the first, but, the amount of chest pain and tenderness being in excess of the average, disease of the spine was suspected, and a surgical opinion was called in—with the result that no spinal disease could be discovered. After a lapse of three weeks, the patient not having improved, but having lost much strength and weight, and suffering from shooting pains down the legs and from increased tenderness of the chest, Dr. Ewart reverted to his former impression and diagnosed disease of the spine, probably cancerous. Throughout the case there was no tenderness of the spine, no pyrexia, no paralysis, but a good deal of pain on movement. After death small cancerous nodules were found in the pleura, the bodies of the vertebræ were infiltrated with encephaloid material and bulged anteriorly. The spine was curved, without any angular distortion. The dorsal nerves were not directly pressed upon, but surrounded with cancerous infiltration, and a few were invaded by the latter. The primary disease was a cancerous tumour of the bladder, which had given rise to no symptoms.

LIVERPOOL MEDICAL INSTITUTION.

THURSDAY, NOVEMBER 5TH, 1885.

Dr. GEE, President, in the Chair.

Dr. HOPE showed a branched renal calculus, weighing four ounces, removed *post-mortem* from a woman 52 years of age. The opposite ureter was blocked by a calculus the size of a hazel-nut, whereby the kidney of that side of the body was disorganised. The patient had suffered from renal colic for many years and died with symptoms of uræmia.

Mr. G. HAMILTON showed some excellent casts that he had made of spina bifida and of meningocele.

Dr. ALEXANDER showed nearly all the joints of a sailor, *æt.* 30 years, who had been bed-ridden for five years with rheumatism. All the joints of the hands and feet, ankles, wrists, knees, elbows, and hips were completely ankylosed. The shoulder joints were moveable to a slight extent, and the opposed surfaces of these joints, where movement took place, were eburnated. The inferior maxillary articulations were moveable and had their cartilages eburnated. The spinal, pubic, and sacro-iliac joints were apparently healthy. The occipito-atloid joints were slightly eroded. The illness commenced nine years before death during a voyage from Australia, when he suffered from scurvy and rheumatism. He had been the subject of gonorrhœa previously.

Dr. MACFIE CAMPBELL showed a patient whom he had successfully treated for empyema by tapping the chest, and where he had secured free drainage by removing a half-circle of bone from the upper border of one of the ribs. The hole thus formed allowed a free discharge of matter until the empyema was quite cured.

Mr. RUSHTON PARKER showed a patient from whom he had removed a sarcomatous growth from the right upper jaw. In doing so, he was able to leave a portion of the jaw to support the cheek and nose, thus avoiding the deformity that resulted where the whole of the upper jaw has been removed. In this case the opposite upper jaw had been previously removed, and the prevention of the

deformity resulting from a double complete removal was a very important matter.

Dr. CATON then read a paper on the Pathology and Treatment of Chorea. After an able review of the received pathology of the disease, Dr. Caton went on to describe the morbid anatomy, and then said that, from a careful consideration of the *post-mortem* changes, he had come to the conclusion that chorea depended upon an inflammation of nerve tissues; the causes of this inflammation might be rheumatic, embolic, tubercular, or emotional as after a fright. He supported his position, saying that chorea often terminated as myelitis (that myelitis did not often produce chorea arose from its destructive tendencies), that fever often accompanied chorea, that complete and rapid recovery of nerve tissue might occur after inflammation, just as complete and rapid recovery of lung tissue might occur after inflammation, and that, as a general rule, at autopsies on cases of chorea clear signs of inflammation of different parts of the nervous system were found. The inflammatory process producing chorea might occur in the brain, spinal cord, or in the peripheral nerves. The treatment recommended by the author consisted of rest in bed, simple diet without tea or coffee, the induction of sleep, if necessary, by chloral, restraint of the muscles and limbs by bandages and splints, and arsenic internally, which Dr. Caton looked upon as a specific in progressive doses.

In the discussion which ensued, and in which Drs. Glynn, Waters, Barr, Archer, and Dickinson took part, a difference of opinion existed as to the drug most efficacious in chorea. The first two speakers thought sulphate of zinc the best, Dr. Barr spoke highly of strychnine, and the others agreed with Dr. Caton that arsenic was the best.

INVENTIONS AND IMPROVEMENTS.

A NEW PISTON FOR SYRINGES.

MESSRS. MAYER AND MELTZER, the well-known surgical instrument makers, of 71, Great Portland Street, have submitted to our inspection a patent self-lubricating and

self-adjusting piston for syringes, &c. The piston consists of two phlanges, the side being made of a seamless band of leather and the interior charged with vaseline. The syringe is lubricated by turning the knob or ring of the syringe which is attached to a screw which passes through the piston rod, and, acting upon the phlanges of the piston, brings them into closer contact, thereby pressing the vaseline (with which the piston is charged) through the pores of the leather, lubricating the syringe, and at the same time causing the leather of the piston to distend and adjust itself to the cylinder of the syringe. The vaseline with which the piston is charged does not in any way affect metal (as would be the case if oil were used), but preserves it and prevents it from corroding, so that there need be no fear of verdigris or other deleterious matter affecting the syringe. Further, the syringe may be laid by for any length of time, and may be taken up in good order and ready for immediate use; the vaseline preserving and keeping the leather soft. The advantages of this invention as applied to enemas, hypodermic injectors, aspirators,

stomach pumps, &c., &c., will be readily appreciated, especially for use in hot climates, where leather or other material used for pistons (with the old means of lubrication) so soon perishes, leaving the instrument corroded with verdigris and perfectly useless.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Thursday, the 12th instant. The minutes of the last meeting were read and confirmed. The President then reported the meeting of the Fellows and Members on the 29th ultimo, and the resolutions then carried were submitted. The following resolutions were then *unanimously* passed:— (1) "That the Council think it not desirable to diminish the privileges of the Fellowship of the College by depriving Fellows of the exclusive rights of electing to the Council and of being eligible to become Members thereof." (2) "That in the opinion of the Council it is quite impracticable for the Council to act on the second resolution passed at the recent meeting." (3) "That it be referred to the President and Vice-Presidents to prepare a statement to be laid before the next meeting of the Fellows and Members; that it is advisable that such statement shall clearly convey the Council's decided opinion that it would not be for the good of the College that the Members generally should vote at the election of Members of Council, and shall explain the reasons for that opinion; and that the statement shall also include the reasons why it is impracticable to give effect to the second resolution. Upon the recommendation of the Committee of Management of the two Colleges, it was agreed that the Ceylon Medical College be added to the list of recognised Medical Schools. It was resolved to hold an extraordinary meeting of Council on Tuesday next (17th) at 4 p.m. for the transaction of other business, which was allowed to stand over, and for the consideration of the following resolution to be proposed by Mr. Hutchinson, "That the Council do take into consideration proposals for widening the basis upon which the Fellowship is obtained." There was but one absentee from the Council, Mr. Cooper Forster, and he would have voted in favour of the above resolutions, had he been present.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations, were admitted Licentiates in Dental Surgery at a meeting of the Board on the 6th inst., viz.:—

Richard Baxter Booth, Kennington; Edward Pyemont Collett, St. Leonards-on-Sea; Allan Lindsay Goadby, Henley-on-Thames; Albert Helyar, Hampstead; Louis Jeffery, Campbell Terrace, N.; John Maberley, Keppel Street, W.C.; Robert May, Kennington Park; Harold Murray, Hampstead; William Palethorpe, Albert Street, N.W.; Samuel Edward Pedley, Railway Approach, S.E.; George Oliver Richard, Birmingham; Robert Wynne Rouw, Lewisham; Louis Edwin Sexton, Plymouth; Tom Gill Williams, Brockley.

All the candidates passed.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, November 5th, 1885:—

James Anderson, The Abbey, Abingdon; David Williams, Pontgarreg, Johnstown, Carmarthen.

The following also passed in the Science and Practice of Medicine, and received a certificate to practise:—

Thomas Francis Shackleton, Grassmere, Honley Road, Catford.

The following gentlemen also on the same day passed their Primary Professional examination:—

Arthur Blair Avarne, London Hospital; John Conyers Bell, Guy's Hospital; Charles Ernest Thomas, Middlesex Hospital.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The Examinations for the Triple Qualification of these bodies in Edinburgh were held in October, when the following gentlemen passed the Third Examination, and were admitted L.R.C.P., Edinburgh, L.R.C.S., Edinburgh, and L.F.P. and S., Glasgow:—

William Macanish, New South Wales; Samuel Ludovici Anthonicz, Ceylon; William Beecham, Wigan; Salvatore de Candia, Waterford; Thomas Sydney Davies, Monmouth; John Benjamin Drieberg, Ceylon; Blenman Buhôt Grayfoot, Barbados; James Carnegie Figg, Bo'ness; William Foreman, Wigan; Hermann

Gerhard Hilbers, Brighton; François Léon Keisler, Mauritius; Michael Columbkil Hannan, Limerick; William Henry Klock, Quebec; Morris Griffith Davies, Carnarvon; Hezlett Hamilton Marshall, New South Wales; James Macgregor, Tralee; James Macky, Londonderry; Frank Charles Pereira, Bangalore; Michael John Petty, Buenos Ayres; Thomas Kerslake Robinson, Melbourne; William Jackson Hooke Macgillivray, Glasgow; Robert Dickson Shiels, Dunbar; Percy Belford Travers Stubbs, South Africa; John Sutherland, Glasgow; John Robert Talbot, Ballina, and George Thomas Woods, Birmingham.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—Double qualification. During the recent sittings of the Examiners the following gentlemen passed their Final Examination, and were admitted L.R.C.P., Edinburgh, and L.R.C.S., Edinburgh:—

John George Brown, Cork; Alfred Valentine Browne, Belfast; Thaddeus Cachick Avetoom, Calcutta; John Cromie, Co. Down; John Hepburn Dudgeon, London; Robert Michael Forde-Cloyne; Edward John Hawkes, Brighton; Richard Kelly, Colongford; Joseph Cocker Hasler, Blackburn; Thomas Patterson-Co. Donegal; Richard Power Rankin, Australia; Edmund John Nuttall, Rochdale; John Joel Mason, Bollington; Charles Oliver Stanwell, Rochdale; Joseph Spilsbury Smith, Sierra Leone; Douglas Lawson Thomson, Hampshire; William Valentine, Lancashire; Herbert Henry Wilde, Weston-super-Mare, and John Thomas Woodside, Cultra, Belfast.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—During the recent sittings of the Examiners the following gentlemen passed their Final Examination, and were admitted Licentiates of the College:—

Charles Edward Glascott, Constantinople, and Frank Charles Osborne, Bognor.

THE ACADEMY OF MEDICINE IN IRELAND.—At the Annual General Meeting of the Fellows, held in the Hall of the King and Queen's College of Physicians on Friday, October 30th, 1885, the following officers of the Academy were elected:—*President*, Robert MacDonnell, M.D., F.R.S. *General Treasurer*, George F. Duffey, M.D. *General Secretary*, William Thomson, M.D. *President of the Medical Section*, F. R. Cruise, M.D., *President of the King and Queen's College of Physicians*; *Secretary*, Alexander N. Montgomery, M.K.Q.C.P. *President of the Surgical Section*, Sir Charles A. Cameron, M.D., *President of the Royal College of Surgeons in Ireland*; *Secretary*, William Stokes, M.D., *Vice-President of the Royal College of Surgeons*. *President of the Obstetrical Section*, Thomas More Madden, M.K.Q.C.P.; *Secretary*, William Cox Neville, M.D. *President of the Pathological Section*, Thomas Evelyn Little, M.D.; *Secretary*, John Benjamin Story, M.B. The other members of the Sectional Councils who were elected were:—*Medical Council*, J. Hawtrey Benson, J. Magee Finny, Samuel Gordon, T. W. Grimshaw, Richard A. Hayes, Henry Kennedy, J. W. Moore, William Moore, and H. C. Tweedy. *Surgical Council*, John K. Barton, William Colles, Charles Coppinger, Henry Gray Croly, Kendal Franks, Edward Hamilton, Edward Dillon Mapother, Edward Stamer O'Grady, and William Thornley Stoker. *Obstetrical Council*, Lombe Atthill, John A. Byrne, J. J. Cranny, Robert F. Dill (Belfast), Andrew J. Horne, George H. Kidd, R. D. Purefoy, William Roe, and William J. Smyly. *Pathological Council*, Charles Bent Ball, Wallace Beatty, Edward Halloran Bennett, Arthur H. Benson, Anthony H. Corley, Arthur Wynne Foot, John V. Lentaigne, John Mallet Purser, and Walter George Smith. The following officers of the Sub-section of State Medicine were elected subsequent to the general meeting:—*Chairman*, Archibald H. Jacob. *Committee*, Sir Charles A. Cameron, *President of the Royal College of Surgeons*; Ephraim MacDowel Cosgrave, Thomas Wrigley Grinshaw, Charles Frederick Moore, John William Moore, and Henry Colpoys Tweedy. The officers of the Sub-section of Anatomy and Physiology have been appointed as follows:—*Chairman*, Francis Tydd Heuston; *Committee*, Henry St. John Brooks, Humphrey John Broomfield, Daniel John Cunningham, John Freeman Knott, John Mallet Purser, and John Alfred Scott.

UNIVERSITY COLLEGE, LONDON.—The first general meeting of the University College Society was held at the College in Gower Street on Tuesday evening last. The Secretary (Professor Morley), in his report, showed that the Society meant to be, and had already to a great extent, become an organization that united all members of the

College, both teachers and students, for the furtherance of social intercourse and fellowship. The number of its members at the close of the Session 1884-5 was 998, and the subscription, which had been placed at the low sum of one shilling, had been sufficient for its purposes. Eight assemblies have been held by the Society during the year now closed, at which the average attendance has been about 800. Other parts of the work of the Society have been the furnishing of the common room of the College for men-students and the laying of two lawn-tennis courts in the quadrangle adjoining the College. The Committee is now endeavouring to bring about the union of all the athletic societies of the College, and to find means for providing a ground within easy access of the College for the recreation and sports of the students. A representative committee, comprising professors and students in each of the faculties, Fellows, and old students of the College, was next elected for the ensuing session, and after the business of the evening a social gathering, at which some 600 persons were present, took place. An interesting collection of pictures painted by students of the Slade School was on view, amongst which we may notice one or two oil paintings exhibited at the Royal Academy and a series of etchings by W. Strang. The proceedings terminated by a concert given in the Botanical Theatre.

HOSPITAL SUNDAY IN DUBLIN.—Sunday last, November the 8th, was "Hospital Sunday" in Dublin, and for the twelfth time in yearly succession a collection was made in all the Protestant churches and Jewish synagogues of the Irish metropolis and its suburbs in aid of the Dublin hospitals. Among the largest collections at the midday services were the following:—Christ Church, Leeson Park, 167*l.* 19*s.* (Preacher, His Grace Lord Plunket, Archbishop of Dublin), St. Matthias' Church, 166*l.* The day was very fine and bright. On the afternoon of the previous day the annual hospital football match took place in charming weather, with the result that a sum of about 60*l.* was secured for the fund.

BRITISH GYNÆCOLOGICAL SOCIETY. — At a special meeting of the Council of this Society on November 11th the following resolutions were unanimously passed. (1) That the Council deeply regret that they feel it incumbent on them to accept the resignation of Dr. Heywood Smith of the office of Secretary of the British Gynæcological Society. (2) The Council desire to express their thanks for the distinguished services he has rendered to this Society, and their belief that in what he did in reference to the Armstrong case he was actuated by what he believed to be the highest motives, while committing a grave professional error.

PHARMACEUTICAL SOCIETY OF IRELAND. — At the November stated monthly meeting of the Council the following gentlemen were appointed Examiners in the room of those retiring in consequence of their five years' term of office having expired:—*Examiner in Arts*, H. C. Tweedy, M.D., University of Dublin, F.R.C.S.I. *Examiner in Materia Medica and Botany*, W. Whitla, M.D., Queen's University, L.P.S.I. *Examiner in Pharmaceutical and General Chemistry*, H. C. Draper, F.C.S.

GLASGOW.—The appeal of the Directors of the Glasgow Western Infirmary for 5,000*l.* to make up a deficit in the accounts of the current year has been so generously responded to that seven thousand pounds have been poured into the coffers of the Institution.

DR. WILLIAM PIRIE, Principal of the University of Aberdeen, died on Tuesday, in his 82nd year, of paralysis. He was appointed Principal in 1877, in succession to Dr. Campbell. By his death the University has lost one of its best friends.

HONOURS TO A MEDICAL MAN.—The Grand Cross of Isabella the Catholic has been conferred on Don Manuel Ortega Morejón, medical officer and secretary to the Municipal Charitable Committee of the City of Madrid.

A PHARMACIST ON THE PHARMACOPŒIA. — Now that the Pharmacopœia has been two months in the hands of the profession and the public, it may fairly be said that sufficient time has elapsed to allow of its merits

and demerits being clearly recognised. Although scattered criticisms have been offered by individuals to various portions of it, some of which criticisms have already been noticed in these pages, the first serious attempt to review the work as a whole was made on Wednesday evening last, before the Pharmaceutical Society, by Mr. Charles Umney. By his former criticisms of its predecessor, Mr. Umney has shown himself well qualified as a practical pharmacist for the task which he has so lately accomplished, and we must congratulate him not only on the matter of his paper, but on the courteous and impartial tone which pervaded all his observations. He knows the difficulties under which the editors have laboured, and he showed himself most anxious to render praise where praise was due. The assay of drugs with a view to standardizing their active principles he regarded as a step of the utmost importance, and he considered that the recognition of this principle was one of the leading features of the new edition, and we may add it is a principle the acceptance of which Mr. Umney has urged for many years. Turning to the details of the work, he divided his remarks into four portions, the first relating to the omissions of drugs formerly official; these met with his unqualified approval, the remedies which have been so discreetly removed had all fallen into disuse, and some such as arca-nut never ought to have found a place in the Pharmacopœia. His second group included the drugs and preparations that have been left unaltered, and here too his remarks were brief, and dealt with points which concern the compounder rather than the prescriber. The ferrum tartaratum and syrupus ferri iodidi are two of the compounds into the mode of preparation of which changes have been introduced that are open to question. In his third group he included those drugs and preparations which have been retained in the new edition, but which have been altered as to strength, character, or tests since the last edition. Thus additional precautions have been adopted in the preparation of ætetic ether to prevent contamination with free acetic acid; the aqua laurocerasi has been standardized so as to ensure its percentage of hydrocyanic acid being uniform; the old emplastrum belladonnæ being impracticable, it is now directed to be made with the alcoholic extract of the root. Mr. Umney pointed out reasons why it would have been better if the leaves had been selected for the purpose instead of the root. There are several minor changes in this group under the head of the extracts and the liquors to which Mr. Umney drew attention, but which we need not stop to consider; the chief complaint he has to make, and it raises a serious difficulty, relates to the standard now fixed for opium. It is decreed that powdered opium shall not contain less than 9½ per cent. or more than 10½ per cent. of morphine. What is to be done with samples of opium which contain a higher percentage of morphine? Mr. Umney is too loyal to the Pharmacopœia to advise his friends, when they consult him, to dilute their opium down to the required strength of morphine, but there can be no doubt that others, not actuated by the same high motives which govern his conduct, will not hesitate to adulterate their opium on discovering that it is, so to speak, over-proof. The other changes in this group do not call for special notice, except that by the substitution of hydrochloric for sulphuric acid in the preparation of tincture of quinine it is hoped that the formation of a precipitate will be avoided. The additions to the Pharmacopœia constitute the least satisfactory part of the work from the pharmacist's point of view: at least such would appear to be the case, since Mr. Umney has several faults to find in this section of his subject. That he and his brother pharmacists should resent the introduction of patent remedies is intelligible enough, and we quite share his objections to ready-made physic as a rule; but it must be remembered that in adding chlorodyne to the list of official preparations the editors of the Pharmacopœia are only following the example of those who went before them, as Plummer's pill and James's powder will testify. The introduction of citrate of caffeine seems to have been a mistake, inasmuch as those learned in these matters tell us that such a compound cannot exist, for at the moment of their solution they resolve themselves into caffeine and acid. Chrysarobinum would appear to have been mis-named or badly described, since Mr. Umney

spoke of having samples of it from ten different wholesale houses, not one of which answered to the description and tests given. In the directions for the preparation of the liquor ammonii acetatis fortior an error occurs, for which, with some ingenuity, Mr. Umney succeeded in finding a simple remedy. The introduction of the paraffinum dnrum he regarded favourably, though the range of melting point, viz., from 110° to 145°, he considered to be much too wide. Altogether Mr. Umney has performed his by no means easy task gracefully, and we have no doubt that when the first revision takes place his suggestions will receive all the attention which they deserve.

**STUDY OF FOREIGNERS IN BERLIN AND VIENNA.**—Dr. Cushing, writing from Vienna in the *Philadelphia Medical News*, No. 9, observes that for persons repairing to Germany for the purposes of medical study it is of much importance to know which of these capitals should be preferred, and why. The Berliners, having acquired such great political and military supremacy, seem somewhat to resent also any doubt as to their scientific superiority. They regard Vienna as having lost ground, the scientific men not working hard enough and being too fond of indulgence and money; while living there is extremely dear. Every effort is being made to render Berlin the medical centre, not only of Germany, but of the world, and immense sums are lavished upon the institutions and hospitals for this purpose. Even now patients are flocking to this capital from all parts, many of whom would have formerly gone to Vienna. But with respect to foreign doctors, while they recognise the great distinction of the Berlin teachers, and that much can be obtained as a matter of courtesy there which must be paid for at Vienna, they still flock to the latter place. There they may concentrate their energy and work all day in one place, while in Berlin the hospitals lie so far apart that men lose much time. So, after a few weeks in Berlin, most of the American physicians find their way to Vienna, and when once settled down to work they stay as long as they can. And yet a course of study in Berlin is absolutely necessary for a complete study of almost any subject. Nowhere else can surgery be seen so thoroughly antiseptic, in principle and detail, and facilities are given not only for observing the operations, but all the dressings, which are not done in the wards, but in the theatre, or in a place arranged on purpose. With respect to the expense of living at Vienna, it is possible that this may be obtained cheaper of an inferior sort at Berlin, but, if a man wishes to live pretty much as he does at home as regards comfort, Vienna is just as cheap, and even cheaper. The assistant medical teachers in the schools, laying themselves out for teaching, expect to be paid for it, which is natural enough. The demand for medical instructors has produced a supply of excellent teachers, who are hard workers and usually speak English and French. They make no claim to be investigators in laboratories, but are clinical workers and clinical teachers. There are also investigators in Vienna, but foreigners see little of them, and, on the whole, they probably do not get so much support and encouragement as at Berlin. "In regard to fees for instruction, to me they seem eminently proper. To be sure, in the smaller German cities, in England, and largely in Berlin, a man who is polite and knows how to ask for and receive a courtesy can get a great deal of clinical instruction for nothing; and at first it is rather a shock to see that he is expected to pay for the same at Vienna. But where there are two or three hundred foreign physicians, all seeking clinical privileges, and many hardly willing to be civil in their manner of asking, patience soon ceases to be a virtue. The demand on the time of the assistants and docentes is so great that either they must close their doors to applicants or make their clinical teaching a matter of business. As a matter of fact, Americans prefer to ask for what they want, get it promptly, and pay for it, rather than to be always asking for favours and receiving courtesies, knowing that they are a source of inconvenience to the donor. That, however, also in Vienna a spirit of professional courtesy exists, and of kind instruction to foreigners clinically, gratis, if they know the language and come at proper time, I cheerfully and gratefully bear witness." "It was with some surprise," Dr. Cushing

continues, "that I found more opportunity to get courses and practical work on bacteria in Vienna than in Berlin. There are at least three laboratories, and two courses of lectures without laboratory work, open to foreign students, and there are some advantages in studying the subjects there as part of practical pathology. The glory of the Vienna School has long been in the intimate relations between pathological anatomy and diagnosis, and under the present able management there is no danger that the school will lose its renown. The concentration of picked cases from the whole empire in one vast hospital makes it easy for the physicians in charge, as well as for those studying here, to follow up every fatal case at the autopsy. Professor Kundrat, the successor of Rokitansky, has greatly enlarged the pathological institute, and with incredible labour has arranged, classified, and increased the pathological museum, so that it is now the finest in the world. The autopsies can be seen by all, and ten foreigners can carry on practical microscopical work in an adjoining room, learning to harden, stain, and cut all sorts of morbid tissues. Upstairs, besides the chemical, histological, and other laboratories, and the museum and library, there is a bacteria room, where three or four can work, studying, breeding, and making preparations of the various micro-organisms. It adds greatly to the interest of the work to be able to follow up cases from the wards to the autopsy-room, and thence to examine microscopically the pathological condition of the diseased organ, and in suitable cases to catch the bacteria in the act, so to speak, to breed them, isolate them, and prove their pathogenic power by inoculations on animals."

**VETERINARY SANITATION.**—Professor Walley chose this as the subject of his recent opening address at the Edinburgh Royal Veterinary College. After referring to the terrible results of rabies, the responsibility for which lay with those in whose hands was the power of instituting the necessary proceedings for the suppression of the malady, he went on to speak of the deadly effects of anthrax fever, and to urge the necessity for its being dealt with in an energetic and determined manner. Tuberculosis was, however, the most insidious of all these maladies, and from the fact that it might be transmitted from cattle to human beings by a variety of channels, it was the most important. Large numbers of cows in the last stages of the disease were to be found in the markets and cowsheds of our large towns every year, and many were sold to low-class butchers, and their flesh subsequently disposed of to sausage makers for the purpose of manufacturing their questionable delicacies; while many thousands of gallons of milk from such animals were consumed, and largely by the most susceptible of the population, young children. He knew no more disgusting sight than to see prepared for the sausage machine large quantities of flesh upon which were hundreds of the little bodies known as tubercles; and it was all the more sickening to the initiated when he reflected that every one of those little nodules was the home of a number of the organisms which possessed the power of propagating the disease. If that was the case with tuberculous flesh, which was usually submitted to a disinfecting process by exposure to heat, how much more forcibly did it appear as regarded milk, which was largely imbibed while cold. Few of the general public were aware that consumptive cows frequently gave a large quantity of milk, and that it had been proved to demonstration that such milk was often surcharged with the virus of the disease. Still fewer were cognizant of the fact that veterinary or other inspectors had no power to seize diseased animals exposed in public places for sale or found in dairies, unless they were the subjects of one of the contagious diseases recognised by the Privy Council, among which consumption was not included. He maintained that it was the duty of the Legislature to give the veterinary inspector authority to take possession of every animal found, either on farms, in dairies, or in markets, which exhibited pronounced evidence of the existence of organic disease.

**CASE OF GENERAL SUBCUTANEOUS EMPHYSEMA.**—Dr. Moschner relates in the *Berliner Klinische Wochenschrift*, September 21st, an example of this not very common affection. He was called on the 8th April to a robust man 63

years of age, who, when in a drunken condition on the previous evening, had fallen into the water. At first he did not seem injured, but about two hours afterwards he was seized with pain and dyspnoea, accompanied by high delirium, his entire body being greatly distended. When Dr. Moschner saw him a few hours afterwards he found his entire body completely distended with air, from his head to the points of his toes. The scalp furnished a loud percussion tone, as did the thighs and even the great toes. The eyes could not be opened, and the eyelids were converted into cushion-like tumefactions. Of the neck nothing was to be discerned, and from the mastoid process to the shoulder was all on a level. The thorax was surrounded by a mass of air several centimeters in size, and the abdomen was stretched like a drum. The scrotum was nearly the size of a man's head, and the penis double its natural size. At every part loud emphysematous crepitation was heard, rendering all attempts at auscultation of the lungs useless. No mark of external injury could anywhere be discovered, but the patient complained of a very painful spot over the third rib. Several punctures were made with a large trocar over the thorax, the air rushing out with a loud hissing, with relief to the dyspnoea; and, smaller punctures having been made in the scrotum, this was reduced to its normal size in about five minutes. Chloral was first administered to the patient to calm his excitement, and afterwards musk and wine were given as stimuli. In the course of four days the emphysema of the head and face had almost disappeared, although a moderate amount continued in the neck, thorax, and extremities, allowing of a fracture of the ribs and the spine of the scapula being detected. Three days later auscultation detected pneumothorax on the right side, and on the left pleuritis confined to the neighbourhood of the fractured scapula. During the whole time the temperature never exceeded 37.8° C., and the pulse varied between 76 and 94 beats. The appetite gradually returned, and twelve days after the injury the patient was able to leave his bed. Six weeks later he was almost entirely well, and was able to resume his alcoholic potations, complaining only of pain in the left side when over-exciting himself.

REGISTRATION RETURN OF BRUSSELS FOR 1884.—On the 1st January, 1884, the population of Brussels was 171,293, viz., 81,274 males and 90,019 females. There were during that year 5,504 births registered, viz., 2,785 male and 2,719 female. Of these births 3,947 (71.71 per cent.) were legitimate and 1,557 (28.29 per cent.) illegitimate. Of the legitimate births, the male were 1,993 and female 1,954; and of the illegitimate 792 male and 765 female. There were 89 twin-births, 38 male and 51 female, 50 legitimate and 39 illegitimate. The general natality amounted to 32.13 per 1000 inhabitants. There occurred during the year 5,350 deaths, viz., 2,767 males and 2,583 females. The proportion of the mortality was 31.23 per 1,000 inhabitants. Of the 5,011 deaths (abstracting 339 still-born) 3,291 took place at home and 1,720 in hospitals. Among children and celibates 2,903 deaths occurred, 1,322 in married persons, 9 in divorced persons, and 777 in the widowed. The number of children under one year of age who died amounted to 1,106 (617 male and 489 female), or the enormous proportion of 22.07 per cent., or more than a fifth of the entire mortality, not counting the born-dead. Comparing the natality with the mortality, its excess is very slight, being only 154, so that the population of Brussels only increased 8.990 per 10,000 inhabitants. Of this excess of births 18 were male and 154 female; the curious fact arising that the increase of female births was more than seven times greater than that of the male. During the year 1,539 marriages were celebrated and 46 divorces granted.—*Revue Scientifique*, October 17th.

THE HISTORY OF OPHTHALMOLOGY IN VIENNA.—Dr. E. Fuchs, who has just been installed as successor to Eduard Jäger, the renowned Vienna ophthalmic surgeon and ophthalmoscopist, in his first lecture eulogized his predecessor and mentioned that he came of a renowned ophthalmological family, his father being Friedrich Jäger, a great ophthalmic surgeon, scholar, and Leibarzt to Metternich, and his grandfather Josef Beer, who may be said to have founded the teaching of eye surgery in Vienna. The way this came

about was as follows. During the last century the subject of diseases of the eye was but little taught or studied in Austria, the practice being mostly in the hands of quacks, but, a great lady connected with the court of Maria Theresa becoming blind, and the medical men who saw her being unable to agree as to whether the disease was cataract or amaurosis, Wenzel was sent for from Paris; he recognized the case as a very dark form of cataract, and performed an operation with a successful result. While in Vienna, he gave some instruction to three young surgeons, one of whom, Barth, was afterwards appointed to continue the teaching of ophthalmology. For his assistant he selected Beer, who soon began to prove himself superior to his master and became so renowned that students flocked to him from all parts of Europe. Friedrich Jäger became Beer's assistant and his son-in-law as well, and his son was Eduard Jäger, the late occupant of the chair.

CONGRESS OF CRIMINAL ANTHROPOLOGY.—A committee of Italian and foreign juriconsults, medical legists, and medical alienists, with a view of affording the labourers in the field of criminal anthropology an opportunity of stating their doctrines, has determined to hold a Congress at Rome from the 15th to 20th November, at which the following questions will be especially treated. 1. Is it desirable that the doctrines of the school of criminal anthropologists should be introduced into the new code? 2. What are the categories that should be established among delinquents, and what are the essential organic and psychical characteristics which distinguish them? 3. What should be the rôle of the physician-expert in criminal trials? 4. What are the best means of obtaining reparation for crimes? 5. Does suicide increase in inverse ratio to homicide? 6. What are the best means to employ against criminal relapse? An exposition of criminal anthropology will be open during the sitting of the Congress. Communications to be addressed to the Committee of Organisation, Via Po, 18, Turin. There will also be held at Rome, from the 21st to 27th November, a session of the International Penitentiary Congress.—*Lyon Médical*, October 4th.

VIVISECTION IN VIENNA.—The Vienna Session has begun with a large number of students; Bamberger's Theatre is being crowded from top to bottom, as well as those of Nothnagel and Billroth. Professor Stricker in his first lecture had something to say on the important subject of vivisection, about which there had been a recent communication from the Minister of Education, providing that all animals must be narcotized when used for vivisection, except when narcotism would vitiate the results. The Professor waxed eloquent on the importance of scientific facts being made one's own through the medium of the senses, and not taken on the mere *dictum* of another person, however eminent he might be. He said, "If a historian attempts to assert that Alexander the Great never lived, I can only either believe or doubt the assertion, I cannot verify it or disprove it; but if a man tells me that there is no tower to St. Stephen's cathedral, I can prove him wrong, because of the evidence of my senses. So it is with the physiological facts shown in lectures. You, having seen these things, can never doubt them, and can judge any author who denies them on his merits."

THE AMERICAN VACCINE COMPANIES.—The *New York Medical Record*, of October 24th, observes that in various parts of the United States outbreaks of small-pox are so numerous that there is a prospect of a wide prevalence of the disease, even if it do not assume a marked epidemic form. Attention is called to the fact that in all large centres bovine vaccine virus is mainly used; and that the steadily increasing demand for this has led to the formation of companies who undertake to cultivate and sell it, with a view to making money. These bodies are not under any official supervision and are at perfect liberty to disseminate worthless crusts or septic poisoning among the public. It is said of a quantity of bovine virus sent to Montreal that most of it proved inert, while other portions gave rise to badly-inflamed arms. "Here, surely, is a most anomalous condition of affairs. It is apparent at once that this cultivating and selling of virus should always be under some official supervision. Most States indirectly

It was absolutely necessary that the plain truth should be stated, and, personally, I feel as much obliged to Dr. Joseph Rogers for his denunciation of the iniquities of 40 years ago as I do to Dr. Collum, the President of our Association, and Mr. Forrest, our former Secretary, for founding it; to Mr. Jos. Smith, Drs. Joseph Rogers, Aberd., and Danford Thomas, Messrs. Outhwaite, Jessop, Bigg, and other working members of the Committee, for the very valuable assistance given to the cause; to Messrs. Steele, Neill Cooke, and Ellis, who have been simply indefatigable as well as able in all that pertained to finance and organisation; and last, not least, to Mr. Gamgee, for bringing his eloquent tongue to advocate our cause and accentuate our carefully prepared and hard-won triumph. Courtesy to the Fellows, who had supported our resolution, caused me to defer mine, that the carefully prepared petition to the "Queen's most Excellent Majesty in Council" be read by the Secretary to the R.C.S.E., till the next, or quasi-adjourned, meeting, as this document contains our demands, and we cannot consistently ask, or take, less. As I handed in a copy to the President and Council in full meeting, they can no longer say that they have "no cognizance" of this document officially. We require all the backing we can get, personal and financial, for, though we have opened the campaign brilliantly, we have to deal with an obstinate, rich, and crafty foe. Our duty is to support our President and those working with him, on whom the brunt of the battle and organisation has fallen; and to stick, after the old Peninsular fashion, "shoulder to shoulder."

I am, Sir, yours, &c.,  
Chairman of the Petition Committee,  
M.R.C.S. Association.

Grosvenor Road, S.W., November 11th, 1885.

#### HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.; Chelsea Hospital for Women, 2.30 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's—1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Milk Analysis and Milk Testing.

##### REVIEWS:

Minor Notices.

##### ABSTRACTS AND EXTRACTS.

##### REPORTS OF SOCIETIES:

Pathological, Medical, and West London Medico-Chirurgical Societies.

##### CORRESPONDENCE:

Reform at the Royal College of Surgeons.

Obviously, increasing differentiation without increasing definiteness would be only confusion. That the ophthalmic surgeon has justified himself in the second factor of evolution needs no proof. I will instance, however, his highly definite work on paralyse of ocular muscles and on abnormalities of refraction. In neurology I may instance the work of Charcot. And here I must say, as the examples are intended to imply, that by definiteness I mean definiteness which connotes exactness.

Now for the third factor. Each different definite worker is working for the whole body medical; his work leads to the greater integration of medical knowledge of other workers. Each different worker helps all the others. Many different workers in the medical field are seriously indebted to the ophthalmic surgeon in this way. To give but one example, and making again an arbitrary limit. Argyll Robertson has given to neurologists, in the pupil-symptom which is called by his name, not merely a new symptom, but a means of investigation of several important diseases. This debt neurologists, Westphal and Erb, working in a different field, have paid back in showing the diagnostic value of loss of the knee jerk.

There is yet another factor in evolution,—increasing co-operation. Each different worker, knowing one subject best, and having great integration of different definite medical knowledge, of necessity cannot have the precise knowledge of other subjects which other different workers have. Division of labour necessitates the co-operation of labourers. The whole of one disease is better understood by bringing to bear on its direct investigation and treatment different workers in different fields. To give but one illustration of the need of integration of different, definite, medical knowledge, and yet of the need, too, of co-operation. The neurologist ought at least to be able to suspect hypermetropia as a cause of head troubles, but only the skilled ophthalmic surgeon can estimate it precisely and correct it accurately.

I think we often err by underrating the complexity of some nervous diseases. I take epileptic paroxysms and their after-conditions as being, together, an illustration of the morbid nervous affection of greatest complexity of symptoms. When its symptomatology is fully displayed, it shows, I submit, the imperative necessity of (1) different, (2) definite, (3) wide knowledge, and of (4) co-operative work. I speak of the "genuine epilepsy" of nosologists, not of epileptiform seizures. Epilepsy is a disease of the "organ of mind," that is to say, of the highest and most complex, &c., centres. The symptomatology of the paroxysm is probably a universal symptomatology, is demonstrably nearly so. It may be said that insanity is more complex than epilepsy; not so, since epileptic paroxysms are not unfrequently followed by temporary insanity. The study of epilepsy, therefore, involves the study of some cases of insanity. These insanities are what I have called after-conditions of the epileptic paroxysms. We ought, of course, to speak of epilepsies as we should do of insanities; for certainly, if two epileptics have different "warnings" of their fits, the "discharging lesion" is in a different part of the highest centres in the two cases. There are many epilepsies, and many insanities. But now I give *en bloc* the symptoms of many severe epileptic fits, of many slight fits, and the symptoms of epileptic fits (or, I should say, epileptiform seizures), artificially produced in dogs; all are, at any rate, symptoms produced by cortical discharges (liberations of energy). Among them are very important eye-symptoms.

At the climax of a severe fit we see the algebraical sums of the co-operations and antagonisms of strongly-developed movements of all the muscles of animal life

accessible to observation; universal convulsion. As to wide involvement of sensory elements in the epileptic discharge, we can say that this is implied by "warnings" of crude and excessive smells, colours, sounds, tastes, by tinglings, &c., of the hands, and by many crude and excessive organic sensations; of what happens in the sensory sphere after loss of consciousness, we can say nothing. Besides colour development, there is another eye symptom, a vertigo, in which external objects seem to move, implying discharge, direct or indirect, of motor cerebral elements representing ocular movements. We find dilatation of the pupils (perhaps, sometimes, there is contraction), there are great pallor of the face, increased flow of saliva, perspiration, alterations of pulse and respiration, passage of urine and fæces, and erection of the penis. Vulpius curarised a dog, thus putting the muscles of animal life out of the reach of an artificially induced discharge of the dog's left sigmoid gyrus (artificial respiration was kept up). Speaking almost only of effects of cortical discharges, which I have not yet mentioned, there were slowing and irregularity of the heart, raised arterial pressure, increased flow of bile, a little paling of the kidneys and diminution of their secretion, contraction of the bladder, and contraction of the spleen.

So we go a long way towards showing that the epileptic paroxysm has a universal symptomatology, having shown that sensations are referred to many different parts of the body, and that effects by efferent (motor and inhibitory) nerves are produced, in different ways, in very numerous parts, "from the eyes to the feet," strictly, I suppose, "from nose to feet." We can add to the list of parts represented by the cerebral cortex. "Bochfontaine and Lepine, on stimulating several points, especially in the neighbourhood of the sulcus cruciatus in the dog, observed increased secretion of saliva, slowing of movements of the stomach, peristalsis of the intestine, contraction of the spleen, of the uterus, of the bladder, and increased respirations" (Landois' "Physiology," ii., p. 942, Stirling's Translation). Bufalini has observed the secretion of gastric juice.

I do not think I need apologise for speaking in this lecture of the non-ophthalmological symptoms of epileptic paroxysms, especially of those of the organic parts. The neurologist and the alienist physician must take into account all the symptoms. They are an important part of the evidence towards showing that the "organ of mind" (highest centres) represents, or co-ordinates, all parts of the body. In strictly equivalent words, the highest centres are centres of Universal Co-ordination. It is thus that they are the organ of Will, Memory, Reason, and Emotion, the four elements of mind or, equivalently, of consciousness. No wonder that the epileptic discharge, beginning in some part of the "organ of mind," produces universal bodily effects, animal and organic. Unless retinal impressions, corresponding to colour of objects, and ocular movements, corresponding to shape of objects, be represented in the highest centres, how are we to account for the physical bases of visual perception and ideation? If the organic parts are not represented in the highest centres, an emotional manifestation, say of fear, is unaccountable; and so too are the physical symptoms of some cases of melancholia, the insanity of fear (anxiety, depression, &c., being only "fear spread out thin"). When a man is thinking, or even dreaming, of a brick, he is having a purely psychological state; the correlative physical state is discharge of some nervous arrangements of his highest centres, representing parts of his body—certain retinal impressions and particular ocular movements. Again, when a man is afraid, he is having a purely psychological state; the correlative physical state is discharge of some nervous arrangements of his highest centres,

representing parts of his body, notably, the organic parts. There are clinical reasons why the ophthalmic surgeon should be interested in symptoms in organic parts. Often enough in other diseases of the cerebrum does he see eye-symptoms with effects produced in organic parts. To say nothing of vomiting, so common with optic neuritis from cerebral tumour, there are acute stages in such cases in which there are alterations of pulse and respiration, retracted belly, and constipation. Consider also the migrainous paroxysm, which is no doubt owing to a cortical discharge, so often beginning by elaborate visual projections, and so often ending by vomiting. Eye-symptoms from disease of the cerebrum cannot, in many cases, be studied isolatedly from organic symptoms. We have not yet done with the complexity of the epileptic paroxysm.

We must note in slight fits movements of chewing or tasting, swallowing, vomiting, and writhing movements of the arms during arrest of respiration. I do not believe that these movements result directly from the epileptic discharge, holding that *such* a discharge, so far as it spreads, puts an end to all movements properly so-called, "runs them up" into convulsion. I suggest that an important eye-symptom at, or near to, the onset of some epileptic fits, the apparent alteration in size or distance of external objects, is, on the physical side, a phenomenon of the same order as the chewing movements; that both are the indirect (reflex) results of epileptic discharges of sensory elements. Ferrier produced, by faradising a monkey's "taste centre," movements like the chewing and tasting movements some epileptics or their friends describe. It is exceedingly important to distinguish movements proper from convulsion, which is a contention of many movements. I suppose everyone would believe that spitting, rubbing one hand with the other, clutching at the throat (in rapid suffocation?) in slight seizures, are movements too elaborate to result directly from *such* a discharge as that which produces convulsion.

There is yet more complexity; when, in severe fits, respiration is arrested, there is carbonic acid poisoning. Asphyxia renders a dog's cerebral cortex inexcitable (Hitzig, Franck, and Pitres), but some lower centres, or parts they supply, or both, are stimulated; thus there will be a multiplication of effects. Asphyxia produces dilatation of the pupil, besides other effects—salivation, sweating, &c. But we must bear in mind that the centres directly stimulated by carbonic acid, or over-acting from lack of oxygen, in simple asphyxia will be, more or fewer of them, in an epileptic paroxysm already engaged to some degree by the epileptic discharge, and that when the fit is over there will be a degree of exhaustion of them corresponding to the degree of prior discharge, and so far an unsusceptibility to be acted on. The pupils are very small after severe epileptic fits.

Now for the mental symptoms of, or rather during, the discharge beginning in part of the "organ of mind." During the epileptic discharge there is defect or cessation of consciousness. Some think that also during it, at the outset of some fits, there arises the exactly opposite mental state of "over-consciousness"; "dreamy state," "seeing faces," and "hearing voices." I believe these super-positive mental states, and adding to the list fear—different miniature insanities—at the onset of different epileptic attacks, to arise during slightly raised discharges of healthy nervous arrangements untouched by the epileptic discharge.

We must be very careful both in ophthalmologica, and neurological studies not to confound sensations of colours, for an example, which are states of mind, with activities of sensory elements, which are states of body. We must not speak of any mental states as

occurring *from*, but as arising *during*, nervous discharges; only physical effects, such as movements, arise *from* nervous discharges. We must also distinguish different degrees of elaborateness of different mental states; "seeing faces" is a greatly more elaborate mental state than colour projections at the onset of an epileptic fit; what I have called the "dreamy state" is vastly more elaborate than "seeing faces." Whilst I think that colour projections at the onset of an epileptic fit arise *during* the epileptic discharge, I believe that so elaborate a state as "seeing faces," and the still more elaborate mental state, the "dreamy state," do not, but that they arise *during* discharges only slightly stronger than normal. The "dreamy state" is a very voluminous mental state; it is commonly called an intellectual aura. As I have implicitly said, I do not believe it to be an aura or warning,—not a thing, I mean, of the same meaning as the crude sensations of colour, &c. Admitting that crude sensations arise *during*, and that convulsions occur *from*, the epileptic discharge, I urge that elaborate mental states arise *during*, and that movements properly so called occur *from*, but slightly raised discharges of nervous arrangements.

The lecturer then spoke of the different associations of different sense-warnings in epilepsies, believing that the "subjective" sensations, smell, taste (or chewing, &c., movements), and the "epigastric" sensation, most often occur in those cases of epilepsy in which there is the "dreamy state," and that the cortical lesions in these epilepsies are in parts of the cortex in the region of the posterior cerebral artery, which vessel supplies, among other parts, Ferrier's centres for smell and taste. He suggested that some cases of epilepsy with colour and sound warnings (with which he had never known the "dreamy state" to be associated) were owing to cortical disease in some part of the region of the middle cerebral artery, which vessel supplies, among other parts, Ferrier's centres for sight and hearing. He considered that the nervous changes (the "discharging lesion") in epilepsies were not primarily, but only secondarily, nervous; that in most cases they were secondary to embolism or thrombosis of small arterial branches; that there were "arterial cortical lesions" in most epilepsies. He had held that some epileptiform seizures have that pathology since 1864 (London Hospital Reports, vol. i, p. 465), and considered that some cases recently published by different physicians proved that hypothesis. The researches of Duret and Henbner on the detailed arterial supply of parts of the brain will enable us to be more definite in our arterio-cortical localisations of "discharging lesions" especially in epileptiform seizures; some cases of this kind were evidently owing to blocking of branches of the middle cerebral. Another way of putting part of the foregoing is to say that epileptiform seizures do not always depend on tumour. This brings us again close to Ophthalmology. If anyone is thinking of removing a brain tumour in a case of epileptiform seizures, he ought to refrain from operating if he does not find optic neuritis (perhaps with one exception). Of course there are epileptiform seizures from brain tumour in which (for years at least) there is no optic neuritis, but without this eye condition we cannot (with perhaps one exception) be sure of tumour. It was from both neurological and ophthalmological knowledge that Dr. Hughes Bennett made the double diagnosis of seat and nature of the disease in the case of tumour which Mr. Godlee removed from a patient's brain.

The Lecturer then spoke of certain important cases of epilepsy complicated with some particular definite and persisting eye-symptoms, pointing to intra-cranial tumour; the investigation by the ophthalmic surgeon of paroxysms of epilepsy so complicated is most desir-

able. [A man had occasionally smells in his nose heralding in slight attacks of epilepsy with the "dreamy state"; there were left-sided "shakings" in the paroxysms. There was double optic neuritis, but no defect of sight; the neuritis passed off under mercurial inunction and iodides, sight remaining good. The patient died apoplectic with left hemiplegia; his case illustrates the dictum that *a man with optic neuritis is to be considered as being in imminent danger of death*; that this patient was in any such danger no one would have surmised who did not find out that there was optic neuritis. Whilst the optic neuritis is the best indication for treatment, and of most prognostic value, such an important variety of epilepsy as this patient had deserves most careful investigation. In this association the lecturer urged that the great thing in the diagnosis of epilepsy is not so much the "quantity or severity of the symptoms" as their paroxysmalness, and that, the slighter a paroxysm, the more necessary, both for the patient's sake and for medical science, is its minute investigation; attacks of epilepsy with the "dreamy state," when very slight, as they often are, are sometimes attributed to hysteria or to stomach and liver derangement. To the uninstructed the accounts given by the patients seem "fanciful." That optic neuritis is often overlooked in its præamaurotic, most curable, stage is certain. The case mentioned was the only case of epilepsy with "dreamy state" the Lecturer had seen complicated with optic neuritis; there was no necropsy; the presumption is that death occurred by hæmorrhage from a vascular tumour in the right cerebral hemisphere. Another case of this kind of epilepsy (bitter taste, "dreamy state," and right-sided numbness), investigated by Dr. James Anderson, was complicated by simple atrophy of the optic nerves; there was loss of sight of the left eye, of the right field of the right eye, almost loss of smell on the left side; defect of taste, more on the left side. (The paroxysmal one-sided symptom (numbness) was right-sided, and the patient was not left-handed; in most cases of this variety of epilepsy the Lecturer thinks the one-sided phenomena, if any, are left-sided.) Having regard to an important case recorded by Mr. Nettleship (Transactions of this Society, vol. iv, p. 285), like this in the optic symptoms (necropsy by Dr. Sharkey), in which there were slight epileptic fits with a feeling of suffocation referred to the nose and mouth, the Lecturer thought that in Dr. Anderson's patient's case there was a basal tumour causing the epileptic fits by involving, or by in some way inducing, changes of instability in the left middle cerebral lobe. Cases with such fixing eye-symptoms, implying gross organic disease, for obvious reasons deserve most careful and minute investigation, not only of the eye-symptoms, but of the epileptic fits also.

Speaking now of the after-conditions of epileptic paroxysms very generally, we have insanity, according to the severity of the fits, in two degrees at least,—in three, I think. There is so-called "loss" of consciousness with actions (post-epileptic "unconsciousness" with mania, for example), and after very severe paroxysms acute dementia (coma). Here I remark that it is vain to attempt the realistic study of epilepsy and its after-conditions, or that of any other insanity, without psychological knowledge. Confounding psychology with physiology of the highest centres leads to crude metaphysical explanations, such as that in post-epileptic coma a man does not move because he is unconscious, although in a slighter post-epileptic condition, post-epileptic mania, there is movement enough when, according to the opinions of most, consciousness is lost. Taking post-epileptic coma after a very severe fit, there is exhaustion of more or less of the highest centres implied by the negative affection

of consciousness, and, in some slighter degree, of more or fewer of the lower (more organised) centres. Westphal and Gowers have noted transitory absence of the knee-jerks after epileptic paroxysms, thus showing there to be sometimes exhaustion of lumbar nuclei, some lowest motor centres. Deep post-epileptic coma is psychically dementia, but is, on the physical side, nothing else than some universal, almost total, paralysis—paralysis not only of animal, but of organic parts also, proportionate to the degree of the prior epileptic discharge upon them.<sup>2</sup> This contention of mine is, however, denied; let us say, what cannot be denied, that the patient is nearly dead. I dare say my calling the psychical side of the condition insanity (dementia or amentia) will be objected to. Let us say that the patient is, or is nearly, mentally dead: this cannot be denied. Moreover, the patient is suffering from carbonic acid poisoning, from slow respiration, from imperfect circulation; thus there will be a multiplication of effects. Possibly the excess of carbonic acid helps somewhat in re-evolution by strongly stimulating the respiratory and other partially exhausted (lowest) centres.

There is one after-effect—a valuable eye-symptom—which is certainly paralytic,—transitory lateral deviation of the eyes, observed by Beevor instantly after severe attacks. Again, the exaggerated knee-jerks and foot-clonus after some fits (Beevor) imply paralysis, signify exhaustion of fibres in the lateral columns, and possibly also of inhibitory centres (Gowers) in the cord itself. Here we have after-effects at the two extremes—eyes (paralytic) and feet (implying some paralysis); it would be remarkable if the rest of the symptoms were not paralytic.

I submit that it would not be possible for a neurologist to scientifically study this exceedingly complex disease without availing himself of the work done by different specialists. We require many different kinds of definite or technical knowledge; all the sagacity in the world will not suffice either for practical ends or for the scientific investigation of complex problems without technical knowledge. No one man can have from his own working enough different definite knowledge to thoroughly investigate the universal symptomatology of epilepsy. It is vain to begin careful analysis of this complex problem without aid from psychology. Could the neurologist analyse the physical condition without help from the physiologist? How, without that help, is he to put in any reasonable order symptoms related to the organic parts, slowing of the heart, raised arterial pressure, and the rest? Recent researches by Gaskell (Proceedings of the Physiological Society, February 14th, 1885) will, I think, help us greatly in our analysis of the organic symptoms. I submit the hypothesis that, in some cases, the first effects of the epileptic discharge on the organic parts are by intermediation of Gaskell's leucentric (inhibitory) or "white-visceral" fibres. Does not the neurologist need the help of the Alienist physician, witness the definite work on epileptic insanity by Falret? To the ophthalmic surgeon he is very directly indebted. Here I will pick the eye-symptoms out of the heap.

Sometimes, but yet rarely, we have optic neuritis common in epileptiform seizure, or simple optic atrophy, as I have illustrated. To speak only of the paroxysm. In some cases there are colour warnings, occasionally followed by the vastly more elaborate mental state, "seeing faces." There are pupillary affections. In one case of uræmic convulsions, the pupils being greatly dilated, I saw the fundus easily during the fits, but could get no glimpse of it in the intervals:

<sup>2</sup> Of course we cannot say that such super-positive phenomena as foot-clonus, passage of faces, &c., after epileptic fits are paralytic, but they signify exhaustion of "controlling" nervous elements, are indirect evidences of paralysis.

Vulpian found that the pupils in his curarised dog enlarged during the artificially induced paroxysm, and that after the fit they were smaller than before the fit. We have vertigo at the onset of some paroxysms. Vertigo is consciousness ceasing; that variety of it in which objects seem to move to one side is an eye-symptom; it implies discharge, primary or secondary, of centres representing particularly the most special of ocular movements. If we have not clear ideas on vertigo in epilepsy, we shall work sad havoc in the investigation of some important varieties of epilepsy. Here the neurologist should avail himself of the definite knowledge the ophthalmic surgeon can give him from cases of paralysis of ocular muscles, in which vertigo is seen in its simplest form, before he studies it in the vastly complex circumstances of the epileptic paroxysm. After that he should take heed of what the aural surgeon can tell him of ear-vertigo. I have seen, so to speak, vertigo during an attack of ear-vertigo—speaking more correctly, I saw the patient's eyes jerk to one side whilst he saw objects jerking to one side (*Brain*, April, 1879). In our "Transactions," vol. iii., I have recorded a case (essentially like one previously published by Schwabach) in which pressure on a diseased right ear produced vertigo and movements of the eyeballs to one side. Such cases are very valuable in the interpretation of vertigo. The variety of vertigo mentioned occurs no doubt in an epileptic fit along with turning of the eyes to one side. Beevor has noted that after some epileptic fits the eyes deviate from the side to which they were strongly turned in the prior paroxysm. This is a matter of great importance. That movements of the eyes are represented in the highest motor centres (frontal lobes motor divisions of the organ of mind), one might infer *a priori*. Ocular movements are the most representative of all movements. Most mentation is carried on in visual perceptions and ideas, and, as there is an element of, or symbolising shape in, every visual perception and idea, there is, of necessity, a representation of ocular movements in the physical bases of these perceptions and ideas, that is, in the highest centre. Ferrier and Gerald Yeo find, by experiments—ablations—on monkeys, that movements of the eyes and head are represented in the frontal lobes. There is another important eye-symptom in epilepsy: apparent alteration in the size and distance of objects. It occurs, I think, most often in those epileptic attacks in which there is the "dreamy" state. It is physically a "motor affair"; that size and shape are not simply "retinal affairs" is easily proven. Here we avail ourselves of the definite knowledge of the ophthalmic surgeon (the micropia after instillation of atropine; in paralysis of an internal rectus; the opposite condition after eserine). But we must not apply the knowledge derived from such simple cases to alterations in size of external objects at the onset of epileptic fits without great caution, the situation being an exceedingly complicated one. I have already stated an hypothesis regarding the mode of production of these phenomena. Dr. Gowers has considered them with his usual ability in his valuable work *Epilepsy*, p. 64—a work rich in ophthalmological knowledge.

Although I have spoken of epilepsy, there are really very many epilepsies, and thus, illustrating by the eye-symptoms (vertigo, colour, alterations in size or distance of objects), we should try to find the particular sequence of symptoms of other kinds, of which each of the eye-symptoms is the prelude. Epilepsy is not a complex thing when it is empirically regarded as a clinical entity, which for some purposes it should be. It is comparatively easy to note the "causes," "warnings," &c., "of epilepsy"; much good work has been done in that way. But, besides investigating in this way, we have to "turn ourselves round" and try

to ascertain what different symptoms result from differently seated "discharging lesions" of the highest centres. We have the large compound question to answer, What is the constitution of the "organ of mind" (highest centres) by which it results (1) that discharge, beginning in different parts of it, produce different epilepsies,—produce, if severe enough, nearly universal effects (no doubt, in different degrees and sequences); whilst (2) other kinds of disease of different parts of the "organ of mind" produce different insanities? (3) In one case we may have, first, in the paroxysm, cessation of consciousness with universal convulsion and equivalent effects in the organic field, and then, after the paroxysm, insanity,—acute temporary dementia (coma) or "loss" of consciousness, with mania. After epileptic fits of different degrees of severity we have different degrees of insanity, from "confusion of thought" to coma. Indeed, some physicians go so far as to say that an attack of mania sometimes occurs instead of an epileptic convulsion; as I have implicitly said, when speaking of movements properly so called and of elaborate mental states, I do not hold this hypothesis. (4) We have to find a means of studying epilepsies and insanities (diseases of highest centres) with diseases of lower centres.

It is impossible even to begin to work methodically towards answering the compound question put if we confuse Psychology with the anatomy and physiology of the nervous system; manifestly referring to (4), it is not reasonable to compare and contrast loss of consciousness from diseases of the highest centres with a monoplegia from disease of middle centres or with any other physical symptom.

We should follow the method of science, and investigate by the use of hypotheses. This may seem a strange remark to those who erroneously suppose an hypothesis to be a conclusion in which we may rest. It is only used for the methodising of work by observation and experiment. I submit that we should adopt the hypothesis of evolution, according to which the whole nervous system is a sensori-motor system representing all parts of the body. I suggest that all parts of the body are represented in each of three levels of evolution (representative, re-representative, and re-re-representative. (Strictly we should speak of four levels; as, when tracing the "ascent" (*vide infra*) from eye-muscles to most complex ocular movements, we should begin at the periphery.) Representation increases in (1) differentiation (complexity), (2) definiteness (speciality), (3) integration (intricacy), and (4) in number of interconnexions, co-operation from lowest centres to highest centres (organ of mind). The "organ of mind" is nothing else than a series of centres representing, or, what is the same thing, co-ordinating, all parts of the body "from eyes to feet" in greatest complexity, &c. Let me compare and contrast the lowest level of evolution with the highest, ignoring the middle level. (The lowest level is cerebro-cerebellar.)

Each lowest centre represents, most nearly directly,<sup>3</sup> some (3) limited particular region of the body (least integration), each some region in (1) fewest, least different, and (2) least definite, combinations; there are (4) fewest interconnexions between these centres. The supposition is that each of the highest centres represents triply indirectly, through middle and lowest, (3) all or very wide regions of the body, that each represents in (1) most numerous, most different, and (2) most definite combinations, and that there are (4) most numerous interconnexions between these centres. (Each highest centre represents all parts, or wide regions, of the body; no two represent all parts, or the same parts, in the same way.) The

<sup>3</sup> I use numbers to indicate the particular factors of evolution previously stated. It is convenient here to state the factors in different order.

evolutionist, it must be added, does not attempt the marvellous feat of "getting the mind out of the body"; he only tries "to get" the physical bases of mind (highest centres) out of the rest of the body. Mental states are only concomitant with nervous states. Taking mental symptoms to be only signs of what is not going on, or of what is going on wrong, in the highest parts of a great sensori-motor mechanism, we may, I hope, find an answer to the large compound question put. We cannot expect to find an answer if we are not thoroughly materialistic as to what is purely material, the nervous system.

Taking an ophthalmological illustration, and yet artificially simplifying it by considering only the first factor in evolution, we might try to trace an ascending complexity of representation from the nerve supply to ocular muscles up to representation of ocular muscles in exceedingly complex movements in the physical bases of visual ideas and other mental states. We should use the "experiments" which disease makes (dissolutions) in endeavouring to trace that ascent; (1) paralysis of ocular muscles from lesions of their nerve trunks (periphery), (2) ophthalmoplegia externa and interna (lowest motor centres), (3) lateral deviations of the eyes in lesions, negative and positive, of the middle motor centres, or negative lesions, of a plexus (internal capsule) just below them (Vulpian and Prevost). In some limited epileptiform seizures we see development of movements of the eyes in very important associations. Possibly the interesting and remarkable paralysis of particular ocular movements, which Priestley Smith has described, are monoplegias owing to negative lesions of some middle centres, (4) deviations of the eyes in and after epileptic fits, which are, I presume, developments of, and losses of, the movements represented in the physical bases of visual ideas and other mental states.

These "experiments" are very rough, but some of them can be supplemented by the very definite experiments, properly so called, of Hitzig and Ferrier. I refer again to the proof which Ferrier and Gerald Yeo have given of the representation of ocular movements, or of the most special of them, in the frontal lobes; these parts of the "organ of mind" I call highest motor centres.

It may be said that such a wide way of studying diseases tends to vagueness. I think we may guard ourselves against this.

In the epileptic paroxysm (dissolution being effected) the universal symptomatology is suddenly presented, and is transitory. But, whilst working at this disease of the highest level of evolution, and at insanities, other diseases of it, we may, at the same time, work at different diseases of the lowest level (ignoring the middle in this illustration), in which, taking numerous different cases, the symptomatology is of nearly all, if not of all, parts of the body. I remind you that the hypothesis is that the lowest level represents all parts of the body; that the middle level is that lowest level, so to speak, "raised to a higher power"; that the highest level is the middle "raised to a still higher power."

In different progressive muscular atrophies we have symptoms nearly, if not quite, all along the lowest level, from ophthalmoplegia externa downwards (some forms of "bulbar paralysis," the common variety, Duchenne-Aran, &c.); "symptoms from the eyes to the feet."

Here is an important ophthalmological matter. It is well known that with destructive lesions of the brachial plexus we have smallness of the pupil on the side of the injury. Ferrier finds that, in the monkey, and presumably it is so in man, the dilator fibres of the iris, contained in the cervical sympathetic, are derived from the anterior root of the *second dorsal*

nerve. In the monkey the second dorsal sends a communicating branch to the brachial plexus, and so it does in most cases in man (Cunningham). Now the second dorsal root (Ferrier) supplies also the intrinsic muscles of the hand. In one case I have observed a small pupil (inability to dilate when shaded) in a case of progressive muscular atrophy at a stage when the hand muscles were almost solely those atrophic. Here again the neurologist has common ground with the ophthalmic surgeon.

So much for atrophy of the animal parts; now for the organic parts. The separation is, of course, not absolute; bulbar paralysis is evidently a morbid affection of parts mixed in function, or rather having both kinds of function.

I submit, quite hypothetically, that we have atrophies of cells of centres for organic parts, like the atrophies of cells of anterior horns and their higher homologues, which produce progressive muscular atrophies; thus I submit that (pernicious) diabetes may be a nuclear atrophy—progressing atrophy of cells of that part of the great vaso-motor centre which especially governs the hepatic artery. I would venture to suggest that Graves' disease is of the same kind of central pathology. (Similarly, *mutatis mutandis*, for myxœdema; atrophic central changes, leading to atrophy of the thyroid. Dr. Ord says that marked bulbar paralysis has been found in two cases.)

In Graves' disease we have an important eye-symptom—that on the patient's looking down the lid does not follow the globe; perhaps by this symptom we may hope some time to fix the seat of the morbid change in the centres. Warner and Bristowe have recorded a case of Graves' disease in which there was also a form of progressive muscular atrophy, ophthalmoplegia externa. This case, so complicated, renders my hypothesis a little plausible. Of course I do not mean that all the super-positive phenomena in Graves' disease are the *direct* consequences of atrophy of cells. The engorgement of the thyroid may be owing to such atrophy of some part of the vaso-motor centre. Some other symptoms, *e.g.*, the palpitation, may be indirect consequences of atrophy of cells of inhibitory centres. There is no reason why atrophy should not begin in cells of Clarke's (visceral) column and its higher and lower representatives, and in spinal and bulbar "regulating centres."

In tabes dorsalis we have, taking numerous cases, symptoms "all along the line," from optic atrophy and pupillary affections downwards "from eyes to feet." In these cases we have morbid affections of many organic parts, among other, gastric crises (Charcot, Buzzard), bladder troubles, and impotence; sometimes loss of smell and hearing; but the most important sensation defect is of resistance, a defect clearly seen in cases where there is the feeling of "padding" of the soles.

Diphtherial paralysis<sup>4</sup> is another disease on the lowest level of evolution, probably (Vulpian, Dejerine, Abercrombie, Percy Kidd) a myelitis of parts of anterior spinal horns and of their higher homologues (possibly the ptomaine generated during the diphtheria acts somewhat like curare and poisons endings of motor nerves). In this disease we have, in severe cases, paralyzes of many different parts from eye (ciliary muscles) downwards—"from eyes to feet." We must not forget the occasional implication of the organic parts—death after slowing of the pulse. (Implication of the accelerating centre?)

We may study the nearly universal symptomatology from different kinds of disease on the lowest level of evolution, made up by the cases mentioned and by others on that level. The ophthalmic surgeon sees eye-

<sup>4</sup> A valuable paper by Benson, of Dublin, on this morbid affection appeared vol. iii., *Trans. Ophth. Soc.*

symptoms from lesions at or near to the "top" of the lowest level of evolution, and in cases which, superficially regarded, are uncomplicated. But, having great integration of medical knowledge of other kinds, he does not regard them as eye disease only, but finds what they mean, what symptomatology they are important elements in. By co-operation of many different workers, each with definite or special knowledge of particular kinds, and each with great integration of more general knowledge, we may hope to thoroughly analyse these very complex symptomatologies. The symptoms are slowly produced, are presented in detail, are persistent or permanent, and, so to speak, are comparatively simple analysing experiments by disease on the lowest level of evolution, simple dissolutions. But now, regarding these symptoms taken *en bloc* as signs of negative lesions of (nearly) all parts on the lowest level of evolution, let me compare and contrast them with symptoms from negative lesions on the highest level.

The condition of a patient after a severe epileptic fit is one of nearly universal, and almost total, paralysis (dissolution effected). He has loss of consciousness, but this has nothing to do with his not moving. The symptomatology is, so to speak, the "evolutionary sum" of all, or nearly all, the symptoms of all the diseases on the lowest level of evolution. This statement needs obvious qualification; one is important. Since the epileptic discharge, beginning in the highest centres, produces effects in nearly all (ento- and epi-) peripheral parts, currents from this primary discharge must have traversed and discharged more or less of the middle and lowest centres in order to "get at" the periphery. Hence the paralytic condition after a severe fit will be a very compound one, all orders of centres being somewhat affected, but in different degrees.

Thus the neurologist, by availing himself of the different definite work which ophthalmic surgeons, aural surgeons, laryngologists, &c., are doing at different points all along the (1) lowest level of evolution, by working himself at different diseases on the (2) middle level (epileptiform seizures, migraine, monoplegias, &c.), by working with the alienist physicians at diseases of the (3) highest centres (epilepsies and insanities), may hope to justify his differentiation. The several workers may hope to add (1) different, (2) definite knowledge to, and further, the (3) integration of, general medical knowledge, and to lead to a higher and more methodical (4) co-operation of different workers. I say once more that this comparative study, that by aid of the hypothesis of Evolution, cannot be methodically undertaken if we confuse Psychology with the anatomy and physiology of the nervous system, not if we take the *organ of mind*, or its activities, to be *mind*. The "*organ of mind*" is simply a series of sensori-motor centres re-re-representing impressions and movements of all, literally all, parts of the body.

**DEATH OF J. B. BAILLIÈRE.**—The father of French medical publishers, J. B. Baillière, died recently in the 88th year of his age, having been blind for several years past, which, however, did not prevent his continuing to take great interest in all that concerned medical literature. Establishing his business in 1818, Baillière conducted it so ably that it attained the highest repute, *Lettré's Hippocrates* and *Cruveilhier's Anatomie Pathologique* being among the famous works which he produced. The first foreign medical bookseller established in London was Baillière, of, Regent Street, a nephew, we believe, of J. B. Baillière.

## CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD  
AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the Principles and Practice of Medicine and on Clinical Medicine.

### LECTURE VI.—CASE TAKING.

*Personal History.*

*Age—(concluded).*

THE period of maturity, the midway stage of life, the aim towards which development tends, and the perfection from which decline proceeds, is characterised in health by an equal balance between waste and repair and a physiological equilibrium of vitality. Unmarked by any distinct evolution of organisation, the essential feature of the period is a regularity of existence, broken only by such accidents as the conditions of life may favour the occurrence of, or by the wilful "abuse of the constitution,"<sup>1</sup> by direct violation of hygienic laws. In the preceding stage, whilst the organism was growing and developing, predispositions to abnormality of structure and function were induced by the very occurrence of those changes, whilst the delicacy of construction and easy disturbance of balance equally favoured the existence of disease, which the exuberant vitality of the period impressed with its own peculiar features. At this time, however, there cannot be said to be any intrinsic aptitude towards disease; but, although escaped from the special ailments of infancy and youth, and not yet within the range of the morbid influences of old age, the individual is nevertheless liable to sickness and death in such degree, compared to the other periods of life, as the tables I have before given you will show. To some extent, perhaps, the functional capability of reproduction which prevails at this period, and which is the great characteristic of maturity, does establish a preponderance of disease of the organs concerned therein, but not to so great an extent as might be supposed, nor by any means of necessity, for a healthy existence with a perfectly normal performance of their powers is to be regarded as the rule rather than the exception. So far as diseases of the generative organs do occur, there is a tolerably well-marked difference in their manifestations in the two sexes, for whereas, apart from syphilis, the affections in the male are mainly local, the maladies of the uterus and ovaries react upon the body generally and reflexly cause the most varied symptoms of most distantly connected organs. If, then, we are not able to find in any normal changes in development a predisposition towards disease, in what direction are we to look for the cause of the illnesses and mortality of this period? Excluding, of course, such diseases as may have continued on from the preceding stages, and those hereditary maladies, such as gout, which this age may develop, we find that the great bulk of disease at this time of life is determined by immediate or exciting causes which are largely under the individual's control, or by accidents which his occupation and surroundings expose him to, but which none the less are largely preventible. During the period of adult life man has a larger share in fashioning his own environment, in determining the conditions of his existence, whether for good or ill,

<sup>1</sup> "On the changes in the body at its different ages and the diseases to which it is predisposed at each period of life."—Dr. T. Jameson, 1811.

than he possesses at any other stage of his life, hence comes it, therefore, that many of his maladies at this time are of his own causing. The abuse of his constitution I have termed it; excesses, with all the improprieties which that word implies, over-feeding, over-drinking, over-working, over-anxiety; or excesses, if I may so call them, in the opposite direction, too little food, idleness of mind and body, insufficient clothing or exercise—will suggest to you the numerous forms of morbidity which you will meet with at this time, and should lead you to associate with the wholly different kind of causation that prevails in adult life, an equally distinct course, manifestation, and termination of the morbid phenomena to what you will find at other epochs of existence, with indications also of the necessarily different plan of treatment you must employ.

Given, then, such inducements to disease as these, their effect upon the organism, or rather the way in which they produce their effects, differs in the main from the broad characteristics of unhealthy function occurring in earlier or later life. Their result is more obviously proportioned to their extent, and much more restricted in their scope. For, whilst in the child a severe illness, in which every function of the body appears almost equally to participate, may follow what seems to be but a most trifling cause, or whilst a similar excitant in the old man may lead to a disturbance of vitality, of such severity as to be fatal, yet so ill-defined and insidious in its progress as to be scarcely recognised till within a measurable distance of the termination, here, in the meridian of life, the same cause would in the majority of cases give rise to a well-marked group of symptoms almost limited to the area of morbid stimulation, or, at all events, where the distant or systemic symptoms are sufficiently distinct as to be manifestly dependent and secondary. It is from the phenomena which disease presents at this stage that the standard descriptions of our nosologies are chiefly constructed, just as, before the significance of evolution was appreciated, the characters of animals and plants for purposes of typical description and classification were entirely taken from their adult state. The contrast which this age presents to the preceding is most noticeable in the diminished susceptibility to peripheral disturbance and the more restricted area over which the effects of such disturbance are felt. The exalted sensibility to external impressions of the neuro-muscular system in the child, as manifested by the readiness with which convulsive symptoms are induced, is considerably diminished in adult life, although affections of these organs are not wanting at this period.

From the point of view of the material structure of the body, the diseases of this age are as distinctive as they are in their causation. The increased coherence of the tissues, their greater firmness and rigidity, with diminished, yet sufficient, permeability, restricts the readiness to serous or hæmorrhagic effusions, so much commoner at earlier ages. The standard pitch of integrity of the tissues in their physico-chemical and vital aspects is the anatomical expression of maturity, just as the complete performance of healthy living represents the physiological acme. The living elements of the tissues are now more confined by a "formed material," which contributes to form the greater bulk of the body as in earlier days the protoplasmic units were in excess. Such a difference must suggest a variation also in the susceptibility to disease and in the manifestation of disease when once established.

Again, maturity is pre-eminently the period at which the temperaments exert their dominant influence. The expressions of these various states, both in configuration of body and manner of being, I shall refer to later;

here it is sufficient to say that these inborn tendencies manifest themselves to their fullest at this time of life, to sink into significance as decline sets in, finally to be replaced by that association of phenomena aptly described as the "senile cachexia."<sup>2</sup> These are the factors which, largely determining the "character" of the individual, sway him to those wilful excesses which I have referred to as being especially active in the causation of disease.

Since, then, the risk to disease of almost all the organs is about equal, as any may be the victims of excess, the enumeration of the maladies which may occur at this period would be but to repeat to you the nomenclature of disease as set forth by the Royal College of Physicians, excluding only those affections which the organisations peculiar to infancy, childhood, youth, and old age limit to those seasons. The digestive organs, from their frequency of abnormal irritation, are very commonly affected, most frequently in a transient and recoverable manner, although sometimes by frequent repetition a habit of disease becomes established which acquires a permanent hold. Affections of the pulmonary organs may be described almost in the same terms, remembering, however, the marked predominance of phthisis, which produces a larger mortality at this earlier period than dyspeptic diseases do. The liability to acute rheumatism, which is at its greatest from about 16 to 25, that is, immediately preceding the establishment of complete maturity, still continues to be considerable up to 35 years of age. Many of the acute specific fevers, as varicella, scarcely occur during this period of life, and all are rare. Typhoid fever, for example, was considered by Murchison to be most frequent between 15 and 20, though liable to occur at any age, and Dr. Broadbent speaks of it as most common in adolescence and the first decade of adult life. In regard to the diseases of that system, which combines with its more restricted functions of governing movement and the reception of impressions the widely diffused control of tissue nutrition, a similar freedom would appear generally to prevail. Such affections as chorea and epilepsy, so characteristic of the first period of life, though still occurring, do so with much less frequency, and certainly so as a first attack. Putting aside cases of nervous disease caused by syphilis or injury, I cannot point to any malady of those organs which may be said to prevail during mature life. The hysterical girl may grow into the hysterical woman; and the perverseness of temperament manifested by the hypochondriac or melancholic may develop at this period, but, on the whole, there is no inherent proclivity to mental disease, except of an hereditary character. The establishment of stability and regularity in the nervous functions, has diminished the risk of disturbance, even if it have not caused to disappear many of the neuroses which the evolution of the organism in the previous period had conditioned.

But, although I describe the morbidity of this period as mainly of an accidental and fortuitous character, rather than inherently induced, at the transitional epochs, from the preceding and to the succeeding stages, very evident morbid imminences prevail. Especially is this seen in the later years of maturity, with commencing decline, and, indeed, until old age is fairly established. Decline, as I have said, usually commences at about 55 to 60 years of age, it being preceded in women about 10 years by the cessation of the catamenia. Associated with this "change of life" are many morbid manifestations which will more suitably be treated of when I speak of sex, but, except in the one respect of arrested reproductive power, the menopause is not to be regarded as the commencing

<sup>2</sup> De l'influence des Ages sur les maladies, par A. N. Gendrin, 1840.

decline, since women very commonly enjoy perfect and even improved health for some years after menstruation has ceased and before old age sets in. Frequently, however, at about this period in both sexes are sown the first seeds of the disease which, accidents apart, will eventuate in the final illness. The growing disposition to that degenerate condition of structure which is the normal of old age, as the opposite extreme distinguishes infancy, finds expression in the obesity which, especially in women, marks the decline. The excessive deposition of fat, itself an expression of impaired nutrition, may by the very pressure it induces on the organs and tissue-elements seriously diminish the general vitality. The gradual deterioration of the elasticity of the tissues, and their liability to distension, are seen in the greater fulness of the venous system, with the congestion and hæmorrhage which such plethora favours. Now begin to occur cerebral apoplexies, pulmonary congestions, hæmatemesis and hæmaturia, whilst hæmorrhoids are a common complaint. Acute inflammatory diseases become rarer, and disease in general, however caused, tends to assume a more chronic character than it has done previously. The errors of diet, long persisted in, have at last told on the alimentary and excretory organs, and dyspepsia has become confirmed, whilst the kidneys, from the prolonged stimulation of irritant excreta, exhibit grave evidences of disease. "The transition from virility to the period of decline," says Michael Levy, "fixes in the organism maladies which, dating from a previous period, have not been obliterated by this revolution of age; it impresses on them the *cachet* of an irremediable chronicity; and, if it do not convert them into habits which are harmless to the economy, lays the foundation in the organism of those influences which sooner or later will be fatal."<sup>3</sup>

A remarkable feature of later middle life is that after the tissues have been maintained for years at a normal standard of structural integrity there arises very frequently a liability to perversion of nutrition which results in the evolution of new growths which are not homologous to the texture in which they occur. Such are carcinomas. Short of such a marked departure as these exhibit, tumours of other types, which do more or less closely correspond to the structures of the tissues they occupy, are frequently met with. I cannot enter here into the speculations which this subject suggests, suffice it to say that before the body declines into that typical decay of old age, whilst the tissues are still at their highest point of structural and functional perfection, by what would seem a misdirected effort of vitality, some new growth is developed which exerts a fatal influence over the entire nutrition of the body. Cancers, although of occasional occurrence in childhood, are most prevalent from 40 to 60 years of age, and with marked frequency first appear in perfectly healthy individuals.

That old age of itself confers an aptitude to disease is certain. But "there is probably no one disease which is met with only in advanced age; rather is it that many which prevail at certain periods are wanting then. The degeneration of every tissue and organ entails a failure in function; and should this failure predominate in any one system we have some exception to what may be taken as the normal standard of the senile state, and therefore a disease of it."<sup>4</sup> "Man kills himself rather than dies," says Flourens, and it is of exceptional rarity that a person dies simply of old age, where the organs present a uniform deterioration, without positive disease in any one. It may not be forgotten that the healthy characters of old age if anticipated in occurrence are to be regarded as signs of

disease, and hence, therefore, a person should look his age and not older. Much judgment, to be attained only by practice and observation, is required to rightly estimate the bodily appearance at various ages; but as a factor in forming a diagnosis it frequently becomes valuable and hence worthy of cultivation. The conditions which favour the occurrence of disease at this period of life are to be found in the degenerations of the tissues which is the normal feature of this age; though why, when a standard of perfection has been reached and maintained, a decline from that should as a matter of fact follow, we can see no shadow of explanation for. Since the elements of the tissues are altered in their intimate molecular constitution, evidenced by the visible and chemical changes in their appearances and composition, it follows that the functional capability, itself dependent on this same constitution, must be altered likewise. In other words, as the structure degenerates the functions are enfeebled and the whole vitality impaired. So long as this affects the various organs of the body in equal proportions a manner of life healthy to this age (but very far from being so if occurring earlier) is pursued and may terminate, as I have said, in rare instances, in what may be termed a normal death. This is supposing the individual have not acquired in some former period a distinctly established habit of disease; but by far the greater number of persons enter on advanced life with some clearly defined disease of one or more organs. Those maladies which I enumerated as appearing in the later years of middle life continue on with growing force, and either of themselves lead to death or reduce the body to such a condition as to allow a fatal effect from some acquired ailment, induced, perhaps, by an environment which would be quite suitable at a previous age, but which, for the enfeebled susceptible tissues of the old, is sufficient to lead to illness.

The maladies of the last period of life then are chiefly those which have continued on from the previous stage, and, hence, are most varied in character. "In old age," says Hippocrates,<sup>5</sup> "men are subject to asthmas, defluxions, coughs, stranguries, pains of the joints, diseases of the kidneys, vertigo, apoplexies, cachexy, itchings of the body, watchings, tumours of the intestines, eyes, and nose, dimness of sight, glaucoma, and deafness." Those which are acquired at this time are usually, in themselves, but slight; "the last straw," which crushes out the lamp of light. Most commonly are they catarrhal affections of the pulmonary organs or intestines, and a little bronchitis, or a slight diarrhoea is the immediate cause of death in very many cases. The greater dependency of the aged, and their lessened ability to resist adverse influences, combine with the ever increasing death tendency to confer on this period an aptitude for diseases only equalled in the earliest days of life.

The general character of illness at this time is very distinct from that of the maladies of growing and mature life. Their essential features are an insidiousness of progress and an obscurity in symptoms. The diseases, in short, require looking for, the patient appears to be a "little out of sorts," only ailing, and yet it may be the illness from which he will never recover, whilst scarcely manifesting any definite symptom that would point to the organs mainly involved. How different from the infantile sickness in which the whole body shares, and when the real disease is hidden in an exuberance of symptoms, or from the well-defined maladies of adult life. The withdrawal of what has been termed the 'peripheral life' to the interior, as seen in the decreasing power of the senses, the wasted skin and enfeebled muscles, with the concentration of the remaining vitality upon the central organs of vege-

<sup>3</sup> Hygiène publique et privée. 5th edition, 1869.

<sup>4</sup> See article "Senility" in Quain's Dictionary of Medicine, by the writer.

<sup>5</sup> Aphorisms, Sect. iii., 31.

tative life, which distinguish senility, impress their characters on its diseases, which develop and end often unrecognised from lack of manifestation.

There yet remains one question, in connection with the bearing of age upon diseases, of the greatest interest and importance. Time does not permit a lengthened examination of it, and I must refer you to Mr. Sedgwick's articles<sup>6</sup> on the influence of age in hereditary disease, but the following quotation from one of his papers will sufficiently indicate the nature of the subject. "Apart from the natural tendency in certain diseases and defects to appear at one period, whether of foetal or air-breathing life, it may, moreover, be noticed that when disease is developed in connection with heredity, especially during the air-breathing life, there is frequently a well-marked limitation by age which is independent of any preference for a particular epoch in the development of the body; the recurrence of the disease in such cases being regulated by the age at which it first attacked the ancestor from whom it was received, or the first member of the family to whom it could be traced; and even if this has happened to be at some exceptional period of life the disease is still apt to be restricted to that age, when it subsequently reappears either in the succeeding offspring or in the more remote descendants. It will, perhaps, without much hesitation, be acknowledged that limitation by age in hereditary disease is, strictly speaking, nothing more than an illustration of the influence of time on development, and that it is one of the results consequent on the changes occurring in the system being progressive."

I have thus placed before you what appear to me to be the most important considerations in respect to the influence exerted by age upon disease. You will have observed that successive periods of life are marked by certain characters of structure and function, and that the diseases of each period have for the most part generally distinctive features. Such information as I have here given should clearly be possessed by you before you enquire the age of your patient, for without it you cannot appreciate the significance of the reply you receive, and in proportion to your failure in this direction do you fall short in the completeness of your diagnosis. Armed with this information, you approach your patient in a much better position to investigate his condition, for a knowledge of the age, and the liabilities it confers, will of itself suggest some of your questions and assist in putting you on the road to discover what is wrong, whilst in the prognosis and treatment its importance is equally considerable.

## APPOINTMENTS FOR THE WEEK.

*Friday, November 20 (this day).*

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Adam Street, Adelphi, 8.30 p.m.—Dr. Heron, on "Koeh's Cholera Organism," with demonstrations.

*Monday, November 23.*

MEDICAL SOCIETY, 8.30 p.m.—Mr. A. Pearee Gould, "Cases of Sarcoma rapidly following upon Injury"; Mr. Walter Pye, "Pyæmia after Removal of a Sarcoma from the Base of the Skull."

*Tuesday, November 24.*

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 p.m.—Mr. Arthur Barker, "On the Distribution of Bacillus Anthracis in the Human Skin in Malignant Pustule"; Dr. John Harley, "A Case of Acute Tubercle of the Liver agreeing completely with the so-called Actinomyces." A series of microscopic specimens illustrative of Dr. Harley's paper will be on view at 8 p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m.—Mr. C. H. Read, "Exhibition of Ethnological Objects from Tierra del Fuego"; Dr. J. E. Billings, Washington, U.S.A., "Exhibition of Composite Photographs of Skulls," &c.

*Friday, November 27.*

CLINICAL SOCIETY, 8.30 p.m.—Mr. Barwell, "A Case of Gastrostomy"; Mr. Dent, "A Case of Gastrostomy"; Mr. John Morgan, "A Case of Gastrostomy"; Mr. Golding Bird, "Jejunostomy in Cases of Cancer of Pylorus." Living specimens: Dr. Felix Semon, "A Case of Congenital Malformations (Web between Vocal Cords, and Coloboma of Eyelid); Dr. C. R. Walker, "A Case of Myxœdema"; Dr. T. D. Savill, "A Case of Myxœdema."

# Medical Times and Gazette.

SATURDAY, NOVEMBER 21, 1885.

THE thirty-eighth session of the General Medical Council was opened on Tuesday last, when the President gave his usual address, indicating the business which was to be laid before the members. After admitting that the present session had been necessitated by the action of the Irish Branch Council, he proceeded to express his belief that an autumn session would, in future, always be necessary for the conduct of legal and other business, leaving the Council free to devote their whole energies to the conduct of educational business at the ordinary meeting in the early part of the year. The disagreement which had arisen in regard to the passing of the preliminary examination in mechanics in Ireland, and the case of the Queen's Colleges of Belfast, Cork, and Galway, were next alluded to. After a brief reference to the new Pharmacopœia which had been issued since the last session, mention was made of Mr. Marshall's expected communication on the results of a statistical enquiry conducted by himself. Sir Henry Acland concluded his address with some general remarks on the position of the profession, and on the prospect or otherwise of a union between the various licensing bodies. The redecoration of the room, and the improvements that have been effected in the matter of ventilation, reflect considerable credit upon those to whom these matters had been entrusted.

THE first business consisted of a series of notices from various licensing bodies, notifying that certain offenders had been removed from their respective rolls, and in one case of a certificate that a qualified practitioner had been convicted of a felonious attempt to procure miscarriage and sentenced to ten years' penal

servitude; the name and qualifications of this person were struck off the Register. A long and important discussion arose on one of these cases in consequence of the refusal of Dr. Aquilla Smith to state the nature of the offence for which the person had been deprived of his diploma. In the end the Council decided to defer the consideration of this particular case until information was before them as to his wrong-doing. The discussion was vigorously kept up, some being of opinion that the Council had no option in the matter if they wished their Register to be correct, but must at once remove any qualification from the Register, the holder of which had already been deprived of it by the body which originally granted it. The position of these gentlemen seems at first sight a very strong one; the person in question is no longer, as a matter of fact, a member or licentiate of the particular licensing body, but the arguments, on the other hand, seem of greater weight. The Act specifically states that the qualification of any person may be removed from the Register if the Council see fit. Unless these words have no meaning, it must have been intended, when the clause was framed, that the Council should have the power to leave a person on the Register even though he had ceased to be on the roll of any of the licensing boards. It was evident that the majority of the Council were of opinion that the latter was most consistent with their duties.

WE could suggest an even stronger hypothetical case than that put by Sir Henry Pitman as indicating that the Council ought not blindly to remove a man from their Register. We will suppose that a man was practising with no other registrable qualification than the M.R.C.P. of London, and that it came to the notice of the College that this man was in partnership with another practitioner. As we understand their by-laws, the college could not allow him to remain a member if he persisted in his partnership. He would, therefore, cease to have a registrable qualification, but surely even the most ardent sticklers for the accuracy of the Register would not deprive him of his right to practise upon such a ground as this, when they had learnt the true nature of the charge for which he had been dismembered. The discussion, which arose out of a piece of dental business on Thursday afternoon, tended clearly to show the correctness of this assumption, and, although Dr. Quain's contention that the Council must not discuss the conduct of the corporate bodies is a very just one, yet, on the other hand the Council must not allow the action of those bodies to be in any way binding upon them. It would probably save a great deal of the time of the Council in the future if the practice of registering the qualifications were given up. Let a man produce a registrable qualification, and then his *name* can be placed on the Register. It seems to us that the Register must not be regarded as the legal indication of a man's qualifications; only a proportion of the practitioners think it necessary to register all their qualifications, and no one would seriously argue that a Fellow of the College of Physicians was only a Member of that body because he had not thought it worth while to expend

five shillings in registering his promotion. Otherwise the Register is full of inaccuracies at the present moment.

THE rest of Tuesday afternoon was taken up with the business which was the prime cause of the summoning the Council for this session, viz., the position of affairs in regard to the Queen's Colleges of Galway, Belfast, and Cork, and the action of the Executive Committee in relation thereto. On the last day of a very long session in the earlier part of this year, as our readers will remember, when all the members were really anxious to get away, Professor Haughton, as chairman of the Committee on the preliminary subjects question, moved that the above-named colleges be removed from those whose examinations are recognised by the Council, alleging that they had ignored the repeated requests of the Registrar for information, and that there were other reasons for the step, which he would give on a more suitable occasion. Thus invited, the Council did not stay to consider the meaning of the step, but struck the three bodies off their list forthwith. Of course these immediately protested, and the Executive Committee very naturally ordered things to be restored to the *status quo* until the matter should have been more fully considered by the Council. The required papers having been sent in, they were referred to a small committee, Professor Haughton announcing that he had no other objection to these bodies being on the list except their neglect to supply the information asked for. A half attempt on the part of Dr. Lyons to censure the Executive Committee for their action in nullifying a decision of the Council drew from the President a simple statement of the case, in which he fully justified the line adopted. On Wednesday, after some considerable time had been consumed in considering the Standing Orders in reference to procedure in the matter of removing names from the Register, Mr. Marshall brought up an *ad interim* report of the Statistical Committee, which contained many facts of interest and evidently represented an enormous amount of labour, but to which it would be quite impossible to do justice in a few lines. A report from the Pharmacopœia Committee was adopted, authorising the present Committee to act as a Standing Committee and publish, as may be necessary, any changes or additions to the Pharmacopœia. A communication from the Local Government Board, asking for information as to whether the licence of the Society of Apothecaries would now convey a licence to practise surgery, gave rise to a prolonged discussion. The defence of the Society in question was undertaken at great length and with much skill by Mr. Simon, and Mr. Teale and Dr. Heron Watson both showed that they had grasped the great importance, and at the same time the great difficulty, of the subject, and the day finished without any decision having been arrived at as to what, if any, answer should be sent.

At the meeting of the Ophthalmological Society on the 12th instant there were as usual several living specimens, drawings, and instruments shown. Mr. Lang read a paper on penphigus of the conjunctiva,

a condition which all must admit to be very rare, seeing that only one case has hitherto been recorded in this country, and that so experienced an observer as Mr. Hutchinson has never met with an instance at all. Now, however, that attention has once again been called to the affection, it is by no means improbable that other cases will be recognised. Mr. Jessop read a paper relative to what we believe to be a unique variety of pupillary changes during the associated movements of the eyes. The patient was or had been the subject of so many abnormal states, both inherited, traumatic, and acquired, that his case was unusually complicated, but he presented three definite and distinct pupillary symptoms, viz., loss of light reflex, loss of sensory reflex, and dilatation of the pupil in association with outward excursions of the globe. Nothing short of a new centre beneath the aqueduct of Sylvius appeared to Mr. Jessop to afford a satisfactory explanation of this unusual group of phenomena. Mr. Snell contributed a paper on deep-seated foreign bodies in the eye, a subject to which he has, as is well known, devoted especial attention. Mr. Nettleship raised a question of great moment in asking for experience as to evil results attributable to cocaine, and, though it is probable that most of the mishaps which he and subsequent speakers were inclined to attribute to this drug were due to the solution used not being quite fresh, still it is by no means certain that this explanation covers all the cases, and it behoves all who use it to closely study their results.

ON Friday, in accordance with a prior announcement, an additional meeting was held for the purpose of hearing Dr. Hughlings Jackson deliver the Bowman Lecture. Founded a little more than a year ago, to commemorate the eminent services of Sir William Bowman, not only to the Society, of which he was the first President, but to the profession and the public at large, by his contributions to ophthalmic science and practice, this lecture bids fair to become one of the chief features of the Ophthalmological Society. As our readers have the opportunity of studying for themselves the masterly analysis of certain of the phenomena connected with the epileptic state contained in Dr. Jackson's thoughtful paper, we need not further allude to it at present, except to say that it was a grand address, worthy of the great occasion on which it was delivered. The proceedings were brought to a close by a vote of thanks to the lecturer, accorded by acclamation on the proposition of Sir William Gull, whose few remarks were in his best style. Mr. Macnamara briefly seconded the vote of thanks. After the meeting the members and visitors were most hospitably entertained by the President of the Society.

THE rival attractions of the Bowman Lecture were not sufficient to cause any appreciable desertion of the Clinical Society on Friday last, a full attendance of members being present. The subject of Purulent Peritonitis was introduced in a paper by Dr. Samuel West, and gave rise to a practical discussion upon the diagnostic features of the disease. Dr. Charles West,

amongst others, took part in the debate, his re-appearance as a working member of the London Societies being gracefully welcomed from the chair. That considerable difficulty must always attend the distinctive diagnosis between purulent peritonitis and mechanical obstruction of the bowels was made very evident by the recorded experience of the surgeons, more than one of whom were able to quote from their own case-books the history of an operation actually undertaken before the error in diagnosis was discovered. It appeared to be generally accepted that a truly idiopathic form of purulent peritonitis may exist, although in the very large majority of cases some local cause can be found if it be carefully sought for. A long and somewhat minute account by Mr. Rivington of an operation performed by him for the relief of femoral aneurysm did not give rise to any discussion, but was supplemented by the history of a remarkable case of aneurysm of the profunda femoris, by Mr. Golding-Bird. A short clinical account of a case of nitric acid poisoning was communicated by Dr. Duckworth, the special feature of the case being the production of hæmaturia during the most acute stage. A long array of living specimens occupied the attention of many of the members until the reading of the first paper was nearly concluded, but none of them were illustrative of any of the subjects discussed at the meeting.

THE communications by Mr. Sutton and Mr. Shattock to the Pathological Society last Tuesday evening were of the greatest interest; the latter dealt with the subject of iridescent calculi, of which he showed a beautiful series of preparations and drawings. His suggestion that albuminuria may have a share in the formation of this particular class of calculi seems to be probably correct, and will, we hope, be borne in mind by those who endeavour to investigate this subject in the future. Mr. Sutton detailed the results of an investigation into the nature of ovarian cysts in animals, arriving at some interesting and important conclusions which have a direct bearing on the subject of cysts in the human ovary. The President brought an almost unique instance of ante-mortem thrombosis in the heart, and Mr. Lockwood showed some dissections and casts of contracted fasciæ, in one of which the disease was associated with a deposit of urate of soda in the fascia. Dr. Chaffey read a long account of a fatal case of hæmorrhage into the grey matter of the spinal cord of a child, and Dr. Moore showed a specimen of gummata in the liver from a case of congenital syphilis. Dr. Hale White brought a liver showing the effects of tight constriction on one portion of it, and he also showed, for Dr. Rake of Trinidad, some hands and feet from cases of anæsthetic leprosy.

THE quarterly meeting of the Medico-Psychological Association was held at Bethlem Hospital on Tuesday, the 17th instant, Dr. H. Rayner presiding in the absence of Dr. Eames, the President for the year. Dr. Conolly Norman read a paper "On some Points in Irish Lunacy Law," in which he explained the different mode of procedure which existed in Ireland in regard

to the admission and discharge of pauper lunatics, and urged the great desirability of assimilating the lunacy laws throughout the United Kingdom. Dr. Hack Tuke read a paper "On a recent visit to Gheel." In the discussion which followed, Dr. Savage and Dr. Pritchard Davies, who had also visited Gheel, gave their experience on the subject, concurring with Dr. Hack Tuke's statements as to the somewhat dull appearance of the place and the moral dangers and difficulties involved in the supervision of so large an area, but at the same time fully recognizing the care and kindness of the authorities.

At the next meeting of the Royal Medical and Chirurgical Society, on the 24th inst., Mr. Barker's paper on the "Distribution of Bacillus Anthracis in the Human Skin in Malignant Pustule" will be read, and also one by Dr. John Harley on a case of "Tubercle of the Liver," in which the appearances of actinomycosis are presented. In this paper the question will be raised as to the reality of the so-called actinomycosis.

THE Council of the College of Surgeons have decided *unanimously* that Members of the College shall not be granted the right of electing to, or putting up for, the Council; but they have shown the germ of a growing courtesy in deigning to explain to the Members the reasons for their decision. These reasons will be conveyed to the Fellows and Members at a meeting on December 17th in a statement clearly conveying the Council's "*decided opinion* that it would not be for the good of the College that the Members generally should vote at the election of members of Council." The statement will also contain the reasons which make it impracticable, in the Council's opinion, to give effect to the resolution passed at the meeting of Fellows and Members on October 29th, to the effect "that no alteration in the constitution, or in the relations of the College, or in any of its by-laws or ordinances, shall be effected without the consent of the Fellows and Members convened to discuss such alterations." As a set-off to their decision not to accept any of the proposals which have been pressed upon them, and perhaps as in some respects a sop to some of their body for not spoiling their unanimity, the Council are engaged in considering whether they cannot widen the basis upon which the Fellowship is obtained. That looks as if they meditate depriving the Members of what little strength and union they have shown by holding out to the more prominent amongst them the bribe of the Fellowship.

It is pretty clear to the onlookers that in this little diplomatic contest between the Council of the College and the Members' Association the latter body is distinctly overmatched. So far, the Council have certainly got the best of it, owing to the astuteness with which they have seized the advantage afforded them by the inconsiderate tongues of the Members. The useless and indecorous abuse indulged in at the last meeting of Fellows and Members, which was certainly not sufficiently discouraged or disavowed at the time by the representatives of the Association, has naturally

alienated the sympathies of the reforming minority in the Council and driven them into the arms of the more conservative majority. It has also, though perhaps to a smaller extent, disgusted many of the independent Fellows, and even some of those Members who were before inclined to throw themselves into the movement directed by the Members' Association. It remains to be seen whether the Council will succeed in detaching the more eminent of the Members from their sympathy with the Association by transferring them to the higher grade. In any case, it is obvious that the Members' Association have a difficult task before them, though there is not the slightest reason to despair of ultimate success. The action of the Council may possibly strengthen the hands of the Association, just as the action of some of the more irresponsible Members of the Association has strengthened the hands of the Council. But it is incumbent on the Association to act with wariness and forethought. They have to deal with men more able, more practised in affairs, more subtle, and probably more determined than themselves, and another false step may ruin the whole movement. One thing is clear; a bridle must be put on unruly speech. If the Association is to live and prosper in its mission, there must be no repetition of the painful incidents of the last meeting in the College theatre. At that meeting it appeared as if the Council were on its trial. At the next meeting, on December 17th, the positions will be reversed. It will then be the Association that will be on its trial.

WE have not been always able to approve of the acts or objects of the Medical Defence Association, because we feel that a too rigid insistence on rights is very apt to place the profession in a position of antagonism to the public, and to imperil that popular goodwill which we are sure all of us value more highly than the exactment to the last letter of all our just dues. But we are thoroughly in accord with the recent action of the Association in respect to the hard case of Dr. Collie, and we cordially endorse almost every word of the temperate memorial which they have sent to the Local Government Board and the Asylums Board managers. We thoroughly agree that "to throw Dr. Collie out of office and practically make a wreck of his career would be a hardship altogether out of proportion to faults which we would not for a moment extenuate, but which we feel were the necessary results of a bad system rather than errors pertaining to one particular and grievously overtaxed medical officer." We trust that the managers will do all that is in their power to repair the injustice which has been perpetrated by them in a moment of perhaps righteous indignation, and confirmed by the Local Government Board with a weakness for which the same excuse cannot be offered. The treatment of Dr. Collie, hard as it is individually, involves a principle, and no rest ought to be given to the Central Board until its officials have been forced to open their eyes to the probable results of the course they have initiated. They now obtain, for comparatively trifling salaries, the services of able men who would easily be

able to make thrice the income if they entered into ordinary practice, but who have been tempted into the service of the Board in the belief that they are thereby avoiding the risks and competition incidental to more remunerative fields of work. If Dr. Collie be sacrificed for the sins of his lay colleagues, the carelessness of the managers, and the supine indifference of the Local Government Board, the security of tenure which service under the latter body is supposed to imply will be at an end. No medical practitioner in the poor law service will, in future, be able to make sure of his position; he will be entirely at the mercy of his own Board, and that independence which is one of the conditions of efficient work will be, all over England, a thing of the past. At a time when every one is demanding that Medical Officers of Health shall be irremovable except by the Central Board, the action of that Board in Dr. Collie's case is a step which is distinctly retrograde. The Board has not acted with the strength and justice which we are entitled to expect of a powerful Government Department. When we remember that, as stated by Dr. MacLagan in his letter to the *Times*, it was largely due to Dr. Collie's untiring efforts that London was saved last year from an appalling epidemic of small-pox, it is difficult to write of the treatment he has received in words that approach to temperateness.

THE death-rate of London experienced a further slight rise last week, and reached 19.6 per 1,000, but the deaths were still 170 below the average. This fortunate deficiency is mainly attributable to the

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past nine weeks.

comparatively slight prevalence of zymotic disease, the number of deaths from them last week, viz., 158, having been exactly two-thirds of the average number.

There was a considerable rise, however, in the mortality from measles, the 51 deaths from which exceeded the average by 7. Diphtheria was also unusually fatal, exacting 26 victims, or 10 more than the average. The 19 deaths from scarlet fever, on the other hand, were as many as 54 below the average. The deaths from diarrhoea and typhoid were also below the average, but those from whooping-cough were well above it. The deaths of three Londoners were recorded in the week from small-pox. There was one more death from hydrophobia, and nine from puerperal fever. The 418 deaths from respiratory disease were nearly up to the average. The health of the 28 large towns as measured by the death-rate was satisfactory, 17 of them having a rate below 20, and only one, viz., Preston, a rate of more than 25 per 1,000.

STRANGE shifts are common at General Election time, but we have never before heard of one party bodily appropriating a manifesto issued by the other party at a previous election. This, however, has been done with great effect by the supporters of Mr. Erichsen, whose candidature for the Universities of Edinburgh and St. Andrew's has, we are glad to hear, been most favourably received by the constituency. Just before the last General Election a circular, signed by Sir Robert Christison and other Edinburgh Professors, was issued by the Conservative party, upholding the claims of Mr. Bickersteth, the well-known Liverpool surgeon, against those of Sir Lyon Playfair, mainly on the ground of his being a medical man. The circular was an able one, but unfortunately, as the Conservatives have gone back on the opinions expressed in it, and are opposing a better medical candidate than even Mr. Bickersteth, it is likely to be of more use to their opponents than it ever was to themselves. They are, in fact, "hoist with their own petard."

MR. ERICHSEN has addressed a letter to the Medical Members of the General Council of the Universities of Edinburgh and St. Andrews, in which he states succinctly what is to be expected of a medical M.P. He is to devote himself to such legislation as is specially connected with questions that affect the education, the practice, and the status of the medical man, and that regulate his relations to the public. He is to interest himself in all legislative measures based upon medical and sanitary science, and having a direct bearing on the physical well-being of the nation, which now receive such inadequate and half-hearted attention. He is to strive to correct the abuse of medical charity; to provide that the public should be more efficiently protected against unregistered practitioners; and to strengthen the hands and reconsider the constitution of the Medical Council of Education and Registration. Mr. Erichsen himself is opposed to all unnecessary State interference in the control of medical education and examinations, as well as to the scheme for giving two of the London Medical Corporations the power to confer degrees in medicine; but is in favour of the creation of a Minister of Public Health. "Surely a wise physician, or an enlightened sanitary reformer, is a person as likely as any other to add to the dignity and usefulness of the Privy Council, or of the House

of Lords." On such secondary questions as those of Compulsory Vaccination, the operation of the Contagious Diseases Acts, the Amendment of the Lunacy Laws and Quarantine, he will act in accordance with the received opinions on these subjects of the most enlightened members of our profession.

THREE phases can almost invariably be traced in the life history of new remedies. The first is that of rapid ascent to the pinnacle of popularity, till all the world rings with the marvellous powers and apparent infallibility of the new-found talisman. Then comes a more sober and level course. Experiments and investigations begin to be instituted by practical observers, and the truth begins to leak out that, although endowed with very marked powers to disturb normal physiological processes, the drug is at times disappointingly inactive in its effect upon diseased tissues. Sooner or later in this stage, however, it is quite certain to be found to be infallible in sea-sickness! Then follows a stage in which the reverse of the medal is directed to the public view. The new drug is found to possess unpleasantly toxic properties when used with the confidence which is engendered of too great familiarity. It is to this stage that cocaine has now, in the natural sequence of events, duly arrived. A warning note comes from Germany, which will probably be echoed before long in the medical schools nearer home. Dr. Bresgen, of Frankfurt, who has had the opportunity of observing the milder forms of cocaine poisoning, especially after the application of the drug to the nasal mucous membrane, records two cases which deserve no ordinary attention, since the poisoned persons were the writer of the paper and his wife. In the case of the lady, a smaller dose was employed, and in both the solution of cocaine was introduced in three drops into the nostrils. The symptoms produced were, first, a feeling of general chill, increasing to absolute shivering, a preliminary exaltation of spirits, followed by depression, feelings of nausea in the throat, staring eyes, and a vacant expression. With difficulty of speaking and thinking there was combined an extraordinary degree of wakefulness. The gait was unsteady, and a feeling of almost paralytic weakness of the limbs was noted. The appetite was lost, and there was, indeed, an absolute loathing of food. These symptoms persisted in greater or less degree for twenty hours. Dr. Bresgen does not accept the view that the whole of them can have been set up by the quantity of the solution absorbed from the mucous membrane of the nose, but rather believes that a large proportion of the cocaine must have made its way into the stomach. He, therefore, advocates the use of a sound, tipped with cocainised cotton wool, in preference to the less cautious method of introducing the drug by dropping, which he employed in his own case.

MR. A. J. DUFFIELD writes to us as follows:—I see by the papers that Dr. Wicherkiewicz has been making trial of Professor Manassein's remedy for sea-sickness—cocaine—and confirms the St. Petersburg professor's high opinion of its value. If a layman's experience be of any worth, let me say that twenty years ago, when returning home from Peru, I brought

with me some 50 lbs. weight of fresh leaves of the *cucu*, and proceeded to experiment on some miserable fellow-passengers who were suffering from sea-sickness by means of a straw-coloured decoction of these leaves. They were all adults—ladies, priests, and Peruvian poets. Every one of the patients fell asleep on drinking a large breakfast-cupful of my tea. They were all cured. But, on changing from the Pacific to the Caribbean Sea, the malady again attacked the priests and the poets—the women were not attacked—and again a single cup of *cucu*-tea had the same effect as before. Much of course depends on the leaves being freshly gathered.

OUR Edinburgh correspondent writes:—The medical classes here are now in full working order, and it is reported that the numbers exceed those of last year by upwards of 50. The class-rooms of the extra-mural lecturers are likewise well filled, so that the school as a whole shows no signs of falling off. As a result of the recent judicial decision regarding the publication of notes of lecturers, a small volume, embodying the gist of the course of Pathology in the University, has been issued. The occupant of this chair, in his introductory lecture, spoke in rather bitter terms regarding the probable effects of this decision. Among other evil results he predicted that lecturers would henceforth, in order to protect themselves, withdraw from their ordinary prelections all original ideas and results, and treat their students merely to a *résumé* of the ordinary matters of the text-books. I doubt if many people will be alarmed at the prospects of this contingency. It might be an interesting, but would not be a difficult, calculation to estimate the gain to science per annum from the original ideas promulgated by the entire medical faculty of our University. Would they be much missed from the courses of lectures? Hardly.

At the opening meetings of the Medico-Chirurgical and Obstetric Societies of Edinburgh, held on the 4th and 11th instant respectively, Professor Grainger Stewart was elected President of the former, and Dr. Halliday Croom of the latter. Both Societies, judging from the value of the papers and discussions contributed during the past session, are in a prosperous and active condition, and it is not likely that they will lose ground during the tenure of office of the new Presidents. Dr. Byrom Bramwell having resigned the Pathologistship to the Royal Infirmary, consequent on his appointment as Assistant Physician, the managers resolved to appoint two gentlemen to undertake the duties of the office, and on Monday elected Dr. Sims Woodhead, Assistant to the Professor of Pathology, and Dr. Alexander Bruce, Lecturer on Pathology, School of Medicine, to the vacant office. The contest was a keen one, and evoked a good deal of interest. The selection must have been a difficult one, as all the candidates had high claims. Some time ago Dr. Thomas Keith, who has long held the office of ovariotomist to the Infirmary, applied to the managers for an assistant who should, besides assisting him during operations, be empowered to take full charge of the wards during his absence, with liberty to operate, and he nominated his son for the office. After considerable delay and, as it is rumoured, some acrimonious

correspondence, the request was agreed to, and his son's appointment confirmed. This mode of procedure marks a new departure in the mode of election of officers in this institution, and it is to be hoped will not be regarded as a precedent. So far as we know, it is the first time that a surgeon has not only claimed a special assistant for himself, but likewise the privilege of nominating the individual for the office. It is not contended in this instance that the gentleman who has been appointed is not a fit and proper person, probably he is the most fit and proper person for the duties; but the manner of election savours of nepotism, and Edinburgh has more than once had reason to regret the results of such a practice.

#### DR. WILKS' BIRMINGHAM ADDRESS.

THE occasions are few and far between which the leading men in our profession have chosen for speaking to their brethren out of the fulness of their hearts and the wealth of life-long experience and thought on the all-important subject of the treatment of disease. Such a retrospective essay as Dr. Wilks has given us, based on his life's work in pathology and practical medicine, and informed throughout by such a measure of the true scientific spirit as is given to but few of even our leaders for their enlightenment, has a value which it is impossible to over-rate. Unlike many public addresses it is unquestionably the outcome of genuine thought on observed facts, is entirely untainted by bias, and has no other motive than to acquaint the profession with the results of the speaker's reflections on the work which has absorbed him so long. From the beginning to the end of the address, indeed, we seem to hear the author thinking aloud. Dr. Wilks has spoken on this occasion more powerfully than anyone before on the question of the drug-treatment of disease. There is a common belief that most physicians may be divided into two classes with regard to the matter, viz., those who do and those who do not "believe in drugs," and the uncritical outsider in the profession looks upon the one class as childishly credulous, the other as indolently infidel. That there is no real question raised in this popular division is clear, as there is no thought given to the meaning of the term "belief in drugs." But it is obvious that there can be but one really scientific class of physicians; those who, from the best attainable knowledge of the natural history of disease, apply to it the best attainable treatment, of whatever kind that treatment may be. Then, and then alone, will any department of treatment find its proper place. Starting from this basis, Dr. Wilks illustrates, by a wealth of examples, the real part played by the pharmaceutical remedies we have at command, and shows how sometimes they may be all important, but more often quite subordinate in their application. It is the *proper place* for the drug treatment of disease to come in, when it comes in at all, which the careful reader will find to be one of the points most thoughtfully urged in this address. And if the results of his study of pathology and of clinical medicine have led Dr. Wilks to the conclusion that, however valuable as isolated scientific enquiries the results of experimental

pharmacology may be, and however useful a few of its practical applications to therapeutics may have been found, yet it is not along this line that a great addition is likely to be made to our methods of treating disease successfully, none even of the pseudo-scientists of the day will venture to bring forward here their favourite allegation of indolent scepticism as the groundwork of such a conclusion.

We do not doubt that there are very many in the profession who will from their own knowledge and experience admit the force of all that Dr. Wilks has said, and read his remarks with all the pleasure and satisfaction that arise from seeing their own convictions confirmed and illustrated by the hand of a master. It is well known, indeed, that there are several such men, even in the highest places. But we have the greatest reason to thank Dr. Wilks for this latest utterance of his, in that but few have plainly expressed themselves to this effect to the profession at large, however much they may speak their minds in private, or even in medical consultations. Most of us, even in this day, though at heart rendering due fealty to scientific truth, carry on our cult, nevertheless, like the early Christians, in remote and hidden places, fearing to expose ourselves to the light of day, in dread of consequences; and some of us having so long dwelt in the cave of mysteries which we dare not renounce, become at last inevitably confused in vision, and mistake the shadow for the substance. How invigorating it is then to read such words as these coming from a teacher of wisdom and experience—words, which however common-place they may seem, nevertheless fall upon many deaf ears to-day; "That the medical man's calling has a necessary foundation in a knowledge of the anatomy and physiology of the human body, and that our present duty is to study disease and discover its causes. The next step will be an endeavour to remove them, and as far as we are successful in so doing we are fulfilling one of the highest objects which anyone can attain to. When all this is accomplished we make use of the best remedies we have to relieve our patients of the maladies we cannot prevent." All perhaps will verbally acknowledge the truth of this scientifically obvious dictum. But it is none the less true that the tendency of the modern therapeutical doctrines is, although often unconsciously on the part of their supporters, to run quite counter to this teaching, and to encourage a concentration of effort on the discovery of new remedies, saying that this way progress lies, to the comparative neglect of the study of the nature and causes of disease, the only real basis for successful treatment. Dr. Wilks lays especial stress on this point when he shows how little the results of the purely physiological study of the action of poisons and other drugs on the healthy body have an application to pathological conditions; and when he urges that as far as the number and action of remedies goes we are in possession of knowledge which outruns pathology and clinical medicine. It is more often, he says, a question in a case of disease as to what drug we should use, or what symptoms, if any, we should endeavour to act upon, than of finding a medicine when a true diagnostic indication is apparent. It is not new medicines which we

want, but a better knowledge of how and when to use those which we already possess. So far, he says again, from therapeutics lagging behind pathology and clinical medicine, we seem to be ever ready with drugs when we require them; and many and striking examples are given throughout the address to show that progress in medical treatment at the present time means not a multiplication of therapeutic weapons, but a better knowledge as to their proper use. Dr. Wilks in the course of his address refers at some length to the evils of medical specialism, and shows how it follows from his previous line of argument, that, with certain exceptions, it is as false in theory as it is pernicious in practice.

This sound and much wanted teaching comes with especial force from such an authority, and must have all the greater weight as emanating from a man whose devotion to scientific research is so well known. Experimental physiology has no warmer adherent than Dr. Wilks, and no one with the slightest knowledge of medicine or clearness of mental vision will see any contradiction to this position when Dr. Wilks is heard raising his voice against the misapplication of some facts ascertained by such research to complex conditions which stand in no natural relation to them, and emphasising the undoubted truth that pharmacology as such has no *necessary* connection whatever with practical therapeutics. The instructiveness and rich suggestiveness of the whole address we have been considering are such as should induce all to study it with the closest attention, and we would express the hope that the author will publish it in a separate form, so that this production of his maturest thought on a most important subject may be as widely read as possible.

#### THE INDIAN CHOLERA ENQUIRY.

WE have received from the India Office a document calling itself "An Enquiry into the Ætiology of Cholera." So far from being able to join a contemporary in the opinion that "it has swept away a prodigious mare's nest" we must confess to having read it with feelings of no small disappointment. It is from first to last an *ex parte* production, to put it in the mildest form, and, if not actually penned, is throughout inspired by one man. It is Dr. Klein's work with the imprimatur of a Committee, the members of which were, with very few exceptions, unfamiliar with bacterioscopy, and committed to such views on the ætiology of cholera that their verdict was a foregone conclusion. The question of ætiology involves much more than the pathogenetic character of a particular bacillus, and we must say, with all respect for such men as Sir J. Fayrer, Sir G. Hunter, and Drs. Norman Chevers, T. Lewis, &c., that we wish that others of equal authority, but holding opposite views, as Mr. Simon, Dr. Buchanan, Dr. Pringle, or Surgeon-General Comyns, "contagionists" as they are incorrectly called, had been on the Committee, the more so as Dr. Burdon Sanderson was unable to attend any of the meetings. Before criticising the actual observations of Drs. Klein and Gibbes,

we may make a few remarks on certain statements which show their bias. They say that "If the comma bacilli were really the contagium it is impossible to understand why direct contagion should not be a very common thing." Not at all. The Reports of the Local Government Board furnish numerous unequivocal instances of the spread of enteric fever throughout a community by water to which the evacuations of a single case have gained access, yet the direct communication of the disease from one person to another is as rare as, in our opinion, that of cholera. Again "if the evacuations were the actual *materies morbi*, such notorious immunity from cholera as is enjoyed by Versailles, by Lyons, and Birmingham, by ships on the high seas, &c., could not easily be understood." Now the evidence of such immunity is at best but doubtful, and has often broken down, and with each epidemic the number of such places is growing less. In enteric fever and in cholera alike the theory of an internal no less than that of an external germ or virus requires also the condition of a suitable "soil" and surroundings, and the apparent exemption of certain localities suggests further enquiry in this direction. When ships are put out to sea in consequence of the occurrence of cholera on board other sanitary precautions are usually taken, but the outbreak of cholera on the high seas is far from unknown. The *Corrèze* had 120 cases and 30 deaths between Saigon and Suez; but still more to the point are the stories of the *New York* and the *Swanton* which had been at sea respectively 16 and 27 days when the first cases appeared, and lost, the one seven, the other thirteen, passengers before sighting land. Nor could it be pretended that they came within a cholera area, for the whole American continent was at that time free. The same remarks apply to the success following the camping out of troops in India; cholera is not infectious in the same way as small-pox, which is little, if at all, affected by surroundings, and in such camps sanitation is efficiently carried out, the troops being also moved again and again to *fresh ground* so often as a single case makes its appearance.

Whether the name "comma bacillus" be well chosen or not, whether it be not rather a *vibrio*, whether, as shown in the subjoined figures (which we are able

to reproduce through the courtesy of the India Office), the spirilla and the comma forms may be produced out of the same cultivation by mounting them as "wet" or "dry cover" preparations respectively, are all beside the mark.

But when we come to examine the report itself more carefully, we find it hard to acquit Dr. Klein of treating his distinguished rival with scant courtesy, and in fact of misrepresenting him, if not wilfully,

certainly from prejudice. He has cultivated the cholera (?) bacillus, it is true, but he positively maintains the absolute identity with it of the commas found in simple diarrhoea, in saliva, &c., of Finkler and Prior's and even of Deneke's, on the strength of their microscopic appearances only, though Koch insists on the impossibility of distinguishing one from the other except by continued and varied cultivation. By these means Mr. Watson Cheyne in this country and a host of German observers have satisfied themselves of the specific differences between Koch's, Finkler's, and Flugge's commas, though Dr. Klein ignores their investigations entirely. That experiments on animals have been attended with so little success need surprise no one; very few specific diseases are capable of being communicated from one animal to another, anthrax, foot-and-mouth disease, glanders, rabies as hydrophobia, and tubercle being almost the sole examples of interchangeable diseases. But though Thiersch's and Burdon Sanderson's mice in pre-Listerian days no doubt died of septicæmia, though perhaps this may have been the case with those of Nicati and Rietsch, it is in the first place simply untrue that Koch did not operate anti-septically, and secondly two if not four of Watson Cheyne's guinea pigs died after duodenal injection, with symptoms which were not those of septicæmia, and were not unlike those of cholera. A modified form of this disease is the most we can reasonably expect when we consider the result, for example, of inoculating a human being and a cow respectively with what is the undoubted virus of small-pox.

We are far from maintaining that Koch has proved his bacillus or vibrio to be the immediate and efficient cause of cholera; but if it be, as he alleges, and as Cheyne and others testify, distinct and distinguishable from all others, however morphologically they may resemble it, and if it be, as they maintain, constantly present more or less in cholera, and as constantly absent in all other diseases, he has shown it to be, if not the cause, a part of the cause, or an effect of cholera alone, and therefore causative, or if not absolutely causative, at any rate diagnostic of cholera. Whether there be a cholera "comma" or not, and how many kinds of "commas" are specifically distinct are questions of simple observation, on which, in the face of such contradictory statements, it is prudent to suspend one's judgment. If Koch were alone in his opinion, if he were an inexperienced observer, or were opposed by an overwhelming weight of evidence, we might dismiss his theory; but the man to whom we owe nearly all our positive knowledge of pathogenic bacilli, and who by demonstrating the relation in which the bacillus of tuberculosis stands to every form of tuberculous and scrofulous disease, has reconstructed an entire department of pathology and therapeutics may fairly claim to be treated with consideration. On the contrary, Dr. Klein's observations are as yet virtually unconfirmed, and his refusal of Koch's challenge to repeat them in the presence of Mr. Cheyne as his representative is incomprehensible.

To return to the "Enquiry." The theory propounded by Drs. Klein and Gibbes is that "The cholera evacuations alone do not contain the virus

either actually or potentially, but, if something else, the extraneous specific organism, finds access to them, this is capable of producing the virus in the evacuation. But this organism does not necessarily require cholera evacuation for its multiplication and for the creation of the virus, since it is capable of doing this also in other suitable soils;" or, as they put it again, "cholera evacuations, *per se*, do not contain, actually or potentially, the organism which by its multiplication creates the cholera virus, a chemical ferment: this organism is extraneous to the body of an infected person: when transferred to a suitable locality, or when finding access to the cholera evacuations or other filth, it is capable of multiplication and of creating the actual virus, a chemical ferment." There is nothing original in this—it is simply Pettenkofer's theory without its reference to, but by no means excluding, the influence of movements of the ground water. But the essence of each is that the *place infects the person and not the person the place*. Whereas we maintain that in all cases a person must have infected the soil or the dwelling in order that other persons may be infected again thereby. But since initial cases are rarely fatal, the very fact of their being able to travel generally presupposing a milder form, they more often than not escape detection. Dr. Klein considers his hypothesis capable of explaining "all the facts concerning the spread of cholera." To this we must demur. Take, for instance, the case of Major Adair, who in August, 1873, rode in company with Judge Alexander from Columbia, in Kentucky, where they had remained for a fortnight during an epidemic, and had attended on a friend who died of cholera. After riding six-and-twenty miles, the Major's symptoms became so severe that they were compelled to stop at the house of a Mr. Kelly. There Adair lay ill for some time, but ultimately recovered; his stools were not disinfected, but thrown into the privy. Kelly, his son and daughter, as well as a man servant, were attacked, and all died except the son. The house stood in an elevated and solitary position, and no case was known to have occurred within twenty-six miles. Dr. Klein thinks that he has disposed of the tank theory of Koch, because, while the water contained comma bacilli it was drunk with impunity. But it is still from the other point of view open to question whether these were Koch's bacilli, and if they were other conditions may have been wanting. In the cases we have alluded to, of enteric contamination of water supplies, hundreds have escaped for one who has been attacked, though the simultaneous appearance of a score of cases immediately following the admission of enteric evacuations into a reservoir, left no doubt as to the connection in any reasonable mind. In conclusion, we repeat that whether Koch's views be right or wrong, they have not been as yet disproved by anything that Dr. Klein has advanced, and that Dr. Klein's alleged observations, which at present rest on his sole *ipse dixit* stand in greater need of confirmation. And on the wider question of the ætiology of cholera, the more we study its history in India, Europe, and America, the more convinced we are that it is, like enteric, a transportable miasm, requiring for its production the germ, known or unknown as yet, contained

in the evacuations of an individual infected however slightly, a suitable soil, whether in the earth, in clothing or elsewhere, and a number of ill-recognised conditions of season and individual susceptibility, perhaps in inverse degrees.

## REVIEWS AND NOTICES OF BOOKS.

### RESEARCHES ON DISINFECTION.<sup>1</sup>

BESIDES the valuable report on small-pox and vaccination, which we have made the subject of a special notice, and those of the medical inspectors on sundry outbreaks of enteric fever, diphtheria, &c., and the circulars issued by the medical officer at the time when an invasion of cholera was apprehended, all of which were referred to in our columns as they appeared, the present volume contains in Appendix B. no fewer than ten papers by Drs. F. Parsons, E. Klein, Heneage Gibbes, Burdon Sanderson and Cash, and Mr. J. P. Laws, detailing their researches on Infection and Disinfectants.

We shall take first Dr. Parsons' report on disinfection by heat, for, though the last in order, it is longer than all the others put together, and possesses the highest practical value. After a short notice of Dr. Henry's observations in 1831, and of those of Dr. Baxter<sup>2</sup> in 1875, as well as of Drs. Carsten and Coert, in Holland, in all of which vaccine lymph was the virus experimented on, and a passing reference to those of Davaine and Dreyer, Dr. Parsons proceeds to examine at greater length the important and elaborate researches of R. Koch<sup>3</sup> on sporiferous and non-sporiferous bacilli. The general results of Koch's experiments tended to show that the efficacy of so-called chemical disinfectants had been greatly overrated, and that steam was a far more powerful germicide than dry heat, for, while bacteria without spores perished after one-and-a-half hours' exposure to a temperature of 212° F., and the spores of mildews to one of 230°-240° F. for the same time, those of bacilli were destroyed only after three hours' exposure to a temperature of 284° F., while it took that time to raise the interior of pillows, bundles of clothes, &c., to that point, and to maintain them at the same temperature long enough for efficient disinfection throughout was always attended by more or less injury to the fabric. On the other hand, five minutes' exposure to steam at 212° F. sufficed to kill the spores of bacillus anthracis, and moist heat penetrated bedding, &c., far more rapidly than dry. Dr. Parsons, in conjunction with Dr. Klein, instituted a series of observations on the action of dry and of moist heat on the bacilli of anthrax with and without spores, and on those of swine-fever and tubercle. These, so far, at least, as regards anthrax, were more favourable to the use of dry heat than those of Koch, for, while two hours of moist heat at 212°-216° F. failed to kill the spores, four of dry heat at the same temperature rendered them innocuous. The bacilli of swine-fever survived five minutes, but not an hour, of moist heat, and those of tubercle exhibited even feebler powers of resistance. Dr. Parsons therefore concludes that an article heated throughout to 220° F. for an hour is not likely to retain infection, while as to boiling water an im-

mersion of one minute is enough to destroy the spores of anthrax bacilli, and therefore all contagia of fevers, &c.

Parsons and Klein could not reconcile their own observations, which confirmed the commonly received views as to the temperature of vapour rising from boiling saline solutions, with the statements of Buff, Kopp, Tamminer, and Magnus, quoted by Koch, Gaffky, and Löffler, that the temperature of such vapours was higher than that of pure water, though they found it easy enough to obtain "dry steam" at a temperature of 250° F. This, however, acted injuriously on most organic matters, especially on leather, while five minutes' complete penetration of any article by steam at 212° destroyed the spores of anthrax, and therefore sufficed for all practical disinfection. They collected a large mass of observations by Koch, Ransom, Roberts, and others, as well as of their own, as to the penetrating power of steam on pillows, rolled blankets, and mattresses. The superiority of steam over dry heat they show to be due to its great specific heat, the "latent" heat evolved when a hygroscopic body absorbs moisture, the greater diffusive power of steam compared with air, and the fact that the condensation of each charge of steam makes way for more. They also found, in operating on bales of rags with a Lyon's apparatus, that intermittent pressure of fifteen pounds to the square inch greatly aided the penetration of the vapour and of the heat to the interior of the bale. They carefully investigated the injury in the way of scorching, over-drying, fixation of stains, alteration of colour, &c., shrinkage and felting, &c., of articles acted on by dry or moist heat, comparing their results with those recorded by De Chaumont, Vallin, Ransom, J. B. Russell, Koch, and Wolffhugel.

For details we must refer to their report; we can only here observe that leather, though it will stand a moderate exposure to dry heat, is utterly disorganised by steam, and woollen goods, if acted on by hot water, lose the elasticity due to the natural grease on which their value depends, and become hard, felty, and threadbare. Cotton, black cloth and silk were less affected by temperatures of 300° than were flannel and blankets, and most articles could stand 250° for a period not exceeding one or two hours without material deterioration. One of the most serious drawbacks to the use of heat as a disinfectant of soiled bedding and clothing was the fixation of stains. In such cases we would suggest previous washing in a machine in cold or merely warm water, which might be boiled before being thrown away. The report concludes with a description, accompanied in several instances by drawings and accounts of experiments, of a number of disinfecting ovens. Of these, Nelson's, Fraser's, Dr. Heron Rogers', Dr. Longstaff's, Taylor's, and Bradford's, which are warmed by heat applied externally, labour under the disadvantage that the heat, being radiant, is very unequally diffused. Dr. Ransom's, Dr. Scott's, Leoni's, Jennings', and Haillet's, are heated by gas, the hot products of combustion, with or without sulphurous vapours, entering the chamber. Several French and German ovens are warmed by hot water or steam pipes, but there is only one of this class in England, at the Monsall Hospital, Manchester; it, however, answers well. Seagrave has devised a hot blast apparatus, but it has not met with approval. A free steam current is used in cleaning feathers, &c., and apparatus on this principle are highly praised by Koch and Wolffhugel, but labour under the drawback that the steam soon loses its heat. Lastly, Washington Lyon's and Messrs. Benham and Bradford's apparatus, employing steam under pressure, are very effective. Dr. Parsons, while unwilling to advertise any particular maker, feels bound to give the preference to Dr. Ransom's self-regulating dry air and W. Lyon's

<sup>1</sup> Fourteenth Annual Report of the Local Government Board, 1884-85. Supplement containing the Report of the Medical Officer for 1884.

<sup>2</sup> Reports of the Medical Officer of the Privy Council and Local Government Board, N. S., No. vi.

<sup>3</sup> Mittheilungen aus dem Kaiserlichen Gesundheitsamte, 1881.

steam pressure ovens, a judgment with which our experience leads us heartily to concur.

To the remaining reports we cannot afford to devote more than a cursory notice, as their practical value is but small. 1. Feeding guinea-pigs with tuberculous matter, human or bovine, produced results identical with those obtained by inoculation. 2. Dr. Klein's researches lead him to doubt the specific character of the micrococcus found in the sputa, but not in the blood, of the subjects of croupous pneumonia, the only result he obtained by inoculation being such as would be produced by ordinary septic bacteria. In the pleuropneumonia of cattle he failed to find bacilli, or to get any positive results from inoculations with fluids from the lungs. 3 and 6. Dr. Burdon-Sanderson and Dr. Cash, in a series of experiments still in progress, directed to ascertain whether it were possible so to impregnate the system with substances known to be germicidal as to counteract the effect of infection, in which they employed the cultivated bacilli of tuberculosis and of anthrax, and as germicides phenolsulphonate of sodium (sulpho-carbolate of soda) and corrosive sublimate among other disinfectants, found the former quite incapable of even retarding the progress of disease, but have been led to hope much from the sublimate. 4. Dr. Klein looks favourably on the effect of air disinfection by means of sulphurous acid in checking the spread of disease, *i.e.*, during the life of the patient, from the results of his observations on swine-fever. 5. Drs. Klein and Lingard found boiling, even for a minute, and moderately weak solutions of various phenyl compounds (5 per cent.), fatal to anthrax and tubercle bacilli. 7. Mr. Laws finds acidulation by sulphuric acid to exert a most unfavourable action on the life and growth of *B. anthracis* and—8. Cresol to be a far more efficient germicide than phenol. To this fact, by no means new, we have always referred the superiority for disinfecting purposes of the crude carbolic acid of the oil-shops over the purer preparations used in surgical practice.

*Harn-Analyse für Practische Aerzte*; von S. LAACHE, Kristiania (Urine Analysis for Practical Physicians); Leipzig: F. C. W. Vogel, 1885, pp. 160. Price 3 marks.—A decidedly practical work on a subject which is important to physicians and surgeons alike. Many new methods have been added to, if they have not superseded, the time-honoured tests for the various morbid conditions of the urine, and a careful summary of them such as the one before us is of real practical value to those engaged in the busy round of professional work. The descriptions both of the healthy and the morbid properties of human urine are brought well up to date, all the most recent work being noticed and commented upon. The subject of albuminuria naturally meets with the fullest share of attention, and it is of interest to note the relative value of the various tests as determined by the author. He places picric acid, which has of late been so largely adopted in England, among the less delicate tests of his series, cold nitric acid heading the list. A useful warning is given against the practice of acidulating alkaline urine with acetic acid before boiling, alkali albumen being thereby converted into a soluble form not precipitable by heat. The albumen of hæmoglobinuria would appear, according to the author, to differ from ordinary albumen in that it does not sink, but floats on the surface of the liquid in a long rosy strand. The various tests for sugar are given at some length, and among them may be noted a few that are little, if at all used in this country. The work is concluded by chapters on the parasitic contents of the urine and the various concretions that are liable to be found in it. The illustrations of crystalline and other deposits are clear and correct.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 13TH, 1885.

THOMAS BRYANT, F.R.C.S., President, in the Chair.

#### *A case of Idiopathic Purulent Peritonitis in a Child of 10 years, with Autopsy.*

Dr. SAMUEL WEST read the following case. Julia S., æt. 10, after a wetting, was suddenly seized with intense abdominal pain. There was no rigor, but vomiting was severe. The pain and vomiting continued severe till her admission four days later. The bowels had not acted since the commencement of her illness, there was no personal or family history of importance, the physical signs were all abdominal: great distension, pain, and tenderness. No tumour felt, but there was thought to be a little dulness in both flanks. Skin hot and dry, but temperature only 99·8; pulse 100. Respiration 28. Vomit frequent, yellow, acid, but not fæcal. Poultices and opium were ordered. On 14th, symptoms unrelieved, and bowels still unmoved. On examination per rectum, a baggy swelling of indefinite nature was felt high up in pelvis. On 15th, the condition of the patient being worse, and all symptoms unrelieved, the abdomen was opened by a mesial incision. Pus found, chiefly in lower part, and evacuated. Cavity washed out and drainage tubes inserted. The child nearly died of collapse upon the table, but rallied sufficiently to be removed to the ward, where she died about six hours later. The autopsy revealed acute suppurative peritonitis, but no cause for it could be found; the whole of the intestines, abdominal glands, and organs were perfectly healthy. The case was, therefore, one of idiopathic purulent peritonitis. Such cases were rare. The case presented great difficulties from its resemblance to some form of intestinal strangulation, but of this there was no clear evidence. Nor was there any history which pointed to perforation as the cause of the peritonitis. Whatever the peritonitis might be due to, it was almost certainly suppurative, and this diagnosis carried with it the appropriate treatment, *viz.*, evacuation. The low temperature throughout added to the difficulty of the diagnosis, but other cases were quoted of acute internal suppuration with low temperature, to which also Dr. Hilton Fagge had referred.

Mr. MORRANT BAKER remarked on the rarity of these cases and read notes of a case under his own care, of which the following is an abstract:—A lad, aged 15, was admitted in April in the present year, suffering from acute intestinal obstruction and in a moribund condition. He lay in a half conscious state, the eyes partly open, the abdomen tense and tender. The bowels had not been open for five or six days. The temperature was subnormal. There had been vomiting, but not of a fæcal kind; no external hernia could be found, and the rectum was quite empty. An incision was made under chloroform in the middle line, and a large quantity of pus was evacuated which was evidently diffused in the peritoneal cavity. The abdomen was washed out with a solution of permanganate of potash, and a drainage tube was used. No relief followed, and the patient died five hours afterwards. On *post-mortem* examination no cause could be found for the peritonitis, the upper part of the small intestine was greatly distended. The main point of interest in this class of cases was the question of distinctive diagnosis, and Mr. Baker was disposed to regard the presence or absence of fæces in the rectum in cases of prolonged intestinal obstruction as of considerable importance. In mechanical obstruction, after the first day or two, the bowel was always found to be empty.

Dr. WEST described at some length the different forms of peritonitis as seen in children, and pointed out the far greater frequency of the sero-purulent form. He thought that many of the purulent cases occurred in association

with some form of blood poisoning, and especially with scarlet fever and its sequela. He mentioned a few cases in illustration of this. He did not think that there were any good grounds to connect rheumatism with it. Any sudden exposure to cold was probably sufficient to set up a peritonitis. In the distinctive diagnosis between peritonitis and mechanical obstruction the position of the pain was important, being generally referred to one side in the latter condition. Obstinate constipation was not always a feature of purulent peritonitis.

Mr. HOWARD MARSH referred to the transference of pain in these cases, and pointed out that a similar condition was sometimes to be noted in acute affections of the vermiform appendix as in a case of which he mentioned the details. The temperature was certainly not always to be depended on. With respect to the cleansing of the peritoneal surface with carbolic acid lotions, he expressed some doubt as to its advantages, and mentioned a case in which, after the use of a lotion of the strength of one part in sixty, very marked poisoning ensued. He preferred to use over so large a surface, either the permanganate lotion, or, better still, a weak iodine water of one part in five hundred or in one thousand. This had for a long time been successfully employed by Mr. Savory.

Dr. HADDEN had made a *post-mortem* examination two years ago on the body of a girl who had died after three or four days' illness. Purulent peritonitis was found, and it was ascertained that the patient had been living in a house in which two people had recently died of blood poisoning.

Dr. F. TAYLOR thought that the diagnostic difference of the seat of pain in mechanical obstruction and purulent peritonitis required some more absolute definition. There could be no doubt that in some cases of peritonitis there was just that form of pain which had been associated with obstruction, and hence the symptom could have but little value as a positive means of distinction.

Mr. GOLDING-BIRD inquired whether the pulse had been closely observed during the progress of the case. He believed, and had always taught, that the indications given by the pulse were of more importance than those of the temperature in distinguishing between simple obstruction and peritonitis. In the "one case it invariably fell, whilst in the other it constantly rose, but the fact had not become sufficiently impressed upon the student mind, mistakes being frequently made even by the more advanced men. The transference of pain in intestinal obstruction had been noted and described by Dr. Fagge, notably in a case of cancerous stricture of the colon, and with distension above it.

Mr. HENRY MORRIS asked the President whether he could endorse the question from his own experience with respect to the presence or absence of faeces in the rectum in cases of intestinal obstruction. He mentioned the particulars of certain cases to prove that the sign is not altogether trustworthy. He thought that the low temperature in peritonitis was generally recognised, and had certainly been always taught at the Middlesex Hospital.

The PRESIDENT believed that the severity of the pain was an important diagnostic feature of peritonitis. In obstruction there was often but very little pain, unless in connection with other acute symptoms. The history would generally serve to distinguish the cases from one another. He agreed with other speakers in the view that the position of pain could not be taken as a guide, although in acute obstruction it was generally central. He thought that idiopathic peritonitis must be recognised, although in the great majority of cases of purulent peritonitis some exciting cause could be found if carefully looked for. Dr. Addison had always held the view that there was no such thing as a purely idiopathic form. He (the President) related the details of three cases of purulent peritonitis, each of which might have been classed as idiopathic if careful search had not succeeded in finding the local cause. In cleansing the peritonæum, he should always prefer to make use of the iodine water, believing it to be the most suitable of the many antiseptics that he had tried.

At the suggestion of the PRESIDENT, Mr. Baker agreed

to communicate his case to the "Transactions" of the Society.

*Two cases of Ligature of the External Iliac Artery for Femoral Aneurysm.*

Mr. WALTER RIVINGTON read the two following cases. J. M., æt. 27, a sailor, was admitted into the London Hospital under Mr. Reeves on September 10th, 1882, with a pulsating swelling in the right groin. Four weeks previously he first noticed a swelling of the size of a half-penny, but took very little notice of it. It enlarged gradually until two days before admission, when it increased rapidly and caused him considerable pain. On admission, the tumour was the size of a cricket-ball, with marked bruit and pulsation. He had a sore on his prepuce and a suppurating bubo on that side, but there was no history of syphilis. An increase in the size of the swelling having become perceptible, the external iliac artery was tied under thymol spray. Owing to the encroachment of the aneurysmal sac above Poupart's ligament, the external iliac was found to be displaced inwards to the inner side of the vein, and so deep that it was not exposed to view. Immediately after the catgut ligature was applied all pulsation and bruit ceased, and the tumour became soft and flaccid. The wound was closed and the limb wrapped in cotton wool. The wound did not remain long aseptic. On the 27th some offensive discharge occurred, and lint soaked in carbolic oil was substituted for the gauze. The tumour had diminished considerably in size. The chief feature was a loss of sensation and motion in the parts supplied by the sciatic and anterior crural nerves. On November 5th there was a mild attack of erysipelas. The right leg was warm, but there was no sensation in it except occasional "pins and needles" and pain in the back of the thigh and knee. Galvanism was tried without avail beyond restoration of slight power over the rectus femoris. Return of pulsation was first noticed in the femoral artery on the 29th November. The wound had healed by December 12th. Pressure sores existed over the trochanter and the heel. The tumour gradually decreased in size till March 2nd, when it was  $4\frac{5}{8}$  inches less in circumference than previous to the operation. The patient's condition otherwise was stationary. Suppuration ensued from the original wound, which reopened on the 27th of March. The clots in the sac broke down; secondary hæmorrhage took place on the 5th, 6th, and 9th of April. On the last occasion the sac was opened all clots cleared out, but, although no blood was lost during the operation, the patient did not rally. The *post-mortem* showed destruction of the external circumflex and commencement of the popliteal arteries, where the aneurysm had originated, and absence of anything like an aneurysmal sac. The external iliac artery and vein were pervious. A slight mark across the artery where the ligature had been applied could be seen. The anterior crural nerve was embedded in inflammatory plastic matter for several inches. The sciatic nerve was normal. The author considered that the loss of sensation and motion was an extreme form of a recognised temporary effect of ligature of a large artery. The collateral circulation was established sufficiently to avert gangrene, but insufficiently to maintain the functional integrity of the more remote and delicate tissues like the terminations of sensory nerves and the motorial end plates in the muscles. The limb was on the verge of gangrene, its feeble vitality being shown by the sores over the trochanter and the heel. The case further illustrated the uncertain behaviour of the ordinary catgut ligature when used for ligaturing an artery in its continuity. Probably the catgut would have held longer if the wound had remained aseptic. Case II. —H. C., æt. 51, was admitted into the London Hospital on July 10th, 1885, for a swelling at the upper part of his left thigh, which proved to be a fusiform aneurysm of the common femoral underneath Poupart's ligament. The size of the aneurysm was about that of a hen's egg. He was treated by the author in 1879 for a left popliteal aneurysm, which was cured by Esmarch's bandage and digital compression. The external iliac artery was tied under the carbolic spray with carbolised silk on the

3rd July by means of an incision three inches long, intermediate in position between Abernethy's and Astley Cooper's incisions. The patient made a good recovery, and was discharged cured on the 22nd of September. The chief points of interest in the case were the circumstance that this was the second aneurysm which had developed on the main artery of the left lower limb, and the use of carbolised silk ligatures cut short and left in the wound.

In reply to the President, Mr. RIVINGTON stated that pressure had not been attempted in his case.

Mr. GOLDING-BIRD asked a question with respect to the pulse at the ankle. He thought that it sometimes formed a distinctive sign between aneurysmal and sarcomatous tumours. He had himself operated upon an obscure case which proved to be an aneurysm of the profunda, in which the main artery was pushed over to the inner side of the thigh. He had performed Astley Cooper's operation in preference to Abernethy's, and the particulars of Mr. Rivington's case had certainly confirmed him in his choice.

Mr. RIVINGTON replied that there had been no perceptible pulse at the ankle. He thought that the condition of complete paralysis in his case was unique, as he had not been able to discover any record of a similar case.

#### *A fatal case of Nitric Acid Poisoning.*

Dr. DYCE DUCKWORTH read the following. A city merchant, æt. 29, was admitted to St. Bartholomew's Hospital on February 11th, 1885, with the history of having swallowed about an ounce of strong nitric acid shortly before. He had been seen by a surgeon, and was found vomiting. Lime water was given to him. He was supposed to have had his luncheon before he took the poison. Calceined magnesia in milk was given freely, and the vomit, previously acid, became alkaline. Opium was given per rectum, and linseed and opiate poultices were laid on the abdomen. The suffering was intense; retching and vomiting; collapse followed. Nutrient enemata with brandy and opium were given. The urine contained blood on two occasions, and albumen twice afterwards. Vomiting and retching persisted at intervals, and the pulse became running. Shreds of putrid mucous membrane were ejected. The temperature rose on the fourth day to 102.2°. Diarrhœa set in, but no blood was passed. There was a suspicion of pericarditis. The patient nearly sank on two occasions, but was revived by nutrient enemata with brandy. On the fifth day he was so much better that his friends believed that he was recovering. He died one hundred hours after taking the acid. On examination, there were signs of inflammation at the fauces and down the œsophagus, stomach, duodenum, and as far as the jejunum. The stomach was contracted, but not perforated. Some local peritonitis over the stomach and liver, but no general peritonitis. The pericardium was sticky. He took, in all, over an ounce of laudanum while under treatment.

Dr. DE HAVILLAND HALL asked why the tincture of opium had been used in this case instead of the subcutaneous injection of morphia.

Dr. DUCKWORTH replied that he preferred to administer sedatives by the natural channels whenever it was possible, and took occasion to protest somewhat strongly against the too frequent use of the morphia syringe.

#### *Living Specimens.*

The following living specimens were exhibited before the meeting:—

Dr. FOWLER—A Case of Pseudo-hypertrophic Paralysis in an Adult.

Mr. BERNARD ROTH—A Case of Severe Lateral Curvature of Spine.

Dr. CROCKER—(1) A Case of General Discolouration; (2) Arsenical Pigmentation.

Dr. COLCOTT FOX—A Case of Pigmentary Disorder.

Mr. J. H. MORGAN—(1) A Case of Gastrostomy; (2) An Unusual Form of Spina Bifida.

Mr. CLUTTON—(1) Cervical Spina Bifida undergoing Spontaneous Cure; (2) Tubercular Ulceration of Palate.

Mr. WALSHAM—Acute Spreading Obliterative Arteritis.

Dr. CHARLEWOOD TURNER—Congenital Cyanosis with Pulmonary Stenosis and Pre-diastolic Bruit.

Mr. KEETLEY—(1) Modified Syme's Amputation; (2) Modified Gritti's Amputation.

Dr. HERRINGHAM—A Case of Chronic Parotitis.

### PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 17TH, 1885.

J. S. BRISTOWE, M.D., F.R.S., President, in the Chair.

#### *Heart lined with Clot.*

THE PRESIDENT said that his specimen was taken from a man who suffered intense pain in his chest and back, and it was assumed that there was cancer of the vertebræ. The man died after much suffering, and it was found that there was no disease of the spine. But there was cancer of the stomach, of which there had been no symptom during life. On examining the heart, both ventricles were seen to be lined with old coagulum, the free surface towards the ventricle was smooth, the carneæ columnæ and musculi papillares were almost concealed in the clot.

#### *Hæmorrhage into the grey matter of the Spinal Cord.*

Dr. W. C. CHAFFEY brought this case forward. A child, aged four, fell down a flight of nine steps, but was able to go to school that afternoon; on the next day she vomited, and on the third day lost some power in legs; on the fourth day there was total loss of power in the legs, and from the fifth day there were urinary troubles. She was admitted on the sixth day; then her speech was good, swallowing was easy, there was no palatal trouble; she had a hacking and ineffectual cough. Pulse irregular, frequent intermittent. Nothing wrong as to spine was found, the cutaneous sensibility was good, her arms were weak, but otherwise normal. The legs were flaccid and paralysed, the reflexes being absent; the abdominal reflexes were present. Next day there was a doubtful slight squint; the day following she was weaker, and a few hours before death the right arm got weak. She died on the 9th day from injury. The temperature had gradually risen. At the *post-mortem* examination the brain and membranes were somewhat congested. The lumbar enlargement of cord seemed bulky; extensive hæmorrhages were found in the grey matter here and in the cervical enlargement; this was most marked in the lower part of the lumbar enlargement, where it extended throughout the grey matter; above, it gradually diminished until it was confined to the anterior cornua. The other viscera were natural. In the bulb the changes were most marked in and around the nuclei. Leucocytes were found massed around the walls of the vessels in some specimens; where the changes were most marked, the motor cells had nearly disappeared.

#### *Cysts in the reproductive organs of animals.*

MR. J. BLAND SUTTON made a communication on this subject, showing that ovarian cysts, *i.e.*, those arising in the parenchyma of the ovary, originated in corpora lutea. The material especially used in this investigation consisted of the uterus and its appendages, furnished by seventy cows of all ages and conditions, fifty pigs, twenty mares in addition to the fifty previously reported upon, and the varied material obtained at the Zoological Gardens. The specimens of ovaries exhibited were selected so as to show all the stages in the formation of the cysts, from the ordinary corpus luteum to cysts as large as Tangerine oranges. The mode of formation of the cysts in these cases admitted of no doubt, for the only instrument needed in the investigation was a sharp knife. The peculiar yellow colour of the material composing these curious bodies rendered the identification indisputable. The various conditions were best traced in cows on whom ovarian cysts occurred with tolerable frequency. Multi-locular cysts were the result of the concomitant growth

of two or more cysts in the same ovary, this being by no means a rare event. The same process could be traced in the ovary of the sow, in asses, in mares, in a tiger, and in monkeys; specimens of cysts arising in this way might also be seen in the ovary of the human female. The question next arose, if these cysts occurred in the corpora lutea of pregnancy and of menstruation, how were they to be accounted for in the ovaries of the child and even the fœtus. Waldeyer and Beigel had both insisted that the ovaries did not remain idle in early life, but that many of the follicles ripened, atrophied, and formed a sort of corpus luteum even in the fœtus. This was no abstract statement; Doran's "find" of an incipient papillary cyst in the tissue of the hilum had stimulated him to examine fœtal ovaries. To his astonishment he found ovarian cysts in the human fœtus very frequent, and three typical specimens were shown that evening. In one specimen, in particular, ova might be seen in the follicles exactly as in an ovary after puberty, but of course much smaller. These observations went to show that in the fœtus, child, or mature female, cysts might arise in corpora lutea. Whilst working over the fœtal human ovaries, he had good reason to endorse the view that the cysts arising in the "hilum of the ovary" took origin in remains of the Wolffian body; on one occasion he was able to make out an almost complete longitudinal section of a Wolffian tubule, and in one specimen the true tissue of the ovary was scarcely represented, but it seemed to be made up almost entirely of Wolffian remains. The remaining specimens were exhibited to show the following points:—(1) A cow's uterus and vagina, showing large cysts in the vaginal wall developed in the lower (posterior) end of Gartner's duct. The ducts of Gartner and Skene's tubes were one and the same structure, the glands described by some as independent structures were only diverticula from the ducts, and were homologous with the vesiculæ seminales of the male. (2) Broad ligament cysts unconnected with the parovarium in mares, cows, pigs, and kangaroos. (3) Examples of hydrosalpinx in pigs and in the cow. This condition seemed not to be infrequent, and was a cause of sterility in these animals.

Mr. ALBAN DORAN observed that the paper, and the specimens by which it was illustrated, were of the highest interest. He was glad to find Mr. Sutton confirmed him in maintaining that ovarian cysts generally arose from the follicles, but he was not prepared to admit that they originated in corpora lutea; he preferred to say that they began in follicles which had undergone involution without any necessary connection with impregnation, menstruation, or rut. It was necessary to distinguish, as Dr. Klein had done in his handbook, between the tissue of the hilum and the parenchyma of the ovary. The former was the blastema which had been found to develop in the embryo around the upper part of the Wolffian body. The dilated lymphatics observed by Mr. Sutton corresponded to the "cystes lacuneux" of Verneuil, which formed conspicuous, but ill-defined, cysts in the broad ligament in cases of myoma of the uterus. To decide the true position of the orifice of Gartner's duct, it was necessary to make sure where the vagina ended, and the vestibule began in different species of animals. Owing to differences in the development of the lower part of the united Müller's ducts, the true vagina was sometimes very long, in other cases functionally replaced by the vestibule.

Dr. J. K. FOWLER had lately met with a cyst in the human ovary closely corresponding with those shown by Mr. Sutton.

Dr. HADDEN had recently seen a case in which there were several cysts in the broad ligament attached to a long pedicle. Was this a fœtal remnant or a parovarian cyst?

Mr. SUTTON said that pedunculated cysts were very common in animals; they were merely dilated tubules of parovarium. The particular advantage of his method of investigation was its simplicity.

*A Liver divided into two parts by a constricting band, one part being fatty, the other cirrhotic.*

Dr. HALE WHITE showed this liver, taken from a man who died with large white kidneys. Stretching across the upper surface of the liver was a deep fissure which began

at the attachment of the posterior part of the suspensory ligament and ran along at the upper surface at the attachment of that ligament for about two-thirds of its extent; then it bent to the right and terminated at the anterior border of the liver, cutting off thus a small piece of the right lobe. The portion to the right of this band was fatty, the rest of the liver being cirrhotic. The fatty portion quickly decomposed and passed into the sponge-like condition so often seen in decomposition of the liver; the cirrhotic part did not decompose nearly so quickly. This opinion was confirmed by microscopical examination. The constricting band was probably due to the patient's wearing a belt; although it was not at all in the usual position, still it was extremely improbable that it was due either to disease or congenital malformation. From its position, and from the fact that the small piece of the right lobe which was nipped off by it was cirrhotic, it was certain that the cirrhotic condition of the left lobe as contrasted with the fatty condition of the right was due to the constriction; this view was confirmed by the fact that the vessels to the left lobe would have been compressed, whilst those to the main part of the right lobe would not, considering the position of the constriction.

Dr. J. K. FOWLER said the case closely resembled the constriction found after tight lacing.

Dr. NORMAN MOORE asked if the vacuolation was not always a *post-mortem* change; he had commonly observed it in summer, but not in winter.

Dr. HALE WHITE agreed that in the majority of cases it was a *post-mortem* change, but there was a true vacuolation occurring with vacuolation in other organs.

#### *Contracted Fingers.*

Mr. LOCKWOOD showed a series of specimens, dissections, and casts illustrating this subject. In one case all the joints contained urate of soda, and this was found in the contracted fascia and in one of the extensor tendons. He also showed a specimen of Dupuytren's contraction; there was no urate of soda anywhere in the body. It was difficult to assign a cause for the contraction in these cases.

Dr. ORD said he had examined many gouty joints and gouty kidneys; he had seen urate of soda simply crystallized in the cartilages without any attendant proliferation; in the kidneys, too, there was frequently no evidence of irritation around the crystalline deposits.

Dr. NORMAN MOORE agreed with Dr. Ord that urate of soda was often found in the sole of the foot or in the front of the neck without any evidence of irritation. It was rare not to find degeneration of cartilage with a deposit of urate of soda; some degeneration almost invariably preceded the deposit.

Mr. BLACK referred to a specimen of carpal bones with deposit of urate of soda, the bones being healthy.

Mr. ADAMS thought that fibroid degeneration of cartilage always preceded deposit of urate of soda. Mr. Lockwood's specimen was a typical one of Dupuytren's contraction; such specimens were very rare.

Mr. SUTTON thought Mr. Black's case might be one of cholesterine formation.

Mr. LOCKWOOD thought it was quite possible that contraction might occasionally be due to urate of soda, even though this generally did not set up irritation.

#### *Gummata of Liver in Boy.*

Dr. NORMAN MOORE said that the boy from whom the specimen was taken had been under Dr. Gee's care in St. Bartholomew's Hospital from December, 1883, to September, 1885, with enlarged liver and ascites. The liver and spleen could both be felt during life. The boy had well-marked Hutchinsonian teeth, but no other signs of specific disease. *Post-mortem.*—His liver, kidneys, intestines, and spleen were all found to show well-marked lardaceous change. The liver was very irregular on surface and outline. In its substance were many yellowish masses of irregular outline, and each surrounded by a red line of engorged liver substance. The intervening substance showed some lardaceous infiltration, but was otherwise natural. Microscopical sections showed these masses, each of which had some

puckering of the liver near it, to be gummata, and in their neighbourhood, and here and there on the liver surface, minute gummata with undegenerate cells could be seen. Very few cases of gummata had been recorded in children. These were certainly due to congenital syphilis.

#### *Iridescence in Calculi.*

Mr. SHATTOCK showed a group of fifty calculi of most varied form, having sharp facets. The largest were two centimetres in greatest measurement, the smallest about the size of a hemp seed. A remarkable iridescent, lustrous, yellow colour was evident in all. This property was confined to a distinct separable surface layer. The inner substance was phosphatic and composed of conical intersecting tufts of fine acicular crystals. The calculi were removed from the prostate of a man. Phosphate of lime and magnesia and ammonio-phosphate of magnesia formed, with carbonate of lime, the chief chemical constituents. A laminated nucleus was found in the centre. Renal and vesical calculi, pseudo-metallic in appearance, had been described in herbivora; these consisted of carbonate of lime. They were very rare in man. Thin sections of the prostatic calculi showed two kinds of structure. The iridescent thin layer was composed of a large number of closely apposed homogeneous concentric lamellæ of great tenuity and translucent. All the calculi examined had a distinct, compact, pale-brown, spherical, laminated nucleus; these were evidently identical with minute prostatic calculi.

Dr. ORD at first attributed the iridescence to defraction, but after examining the specimens and drawings he must give that view up. He agreed as to their mode of production, both with regard to the matrix being formed from colloid and as to the carbonate of lime as the inorganic constituent. These calculi had been formed very slowly: an important element in the case.

#### *Card Specimens.*

Dr. GULLIVER—Hæmorrhage into Supra-Renal Body.

Dr. HALE WHITE—(1) Melanotic Scirrhus of Liver; (2) Hæmorrhage into Long Bones in a case of Purpura Hæmorrhagica.

Dr. BEAVAN RAKE (by Dr. Hale White)—(1) Hand and Larynx from a case of Mixed Tubercular and Anæsthetic Leprosy; (2) Hand from a case of Anæsthetic Leprosy, showing Spontaneous Amputation and Arrest of the Disease; (3) Extreme Ulceration of Larynx with Perforation, from a case of Anæsthetic Leprosy; (4) Thickened Median Nerve from a case of Anæsthetic Leprosy.

Mr. HURRY FENWICK—Miliary Tubercle of Bladder.

Mr. HERBERT LARDER—Cancer of Œsophagus.

Dr. PERCY KIDD—Tuberculosis of Uterus and Fallopian Tube.

Dr. W. B. HADDEN—Ulcerative Endocarditis of Right Side.

Mr. D'ARCY POWER—Intra-Ossous or Central Necrosis of Femur.

## GENERAL MEDICAL COUNCIL.

### THIRTY-EIGHTH SESSION.

FIRST DAY—TUESDAY, NOVEMBER 17TH, 1885.

*President's Address—Cases of Goold, Clarkson, Millerchip, and Evans—The Case of the Queen's Colleges of Belfast, Cork, and Galway.*

THE PRESIDENT (SIR HENRY ACLAND) delivered his address, of which the following is a summary:—The subjects, he said, which would demand the attention of the Council were—1st, the removal of names from the Register; 2nd, the consideration of their Penal Bye-Laws; 3rd, the conditions for registering the Irish Students; 4th, the claims of the Colleges of Galway, Cork, and Belfast; 5th,

the Visitation of the Universities; 6th, a Report on the New Pharmacopœia; 7th, the Statistics which had been prepared by their Statistical Committee; and lastly, certain other questions of large import which they would be asked to bear in mind, even though no resolutions concerning them were formally brought forward. (1) It would be a failure of administration to continue to print in new volumes of the "Register" the names of persons convicted of crime in the previous year, and upon whose cases they had not given judgment. This, of course, pointed to a short meeting for judicial functions at the end of every year, the spring meeting being mainly educational, the other, generally a shorter one, for general and legal business. The Irish Branch Council, on September 11th, passed a special resolution on this subject. (2) The revised penal clauses of the Standing Orders would be laid before them, having been submitted to a keen scrutiny by their Solicitor and by Counsel. The great powers which the Council possessed implied a corresponding responsibility for caution in their use. It was satisfactory to believe that their course hitherto had been such as to call for little improvement, though it had been often criticised. The proceedings in the civil courts did not encourage them to think the decision, as to what is moral or professional misconduct, was in every case to be readily arrived at. It facilitated the work of the Council when it had been decided by a legal tribunal whether certain acts were or were not illegal. That question settled, it was easier to say whether their illegality implied professional misconduct, or their legality was inconsistent with professional rectitude. Professional men could often do what as honourable men they should leave undone. These questions would arise in future, as they had arisen in the past, and sometimes they would be easy, and sometimes difficult, of solution. (3) The Conditions for Registering Irish Students. The Resolution of the Council that an examination must be undergone in Mechanics previous to registration having taken many Irish students by surprise, the Executive Committee had directed that the registration of the applicants could take place whenever they passed, and the time of passing be antedated, so that they should not lose the year by a circumstance which, in many if not in all cases, was not the fault of the youths themselves. This was a typical instance of the inconvenience which might arise from changes which affected the teaching of the schools, and showed the necessity of avoiding as far as possible frequent alterations in details. After alluding to (4) The Claims of the Colleges of Galway, Cork, and Belfast, the President went on to speak of (5) The Visitation of the Universities. In 1883 the Council directed the appointment of Visitors to inspect the Examinations of all the Universities. At the commencement of the year the arrangements were completed. From England the laborious task was undertaken by Dr. Bristowe, Mr. Holden, and Dr. Barnes; from Scotland by Dr. Balfour, Dr. George Buchanan, and Dr. Leishman; from Ireland by Dr. Finney, Mr. Macnamara, and Dr. Kidd. The Visitors were distributed, so that England was visited from Scotland and Ireland, Scotland from England and Ireland, and Ireland from Scotland and England. Although most of the Visitors' Reports were nearly ready, none were yet complete; they would be forwarded to the several Universities, with an invitation for their remarks upon them. (6) The Chairman of the Pharmacopœia-Committee would communicate some details as to the completion of the Third Edition, and as to its reception in this country. The thanks of the Council were largely due to Dr. Quain, and to the editors who acted with him. (7) Mr. Marshall had presented his first Report on certain Statistics of the Medical Profession, compiled with much labour in conjunction with his colleagues and the Registrar. He would not anticipate any of the conclusions at which they arrived, further than to observe that it was an open secret that Students still migrated as they did in the Middle Ages—and as they did in Germany now—in quest of teachers whose reputation attracted them, and of other advantages they believed they obtained through this movement. This subject was entangled with various prejudices and fallacies into which they could not now enter.

In conclusion, The PRESIDENT said, "I will briefly allude in the last place to certain other questions of large import

which are in all our minds. I do not presume to refer directly to the political movement which begins to-morrow by dissolving a Parliament among the most powerful at its outset that has ever met, but nevertheless I must refer to some of the lessons which we may indirectly take to heart, from their bearing on our own work. In the fifteen years that have passed since Mr. Simon, then the Medical Officer of the Privy Council, addressed the Council in 1869 on behalf of the Lord President, successive Governments—as has more than once been remarked—have, with much good will and most friendly co-operation, sought to help the cause of Medical Education. Though every Medical Bill brought in by the Government has been withdrawn, yet the progress of Medicine in the twenty-seven years that have elapsed since you were constituted a Council has been unsurpassed at any period of history. There seems to be a lesson to be drawn from this, and the lesson is that this Council, and all the Licensing Bodies now empowered to put names on the Register, ought to be able to say that, although Parliament has been through all these years baffled, yet a State Examination, however expedient for State reasons, would not be more certain in its action, nor more practical to its end, than the Examinations for which this Council and they are responsible. Many of the best minds in our profession have wished, and still wish, that a State Examination should be instituted. The proposed substitute for it was to have been a voluntary combination of the several English, Scotch, and Irish Licensing Bodies. It must be acknowledged this substitute has failed. Neither in England, in Scotland, nor in Ireland, have all the bodies combined, notwithstanding the long-continued and earnest endeavours conscientiously bestowed upon the scheme. It has been most successful among the Corporations in Scotland. In Ireland it does not exist, though all the Licensing Bodies are situate in the Irish Metropolis. In England it has ended in the union only of two great Corporations, and the independence of all the others. The attempt of one English University to make a union with these Corporations met, unfortunately as I think, with such disfavour that it is known already that it must fail. The two Corporations themselves, it is commonly said, are seeking the power to grant “Degrees”—that is, “higher titles”—to those or some of those whom they license. The London Society of Apothecaries also asks that its testamur in Surgery should be accepted as a surgical qualification; and you will be called upon to say whether, on the merits, it be entitled thereto. The records of the London Medical Schools and Examining Boards would furnish a most interesting illustration of individual exertion as distinguished from State aid in the progress of England. From this and other causes there is now less chance than ever of a diminution of the number of Medical License-giving Bodies than before. This was the result that was expected by one of the chief supporters of the “conjoint” system of examination, and one of the best and truest of men, Dr. Parkes, not long before his death.

The practical conclusion that would seem for the present to follow from these circumstances is expressed in a Report of the Branch Council of Scotland to the effect that the General Council should establish a systematic inspection of each and all the Licensing Bodies every year. Whether this is preferable as a permanent arrangement to three State Boards in London, Edinburgh, and Dublin, with the resulting independence of all the Bodies, is open to argument. But it is in the power of the Council to make this inspection as often as it judges necessary, and to report definitely to the Privy Council any Body that fails in its duty, if there be any such. Fifteen years have shown that the Council must rely on its own powers rather than on the good will, great though it has been and is, of the Government of the day. We meet here to take counsel together how the Medical mind of the future may be most wisely trained in the complex relations of culture, of science, and of practice. We return to our several institutions to put into action, as best we may, the common consultative results, not only for our purposes, but for the good of the nation at large, and in various degrees and ways for the promotion of medical science, and the progress of human knowledge in its bearing on public and personal health. We ought to be in fact, and by the Act we are, to a great

extent, bound to be ourselves our own inspectors. It is true that every Licensing Body sends hither a representative to bring its experience to the rest, but it is as true that each representative is, on returning to his own institution, guardian of the conclusions arrived at by the majority of the institutions, and by the representatives of the Crown. He has the power under Clause 18 of the Act to attend any Examination related to any part of Medical Education, whether of his own, or of any other Medical Licensing Body, whether deputed by the whole Council or not. The truth is—and it is well to look it in the face—the vexed questions of Independent Licensing Bodies, Conjoint Boards, and State Examinations, are part of one of the great political problems of our time—*i.e.*, the relations of central control to Local Institutions. The failure, half a century ago, of the latter brought the power of the central authority more closely to bear on local details. But there is real risk, as seems to many statesmen, of Central guidance becoming so constant as to injure the manly independence which has created England. I confess to a doubt long felt whether the present Licensing Bodies, either Universities or Corporations, ought to give qualifications if they each need an Inspector to watch every examination. The course which this Council has taken with regard to its recommendations illustrates and confirms these views. Whereas the tendency was, and rightly, some years since to issue recommendations in more and more detail, the last revision, by common consent, and after the most careful consideration, has reduced them to a few general regulations resting on broad educational principles. All this being so, it would not become me to make more than passing allusion to the great educational movements which are being discussed in London, or to modes of teaching, or to the best way of utilizing the unequalled clinical opportunities afforded by this vast population. But I cannot wholly pass the subject by. It has become mixed up with two questions of much real import to this Council—the state of teaching, and the meaning of titles. I will to-day pursue neither subject. Though this Council has mainly to do with results, it is required to ascertain the methods of producing them. Though it is only to do with the testing whether men have the skill and knowledge necessary for their profession, it has to record, on its Register, titles that profess to represent more than this. It would be to close our eyes to a fact known to all, that part of the movement of Students is due to seeking these titles for their supposed social value. But it would be worse than blindness not to see that part of this movement is also because they believe that teaching is better organized in one place than another, and so their parents enable them to move accordingly. Why should they not do so? They adopt this course in Germany with manifest advantage. Are we sure that there is no narrowness and want of elasticity and power of combination in our views on this matter? I have thus ventured respectfully to give utterance to some thoughts of the present state of our functions and duties, and of the relation of the Medical Profession and its various Institutions in Great Britain, to the Legislature, because I feel that each time we meet it may be for me, and soon must be, the last. I wait only to feel sure that my earnest desire to carry out your wishes, in such ways as I am able, can no longer serve you, in order to retire from the most honourable and the happiest work that I have, and to make way for a younger and a stronger man.”

Mr. MARSHALL moved and Professor HUMPHRY seconded a vote of thanks to the President for his address, and that it be entered upon the minutes. This having been supported by the Reverend Dr. Haughton, was agreed to.

Mr. MARSHALL then moved that the qualification of M.R.C.S., formerly held by Francis Goold, be removed from the Register, he having ceased to be a member of the College of Surgeons in accordance with a resolution to the effect—“That, in the opinion of the Council, the criminal offence of which Francis Goold has been convicted is of such nature as to render him unfit to remain a member of the College, and that he accordingly be removed from being a member of the College.” He said that the felony of which he had been convicted was manslaughter, and the College of Surgeons had carefully investigated the case.

Dr. HUMPHRY seconded the motion.

Some discussion followed as to the powers of the Council in the matter, and Sir HENRY PITMAN pointed out that if a name was to be struck off for felony the felony must have been committed in the United Kingdom, which was not the case in the present instance.

The motion was then agreed to.

Mr. MARSHALL then said that Goold's name now appeared on the Register without a qualification at all, and therefore his name must, as a matter of course, come off the Register as he was no longer a qualified practitioner. He said that the College of Surgeons were quite satisfied that he was not a competent person.

Mr. SIMON thought that the action of the Council was a little unusual in this matter, seeing that the conviction had taken place in December, 1876. He held that the name did not of necessity go, when the qualification was removed, it required a separate resolution.

The motion was then agreed to, and the name ordered to be removed from the Register.

Mr. MARSHALL then drew attention to the following resolution of the Council of the College of Surgeons: "That, in the opinion of the Council, the advertisements issued by Mr. Thomas Clarkson are, in the terms of Clause 2, Section XVII of the By-Laws, 'prejudicial to the interests, and derogatory to the honour of the College, and disgraceful to the profession of Surgery'; and that, in consequence of the issue thereof by him, and his refusal to discontinue them, he be removed from being a member of the College." He said it was not a case of a legal conviction, but of issuing advertisements which had been described as scandalous. The Council had written to ask Mr. Clarkson if they had been inserted by his direction and authority, and he had, in reply, stated that he had been in practice for more than forty years, and that his remedy was not a secret one. He was then cautioned by the Council that if he would cease to publish his advertisements they would take no further proceedings against him. His answer was that he had paid for his advertisements until the end of the year, and that after that he would consider the matter, and that he considered the action of the Council arbitrary. Mr. Marshall then read the advertisement complained of, in which he announced a specific for bad legs. His diploma of membership was dated 1832. He asked the Council to remove from the Register his qualification of M.R.C.S. He had another qualification and therefore there was no question of removing his name from the Register.

Dr. QUAIN briefly seconded the motion. The College of Surgeons had removed his name, and that was enough for them, they need not go into the reason for it.

Mr. SIMON disagreed from the remarks which had just fallen from Dr. Quain, the Council had a discretion to exercise, and it was right they should have the facts before them.

After some remarks from Dr. Aquilla Smith, the motion was carried. As Mr. Clarkson was also a licentiate of the Society of Apothecaries, some conversation then ensued as to whether the Council should draw the attention of that body to them or leave the matter in the hands of the Society's representative; ultimately the latter course was adopted, Mr. Bradford undertaking to bring the case under their notice.

The case was then brought forward of a duly qualified practitioner (named Millerchip) who had been convicted of using an instrument with intent to procure abortion, and sentenced to ten years' penal servitude.

Sir HENRY PITMAN moved that his name and qualifications should be removed from the Register, stating that, though he was safe for the next ten years, it was important that they should purify their Register.

The motion was seconded by Dr. AQUILLA SMITH.

The PRESIDENT said that he thought this case would justify (if there was any need of it) his summoning the Council at this time. It would not do for them to issue the Register with such names upon it.

After a question from Dr. Lyons, the motion was agreed to.

Dr. AQUILLA SMITH then drew attention to the following resolution from the King and Queen's College of Physicians in Ireland. "The name of Dr. Robert Locke Evans, of Carrickfergus, was, by resolution of this College, October

2nd, ordered to be erased 'from the Roll of Licentiates in Medicine and Midwifery,' and moved that the two qualifications, which had been taken from him, should be removed from the Register; as he was also licentiate of the College of Surgeons, there was no question of striking his name off altogether.

This was seconded by Dr. BANKS.

The PRESIDENT observed that it had been the custom when a qualification had been removed in this way for the Council to direct their Registrar to remove such qualification from the Register.

Mr. SIMON said that the motion seemed hardly respectful to the Council, and he thought that Dr. Aquilla Smith ought to have stated some particulars to them as to the offence; it might happen that they would be asked to vote a man off the Register without knowing why they were to do so.

Mr. TEALE contended that they must know the reason for which they were to strike a man off, as the Act especially provided certain offences for which a man was not to be taken off the Register.

The Rev. Dr. HAUGHTON said that though a Fellow of the College in question he did not remember the nature of this man's offence, but he thought that the Council certainly ought to have information on the point.

Dr. QUAIN asked who was to regulate the morals of a corporation except the corporation itself, and he held that nothing could be more anomalous than that they should refuse to remove a qualification which another body had already taken away.

Mr. SIMON said he would put a hypothetical case and assume that this man did not hold any other qualifications than those which they were now asked to remove. Were they to strike the man off the Register, for that what was what it would amount to, without knowing what was against him. The Act provided that they might remove a man if they saw fit, but how could they see fit unless they knew what he was charged with.

Dr. AQUILLA SMITH said that he meant no disrespect to the Council, but that he would not give any explanation unless instructed to do so by his college; he might, however, state that the man had not been struck off their roll for any peculiar views of theory or practice.

Dr. BANKS said that he did not know the cause in this particular instance, but he was certain that this college never removed a man's name who did not thoroughly deserve it.

Dr. STRUTHERS contended that they could not remove a man from the Register simply because a corporation had struck him off its books.

Dr. QUAIN said that the position of affairs was this: this College told them that the man no longer held a certain diploma, and they could do as they pleased about it. They must not leave a falsehood on their Register. He contended that they had no right to sit in judgment on the corporations.

Dr. LYONS appealed to Dr. Smith to give a statement of the facts; he would not have the smallest hesitation in mentioning them if he knew them.

After a few words from Dr. Fergus in reference to the opinion of their solicitor which appeared on the agenda paper,

Dr. HUMPHRY said that it was clear that the Council had a duty to perform in this matter. A man was admitted to the Register when duly qualified in virtue of a right, but he was not to be removed unless the Council saw fit. They did not doubt the good grounds of a college in removing a man, but the Council must have some grounds for removing a qualification. The last section of the Act showed that they had a right to ask what had been the cause of the removal. In the case before them there was only one man round the table who knew the nature of the offence. He did not consider there was any falsehood in keeping the man's name on the Register provided he had been duly admitted.

The PRESIDENT read an amendment proposed by Mr. Simon, and seconded by Sir Henry Pitman, to the effect that the further consideration of this case should be postponed until the Council had information as to the nature of the offence.

The SOLICITOR to the Council having been referred to, said that if they allowed the qualification to remain, their Register would be incorrect. This was the only case in his experience in which the information had been withheld.

Sir HENRY PITMAN said he would put a hypothetical case to the Solicitor. Supposing a man had been struck off the roll of a licensing body without good reason, on the ground of holding some theory, for instance, and the fact became known to the Council, what ought they to do?

The SOLICITOR thought they were not bound to strike the name off, but they ought also to keep their Register correct.

After further remarks from Mr. Simon, Dr. Humphry, Dr. Quain, and Dr. Banks much to the same effect as those already given above,

Dr. MATTHEWS DUNCAN said that as to the allegation that their Register would be untrue, he did not admit it. They could leave the qualification on their Register, for all that would be implied would be that at a certain date he had belonged to such a corporation, and had been registered accordingly, and that he was still registered.

Dr. STRUTHERS said that this was not a matter of law, but of conscience.

The PRESIDENT admitted that there was a real difficulty in the matter, and he thought that they ought to get a careful legal opinion upon it. To some members it appeared that they had no right to give an opinion upon this matter without further information.

The amendment was then put and carried.

The amendment was then put as a substantive motion, when Dr. LYONS rose to move an amendment. He said that the matter was one of a general principle, and not a special question that had really been under debate, and he therefore moved as an amendment that the opinion of counsel should be taken as to whether the Council could insist upon the information being given them before removing a name.

Mr. SIMON said that he objected to the amendment; he should decline to be bound by the opinion of counsel on a matter of this sort; he would never vote blindfold on any question, but claimed the right to exercise his discretion.

Dr. HERON WATSON thought that they ought to get the opinion of counsel as to the legal definition of the word "members" in clause 28 of the Act. Did it include fellows and licentiates as well as members?

The PRESIDENT considered that this was an important public matter, and it was quite right that it should have been discussed.

The amendment was then put and lost, and the motion carried.

Communications were then read from the Queen's Colleges of Galway, Belfast, and Cork, referred from the Executive Committee.

The Rev. Dr. HAUGHTON said that there were two points to which he might call their attention, though he only intended to deal with one of them. The first, to which he should not further allude, was the question as to the right of the Executive Committee to order the Branch Councils to do anything. The other was as to the preliminary examinations of the three Queen's Colleges. At the last meeting of the Council, the subject of the preliminary examinations had been referred to a committee, of which he was the chairman, and, as they had received no returns from Galway and Belfast and only very incomplete ones from Cork, they were not in a position to judge of the examinations conducted by those bodies, and the Council had, therefore, on the recommendation of that committee, refused to recognise their examinations. Now, however, they had obtained returns from them, and he proposed that they should be referred to the committee, and he had little doubt but that their report in the morning would be favourable. He proposed Dr. Storrar and Dr. Watson as members of the committee.

Mr. TEALE seconded the motion.

Dr. STORRAR said that he was surprised at the claim of these bodies, as they had not a leg to stand upon; they were not universities or examining bodies, but merely colleges; their examinations were only such as would be held at schools. If they admitted their certificates, why not those

of University and King's Colleges in London; and if these, then why not those of the provincial colleges and medical schools. The admission of these three colleges was an entire abuse, and there was good ground for doubt as to whether the Council could look upon their examinations with confidence. They were originally accepted on the statements of Sir Dominic Corrigan, and later on when repeatedly pressed, he refused to give any information about them. He did not think the matter ought to be referred to a committee at all.

Dr. BANKS said that the Queen's Colleges had done much for higher education in Ireland, and their standard was higher than that demanded by the Council, for they insisted on Greek. He hoped they would restore them as fit and proper bodies to conduct the examinations. As to the Colleges not having answered the letters, he had been assured by each of the presidents that they had never received any communication from the Council. He thought that Dr. Storrar was disqualified from serving on the committee.

Dr. STORRAR said that the question was with him a matter of principle, and he felt that his views debarred him from being on the committee, and ultimately he declined to serve.

Dr. STRUTHERS said that these three colleges had had great difficulties to contend with, and had succeeded, notwithstanding opposition. They were important educational bodies and not mere examining bodies. These bodies thoroughly fulfilled their requirements, and why should they not recognise them. He would propose to replace them at once without reference to a committee.

The Rev. Dr. HAUGHTON said that they could not do this; it would not be just to the colleges themselves, as they had not yet examined their papers.

Dr. MATTHEWS DUNCAN said that Dr. Storrar had argued that they were subordinate bodies, but were they affiliated?

Dr. STORRAR said they were not, but could they give degrees? They were, in his opinion, analogous to the colleges at Oxford or Cambridge.

Dr. BANKS said that they not affiliated, but the majority of the students went to the Royal University of Ireland.

Dr. LYONS said they would not be in order in having a detailed discussion on these colleges now. He wished to ask what was the real power of the Executive Committee—could it override and nullify the decisions of the Council itself? At their last session they had arrived at a resolution, coerced into it by the strength of the speaker, cutting away the claims of many young men who had acted on the faith of what had already been promised them. If that resolution had been kept, these young men would have been seriously inconvenienced, but the Executive Committee had by a majority nullified that resolution. It seemed to him to be a bad precedent, and he wished to know whether it was competent for them so to act.

Dr. HUMPHRY observed that this speech was entirely out of order; they had a resolution before them, and Dr. Lyons' motion could be discussed afterwards.

Dr. Haughton's motion was then carried, Dr. Humphry's name being substituted for that of Dr. Storrar.

The PRESIDENT then said, that as it seemed to be the wish of the Council, he would make a short statement on the matter to which Dr. Haughton and Dr. Lyons had referred. At the conclusion of the last meeting the three colleges were struck off the list of recognised bodies on the recommendation of Dr. Haughton, who said that there were reasons for the step which he would give on another occasion. The result was that a remonstrance at once came from each of the bodies in question. The Executive Committee on behalf of the Council thought it their duty to say that they might remain as before until the matter could be again discussed in full Council; in this matter the Executive Council acted only for the Council, and not in any way in opposition to it. When the Council was not sitting it was the function of the Executive Committee to act for them, and when the Executive Committee was not sitting, the President had to represent the Council. If any examination was thought to be insufficient, it was part of the business of the Executive Committee to take it off altogether. The action of the Executive Committee had not

been to settle the matter, but only to defer it till another meeting of the Council. The decision was not fully taken on its merits on the previous occasion.

The Rev. Dr. HAUGHTON said, that on the former occasion he had no other reasons than that they were absolutely without information; they were not then in a position to go into the merits of the question.

The PRESIDENT hoped that the action of the Executive Committee would not be allowed in any way to prejudice their decision in the matter. The subject then dropped.

Some formal business having been transacted, the Council adjourned.

#### SECOND DAY—WEDNESDAY, NOVEMBER 18TH, 1885.

##### *Standing Orders as to Penal Procedure—Report of the Statistical Committee—Report of the Pharmacopœia Committee—The Surgical Qualification of the Apothecaries' Society.*

THE first hour and a half was occupied with the consideration of the proposed revision of the Standing Orders with regard to complaints against registered practitioners, and the removal of names from the Register. The Counsel who had advised the Executive Committee, Mr. Muir Mackenzie, was present throughout. He pointed out that the new rules had been very carefully considered, and made to accord with rules of procedure elsewhere, and he believed that no loophole was left which could be taken advantage of. The report was considered in Committee, the clauses being taken *seriatim*. After much discussion certain of them were referred back to Mr. Mackenzie for further consideration, the main objector being Dr. Heron Watson, who was not satisfied that sufficient provision had been made for dealing with cases of felony or misdemeanour committed out of the United Kingdom. Ultimately several of the clauses were agreed to, but those relating to the initial steps to be taken before any actual proceedings were instituted by the Council Mr. Mackenzie undertook to recast.

Dr. SCOTT ORR moved, and Dr. Aquilla Smith seconded, the following resolution, which was agreed to without comment or explanation: "That the list of names and qualifications erased from the *Medical Register* by order of the General Medical Council, for the reasons assigned in each case, be published annually as an *Appendix* to the *Medical Register*."

Dr. SCOTT ORR then moved the following resolution: "That intimation, by means of a registered letter, be made to those whose names are erased from the *Medical Register* by order of the Medical Council." He said that his reason for doing so was that a case in point had recently occurred in Glasgow. A practitioner, who had been removed from the Register in 1881, had continued to issue bills, stating that he was a registered practitioner. Eventually he was prosecuted by the Procurator Fiscal, when he pleaded in defence that he had had no notice that he had been struck off the Register. At the trial the minutes of the Council notifying the fact of his being removed from the Register were not admitted as evidence, and a verdict of not proven was returned on the ground that there was no evidence that he had ever been informed of his suspension. It was to prevent the recurrence of such a thing that he had framed the resolution now before the Council.

Mr. SIMON said that he entirely agreed with Dr. Scott Orr as to the desirability of some such proviso as that he proposed, but he wished to say a few words with reference to the former resolution, which had been put without his being aware of it. He considered it exceedingly inexpedient, and he doubted very much whether it was legally justifiable. That a man should be perpetually gibbeted year after year for an offence once committed was quite contrary to the spirit of the age. [At a later period of the day, Mr. Simon gave notice that he should move that the resolution be rescinded].

Dr. STUTHERS asked whether it was intended to make the announcement annually, to which Dr. Scott Orr replied that he intended all the names to be published every year.

Dr. QUAIN pointed out that the sending of a registered letter would not constitute sufficient evidence, and he hoped that Dr. Scott Orr would accept an amendment, to the effect that the Council should instruct their solicitor to serve personally formal notice of the decision of the Council on the culprit, in the event of his not having been present in person and heard the result.

The motion as thus altered was then agreed to.

Dr. SCOTT ORR then moved the following resolution: "That on the application of any of the medical authorities in the United Kingdom the Registrar of the Council be in future empowered to present such medical authority with a bound copy of the minutes of the Council as they are published," and in doing so said that formerly, some ten or twelve years ago, it had been the custom for copies to be given, but that it had been discontinued, and on a recent occasion in Glasgow one of the visitors of the Council had been put to much inconvenience by not being able to refer to a back number of the minutes.

The motion was seconded by Dr. QUAIN.

Dr. STRUTHERS said he quite sympathised with the motion and spoke of the hardship he had suffered himself on a former occasion by being obliged to purchase a copy of the minutes out of his own pocket. He moved, as an addendum, that the reference should be extended to back numbers if asked for within a year.

The motion so amended was carried.

After the usual adjournment for tea Dr. HERON WATSON gave notice of a question asking the intentions of the Branch Council for England as to the case of a registered practitioner (a member of the College of Physicians) who had given evidence in a recent criminal case and whose conduct had been condemned by the presiding judge in very severe terms.

The PRESIDENT then stated that he had received private notice of a motion to which he could not make any reference in the presence of strangers, and the latter were accordingly ordered to withdraw.

On their re-admission Mr. MARSHALL brought up the report of the Statistical Committee, composed of himself Dr. Haldane, and Dr. Aquilla Smith. He described it only as an *ad interim* report, and he did not then intend to speak as to its value, but he had strongly felt that it was the duty of the Council to undertake such work as this. At the commencement they decided to limit their enquiries to the years 1871 to 1880, and the following were the points to which they directed their attention: (1) The duration of the period of professional study, so far as this is indicated by the length of time allowed by different students to elapse between the date of their registration as students, and that of their acquisition of a registrable qualification, as shown by reference to succeeding editions of the *Medical Register*; (2) the relative numbers of those who obtain and register a complete or so-called double qualification at once; of those who, on the other hand, obtain and register at first only a so-called single qualification, which they afterwards supplement with another; and lastly, of those who appear to remain satisfied with a single qualification only; (3) The interval which is allowed by different students to elapse between the acquisition of a first or single qualification and of a second complementary qualification; and also, the different order and source in and from which such first and second qualifications are obtained; (4) the identity or difference which may exist between the place of registration of students and that of their registration as qualified practitioners; (5) A similar comparison between the locality in which given qualifications have been obtained, and that at which their registration has been effected." He said that the Committee had judged it best to lay before the Council such information as they had been able to gather rather than wait to present a full report with generalizations. He could not speak in terms of too great praise of the services rendered by the Registrar in connection with this enquiry; he had compiled no less than 198 tables or sheets extending over the whole period of ten years, and those sheets would ultimately form the basis of the full report. Up to the present time they had spent a sum under 200*l.*, but he did not think that the question of expense was one that they ought to lay much stress upon. He thought that this kind of enquiry

was a duty they ought to undertake in order that they might be able to answer any questions on the subject that might be put to them, and he believed it would prove of use both to the Council and to the profession at large. He moved that the report be received and adopted.

After a few observations from Dr. DUNCAN and Dr. STRUTHERS the motion was carried.

Dr. QUAIN then moved that the report of the Pharmacopœia Committee should be received, entered upon the minutes, and adopted. It contained the following provisions, which had been introduced with a view to the formation and publication from time to time of an addendum: "The Committee suggest the advisability of re-appointing the present Committee as a standing Committee, with power to appoint a Sub-committee, with the following duties:—(1) To superintend generally all matters relating to the Pharmacopœia; (2) to appoint one or more persons to report to the Sub-committee on the subjects of materia medica and therapeutics; (3) To prepare for publication, by way of appendix to the present Pharmacopœia, when necessary, such changes or additions as may be deemed desirable, for which purpose a sum, not exceeding 100*l.* per annum, should be placed at their disposal, for the payment of a reporter or reporters, and for conducting such enquiries as may be thought desirable; (4) to report annually to the General Council on their proceedings during the previous year." This having been seconded by Dr. Heron Watson, was agreed to.

The next communication was one from the Local Government Board, enclosing some correspondence relative to whether the newly instituted examination in surgery at the Society of Apothecaries constituted a qualification in surgery such as ought to be accepted for poor-law appointments.

Sir HENRY PITMAN moved, and Dr. STRUTHERS seconded, that the communication be received and entered upon the minutes.

Mr. SIMON thought that the contention raised in the correspondence was a just one. The licentiate who made the application had been examined in the three branches of professional knowledge that the Council insisted upon, and he saw no reason why the Local Government Board should not recognise him as duly qualified. The word qualification had two meanings, one referring to the skill of the individual, the other to his title to practise. The question was whether the title implied the required skill and knowledge. The Medical Act required no definite limitations and it specifically recognised half qualifications. So far as the examination extended, so far must it be regarded as evidence of skill. Last year they had passed a resolution requiring that a candidate should have passed in all three subjects before registration; when taken into conjunction with clauses 20 and 22 of the Medical Act, this was virtually a compulsory resolution. If the Society of Apothecaries had not acted in accordance with it, it would have been the duty of the Council to have cited them to appear before the Privy Council. The examination in surgery had been instituted, and it had not been impugned, and the Council must therefore answer that they saw no reason why the licence should not be understood to cover in equal degree all branches comprehended in the examination. It might be asked if the Society of Apothecaries had gone beyond their right in founding this examination, but the lapse of time that had occurred without their exercising such a right was no argument that they had not all along possessed the power; the term medicine, as used by the society in question, was a large one, and would include surgery, just as it had done in the case of the College of Physicians.

Mr. BRADFORD said that the Society of Apothecaries, having determined to extend their examinations, had relegated the surgical portion to persons belonging to the College of Surgeons, and he contended that the Society was perfectly justified in doing so. Candidates could not now receive the licence of the Society to practise unless they passed the examination in surgery, or had obtained a surgical qualification elsewhere. The number of men who were in practice with the licence alone, without any surgical qualification, had for years been very small, and was steadily diminishing.

Mr. TEALE believed that this was one of the most difficult questions that had ever come before the Council; it all turned on the meaning of the word qualification. They had resolved that imperfectly educated and imperfectly qualified men should not be put on the Register, and had endeavoured to secure that every one should be qualified in ability and knowledge. But having secured this, did this give the qualified man a legal right in all things? The Act alluded to persons qualified to practise medicine, or surgery, or both. He did not think that the meaning of the word qualification had ever been legally defined.

Dr. HERON WATSON thought that this was a very dangerous question for the Council to pronounce upon. In 1859 the question had been before the Council in a slightly different form, at the time when the members were choosing which branch they would represent, and on that occasion the representatives of the Apothecaries societies both chose to represent medicine. The Scottish Universities, when they felt this difficulty, had gone to the Privy Council and got permission to give a double qualification. He thought that the only safe thing to do would be to appoint a small committee to consider what answer should be returned to the Local Government Board.

Dr. STRUTHERS spoke as to the superiority of the Scottish examining bodies in this respect; they had recognised the necessity from the first of the double qualification and this had led to the formation of the conjoint boards.

Dr. STORRAR thought that the experience of the University of London in this matter might be of some assistance. When the Act was passed, they found themselves in great difficulties, because the degree of master in surgery ranked with that of bachelor of medicine, instead of that of doctor of medicine, and in order to remedy this, they had to get a new charter permitting of the establishing of the degree of bachelor of surgery.

Mr. SIMON referred to the case of the College of Physicians, and contended that medicine and physic were the same thing, and that if physic included surgery in the one case, it should do so in the other also.

Sir HENRY PITMAN reminded Mr. Simon of the charter of Charles 2nd, in which no one was allowed to practise surgery in London or its immediate precincts, unless he was a licentiate of the College of Physicians.

Mr. MACNAMARA wanted to know whether the M.B. degree of London University was not a registrable qualification, and whether the holders of it were not entitled to practise both medicine and surgery; he asked Dr. Storrar if it was his contention that they could not practise surgery. To this Dr. Storrar replied that he did not know whether they could recover fees in surgery.

Dr. CHAMBERS said that the M.B. degree at Oxford certainly entitled a man to practise all the three branches, and at present they had no degree in surgery there at all.

Dr. AQUILLA SMITH said that he should be very chary of expressing any opinion on the matter, and he doubted if they had a right to speak on it. He held that the Society of Apothecaries could not of their own free will create a licentiate in surgery.

Mr. COLLINS said that the Society of Apothecaries had been forced to do this by the Council, and he thought it would be very difficult for them to say that it was not a qualification in surgery.

The PRESIDENT said that it was clear that some sort of answer must be sent, the question was a very simple one, and they could not refuse to reply. The motion to enter the communications on the minutes was then agreed to, and Dr. Watson gave notice of a motion to refer the matter to a committee in accordance with his remarks.

The Council then adjourned.

THIRD DAY—THURSDAY, NOVEMBER 19TH, 1885.

*Standing Orders as to Penal Procedure—The Publication of a Black List—Dental Business.*

Dr. HERON WATSON put the following question in accordance with notice given on the previous day:—"Whether any action is proposed to be taken under clause 29 of the

Medical Act (1858) by the Branch Council for England, or by the General Medical Council, in connection with the case of a registered medical practitioner, a member of the Royal College of Physicians of London, whose name has recently been brought before the public as a witness in a criminal case, on whose professional conduct the Judge animadverted in very strong terms."

The PRESIDENT stated that he presumed there could be no doubt as to who was referred to in the question. The case was now under the consideration of the Royal College of Physicians, and a complete enquiry was being made by that body.

Dr. HERON WATSON said he presumed that this meant that the matter could not be brought up at once.

The PRESIDENT said that it would be for the Branch Council to determine whether the matter should be taken up or not. He presumed that the enquiry at the College of Physicians would be concluded before the next meeting of the Branch Council.

The consideration of the Standing Orders as to Penal Procedure was then resumed in Committee, but any detailed report of them is impossible. At the suggestion of Dr. Quain the resolution adopted on the previous day, relative to the serving a notice of his erasure on a person who had been struck off the Register, was, after a verbal alteration by the Solicitor to the Council, ordered to be added to these Standing Orders.

Mr. SIMON then proposed to rescind the following resolution which had been passed on the previous day, viz.: "That the list of names and qualifications erased from the Medical Register by order of the General Medical Council for the reasons assigned in each case be published annually as an Appendix to the Medical Register."

He said that the resolution had been adopted on the previous day without any debate, and even without the proposer of it having an opportunity of giving his reasons. It meant that the Appendix was to contain a record of all the names of those who had been struck off the Register. It would be keeping up an amount of punishment that would be utterly unjustifiable, and he was much inclined to doubt the legality of it. There were besides various reasons of convenience, which would be well known to the President and Registrar, why it would be inexpedient to adopt this course.

Mr. MARSHALL fully agreed with all that Mr. Simon had said. He thought it was quite enough for them to purge their Register; to go beyond that might lead them to an accusation of persecution, even if it were not absolutely illegal.

Dr. SCOTT ORR sympathised very much with what Mr. Simon had said, but he nevertheless felt that it was necessary to have some record of the kind published for the benefit of the profession generally. Such an appendix would be of use in a Court of Law. Perhaps it was not necessary that it should be published annually. Such a step might appear cruel, but the offenders were not entitled to much consideration.

Dr. AQUILLA SMITH said that he certainly should oppose Mr. Simon's motion, and he thought Dr. Scott Orr had given ample reasons for the resolutions. As a fact, they did already publish this list, and it would be quite in accordance with the Standing Orders.

Dr. HUMPHRY pointed out that the Register was intended to indicate who were licensed practitioners, and they were bound to keep it correct, but they were not bound to publish in it those who had been struck off. So far as the public and the legal profession were concerned it was quite sufficient that the man was not on the Register. To the medical profession it was also important that those who had been struck off should be known, and this was secured by the list which was printed and sent round to the licensing bodies and those to whom the information was of importance.

Mr. TEALE pointed out to Dr. Scott Orr that, even had this list been published in an Appendix to the Register, the man at Glasgow would have contended that he had never seen it.

Mr. COLLINS called attention to the fact that no provision had been made for removing from this Black List

those whose offences had been condoned, and who had been re-registered.

Dr. HERON WATSON thought that this last point was fully provided for in the Act. He considered it most unfortunate to open up the work done the day before. He had no doubt that the publication of this Appendix would be a great convenience, and it would be a great pity that it should not be included. It was important that the licensing bodies should be kept informed in this matter. The only difficulty that he saw in the matter was as to how this Black List was to be kept correct; that he admitted to be a practical difficulty.

Dr. STRUTHERS did not like gibbeting a man for all time; he was inclined to move an amendment limiting the publication of the names to those removed during the previous year.

Dr. PETTIGREW considered that it was very important to have the list always at hand. It was necessary that at least the licensing bodies should always know who had been struck off.

The SOLICITOR, having been asked his opinion, said that a confidential list of the kind could certainly be distributed to the licensing bodies, but he was doubtful whether it would be legally right to publish such a list in the Register. Such a course was not adopted in the case of barristers or solicitors who had been struck off.

The PRESIDENT observed that the present Black List was published at 6d. a copy, to which the Registrar replied that no copy had ever been sold, and he believed that the Council had never authorised its sale.

After some remarks from Sir Henry Pitman and Dr. Lyons, the President said he thought the arguments used by Professor Humphry were absolutely conclusive.

The amendment was then carried by 13 to 4, the names being taken down.

The Council next proceeded to the consideration of some dental business, the matter having been brought up at the instance of the Executive Committee, and concerned the withdrawal of a man's licence by the Royal College of Surgeons in Ireland, he having contravened their by-laws by issuing advertisements. Mr. Macnamara moved that his qualification be erased, and this was seconded by Dr. Scott Orr.

Dr. QUAIN said that, in order to raise the question, he should contend that advertising was no offence in a dentist, and that it was not a sufficient cause, therefore, to justify them in striking one off the Register.

Dr. MATTHEWS DUNCAN considered that his offence was that he had violated the regulations of his College.

Mr. MACNAMARA said that every licentiate on receiving his diploma undertook not to advertise, and if he did he was struck off their roll. His College had a right to make any regulations they pleased. The Council, it seemed to him, must erase the qualification.

Dr. AQUILLA SMITH said that this case was identical with the one he had brought forward. He drew attention to the fact that on three occasions the Council had erased the name and qualification of a man at the request of a licensing body without enquiry as to the nature of the offence. The Council must not put the corporate bodies on their trial.

After some unimportant observations from various members, Dr. HERON WATSON characterised the proposal as a dangerous one. It was evident from the wording of the Dental Act that the mode of action to be followed was not the same for dentists as for medical practitioners. He thought they had better refer the matter to the Dental Committee.

Sir HENRY PITMAN pointed out that the Act did not make any mention of the word qualification.

Dr. QUAIN urged that they could not leave upon their Register a qualification which did not exist. They must keep their Register correct.

Dr. HUMPHRY said there was no provision in the Dental Act for erasing a qualification. If they erased it the name must go also as a matter of course. This was the first case of the kind under the Act, and they had better have legal advice.

Mr. SIMON agreed with Dr. Duncan that an entry made in the Register was not necessarily vitiated by the qualifica-

tion being subsequently withdrawn. It did not follow that they should erase the qualification, as it was the ground on which the name was originally entered, and the entry was therefore everlastingly correct in that sense. In the Dental Act the qualification was not particularly referred to. He asked if a name was to remain on the Register without a record of the grounds on which it was placed there. Because a man entered into a particular contract, and did not keep it, was not a sufficient reason for striking him off the Register; this contingency had evidently been contemplated by the framers of the Act. The mere fact of his having lost his original qualification would not justify them in acting without enquiry. He should move that the matter be referred to the Dental Committee.

Dr. QUAIN had foreseen this great difficulty coming; they were practically enquiring into the conduct of the College of Surgeons of Ireland. What an anomalous state of affairs it would be if they enquired into the matter and left the man on the Register!

Mr. MACNAMARA said it was clear from clause 15 of the Dental Act that the matter must be referred to the Dental Committee.

Dr. BANKS considered that this case was precisely analogous to the one brought up by Dr. Smith.

Dr. STRUTHERS thought that on the face of it advertising seemed an innocent proceeding. It was a matter of public comment that there was too much advertising in the medical profession.

The SOLICITOR said they must take the name off if the qualification was gone. They ought, however, to summon the offender before them.

Sir HENRY PITMAN said that according to the opinion of the Solicitor the qualification would be removed by the Registrar on receiving due intimation, and the name would be taken off the Register without the matter ever coming before the Council at all.

Mr. SIMON, after some unimportant observations from other members, said he should move an amendment referring the matter to the Dental Committee. He denied any intention to interfere with the internal government of any bodies. The striking off of a qualification seemed to involve removal of the name. It was said they could not keep their Register correct without erasing the qualification. That seemed to him to be a separate question. It was to be remembered that under the Dental Act there was an appeal against their decision. Of course he acquiesced entirely in the decision of the College of Surgeons of Ireland, but the question of depriving a man of his means of livelihood must be treated separately on its merits. Was this such an offence within the meaning of the Act as to disqualify him from practising dentistry?

After a question from Dr. QUAIN as to the nature of the enquiry to be instituted by the Dental Committee, the amendment was put and carried.

[Left sitting.]

## SPECIAL CORRESPONDENCE.

### UNITED STATES.

(From Our New York Correspondent.)

*Prospects of the Washington Congress—The American Medical Association—Dr. Jacobi on the Code question, and on International Collective Investigation—The New York College of Physicians and Surgeons.*

New York, November 6th, 1885.

Apart from the affairs of the Ninth International Medical Congress, scarcely anything of a purely medical character has excited general interest here of late. Concerning the Congress but a languid feeling is now entertained, the profession having for the most part settled down into the belief that the supporters of the new organi-

sation have set themselves unalterably against any change in their peculiar ideas of how the affair ought to be managed, consequently it is generally felt that, notwithstanding the ample justification there would be for the Congress to withdraw its acceptance of our invitation, a gathering that will pass for an International Congress will take place in Washington at the appointed time. The prevalent conviction is, however, that the meeting will not be even decently representative of the American profession, to say nothing of its pretensions to an international character. Although the funds are likely to turn out small, as the result of the quarrelling that has taken place, and although the people of Washington bear the *gaucheries* of the last Washington meeting of the American Medical Association too fresh in their memories to be very prodigal in the matter of invitations to their houses, the slender resources of the concern need not be seriously taxed to satisfy the Jonathan Wilds who will make up the bulk of the assemblage. Of course, this disgraceful state of things is hard to bear, and the leading journals have done their best to prevent it. Much better would it be for us to submit to the seeming indignity of having the meeting of the Congress held in some other country, but the *sans culottes* who for a number of years past have been gradually getting possession of the American Medical Association are amenable to no considerations that run counter to their own insatiable greed for notoriety, at any cost, and the Association will probably be unable to say them nay, even if it would. But it is one of our national characteristics to bow to the inevitable with as much grace as we can command. The consolatory feature in the case is, that it is likely to result in the overthrow of the power so long wielded by the American Medical Association over a long-suffering profession, and by the editor of the Association's *Journal* over that body itself. Already a proposal to organise a new national medical society is being seriously talked of, and this undertaking, if properly carried out, will be immensely more advantageous to us than anything that could possibly happen in connection with the Congress.

The season of society meetings has now fairly set in, but it cannot be said that anything notable has yet occurred in the proceedings: there have been no absorbing debates like last winter's discussion on the management of lying-in women, which took up the time of several meetings of the New York Academy of Medicine. Nevertheless, the President's address at the opening meeting of the Academy has awakened considerable attention. Although it emphasised the undeniable victory of the Medical Society of the State of New York in having extorted from the American Medical Association such an "interpretation" of its code of ethics as practically justifies the New York code, still, even by "old code" men, the address is generally admitted to have been wise and conciliatory. On the whole, it dealt gently with code matters, and its author, Dr. Jacobi, passed to the consideration of the subject of the collective investigation of disease as proposed by your countrymen at the Copenhagen meeting of the International Medical Congress. It is doubtful if the project can be worthily worked in connection with the Washington Congress, but Dr. Jacobi's enthusiasm is none the less to be admired. It is noteworthy that, although he is a member of the committee on the subject appointed at Copenhagen, and therefore a recognised officer of the Congress, he is among those whose nomination to official positions in the forthcoming Congress the American Medical Association has so hardened its heart as to refuse to tolerate.

Side by side with the work of the societies begins that of the larger colleges. The leading New York college, the College of Physicians and Surgeons, nominally the medical department of that old and rich institution, Columbia College, but really a private corporation with Columbia available only as an ornament, is still condemned for a season to remain in its dingy and wholly inadequate quarters in Fourth Avenue; but there is reason to expect that its next annual course will be held with all the pomp and circumstance that Mr. Vanderbilt's generous endowment has made possible. For several years past the alumni association of the college has maintained an annual course

of lectures, somewhat after the plan of various annual courses given in England, styled the Cartwright Lectures. The first of these courses was given by Professor Bartholow, of Philadelphia; the second by Professor Dalton, of the college faculty, and the third by Professor Wilder, of Cornell University. It is understood that the forthcoming course is to be given by Professor Osler, formerly of Montreal, but now of Philadelphia, who lately gave one of the courses in London. Heretofore, the managers of the fund have contrived to provide respectable lecturers, but the work they have done has not been looked upon as very striking; consequently the foundation has not quite answered the expectations that were based upon its establishment. It is very generally felt, however, that an excellent course is to be looked for from Dr. Osler, and, in view of his success as a teacher in Montreal and in Philadelphia, and as a lecturer in London, that feeling must be held to be well-founded.

## MEDICAL NEWS.

### UNIVERSITY OF LONDON.—M.B. Examination, 1885.—Pass List.

*First Division.*—Charles Edward Adams, B.Sc., Charles Joseph Arkle, Lawrence Barnett, University College; Rayner Derry Batten, James Berry, St. Bartholomew's Hospital; John Irvine Boswell, Guy's Hospital; James Harry Ernest Brock, University College; James Calvert, B.A., B.Sc., St. Bartholomew's Hospital; John Walter Carr, University College; Edward John Cave, St. Bartholomew's Hospital; Letterstedt Frederick Childe, Guy's Hospital; William Tusting Cocking, University College; Arthur Frederick Davenport, University of Edinburgh and University College; Arthur William Dingley, University College; John Elliott, B.Sc., St. Bartholomew's Hospital; Willmott Henderson Evans, B.Sc., University College; Henry Holdrich Fisher, St. Bartholomew's Hospital; Edward Wilberforce Goodall, Guy's Hospital; Frank Hichens, London Hospital; George William Hill, B.Sc., St. Mary's Hospital; Frank Hinds, University College; Charles Barclay Innes, St. Bartholomew's Hospital; Arthur John Jefferson, Herbert Henry Lankester, St. Thomas's Hospital; John Marriott, Charing Cross Hospital; George Hyde Melson, Queen's College, Birmingham; Mary Elizabeth Pailthorpe, London School of Med. and Royal Free Hospital; Walter Pearce, B.Sc., St. Mary's Hospital; Herbert Wilson Pilgrim, University of Edinburgh and University College; Alfred Edward Price, Reginald Maurice Henry Randell, Guy's Hospital; Henry Betham Robinson, St. Thomas's Hospital; James Henderson Sellick, Guy's Hospital; Thomas Sydney Short, King's College; Alfred Martin Sutton, Guy's Hospital; James Swain, Westminster Hospital; Philip Dymock Turner, University College; John James Dean Vernon, Guy's Hospital; Philip Percival Whitcombe, St. Mary's Hospital; Richard Thomas Williamson, Owens College; William Alfred Wills, Westminster Hospital.

*Second Division.*—Richard William Brogden, Guy's Hospital; Augustus Henry Cook, University College; Joseph George Harsant, Frederick Lever, B.Sc., Edward Pain Mourilyan, Guy's Hospital; Edmund Cleaver Pettifer, St. Bartholomew's Hospital; Frank Tratman, Frank Joseph Wethered, London Hospital; Patrick Watson Williams, Bristol Medical School; Louis Edmund Wood, St. Mary's Hospital.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentleman passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise on Thursday, November 12th, 1885:—

Walter George Earle, 12, Rothwell Street, N.W.

The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise:—

Gustavus George Gidley, Honiton, Devonshire; John Engenie St. George Queely, Ingham, North Queensland; Samuel Edwin Lambert Smith, General Hospital, Birmingham.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—An extraordinary meeting of the Council was held on Tuesday last, the 17th inst. The minutes of the previous meeting having been read and confirmed, the Council proceeded to discuss the statements prepared by the President and Vice-Presidents which is to be submitted to the next meeting of the Fellows and Members. It was approved and adopted, and after its confirmation at the next meeting of the Council will be published. It was agreed that the meeting of the Fellows and Members shall be held on Thursday, Dec. 17th, at 3 p.m. It was resolved that the report of the Committee of Delegates

from the two Colleges concerning the bestowal of the title of Doctor be deferred to another extra-ordinary meeting of the Council, to be held on Tuesday next, the 24th instant; at which also Mr. Hutehinson's motion (which was seconded by Mr. Thomas Bryant) is to be further considered. The Council voted 50% towards the repairs of Holy Trinity Church in Little Queen Street (the parish church of the district). The Council then adjourned.

**DR. COLLIE AND THE EASTERN HOSPITALS.**—At a meeting of the Council of the Medical Defence Association, held on Saturday last, the President, Dr. Richardson, in the chair, the following memorial was drawn up, and ordered to be signed by the President and Secretary, for presentation to the President of the Local Government Board and the Asylums Board:—“Sir,—We are directed by the Council of the Medical Defence Association to present to you the following memorial on the case of Dr. Collie, medical superintendent of the Eastern Hospitals in London. Your memorialists, who are constantly having under their consideration evidence relating to public medical duties and offices, have carefully studied all the points of evidence in the above case, and beg, with much respect, to submit the following conclusions:—1. That Dr. Collie, appears to have been at fault in four directions—(a) In regard to the supervision of the diet sheets of the hospital; (b) in failure of keeping the records of cases; (c) in neglecting the record of destroyed clothing; (d) and in supervision of expenditure relating to the above. 2. That much of this error was due to the circumstance that at the time of its committal Dr. Collie was being subjected to a degree of physical and mental strain which was unexampled, and sufficient to account for and excuse a large amount of the omissions with which he was charged. The facts that he personally attended 15,000 cases of fever and small-pox during his residence at Homer-ton; that he was engaged in the inspection of sites and buildings, which constantly took him away from the immediate sphere of his proper duties; that his daily work for a long time included the imposition of attendance at three hospitals, one of which was five miles away; and that he has had to organise at briefest notice other hospitals—are sufficient, as all medical men will keenly feel, to account for the inevitable neglect of duties purely clerical in favour of distinct professional work and responsibility. 3. That, in regard to the charges themselves, the Council are forced to the conclusion that, while many other persons are deeply at fault, Dr. Collie is the only person upon whom any punishment has been directly visited. 4. That in no instance can any moral or professional charge be brought against Dr. Collie during the whole period of his tenure of office, nor up to the close of fourteen years any charge whatever. 5. That the previous labours of Dr. Collie have been of extreme value in various professional and public directions; that his medical duties—as the Local Government Board has stated—have been efficiently performed, and that he has successfully exerted and distinguished himself in ambulance organization for the conveyance of infectious cases to hospital ships and hospitals. From all these considerations, we are of opinion that to throw Dr. Collie out of office and make a wreck of his career would be a hardship altogether out of proportion to faults which we would not for a moment extenuate, but which we feel were the necessary results of a bad system rather than errors pertaining to one particular and grievously overtaxed medical officer. We pray, therefore, with the greatest respect, that Dr. Collie's suspension may be removed. Signed, on behalf of the Council of the Medical Defence Association, Benjamin W. Richardson, M.D., F.R.S., President, Geo. Brown, M.R.C.S., Hon. Sec.”

**THE PROFESSION AT NOTTINGHAM AND THE ANTI-VACCINATIONISTS.**—A very numerous meeting of the medical profession was held on Saturday at the instance of the Nottingham Medico-Chirurgical Society, “to consider if any and what steps should be taken by the medical profession of Nottingham in view of the persistent attempts which are being made to impair the efficiency of the Vaccination Laws.” The following resolution was adopted, with the request that it should be signed by the President on behalf of the meeting:—“That the medical practitioners of Nottingham, being convinced that vaccina-

tion is the only security against small-pox, and that the evils incident to the operation are, as compared with the immunity against the disease which it confers, so slight as to be practically of no importance, are of opinion that the only way in which small-pox can be eradicated is by vaccination being universally adopted. — Signed, JOSEPH WHITE, President of Nottingham Medico-Chirurgical Society."

**THE BRITON'S ADVANTAGES.**—In concluding his opening address to the Statistical Society on the 17th instant, the President, Sir Rawson Rawson, said that the result of the comparison of the vital statistics, the demographic elements, of the several countries of Europe had been very gratifying. Great Britain—our sister kingdom, Ireland, being in this as in many other matters an exception—had been shown to occupy a coign of advantage in most of those elements which constituted the strength and growth of a population. Among these might be noted the smallness of its departure from a normal condition, considering the adverse influences of a very large advance in the corrupting ways of modern civilization, its high marriage-rate, its large proportion of early marriages, its moderate birth-rate, its low rate of illegitimacy, its low and decreasing death-rate, indicated alike by the saving of infant life and by increasing longevity; and lastly, to these might be added the advantages which England enjoys in the possession of the necessary means of expansion for its rapidly increasing population.

**UNIVERSITY OF LONDON.**—Two seats on the Senate of the University, lately occupied by Sir Henry Maine and Dr. W. B. Carpenter, are vacant. The filling up of these vacancies falls to the Crown. The Brown Professor—Professor Horsley—the only teaching professor that the University at present possesses—will deliver his annual course of lectures in the University theatre about the middle of December.

**GUY'S HOSPITAL.**—The students' refreshment-room at Guy's Hospital has been completely redecorated, and now presents a most pleasing effect. One of Morris and Company's most beautiful papers has been used to paper the wall, round which a new wooden dado has been placed. This change will render the Guy's refreshment-room doubly attractive to the students, with whom it has always been very popular. The authorities have found in many ways it is a great convenience and advantage to the students to be able to obtain their meals within the building.

**PHARMACEUTICAL SOCIETY OF IRELAND.**—Dr. George T. Duffey, late Vice-President of the King and Queen's College of Physicians, has been appointed by His Excellency the Lord Lieutenant and Privy Council of Ireland, on the nomination of the President and Council of the Pharmaceutical Society of Ireland, a Visitor of the Examinations for the license of that body. The office of Visitor has been now for the first time instituted.

**EDINBURGH MEDICO-CHIRURGICAL SOCIETY.**—At a meeting held on the 4th instant the following office-bearers for the ensuing year were appointed:—President, Prof. Grainger Stewart; Vice-Presidents, Dr. J. Batty Tuke, Dr. John Dunean, Dr. Peel Ritchie; Councillors, Dr. Rattray, Dr. A. Moir, Mr. J. Symington, Dr. Macbride, Dr. John Smith, Dr. Littlejohn, Dr. Troup, Dr. Allan Gray; Treasurer, Mr. A. G. Miller; Secretaries, Dr. James, Dr. Cathcart; Editor of "Transactions," Dr. William Craig.

**PARIS SOCIETY OF SURGEONS.**—At the meeting of the Society, held on November 11th, M. Arthur Heulhard showed the surgical instruments and appliances invented by Rabelais. It was known that Rabelais was for a long time Professor of Medicine at the University of Montpellier, but little appears to have been known concerning the part he played in the development of that science in the sixteenth century. In a learned paper read to the Society M. Heulhard sought to throw light on that point.

**SMALL-POX IN MONTREAL.**—It is reported from Montreal that 2,641 deaths from small-pox have occurred there since the scourge began, 2,404 of these being French Cana-

dians. Sixteen hundred of the number were children under five years of age.

**ERRATUM.**—On page 662, first column, line 25 from the bottom, for "lunary" read "nonary."

## VACANCIES.

**BINGHAM UNION.**—Medical Officer to the East District, in succession to Mr. W. W. Morris, resigned. Area, 19,122 acres. Population, 4,109. Salary, £30 per annum.

**BIRMINGHAM, PARISH OF.**—Medical Officer to the First District, in succession to Mr. T. B. Gould, resigned. Salary, £4 4s. per week.

**BRISTOL GENERAL HOSPITAL.**—House Surgeon. Salary, £120 per annum; board, lodging and washing, will be provided in the house. Candidates will be required to possess a registered Medical and Surgical qualification, and produce testimonials of good moral character and ability, and must send certificate of registration. A copy of the rules will be forwarded on application. Applications to be addressed to the Secretary before December 2nd.

**CHILDREN'S HOSPITAL, BIRMINGHAM.**—Assistant Resident Medical Officer. Salary, £40 per annum, with board, washing, and attendance in the Hospital. Candidates must be duly registered. Certificates of Registration with testimonials to be sent to the Secretary not later than December 1st.

**ISLE OF THANET UNION.**—Medical Officer to the Ramsgate District, in succession to Mr. W. Curling, resigned. Area, 3,552 acres. Population, 23,073. Salary, £95 per annum.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, BLOOMSBURY.**—House Physician. (*For particulars, see Advertisement.*)

**PWLLHELI UNION.**—Medical Officer to the Aberdaron District, in succession to Mr. J. E. Jones, deceased. Area, 17,874 acres. Population, 3,479. Salary, £50 per annum.

**ST. MARYLEBONE GENERAL DISPENSARY, 77, WELBECK STREET, CAVENDISH SQUARE.**—Resident Medical Officer. Salary, £105 per annum, with furnished apartments, attendance, coals, and gas. Candidates must be registered and hold a Medical and Surgical qualification. Applications and testimonials to be forwarded not later than 30th November, and Candidates must attend at the Dispensary, on 2nd December, at 4.30.

**WINDSOR ROYAL INFIRMARY.**—House Surgeon. Salary, £100 first year, £120 after, with residence and attendance, but not board. Candidates must be qualified and unmarried. Applications, with testimonials, to be sent to the Secretary on or before Nov. 25.

## DEATHS.

**BLAND, GEORGE, L.R.C.P.,** late of Minster, at Grays, on Nov. 14.  
**CAMERON, SURGEON-MAJOR JOHN, M.D.,** Bengal Army, at Adelaide, South Australia, on September 27.  
**CONRY, THOMAS, Staff-Surgeon R.N.;** of Clonryn, co. Longford, at Melville Hospital, Chatham, on November 15, aged 45.  
**OLUGIN, JOSEPH, M.R.C.S.,** at 45, Albany Villas, Brighton, on October 10.  
**PIGOTT, PETER, M.R.C.S., L.S.A.,** at Davos Platz, on November 11.

## NOTES, QUERIES, AND REPLIES.

### REFORM AT THE ROYAL COLLEGE OF SURGEONS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—The letter by a "Junior Fellow" in your impression of the 7th inst. is quite in accordance with what might be expected from one holding that Diploma. At the same time it is an imperfect answer as to the position the Members should hold with regard to the College. Rules and regulations that answered in the past, are not always consistent with the advancements made to the present date. It is difficult to accept the assurance of the liberality of the College, when it is well known that no College or University can be found to charge so high a fee for a simple licence, and then only a partial one, as it excludes the practice of Medicine and Obstetrics. I think the College should have applied for a supplementary Charter to include the wanting parts of its Diploma. Failing, or declining to entertain that suggestion at the time of its union with the Royal College of Physicians, it should have shown some consideration for its members, and arranged with that body to grant the L.R.C.P. on no examination or on a very modified one. Some may be disposed (as they have a Medical Diploma) to reject that suggestion. But when it is remembered that in 1815 any horse or cow doctor, herbalist, quack or chemist who could assert that he had practised medicine on his fellow man, was allowed to register as Physician, Surgeon, and Obstetrician, and at a more recent date the University of St. Andrews allowed Surgeons to take the M.D. on such easy terms, that each train arrived crowded with Surgeons, and the examination, though an examination, was arranged in such a manner, that each Surgeon returned home with the desired Degree: surely if the University acted so liberally, and I am sure its graduates have never disgraced their Alma Mater, a somewhat similar arrangement could have been made with the Royal College of Physicians. But no, the College had from the members all it could get, and they might go to Putney with their half diploma, for all the Lincoln's Inn people cared! Though late in the day, it is not too late for them to give the above their consideration. The "Junior Fellow" states it is the best diploma, and asks, if not satisfied, why did you take it? It is the most expensive, and in actual general practice the least useful of all the British Diplomas. Why did I take it? Well, because in the Colonies the M.R.C.S. was considered the best English qualification. We knew nothing about

"double-barrelled doctors," poor law appointments, Hospital and other appointments, requiring a "double-shotted" Doctor. In mighty ignorance I passed by the cheaper and better L.R.C.P., and went for the M.R.C.S. A Medical or Surgical Diploma ought to be so worded as to be inclusive of all subjects coming under the designation of Physic, and a fee of 5*l.* to 10*l.* is enough for any licence. 50*l.* or 100*l.* might be charged for an M.D. Before closing my letter, I may make a few observations regarding the proposed M.D. by the Royal College of Physicians and Surgeons. Abroad the practice of a Medical College granting the Degree of M.D. has been tried, but in practical working it is found that socially it takes an inferior place to the M.D. bearing the University stamp. So much so, that not a few of the better men have subsequently repaired to a University in order to obtain the distinctive M.D. stamp. The Examining Boards now demand very heavy fees for their licences; and in the case of the Scotch Colleges they thrust on the unwilling candidate two Surgical Diplomas. Of what use is the extra one? If this practice continues, the student may turn the tables very suddenly on the various Medical Corporations and seek out of England a *Registerable* Physician and Surgeon's Diploma and University M.D. at about a fourth of the cash of the British. It may not be generally known, but at Kingston, Ontario, Canada, there is the Queen's University, and the Royal College of Physicians and Surgeons. I was informed by an M.D. (Montreal) that the opinion of a leading Canadian Q.C. was taken, regarding the Registrar of the College of Physicians and Surgeons of Kingston, and he gave as follows: "The Kingston College has a *Royal* Charter, and as such carries with it the power to register and practise in Great Britain and Ireland and the Colonies." Registration in England is *not a grace*, but can be demanded by *legal right*. This College is the only Canadian body, granting degree or diploma, that can exercise that privilege. A cabin, 1st class, passage to Canada is 10*l.*, under \$100, or 20*l.* would cover fees, diploma from \$5 to \$10. Board and residence from \$2.50, or 10*s.* 6*s.* per week to \$5. Of course \$2.50. is a low figure, but board and lodging can be obtained for that; but for \$4 to \$5 very good board can be obtained. Say that the student desires to study close economy, the following may be given as a rough statement:—

	\$
Passage out and home ... ..	100
Board for 4 years, at \$3 per week ... ..	624
Fees ... ..	100
Diploma, say ... ..	10
	\$334

In rough calculation £160 for 4 years' study and board and lodging. Clothing about same as in England (?) Pocket money (?) Books (in my Canadian student days) were reprints of British works, cheaper than the originals.

With an apology for so great a trespass on your space,

I am, Sir, yours, &c.,

FOREIGN AND COLONIAL GRADUATE,  
AND M.R.C.S., England.

#### REFORM AT THE ROYAL COLLEGE OF SURGEONS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—It was with the greatest indignation that I read in your last number of the decision of the Council of the College of Surgeons not to allow Members of the College to take part in elections to the Council. I have made up my mind to a course which I hope will commend itself, and be initiated by every Member who has the real interests of the College at heart. From this day forward, I shall not call in consultation or send another patient to any single Member of the Council who passed that resolution. In fact I shall "boycott" them all.

I am, Sir, yours, &c.,

A PRACTITIONER OF FIFTY-TWO YEARS' STANDING.

[We trust our esteemed correspondent will do no such thing.—EDITOR M. T.]

do we not treat spasmodic strictures of the circular fibres of the œsophagus by dilatation by bougies? The medical man, be he physician or surgeon or family attendant, who has learned to appreciate the degree in which perverted action of the sphincters can disturb the balance of the healthy working of the cavities which they command, has acquired the key to a very numerous class of bodily ills and discomforts.

As the type of perverted sphincteric action, let us take the instance of "fissure of the anus." Commencing, perhaps, in a slight tear or scratch of the mucous membrane, just within the grip of the sphincter, it is continued as an abrasion, or a clack, or a fissure, or even as a definitely excavated ulcer. Becoming irritable and painful, and suffering from the grip of the sphincter, the ulcer acts upon the sphincter, provoking it to spasm, and in time induces even hypertrophy. Meanwhile, the strangling grasp of the sphincter reacts upon the raw surface, and deprives it of the physiological rest needful for its recovery. Surgery has recognised the mutual interdependence of a sore within the anus and irritability of the sphincter, and has perceived a two-fold line of treatment. "Heal the sore, and the irritability of the sphincter will cease," "destroy the undue activity of the sphincter, and the sore will heal." Attempts to cure the sore by soothing and caustic applications have often been made, sometimes with success. Failing such local remedies, the surgeon attacks the sphincter itself, and by division of more or less of its fibres sets it at rest and cures the disease. Such was the standard method of dealing with the sphincter and for the cure of fissure in my student days and during the earlier years of my professional life, and I believe it lingers as the orthodox treatment in the minds of some of our surgeons. It is now some twenty years or more since I first heard of the then new method of forcible dilatation of the sphincter and as a substitute for division by the knife. Brought out in Paris by, I believe, M. Verneuil, it was introduced into this district by Mr. Jonathan Hutchinson, who, when meeting my father in consultation, suggested and performed dilatation as a substitute for the knife. From that time my father abandoned the knife, and I followed his example.

This introduction of forcible dilatation has proved an inestimable boon to surgery. In the first place it has introduced a more exact and, as it seems to me, a more scientific method of dealing with the variable conditions of sphincter which are found in such cases. The educated dilating fingers of the surgeon have a far better consciousness of the amount of resistance to be overcome, and of the degree of the relaxation to be demanded and attained, than can be attained in using the knife. Failure to cure is, in my experience, and I believe in the experience of my colleagues, extremely rare. The main object aimed at is attained far more effectively and satisfactorily by the use of the fingers than by the knife or even by the three-branched dilator. There are, indeed, rare instances in muscular men in which a mechanical dilator, such as the ordinary three-branched dilator of the female urethra (Weiss), or a special short-branched modification of it devised by my colleague Mr. Jessop, is of use when the power of the surgeon's fingers or thumbs proves insufficient for the purpose.

But it is not in fissure alone that this beneficial result of dilatation is to be found. We have learnt to appreciate its value as an aid in other operations.

I have spoken of "fissure" as a cause of spasm, in which there can be detected by the finger an actual breach of surface of mucous membrane, be it in the form of abrasion, crack, or ulcer. There is, however, a class of cases in which, without such tangible reason, the sphincter is too powerful, resisting the introduction of the surgeon's finger, and is the cause of habitual

constipation, long delay at the water-closet, retention of flatus in the colon, and colicky pains in the left loin. Such pains are often attributed to disturbance of the kidney or to rheumatism. Whenever a patient has pain in the left lumbar region, accompanied by constipation and tedious visits to the water-closet, and above all, if there are occasional streaks of blood on the evacuations, suspect spasm of the sphincter, and examine the anal aperture with the finger.

A third class of cases is most deceptive and may easily escape detection. There are present some of the symptoms of fissure, obstinate constipation, colicky pains in the loin, and great difficulty and pain in defœcation, and yet examination of the anus discloses neither fissure nor ulcer, nor spasm of sphincter. Should, however, the surgeon, relying upon the presence of the general symptoms of a tight sphincter, determine to test the point by examination under ether, he will find, on introducing the forefinger of each hand, that the sphincter yields readily, *up to a certain point*, just sufficient perhaps to admit the two fingers, and to allow the escape of a soft or a solid evacuation of small calibre, but that beyond this it is absolutely rigid, like a ring of cartilage, far more unyielding than the ordinary sphincter in fissure, and needing all the power of, sometimes proving almost too much for, the surgeon's fingers to break through.

Another class of cases in which dilatation of the sphincter proves of great value is to be found in *slight internal bleeding piles*, which may often be cured thereby. This fact was first taught to me by my father some twenty years ago, when, in accordance with his suggestion, I cured, by forcible stretching of the sphincter alone, a gentleman who was suffering from considerable hæmorrhage from internal piles. My father probably deduced the principle of treating bleeding piles by reducing the power of the sphincter from the late Professor Syme, substituting dilatation for the incision recommended by Syme. Professor Syme, in his "Observations on Clinical Surgery," p. 85, under the heading Hæmorrhage from the Rectum, says:—"Another source of hæmorrhage from the rectum, which could not have been readily anticipated, is spasmodic stricture of the anus. The fissures and ulcers which are so frequently connected with this condition usually discharge a little blood, although hardly so much as to constitute a prominent feature in the case; but, independently of any such complication, a mere contracted state of the sphincter may occasion the most profuse and serious bleeding." In a case related "I found that the external part of the sphincter was tightly contracted, and, knowing that this might be the cause of the bleeding, I made a division of the tight muscular fibres. No blood was subsequently discharged, and the patient soon regained his healthy aspect." From that time it has been my practice to treat moderate hæmorrhoids by dilatation in the first instance, reserving further operation by ligature for those cases (a small minority) in which mere dilatation did not prove adequate.

Let us enquire what has been the history of this question:—

In 1877 M. Verneuil, the originator of dilatation, brought the subject of the cure of hæmorrhoids by dilatation before the Surgical Society of Paris, and was supported by hardly a single speaker, many of those who spoke betraying the most profound ignorance of the subject and a complete inability to grasp the principles of dilatation.

Mr. Bryant, in the last edition of his work on Surgery, published so recently as 1884, after condemning "forcible dilatation, as practised abroad, as a barbarous treatment," speaks of this method of treating internal piles as follows:—"In Paris a plan of treatment has been successful which claims attention, as it receives

the support of M. Verneuil," but he does not seem either to have used it or to approve of it.

Mr. Allingham, in his work on the rectum, published in 1882, describes more fully the views of M. Verneuil and M. Fenton, both of whom arrived independently at the same conclusions about the sphincter and its relation to hæmorrhoids.

Leaving now the cases in which dilatation of the sphincter is the sole or chief means of cure, let us consider other cases in which it becomes a very important accessory to treatment.

First and foremost in any removal of piles, whether by ligature, cauterization, or nitric acid, undoubtedly the first step to be taken by the surgeon should be to produce thorough relaxation of the sphincter by forcible stretching.

Much is gained thereby. In the first place internal

piles, previously out of sight, within the anus, are brought to view, and are entirely at the command of the surgeon to work his will upon. In the second place, by reducing for a time the power of the sphincter, the parts are set at rest during the earlier days after the operation, when an untamed sphincter would be roused to abnormal activity, and severely grasp and worry the wounded bowel. In fact, we secure by dilatation greater facility for dealing with the bowel during the operation, and physiological rest in the early painful days which follow the operation.

The accompanying sketch *ad naturam*, made by my dresser, Mr. Herbert Child, vividly shows the result of stretching in a case in which, previous to the dilatation, the anus appeared normal, no piles being visible.

Mr. Allingham (p. 134) says that in operating on piles "I gently, but completely, dilate the sphincter ani."

Contrast with this the old-fashioned plan of making a patient sit "for half-an-hour on a bidet over hot water," struggling to force his piles down through a recalcitrant sphincter, as a preparation for operation.

*Vide* Erichsen, vol. ii., p. 89, and Bryant, vol. i., p. 805.

In another class of cases I have found dilatation of great value. Whenever, in deeply extending fistula, free division into the rectum would involve a risk of permanent incompetence of the anus, I have been enabled by dilatation of the sphincter to rest content with but partial slitting up of the fistulous sinus, and

have found that the enforced quiescence of the sphincter has allowed the rectal end of the sinus to heal. In attempting this, it is necessary to make the skin opening large, like the base of a triangle of which the rectal end of the fistula forms the apex, care also being taken to vigorously scrape away all granular lining of the fistulous track by Lister's scraper or Volckman's spoon.

Again, dilatation sometimes enables us to pass the fingers or portion of the hand much higher up the rectum and thus to discover a stricture or cancer not otherwise to be detected by an ordinary digital examination.

Lastly, on two or three occasions, moderate dilatation has proved to be of infinite value in children suffering from obstinate constipation resulting from soreness or cracks within or near the anus.

In one instance a child about three years old was brought to me on account of fæcal incontinence. The bowel seemed to be incessantly acting. On examination I found a sore at the anus, and the sphincter in painful spasm. Examined under an anæsthetic, the rectum proved to be loaded with a large soft fæcal mass, rigidly guarded by a resentful sphincter. Dilatation of the sphincter set free the mass, restored healthy action of the bowel, and cured the patient.

In conclusion let me state my belief--

(1) That spasm of the sphincter ani, as a cause of constipation, suffering, and ill-health, is often overlooked, and patients are allowed to suffer for years who might be cured in five minutes.

(2) That spasm of the sphincter can be arrested by forcible dilatation more satisfactorily, more certainly, more scientifically, and with greater safety, than by division by the knife.

(3) That in all operations on the rectum and anus dilatation of the sphincter is an essential, almost an indispensable, element in the treatment.

## TWO CASES OF RECTUM TROUBLE, COMPLICATING OTHER AILMENTS.<sup>1</sup>

By J. W. TEALE, M.A. (Oxon.), F.R.C.S. Eng.

THE two cases which I propose briefly to bring before the members of the Society present, I think, some features of interest, and may be considered as supplementary to a series of cases related by Dr. Myrtle, of Harrogate, about two years ago in the *British Medical Journal*. In April, 1884, a young man, æt. 30, the active partner in a large manufacturing business, consulted me. I had previously attended some members of his family. His sister died of phthisis following a pneumonic attack, and one of his brothers who developed phthisical symptoms had twice made a voyage to Australia and back by my advice. Mr. W. had had a succession of colds with cough during the winter, had been losing weight, and had had night perspirations. He looked thin and haggard; examination revealed nothing more than slight dulness at right apex, and a somewhat prolonged expiratory murmur.

As many interests were involved in the opinion I might give, I advised Mr. W. to see Dr. Clifford Allbutt of Leeds with me. Dr. C. Allbutt soon came upon the weak spot, and feared with me that the case might be one of threatened phthisis. We ascertained

that Mr. W. had suffered for years from obstinate constipation, with painful defæcation, for which he had been in the habit of taking powerful cathartics.

On returning to Scarborough, I examined the bowel and found a painful fissure and an extremely tight sphincter.

I advised that the trouble should be removed by operation and at once; and, having put him under ether, I stretched the sphincter ani freely, and kept him in bed for ten days on slop diet. In a fortnight the results were both striking and satisfactory. The bowels acted naturally and painlessly, the cough was nearly well, and the night sweats had gone; and it was difficult to detect any difference in the breath-sounds of the two apices. I sent him to Ilkley for a month, after which he had so completely recovered, that I allowed him to return to business cautiously. He has remained well up to the present time.

CASE No. 2.—About the same time, March, 1884, I was called to see a clergyman from the West of England, who had been sent to the seaside to brace up his shattered nerves. His nerves were shattered, and his body also. The wreck of a fine, powerful man, æt. 50, he lay in bed, haggard, lacrimose, irritable, and wretched. He said he could not walk for excruciating pains in the feet. He complained of constant diarrhœa, accompanied by severe hæmorrhage and excruciating pain. Whisky and water was his chief solace, and his red-tipped tongue and enlarged liver showed that this was doing its work effectually. To make any satisfactory diagnosis as to the bowel condition was under these circumstances simply impossible.

Not without great difficulty, I persuaded him and his friends that relief was out of the question unless I could make out the nature of his ailments under ether, with permission to operate, should it prove necessary. Mr. Teale, of Leeds, was sent for to meet me. On examining him when fully under ether, we found the sphincter in a state of intense and acute spasm, and some inflamed internal piles tightly grasped by it. There was no evidence of malignant disease, to the possibility of which the severe hæmorrhages pointed. We stretched the sphincter freely, leaving the piles to shrivel when the constriction was removed.

In the first three motions after the operation there was a little blood, and then no more. Then formed motions were gradually passed without pain, a thing unknown for years. Stimulants were at once and entirely stopped. For a long time our patient remained very low and depressed, and, though relieved as to his bowel pains, yet complained much of his feet, and made no attempt to walk.

By the aid of the massage, however, and hot salt-water baths, he at last, and by degrees, began to walk about. Six months after the operation he returned to his duties strong and in good health, able to walk ten miles a day, and to enjoy a good day's shooting on the moors. He continues well.

*Remarks.*—(1) These two cases illustrate, I think, the advantage of grappling with and relieving any surgical trouble that may exist, irrespective of the medical aspects of the case.

(2) When once the question of operation is mooted, or, what amounts to the same thing, an examination under ether for purposes of diagnosis, the sooner it is done, the better. Patients rarely improve whilst waiting for an operation, and, although in feeble health at the time, often do well afterwards, better perhaps than when they are in rude health at the time. A few days' complete rest in bed on light diet often has a most salutary effect in giving rest to the overtaxed vital organs.

I do not enter into any details as to the operation itself, as Mr. Teale has fully described this in his

<sup>1</sup> Paper read before the Members of the Leeds and West Riding Medico-Chirurgical Society, October 9th, 1885.

lecture. I usually perform it with the fingers. It requires some practice to know what amount of stretching is required. I have once had some temporary anxiety from over-stretching, but have more than once had to repeat it, from its not having been done freely enough at first.

**HÆMORRHAGIC AMBLYOPIA CURED BY DILATATION OF THE SPHINCTER ANI.**

By ROBERT N. HARTLEY, B.S. (Lond.),

Hon. Surgeon to the Leeds Public Dispensary, &c.

The following case seems to me to well illustrate two points, first, the serious amount of amblyopia liable to be produced by frequently recurring hæmorrhages extending over a long period of time, and second, the value of the surgical procedure of free dilatation of the sphincter ani under ether. A man holding a responsible position in one of the large leather factories of this town consulted me in June last on account of a gradual loss of sight. He thought he was "going blind," and that he should be obliged to resign his situation. As a matter of fact, there was very serious visual defect, the distant vision of each eye being only equal to  $\frac{2}{70}$ , while no type smaller than No. 14 Jaeger could be read. There was nothing in the appearances of the eyes (ophthalmoscopic or other) to account for so much defect, except a slight pallor of the discs. From his appearance I suspected that he might be suffering from loss of blood in some way, and a little close questioning elicited the following facts.

For ten years he had suffered from repeated bleedings from the anus. The bowels were never moved without great pain, and seldom without bleeding, sometimes slight, but often profuse, and the last three months he had frequently to leave his work and go home on account of severe bleeding, which saturated his clothes, etc. He was constantly taking either purgatives or astringents. Introduction of the finger into the bowel caused such intense pain that a thorough examination was impossible without an anæsthetic. I told him that I thought the failure of sight was due to the bleeding, and advised that this should be treated. Accordingly, in a few days, he was put under ether, and I found an enormously powerful sphincter ani, the internal fibres being especially marked as rigid rings extending for some distance up the bowel. I freely and thoroughly stretched with the fore and middle fingers of each hand the rigid sphincter until all sense of resistance had ceased, and all the fingers of one hand in the form of a cone could be easily pushed into the rectum. The congested and swollen mucous membrane now protruded, and the surface of it was seen to be here and there marked by irregular ulcerated patches, which had no doubt been a chief source of the hæmorrhages. Nothing more was done except the swabbing of the parts with carbolised glycerine. After three days' rest in bed the bowels moved spontaneously for the first time since the operation, with little or no pain, and with no bleeding.

Six weeks afterwards he came into my consulting room and said, "I feel a new man, I have never bled once since I had the ether; I have never had a dose of medicine, and my bowels act every morning without pain or difficulty."

He still remains (October 1885) in the same happy condition, and his acuity of vision is now perfectly normal— $\frac{2}{20}$  and J. 1.

**ON THE INFLUENCE OF AGE AND SEX UPON THE DEATH-RATE FROM PHTHISIS.**

By H. HANDFORD, M.D., M.R.C.P.,

Physician to the Nottingham General Hospital.

HIPPOCRATES<sup>1</sup> says the years 18-35 are most affected with phthisis. Celsus<sup>2</sup> also considers the same period most liable. Aretæus<sup>3</sup> says "the old seldom suffer from this disease, but very rarely recover from it." Lacunec<sup>4</sup> considered that tubercle was distributed very widely even among persons of very advanced age. Trousseau<sup>5</sup> gave as his opinion that the greatest number of deaths from pulmonary phthisis occurred during the first year of life.

The best way to ascertain the influence of age and sex on the incidence of phthisis, in the absence of copious statistics of non-fatal as well as of fatal cases, is to take the death-rate from phthisis for each sex and at the different groups of ages for equal numbers of each sex living at each group of ages. This has been done for Prussia by Würzburg<sup>6</sup>, and the following tables, except the last (1871-80, England), which I have worked out from the Registrar-General's returns, are taken from his article.

DEATH-RATE FROM PHTHISIS per 10,000 living at each group of ages.

Groups of Years.	UNITED STATES.— 1870.			PRUSSIA.— Average of 5 years 1875-9.

65-75	23.8	16.3	20	20.2	12.3	16.3	18.3	10.4	14.0
75-85	9.8	7.5	8.6	6.9	4.7	5.9	6.0	4.0	4.9
Over 85	5.4	4.7	5.0	3.4	2.6	3	2.4	1.4	1.7
All ages	25.8	27.7	26.7	24.6	24.8	24.7	21.4	19.9	20.6

If these figures are represented in a graphic manner as charts, it will be evident at a glance that the liability to phthisis is much greater at advanced ages than is generally supposed.

The statistics of the different countries vary much. This is probably owing very slightly to race, rather more to climate, largely to occupation, mode of life, food, the sanitary condition of dwellings<sup>7</sup>, the proportion of town to country dwellers, and somewhat to the prevailing views of pathology of the medical profession of the country. It is very possible that many of the cases at the more advanced ages which are returned as phthisis in some of the continental tables would be returned under a different heading in the English tables, preconceived views influencing the diagnosis. It is not otherwise possible to explain the very great

<sup>7</sup> The continental plan of living in flats, and so crowding a large number of people under one roof, is supposed by Würzburg and others to favour the production of phthisis.

ENGLAND.

Age in years.

UNITED STATES AND PRUSSIA.

Age in years.

The continuous line represents the death-rate in the United States in 1870, the broken line the death-rate in Prussia 1875-79.

difference in the percentage of deaths at the ages beyond 50 in the tables of Prussia, Sweden, and the United States on the one hand, and of England on the other. The progressive fall in the death-rate from phthisis in England in both sexes and at all groups of ages in the three decennial periods 1851-60, 1861-70, 1871-80, is most striking. This decline,<sup>8</sup> moreover, appears to have been real and not only apparent; for though, doubtless, the term phthisis is often used in certificates with considerable looseness, yet there has been no corresponding increase of mortality under those headings which might be confounded with it. Indeed, coincidentally with the decline in phthisis, there has been a decline in the deaths ascribed to other forms of tuberculosis and to those from diseases of the respiratory organs. This fall in the death-rate from phthisis has been due, no doubt, partly to improved hygiene, whereby the number of attacks has been diminished, but also largely to more rational treatment by means of which some recover absolutely, and an increasing number have the disease partly or entirely arrested and die of other maladies. The prolongation of life by modern treatment in cases of phthisis was clearly pointed out by Williams,<sup>9</sup> and his views are in some measure supported by the death-rates of the last three decades. The maximum rate, which in the two previous decades had fallen in the group 25-35, was removed in the last decennial period to the group 35-45. It is more probable that this change has been brought about by a prolongation of the lives of those attacked, so that they die at a more advanced age, than that the attacks have occurred at a later period, for which there would appear to be no reason assignable.

The percentage of deaths at the early ages is very fairly constant in the different countries, and there is a remarkable agreement showing that *the period from 5-10 is that of least liability*. In Sweden and Copenhagen, however, it is 10-15. The death-rate during the first year of life, as shown in the United States and Prussian tables, is large, and it does not reach the same figure again till about the period 15-20 or rather later. The limit of 18-35 set by the ancients as the period of special liability is too narrow. According to the English tables, 1851-70, the period should be at least 20-45, or better, 15-65, before and after which ages there is a sharp falling off. The table for 1871-80 gives as the period of *greatest* and nearly uniform liability 25-45, and still of great liability 20-55, before and after which there is a rapid decline, though not till after the age of 75 is passed does the rate become comparatively insignificant. In all the tables, except the English, there is an *increasing* rate up till 70 or later. In Prussia the liability diminishes after 70, but in the United States it goes on increasing up to 80. One explanation of this divergence from generally accepted opinion lies in the fact that the number of individuals living at each age diminishes rapidly as the age advances, and consequently the total number of deaths from phthisis at the more advanced ages is small, though the proportionate number to those living at that age may be very high. That, however, will not explain the great difference on this point between the English and the United States tables.

In the Prussian statistics the death-rate from phthisis among the town and country dwellers was compared, and was found to be rather higher among the former, but the difference was very much less than would be supposed.

As regards sex: in Prussia, Sweden, and Copenhagen the deaths of males exceed those of females very

markedly, while in England and the United States the female deaths are very slightly in excess, except in the decade 1871-80 in England. These are the total results, but when we examine the rate at the different groups of ages we see that there is a very general agreement in all the tables.

During the first year of life there is a preponderance of male deaths. For the next years, up to ten, the proportion remains very equal, but eventually the female deaths are slightly in excess. *At the age-period 10-15 in all the tables the female deaths are nearly double the male*. The home and school life and the employment of children between these ages are not sufficiently different in the two sexes to account for such a sudden change. The years 10-15 embrace the period of puberty, the establishment of which produces a greater disturbance, and causes a more rapid general development in the female than in the male. At this time, and at no other, the female, inferior to the male in stature and weight from birth onwards, *rapidly catches him up and surpasses him; so that between the ages of 12½ and 15 or 16 females are both taller and heavier than males*. It is probable that this

The average WEIGHT and STATURE of both sexes, from birth to 21 years of age, of the General Population of the United Kingdom.

Stature without shoes. Weight including clothes. From "Life History Album," by Francis Galton, F.R.S., pp. 84-5.

excessively rapid growth, together often with some drain upon the strength from the menstrual flow, renders the female sex an easier prey to tubercle than the male. A high state of nutrition seems inimical to the growth of tubercle, and Koch expressed the opinion at the first Wiesbaden Medical Congress that "The human body does not at all times offer an equally suitable nutrient medium to pathological micro-organisms." This applies to the tubercle bacillus very specially. I have noticed clinically that the children of phthisical parents, and those with a well-marked phthisical family history, frequently menstruate at an unduly early age—viz., 12 or 13 years—and often profusely or too frequently. It has seemed to me that the drain on the nutrition thus set up renders the body a more suitable soil for the growth of tubercle, and the above statistics, failing any other explanation, would appear to strengthen that view.

From 15-20 the female deaths are double the male

<sup>8</sup> Forty-fifth Annual Report of the Registrar-General, p. xix.

<sup>9</sup> "Pulmonary Consumption." 1871.

in the United States, half as many again in England, slightly in excess in Prussia and Copenhagen, and slightly below the male in Sweden. From 20-40 or 45 the female deaths still remain in excess in England and America, except in the decade 1871-80 in England. Here the male deaths are very slightly in excess, but the difference is remarkably less than after the year 45 is passed, when the male deaths are, as a rule, nearly half as many again as the female. In the other countries the great excess of the male deaths shows itself at this period 20-45 also, though the difference is much less than at more advanced ages.

Here again, then, the simplest explanation seems to be the drain put upon the strength and general nutrition by child-bearing and lactation. It is difficult to find any condition in the occupation or habits of women between the ages of 20-45 which should render them more liable to phthisis than men at the same age, and which would not be equally operative from 45 onwards, when in all the countries there is a very marked predominance of male deaths.

The predominance of male deaths after the age of 45, and in Prussia, Sweden, and Copenhagen after the age of 20, has been attributed to the fact that the male is, as a rule, the bread-winner, suffers more from hard work and the struggle for existence, and is more exposed to the weather.

Professor Humphry,<sup>10</sup> however, attributes to the female sex a greater inherent vitality than to the male, and considers this view strongly supported by the fact that of 89 persons who had reached the age of 100 years, and who died during the year 1873, only 10 were males and 79 females. In the year 1881 the deaths of 91 persons were registered in England and Wales, and returned as aged 100 years and upwards: of these 25 were males and 66 females. In 1882, of 71 such deaths, 17 were males and 54 females.

It should be remembered, too, that the male general death-rate is considerably higher than the female,<sup>11</sup> but the disproportion in the death-rate from phthisis of the two sexes in Prussia, Sweden, and Copenhagen is *much greater* than in the general death-rate. In England and the United States, on the contrary, the fact that the female deaths exceed the male is of all the more significance, inasmuch as the usual proportion for the general death-rate is reversed. In England the mean annual general death-rate for the decennium 1872-81 was 22.4 male and 19.8 female deaths per 1,000 living of each sex. This difference is, perhaps, more readily appreciated by putting it in this way: out of equal numbers living of each sex there died 1,131 males to 1,000 females. How much of this increased vitality is due to greater temperance in alcohol and tobacco, more moderate diet, and less laborious work, it is impossible to say.

<sup>10</sup> *Lancet*, May 9th, 1885.

<sup>11</sup> The deaths from accident in the male are about balanced by the perperal deaths of the female.

**SMALL-POX IN MADRID.**—There is generally more or less small-pox in Madrid about this time of year. Just now, however, the disease is said to be assuming rather alarming proportions in St. Bernard's Asylum and in some districts of Madrid, and compulsory vaccination has actually been suggested, but this comparatively simple measure is considered to be too much of an interference with the liberty of the subject for our Spanish friends to endure. They would rather apparently have the small-pox. Some of the medical men have written to the *Medical Press*, describing the serious character of the epidemic; no deaths seem, however, to have been reported at present, though some of the cases in the Asylum are said to have been confluent.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### CUMBERLAND INFIRMARY, CARLISLE.

#### OVARIAN TUMOUR—PARALYSIS OF RIGHT ARM AND LEG—HEMIOPIA—BRONCHITIS AND PHLEBITIS—OVARIOTOMY—RISKS ENCOUNTERED ON TABLE—RUPTURE OF WOUND ON FOURTH NIGHT—PROTRU- SION OF BOWELS—SLOW GRANULATION OF WOUND—RECOVERY.

(Under the care of Dr. LEDIARD.)

Mrs. W. was sent into the Cumberland Infirmary on June 24th, 1885, by Dr. Sanderson, of Penrith; she came from Morland, was 43 years of age, married, and had four children, the youngest being six years old. The abdominal tumour had been noticed for one year. Suddenly, four months ago, she was paralysed in the right leg and arm; there was no loss of consciousness, the attack commencing with anæsthesia in the left hand, but it all came on in a few hours. She states that the face was unaffected. For eight months there had been hemiopia, affecting the left eye, the right remaining good.

On examination it was found that the tumour rose from the pelvis on the left side, was nearly centrally placed, and freely mobile; a sound introduced into the uterus showed that there was no connection with that organ, and no adhesion, whilst the peritonæum was free from fluid. During breathing, coils of distended gut were invariably noticed in the middle line, midway between the pit of the stomach and the navel; these coils always moved up and down, and seemed to point to some omental or intestinal adhesion to the tumour. I will explain subsequently to what this symptom was due.

A needle of fair size attached to an aspirator was used to the tumour, but the result seemed to point to the mass being solid.

The patient was very thin, was unable to raise the right arm to the mouth, although able to walk slowly.

The pupils were unequal, and the appearances in the fundus of the left eye were strongly suggestive of some antecedent embolism of the central artery, resulting in the hemiopia complained of. The left radial artery was felt with difficulty, whereas the right radial, although very feeble and rapid, was easily distinguished. The pulmonary state was one of considerable doubt and anxiety, for there was more or less constant cough and expectoration. At one time dulness at the left base and a suspicion of fluid was present; occasionally there were curious attacks of dyspnoea lasting some hours, pointing to embolism. The patient was obliged to keep her bed for the most part, and the temperature was variable.

There was no cardiac murmur heard, but the heart's action was very feeble.

After keeping Mrs. W. under observation for two months, and after an attack of phlebitis affecting the left lower extremity, a consultation was held. The nature of the tumour was one doubtful point, and the general condition was such as to render operative interference probably disastrous. In two months no fixation of the tumour had occurred, and very little increase in size, whilst the peritonæum was still free

from fluid. The tumour was probably not of malignant origin. It was decided to explore the abdomen and remove the tumour if possible.

*Operation.*—Chloroform was considered "*hors de lieu*" on account of the heart, whilst ether seemed equally objectionable from the bronchial trouble. That the patient nearly died on the table under ether was not surprising to me, but the amount of bronchial mucus churned up was the cause of this; twice all operative manipulation was arrested, in order to restore the respiration and blackened visage, whilst the pulse, feeble at the commencement, was thought to have ceased beating. As rapidly as possible the tumour was tapped and found semi-solid, the hand was then gradually thrust into the mass, and cyst after cyst broken down with the fingers and their contents evacuated, until the remaining portion was sufficiently reduced to enable the enveloping cyst to be withdrawn. The pedicle was ligatured with silk and dropped into the abdomen.

The incision of three to four inches in length was now sewn up with some dozen catgut sutures, both deep and superficial.

The tumour proved to be an ordinary multilocular semi-solid growth, which was absolutely non-adherent and gave no trouble whatever to remove. The appearance of the distended coils of gut, before mentioned, was due to great laxity of the abdominal wall in the middle line, which admitted of the abdominal contents lying next to the subcutaneous cellular tissue.

The patient rallied well enough, but for a few days her cough was not only extra troublesome, but she had occasional vomiting.

Upon the fourth night the house surgeon was called to find that during coughing all stitches had given way, and that a large protrusion of bowel had occurred, causing great collapse. Silk sutures were re-applied, and the dressing, which had been strictly Listerian, was readjusted. Notwithstanding this drawback, the patient held on, coughing night and day, but taking all nourishment given.

The wound again caused fresh trouble, for, although the peritonæum united and shut off the abdominal cavity, yet no union of muscle and skin ensued, and granulation slowly went on. The patient was reduced more than ever; it would be impossible to achieve success under greater disadvantages, except disadvantages connected with operative detail.

Subsequently the progress of the case was more or less even, the temperature fluctuated, but never rose above 101°, whilst the abdomen kept free from pain and distension.

The right arm became more powerless, but not from further brain mischief, but from increased muscular weakness.

The patient was lifted to a couch with an unhealed wound at the end of a month, but even then a return of strength seemed as far off as ever, and on the 17th of September a large amount of pus welled up from the lower end of the wound; and a long drainage tube was now inserted with an idea that the source of the pus was not far from the pedicle. This tube was shortened from time to time, until it was pushed out of the wound on October 14th, whilst the long expected improvement began.

*Remarks.*—The record of this case, given without any varnish, will be read with interest by those who may have had unpromising patients of a like nature to deal with, whilst to myself the lessons are many. That the dangers were not overlooked, there is ample evidence to show, and my feelings of gratitude to those who had the immediate charge of Mrs. W. prior and subsequent to operation are not wanting. I wish to lay stress upon the opening up of the wound on the fourth day;

this accident caused the patient intense alarm, and even after the sutures were put in afresh she could not be reassured that the disaster would not be repeated. It is to be recollected that in this instance the dressings were Listerian, and that the sutures had not been touched or even once removed; yet catgut was found unable to bear the strain of coughing. I trust that surgeons in the country, who are undertaking ovariotomy as readily as they would a herniotomy, will bear this case in mind.

Fishing gut or silk suture will hold where catgut will not. I have sewn up with all three materials, but this is not the first time that I have found catgut untrustworthy.

That the accident is necessarily fatal, no one with any experience will declare, and, if all the cases in which it happened were recorded, in many it would be found that recovery was scarcely retarded. Too early removal of stitches would invite the catastrophe, but with stitches untouched I am taught that there may be danger in using catgut.

I must conclude my remarks without alluding to the origin of the emboli, but the hope that Mrs. W. will be in some unexplained manner less liable to recurrence of them without her tumour than with it is not perhaps unreasonable.

Mrs. W. began to stand on October 23rd, to walk on October 26th, and went home November 21st. This will indicate her general condition better than any description.

## APPOINTMENTS FOR THE WEEK.

*Friday, November 27 (this day).*

CLINICAL SOCIETY, 8.30 p.m.—Mr. Barwell, "A Case of Gastrostomy"; Mr. Dent, "A Case of Gastrostomy"; Mr. John Morgan, "A Case of Gastrostomy"; Mr. Golding Bird, "Jejunostomy in Cases of Cancer of Pylorus." Living specimens: Dr. Felix Semon, "A Case of Congenital Malformations (Web between Vocal Cords, and Coloboma of Eyelid); Dr. C. R. Walker, "A Case of Myxœdema"; Dr. T. D. Savill, "A Case of Myxœdema."

*Monday, November 30.*

MEDICAL SOCIETY, 8.30 p.m.—Dr. Stephen Mackenzie, "On Ulcer of the Stomach"; Mr. A. Boyce Barrow, "On the Treatment of Varicocele."

*Tuesday, December 1.*

PATHOLOGICAL SOCIETY, 8.30 p.m.—Dr. Gulliver, "Stricture of Small Intestine, and Hæmorrhage into Adrenals"; Mr. D'Arcy Power, "Two Cases of Osteitis Deformans"; Dr. Norman Moore, "New Growths in the Heart and Viscera"; Dr. Carrington, "Malignant Disease of Thyroid Body"; Mr. Arbuthnot Lane, "Pressure Changes in the Joints and Extremities"; Mr. Hutchinson, jun., "Subperitonæal Lipoma"; Mr. Stonham, "Two Specimens of Lipoma of the Spermatic Cord"; Dr. Haig, "Aneurysm in Wall of Left Ventricle"; Dr. Hadden, "Two Cases of Joint Affection in Locomotor Ataxy"; Dr. Silcock, "Syphilitic Ulcerative Tracheitis"; Mr. Shattock, "Perforation of the Palate [by Hypertrophied Upper Incisor in the Rat] (Card); Mr. Fenwick, "Ulceration of the Bladder after Fracture of the Spine" (Card); Mr. Battle, "Portions of Thumb, with Vessel and Nerves, amputated by String" (Card); Mr. Battle (for Mr. Croft), "Bullet flattened by Frontal Bone"; Mr. Bruce Clarke, "Early Puberty" (Living).

*Wednesday, December 2.*

OBSTETRICAL SOCIETY OF LONDON, 8 p.m.—Specimens will be shown by Dr. Lewers and others. Papers: Dr. Arnold W. Thomson, "A Case of Protracted Pregnancy"; Drs. Matthews Duncan and Thin, "On the Inflammations and the Histology of Lupus of the Pudendum"; Dr. H. Roxburgh Fuller, "A Case of Spurious Labour."

*Friday, December 4.*

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, 8 p.m.—Mr. H. Percy Dunn, "Sae and Adjaent Parts of a Large Omental Hernia," "Pendulous Growths from Mucous Membrane of Stomach," "Tubercular Disease of Testes," "Tubercular Disease of Kidney"; Mr. C. B. Keetley, "Osteotomy of Hip," "Case of Complete Obliteration of One Nostril by Syphilis (Congenital)," "Case of Removal of whole of Lower Lip for Epithelioma"; Mr. Leonard Mark, "Drawing of above Case before Operation"; Mr. J. R. Lunn, "Drawing of a Case of Epithelioma of Lip." Papers: Mr. Dunn, for Surgeon Harold Hardley, I.M.S., "Some Cases of Interest from the late War in the Soudan"; Mr. C. B. Keetley, "Antiseptic Surgery at the West London Hospital"; Dr. Sinclair Thomson, "Suez as a Health Resort, with Notes by the Way."

## Medical Times and Gazette.

SATURDAY, NOVEMBER 23, 1885.

THE General Medical Council concluded their session on Saturday last, having, probably to the surprise of all of them, managed to spin out their business for five days. The results, so far as the three points for which they were summoned are concerned, may be soon told. Two decisions arrived at during the last session have been under consideration: one of them has been reversed, the other tacitly evaded; in both these respects the action of the Executive Committee has been practically confirmed, notwithstanding the indignation which many members displayed at this body's daring to override the decisions of the General Council. So that, as far as these two points are concerned, the sitting was altogether superfluous, as matters would have remained precisely as they are now, in consequence of the action of the Executive Committee, until next session. The other reason for having an extra meeting at this time was in order to bring the Black List up to date. In this respect the session has been of real benefit; not only have those offenders who deserved it been removed from the register in time to disappear from next year's volume, but, thanks to Mr. Collins, the names of those whose offences have been condoned, and who have been restored to the Register, have been wiped off the Black List; and further, the names of those who are known to be dead are to be removed. Thus a grievous wrong which has been done to the memory of a deceased man will be remedied; for a few sessions ago a practitioner who had been removed from the Register for

felony contrived to get himself re-registered under the name of another person who had died in the Colonies; the fraud having been found out, the assumed name was ordered to be removed from the Register, but, as it was entered in the Black List, it has ever since been made to appear that a man who had never been guilty of any offence whatever had been struck off the Register—a great hardship on his relatives, if, indeed, the publication of the name was not absolutely libellous. A great part of the last two days was occupied with the question whether the examination in Surgery, which the Apothecaries' Society, in their endeavours to conform to the wishes of the Council, have instituted, gives a legal qualification to practise surgery; this is so obviously a question for the lawyers that we can hardly understand how the Council ever came to discuss it. There is nothing in the Medical Act which gives them the slightest authority to decide such a matter, and, although the debate was introduced in an admirable speech, quite the best of the session, by Dr. Heron Watson, and drew from Mr. Simon a bit of very fine special pleading, we regret to say the whole discussion was sheer waste of time.

Two interesting papers were read and discussed at the Royal Medical and Chirurgical Society on Tuesday last. The first, by Mr. Barker, on the Distribution of the Bacillus Anthracis in the Human Skin in Cases of Malignant Pustule, was intended to show the value of local treatment by excision or cauterisation, or both, and to explain this on the ground that the bacilli displayed a remarkable predisposition for the more superficial parts of the skin, and that they only penetrated to the deeper parts slowly and in small numbers. Mr. Davies-Colley, while admitting the general accuracy of these observations, pointed out that in some cases there were no external signs of the disease, and that the chief lesions occupied either the lungs or the intestines. He inclined to think that the severity of malignant pustule depended on some special qualities of the bacillus originally infected, and that the secondary colonies derived from these were less active and less dangerous. The second was by Dr. John Harley. He read a carefully prepared paper on a case, recently under his care in St. Thomas's Hospital, of what he called "Acute Tubercle of the Liver," agreeing completely with the so-called "Actinomycosis." In fact, this case had already been described as one of the latter disease. Dr. Harley's arguments were well sustained; and, even if they failed to convince the "organised opposition" which was directed against them by some of our rising younger pathologists, it must be admitted that they were of such a nature as will necessitate a renewed study of the disputed facts. Neither party had a complete case, and each admitted a resemblance in some points, more or less, the one to tubercle, the other to actinomycosis. We can only hope that ultimate victory may be on the side of scientific truth.

At the Medical Society on Monday evening last, Mr. Gould read notes of three cases of malignant

disease arising in connection with traumatism, and then raised a discussion on the supposed relation between the two. He quoted from current literature similar cases which had been recorded, and the views held by the various authors of these cases. Was there a tumour diathesis, and did the injury simply serve to wake up latent potentialities dependent on this diathesis, or was the injury *per se* the cause and origin of the malignant growth? Mr. Gould rather favoured the latter view. Mr. Harrison Cripps commented on the subject, expressing his own conviction that malignancy was an accidental condition due to the presence of organisms in the blood or juices of the body. So long as these remained within their proper channels, no harm came, but when, as the result of injury, these juices were extravasated, at first a local and then a general malignant infection resulted. Mr. Lawson supported Mr. Gould's views; there could be no sort of doubt that injuries constantly gave rise to malignant growths, both sarcomatous and epithelial, Mr. Barwell propounded his known views on "traumatic malignancy." Mr. Parker believed in a constitutional tendency, and thought the accident merely precipitated events; patients seldom died of the local manifestations, but of the secondary deposits, which took place quite apart from the injury. Mr. Sutton showed that there existed among animals a similar tendency to develop malignant disease after injury, and in parts most liable to injury.

THE first ordinary meeting of the Society of Medical Officers of Health was one of no little interest. Dr. Heron read a paper, an abstract of which will appear in our usual reports on the cholera bacillus, and others resembling it in form. He exhibited not only specimens of Koch's, Finkler's, Miller's, and Flügge's under the microscope, but a number of tubes containing pure cultivations of Koch's, Finkler's, and Flügge's bacilli, showing their characteristic differences, which he maintained were so marked and so constant as to absolutely establish their specific difference, and to afford a means of distinguishing mild cases of cholera from severe diarrhoea, in which Finckler's form only is found.

AT the last meeting of the Council of the College of Surgeons (as will be seen elsewhere in our columns) the terms of the advertisement conveying a general meeting of the Fellows and Members on the 17th proximo, and the object of the meeting, were agreed upon, viz., "to receive a statement from the Council in reference to the resolutions carried at the meeting of Fellows and Members on October 29th ult. The meeting cannot, therefore, in any sense be regarded as a continuation of the discussion of the resolutions submitted at the former meeting; speakers will do well to bear this fact in mind, for by the rules of the College, not less than of the usage which obtains at all public meetings, no other subject than that before the meeting can be discussed. We would commend to all who may contemplate being present at this meeting the remarks we made on the subject in our last issue.

THE sixth session of the Edinburgh Health Society was inaugurated a few days ago by an introductory

address from Dr. Byrom Bramwell on the causes and prevention of disease. Dr. Bramwell duly impressed on his hearers the absolute importance of the correction of sanitary defects, both as regards the individual and the community at large. The avoidance of some of the more important exciting causes of disease by a careful attention to personal clothing was duly insisted upon, nor did he omit to lay proper stress upon the vital necessity of precaution against the spread of infectious diseases. Edinburgh is undoubtedly one of the healthiest cities in the United Kingdom, and the interest displayed by the public in these lectures in great measure serves to explain this fact.

It is a matter of great satisfaction to the friends of Professor MacLagan, of Edinburgh, that he seems to have almost entirely recovered from the ill-health under which he laboured during the summer session. We understand that a considerable number of men have taken advantage of his recently completed laboratory for the study and teaching of matters relating to public health. The institution of this laboratory provides for a want much felt by men studying for Health appointments.

OUR Paris correspondent writes:—An action for manslaughter has been brought against the celebrated dentist, M. Duchesne, for having caused the death of one of his patients by the inhalation of nitrous oxide. The patient was a gentleman of fifty, who came to have a tooth drawn. He was anæsthetized by M. Duchesne himself, but without the assistance of a doctor; the tooth was drawn without difficulty, and the whole scarcely lasted ten minutes, but the patient never revived, and in all probability he was dead before the tooth was drawn. M. Duchesne is prosecuted for having used an anæsthetic without the assistance of a legally qualified practitioner. A physician, Dr. Rivet, was usually in attendance, but on this occasion he was absent. M. Duchesne states that patients are usually accompanied by their family physician, but in this case the family doctor declares that, had he been consulted, he would have opposed the operation, as he considered his patient to be labouring under disease of the heart. There was, however, no evidence of this at the *post-mortem*. The verdict has not yet issued, but the scientific interest of the case resides in the fact that nitrous oxide, so freely used as an anæsthetic by many surgeons and by nearly all dentists, is quite as dangerous as chloroform, and ought never to be administered without proper precautions and a preliminary examination into the state of health of the subject.

M. PASTEUR still pursues the course of his experiments, and nearly 70 persons bitten by mad dogs have been inoculated at his laboratory. There has been some talk of creating a "clinique" for M. Pasteur and his rabid patients. The proposal, however, has been hitherto non-suited upon the ground that the celebrated bacteriologist is not a medical man, and, holding no diploma, has no legal right to practise. It might also be said that, before lending the weight of official authority to the system of inoculating hydrophobia, it might be as well to let the matter be well

tested, the proposition in itself being at least rather startling, to say nothing more. At all events, the friends of "progress," who are always ready to cry loudly against persecution, cannot in the present instance inveigh against Government, which has certainly allowed more liberty to M. Pasteur for the prosecution of his experiments than he would have found on this side of the Channel.

THE *Gazette Hebdomadaire* states that, since M. Pasteur's announcement, the prophylaxis of hydrophobia has occupied the attention of all Paris, in the press, the societies, and the salons, the impressions varying from enthusiasm to scepticism. Fortunately the most prudent and the wisest of all who occupy themselves with M. Pasteur's investigations is M. Pasteur himself, as shown by his statement of his views before the Conseil d'Hygiène. In possession of a method which at all events has been very successful among animals, he has believed himself authorised to extend its application to man, but he is the first to admit that time must be given to form a final judgment upon the matter. In the meantime, patients are arriving from all parts, including Algeria; and, in spite of the length of time that may have elapsed since the bite, M. Pasteur undertakes the cases, in the hope that the inoculation may be still effective five or six weeks, and perhaps longer, after the accident. Experience can alone decide this point. In the meantime there is a sufficiency of virus in the laboratory, and this is kept up by daily inoculations; but if the present eagerness continues a special institution will become indispensable.

SIR WILLIAM GULL has recorded the following supplementary note, to prevent any possible misconception of the purport of his remarks in the Transactions of the India Office Cholera Committee, upon which we commented last week—"It appears to be abundantly proved that cholera is not an infectious or contagious disease. The soil and other local conditions of the place in which it prevails are responsible for it, and not the sick who suffer and die of it. It is by sanitary measures, and not by isolation of the sick, that its occurrence and spread can be prevented."

MEDICAL baronetcies and knighthoods are as sour grapes to many members of the profession, possibly because they have sometimes fallen into unworthy mouths. Few, however, will fail to be gratified at the honour which has been bestowed by the State on Dr. Sawyer of Birmingham. Dr. Sawyer has never laid himself out, as many do, for titular reward. His reputation has been won solely by steady and conscientious work on behalf of his hospital, his school, and his town, and the bestowal of a knighthood upon him is a happy recognition of the claim of the medical profession in our growing provincial towns to a share of the honours hitherto mainly confined to practitioners in London, Edinburgh, and Dublin. Sir Peter Eade and Sir James Sawyer should be the forerunners of a long line of provincial medical knights.

The death-rate in London for last week shows a slight further rise, but is still considerably below the

average of previous years. Under the head of zymotic diseases 160 deaths were recorded, exactly the same number as that given in the returns for the preceding week. Of these, measles and whooping cough were by far the most numerous, 44 and 42 deaths respectively having occurred from these maladies. Enteric fever caused 24 and diphtheria 20 deaths, whilst scarlet fever is only credited with 11 victims. There were

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past ten weeks.

but 2 deaths from small-pox, and only 74 patients remaining under treatment at the end of the week in the Metropolitan Asylum Hospitals. The deaths of 9 women were registered as resulting from puerperal fever. A further rise in the deaths from diseases affecting the respiratory system brought the total up to 454. The most striking feature in the weekly return, however, is the statement that the denizens of the metropolis enjoyed 23.2 hours of sunshine, a marked contrast to the 0.0 recorded in the preceding week.

THE Scottish Registrar General's return for the third quarter, which has recently come to hand, gives the total death-rate for the quarter as 16.2, or 1.8 below the average for this particular quarter, in this respect, therefore, closely approximating to the results recorded in England and Wales. In the different districts the death-rate varied between wide limits; thus in the principal town districts it was 18.4, in the large town districts 16.3, in the small town districts 15.8, in the insular rural districts 13.9, and in the mainland rural districts it was 13.6. Of the eight principal towns, Paisley heads the list with a death-rate of 23.3, Glasgow following close behind with 22.0, whilst Edinburgh and Aberdeen share the honours of lowest mortality with 13.8. Seeing that these eight towns contain about 32 per cent. of the whole population, it

is the usual practice to assume that the diseases prevalent in them prevail to a like extent throughout the rest of the country. We notice that the deaths from measles and whooping cough progressively declined as the quarter advanced, whilst those from scarlatina increased. The weather during August and September seems to have been unusually cold, which perhaps accounts for the large number of deaths from diseases of the respiratory organs that took place during those months.

At a recent meeting of the Society of Physicians of Vienna, Dr. Paltauf showed some microscopical specimens illustrating the pathology of swine-erysipelas. The specimens had been prepared from organs which he had received from Styria in 1882, and Dr. Paltauf had, in 1883, detected in the skin, lungs, and spleen, as well as in their capillaries, a considerable number of bacilli, as slender as tubercle bacilli, but somewhat shorter. As but little was known at the time of the affection in question, Pasteur being then the only investigator who had shown that the "mal rouge" had its specific organism, viz., the figure-of-eight microbe, and as Dr. Paltauf had no fresh material whereon to repeat his observations, he was unable to deduce any results of importance from his discovery. But the recent investigations of Löffler and Schütz, described in the Reports of the German Sanitary Board, and the observations made in the spring of the present year by Lydtin and Schottelius in connection with the protective inoculations in the Grand Duchy of Baden, showed that there were present in cases of swine-erysipelas bacilli subtiles which resembled those found in the septicæmia of mice, and which were to be regarded as the specific cause of the disease. These microbes had been submitted to pure cultivations, and swine, rabbits, pigeons, and mice had been successfully inoculated with them, guinea pigs and fowls proving "refractory." Löffler, however, in a case which appeared to be a typical one of swine-erysipelas, had discovered another variety of microbe, which behaved quite differently both on cultivation and inoculation. He proposed, therefore, that the disease caused by these bacilli should be termed swine-plague, or swine-septicæmia, in contradistinction to swine-erysipelas. Prof. Schottelius had proved that the "mal rouge" and the swine-erysipelas of Germany were the same disease, and the inoculation liquid of Pasteur had been shown to contain the same bacilli that had been described by Löffler and Schütz as characteristic of swine-erysipelas. Schütz, Schottelius, and Lydtin had all confirmed the success of the protective inoculations of Pasteur. Dr. Paltauf, therefore, as the result of his investigations in 1883, was able to recognize the Austrian epidemic as identical in nature with those of France and Germany. He strongly recommended experiments in protective inoculation in Austria, as the disease was very fatal in that country, as many as 1,500 animals having died of it in 1883 in the province of Carinthia alone.

At the meeting of the same Society on the 23rd October, Professor Kaposi showed a young girl affected with the rare disease, "Xeroderma pigmentosum," which he had been the first to describe in 1870. The

affection was characterised by the appearance towards the end of the first year of life or the beginning of the second, of brown patches, which might be mistaken for freckles, on the face, hands, and back. After a certain time these patches increased, and later on, in severe cases, the skin beneath them became atrophic, and ectatic vessels appeared in it. At a later stage, carcinomata, sarcomata, flat epitheliomata or papillomata developed, and at last the patient died. When he wrote about the disease in the "Medizinische Jahrbücher" for 1882, he had collected eight cases, and it was only since then that other physicians, as Geber, Taylor, Neisser, Pidal, &c., had published cases of it, so that it was evident that the disease had not before been diagnosed. The girl whom Professor Kaposi showed the Society was the sole sufferer out of a family of nine children. Her face presented pigmentations and several wart-like growths, which had been removed a year ago and had subsequently returned. Professor Kaposi added that these pigmentations did not always warrant one in believing that the case was of a dangerous nature; he knew many persons with such pigmentations, who presented no trace of carcinoma. A second case shown by Professor Kaposi was one of "Idiopathic Multiple Pigmentary Sarcoma." He had described this disease in 1870 as an affection which has to be distinguished from other malignant forms by the fact that it appeared from the very first on both hands and feet at once, and sometimes resembled syphilis and sometimes lepra tuberosa. Kaposi had since then observed 25 cases, and all agreed in their characters. On the parts above-mentioned there appeared infiltrations, and later on extravasations of blood, which resulted in pigmentation; at a later period nodules formed, which either disappeared entirely or left dark patches; the skin of the hands became thickened so that the fingers could not be flexed. The nodules sometimes appeared also only on one of the extremities or on the face, sometimes also in internal regions, as the lungs, the liver, and the spleen, and in this event they had the character of a cavernous tumour. Professor Kaposi proposed to treat the patient with arsenic.

THE subject of Cocaine Intoxication was introduced to the Berlin Medical Society at one of its last meetings by Dr. P. Heymann. It would appear that hitherto there have been but few instances noted, and in these the manifestations have been limited to giddiness and a peculiar feeling of weakness and loss of control over the lower limbs. In a few cases there have been hallucinations and even fits of maniacal excitement. The case which Dr. Heymann records (*Deutsche Medicinische Wochenschrift*, No. 46) was that of a boy suffering only from a small papillomatous growth in the larynx, which had recurred again and again after its removal, once under cocaine, in many sittings. The patient required the use of a very liberal application of the solution to the pharynx and larynx before anæsthesia could be produced. The little tumour was quickly removed, but not before the patient began to show signs of intoxication. On being placed on a sofa, he lay for five hours in an apathetic half-sleepy condition, with open eyes. He had no

hallucinations, or could recollect none, and when able to speak did so in a hesitating, but nevertheless intelligent, manner. There was considerable difficulty in walking, the gait being very uncertain. He did not complain of hunger or of any special pain, only of general feelings of discomfort. The pupils were not dilated, but reacted normally to light. Pulse, temperature, and respiration appear to have been all slightly increased, but both the heart and lung movements were otherwise normal and regular. At a rather later stage the difficulty of walking was increased, owing to an apparent inability to control the movements of the legs. The symptoms did not pass off until ten hours after their onset, the patient then for the first time obtaining sleep, from which he awoke but little the worse, apparently, for his experiences of the previous day.

UNCONSCIOUS guile is touching, even when met with in our own ranks. A recent instance was recently brought before the Société de Chirurgie of Paris by a surgeon who wished to prove that antiseptic precautions afford no safeguard against the occurrence of erysipelas. He stated that thirteen cases of this disease had been under his treatment during the year, of which five had developed within the wards, and six had been brought in (two remaining without explanation). This candid avowal is very striking, but a different deduction might possibly be drawn.

It is announced that Dr. B. W. Richardson will deliver a course of Cantor Lectures at the Society of Arts in May next on "Animal Mechanics." Dr. Meymott Tidy will shortly give a lecture at the same institution on "The Treatment of Sewage." The opening lecture of the first series of the Cantor Lectures was given on Monday by Mr. J. Mayall on "The Microscope." The portion of the subject treated of was the early history of the microscope, and much interest was added to the account given by there being a collection of some 200 old microscopes shown. This collection will remain for inspection till next week, while in the library will be found a collection of modern instruments. No such opportunity of studying the history of the microscope has been offered before.

As far as the elections have yet gone, only two members of the new Parliament can be claimed by the medical profession, viz., Sir Guyer Hunter, whose election for Central Hackney will cause wide satisfaction, and Mr. Vanderbyl, the new Liberal member for Portsmouth. Sir Guyer Hunter brings to the House of Commons a special knowledge, and an administrative ability, and an energy which will be extremely valuable. Men with experience of India always hold a peculiar position of authority in the House, but when to that experience is added, as in Sir Guyer Hunter's case, a sound knowledge of medical and sanitary science, the collocation becomes unique.—Sir Guyer Hunter, who is a K.C.M.G., received his medical education at Charing Cross Hospital. He entered the Indian Medical Service, Bombay Presidency, in 1850, and served throughout the Burmese War and the Indian Mutiny. In 1876 Sir Guyer

Hunter was appointed Principal of the Grant Medical College, and in 1879 Vice-Chancellor of the University of Bombay. He retired in 1880, and on the outbreak of cholera in Egypt was despatched by the Government on a special mission to that country, the incidents of which will still be in the memory of our readers. Mr. Philip Vanderbyl, the member for Portsmouth, was born at the Cape in 1827. He was educated at the Edinburgh University, where he graduated with honours in medicine and obtained a gold medal. He subsequently became a member of both the Royal College of Physicians and the Royal College of Surgeons. He has been President of the Royal Medical Society of Edinburgh, and was subsequently a lecturer on anatomy and histology at the Middlesex Hospital. He retired from practice in 1858, and is now an Australian merchant and banker, and a director of the East and West India Dock Company. We hope that by next week this list will be considerably increased. Besides the well-known candidatures of Mr. Erichsen, Mr. Ernest Hart, Dr. Alfred Carpenter, and Dr. Herbert Watney, the medical candidates include Dr. Balthazar Foster (Cheshire), Dr. Danford Thomas (West Islington), Dr. P. Royle (South Manchester), and Dr. Macdonald (Ross and Cromarty), and Dr. Finlay, Q.C. (Inverness Burghs); though the last two have forsaken medicine for the law. If a fair proportion of these candidates are returned, and the old medical M.P.'s re-elected, we ought to have a compact little phalanx in the Lower House which will have much weight in medical and sanitary affairs.

WE learn from our Bombay Correspondent that much disappointment and discontent are felt in the Indian Medical Service at the manner in which its members have been neglected in the distribution of State honours after the recent Soudan campaign. No department of the public service which took part in that miserable *fiasco* did their work better than the Indian Medicals, and yet only one of them is mentioned in the *Gazette*, and he the principal medical officer, whom not to have mentioned would have amounted to little short of insult to the service; so that the profession view the mention of his name and the trifling honour awarded him as merely perfunctory. It was anticipated that this injustice would have been remedied in a supplementary *Gazette*, but nothing of the sort has appeared. The services of members of the sister service have been recognised, for no fewer than 29 of them have been either decorated as Companions of the Order of the Bath, promoted, or otherwise rewarded. It has been publicly reported that, without the assistance of the Indian Medical Service, British troops could never have taken the field in the way they did. Surgeon-Major Boustead (of the Bombay Establishment), who was present, lent the British Medical Department 50 odd dholies and 250 men fully equipped, in order to enable the Army Medical Officers to go into the action of Hasheen, their own transport for the sick and wounded, &c., not having arrived in time. Further, there were five times as many wounded amongst

native troops as British troops after each engagement, at Hasheen and Tamai. What is the excuse, then, for the invidious distinction between the two services? Are Indian medical officers inferior in professional skill, qualifications, and status to their brethren in the Army Medical Department? There were four very senior medical officers who accompanied the Indian contingent, and all did their work, arduous and trying as it was, to the entire satisfaction of the authorities. Yet not one of them has been even named in the *Gazette*. Contrast this with the way in which rewards have been showered on the sister service. Several junior members of the British Medical Service have been promoted from Surgeons to Surgeons-Major, while many Surgeons-Major have been raised to Brigade-Surgeons. If such distinctions are to be drawn, the Government would do well to proclaim the fact, which would enable intending candidates to know beforehand what sort of treatment they may expect.

### THE BOWMAN LECTURE.

DR. HUGHLINGS JACKSON has once more taken occasion to bring his favourite subject, the philosophy of epilepsy, before the profession: for this, in truth, is the gist of the profound and suggestive lecture which is entitled "Ophthalmology and Diseases of the Nervous System." In reading this lecture with its manifold illustrations and the evidences of minute observation which it contains, all who are sufficiently acquainted with Spencer's thinking to understand the value of its application to the higher neurology must earnestly desire to see the whole of Dr. Jackson's work in a less fragmentary form than it has hitherto assumed. It is nothing less than deplorable that the results of all the thought and observation which Dr. Jackson has given to this subject, in such measure as to entitle him to be regarded, by the medical mind at least, as the promulgator of a new philosophy, should be discoverable to the student only in the back numbers of periodicals and dissipated or buried in not very attainable volumes. Interesting and important as are the many clinical points that Dr. Jackson raises in this lecture, and deserving of the closest study, we think that we may be doing better service to the profession by emphasising here the statement we have just made, than by attempting a criticism or even a *résumé* of the material before us which was printed at length in our last issue. It cannot be denied that this lecture, or, indeed, almost any lecture by Dr. Jackson, is intimately dependent on his previous utterances; nor that every reader who is to profit by anything fresh that Dr. Jackson has to say must first have possessed himself of a neurological "Grammar of Assent" as an introduction to the higher teaching set before him from time to time. There are doubtless very many who desire to understand, for instance, among other points, the theory of Epilepsy as put forward and periodically amplified by Dr. Jackson; and it is equally certain that many have lost the key and consequently fail to solve the difficulties which present themselves in the highly condensed papers and sketchy lectures of the author. We do not urge

that the neurological subjects which Dr. Jackson deals with should be treated in such a manner that he who runs may read; they will always, from their intrinsically complex character, require close study. But they are of sufficient scientific and practical importance, and quite intelligible enough in themselves, to make it very desirable that the intelligent medical man shall be able to inform himself of Dr. Jackson's views without having necessary recourse to the several libraries where Spencer's books and Dr. Jackson's papers may be rather laboriously found. To the scientific neurologist wholly devoted to his work Dr. Jackson's teaching is of course well known throughout the world; but we would plead for others who would certainly be benefited could the result of this teaching become more common property than it now is. We will not say that Dr. Jackson's writing needs a commentator; but this much we would urge that the medical world would be the wiser were every line of this writing a paragraph, every paragraph a page, every page an essay, and every essay a book. This, with a greater attention to consecutive arrangement, and possibly a little more sympathy with what is called average intellect, would not only make Dr. Jackson's finished work one of the most valuable treatises on scientific neurology in existence, but would also gain for him the sincere recognition of many practical physicians and earnest students.

---

### THE MOVEMENT OF OUR STUDENT POPULATION.

In his periodical reports the Registrar-General used to sum up some of his most interesting statistics under the head of "Movement of the Population." In the elaborate report which Mr. Marshall presented to the Medical Council last week, as Chairman of their Statistical Committee, we have similar statistics with regard to our young medical population. What exact practical lessons the Council hope to derive from these laborious investigations, and whether they will prove worth the time, thought, and money spent upon them, are questions which we do now feel called upon to consider. It is evident, however, that, if the enquiry were worth making at all, it was worth making in a thorough and scientific manner, and it cannot be denied that, with the enthusiastic co-operation of the Registrar, Mr. Miller, assisted by an expert statist and skilled clerks, selected and instructed by himself, the Committee have been able to present to the profession a most complete and interesting summary of the careers of the students whose names appear in the Students' Register of 1871, and an equally interesting, though necessarily less complete, account of the careers of the students who joined the profession in the decennium 1871-1880. Everything has been done to render the report easily intelligible, the charts which are appended to it enabling the reader to grasp at a glance the main results of the enquiry. The object of the enquiry was to discover (1) the period of professional study occupied by the students of each year; (2) the proportion of students who took a double, two single, and one single qualification re-

spectively ; (3) the interval allowed to elapse by the second class of students between taking their first and their second qualification, and the source of such qualifications ; (4) statistics as to the place of registration as students and the place of registration as practitioners, and (5) statistics as to the source of the respective diplomas and the place of final registration. In addition to these points the enquiry gives us the means of answering several important and interesting questions—such, for example, as relate to the supply and waste of the student element in the profession ; the supply and waste of the registered practitioners ; the destination of the singly and of the doubly qualified ; the migration, distribution, and settlement of the several kinds of medical practitioners ; their increasing or decreasing ratio to the population in various districts, and in urban and rural localities, &c.

We can only here deal with a few of the results arrived at by the enquiry, the most salient of which may be thus summarized—(1) great waste of student life ; (2) gradual increase in the period of medical study ; (3) increased prosperity of the Scottish and Provincial Schools as compared with those of London ; (4) extensive immigration to England of Scottish and Irish licentiates ; (5) excessive proportion of English students taking Scottish diplomas ; (6) great increase of late years in the proportion of students commencing their medical studies as pupils of private practitioners. Of the 1,253 students who appeared on the Students' Register of 1871, at least 30 per cent. have failed to qualify, while 8·78 per cent. have taken only a single diploma, which, in nearly half the cases, was the Membership of the English College of Surgeons. It would be interesting to learn something of the 376 students who never became practitioners. How many were of weak health? how many of weak brains? how many forsook medicine for more attractive careers, and how many were driven from it into less exacting ones? But for the answers to such enquiries we must go rather to the Deans of the medical schools than to Mr. Miller. The figures, however, show an appalling waste of life, and should make one hesitate in recommending a young man to brave a struggle from which only two out of every three emerge victorious. It is somewhat satisfactory to find that the proportion of unsuccessful students was less in England than in either Scotland or Ireland. But in the case of the singly licensed the position of affairs is reversed, the proportion of English students who seek or obtain only this qualified amount of success being much larger than that of either Scottish or Irish students who content themselves with an incomplete diploma. As to the time of medical study before qualification, we find that in the case of the singly qualified it was 5·04 years, and in the case of the doubly qualified 4·767 years. Of the diplomas registered by the students of 1871, nearly 40 per cent. were conferred by the English College of Surgeons, over 22 per cent. by the Edinburgh College of Physicians, and nearly 18 per cent. by the London Apothecaries' Hall. The London University comes, as might be expected, nearly at the bottom of

the list with a percentage of 1·48, or exactly the same as the Dublin Apothecaries' Hall. The table from which we take these figures contains some very startling intelligence as to the number of English and Irish students who qualify in Scotland. The Edinburgh College of Physicians, for instance, gave its diploma to nearly three times as many English and Irish students combined, as to students of its own country. As many as ninety-two, or over 16 per cent. of English students, took its diploma ; while no fewer than 160 English and 111 Irish students took one or other Scottish qualification. In spite of the indignant protests, invariably made by Scottish members of the General Medical Council when this extreme favour of their corporations to the students of other countries is pointed out to them, we cannot help saying that these figures, above quoted, show a scandalous disregard on the part of those corporations for the efforts made by the English licensing bodies to keep up the pass standard. The same success, though possibly a success which justifies greater pride, in tempting the English student over the border, is seen in the table which gives the proportion of practitioners who registered at the different branch offices. As many as 508 of the successful students of 1871 registered themselves as practitioners in England, whereas only 409 had registered as English students. In the case of Scotland and Ireland the proportion is reversed, 237 and 231 of the successful students having registered as Scottish and Irish students respectively, while only 187 and 182 registered themselves respectively as Scottish and Irish practitioners. These figures show what a large proportion of doctors practising in England have either been born or licensed in one of the sister kingdoms.

The facts given in the Report concerning the great increase in the numbers of Scottish and Provincial students, and the very slight increase in the number of London students, are only too well known, but they are brought out with especial clearness by means of charts showing the curves of variation from 1871 to 1880. Between those years the total annual entry in the three kingdoms increased from 1253 to 2106, and the curve representing this increase in the chart makes an angle of over 45° with the horizon. The curves representing the Scottish and Irish increase are close together and absolutely parallel, forming a gradient of 2 in 9. The English curve forms a gradient of double that incline, but when we break it up into constituent curves, representing respectively the provincial and the metropolitan increase, we see that the former has a gradient of 3½ in 9, while the gradient of the latter is only a little over 1 in 9. In other words, in the ten years under consideration the annual entry of provincial students increased from 175 to 520, while that of London students only increased from 388 to 476. A great deal of this increase is, no doubt, apparent rather than real, for with the year 1877 there seemed to set in a return to the old fashion of pupilage, and many of the students thus credited to the provinces have, no doubt, received the essential portion of their education at some London hospital. This change in the manner in which a considerable proportion of our

English students commence their acquaintance with medicine is one of the most striking facts brought out in the report. It is a change which is also seen, though to a much slighter extent, in the case of Irish students, but not at all in the case of the students of Scotland, of whom all but about one per annum register themselves as commencing their studies at an established medical school. In England, between the years 1871 and 1876, only about 50 students a year were registered as receiving their earliest medical training away from a recognised school or hospital. In 1877 this number increased to 75 and in the following year to 169, while in 1879 and 1880 as many as 280 and 262 students respectively were registered under the heading "other places of study and pupilage." Whether this change is a change for the better, is a very open question, but it is evidently due to a reaction against the excessively scientific training now given at the recognised schools, and perhaps to the discovery that many of the practitioners turned out by those institutions have but a very slight practical acquaintance with the art which they have chosen to practise. The few points which we have picked out for comment from Mr. Marshall's report will serve to show the great interest it presents to all who are concerned in medical education, but we are still doubtful whether the Medical Council are justified in spending their revenues on enquiries the practical usefulness of which is, to say the least, problematical.

## REVIEWS AND NOTICES OF BOOKS.

### AN EDINBURGH PROFESSOR.<sup>1</sup>

IN reading an old man's reminiscences of the celebrities of his youth, it is always somewhat difficult to distinguish the *Wahrheit* from the *Dichtung*, in other words, to know what correction, if any, to make for errors in refraction. The "self-esteem of generation"—that special form of egoism which is loath to concede to other generations any special pre-eminence in character, ability, beauty, grace, or virtue—would persuade us that the necessary correction is often very considerable—considerable in direct proportion to the degree of excellence claimed for our dead rivals. According to this view the excellence is often rather in the biographer than in his models. He has read into them, and reproduced for us traits which we, if we had lived at that time, should never have recognised, just as bygone portrait painters show us men and women, the like of whom we have never the good fortune to meet with in this commonplace age. (The same reasons, to quote a modern instance, will perhaps account for Mr. Randolph Caldecott's always finding himself among people worth drawing.) It is not impossible that fifty years hence some aged romancer may throw the glamour of his imagination over the most ordinary of our present contemporaries and get them credit for finer character and wit than we know them to possess. For, be it noted, it is mainly in respect of those qualities that distance lends enchantment, the actual talent of the men with whom we are concerned being more exactly assessable from what they have left behind them. We can tell from a man's

writings and discoveries what ability he had; but of his finer shades of character, and of his immediate influence on other men, only tradition, and often a lying tradition, tells us. Yet, let our conceit make what deductions and qualifications it may, it is not to be denied that the men described in the book before us, and still more flatteringly portrayed in other volumes dealing with the same place and period—Edinburgh in 1820–50—were remarkable for a vitality and force of character not common in the men of to-day. The Edinburgh school is not now deficient in teachers of power and ability, but even they would probably admit that, in everything that goes to make men memorable, they are far outshone by the rich array of teachers and practitioners who flourished in the early part of the century. Gregory, Abercrombie, Alison, the Hamiltons and John Barclay; Leslie, Playfair, Pillans, John Wilson; Syme, Liston, Fergusson, Lizars, the Bells, Simpson, Goodsir, John Brown, and Christison himself, formed a series of remarkable personalities, who would have made any centre of learning famous, and whose appearance in a small city within the short space of half a century constitutes one of those freaks by which Nature shows what she can do when circumstances allow her. But, as we have said before, it is not so much in the matter of sheer ability—though the ability of some was world-famed—that these men were most memorable; it is rather their abundant vitality, their character and their originality that impress us. Almost every one of them was, according to their biographers, a man worth studying. Their jests and their mannerisms, their boon-companionships and their pugnacities, their lecture-room quips and their social cranks, their prejudices and their kindlinesses, their hot tempers and good hearts, their oddities and their sound sense, were abundant enough to furnish forth ten times their number of ordinary mortals. They and their personal traits are excellently described in Sir R. Christison's autobiography, with much of the crispness, though with none of the acridity, of Carlyle. The author brings their portraits before us in a few well-chosen words. Dr. James Hamilton, the Professor of Midwifery, "was a little man, frail-looking, but strong; uncommonly fair, not at all comely, and undeniably wigged. He had a quick, short, nervous step, and a slight stoop and downward look, as if his eyes took account always of what his feet were doing. His voice was harsh, and his intonation Scotch, pure and unsophisticated. . . . As a critic, he seemed to be in his favourite element; and a searching, unfair, unfeeling critic he was." This propensity brought down upon him the great Dr. Gregory and the stout cane which he always carried, "which never touched the ground, but was held over the shoulder or 'at the trail,' as if ready for action and significant of combativeness." Principal Baird is brought before us as "a portly man of middle stature, of great weight, but of strength suitable for carrying it easily; with a round, plump, benignant countenance; of kindly disposition, conversing ever with a dominant smile on his visage; a good scholar, of polished manners and winning address." Little vignettes of this kind, sketched with a few apt lines, are scattered throughout the volume, and add greatly to its interest and value as a record of past times and men. The word-portraits of the great Frenchmen—Laplace, Guy-Lussac, Thenard—whom he saw when studying in Paris in 1820, are equally vigorous; much more so than the meagre descriptions of Dr. C. J. B. Williams, who visited the French capital a few years later, though the youthful pencil sketches reproduced by the latter author in his "Memoirs" do much to make up for his inadequate letter-press.

But it is more for his unconscious portrait of himself than for his pictures of his teachers and colleagues that

<sup>1</sup> The Life of Sir Robert Christison, Bart. Edited by his Sons. Vol. I. Autobiography. Edinburgh, William Blackwood and Sons, 1885.

Sir Robert Christison's autobiography will be valued. We see him growing from an active, restless, studious boy, fond of games, and yet studying with avidity the most diverse subjects, into an enthusiastic student, and then, at an early age, sobered down into a hard-working conscientious professor and expert, with sound sense and good judgment for his leading characteristics. And yet, all through, we catch gleams of the joyous vitality and humour which kept him from becoming what he, a professor's son and himself a professor before the age of 25, might have so easily become—a learned prig. Dr. C. J. B. Williams, who was one of Christison's earliest pupils, hardly does justice to his character or abilities in the brief mention made of him in the "Memoirs." He describes him as "an industrious and careful compiler," who "made his lectures useful by the amount of information which they contained." But to Dr. Williams he seemed to have "little capacity for original research or to be profound in either physiology or medicine (*sic*). Yet he held his ground steadily among colleagues more talented and turbulent than himself, and fulfilled a long and honourable career." Dr. Williams is perhaps hardly the author to go to for a just and sympathetic estimate of his contemporaries, but the above sketch of a man, who was not less celebrated in his own line as a successful investigator than Dr. Williams was in his, cannot have commended itself to anyone who knew Christison and his scientific powers. When the second volume of the present work appears, with a chapter on Christison as a physician by Professor Gairdner, and a chapter on his scientific career by Professor T. R. Fraser, it will be seen by all how inadequate is Dr. Williams' estimate of him. Christison was no doubt greatly favoured by circumstances, just as Dr. Williams was. As young men they both went to Paris, then the scene of the greatest scientific activity, and they both brought home with them an acquaintance with new methods of investigation, which at once raised them to a somewhat fortuitous pre-eminence over rivals who had not enjoyed their advantages. But they showed that they were able to make the most of their opportunities, and both Christison, as the expert in chemical and toxicological analysis, and Williams, as the expert in stethoscopy, did much, not only to further their respective branches of enquiry, but to popularize them amongst their pupils. An equally interesting parallel might be drawn between their characters—of Christison's temperateness in the midst of pugnacity, and Williams' pugnacity in the midst of moderation—but we forbear to press it. Their autobiographies, however, may be most instructively read side by side, and we do not think that there will be much difference of opinion as to which makes the pleasanter reading.

There are several points of medical interest raised in Sir R. Christison's life, upon which we have less space to touch than we could wish. Take, for instance, the case of blood-letting in fevers. In his recent address Dr. Wilks contended that "If there be any difference of treatment from past times, it is not due to any change in the constitution of human beings. There is not a single fact to support so preposterous a supposition; the only suggestion for it being that some senile doctor found that his patients did not necessarily die under his old treatment any more than they do under his new." We do not think that anyone who reads Sir R. Christison's statement of the case for blood-letting in fever, not now, but in the Edinburgh epidemic of 1817-20, will admit that that is a fair representation of the "senile" view. During the first half of his life he tells us "acute local inflammations were attended with a violence of arterial action unknown in the latter half. . . . The younger generation of physicians may follow their leaders by denying the

occurrence of any such change in the constitutional character of disease. But they can be no fit judges who were not practical observers of both phases of the case; and all my professional brethren, old enough to have seen both, agree with me that for a long time past they have never met with such pulses, for force and hardness, in pneumonia, pleurisy, nephritis, rheumatism, &c., as they constantly encountered in their earlier days." That seems to us to represent a position which, if not unassailable, is certainly deserving of respectful treatment, and we cannot help thinking that Christison, in leaving the question to be settled by posterity, errs less on the side of dogmatism than Dr. Wilks, of whose address we have shown our general appreciation so heartily already that we may perhaps be forgiven this slight drawback. In conclusion, we must once more give expression to our sense of the value and interest of Sir Robert Christison's autobiography, which we believe is destined to take a very high place amongst the rare *obiter dicta* of our professional leaders.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 24TH, 1885.

Dr. GEORGE JOHNSON, F.R.S., President, in the Chair.

#### *On the Distribution of Bacillus Anthracis in the Human Skin in Malignant Pustule.*

MR. BARKER related the notes of a case of malignant pustule in which excision on the tenth day after the appearance of the first pustule was followed by rapid and complete recovery. The case was that of a young, healthy man, a brush-maker, who noticed a small pustule on his neck on May 28th, 1884, which he squeezed with his nails. This became very sore and increased rapidly in size, while at the same time he began to feel very ill with insomnia, thirst, malaise, pains in the bones; later on, he experienced rigors, anorexia, and headache. On admission to University College Hospital on June 7th, he was found to be suffering from a large so-called malignant pustule on the left side of the neck. This consisted of a central dark-brown eschar surrounded by a zone of flattened pustules, and outside these a hyperæmic zone; beyond the latter the whole side of the neck was œdematous, with an intensity of hardness rarely seen. The treatment consisted in excision of a portion of skin about  $3\frac{1}{2} \times 2\frac{1}{2}$  inches, including the whole area of vesiculation and a margin outside this of about half an inch broad. The base of the wound was cauterised freely with the actual cautery, dressed with iodoform, and covered with iodoform wool. The recovery was rapid and complete. The distribution of the bacilli in the skin about the centre of inoculation was then discussed, the main conclusion arrived at regarding this point being that the organisms displayed a remarkable predisposition for the most superficial parts of the dermis, and only penetrated into the deeper parts very slowly and in relatively small numbers. Enormous colonies were found spreading over the surface of the papillæ, causing vesiculation of the epidermis, while in the bodies of the papillæ and in the deeper parts of the cutis only a few scattered bacilli were found; none could be detected in the vessels of the skin anywhere; under the eschar the active growth of the organisms appeared to have been arrested. That the disease remained essentially local for a considerable time appeared to the author a justifiable opinion from these observations, while the history of the case, together with the result of operation, pointed to the same conclusion.

Mr. DAVIES-COLLEY was pleased to have heard the paper, and that it had been brought forward, for it would serve to draw attention to the occasional occurrence of this form of disease. He was not quite so sanguine as Mr. Barker appeared to be as to the effects of the removal of the local disease; for fatal cases occurred notwithstanding. The characteristic bacilli were found in other organs and tissues away from the wound, and also in the sputa, the fæces, and the urine of affected patients. Nevertheless, local removal was advisable; for, in his own opinion, the secondary colonies were far less malignant than those in the first direct inoculated pustule. He remarked also on the differences presented by cases among themselves, and in those originally reported in Bradford, where lung and intestinal lesions predominated over external ones.

*A Case of Acute Tubercle of the Liver agreeing completely with the so-called Actinomycosis.*

Dr. JOHN HARLEY related the case of a man, aged 30, who was under his care, and died, after a year's illness, of abscess of the liver, secondary abscess in the right loin, and lobular pneumonia. The liver abscess, which formed a prominent projection of the left hypochondrium, was incised and remained open up to the time of his death, ten weeks after admission. Very small quantities of thick creamy pus were constantly discharged. The patient presented the usual aspect of tubercle, and the tongue became aphthous soon after admission. He died of exhaustion, but experienced only slight pyrexia throughout. The incised abscess communicated with a large pale shreddy mass about the size of an orange, in the left lobe of the liver; and scattered throughout the gland were numerous more or less spherical masses of pale, almost white, deposit. Two were of the size of oranges, and had begun to soften at the centre. The incised tumour was but little diminished; it was purulent, but the pus could not be evacuated, being retained in a remarkable felt-like close-woven stroma. The smaller masses were formed of aggregations of a few yellow tubercles, seen on the surface to be surrounded by congested liver tissue, and resembling caseous tubercle in hepatised lung. The lungs were similarly affected, but to a very limited extent. There were evidences of a previous attack of pericarditis. On examining sections of the liver, it was found that in the morbid areas the lobules were wholly replaced by leucocytes and central granular masses, which exhibited very distinctly the characters described as *actinomycosis*, a development, as it was stated, of *Actinomyces bovi*, a hyphomycetous fungus. The stroma of the tubercular tumours was shown to be formed of the interlobular vessels and the connective tissue surrounding the lobules, the latter being completely excavated and converted into sacs  $\frac{1}{2}$  to the  $\frac{1}{5}$ th of an inch in diameter, communicating with the interlobular network by many apertures. These cavities in the general network were occupied by the radiated granules. After giving a full description of the morbid products, and describing the formation of the tubercles, the author concluded by referring to the question of its vegetable origin. He unhesitatingly answered this in the negative. "I am bound," he said, "to admit that the case which I have described agrees in every particular with most of the typical cases of actinomycosis that have been recorded, and my figures correspond exactly with those of Lebert, Israel, and others, and yet I am perfectly satisfied, and hope to prove to the Society, that there is no fungus whatever associated with my case. If this be so, then much, if not all, of the so-called actinomycosis must be relegated to its old and, as I believe, its proper place, namely tubercle." The author gave a full account of the concretions which had been described as *Actinomyces*, and he claimed to have shown by microscopical, physical, and chemical processes that the striations which were assumed to be the asci of the plant were nothing more than the earliest indications of that calcareous degeneration to which tubercular deposits were so liable, and which had no more connection with fungus growth than a gall-stone had.

Dr. SHARKEY began by admitting that he represented "an organised opposition" to the view just propounded in Dr. Harley's paper. Against the tubercular view was the size of the "tubercles" present in this case; the latter were

usually very minute. At the *post-mortem* examination he had been unable to say what the case was, nor would Dr. Bristowe express any opinion, so unusual were the appearances. Dr. Harley, on the contrary, at once expressed the opinion that they were tubercles. Something had been said about the absence of caseation; was not this fact itself an argument against the tubercular view? He was at a loss to explain Dr. Harley's micro-chemical tests, for his own results had been entirely different. He found that soaking in acetic acid only made the mycelial threads the more clear, while soaking them in liq. potassæ had no effect at all. In one place there was adhesion through the diaphragm with the lung, and in the latter there was the same fungus growing as luxuriantly as in the liver. Whether studied clinically, pathologically, or micro-chemically, he felt fully justified in regarding the case as one of an actinomycosis—a radiating fungus—not perhaps the *A. bovis*, for this one differed in some respects from those occurring in animals.

Dr. ACLAND described a series of specimens which were on view, and which, in his opinion, pointed very clearly to the real nature of the case. He admitted that the crucial test was wanting, viz., pure cultivations, but the reasons were obvious. The disease was certainly a fungus, and not tuberculous.

Mr. SHATTOCK supported the fungoid as opposed to the tubercular view.

Mr. WATSON CHEYNE spoke to the same effect.

Dr. HARLEY replied; he maintained his own views with great plausibility.

The Society then adjourned.

---

## OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, NOVEMBER 12TH, 1885.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair.

Dr. SEYMOUR SHARKEY showed a case of partial ophthalmoplegia externa and interna, with locomotor ataxy. The patient was a man, aged 37, who had had *tabes dorsalis* for three or four years. There was ataxy (without paralysis), loss of knee-jerk, and some loss of sensation in the legs. He had had rheumatic fever twelve years previously, but not syphilis. The optic discs were normal; there was practically no ptosis. The left eye retained a fair degree of downward movement, and some downwards and outwards. There was no movement in other directions. The right eye had a fair degree of movement inwards, and inwards and upwards, and downwards, but hardly any outwards, or downwards and outwards. Mr. Nettleship had found that the left pupil measured 4.5 millimètres, and the right 4 millimètres, but neither acted to light or accommodation. A slight transient diplopia was noticed by the patient when any sudden movement was made. Vision was  $\frac{6}{12}$  in both eyes; there was hypermetropia. The patient had perfect vision for colours. In reply to the President, Dr. Sharkey said that the man denied all history of syphilis, but, as had been noticed in other cases, there was a history of rheumatism.

Dr. W. A. BRAILEY showed a case of retinal detachment, which had much the appearance of a sarcoma of the choroid. The man, fourteen years ago, whilst in a stooping posture under a tunnel, felt that something had happened to his eyesight, and, on coming into the light, one half of each field of vision was noted to be blind. Owing to the presence of iritis in the left eye, the fundus on that side could not be properly examined. As the detachment might have been due to hæmorrhage, he had made a large iridectomy upwards, and subsequently the field of vision and acuity had improved. French observers had noted great improvement after iridectomy in cases of detachment of the retina. In reply to Mr. Nettleship, Dr. Brailey said that the hemiopia was noticed as soon as the man left the tunnel, and that the iritis came on about Christmas, 1884, and apparently had no relation to the hemiopia.

Mr. BRUDENELL CARTER showed a pair of scissors specially made for the division of the capsular bands or iris after cataract-extraction.

Mr. J. B. STORY showed an instrument for irrigating the lids in severe ophthalmia. The instrument consisted of a length of fine india-rubber tubing stiffened with wire where introduced beneath the eyelids. He also showed a young man who presented aneurysms of the retinal vessels. A drawing of the retinal vessels, by Mr. A. H. Benson, had been exhibited to the Society in 1883, and published in the Society's *Transactions*. At the present time it was possible to see five or six aneurysms scattered about the fundus of the eye, some connected with arteries, others with veins. In reply to the President, Mr. Story said that the retinal aneurysms did not now exactly correspond with those observed at the time the drawing was made.

Mr. HENRY POWER showed a case of severe retinitis in a boy, who had also paralysis of the left sixth nerve. There had been some headache, slight nausea, and constipation. There was no albuminuria and no evidence of syphilis, but some history of rheumatism, and a systolic *bruit* at the left apex of the heart. Possibly a cerebral tumour was the cause, but it was curious that no further symptoms were present.

Dr. ANGEL MONEY said the boy's voice was nasal, and the knee-jerks could not be readily got, if at all. The boy said his throat had been sore. Was there any reason to suspect a post-diphtherial disease?

Mr. BRUDENELL CARTER enquired how long the boy had been under observation. He related a curious case of identification in a man who had optic neuritis three years before his death; a necropsy showed that a cerebellar tumour was the cause.

Mr. POWER, in reply, said there was no albuminuria; diphtheria might have been present, but there was no definite history of it. The boy had been under observation since October 23rd.

#### *Pemphigus of Conjunctiva.*

Mr. LANG read a paper on this subject. Mr. White Cooper had recorded the first case of this disease in vol. i. of the *Royal London Ophthalmic Hospital Reports* in 1858. No other case had been published in England. Campbell in America had described one. The remaining twenty cases had been described by continental writers. Stellvag, in 1870, described a disease called "Syndesmitis degenerativa. Von Gräfe, in his *Archiv* for 1878, described the same disease as "Essentielle Schrumpfung der Bindehaut." Steffan had also written on the subject. The first case of Mr. Lang's was a woman, aged 52, who had been subject to ulcerated sore throat since childhood. In the spring of 1883 the white of the eye became red, the lids drooped, and there was a discharge, accompanied by pain and heat. The case was described in the *Ophthalmological Society's Transactions*, vol. iv., p. 20. For the last seven months the disease had remained stationary. The right palpebral fissure was much shorter and narrower than normal, both lids being completely adherent to the globe. The eyelashes were unaltered. The conjunctiva was replaced by a dry, black, opaque membrane. At only one point was the cornea moist and transparent. The left eye was in much the same condition. The globes were almost motionless, but the lids could be completely closed. The mouth and throat were normal, except for a small round grey patch on the soft palate. The second case was that of a young woman, aged 24. In the spring of 1871 the left cervical glands began to enlarge. In 1876 the ends of the fingers gathered, and blisters came on the backs of the hands and the front of the body; since then she had never been free from the eruption. The same year the eyelashes turned in, and the whites of the eyes became red. A vigorous shake of the hand would produce a blister. The condition had not altered during the last three years. There were several thin large scars in the neck, and the palms of the hands and fingers were smooth, thick, and contracted. The toes and the backs of the hands were in the same scarred condition. The mucous membrane of the lips, mouth, and tongue was considerably altered. There were vesicles, filled with clear yellow fluid, on the left side of

the tongue. Three years ago Mr. Adams performed Burow's operation for inverted lashes.

Mr. ADAMS FROST said there was a case of xerophthalmia of one eye only at St. George's Hospital, during the previous year, which closely resembled the cases described by Mr. Lang, but no pemphigus occurred on the body. Transplantation of rabbit's conjunctiva had improved the vision.

Mr. NETTLESHIP had seen a somewhat similar case, though he had not at the time recognised that the case was one of pemphigus. A man, aged 45, was referred to him by his colleague Dr. Semon; he had had some trouble about his nose for two years, it being sore and raw, and scabs forming in it from time to time. When he came to him there was muco-purulent conjunctivitis of the right eye, but no inversion of the lashes. Two months later the lower cul-de-sac was retracted and the eyelashes were giving trouble, and the man was getting worse. On drawing the lid out, one or two aphthous-looking patches were seen, similar to those observed in Mr. Lang's cases. The man had had syphilis and presented a scaly eruption of one palm. He thought that the mucous membrane of the nose might be going through the same condition as that of the eye.

Mr. JULER thought that the collateral evidence of pemphigus in Mr. Lang's second case was very slight. He had had under his care a case of a dry condition of the conjunctiva, in which there was no definite eruption, and during his absence the house-surgeon had made free incisions, after which the eye did badly.

The PRESIDENT said that, though he had seen many cases of pemphigus, he did not remember ever to have seen it upon the conjunctiva.

Mr. LANG, in reply, said that he had seen two other cases of this affection: one was many years ago, in a man aged 70; the eye-lids were thin and the cornea seemed to be covered by a thin skin; and the other was in a man who died of general pemphigus, and who had one on his conjunctiva; the cornea of this eye afterwards sloughed.

Mr. SPENCER WATSON said that, having just examined the nostrils of Mr. Lang's patient, he found them obstructed by a shining body which he took to be probably a polypus.

#### *Pupillary Movements associated with Extrinsic Movements of the Eyes.*

Mr. W. H. JESSOP showed a patient who presented a peculiar anomaly of the movements of the pupils. The patient was a man, aged 33, who, when 14 years old, was admitted into the Great Northern Hospital with fracture of the skull; a depression in the skull, the result of this injury, was still apparent. For the last ten years he had suffered from gout, probably connected with his occupation (painter). Four years ago he had left hemiplegia, and the face was still paralysed; there was no affection of the eye-lids; there was no wrist-drop or perversion of the reflexes. With all movements of the eyeball with which the external rectus was associated, the pupil dilated to 7.5 millimètres, while, with all movements inwards, the pupil contracted to 3.5 millimètres; this was the case with both eyes. On convergence and accommodation the pupils contracted to 3 millimètres. The pupils did not react to light or sensory irritation; the contraction of the pupil occurred much more quickly than the dilatation. When the external rectus was in action, the dilatation was like that produced by sympathetic irritation; when the movement was inwards, the contraction was like that produced by stimulation of the third nerve. With regard to the situation of the lesion, Mr. Jessop remarked that the loss of the light-reflex and of the sensory reflex, combined with good action on accommodation and good conjugate deviation, rendered it probable that the lesion was in the nervous path beneath the aqueduct of Sylvius, and below the anterior part of the corpora quadrigemina.

Dr. BEEVOR said that he had ascertained from the patient that when he had the attack of hemiplegia there was also hemianæsthesia, and it seemed to him that this would throw the lesion further back than Mr. Jessop had suggested, and place it probably in the posterior third of the internal capsule.

Dr. ORMEROD said that, if the centre was where Mr. Jessop placed it, how was it that in cases of tabes dorsalis, where the light-reflex was often gone, but that of accommodation preserved, this condition was not found; as far as he knew, it was unknown.

Mr. LANG mentioned a case, which had lately been recorded by Mauthner, where, with ophthalmoplegia externa, the pupil was observed to dilate when the eye was moved outwards. He had seen a case in which the reverse condition was present.

Mr. GUNN said that in a case of sixth nerved paralysis he had seen the pupil at first contract and afterwards dilate on outward movement.

Mr. JESSOP said that his patient had no paralysis of the rectus externus. He could not give any answer or explanation to Dr. Ormerod's question.

Dr. BEEVOR wished to add that, since the last meeting when the man was exhibited, he had tested several ataxic patients, but had not found this pupillary reaction present.

#### *Is Cocaine ever harmful?*

Mr. NETTLESHIP said that he wished to know whether any member of the Society had reason to be dissatisfied with cocaine or with cocaine discs. During the last six months at St. Thomas's Hospital he had had a run of cases of panophthalmitis after iridectomy or cataract, and he had largely used cocaine discs. Cocaine was very hygroscopic, and the discs were therefore apt to be moist, and so might favour the development of organisms. He also wished to ask whether cocaine itself ever did any harm in solution. Kaeser, of Philadelphia, had lately expressed a belief that a three per cent. solution caused panophthalmitis, and Graefe, of Halle, had seen interstitial keratitis follow its employment. Mr. Hurry Fenwick had thought that it produced a discharge from the urethra when injected into the bladder.

Mr. MCHARDY said that he had had a run of panophthalmitis after using cocaine in solution, and after careful enquiry he had come to the conclusion that it was because the cocaine was not fresh; he had then made it a rule not to use any that was twelve days old, and none of his cases had gone wrong since. He used an eight per cent. solution in camphor water.

Mr. EDGAR BROWNE (of Liverpool) said that he had suspected cocaine for some months, as he had had a run of ill-luck since he used it. He always had the solution made up with camphor water, and kept a lump of camphor in it, and his solution was almost invariably prepared fresh just before use.

Mr. STORY said that at St. Mark's Hospital they used a two per cent. solution of cocaine, made up with a saturated solution of boracic acid, and they had never had any bad results from it. All of them could remember preceding epidemics of panophthalmitis without any obvious cause, and he did not see why cocaine should cause it any more than atropine. He doubted whether micrococci would grow in cocaine discs at the temperature at which they were ordinarily kept, and it seemed to him perfectly probable that the cocaine was guiltless. The last epidemic of panophthalmitis that had occurred at his hospital had been two years previously, and the first case on that occasion was one where the cause could not be known; the same instruments immediately afterwards had been used for a second case of cataract, which had perfectly recovered.

Mr. GUNN suggested that solutions of atropine were not always fresh, and might sometimes have been the cause of epidemics.

Mr. LANG said that in the only case of panophthalmitis he had met with in his own practice it was proved that the cocaine was not fresh; in fact, a fungus could be seen flourishing in the bottle.

Mr. NETTLESHIP said that he had learnt that there was this difference between his practice at Moorfields and St. Thomas's that at the former the cocaine solution was made up with a saturated solution of boracic acid. He said that of course he had seen epidemics of panophthalmitis before, but he had never known anything like so bad a batch as that to which he was now referring, for he had lost seven eyes in eight months.

#### *Deep-Seated Foreign Bodies, with Preservation of Sight.*

Mr. SIMEON SNELL (Sheffield) referred to three cases of pieces of steel in the retina, which had come under his observation. One was recorded in the Royal London Hospital Reports for 1879, and sight remained perfect when the patient, a young man, was lost sight of many months after the accident. The fragment lay in the retina near the disc, and had passed through the sclerotic. The second was in a man, aged 42, and the chip passed through cornea and lens, lodging in the retina, near the periphery; for some time vision was excellent (1 J.), cataract then formed, underwent absorption, and good vision returned. At the end of five years the eye remained quiet so far as the foreign body was concerned. The accident in the third case, a man, aged 26, occurred in May, 1883; the chip penetrated the sclera, just external to the cornea, lodged in the outer and lower part of the retina. When first seen in August, 1883,  $V = \frac{2}{3}0$ ; fragment looked black and lustrous, and surrounded with whitish exudation, as in the other cases. November 27th.—The situation of foreign body was obscured by a patch of whitish exudation. On February 22nd, 1884, he came with iritis and great pain; the condition became rapidly worse; and on February 25th the sclerotic was punctured between the internal and external recti, and the piece removed with the electro-magnet; cataract was developed, but at the present time perception of light was excellent, and so was tension, and with extraction (iridectomy had already been done) sight would, it was hoped, be restored. Mr. Snell discussed the question as to whether or not the chip had left its place in the retina and fallen into the vitreous, as he supposed at the time of the operation; no foreign body was, however, at any time clearly seen with the ophthalmoscope in the vitreous, and the foreign body was coated on one side and not on the other, and the position of scleral wound brought the chip well within the field of the magnet. He inclined to the view that the piece remained in the retina, and was removed therefrom by the magnet. The fragment weighed four milligrammes. Reference was made to the cases collected by Knapp, thirteen in number, and to other recorded cases. Experience taught how frequently these particles were tolerated in the back of the eye, but reference was made to those cases which were more easily accessible, and in which the use of the electro-magnet would be serviceable. Generally speaking, however, it appeared that they might be left alone, and interference would be fraught with more danger. Galezowski and Stevens (New York) had each reported a case of removal of a splinter from the retina with a magnet. Mr. Snell also related an instance of a small particle of shell, tolerated, with perfect sight, in the vitreous for twelve months; it had passed through the cornea and lens. There was also paralysis of accommodation, the cause of which was not certain; the injury seemed insufficient; the patient and others of the family had not long before suffered from sore throats, but their medical attendant did not allow that it was diphtheria, nor were there any other marked sequelæ.

#### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, NOVEMBER 4TH, 1885.

J. B. POTTER, M.D., President, in the Chair.

THE following specimens were shown:—

- (1) Dr. LEWERS—Unusually Large Vein in Wall of Uterus.
- (2) Dr. LEWERS—Malignant Disease of Sigmoid Flexure invading Uterus.
- (3) Dr. W. S. A. GRIFFITH—Broad Ligament Cyst with Septa in its Interior.
- (4) Dr. HERMAN—Drawing of Chancre on Cervix Uteri.

#### *Suppuration and Discharge of Pelvic Dermoid Cysts.*

Dr. HERMAN read a paper on the above subject, of which the following is an abstract. The author first said that, while under ordinary conditions, pelvic

dermoid cysts were best treated by laparotomy, yet that, when such a cyst had suppurated and burst into one of the pelvic mucous tracts, there would usually be extensive pelvic adhesions, making the operation for the removal of such a cyst more than commonly difficult and dangerous; and, on the other hand, the suppurative process offered some prospect of cure without extirpation. The object of the paper was to assist in the treatment of these cases by offering as complete an answer as could be given to the following questions. (1) When a pelvic dermoid cyst suppurates and bursts, what may be the course of such a case? (2) What prospect of cure does this event offer? (3) Is this cure complete? (4) How can the cure be best promoted by treatment? It was commonly believed that so long as any part of the lining of a dermoid cyst remained the cavity would not close. He thought there were sufficient cases to show that either this did not always hold good, or that suppuration usually so altered the character of the lining membrane as to make it capable of contracting and closing. The author had had under his own care three cases in which dermoid cysts had suppurated, in two of them bursting into the vagina, in one into the bladder. He had collected from various sources a large number of other cases, and from examination of them he drew the following practical conclusions:—(1) The suppuration of a dermoid cyst is sometimes a favourable event, leading to its cure; (2) This is especially likely to be the result if the cyst be small and unilocular, and if it have opened into the vagina. (3) An originally very small cyst may, when it suppurates, rapidly attain a very large size. (4) When the cyst is small it may become inverted through the aperture of discharge, become polypoid, and be spontaneously expelled or easily removed by the surgeon. (5) This process may be imitated by the surgeon, but it is not safe unless it can be very easily done. (6) When a suppurated dermoid cyst has been emptied, it contracts, and its cavity either becomes obliterated or remains as a small sinus which causes no trouble. (7) The first indication in the treatment of a cyst which has burst, is to empty it, for cure by suppuration depends upon the cyst being emptied. (8) The opening of the cyst should be enlarged as much as can be safely done, the cavity explored, and its solid contents removed as completely as can be done without violence to the integrity of its wall. (9) If the cyst have discharged into the bladder, its cavity should be reached by vaginal cystotomy, not by dilatation of the urethra. (10) If the cyst be multilocular, or if, after having been emptied as thoroughly as possible, it do not rapidly contract (from which it may be inferred that it has not been completely emptied), it is likely that it will discharge indefinitely and exhaust the patient's strength; and therefore it should be removed by abdominal section without long delay.

Mr. KNOWSLEY THORNTON said he would refer to a few points only. First, as to cysts which opened into the bladder, the evidence must be very clear that they were ovarian, for dermoid cysts occurred in the utero-vesical cellular tissue. Second, unilocular dermoid cysts were very rare: most dermoid cysts were multilocular, or associated with ordinary multilocular ovarian tumours. Third, the pathology of dermoid cysts was against cure by suppuration, though it might happen from the violence of the putrid inflammation entirely destroying the skin, &c., lining the cyst. Unless the lining membrane was entirely removed or destroyed, they did not heal. The fact that they were occasionally malignant was against attempting a cure by incision and drainage. He had treated a case in which the tumour burst into the bladder. He attempted to remove it by abdominal section, but found it impossible. He then attempted to cure by drainage, but after many weeks the patient died worn out by discharge. He thought abdominal section was the better treatment, where possible, than lingering suppuration. With regard to the side issue of cystotomy *versus* rapid dilatation of urethra, he entirely agreed with Dr. Herman.

Mr. ALBAN DORAN said that many dermoid cysts of the abdomen which had been described as non-ovarian were really ovarian cysts which had become separated from their pedicles. Pelvic dermoid cysts were undoubtedly non-ovarian in some cases.

Dr. BRAXTON HICKS thought that many of these dermoid cysts were of the nature of the tumours called *foetus in foetu*. In one case which he tapped, six weeks after, he attempted removal, but found it impossible.

Dr. ROUTH thought most of them were in reality *foetus in foetu*. If a whole *foetus* might be enclosed, a portion might be. So far as he knew, no cyst containing teeth could have other than ovarian origin.

Dr. PLAYFAIR rose to endorse what had been said by Dr. Herman as to the advisability of not attempting to operate through a dilated urethra. Rapid dilatation of the urethra was very far from being as simple and safe as it was generally considered to be. His results from vaginal cystotomy had been so satisfactory that he was quite disposed to agree with Dr. Herman that in the class of cases he referred to it was likely to be preferable to urethral dilatation.

Dr. GALABIN thought that Mr. Doran's views, if confirmed, might throw light on the mode of origin of these growths. Dermoid cysts, due to inversion of epidermis only, produced pain and fat. Growths due to attachment of one ovum to another were generally found at some external part. Cysts producing teeth or bones were hardly ever found where they could not be derived from the ovary. If it happened that a liberated unimpregnated ovum became implanted on the peritonæum and there grew, this explained why such growths were found in the pelvis and not in other parts. He was strongly of opinion that vaginal cystotomy was far preferable to dilatation of urethra for the removal of any growth. He had been struck with the facility of the operation, the rapid recovery of the patient, and the ready closure of the opening.

Dr. HERMAN said that, although many dermoid cysts were multilocular, cases given in his paper showed that some were unilocular and might be emptied. He agreed with Mr. Thornton that intentionally to treat a dermoid cyst by incision was not good practice; but his paper dealt with cysts that had already burst or could not be distinguished from abscesses. The case mentioned by Mr. Thornton, in which he had been unable to remove a suppurated cyst, showed the utility of considering the questions raised in the paper.

*A Case of Obstructed Labour in which Spontaneous Version followed an Unsuccessful Attempt to deliver by the Crotchet after Perforation.*

Mr. S. D. HINE (Ilminster) read a paper on the above subject. The patient had been in labour 30 hours, liquor amnii had escaped 21 hours. The cord was prolapsed, the head presented in first position, os uteri dilated, uterus in state of tonic contraction; conjugate diameter of brim under three inches; head immovable above it. After ineffectual attempts to deliver with forceps, the skull was perforated, and for about an hour endeavours were made to deliver with the crotchet, but in vain. A consultation was then held, which lasted about ten minutes, and on examination at the end of this time the head presentation was found changed into a breech, a foot was then brought down, and the child thus delivered.

Dr. ROBERTSON asked why turning was not done before.

Dr. BARRACLOUGH thought that turning might have been done after perforation. Art ought to have anticipated nature.

Dr. AUST LAWRENCE preferred forceps to turning in cases of contracted brim. He did not think that a living child could here have been brought through by turning.

Dr. PLAYFAIR thought the practice followed in this case was correct. There were two reasons why turning should not have been done: (1) the long prolapse of the cord, (2) tonic contraction of uterus. Turning was a valuable occasional resource after craniotomy, but he did not think it should be the rule.

---

THE Library of the College of Surgeons will be closed on Friday and Saturday, and on Monday at 4 o'clock, for the purposes of the Final Examination for the Fellowship, 29 candidates having entered.

## GENERAL MEDICAL COUNCIL.

## THIRTY-EIGHTH SESSION.

THIRD DAY—THURSDAY, NOV. 19TH, 1885—*continued.*

Permission was then given by the Council for the prosecution of a dentist at Sheffield for an alleged infringement of the Dentists' Act.

The Report of the Committee on Preliminary Examinations was next brought up, in which the Committee stated that they had examined the papers of the Queen's Colleges of Belfast, Cork, and Galway, and considered the standard of percentage of pass marks, and were of opinion that these examinations ought to be restored to the list of those which they recognised. The Report having been received and entered upon the minutes, it was, upon the motion of Dr. Humphry, seconded by Dr. Banks, resolved that the examinations of these bodies should be replaced in the list of recognised preliminary examinations.

The rest of the day was taken up with the discussion of the subjoined motion by Dr. LYONS, who, at the close of the debate, by permission of the Council, withdrew his motion, stating that sufficient had been gained by the discussion: "That this General Medical Council expresses its regret that the Executive Committee considered itself compelled to overrule a decision arrived at by the General Medical Council on a subject of importance in regard to certain Colleges in Ireland; that, while disposed to condone this act in view of the urgency of the questions involved, they trust it will not be drawn into a precedent which would be of evil example in the future and likely to lead to much inconvenience and irregularity."

FOURTH DAY—FRIDAY, NOVEMBER 20TH, 1885.

*The Improved Ventilation of the Council Chamber—A Complete Qualification—Report on the Standing Orders as to Penal Procedure—The Local Government Board and the Surgical Examination at the Society of Apothecaries.*

After the minutes had been confirmed, Mr. COLLINS drew the attention of the Council to the fact that there remained on the so-called Black List the names of some persons whose offences had been condoned, and who had been restored to the Register; the fact of their restoration to the Register was duly indicated, but he contended that they ought altogether to have been taken off the Black List. The Registrar explained that the present practice had been adopted on the advice of the late solicitor to the Council, Mr. Ouvry, who thought it would be the safest course to adopt.

Dr. MATHEWS DUNCAN said that he would be very glad to second the motion; not that the Register was in any way inaccurate; it was not erroneous that these names should be in the Black List, but they were to be removed because it was the pleasure of the Council that they should be removed.

The PRESIDENT said that it was a matter of which notice should have been given. He said that, if it should be referred to the Executive Committee, it would be carefully considered by them.

Sir HENRY PITMAN thought that the best plan would be to give notice of it at once and deal with it later in the day if possible; it ought not to be referred to the Executive Committee, as it was important it should be settled at once. A new list would have to be prepared, and be in the hands of the Members of Council and licensing bodies within one month, and it was important, therefore, that there should be no delay. Mr. Collins accordingly gave notice of a motion to the above effect.

Dr. QUAIN, as Senior Treasurer, then made a report as to the structural alterations that had been made in the room

with a view to the better warming and ventilation. He said that originally it had been the lecture-room of the Chemical Society, which perhaps accounted for the bad smells that had been noticed. On taking up the floor, they had found a quantity of old rags and a large pool of water beneath, which no doubt explained why the room had always been so unhealthy; a complete layer of concrete had been laid down, and a pipe from the front area laid under the floor to act as a ventilating shaft. Means had been adopted to secure the admission of fresh air and to properly warm it, and a powerful extracting ventilating shaft had also been added.

Dr. BANKS and Mr. TEALE having added their testimony as to the improvements that had been effected, Dr. HERON WATSON proposed that a special vote of thanks should be put on record to the Treasurers in recognition of the greatly improved ventilation and comfort of the Council.

Dr. CHAMBERS commented on the improvements, and observed how the Council were now cheerful and joyful, and would be quite sorry when the session was ended instead of rejoicing at getting away. He thought that not only their own thanks, but also those of their wives, were due to Dr. Quain in an especial manner for his services in the matter.

The vote of the Council having been accorded, Dr. QUAIN briefly expressed his thanks for the compliment paid him.

Dr. MATHEWS DUNCAN, in pursuance of a notice he had given, then asked the President to state how far in the different divisions of the kingdom arrangements had advanced with the object of securing that all registered qualifications were complete and not partial. He said that it had been lately stated that during the past 25 years medical affairs had made more rapid progress than had ever been made before. Many Bills had been introduced, but, he was glad to say, had not passed, and he was pleased to hear that there was no prospect of further legislation. It was therefore their duty to attend to further improvements, and none was of more importance than that a man should not be able to get on to the Register without a complete qualification. It would, he held, be a great omission on the part of the Council if they did not from time to time take steps to secure this, the most important, point in medical education.

The PRESIDENT then read the resolution of the Council of the previous year, relating to this subject, and said that that resolution had been sent by circular letter to each of the licensing bodies, of which only four had sent any answer. These were the Royal University of Ireland, the Apothecaries' Society of London, the University of Dublin, and the University of Durham. All the licensing bodies, he said, were well aware of the desire of the Council in this matter.

Dr. STRUTHERS thought that it would be better to ask the rest of the bodies, as a matter of form, to send in a reply.

Mr. COLLINS said that immediately after the passing this resolution in May last he had brought the subject under the notice of the Apothecaries' Hall in Ireland, and they had endeavoured to conform to the wishes of the Council. They had instituted three examinations, whereas previously they had only two, and they had also insisted on a five years' course of study, of which the first year must be spent with a general practitioner, whilst two years and nine months were to be spent at a medical school and hospital, leaving fifteen months throughout the whole period for holidays.

He was about to move that the amended regulations of the Apothecaries' Hall be laid on the table, when the PRESIDENT intervened and could not allow any speech, as there was no subject before the Council.

Professor HUMPHRY pointed out that there was no reply necessary to the circular which the Council had sent to the various licensing bodies, and Dr. HERON WATSON expressed the belief that the required information could always be obtained from the reports of the visitors.

Mr. MACKENZIE (the Counsel) and Mr. FARRAR (the Solicitor to the Council) being present, the consideration of some of the clauses of the Standing Orders relating to Penal Procedure, which had been reserved for Mr.

Mackenzie's opinion, was resumed in committee. The chief point under discussion related to the mode of commencement of proceedings against a man who had been convicted out of the United Kingdom. Mr. Mackenzie said that the clause had better be left as drafted, as it would then have a general application, for the proceedings were initiatory to the infliction of a penalty, and they must give the accused the opportunity to be heard. It was just possible that a case of misdemeanour might arise in which there was a question of mistaken identity.

Dr. HERON WATSON pointed out that the words "and to attend" were used; if he was in prison, he could not personally do so, and he might come over afterwards and object to the decision on this ground.

Mr. MACKENZIE said that the notice would reach him, and he could be represented or write. The Council could not do more than give him notice and invite him to attend; there was a special proviso leaving the matter of the notice in the hands of the President to meet cases occurring out of the Kingdom.

Dr. HUMPHRY said that hitherto the Council had gone on the principle laid down in the Act that, where a conviction had taken place, no enquiry was necessary; was it not better that they should continue to do so?

Mr. MACKENZIE thought that all proceedings of this kind should be taken in accordance with the practice in the Courts of Justice; it was both wiser and safer to give notice.

Some other minor points having been settled, the Council resumed, when the Report of the Committee was brought up and adopted.

The SOLICITOR then, at the instance of the President, made a statement with regard to his written opinion on the case of the dentist, which had been before the Council on the previous day. He admitted that generally the Council had known the reason why they were asked to remove a man's name from the Register. He was clearly of opinion that, when a qualification had ceased to exist, they were bound to remove it.

Some desultory conversation then took place for some time on the much-vexed question of whether the Council were bound to remove a name at the invitation of the licensing body, which ultimately the President put a stop to, saying the question was evidently far too difficult to be settled off-hand, and that they could not expect Mr. Mackenzie to give an opinion without consideration.

Dr. HERON WATSON then rose to move that the letter of the Local Government Board be referred to a committee for report at the next meeting of Council. He said it was not the first time in the history of the Council that the Local Government Board had asked them to solve exceedingly difficult questions. In this case the question put was a very simple one, but the answer was not so simple. He had looked the matter up with a view to finding precedents, and he proceeded to read a great many abstracts from the first two volumes of Minutes, all bearing more or less closely upon the question in hand. They mostly consisted of applications from the Poor Law Board to know whether such and such a qualification entitled the holder to practise medicine or surgery, as the case might be, and there were several communications from the War Office to the same effect. Several eminent legal opinions had been obtained; in most of the instances the answer came to the same, that the Council declined to have anything to do with the matter, and regretted that they were not able to give a definite answer to the question. Mr. Simon's amendment in the shape of a letter he characterised as not giving a plain straightforward English answer, and he held that the matter was much more intricate and required much more consideration than that letter would seem to imply. The records from which he had quoted had been called antediluvian, but they contained precedents, and weighty ones, in his opinion. In those early days the Council had displayed the most singular care in the consideration of these difficult subjects; they had appealed to the best legal advice, and they had often given either an evasive answer or replied that the question was merely a legal one, and that they could have nothing to do with it. The only way in which the matter could be attended to efficiently and thoroughly sifted would be by means of a

committee, thus alone would they walk in paths of safety; they must take care that they should not be confronted with results which they might have to go back upon. If they accepted this as a qualification in surgery, they ran the risk of having a fight between the corporations, each one claiming the right to give a complete qualification. No conjoint scheme existed in Ireland, and the bodies there would all claim the right at once. The mode in which the Scottish Universities had dealt with the matter by appealing to the Privy Council and the University of London by getting a fresh charter was much to be preferred to this attempt to get in by a side wind. The Poor Law Board had constantly come before them to fight these battles, and the Army Medical Department had also done so frequently, but, curiously enough, the Admiralty had never done so. They ought to be able to give a satisfactory answer to a plain question in a straightforward English manner. There were a large number of precedents, and the question implied serious legal difficulties. If they did answer the letter straight off, it should be to respectfully decline to give an opinion upon a purely legal matter.

Dr. SCOTT ORR seconded the motion.

Mr. SIMON, who had an amendment upon the paper, then said that he thought there was a very good reason why it should not be referred to a committee. Were they going to leave a letter dated last May a whole year without answer? Seeing that they were now sitting, it would be trifling with a Government department and with their own position to postpone their reply. He should certainly be willing that they took the letter into consideration for the purpose of answering it, and he thought the Registrar should be directed to write in a particular way; the letter which he had put as an amendment was undoubtedly as direct as the Council could make it. Dr. Watson had nevertheless called it ambiguous and roundabout. For himself alone, he would not hesitate to reply to the Local Government Board that the contention was well-founded. But there might be differences of opinion, and he had endeavoured in his draft to give the arguments and construct his letter in the most conciliatory form. Besides divisions of opinions, there might be divisions of interests between the different bodies represented round the table. He had borne in mind the antecedent circumstances in which contentious questions were involved. They must put before the Local Government Board the circumstances under which the Society of Apothecaries had acted in *inevitable* obedience to the resolution of the Council. He appealed to each member of the Council to know how the Society could have given effect to it in any other way. The Society had *vainly* sought to be admitted into co-operation with the other bodies; this was an essential element in the case, and the only way left to it of complying with the requirements of the Council was to extend the examination so as to include surgery. If it had not done this, the Council would have been bound to cite it before the Privy Council, and he asked if the Society of Apothecaries was to accept annihilation; surely the Council did not wish to "boycott" it. Its examination was now complete in form and not impugned in substance, it had not yet been revisited, and therefore, *primâ facie*, in the absence of condemnation, they were bound to assume it to be sufficient. The first part of his letter to the Local Government Board merely stated facts; he thought they could not do less than this. It ran as follows: "To bring under notice of the Local Government Board the resolutions passed by the General Medical Council on 10th October, 1884 (as reported in Section III of the minutes of the meeting of that day), and that those resolutions have to be read in connection with Section XVIII and Sections XX-XXII of the Medical Act," and "to state that the Society of Apothecaries, in having added the subject of surgery to the previous subjects of examination for the Society's Licence, and in having thus caused the examinations to cover all three branches of professional practice, has acted in conformity with those resolutions of the Council." Next, as to the legal aspect; he would first express his own personal convictions. He thought that without doubt the Society of Apothecaries was fully entitled to enlarge the scope of its examination, and that with scope of examination went scope of legal qualification, except where otherwise provided by

law. In the Medical Act no limitation was made on the right to practise except such as went with scope of examination. An authority to examine in medicine with a view to practise must be held to include surgery except where such exclusion was made. That medicine included surgery was obvious from such expressions as "the Medical Council," "the medical profession," and the like. If there were any doubt on the matter, the statute of Henry 8th made it quite clear that physic included surgery, the word physic there used having precisely the same meaning as medicine. The Society of Apothecaries had a right to constitute medicine as inclusive of surgery. The Council had decided that a man had not the requisite skill and knowledge which they deemed necessary for admission into the profession unless he had been examined in medicine, surgery, and midwifery, but if they looked at the Medical Act they would see that no limitation was imposed upon any authority. This was his private opinion in the matter, and he did not ask the Council to affirm as much in his draft letter, but merely "to say that the Council is not aware of any illegality in the extension thus given to the Society's examinations, or of any legal reason why the surgical branch of the examinations, as now conducted, should not be regarded as on the same footing with the other branches." Would anyone say that he was aware of any enactment or judicial sentence contrary to the opinion that he had there expressed? Next he proposed "to point out that in those respects the claim of the Society of Apothecaries at the present time is akin to that which was recognised in the case of the Royal College of Physicians in the year 1862, when the College first adopted the subject of surgery among the subjects of examination for its licence, and moved the Poor Law Board thenceforth to recognise the licence of the College as comprising a qualification in surgery, and that the course then adopted by the Poor Law Board towards the licence of the College of Physicians seems a precedent applicable to the question now raised before the Local Government Board as to the licence of the Society of Apothecaries." He had reason to believe that on a former occasion reference was made to the Act and to the position that medicine included surgery. Some years previously the Local Government Board, being satisfied that the examination at the College of Physicians was satisfactory, accepted their licence as a valid qualification in surgery. In the next paragraph he called the attention of the Local Government Board to the supervision conducted by the Council, to which all the examining bodies were subject, in the following terms—"to observe finally that, as regards those relations of the question which are of most concern to the public, the surgical branch of the Apothecaries' examinations, equally with the other branches of those examinations, and equally with all examinations of the other Licensing Authorities, is subject to the supervision of the Medical Council under Section XVIII of the Medical Act, and that, if the examination should prove inadequate to its professed purpose of securing the requisite knowledge and skill for the efficient practice of surgery, it would (under Sections XX-XXII of the Act) be the duty of the Council to represent it in that light to the Privy Council, with a view to the making of such order by the Privy Council as might in the circumstances be judged right." If the examination was sufficient, why should it not be accepted; if there were any legal difficulties, let the Local Government Board settle them; all they could say was they were not aware of any illegality. If it was not legal, why was the examination instituted; but if it was satisfactory, then, in the name of common sense and justice, unless there was some legal exclusion, on what ground was a man to be excluded from practising that in which he had properly proved his skill and knowledge? Mr. BRADFORD seconded the amendment.

Dr. MATTHEWS DUNCAN observed that the difference between the two speakers was not so great after all; one wished to refer the matter to a committee, the other to say that, so far as they could see, it was not illegal; this amounted to nothing, in effect. But the difference between the speeches was enormous. He thought that nothing could be more out of harmony with the intentions of the Council than Mr. Simon's speech. Was it to be in the power of everybody to assume the power of giving a

licence? If the Society of Apothecaries had this power, why had they gone to Parliament a few years previously to get power to amalgamate with the other bodies? The resolution of the Council referred to competency; the examination might be sufficiently good, but that did not imply a licence to practise in that subject. It was felt that the resolution when it was passed did constitute a very real difficulty to the Society of Apothecaries; that it might mean annihilation. He had, however, very great sympathy for the Society, and he hoped it would find a way out of the difficulty, as it deserved well of the profession. The College of Physicians had claimed to give a licence in surgery, but they had since repudiated that action by the conjoint scheme, if, indeed, it ever was valid; it was never admitted as a licence in surgery except by the Poor Law Board. However, they had nothing to do with that. Mr. Simon's contention could not be proved valid by any existing document. The analogy of the Universities was misleading, as they did not give a licence, but an honour which carried a licence. To say that there were interests of bodies involved was a repetition of a scandal and an unjust scandal; there was no truth in the suspicion that they were actuated by unworthy motives.

Sir HENRY PITMAN said that he was only able to agree with one point in Mr. Simon's remarks, and that was that it was their duty to reply to the letter, and that it would be discourteous to postpone doing so. They certainly ought to send an answer. He took objection to Mr. Simon's statement that the College of Physicians only began to give a licence in surgery when the Poor Law Board applied to them. The power had been conferred upon them in the reign of Henry 8th on account of the cunning of the surgeons, who charged very high fees and did their patients very little good, and for many years their licentiates did practise surgery and dispense medicines; he supposed that they ceased to examine in surgery when the College of Surgeons obtained their charter. But it was to be remembered that omittance was no quittance, and so they resumed their examination in surgery, and applied to the Poor Law Board to recognise their licence in surgery. The Medical Act expressly used the words "licensed to practise medicine or surgery, or medicine and surgery," thus clearly recognising that a single qualification might cover both. The letter certainly ought to be answered, but they were not the proper body to determine the question; it was too delicate a matter for them to entertain the idea of being able to define the legal power of any of the licensing bodies. It was a purely legal question, and it was no part of their duties to interpret the value of qualifications. As to the rights of the matter, the College of Surgeons had added an examination in medicine, but they had not claimed, in consequence, to give a licence to practise medicine; it was open to the Society of Apothecaries to institute examinations in any subject they pleased, but that was very different from giving a right to give a licence.

Mr. COLLINS, referring to the Apothecaries' Hall in Ireland, said they had proved their claim to give a licence to practise medicine in the United Kingdom, they did not claim to give a licence in surgery. They had done this legally for at least three hundred years.

Mr. MACNAMARA thought that if they accepted either the motion or the amendment they would get into a false position. The motion was merely putting off the evil day, and he agreed with Sir Henry Pitman that they ought to send a courteous answer, declining to have anything to do with the matter; nothing would be gained by referring it to a committee: Dr. Heron Watson had already done all that a committee could possibly do. He strongly objected to Mr. Simon's proposal, it tended in the direction of constituting another authority for the purpose of conferring medical and surgical diplomas; it was contrary to their whole tendency, which had been to consolidate and not to multiply. He regretted that this consolidation had not already been carried out in Ireland as yet, but he hoped they would have a conjoint Board there one day. The contention that a medical society should confer a qualification in surgery was a step most seriously to be deprecated; it raised the question of competing bodies and seemed to convey an endorsement of the Society of Apothecaries,

He would like to meet it with a direct resolution that the Council felt a difficulty in recommending the Local Government Board to accept as a complete qualification that of any body not hitherto legally possessed of that right. The Colleges of Physicians and Surgeons had given up their right to give separate qualifications, and was the Apothecaries' Society now to have the right to give the same qualification by itself? If they granted it to that body, at the next meeting of the Council the College of Surgeons of Ireland would demand the same for itself.

Mr. TEALE moved the adjournment of the debate. The Council then adjourned.

FIFTH DAY.—SATURDAY, NOVEMBER 21ST, 1885.

*The Local Government Board and the Surgical Examination of the Apothecaries' Society — Elementary Mechanics—The Black List—The Curriculum of the Apothecaries' Hall in Ireland.*

MR. MARSHALL, in resuming the debate, said that he would rather not have referred at all to the subject of corporate interests, but, as allusion had been made to it, he could not pass it over altogether. They would all remember the attempt on the part of the seven bodies in England to unite—three Corporations and four Universities; it had dragged on a long time and had at last fallen through. In such a matter there must be opposed interests, and it was perfectly right for each of them to endeavour to protect the legitimate interests of the body to which they belonged. Long before the attempt to unite the Universities, there had been an attempt to unite the three Corporations, and before that an attempt to amalgamate the Colleges of Physicians and Surgeons. The attempt to unite the three Corporations fell through because of the desire of some to include the Universities. That did not look as if the College of Surgeons was anxious to exclude the Society of Apothecaries. After the failure of the larger conjoint scheme, great pressure was brought to bear upon them to effect a consolidation. They proceeded on an invitation from the College of Physicians to unite with that body; in the face of the previous failure, ought they to have tried to include the Society of Apothecaries? Ought the College of Surgeons to have rejected the invitation, was it not rather their duty to co-operate, both in the interests of the public and the profession? Would the conjunction of the Society of Apothecaries have added anything, either in the way of utility, stability, or dignity, to the two bodies combined? Could such a union have improved their curriculum or examinations? Would it have added to the strength, power, force, credit, judgment, or knowledge of the conjoint body? Would it have added to the strength of the double diploma? The answer to all these questions was that the union would have added nothing. It would have added to the expense to the student, as three sets of examiners would have had to be paid instead of two, and the student would not have benefited by the addition to his title. Speaking merely for the interests of the College of Surgeons, he contended that the junction with the College of Physicians was not entirely to their advantage; they ran the risk of losing a certain number of candidates who would have come to them for a surgical diploma from the Society of Apothecaries. Moreover, it was a much easier matter to arrange the union of two bodies than of three. Turning to the question more immediately before the Council, he held that they would be travelling out of the lines of their duty if they attempted to deal with a legal qualification. Only two qualifications were mentioned in the Act, and they clearly did exist. It was not for the Council to say what were qualifications and what were not; they could neither give nor take away a qualification, and they had better decline to give an opinion or even attempt to guide opinion on the point. In passing the resolution which had been so often alluded to, the Council never contemplated giving a claim to anybody to an extended qualification; he very much doubted whether the Society of Apothecaries could give a man a right to practise surgery. They required only such an amount of surgery

as was necessary to the practice of medicine. The analogy that Mr. Simon had drawn with the College of Physicians was altogether false and futile. Mr. Simon said that the cases of the two bodies were akin; that might mean a very wide separation: they certainly were not identical or like, or even similar. It was absurd to contend that modern medicine included surgery; the old use of physic did, but it did so no longer. He objected to the last clause in Mr. Simon's amendment in regard to the threat, as he did not believe they could carry it out; all that they could demand from the Society of Apothecaries was the most meagre and perfunctory examination in surgery. He had known many cases where licentiates of the Society were not allowed to recover fees in a court of law for treating a case of fracture or other surgical case.

Dr. HUMPHRY hoped that the Council would not diverge into all the matters to which Mr. Marshall had referred. The question asked them was perfectly simple, viz., was an L.S.A. entitled now to practise surgery as well as medicine? He reminded his hearers that in 1860 the Local Government Board issued regulations regarding the qualifications they required from those holding office under the Poor Law Board; they required a qualification in medicine and one in surgery; for the latter they announced that they would recognise the diploma of the College of Surgeons, for the former either the licence of the Society of Apothecaries or that of the College of Physicians. At a subsequent date the College of Physicians represented that they were entitled to give a licence in surgery as well as in medicine, and their claim was allowed. At a still later date the College of Surgeons had instituted an examination in medicine in connection with their diploma, but they had never claimed the right to give a licence to practise medicine, and they did not intend to do so. Now the Society of Apothecaries had added an examination in surgery, and then applied for recognition before the Local Government Board. The Local Government Board, not feeling clear on the matter, had consulted the legal advisers of the Crown, who had advised them to take the opinion of the Medical Council upon it; so that the position they were now in was whether they were to venture to interfere where the lawyers had been unwilling to give an opinion. The case of the Universities was somewhat different, for since the time of Queen Elizabeth the University of Cambridge had had the power to grant licences to practise surgery. But in all cases that had arisen since the Medical Act there had been required a special Act for the purpose. Surely it could not be contended that under the Medical Act medicine included surgery, for there were distinct references to the fact that qualifications in both were to be obtained from distinct bodies. The resolution which they had passed in the previous year did not mean that they would have a legal qualification in both subjects, and it would be a serious step for the Council to take to recognise a new qualification by a licensing body.

Dr. QUAIN said that the matter was very simple; a licentiate of the Apothecaries' Society when registered was a duly qualified medical practitioner. Last year the Council had expressed an opinion that he ought to prove his competency in surgery, but that did not make him legally qualified to practise surgery. He was a competent practitioner, and it was open to anyone to take him as such or not. The College of Surgeons had for years been flooding the country with very imperfect practitioners, men with a little knowledge of anatomy and surgery, and nothing else, but that was all at an end now, as they had joined with the College of Physicians.

Mr. COLLINS said a few words in defence of the Society of Apothecaries, which he said the College of Surgeons had intentionally tried to "boycott," as he was in a position to state positively. The Society was one of the most ancient medical corporations, and next to the College of Surgeons the largest constituency in England. It was quite ready to combine with the other bodies, but was not allowed to do so.

Dr. STRUTHERS observed that they had been condensing and strengthening the examinations, and Mr. Simon's amendment would undo it all; the bodies would all fly asunder again. He considered that Mr. Simon was introducing a new medical Bill by a side wind. He could not

see where the grievance of the Apothecaries' Society was; the resolution was an old one of the Council, and was not addressed to that Society in particular. He asked whether the Society had within itself the means of conducting an examination in surgery, and proceeded to quote an unfavourable report on the examination in Anatomy at the visitation. He had no sympathy whatever with the Society on account of its behaviour towards himself and other Scotchmen before the passing of the Medical Act.

Dr. CHAMBERS said that they had heard a great deal about the interests of the bodies in the course of the debate, but very little about the interests of the public. The Universities had from very early times given a licence to practise surgery, and he had no doubt this was a charitable institution for the benefit of the poor, as it was especially stipulated that they were to charge small fees. Lately, this demand of the public had been supplied by the Society of Apothecaries, who had provided men to practise amongst the poor, men who did not mind doing counter-work. The other licensing bodies could not supply in sufficient numbers attendants on the poor in the same way, and, if the Apothecaries' Company was prevented in the future from doing this, some other body would have to be instituted to carry on the work. What was wanted by the Local Government Board was attendance upon the poor, and the Society of Apothecaries was best qualified to supply men to fill such posts.

Dr. HERON WATSON said that Mr. Simon had made several interesting abstract propositions in his amendment, to which, taken by themselves, there was perhaps not much objection, but in giving such an answer to a definite question they ran the risk of creating a dangerous precedent. Mr. Simon had said that it was monstrous to delay nearly a year before giving an answer to a Government department, but there was no reason why they should not defer their answer. On a previous occasion, in the early days of the Council, when the matter had been referred to a committee, nearly two years had been allowed to elapse before an answer was sent. The amendment did not satisfy any of the requirements; they had not had official information that the examination in surgery had been established, and it had not been visited. Then he objected to the proposal to state "that they were not aware of any illegality . . . and saw no legal reason why;" *i.e.*, they were to state that they regarded the Society of Apothecaries as having a legal right to give a qualification in medicine and surgery. The case was not akin to that of the College of Physicians, who had a charter. It might be said that it was not the Society who brought this forward, but only one of their licentiates. They were being asked to extend the legal rights of the Society; he had much sympathy with it, but this they were not entitled to do. He considered that the best plan was to adopt the course taken on a former similar occasion and refer the matter to a committee, and write in the meantime to the Local Government Board to that effect.

The amendment was then put, and lost by 3 votes against 15.

Mr. MACNAMARA then said that he could not agree with Dr. Watson as to the desirability of this being referred to a committee, he did not see what a committee could possibly find to do. He agreed that some answer ought to be sent, and he suggested the following by way of an amendment:—"That this Council, in accordance with widely diffused public and professional feeling, having devoted its best attention to consolidating professional examinations, feel a difficulty in recommending the Local Government Board to accept as a complete qualification in medicine and surgery the licence of any single corporation not hitherto legally possessed of such right." He thought that he had treated the Society of Apothecaries with great consideration, as he had placed them on the same level as his own college. He held that it would be exceedingly wrong of them to let the Local Government Board believe that they adopted the examination when they had not visited it; not even had the curriculum as to surgery been stated to them; in fact, they did not know whether the Society had followed out their recommendations or not. When they did know all these things it would be time enough to take the matter into their consideration.

Mr. COLLINS seconded the amendment.

Dr. AQUILA SMITH said that he accepted the principle of the amendment, but he took objection to the words "feel a difficulty," they ought to say "will not" or "cannot."

Dr. HUMPHRY also took objection to the wording; they ought not to commit themselves to a positive statement as to what a body possessed a legal right to do.

Mr. SIMON contended that this was more ambiguous than his own amendment; it had been his contention throughout that the Society had this right claimed, but that it was a matter which could be tried elsewhere. He was primarily anxious that some answer should be given, and the amendment did not help matters forward; it implied a legal opinion which they were not prepared to give. It was for the Society of Apothecaries to go before the Local Government Board and state their view of the facts.

Mr. MACNAMARA'S amendment was then put and lost.

Some conversation then took place as to whether Mr. Teale and Dr. Struthers, who had each given notice of amendments, should be allowed to fuse theirs into one. This having been done, Mr. Teale said that the matter seemed to involve two distinct points, one a legal one as to the meaning of the word qualification, and the legal power of the Society of Apothecaries to enlarge their licence; and to this, in his amendment, the Council said that they could not express an opinion. They did not know the nature of the surgical examination, and so his amendment proposed merely to state the fact that an examination in surgery had been added, but they would not be justified in adding a shade of expression of opinion as to it without further visitation, especially in view of the unfavourable opinion expressed in the Visitors' report as to the clinical examination.

Dr. STRUTHERS seconded the amendment.

Dr. HERON WATSON objected to anything being said about the examination in surgery by the Council: they had no proof that it was a competent examination, such as would suit their requirements. The Council ought not to be rash in this matter: they should either refer the subject to a committee or decline to have anything to do with it.

After some remarks by Mr. BRADFORD and Dr. SCOTT ORR, the amendment was by leave withdrawn, and Dr. STORRAR proposed an amendment to the effect that the Council begged to inform the Local Government Board that hitherto the certificate granted by the Society of Apothecaries had only conveyed a licence in medicine, and that the fresh point raised by the Board involved matter upon which the Council respectfully declined to give an opinion. This was agreed to, and on being put as a substantive motion was also agreed to.

Dr. STRUTHERS had a motion upon the programme on the subject of the visitations, but asked leave to withdraw it, the PRESIDENT stating at the same time that the report on the visitation of the Universities would be ready in a few weeks, and would be sent confidentially to the members of the Council before the next meeting.

Mr. MACNAMARA moved the following resolution, "That the operation of Resolution 8, passed on the 15th October, 1884, *viz.*, 'Elementary Mechanics to be passed before registration,' be suspended for the present, and that it be referred to the several Branch Councils to enquire and report to the General Medical Council at its next meeting upon the feasibility of enforcing at the present time this regulation in the several divisions of the kingdom." He said that both in Ireland and Scotland there had been felt to be a difficulty about this matter. The Executive Committee had, in direct contravention of the resolution of the General Council, suspended the resolution, but the Irish Branch Council had refused to follow the guiding of the Executive Committee, and had preferred to abide by the decision of the Council itself. The Scottish Branch Council had deliberately disobeyed the General Council. The matter ought to have been first submitted to the Branch Councils, and these difficulties could have been obviated. His college had passed a resolution to the effect that it was impossible to carry it out, for the simple reason that the subject was not taught in the elementary schools in Ireland, and the University of Dublin, as was well known, did not intend to obey the Council in this matter.

Dr. HERON WATSON seconded the motion, though he had

voted for the resolution on the former occasion, but in Scotland the preliminary examination was not held till the middle of October, whereas registration was required to take place by the first of the month, thus making it impossible for the student to have previously passed in elementary mechanics.

Dr. FERGUS said the subject was by no means a new one, ample warning had been given; there was no subject which had so often been before them, or on which they were so unanimous, and their conclusions had not been arrived at suddenly. After referring to the former resolutions, he asked, if a student was allowed to register without having passed in this subject, how were they to obtain any guarantee afterwards that he did so.

Dr. STORRAR deprecated dealing with the subject at all at so late a period of the session; they had no time to discuss it, and it had better be deferred till the next session. He strongly objected to the idea of striking out a subject because it was said that it could not be taught; it was the business of the examining bodies to find some means of teaching it.

Mr. TEALE said that the Executive Committee had provided a temporary method of meeting the difficulty by allowing a student to commence his studies without registration, and when he had passed in mechanics his registration could be ante-dated.

Mr. SIMON protested against legislating on this subject any more, they had considered it again and again; they could not suspend this subject without embarrassing their whole scheme of education.

Mr. MACNAMARA said that the Executive Committee had already thrown doubt on the action of the General Medical Council. He wanted to impress upon them the impossibility of securing any instruction in this subject in Ireland, except in the four chief centres. Dr. Fergus seemed to think that the Council could reform the schools in Ireland. His proposition seemed to him a most reasonable one. If they agreed to the ante-dating scheme, they secured a thorough education; if they did not, they could only get cramming.

Dr. HUMPHRY said that, although he had been the mover of the resolution on the former occasion, yet he thought they ought to be very cautious; he had reason to know that certain important authorities were beginning to recoil at the annoyances imposed upon them by the Council. It was no doubt a great difficulty; at present mechanics were not taught in schools, but he hoped they soon would be.

After a few further observations, Mr. Macnamara's motion was agreed to, the words "be suspended for the present, and that it" being omitted, so that things are left just as they were before this session, and the *ad interim* suspension of the Executive Committee is still in force.

Mr. COLLINS then moved the following resolution, which was carried after a few minor observations had been made, "That names which, after erasure from the Medical Register, have at some subsequent time been by order of the Council restored to the Register, and also the names of those of whose death sufficient evidence has been obtained, be not in future included in the Erasure Lists issued by the Council, and that the title of future Erasure Lists be adapted to this intention."

Mr. Collins then moved to lay a copy of the curriculum of the Apothecaries' Hall on the table, and that it be entered in the minutes with a view to show how that body had endeavoured to give effect to the wishes of the Council. But on its being pointed out to him that it would be inconvenient if all the other bodies were to do the same, and that it was quite sufficient if a copy of the regulations was accessible in the office, he withdrew his motion.

This terminated the business of the Session.

**CHARITABLE BEQUESTS.**—Miss Margaret Strachan, of Clematis Cottage, Broughty Ferry, has bequeathed legacies to the following local institutions:—To the Dundee Royal Infirmary, 1,500*l.*; Convalescent Hospital, 1,000*l.*; Deaf and Dumb Institution, 500*l.*; Institution for the Blind, 500*l.*; the Brechin Infirmary, 1,500*l.*; and the Forfar Infirmary, 1,000*l.*

## MEDICAL NEWS.

### THE DUBLIN HOSPITALS COMMISSION.

THE Dublin Hospitals Commission have held several further meetings for the reception of evidence. On Tuesday, the 10th instant, the Rotunda Lying-in Hospital engaged the attention of the Members of the Commission, and it was put in evidence that the hospital was founded in 1745 for the relief of poor lying-in women in Dublin. It is governed by a Board limited to sixty members, of whom eleven are ex-officio, and the administration is conducted by a Board of Directors. The hospital receives an annual grant of 700*l.* from the Government, which was originally given because the institution had constantly received grants from the old Irish Parliament when in need of funds. After 22,500*l.* had been thus contributed, the Commission of 1854 recommended the continuance of the grant, as the teaching given in the hospital was considered of national importance. The average daily attendance of students during the past three years has been from 50 to 60. During the twelve months ended the 31st March, 1885, the total number of intern patients was 1,774 and of extern 10,869. The professional staff comprises a consulting physician and a consulting surgeon, non-resident, and a Master, with two assistant physicians and a clinical clerk, all resident. The total income last year was 4,288*l.* 3*s.* 8*d.*, and the total expenditure 4,326*l.* 3*s.* 11*d.* The gross average annual cost per bed was 84*l.* 16*s.* 6*d.*, which included 18*l.* 14*s.* 4*d.*, cost of maintenance, 36*l.* 19*s.* 8*d.*, cost of establishment, and 5*l.* 4*s.* 4*d.*, cost of management. The witnesses examined were Dr. Arthur Vernon Macan, the present Master of the hospital, who gave his evidence in a manly, straightforward, manner which commanded general admiration, and Mr. Joseph Mullen, the Secretary to the hospital.

At the next sitting of the Commission, on Saturday, the 14th instant, evidence was received regarding the Westmoreland Government Lock Hospital. The hospital was founded in 1872, during the Viceroyalty of the then Earl of Westmoreland, and is governed by a Board of Governors. The Members of the Board are appointed by the Lord Lieutenant for the time being, and they hold office for life. The hospital receives an annual grant of 2,600*l.* of the sum annually voted for "Hospitals and Infirmarys, Ireland" in the Civil Service Estimates, to which has recently been added a grant of 250*l.* from the War Department for support of ten extra beds at 25*l.* each, the War Office undertaking to pay 25*l.* for every extra bed occupied above ten, but not exceeding 20 extra beds in all, or 500*l.* No specially organised system of nursing has been adopted. Up to 80 beds can be maintained with the funds provided by the ordinary Government grant and the grant of 25*l.* per bed occupied at the expense of the War Office. There is space for 100 or 150 beds if there were funds to keep them up. During twelve months ending 31st March, 1885, the number of patients treated as extern patients, including dispensary, accident, and midwifery cases, was 828. The professional staff consists of one resident surgeon, apothecary, and accoucheur, and two visiting surgeons. All the members of the staff received remuneration from the funds of the hospital—two visiting surgeons 120*l.* and 110*l.* respectively as salary per annum; one resident surgeon 100*l.* salary and 1*l.* 1*s.* for each midwifery case. The witnesses examined were Mr. Donnelly, the resident surgeon, Dr. Henry Fitzgibbon, one of the visiting surgeons, and Mr. Edward Fottrell, one of the governors. Mr. Donnelly expressed himself as unfavourable to the introduction of clinical teaching in the hospital, while Dr.:

Fitzgibbon considered that such teaching would be most useful to senior students with proper safeguards and restrictions. Evidence was then gone into regarding the Hospital for Incurables at Donnybrook, founded in 1743. Government grant, 250*l.* Not being a clinical hospital, there are no students attending the hospital. The number of intern patients treated during the twelve months ending 31st March last was 216 incurable patients, who had been elected for life by the vote of the governors. Mr. Wharton, the Visiting Surgeon, Mr. David Drummond, J.P., Chairman of the Board of Governors, and Mr. William Watson, the Honorary Treasurer, were the witnesses examined. On Monday last evidence was received relative to St. Mark's Ophthalmic Hospital, founded by the late Sir William R. Wilde in 1844, and also to the Coombe Lying-in Hospital. Mr. John B. Story, Sir James Mackay, and Mr. Hughes, the Registrar, were examined on behalf of the former institution, of the position and prospects of which they gave a very good account.

At the sitting of the Commissioners on Tuesday, November 17th, evidence was first given with reference to the City of Dublin Hospital. It was stated that the hospital is utilised for purposes of medical education, the daily average number of students actually attending during the last three years being 76. The professional staff comprises two visiting physicians, three visiting surgeons, one gynæcologist, one ophthalmologist, two consulting physicians, one consulting surgeon, a resident consulting house surgeon, two surgical residents, and one medical. The total income last year was 4,741*l.* 15*s.* 8*d.*, and the expenditure 4,240*l.* 8*s.* 3*d.* The average daily number of beds occupied throughout the year was 70, at a gross average cost of 60*l.* 11*s.* 6*d.* Mr. W. I. Wheeler and Mr. H. G. Croly, surgeons to the hospital, were among the witnesses examined on its behalf. The next hospital with reference to which evidence was given was the Mater Misericordiæ, founded in 1861 by Sisters of Mercy, who commenced the work by a donation of 10,000*l.* out of their own funds. The hospital does not receive any grant from Parliament. Its total income last year was 8,238*l.* 2*s.* 5*d.*, and the total expenditure 7,981*l.* 6*s.* 5*d.* The average daily number of beds occupied throughout the year was 160, the gross average cost of each being 49*l.* 17*s.* 8*d.* During the year 2,722 intern patients and 23,000 extern patients were relieved. The professional staff comprise three clinical physicians, three surgeons, one assistant physician, one assistant surgeon, one obstetric surgeon, one dental surgeon, and six resident pupils. Thirty-four beds are on an average under the control of each of the three physicians, 30 under each of the three surgeons, and 10 under the obstetric surgeon. Dr. C. J. Nixon, senior physician, and Mr. P. Hayes, one of the surgeons, were examined on behalf of this institution.

The Commission again met on Saturday, November 21st, when evidence was first received regarding the Jervis-street Hospital, founded in 1718 by six surgeons practising in Dublin. The annual grant from Parliament is 50*l.* Irish, a continuance of which is claimed, as the funds of the hospitals are insufficient to maintain the patients who daily seek admission. The hospital is used for the purposes of medical education, the average number of students on the books during the last three years being twenty-five. This does not represent the attendance of pupils in ordinary years, as the re-construction of the hospital has necessarily greatly diminished the number. The nursing is undertaken by sisters of mercy, having under their control ward-maids. The average number of beds in daily use is 25. The number of intern patients during the previous twelve months was 622, extern about 20,000. No member of the visiting staff

receives any remuneration. Mr. Arthur Chance, one of the surgeons, and Honorary Secretary to the Medical Board, and Dr. S. M. MacSwiney, were the principal witnesses examined.

Evidence was then gone into regarding the National Eye and Ear Infirmary, Molesworth Street, Dublin, founded in 1814. It receives no Government grant. The total number of beds is 28, and the average daily number of beds in use 22.61. Both Dr. Fitzgerald and Dr. Swanzy tendered evidence in favour of an amalgamation with St. Mark's Ophthalmic Hospital, the surgeons of which institution, however, did not wish for amalgamation on the ground that there was a healthy and useful competition between the two hospitals. The Commission then received evidence regarding the Dublin Orthopædic Hospital.

The sittings of the Commission were resumed on Monday, November 23rd, when evidence was received respecting Sir Patrick Dun's Hospital, the hospital attached to the School of Physic in Ireland. This hospital, which receives no Government grant, was specially founded for the purpose of medical education in 1800. The average number of students on the books is 86, and there are 80 beds. During the past twelve months there were 912 intern and 9,234 extern patients; and the total income amounted to 4,309*l.* and the expenditure to 5,083*l.*, there being a balance against the institution at the end of the year of 773*l.* 14*s.* 2*d.* The gross average annual cost per head was 73*l.* 13*s.* 6*d.* The Rev. Samuel Haughton, M.D., F.R.S., Senior Governor of the Hospital, gave some very interesting evidence in his own amusing style. He thought that there should be two central hospitals for fever—one on the north, the other on the south side of the city. Dr. E. H. Bennett, Senior Surgeon, and Dr. J. M. Purser, Senior Physician, were also examined, and expressed themselves in favour of having large hospitals in lieu of numerous small hospitals, as at present.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN extra-ordinary meeting of the Council was held on Tuesday last, November 24th. The minutes of the last meeting having been read and confirmed, a report from the President and Vice-Presidents, dealing with the resolutions passed at the late meeting of Fellows and Members, was presented and confirmed. The report concluded with the following Statement, which had been prepared by the President and Vice-Presidents, in reference to those resolutions, and in explanation of the views of the Council.

"With reference to the first resolution of the meeting,—The Council have carefully considered the question which some Members of the College have recently raised, and it does not appear to the Council that the main argument which these Members advance to support their claim, that all the Members should be entitled to vote in the election of Members of the Council, is a valid one. It is founded on the analogy which is assumed to exist between the payment of a fee for examination and the diploma and the payment of taxes. The statement is in effect this: that, inasmuch as the payment of taxes by an individual confers on him the right to a vote in the choice of a representative, so the fee which is paid by a candidate to the College, when he receives from it a diploma which gives him the legal right to practise, also carries with it a right to a vote in the election of the Council. The Council are of opinion that the two cases are not alike. The only advantage which the taxpayer secures by the payment of taxes is derived from the outlay of the money which is thus raised, and it is therefore reasonable that he should have some voice in the manner in which it is spent. But for the fee which a candidate pays in becoming a Member of the College, he receives the full value in his diploma. Nay, it must be said that in his diploma he receives far more than

the equivalent of his money in the rights, privileges, and immunities which he thereby acquires. Moreover, there can be no doubt that the Membership of the College carries with it, beyond the right to practise, professional and social advantages which are directly derived from the College itself. The argument that the Members of the College, being more numerous than the Fellows, are consequently entitled to vote in the election of the Council, is to be met by referring to the charter of 1843, by which a constituency of Fellows only was provided. The Council would point out (1) that Members of the College, prior to the date of that charter, are eligible for election as Fellows; (2) that Members of a later date can become Fellows by passing the required examination; and (3) that the Council already possess the power of electing annually two eminent Members of twenty years' standing to the Fellowship—a power which has been, and may at any time be, exercised. The College of Surgeons has of late been often spoken of as if it were only a corporation, and the Council had no responsibility or relation except to its Fellows and Members. It is a corporation, but it is something more; and the Council are not only the representatives of the Fellows, and have not only responsibilities to the Fellows and Members, but the College holds an important relation, and its Council have grave responsibilities, to the whole profession, the general public, and the State. The Council cannot regard the Members of the College as mere taxpayers to a corporation, and they cannot discover in this view, which appears to them inadequate, any support to the claim which is now urged by some Members. Moreover, this claim could not be conceded without serious interference with the privileges of the Fellows. The exclusive rights of electing Members of the Council, and of being eligible for a seat on the Council, are among the chief advantages which the College itself confers on the Fellowship. It appears to the Council neither wise on behalf of the College, nor just to the Fellows themselves, to deprive them of this distinction. The Council passed the resolution unanimously, as they are strongly of opinion, not only that the existing rights of the Fellows should be preserved, but that their rank in the College of Surgeons should be fully recognised; for they are anxious, in the highest interest of surgical education, to encourage Members of the College to obtain the Fellowship.

"In reply to the second resolution of the meeting, the Council regret that they cannot assent to the terms of the second resolution of the Fellows and Members. In their opinion the conduct of the business of the College would be liable to serious hindrance if, for instance, no change in a by-law or ordinance could be effected without the consent of a general meeting of the Fellows and Members. This would often create inconvenient delay, and, in the event of any great difference of opinion between the meeting of Fellows and Members and the Council, lead to complete obstruction. For the Council cannot admit that the Fellows and Members in general can be such competent judges of what is required, in this respect, for the welfare of the College as the Council themselves, who, from their opportunities and experience of the business of the College, must be much better qualified to consider such questions when they arise. Moreover, it is certain that any general meeting convened for the purpose would consist only of a small fraction of the whole body of Fellows and Members, and neither by this, nor by any other means which could be devised, would the Council be able to obtain satisfactory information as to the opinion of the majority of the Fellows and Members. It may be added that no by-laws can be made and ordained or abrogated and annulled without recourse to a most deliberate process (see Section III. of the By-Laws), involving several references to a committee, not less than four meetings of the Council, consultation with the legal advisers of the College, submission of the formulæ to the Secretary of State, and, under recent enactment, in special cases, to the Privy Council for approval, and finally, ratification by two of Her Majesty's Judges. With the larger questions which more rarely arise, such as those which concern the constitution of the College, the case would be different. On these questions the Council will always be glad to have an opportunity, so far as practicable, of consulting the Fellows and Members."

The terms of the advertisement to be issued, convening a meeting of the Fellows and Members (at which the foregoing statement will be presented) were then discussed, and the following agreed to:—"To receive a statement from the Council in reference to the Resolutions carried at the meeting of Fellows and Members on October 29th ultimo."

The question of granting the title of Doctor was then entered upon. The following Report of the Committee of Delegates of the two Colleges was received, and ordered to be entered on the Minutes, as also the Resolution of the Royal College of Physicians, adopted by them on October 22nd (that it is desirable that persons examined by the R.C.P. Lond. and the R.C.S. Eng. conjointly, and found duly qualified either by the ordinary or by an additional examination, should have a degree in medicine and surgery conferred on them). "The Committee have to report that they have fully considered the question referred to them, viz., the advisability and practicability of granting the title of Doctor to persons who have obtained the diplomas of the two Colleges. They have also considered the memorial, signed by more than 600 teachers, practitioners, and students in medicine, and referred to them, advocating the amalgamation of the two Colleges into one Royal College of Medicine, for the purpose of granting Degrees in Medicine and Surgery. After careful deliberation the Committee have unanimously agreed to the following Resolutions as expressive of their opinion on the subject:—i. That it is desirable that persons examined by the Royal College of Physicians of London and the Royal College of Surgeons of England conjointly, and found duly qualified, should, in virtue of that examination, have a degree in Medicine and Surgery conferred upon them. ii. That the curriculum of study and the examinations to be undergone for the Licence of the Royal College of Physicians of London and the Diploma of the Royal College of Surgeons of England are equal to those required by most of the Universities for degrees in Medicine and Surgery. In conclusion, the Committee are of opinion that, should the two Colleges approve the foregoing Resolutions, means could be found for giving effect to them."

Thereon came a motion by Mr. Marshall (seconded by Mr. Durham) to consider and report to the Council whether it be desirable that persons who have become qualified under the conjoint examination of the two Colleges should after an additional examination have conferred upon them, either by the two Colleges or by a graduating body in London (of which the two Colleges shall form an essential part), a degree in Medicine and, subject to further consideration and ultimate approval of the Council, a degree in Surgery also. To this an amendment was moved by Mr. Smith, and seconded by Mr. Macnamara, That the Report be approved, adopted, and entered on the Minutes, which was lost. Sir Joseph Lister then moved, and Sir Spencer Wells seconded, a further amendment, which was carried (and also as a substantive motion): "That it be referred to a Committee to consider and report to the Council on the question whether it is desirable, and if so under what conditions, that degrees in Medicine and Surgery should be given by the two Colleges in combination." The following Committee was then appointed:—Sir James Paget, Mr. Marshall, Mr. Hutchinson, Sir Joseph Lister, Mr. Hulke, Mr. Durham, Mr. Macnamara. Mr. Hutchinson's resolution concerning the Fellowship was deferred to the next ordinary meeting of the Council on December 10th. Mr. Macnamara gave notice of the following motion: "That it be referred to the Court of Examiners to consider and report to the Council whether any, and if so what, measures would best be calculated to extend the scope of the examinations for the M.R.C.S. in Clinical Surgery."

The Council then adjourned.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology for the Diploma of Fellow at a meeting of the Board of Examiners on the 23rd instant, and when eligible will be admitted to the Pass Examination, viz.:—

David Philip James, St. Bartholomew's Hospital; Percy Wm. McDowall Howse, Henry Cropley, William Henry Kelson, Lon-

don Hospital; John McLachlan, Edinburgh University; Ernest Kenneth Campbell, Edinburgh, St. Bartholomew's, and Dublin.

Passed in Anatomy and Physiology on the 24th inst. :

John Lloyd Roberts, Guy's Hospital; James George Ernest Colby, Oxford and St. Bartholomew's; Hugh Cameron Kidd and Knankai Totsuka, St. Thomas's Hospital; Ernest Charles Arnold, St. George's Hospital; John Edward Barnett, Charing Cross Hospital; Alfredo Anatonnes Kantback, Liverpool Infirmary; James Edwin Thompson, Manchester; Cecil John Davenport, St. Bartholomew's Hospital.

29 candidates presented themselves for examination, of whom 14 were referred for 6 months.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Thursday, November 19th, 1885 :—

Charles Delamark Freeman, 218, Marylebone Road, N.W.; Percy John Rendall, 20, Ladbroke Square, W.

The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise :—

John Augustus Bradbury, Claude Villa, Love Walk, Denmark Hill.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the usual monthly examinations for the Licences of the College, held on Monday, November 9th, 1885, and following days, the undermentioned candidates were successful :—

*For the Licence to practise Medicine—*

Alfred Brown, Horwick, Lancashire; John Paul Cavenagh, Dublin; William Frazer, M.D. Univ. Dubl., Bournemouth; Cathleen Honoria Graham, Cheltenham; James Henry Halpin, Wicklow; Godfrey William Hambleton, Forest Hill; Samuel Henry Nazeby Harrington, Liverpool; Cyril George Hutchinson, Osmarton Rectory, by Derby; Michael Colville Kennedy, Dublin; William Archer Mahon, Clonskeagh, Dublin; John L'Estrange McGrane, Banagher, King's Co., Guy Percival L'Estrange Nugent, M.B. Univ. Dubl., Dublin; Henry Pollen, M.B. Univ. Dubl., Gisborne, New Zealand; John Nalton Robson, Edinburgh; Robert John Sheperd, Dublin; Robert Stopford, Wigan, Lancashire; Ernest Hastings Tweedy, Dublin; Catherine Jane Urquhart, Grange, Edinburgh; Hugh Whelan, Limerick.

*For the License to practise Midwifery—*

Alfred Brown, Cathleen Honoria Graham, James Henry Halpin, Samuel Henry Nazeby Harrington, Michael Colville Kennedy, Robert Stopford, Robert Thomson, M.D., R.U.I., Bangor, Co. Down, Ernest Hastings Tweedy, Catherine Jane Urquhart.

At a special Examination for the License to practise Midwifery, held on Wednesday, November 4th, the following candidate was successful :—

Thomas Walton Dwyer, M.D., R.U.I., The Ovens, Co. Cork.

**THE CITY OF DUBLIN HOSPITAL.**—The financial exigencies of this Institution have rendered it imperative on the Board to issue an urgent appeal for public aid. It states that "the applications for admission are so numerous that 80 beds at least ought to be kept up; but, if this appeal does not bring in the required amount, the directors will reluctantly be obliged to reduce the number to 50, or probably a lesser number, and a corresponding reduction will be made in the amount of help that would otherwise have been afforded to our poor brothers and sisters in their distress, many of whose lives have been saved by the skill of the medical and surgical staff and the excellent system of nursing the hospital affords, besides aids and comforts to many more than it does if the public will only supply it with the funds to do so." While the management has, as much as possible, economised the expenses, the directors state that the annual yearly expenditure has been in excess of the regular income by upwards of 500*l.*, and, but for legacies and other exceptional receipts (not come to hand this year), they must have reduced the number of beds.

**METROPOLITAN ASYLUMS BOARD.**—At the last meeting of the Board it was stated that the returns from the fever asylums showed that 58 acute cases had been received in the fortnight, as against 71 in the previous fortnight; four had died, and 57 had been discharged, leaving 346 cases under treatment, as against 339 a fortnight ago. Of the whole number, 296 were cases of scarlet fever. The two wards of 30 beds each, of the North-Western Asylum,

lately used for small-pox cases, had been disinfected, cleansed, and painted, and were now available for fever cases. With respect to small-pox, 28 acute cases had been received from the parishes and unions, as against 32 in the previous period. Two had died, as against six in the previous period, and 44 had been discharged recovered, leaving 81 under treatment, as against 93 in the previous fortnight, and 80 of these were in the hospital ships, the others being in the South-Eastern Asylum.

**ST. THOMAS'S HOSPITAL APPOINTMENTS.**—The following gentlemen have been selected as House Officers from Tuesday, 1st December :—Resident House Physicians, J. S. Hutton, L.R.C.P., M.R.C.S., L.S.A., E. D. Ritchie, M.R.C.S., L.S.A.; Non-Resident House Physician, F. M. Haig, M.R.C.S., L.S.A.; Assistant House Physician, F. D. Crowdy, M.B. Oxon., M.R.C.S., L.S.A.; House Surgeons, R. Lawson, M.R.C.S., L.S.A. (Extn.), B. Relton, M.R.C.S., L.S.A. (Extn.); Assistant House Surgeon, Cameron Kidd, L.R.C.P., M.R.C.S.; Resident Accoucheur, H. H. Lankester, M.B., M.R.C.S., L.S.A. Lond.; Ophthalmic Clinical Assistant, G. D. Johnston, L.R.C.P., M.R.C.S. (Extn.); Clinical Assistant in the Skin Department, A. A. Brockatt, L.R.C.P., M.R.C.S.; Clinical Assistant in the Throat Department, S. Plowman, L.R.C.P., M.R.C.S., L.S.A. (Extn.); Clinical Assistant in the Ear Department, A. E. Godfrey, L.R.C.P., M.R.C.S.

**HOSPITAL SATURDAY FUND.**—The Board of Delegates met on Saturday, when Mr. R. Frewer, the secretary, reported that the workshop and street collections combined then amounted to 10,700*l.*, which was slightly in excess of the entire sum realised last year. After payment of all expenses, 9,500*l.* was divisible among the hospitals, dispensaries, convalescent homes, and surgical appliance societies of the metropolis, being 500*l.* more than was awarded in 1884. The distribution committee reported, concerning complaints which had been preferred as to the nursing staff of University College Hospital being limited to one particular religious sect, and other matters, that they had instituted a thorough enquiry into the allegations made. The result was (1) they had no reason to doubt the efficiency of the nursing staff; (2) they found that the expense of that staff was not greater than that at other metropolitan general hospitals; (3) that persons wishing to be taught nursing at University College Hospital were not subjected to religious tests. Hence the right of this hospital to participate in the awards of the fund was not in any way affected by the result of the committee's enquiry.

**THE LATE SURGEON-MAJOR WOODROFFE.**—We have to record the death of Surgeon-Major Charles William Woodroffe, A.M.D. He entered the service in 1851, being appointed Assistant-Surgeon to the 13th Light Infantry (Prince Albert's), and in 1858 was promoted Surgeon to the 2nd Battalion 1st Foot (Royal Scots), having been previously employed on the staff at the Ionian Islands. Afterwards, as Surgeon of the 88th Royal Irish Fusiliers in 1866, he was subsequently engaged on the staff at Cork and Dublin. He served in China from 1858 to 1861 (medal and two clasps for Taku Forts and Peking), and retired in 1870.

**ANONYMOUS CHARITY.**—A mysterious package was on Thursday night handed to the Secretary of the Swansea Hospital. On being opened it was found to contain 500*l.* Two years ago a cheque for 1,150*l.*, and last year a cheque for 1,000*l.*, were given in the same mysterious manner. All attempts to ascertain the name of the donor have hitherto been futile.

**CHARITABLE BEQUESTS.**—Mr. Abraham Altham, late of Burnley, Lancashire, bequeaths 500*l.* towards erecting a children's ward to the Victoria Hospital, Burnley, and 500*l.* to the endowment fund of the said hospital.

**A DRAMATIC RECITAL** will be given on Saturday, Dec. 12th, at the Steinway Hall, by Mrs. Newton Phillips, in aid of the funds of the Samaritan Free Hospital.

**UNIVERSITY MEDICAL STAFF CORPS.**—On Nov. 18th a well-attended meeting of medical students was held in the surgery class-room of the University of Edinburgh, to hear an address from Surgeon-Major Evatt, of the Army Medical

Department. Professor Annandale presided, and was accompanied by the Lord Advocate, Professor Chiene, and Surgeon-Commandant Cantlie of the London Volunteer Medical Staff Corps. Each student was supplied with a plan of an army in the field, and the various arrangements for the treatment of wounded were explained by the lecturer, who referred to improvements which had been effected in this direction since the time of the Crimean War. The present army medical service, he said, consisted of only 800 men, and what was wanted was a proper Red Cross organisation. In London there were 366 medical students under the command of Dr. Cantlie, and if the civil doctors would take up this question of army hospital administration it would, he thought, be for the interest of England. If they had ambulance corps attached to all the Volunteer corps they would get more men to volunteer their services in time of war. Dr. Cantlie, in the course of some remarks, said the Volunteer army in England was at present almost a sham, because it had no medical service. The Volunteer doctor was an absolute sham. It was just as noble to carry a stretcher as to carry a rifle. It was probable the Government would allow two companies to Edinburgh University some time in spring, and perhaps Aberdeen and Glasgow would supply the other two companies of sixty men each. The Lord Advocate was of opinion that what they wanted was an arrangement by which Volunteers could carry out an engagement in time of peace very much as they would do in time of war. If such a company as had been referred to was formed in the University and attached to his brigade he should be glad to lend them the necessary apparatus. On the following day Surgeon-Major Evatt and Surgeon-Commandant Cantlie addressed a meeting of students in the surgery class-room, Marischal College, Aberdeen, in connection with the proposal to form a branch of the Volunteer Medical Staff Corps. Professor Alexander Ogston presided. The proposal was taken up by the students with great enthusiasm.

**SANITARY INSTITUTE.**—The Sanitary Institute has just completed the preparation of a volume which will be of great interest to the statistical world, containing selections from the reports and writings of the late Dr. W. Farr. The selection of the papers and reports and the editing of this work have been undertaken by Mr. Noel A. Humphreys, of the Registrar-General's office. The volume consists of 550 pages, and is divided into six parts. Part (1) Population; (2) Marriage; (3) Births; (4) Deaths; (5) Life Tables; (6) Miscellaneous. It has long been the source of much regret among students of vital statistics and others practically interested in that branch of sanitary science that from the form and manner of the publication of Dr. Farr's valuable papers on statistics they have not been generally available, being scattered over a long series of blue books and other reports. The object of the Institute in publishing the selection is to give those interested in the subject a ready means of studying the valuable writings and tables of that eminent statistician.

**THE CHOLERA IN FRANCE IN 1884.**—From a document issued by the Sanitary Bureau of the Ministry of Commerce it appears that the cholera epidemic of 1884, commencing 30th June in the department of the Var, ceased 10th January, 1885, in the department of Vendée, having traversed thirty departments and attacked 477 communes, and giving rise to a mortality of 7,820 deaths. Moreover, there were 800 deaths from the disease in the province of Constantine, in Algeria, between 19th September and 8th of January. The epidemic of 1834, having produced only 7,820 deaths in France, was a benign one compared with that of 1832 with its 102,735 deaths, that of 1849 with 100,661 deaths, and that of 1854 with 143,468 deaths. No returns of the deaths from the epidemic of 1866 have been published. If the epidemics of 1832 and 1849 have made a much stronger impression than that of 1854, which is much less spoken of, this arises from the fact that the first two epidemics were chiefly manifested in the towns, while that of 1854 principally ravaged the rural populations.—*Journal de la Société de Statistique*, November.

**THE LATE PROFESSOR HAESER.**—The *Berliner Klinische Wochenschrift* (September 23th), speaking of the death of

Professor Haeser, the senior among the Medical Faculty at Breslau, observes that his importance in relation to the study of the history of Medicine is now well demonstrated by the impossibility of finding a suitable occupant for the chair which his death has rendered vacant. With him disappears the last professorship of the History of Medicine in Germany. This must be regarded as a misfortune for the coming medical students, for, just as the history of a State can be but ill understood without a knowledge of its commencement in antiquity, so our medical art cannot be comprehended in its various phases without a knowledge of their origin and gradual development. How much Haeser did as an historian and as an epidemiologist, and the influence of his teaching will never be forgotten; and, if he had never done anything beyond writing his *Lehrbuch der Geschichte der Medicin*, he would have raised to himself a *monumentum aere perennis*.

**RESECTION OF THE MASTOID PROCESS IN OTITIS.**—In cases of otitis media Professor Studgaardt, of the General Hospital, Copenhagen, has had considerable success from resection of the mastoid process. He cuts through the soft parts, and then, with a chisel, chips off portions of bone and opens up a passage to the seat of the disease, scraping away any granulations that may have formed with the sharp spoon, thoroughly draining the ears, and applying a sublimate bandage. Ten cases have been operated on in this way. Of these, seven recovered the power of hearing completely, or nearly so. The other three very imperfectly. Erysipelas occurred once; once the labyrinth separated as a sequestrum. In one case, where there had been cerebral symptoms, they temporarily disappeared after the operation, though subsequently an intracranial abscess supervened. The general and local symptoms were in all cases much improved. In one case the transverse sinus was wounded, but the bleeding was controlled by tampons, and no bad results followed. The ages of the patients varied from 2 to 66, and they were of both sexes. A similar operation has been resorted to by one of the Professor's colleagues in the General Hospital, Dr. Tscherning.

**RAPIDITY OF FLIGHT OF CARRIER PIGEONS.**—The distance of Paris from Versailles is 20 kilometres, and the Paris pigeons in 1873 conveyed the minutes of the Académie des Sciences in 10 minutes, which is at the rate of 2,000 metres per minute. The same rapidity has been attained between London and Dover; the distance being 113 kilometres, as the bird flies, from Paris to Moulins (290 kilos), a rapidity of from 1,600 to 1,700 metres has been attained. These figures, however, are maxima; and for distances up to 500 kilos in clear weather the mean flight scarcely exceeds 1,000 metres, while in stormy weather it only reaches 600 or 700 metres.—*Revue Scientifique*, November 14th.

**THE CONGRESS OF CRIMINAL ANTHROPOLOGY.**—The *Semaine Médicale* of the 18th November has commenced the publication of the proceedings of this Congress and that on Penitentiaries, which were held in Rome simultaneously from the 16th to 20th November. The Congress was almost exclusively attended by French and Italian *savants*, and seems likely to furnish some very interesting facts. A preface precedes the report, giving a good account of the scope of the enquiries which have undergone discussion, and the physical conditions which so often characterise the perpetrators of crime.

**YELLOW FEVER IN PERU.**—Some months ago, several cases of yellow fever having occurred in Lima and its port Callao, the Lima Academy of Medicine nominated a Commission consisting of Drs. Macedo, Villar, Salazar, Barrios, Roca, Artola, Becera, Bignon, and Ulloa, to investigate yellow fever in general and this epidemic in particular. These gentlemen have now presented a report which consists entirely of a statement of their views as to their functions, with a string of questions to be propounded to medical men who may be able to give information, and to which questions the Academy is asked to give its authority.

**PORRO'S OPERATION IN JAPAN.**—In the *Berliner Klinische Wochenschrift*, October 19th, is published a successful case of Porro's operation by two Japanese, Drs. Omori and Ikeda, of Fuknoka, being the first instance of

this operation being performed in that country, where, however, ovariectomy has been performed. The infrequency of Cæsarian section in Japan is explained by the rarity of true rickets and especially of osteomalakia in that country. The authors of this communication acknowledge how much they owe to their German teachers of surgery.

**HÆMORRHAGE AFTER EXTRACTION OF A TOOTH.**—Dr. Blackwell relates an instance of this occurring in a young man who was a "bleeder" (*Philadelphia Medical Reporter*, October 10th), and which he succeeded in arresting, after the failure of various remedies, by placing powdered plaster of Paris in the socket and repeating the application until a clot was formed.

**MONUMENT TO RUSSIAN SURGEONS IN SOPHIA.**—The two chief Russian medical weeklies, the *Vrach* and the *Russkaya Meditsina*, just received, present their readers with pictures of a large stone "Memorial" which has been erected to the memory of 531 medical officers who fell in the war with Turkey during 1877-78. The site of the monument is the Alexander Place, Sophia. It is stated that a similar erection is contemplated in the Caucasus.

**THE SENSIBILITY OF THE TELEPHONE.**—M. D'Arsonval has shown that the nerve of the frog, hitherto regarded as the most perfect of galvanoscopes, is 200 times less sensitive than the telephone. In consequence of this property several physiologists now employ this instrument in their researches.—*Revue Scientifique*, November 7th.

**MALA PRAXIS.**—Dr. Kühner, of Frankfort, who is engaged on a work on Mala Praxis, asks us to invite our readers to send him notes of any cases that may have come within their knowledge, and any other information on the subject they may possess.

#### APPOINTMENTS.

- BAINBRIGGE, WILLIAM P. Y., M.B., C.M. Glas.—Medical Officer to the Hanbury District, Droitwich Union, *vice* Mr. R. Holyoake, resigned.
- BARCLAY, WILLIAM B., L.R.C.P. Edin., L.R.C.S. Edin.—Medical Officer to the Bacup District, Haslingden Union, *vice* Mr. John Snell, resigned.
- BRISTOW, WILLIAM MOSS, M.R.C.S., L.R.C.P. Edin. (late House Surgeon), re-appointed House-Physician to the Liverpool Royal Infirmary.
- BUSH, JAMES PAUL, M.R.C.S., L.S.A.—Surgeon to Out-Patients, Bristol Royal Infirmary, *vice* Harsant, appointed Surgeon.
- BUTTERY, GEORGE B., L.R.C.P. Edin., L.M. Edin., L.F.P.S. Glas.—Medical Officer to the First District, Parish of Birmingham.
- CAIRD, F. M., M.B., C.M. Edin., F.R.C.S.—Assistant-Surgeon to the Royal Infirmary, Edinburgh.
- COLLINS, A. WARD, L.R.C.P. Lond., M.R.C.S.—House-Surgeon to the Liverpool Royal Infirmary.
- COOPER, CHARLES B., L.R.C.P. Lond., M.R.C.S., L.S.A. Lond.—Assistant House Surgeon to the Liverpool Northern Hospital.
- CORRY, WALTER W. S., L.R.C.S.I., L.A.H. Dub.—Medical Officer to the Lastingham District, Pickering Union, *vice* Mr. Arthur Wood.
- CULHANE, FREDERICK WILLIAM SLATER, M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Third District, Hastings Union, *vice* Mr. W. G. Jones, resigned.
- DAYMAN, BARNFIELD, L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the Fourth District, Romsey Union, *vice* Mr. H. Dayman, deceased.
- DICKINSON, JONATHAN, M.R.C.S. Eng., L.S.A., L.M. Lond.—Medical Officer to the Workhouse, Stepney Union, *vice* Dr. Robertson, resigned.
- DWYER, Dr. C., re-elected House Surgeon to the Mater Misericordiarum Hospital for the ensuing year.
- EMMERSON, WILLIAM L., M.D.—Analyst for the Liberty of Peterborough.
- GEMMELL, J. E., M.B., C.M. Edin.—House Physician to the Liverpool Royal Infirmary.
- GOULD, THOMAS B., M.R.C.S. Eng., L.M. Edin., L.R.C.P. Edin.—Medical Officer to the Third District, Parish of Birmingham.
- HAIRSINE, HUDSON, L.K.Q.C.P.I.—Medical Officer to the North-East District, Patrington Union, *vice* Mr. T. R. Johnson, deceased.
- HARE, F. W. E., M.B. Dur., M.R.C.S.—Assistant Resident Surgeon to the Brisbane Hospital.
- HARRIS, VINCENT D., M.D. Lond., F.R.C.P.—Assistant Physician, City of London Hospital for Diseases of the Chest, Victoria Park, has been appointed a Physician, *vice* Dr. J. B. Berkart, resigned.
- HARSANT, W. H., F.R.C.S., L.S.A.—Surgeon to the Bristol Royal Infirmary, *vice* Cross, resigned.
- HAY, WILLIAM HENRY, M.D. Aberd., M.R.C.S. Eng., L.S.A. Eng.—Medical Officer to the Second District, Bridport Union, *vice* Mr. J. F. H. Ellerton.
- HUGHES, S., M.B., C.M. Edin., M.R.C.S.—Re-appointed House Surgeon to the Liverpool Royal Infirmary.
- KAYE, JAMES R., M.B. Glas., C.M. Glas.—Medical Officer to the Second District, Parish of Birmingham.
- KEMP, JOHN R., L.R.C.P. Lond., M.R.C.S.—Assistant-Surgeon to the Central London Ophthalmic Hospital.
- LAWSON, JOSEPH, M.B. Dub., L.R.C.S.I., L.M.I.—Medical Officer to the Hebden Bridge District, Todmorden Union.

- LEES, W., M.R.C.S., L.S.A.—Visiting Surgeon to the General Infirmary, Chester.
- LLOYD, HENRY, M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the St. Asaph District, and to the Workhouse, St. Asaph Union, *vice* Mr. F. L. Heaton, resigned.
- MCDUGALL, HERBERT A. H., M.R.C.S. Eng., L.R.C.P. Edin., L.S.A. Lond., L.M. Edin.—Medical Officer to the Pontesbury District, Aitcham Union, *vice* Mr. A. A. Gillitbi, deceased.
- NASH, WILLIAM G., M.R.C.S. Eng., L.S.A.—Medical Officer to the Fifth District, Lutterworth Union, *vice* Mr. C. Hedley, deceased.
- RACKHAM, ARTHUR RICHARD, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the North Elmham District, Mitford and Launditch Union, *vice* Mr. R. L. Mosley, resigned.
- ROBERTSON, ROBERT, M.D.—Assistant Physician to the Royal National Hospital for Consumption and Diseases of the Chest at Ventnor, Isle of Wight.
- SAUNDBY, Dr. ROBERT, M.D. Edin., M.R.C.P. Lond.—Consulting Physician to the Birmingham and Midland Counties Eye Hospital, and Consulting Physician to the Birmingham Dental Hospital.
- SIMMONS, HAROLD, M.R.C.S., L.S.A. Lond.—House Physician to the Royal Hospital for Diseases of the Chest, City Road.
- SKENE KEITH, F.R.C.S.—Special Assistant in Dr. Thomas Keith's Ward, Edinburgh Royal Infirmary.
- STADDON, JOHN H., L.R.C.P. Edin., M.R.C.S. Eng.—Medical Officer to the Workhouse, Ipswich Union, *vice* Dr. W. A. Elliston, resigned.
- STEER, WILLIAM, M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Workhouse and to the Infirmary, Parish of St. George-in-the-East, *vice* Dr. M. J. O'Connor, deceased.
- THOMPSON, JAMES, A.B., M.D., M.B., C.M. Glas.—Medical Officer to the Brailes District, Shipston-on-Stour Union, *vice* Mr. T. H. Hitchins, resigned.
- THOMPSON, WILLIAM.—Analyst for the Borough of Stockport, *vice* Mr. O. Wilkinson.
- THYNE, THOMAS, M.D. Edin., M.R.C.S. and F.R.C.S. Eng.—Medical Officer to the First District, and to the Workhouse, Barnet Union, *vice* Dr. J. Livingston, deceased.
- WEIGHTMAN, A. E., L.R.C.P. Edin., L.R.C.S. Edin. (late House Physician).—Re-appointed House Surgeon to the Liverpool Royal Infirmary.
- WILSON, REGINALD W., M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Workhouse and Infirmary, Croydon Union.
- WOODHEAD, GERMAN SIMS, M.D., F.R.C.P. Edin.—Pathologist to the Royal Infirmary, Edinburgh, *vice* Byron Bramwell, M.D., F.R.C.P. Edin., resigned.

#### VACANCIES.

- BRACKLEY UNION.—Medical Officer to the Second District, in succession to Mr. R. J. King, resigned. Area, 14,901 acres. Population, 1,984. Salary, £60 per annum.
- BRISTOL GENERAL HOSPITAL.—House Surgeon. Salary, £120 per annum; board, lodging and washing, will be provided in the house. Candidates will be required to possess a registered Medical and Surgical qualification, and produce testimonials of good moral character and ability, and must send certificate of registration. A copy of the rules will be forwarded on application. Applications to be addressed to the Secretary before December 2nd.
- CHELSEA HOSPITAL FOR WOMEN, FULHAM ROAD, S.W.—Honorary Assistant Physician. Candidates must be Graduates in Medicine of a recognised University, or Fellows or Members of one of the Colleges of Physicians of London, Edinburgh, or Dublin, registered, and not practising Pharmacy. Form of application to be obtained of the Secretary, to whom they must be returned by Nov. 30.
- CHILDREN'S HOSPITAL, BIRMINGHAM.—Assistant Resident Medical Officer. Salary, £40 per annum, with board, washing, and attendance in the Hospital. Candidates must be duly registered. Certificates of Registration with testimonials to be sent to the Secretary not later than December 1st.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, E.—Assistant Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to be sent to the Secretary's Office, 24, Finsbury Circus, E.C., on or before December 7th.
- DORE UNION.—Medical Officer to the Kentchurch District and to the Workhouse, in succession to Mr. John Powell, resigned. Area, 23,368 acres. Population, 3,048. Salary, £60 per annum. Salary for Workhouse, £20 per annum.
- LINCOLN UNION.—Medical Officer to the Twelfth, in succession to Mr. F. Hall, resigned. Area, 12,398 acres. Population, 1,74. Salary, £15 per annum.
- NEWMARKET UNION.—Medical Officer to the Fifth District, in succession to Mr. R. Lucas, deceased. Area, 15,157 acres. Population, 3,377. Remuneration by Fees.
- ST. MARYLEBONE GENERAL DISPENSARY, 77, WELBECK STREET, CAVENDISH SQUARE.—Resident Medical Officer. Salary, £105 per annum, with furnished apartments, attendance, coals, and gas. Candidates must be registered and hold a Medical and Surgical qualification. Applications and testimonials to be forwarded not later than 30th November, and Candidates must attend at the Dispensary on 2nd December, at 4.30.
- STIRLING DISTRICT ASYLUM, LARBERT, N.B.—Assistant Physician. (*For particulars, see Advertisement.*)
- TORBAY HOSPITAL AND PROVIDENT DISPENSARY, TORQUAY.—Junior House Surgeon and Dispenser. Salary, £90 per annum, with board, lodging, and attendance. Candidates must be qualified in Medicine and Surgery, registered under the Medical Act, and unmarried. Testimonials to be sent to the Hon. Secretary, W. H. Kitson, Esq., Torquay, not later than January 1, 1886.
- WESTERN GENERAL DISPENSARY, MARYLEBONE ROAD.—Ophthalmic Surgeon. Applications to be sent to the Hon. Secretary, from whom particulars can be obtained, by December 7th.
- WHITECHAPEL UNION.—Assistant Medical Officer to the Infirmary, in succession to Dr. M. Davies, resigned. Salary, £150 per annum.

## DEATHS.

EVANS, EDWARD CHARLES, M.R.C.S., at Tirphil House, Tirphil, on November 19th, in his 42nd year.  
 LEREW, F. W., M.B., at Sandhurst, Australia, on October 15th, aged 27.  
 LISTER, JOHN, M.R.C.S., of Halifax, on November 22nd, in his 90th year.  
 MANGET, E. A., M.D., at Barbadoes, on November 2nd, in his 71st year.

## NOTES, QUERIES, AND REPLIES.

## REFORM AT THE ROYAL COLLEGE OF SURGEONS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Looking over a recent report of one of the Canadian Universities, I find that the class fees are now at a much higher scale than when I studied there, and as stated by myself in your No. of 21st instant. The fee for M.D. and M.C. is \$20. I shall be obliged if you will permit me to correct my error.

I am, Sir, yours, &c.,  
 FOREIGN AND COLONIAL GRADUATE,  
 AND M.R.C.S., England.

## LIFE AT PORT ELIZABETH.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Would any of your readers kindly inform me of the prospects, fees, &c., of a general practitioner who wishes to commence in Port Elizabeth or Cape Town. I should be greatly obliged for the above information.

I am, Sir, yours, &c.,  
 J. M.

## COMMUNICATIONS RECEIVED—

Dr. W. H. ALLCHIN, London; Mr. J. MAUGHAN, Liverpool; Dr. DOUGLAS, Hounslow; THE SEC. OF THE SOCIETY OF APOTHECARIES, London; Dr. WARD COUSINS, Southsea; THE SEC. OF THE INDIA OFFICE, London; Mr. GEO. RENDLE, London; Mr. ROBT. OPPENHEIM, Berlin; OUR VIENNA CORRESPONDENT; Dr. J. J. PRINGLE, London; THE MANAGER OF THE ROYAL AQUARIUM, Westminster; Dr. MACASKIE, Bamburgh; FOREIGN AND COLONIAL GRADUATE, London; THE SEC. OF THE OBSTETRICAL SOCIETY, London; THE SEC. OF THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, London; THE REGISTRAR-GENERAL, Edinburgh; THE HON. SEC. OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY, London; THE SANITARY COMMISSIONER OF THE PUNJAB, Lahore; THE REGISTRAR-GENERAL, London; THE SEC. OF THE PATHOLOGICAL SOCIETY, London; THE SEC. OF THE MEDICAL SOCIETY OF LONDON; Mr. SCRAGG, London; Mr. W. G. BARTON, Hereford.

## BOOKS RECEIVED—

Die Electrolyse als Mittel zur radicalen Beseitigung an abnormer Stelle gewachsener Haare, von Dr. P. Michelson—Gonorrhoea in the Female, by Andrew F. Currier, M.D., New York—Bericht der K.K. Krankenanstalt Rudolph-Stiftung in Wien, vom Jahre 1884—The Turkish Bath, by Richard Metcalfe—Katalog des Medicinischen Verlags von F. C. W. Vogel, Leipzig—The Transactions of the Edinburgh Obstetrical Society, Vol. X.—Transactions of the Academy of Medicine in Ireland, Vol. III.

## PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—The Hospital Gazette—Revue Médicale—Canada Medical and Surgical Journal—National Church—Nordiskt Medicinskt Arkiv—The Canada Lancet—The American Journal of Obstetrics—Night and Day—Weekblad—The Medical World—The Alienist and Neurologist.

## HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.; Chelsea Hospital for Women, 2.30 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1¼ p.m.; Guys, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## INTRODUCTORY ADDRESS TO THE DISCUSSION ON THE CLINICAL ASPECT OF GLYCOSURIA.<sup>1</sup>

By F. W. PAVY, M.D., F.R.S.  
Senior Physician to Guy's Hospital.

In the remarks which I am about to make, I shall, in accordance with the intention of those who have framed the course of procedure at this meeting, confine myself strictly to the clinical aspects of diabetes or glycosuria, and of these I propose to take up more particularly certain points.

In the first place, as to the age at which the disease begins. The table presented shows the ages in decennial periods at which diabetes in 1,360 cases set in. The table is compiled from the reports contained in my consulting-room case books.

Some years back I commenced to keep a systematic record of all the cases that came before me in my consulting-room practice, and it is from this source that the figures are derived. The cases, therefore, belong exclusively to the class of patient seeking advice at the physician's residence. The age expressed is that at

which the disease commenced as far as by careful enquiry I could ascertain. .

TABLE showing the Ages in 1,360 Cases of Diabetes at which the Disease set in.

Ages.	Actual Number.			Ratio to total number per cent.		
	Males.	Females.	Males and Females.	Males.	Females.	Males and Females.
Under 10 years ...	3	5	8	0·22	0·36	0·58
From 10 and under 20...	35	22	57	2·57	1·61	4·19
" 20 " 30...	69	28	97	5·07	2·05	7·13
" 30 " 40...	154	70	224	11·32	5·14	16·47
" 40 " 50...	260	79	339	19·11	5·80	24·92
" 50 " 60...	281	137	418	20·66	10·07	30·73
" 60 " 70...	138	44	182	10·14	3·23	13·37
" 70 " 80...	25	9	34	1·83	0·66	2·49
Over 80 ...	1	—	1	0·07	—	0·07
Total ...	966	394	1,360	71·00	28·97	100·00

On inspecting the table, it will be noted that 30·73 per cent., or nearly a third of the cases, occurred between 50 and 60 years of age, and 24·92 between 40 and 50. For these two periods taken together, the cases amount to 55·65 per cent. of the whole. Between 40 and 60, therefore, represents by far the most common period of occurrence of the disease. From this period there is a sharp and increasing fall in both

<sup>1</sup> Delivered in the Section of Medicine at the Annual Meeting of the British Medical Association in Cardiff.  
VOL. II. 1885. No. 1849.

directions. I have no private record of the cases that have come before me in my hospital practice, but my impression is that the statistics would come out differently, and that the great bulk has consisted of patients of from 15 or 18 up to 35 or 40 years of age. My hospital experience certainly does not supply me with the number of cases at a comparatively advanced period of life that I am meeting with in private practice.

Of the eight cases enumerated in the table under 10, two occurred at two years of age, one at 3, one at 5, two at 7, and two at 9.

Of the cases between 70 and 80, ten occurred at 70, seven at 71, five at 72, three at 73, two at 74, one at 75, two at 76, three at 78, and one at 79. The case over 80 was at 81.

I have the particulars of a case not included amongst the above, in which the patient was 12 months and 3 weeks old at the time of my seeing it. I was called to the case by Dr. Finch, of Blackheath, in June, 1879. The history given was that, for the past few weeks, the infant had been rapidly wasting, had shown great greediness after fluids, and was passing an excessive quantity of urine which saturated the articles worn, and rendered them stiff on drying. This circumstance had attracted the attention of the nurse before the nature of the case was recognised. From a letter subsequently received from Dr. Finch, I learnt that the patient continued to grow worse, and died about a month after I saw it.

As regards the family history, there are some interesting points to be noted. There can be no doubt that the disease runs in families. Of this I am enabled to bring forward some remarkable instances. A lady, aged 50, came to me for the first time, in June, 1873, suffering from diabetes. In April of the preceding year, her sister, also then 50 years of age, had already consulted me for the same complaint, and in March, 1879, the elder sister, 57 years of age, applied to me under similar circumstances. All three patients are living at the present time. I have seen them within the last few months. Both their parents were the subjects of the complaint and had been seen by me, so the daughters told me, a long time previously in consultation. A gentleman, aged 56, came to see me in August, 1872, with a recent attack of diabetes. He informed me that his brother, aged 60, was suffering from the disease, and that one of his sisters had died of it, aged 41. In January, 1876, a surgeon, aged 32, residing in London, came to me with sugar in his urine; he, too, had lost a sister, aged 10, and a brother, aged 25, of the disease. This gentleman still continues in good health.

Another striking case was that of a lady, whom I saw for the first time in March, 1876, and who had recently become the subject of diabetes. On questioning her, I ascertained that two aunts, on her father's side, and one on her mother's side, had died from the disease. The patient herself was one of a family of five. Of these five, a sister died of diabetes, aged 21, and a brother aged 28, and she had one brother living, aged 35, the subject of the disease, so that four out of five members of the family were diabetic. The remaining sister was healthy herself, but she had lost a child, aged 2 years, of diabetes. I have notes of the case of a lady, aged 56, who consulted me for the first time in May, 1877. She was one of twins, and both she and her twin sister were diabetic, the latter coming under my care in May, 1879. A boy was brought to me, November 14th, 1884, aged 14, just having become the subject of diabetes. He belonged to a family of eight. In 1882, a sister died of the disease, aged 4 years. In 1883, a brother died, aged 11 years, of the disease. Thus diabetes had shown itself in three out of the eight. There was no history of the disease in the family of

either of the parents. In April, 1878, a boy of 16 was brought to me, by his father, for diabetes. The patient died towards the latter end of 1879, and in October, 1880, the father, then aged 44, became the subject of the disease. Thus the complaint first showed itself in the son, and not till afterwards in the father. Another instance of a similar nature is presented by the case of a lady, aged 42, whom I first saw in May, 1882, and who had then been suffering from diabetes for nine months. A sister became the subject of the disease shortly afterwards, and during the present year the mother has presented symptoms of the complaint, and has been discovered to be suffering from it.

The liability of several members of a family to become the subjects of the disease is strikingly shown by the instance of a patient, aged 46 years, whom I saw for the first time in October, 1878. He belonged to a family of twelve, and five out of the twelve, including the patient, were the subjects of diabetes. Another patient, aged 37, who consulted me in February, 1885, for diabetes, belonged to a family of eight. Three of his brothers had died of the complaint, aged 15, 27, and 43 years respectively. The most remarkable instance touching family history that I have come across is the following. The mother of five children (four girls and one boy) had died of diabetes, which had carried off her own mother before her. In May, 1877, having occasion to see one of the children with reference to diabetes, I at the same time examined the urine of four of them. In the other, the opportunity did not present itself. The urine of the eldest girl, aged 16, had a specific gravity of 1043, and contained 58.76 per 1,000 of sugar. That of the second girl was free from sugar, but the fourth girl's urine contained 31.61 per 1,000, and the brother's 29.89 per 1,000. Three, therefore, out of the five in family were, from my own knowledge, passing saccharine urine, one was not doing so, and in the case of the fifth I had no knowledge of what existed. In February, 1884, this fifth case, which consisted of the third girl, was brought to me; she was then aged 19, and her urine was loaded with sugar. She died shortly afterwards. I was informed, on that occasion, that the other members of the family were then in a fair state of health, and that the eldest sister was just about to be married.

A curious instance with regard to family history, not falling under my own observation, was communicated to me by a medical practitioner living in the Canary Islands, who himself formed one of the subjects of the disease. The father suffered, not from "diabetes, but from shaking palsy," diagnosed by Dr. Lassègue, of Paris, as due to disseminated sclerosis. This person had three sons, *a*, *b*, and *c*, born of different mothers: *a* became diabetic at 53, *b* at 55, and *c* at 43. There was no history of diabetes on the side of either of the mothers, who all died late in life of complaints of quite a different nature. There was another child of the same father, of whom, from social reasons, nothing could be ascertained. The fact of all three sons, of one father, becoming diabetic, though born of different mothers, is very remarkable.

From what I have seen of this disease, I think there is reason to believe that it is distinctly more common amongst members of the Jewish race than amongst others, and that it is, moreover, with them, according to my experience, more amenable to treatment.

Now as to the mode of onset of the disease. In one set of cases this takes place gradually and insidiously; in another, quite suddenly. I do not doubt that in many instances it may exist for some considerable length of time without exciting any suspicion of its existence. I have occasionally been enabled to prove this in patients living in the country, especially in clergymen and persons who wear clothes of black

cloth, through the white stains which are left, on drying, from the urine which has splashed over the trousers while micturating against a wall or on the ground. Such stains are very troublesome to remove by brushing, and when found on trousers which may have been put aside and not worn for a few years, as sometimes happens, we are at liberty to assume that the urine at that time contained sugar. I have heard of hotel servants, whose duty it is to brush the clothes, recognising diabetic patients from the difficulty experienced in brushing out these stains. I have noticed that it is especially in elderly people that we find this gradual onset.

I will now refer to instances where the disease has come on suddenly. In December, 1876, I was consulted by a lady, aged 35, in whom diabetes had supervened quite suddenly four weeks previously. She was, at the time of the attack, nursing a two months' old infant, when her supply of milk ceased all at once, and, contemporaneously with the cessation of the lacteal secretion, she noticed that she became very thirsty, and passed an abnormal quantity of urine. Four years previously she had sustained a severe nervous shock, with injury to the spine, in a railway collision, which led to her being bed-ridden for a period of eight months. She was, however, supposed to have recovered perfectly from this accident, and I am, of course, quite unable to say whether it had any bearing on the production of her subsequent illness.

Another instance of the disease coming on suddenly occurred in a lady, who dated her illness from one evening when she had dined out with friends. Previous to this, her health had been in all respects good. In the course of the evening she became very thirsty, with a thirst that nothing could quench, and she was at once afterwards recognised to be suffering from diabetes. Here the history was very clear, nothing unusual had been remarked during the day, until in the evening the thirst manifested itself.

Then, as to its duration; this varies within very wide limits. It may go on for years without seriously impairing the patient's general health, or it may terminate very speedily in death. Let me first refer to cases where the result is rapidly fatal, such, for example, as that of a gentleman, aged 46, whom I saw in 1870, and in whom the diabetic condition had only been definitely recognised on the previous day. His symptoms were now marked and urgent, and the patient assured me that certainly nothing unusual had existed a month previously. Two days later, I was summoned to Croydon to see him by his medical attendant, and found him dying from diabetic coma.

Again, in July, 1883, I was consulted by a gentleman, aged 39, whose diabetes dated, as far as it was possible to ascertain, from a week previously (he had already lost a sister from the disease); three weeks later, I heard that the patient, who had returned to Liverpool, where he resided, was dead. From the description given me of his illness, I gather that what was in all probability a carbuncle had formed over the parotid gland, which had determined the fatal result.

The most acute case I think I have ever known was that of a gentleman, aged 55, whom I saw on April 24th, 1884, at Blackheath, in consultation with Mr. Moore and Mr. Roper. The patient had been under the care of my neighbour, Dr. Russell Reynolds, on account of epileptic attacks, to which he had been subject during the last few years. Albumen had been known to be present in his urine for five or six years past. It happened that his urine was examined, both for albumen and sugar, three weeks previous to my visit, and found free from sugar. It may, therefore, be assumed that no diabetes existed at that time. When I saw the patient the diabetic symptoms were severe in the extreme; the thirst was most urgent,

and his tongue, mouth, and fauces were of that bright red colour which so often goes with a severe form of diabetes. Three days later I was again called in, only to find the patient in a state of diabetic coma, which soon terminated fatally.

The cases which go on for years, the patient meanwhile enjoying a fair state of health, are, as I have already stated, most commonly met with in elderly people, although a similar chronicity is occasionally met with in younger people. I remember a lady, whom I saw for the first time in November, 1871; she was then 48 years of age, and had been suffering from diabetes for ten years. In September of last year she was still in very fair health, which makes upwards of twenty years that she has been the subject of diabetes. I may state that it is by no means out of the way for elderly people from time to time to tell us that they have been diabetic for twenty or twenty-five years past.

With reference to young people, a gentleman, aged 22, fell under my care on June, 1874, having already been diabetic for three years. He continued in quite a satisfactory condition until May 30th, 1876, all the time passing saccharine urine, but the disease otherwise appearing dormant, when suddenly active symptoms declared themselves, and death rapidly supervened.

Another case of long duration occurred in a lad of 17, who was brought to me from Wellington College in April, 1874. I saw him off and on until December, 1879. I have not heard nor seen anything of him since, but he was in a fair state of health when I lost sight of him.

Another case is that of a young lady of 19, first seen by me in January, 1881, whose mother had died diabetic, and whose aunt, the wife of a medical practitioner, has come to me with diabetes during the last six months. The patient herself had been suffering from the disease for four years previously, but has been doing exceedingly well up to the present time. Here, then, is a case in a young subject, where the disease has been existing for eight and a half years. The patient still passes a large quantity of sugar in her urine; but I saw her only a few days ago, and there is nothing in her appearance which would lead one to suppose that she had anything the matter with her. She is plump instead of presenting the emaciated appearance of the disease. She married some two years since, and her first pregnancy terminated in a miscarriage; she subsequently gave birth to a child at term, which only lived a short time, though whether the diabetes had anything to do with this I cannot say, as there was a history of syphilis on the father's side, and the infant had a rash soon after birth.

Although diabetes, when once developed, generally persists, cases occur where it has disappeared. I have, from time to time, met with these cases in my practice; I do not allude to a mere control of the disease under dietetic management, but a complete eradication. For instance, in May, 1881, I saw a gentleman, aged 41, who was the subject of the disease, and was passing a large quantity of sugar in his urine, which had a specific gravity of 1036 and contained 57 per 1,000 of sugar. This patient was highly neurotic. My last recorded observation about him is dated March 13th, 1884, at which time the sugar had entirely disappeared from the urine, although the patient was not dieting himself in the least, and ate of anything that came before him. Curiously enough, his wife has become the subject of the disease. She consulted me on that account in January, 1884, and I rather apprehend that it will not disappear with her in the same manner that it has disappeared with her husband.

Again, sugar may be only temporarily present in

the urine. I referred just now to the red or injected condition of the mouth and fauces that is frequently met with in diabetes; and, some time ago, I was led to examine the urine of a patient because of the intensely red colour of the interior of the mouth, which was also tender; the lips, moreover, were intensely injected, as were also the hard and soft palate. The result of the examination of the urine was that on one occasion I found 4.84 per 1,000, and on another occasion 8.91 per 1,000 of sugar. It was, however, only a passing condition; I have seen the patient many times since, and can state that he is not diabetic. About the same time, a gentleman whom I had seen on several previous occasions, and knew not to be the subject of diabetes, called on me, and I had some urine examined with respect to the question of phosphates. As is customary, a full analysis was made, and the result showed, to my astonishment, that sugar was present. I immediately asked the patient what he had taken for breakfast, the urine examined being passed at the time of consultation in the morning, and he informed me that he had indulged freely in marmalade. To this, no doubt, the sugar in the urine was due, the sugar taken with the food having been beyond the assimilative power existing, since none was found on subsequent occasions, and there was really nothing to lead me to suspect diabetes in him.

It is worthy of notice that diabetes insipidus and mellitus may exist together, and you can prove their co-existence in the following manner. Take, for example, a patient who is suffering from thirst, and is passing a large quantity of urine containing sugar, but in whose case, as shown by the specific gravity and quantitative examination, the amount of urine is out of the usual proportion to the sugar present. Put him upon the ordinary restricted diet for diabetes, and the sugar may entirely disappear, whilst the quantity of urine keeps up. I have seen cases in which, with a disappearance of sugar, the quantity of urine has nevertheless kept up to eight, nine, or ten pints in the twenty-four hours, with a specific gravity of from about 1,005 to 1,007. The diabetes mellitus has been got under by the dietetic management, but the other has remained. Where the two conditions co-exist, the quantity of water passed is, as I have said, out of proportion to the amount of sugar present. In the ordinary form of diabetes, the amount of urine voided stands in relation to the amount of sugar to be eliminated, the sugar, in escaping, carrying off water from the system with it. A patient whom I saw with Dr. Eustace Smith, in 1876, passed ten pints of urine in twenty-four hours. The specific gravity was 1,013, and the amount of sugar 19.10 per 1,000. The case affords an illustration of a great excess of urine without a correspondingly large elimination of sugar.

I will now give the history of a case where diabetes mellitus was followed by diabetes insipidus, the latter ultimately disappearing in its turn. A lady, aged 55, the wife of a clergyman in Wiltshire, consulted me in October, 1881, for diabetes mellitus. It was the ordinary form of the disease, and, under dietetic and medicinal treatment, she so far improved that on December 5th, 1881, her urine no longer contained any sugar. On August 4th, 1882, I received a letter from the patient, asking for an appointment, as she was again suffering from thirst and passing an excessive quantity of urine, and feared the disease had returned. The urine brought for examination, to my surprise, presented the following characters. Night urine, specific gravity 1007, no sugar; morning urine, specific gravity 1005, no sugar. This lady was at the time upon a restricted diet, but, seeing that no sugar was present, I desired her to take four ounces of ordinary bread *per diem*, and this was unattended with the return of sugar in the urine. In August, 1882,

her night-urine was of specific gravity 1015, and her morning-urine specific gravity 1013, no sugar in either specimen. She was now taking pretty nearly an ordinary diet, so that both diabetes mellitus and insipidus had disappeared. On a subsequent examination (November, 1883), the night-urine was of specific gravity 1031, and the morning-urine 1010, no sugar in either.

In bringing these cases before you, I abstain from offering any exposition of my own ideas as to causation because that would be trespassing on the domain of pathology; but, in connection with the association of diabetes insipidus with diabetes mellitus, I may refer to a certain other collateral condition which I have occasionally met with. I have seen cases, for instance, where the subjects of diabetes perspired only on one side of the body. One of my patients, a gentleman, presented this peculiarity in a remarkable degree. Large drops of perspiration stood out upon one thigh, whilst the other was quite dry. Another patient, a gentleman of 48, whom I saw in November, 1876, said to me, "I don't know why it is, but I find that slight mental exertion causes profuse perspiration on the right side of my head, and very little upon the left." I cannot refrain from simply saying, in passing, that I believe the disordered nerve-conditions which may cause these phenomena have some connection with the pathological state at the foundation of diabetes mellitus.

With regard to the physical condition of organs in diabetes, I have, in several instances, found a hypertrophic state of the liver associated with the disease, sufficiently often, in fact, to warrant the supposition that there is some connection between the two. The enlargement of the liver is marked, but I cannot say whether it is the ordinary form of hypertrophic cirrhosis; and, in any case, a patient so affected may go on satisfactorily for years. Some patients presenting this condition of enlargement only pass a moderate amount of sugar, even with some latitude in diet, and, in harmony, do not manifest the ordinary symptoms of diabetes to any marked extent.

Next, as to abnormal conditions of the nervous system. I am perfectly satisfied that certain symptoms of disordered nerve-action, especially spinal, are very apt to accompany diabetes. I have seen so many cases of ataxia associated with this disease that I have been for some time past led to consider that there is some connection between the two. They sometimes come on together, and sometimes the ataxia precedes the diabetes, or, on the other hand, the diabetes may have existed long before the ataxia shows itself. A patient, a lady, aged 48, whom I saw for the first time in 1871, and who had then been diabetic for ten years, presented no symptoms of nerve-disorder till February, 1880. She then began to complain of pains in her limbs, and, by April of that year, she was decidedly ataxic.

The usual account given by these patients of their condition is that they cannot feel properly in their legs, that their feet are numb, that their legs seem too heavy—as one patient expressed it, "as if he had twenty-pound weights on his legs, and a feeling as if his boots were a good deal too large for his feet." Darting or "lightning" pains are often complained of. Or there may be hyperæsthesia, so that a mere pinching up of the skin gives rise to great pain, or, it might be, the patient is unable to bear the contact of the seam of a dress against the skin, on account of the suffering it causes. Not unfrequently, there is deep-seated pain, located, as the patient describes it, in the marrow of the bones, which are tender on being grasped; and I have noticed that these pains are generally worse at night. With this, there is the usual loss or impairment of the patellar tendon-reflex.

Sometimes pains and manifestations of perverted sensibility are noticed without ataxia. It is not always the legs that are affected; the arms may suffer, as happened in the case of a gentleman who had been to see me several times for diabetes. This patient had done very well—better, indeed, than might have been expected, for he had not exercised the care that prudence would dictate he ought to have shown in the matter of diet, having frequently indulged in champagne, sweets, and such-like articles. Within the last year or so, however, he has had these nerve-troubles in one arm. It was put down by the local practitioners to gout; but the skin and flesh were tender, and the bone was painful. There was, moreover, some wasting of the limb. Under the circumstances, I sent him to Dr. de Watteville, to see what galvanism would do for him.

Another disease which I have seen in connection with diabetes is exophthalmic goitre; but I am not in a position to insist on the relationship in this case, as I do with ataxia. A patient, a lady, aged 60, whom I saw in August, 1877, and who was then suffering from moderate diabetes, also presented a distinct systolic *bruit*, a large and throbbing thyroid, and some amount of exophthalmos. Another lady, whom I saw in August, 1883, and who had just arrived from Montreal, was the subject of exophthalmic goitre and diabetes, which had developed concurrently.

Now, with regard to what has been called "acetonæmia," I may say at once that I do not believe in the theory involved in the term "acetonæmia." Of course, the coma is not a matter for belief; we all know that patients are very apt to die in a comatose state—a fact I mentioned in my work on *Diabetes*, the second edition of which was published in 1869; and the same observation had been previously recorded by our countryman, Dr. Prout. Why, therefore, it should now be called "Küssmaul's" coma, I cannot conceive, seeing that he only described it in 1874. So far as I am enabled to judge, this comatose state arises from a deprivation of power in certain nerve-centres; and thus fatigue, or anything which tends to throw the patient off his balance, will tend to produce it. I have often met with it in patients who have undertaken a long journey to see me. They were buoyed up by hope on their way to London; but, when they presented themselves in my consulting-room, I have been enabled even then to recognise the first indications of the advent of coma, and the patient has died in the course of a day or two.

I am inclined to consider that the coma depends, as I have said, rather on the exhaustion of certain nerve-centres than on the action of any direct poison in the blood. A simple attack of vomiting may lead to it in a diabetic patient who has not been able to eat anything for a day or two. It is usually ushered in by a rapid pulse and a peculiarity in the breathing. There is a breathlessness, or out-of-breath condition, not dependent on any impediment to the entrance of air into the chest, but simply as though the patient were unable to get sufficient for his requirements in the peripheral parts of the system. He becomes drowsy, and this deepens into a comatose state, terminating in profound coma and death.

It has long been known that a fatty condition of the blood is frequently observable in diabetics, and this has been suggested as a possible explanation of the coma, through the production of fatty emboli. But I maintain that this fatty condition of the blood is a purely physiological state. Fat shows itself normally in the blood after the ingestion of a meal containing much fatty matter. When formerly lecturing on physiology, I used to demonstrate this in the blood collected from an animal shortly after the free ingestion of fatty substances, and which, after standing for a little time,

presented a well-marked cream-like layer on its surface from the aggregation of the fatty particles. It is, I repeat, only a physiological condition; and its presence in the blood of diabetic patients may be accounted for by the great amount of food they take, and especially from the fatty nature that frequently occurs of a large proportion of it.

Albumen is sometimes present in the urine in diabetes, and may continue for years without being accompanied with any serious results. Not unfrequently, a decided quantity of albumen at the commencement of treatment may decrease and disappear as the patient improves. When present in small amount, I do not attach any significance to it. Other cases, however, exist which pass on to well-marked Bright's disease, and it is to be noticed that, generally, as this condition becomes established, the diabetes shows a tendency to subside. I remember a lady with diabetes who became the subject of Bright's disease, and the sugar entirely disappeared from her urine in a manner that permitted her taking any kind of food without passing sugar.

I trust I have not wearied you with the length of these remarks. They have been founded exclusively upon the information derived from the experience which has been thrown in my way in connection with the disease, and the points touched upon have been those which appeared to me to be the most worthy of being brought forward.

---

## CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD  
AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the  
Principles and Practice of Medicine and on Clinical Medicine.

### LECTURE VII.—CASE TAKING.

#### *Personal History.*

#### *Sex.*

DOES sex of itself confer any peculiar liability to disease, or does it exert any influence upon disease when once established? The answer to these questions will demonstrate the assistance to be derived from the knowledge of a patient's sex in forming a diagnosis of such patient's malady. It is almost impossible, on entering on this enquiry, to avoid the consideration arising, is there or is there not any essential difference between the sexes beyond such as is connected with the manifestly distinct part they play in the reproduction of the species? Is there besides the differences in the structure and functions of the organs of generation some intrinsic difference either of degree or kind in their vitality? The subject is one that has given rise to much speculation and wordy disputation; but, without debating with Van Helmont the theme *propter uterum est mulier*, we shall, I think, see some reason to believe that there is *ab initio* a difference in the constitution of the sexes—a difference that is not appreciably recognised in every individual, but which in the aggregate is very apparent.

Insomuch as in the case of age, with which indeed sexual influence is at many points closely allied, most of our information is to be derived from statistics, it becomes necessary to commence with a statement of the relative numbers in which the two sexes exist before considering any circumstances which affect

either separately. The following table, from the 46th Annual Report of the Registrar-General for 1883 (published 1885),<sup>1</sup> shows the distribution of the sexes at different age periods in England and Wales per 1000 persons.

Ages.	Persons.	Males.	Females.
At all ages .. ..	1,000	487	513
Under 5 years .. ..	135	67	68
5—10 „ .. ..	121	60	61
10—15 „ .. ..	108	54	54
15—20 „ .. ..	98	49	49
20—25 „ .. ..	90	43	47
25—35 „ .. ..	145	70	75
35—45 „ .. ..	114	55	59
45—55 „ .. ..	84	40	44
55—65 „ .. ..	59	28	31
65—75 „ .. ..	33	15	18
75 and upwards ..	13	6	7

That is, of 1,000 persons living there are 487 males and 513 females, and it will be noticed that at all ages females are either equal in number to the males or exceed them.

Turning, however, to the annual number of births, we find that every year a greater number of males are born than females, and, to take the year 1883 as an example, of a total of 890,722 live births 453,076 were males and 437,646 females. That is, for every 100 females 103·5 males were born. The average for the preceding decennium was 103·8 males, the maximum being 104·3 in 1874 and the minimum in 1883. It would seem, therefore, that the greater proportion of males born over females is slightly declining.

But if, notwithstanding that there is this excess of males born, they at all subsequent ages number the same, or less than the females, it is clear that the male mortality must be considerably above that of females, and this the following figures show. In 1883, of the 522,997 deaths registered 269,262 were males and 253,735 females, or for every 1,000 persons living 19·5 persons died, in the ratio of 20·67 males and 18·46 females. (Since registration began, the maximum death-rate per 1,000 living of both sexes was 25·1 in 1849 and the minimum 18·9 in 1881, as contrasted with 19·5 in 1883.)

In my fourth lecture I gave you a table of the rates of mortality of the two sexes at twelve different age periods, from which it will be seen that the higher death-rate of males over females as estimated for all ages collectively equally prevails at each different age, and this especially within the first year of life and after 60 years of age. It is indeed the excessively high rate of mortality among male infants which soon reduces the excess of males born below the number of females living. As still further emphasising the higher liability to death among males, I may refer to the supplement to the 45th Annual Report of the Registrar-General, which has been issued within the past few days. From it we learn that, whilst the mean annual death-rate in England and Wales for the decennium 1871—80 was 21·27 per 1,000 and was lower than in any previous decennium, the decline in the mortality was not equally divided between the two sexes, that of the female having fallen 6·02 per cent.

<sup>1</sup> Civil registration commenced in 1838, and an Annual Report (with a decennial supplement) has since been published by the Registrar-General. It deals with the Births, Deaths, and Marriages of *England and Wales only*, and this should be understood in respect to any figures quoted in the text, unless otherwise stated.

and that of the male only 4·24 per cent. since the immediately preceding decennium. And further that, whilst the rate has risen for the later periods of life and fallen for the earlier periods, as seen in the great diminution in infant mortality, the death-rate was higher than in the previous ten years at each age period after 35 in males, but that it did not rise until after 45 in females. It follows as a corollary to this that the expectation of life among women at any age is greater than among men, and the life table that I gave you in a previous lecture fully bears this out, and the new life table published within the past few days supplies additional confirmation of the same.<sup>2</sup>

The following table, as showing the number of deaths in the two sexes in 1883 from different causes (using the group-terms of diseases employed by the Registrar-General), will be of interest and sufficiently explains itself. It may be remarked, however, that the actual mortality from the various diseases does not exactly correspond to the sexual prevalence of the maladies, as will be seen from what follows<sup>3</sup> :—

Disease.	Males.	Females.
1. Zymotic .. ..	34,453	36,101
2. Parasitic .. ..	536	563
3. Dietetic .. ..	1,155	608
4. Constitutional .. ..	44,621	46,582
5. Developmental .. ..	20,893	22,812
6. Local .. ..	137,413	127,264
7. Violence .. ..	13,229	4,824
8. Not specified .. ..	16,787	15,041
All causes at all ages =	269,262	253,735

From all which it would appear that fewer females than males are born; that at every age, and consequently at all ages collectively, the death-rate is lower among girls and women than among boys and men; that the difference is most perceptible in the first years of life; that in both sexes an improvement (*i.e.*, a diminished death-rate) is taking place; that this is more marked in females than in males at all ages, up to 45 in the former and only to 35 in the latter; and lastly, that the mean expectation of life of a male child at birth is 41·35 years and of a female 44·62 years. No doubt, in attempting to explain this lessened mortality in the female sex, much importance must be ascribed to the more protected circumstances of their life, and in many respects the more favourable condition in which they live. But it cannot be this entirely, since the environment of infant life is the same for both sexes, however much it may vary among different social classes. It is not easy to see what in the surroundings determines that far more male infants should die than females, even when due allowance is made for the greater liability to injury at birth in males, from their average larger size, a circumstance which is not without an effect, as seen in the greater proportion of still-born males. We cannot, I think, resist the conclusion that inherently in the female organism the death tendency is not so strong as in the male, and the very much larger number of women than men who live beyond a hundred gives support to the idea.

<sup>2</sup> In the fourth lecture, where the English Life Table as prepared by the late Dr. Farr is given, I expressed the belief that a table constructed on the recent Census and Annual Reports would show a higher expectation of life at almost all ages. In the recently published Supplement to the Registrar-General's 45th Report a new life table is given, which justifies this anticipation, and should be compared with that printed at page 630.

<sup>3</sup> 45th Annual Report of the Registrar-General, p. 138, where may be seen the mortality from the different diseases comprised within these group-terms.

The data for calculating the annual expectation of sickness in the sexes are admittedly meagre, and the results are far from conclusive, but, so far as they go, they would tend to show that the degree is about the same. In Mr. Sutton's tables, referred to in my fifth lecture, it is estimated that—

Ages.	Annual Expectation of Sickness.	
	Male.	Female.
From 15—20 .. .. .	·666	·666
„ 20—25 .. .. .	·737	·737
„ 25—45 .. .. .	·995	·995
„ 45—65 .. .. .	2·736 weeks	2·751 weeks
From 15—65 .. .. .	1·314 week	1·334 week

If, however, these figures are only so far correct as to show that the amount of illness is about equal, it would certainly strengthen the view that the female vitality is more resistant if, with an equal amount of sickness, the mortality rules higher in males.

The foregoing remarks deal rather with any influence sex may exert upon disease when once established, either in determining its duration or in favouring a fatal result. There remains the more interesting and more practically important enquiry, does sex of itself influence the causation of disease; which is met by investigating any special prevalence of disease that may exist among males or females. It will be at once apparent that the difference between the sexes as regards the occurrence of disease is both absolute and relative; that there are some maladies peculiar to each, and some common to both, though perhaps varying in the frequency of their appearance in one or the other.

The affections comprised within the former group are manifestly those connected with the organs special to each sex, which for the most part are those concerned in the function of reproduction. Inasmuch as, when considering the subject of age, I pointed out to you that it was particularly at those periods of life when organs take on a special activity or cease from the same that the liability to disease is greatest, it would follow that at puberty and the menopause the special sexual diseases are of most frequent occurrence. The establishment of the reproductive process in the male is of far less importance in the causation of disease than it is in the female, and, as there is no epoch in the life of men that can be fairly regarded as corresponding to the "change of life" in women, the activity and development of the reproductive function scarcely predispose them to disease. But in the woman the evolution of the generative organs reacts on the body generally, and establishes a liability to illness which asserts itself in a large number of cases. "On the approach of puberty," says Dr. Emmett, "the nervous system becomes dominant in the female organisation and is as susceptible to external influences as the barometer is to atmospheric changes. But the simile is not applicable later on, since an impression for good or evil, once made upon the nervous system, especially while in the adolescent period, is permanent. It may lie dormant in the after-life of the individual, but will almost surely be transmitted to future generations. At this period of life, when natural laws are disregarded, the young girl lays the foundation of a defective organisation. The boy develops imperceptibly from youth to manhood, his generative function

is perfected without special nervous disturbance and even stimulates his growth; moreover, defects in his physical condition can be remedied in after-life to a much greater extent than is possible in the female. On the contrary, with her, the transition to womanhood is rapid; her organs of generation acquire a preponderating influence in her complex organism, and her nervous system is fully taxed to secure and maintain that general harmony of function which constitutes health. The slightest defect in her sexual organs may through the medium of the sympathetic nerves produce functional derangement elsewhere." The specially feminine maladies will be those connected with the onset, occurrence, and cessation of menstruation, with pregnancy, parturition, and lactation. Of these functions, which may be performed in a perfectly normal manner, each, so far as it goes, adds a fresh liability to disease on the part of the female. And yet with these additional risks there is no increase in the mortality in women during the child-bearing stage of their life over men during the same period; and the ages of 40 to 50, when the maladies of the climacteric occur in women, are less fatal to them than to men.

I am not concerned to give you a detailed description of the special diseases associated with these different functions peculiar to women; enough if I point out their general characteristics. The slight systemic disturbance which almost invariably precedes the first appearance of the catamenia may in some cases attain considerable proportions and result in the establishing such a disturbance of the harmonious co-ordination which should prevail among the various bodily functions as to constitute the affection we designate hysteria; or it may be that some more definite neurosis is established such as epilepsy, which, I may add, occurs also in boys with great frequency for the first time at puberty. The onset of menstruation, and indeed very commonly its maintenance for some few years, is singularly liable to be associated with a simple anæmia or chlorosis to a very marked extent, and it is easy to see the various ailments of malnutrition which may follow from such a state. The periodic recurrence of the menstrual flow is the cause in many women of illness of all degrees of severity; the imperfect performance of the function itself, a too scanty discharge, even to suppression, or an excessive flux, will determine both local and general discomfort, the latter in the form of neuralgias, perversions of digestion, and all forms of mental disturbance, with perhaps a general malaise that absolutely prevents the performance of any ordinary duties. The condition of the woman during the menstrual period is also one that frequently renders her specially liable to contract disease due to that complex factor designated "catching cold," or still more to the subtle poisons of the acute specific fevers. The very distinct influence that menstruation exerts over the general health of the woman is often to be well seen in the course of these specific fevers, when, if the flow should occur during the attack, a very distinct inclination towards the typhoid type is manifested, to be passed out of when the catamenia have ceased. Another very frequent malady associated with disordered menstruation is leucorrhœa, which intensifies the injurious effects of the anæmia which it usually accompanies. Throughout the period of the highest functional activity of the generative organs their liability to disease is greatest. Most uterine and ovarian affections occur within this time, and this apart from the special dangers of pregnancy or the menstrual disturbances which I have just mentioned.

But it is in association with the loss of the reproductive power in women, and the cessation of the catamenia, that the greatest imminence to disease is met with. Frequently, as with the establishment of

\* "Principles and Practice of Gynæcology," 1884.

the function, no appreciable departure from health is observed, but in many other cases appear the first indications of that malady which will sooner or later become the fatal illness. The nervous affections which are apt to predominate at this epoch are chiefly of a neuralgic and hysterical character, occasionally even hypochondriasis or melancholia. Epilepsy rarely occurs for the first time at this period, thus offering a marked contrast to puberty. Other neuroses, as indeed most other ailments which have prevailed in previous years, are liable to be exaggerated at the climacteric. The flushings and perspirations so characteristic of this stage may be so violent and profuse as to claim recognition as disease, as in a minor degree they may be regarded as normal. Plethora of various organs are frequent, with occasional attendant hæmorrhage from mucous surfaces, or the congestion may, from the character of the organ so affected, become of serious import, as is seen in cerebral plethora. Sometimes it has been observed that there is a revival of ailments that had ceased with puberty, and the woman suffers from skin eruptions or otorrhœa, which had been in abeyance since her girlhood. On the other hand, it cannot be denied that the change of life, followed, as it very usually is, by a period of sound health, actually exerts in many instances a sanative influence upon the entire organism, and abolishes for ever many maladies, both mild and severe, which have rendered existence almost a burden for many years. With the atrophic and degenerative changes which take place in the uterus and ovaries at the change of life, the liability to the development of homologous new growths in these organs almost entirely ceases, as on the contrary heterologous neoplasms appear with marked frequency.

That pregnancy, parturition, and lactation each confers a proclivity to disease is well known. Many of the resulting maladies are to be attributed to the direct mechanical effect of the gravid uterus or the actual process of delivery. The peculiar condition of the blood in this state favours some, whilst others are brought about in a reflex manner. Thus perversions of appetite, such as complete anorexia, heartburn, flatulence, and other signs of dyspepsia, constipation and vomiting, are some of the affections of the digestive organs. Dyspnoea and palpitation illustrate cardio-respiratory disturbance. Anæmia from insufficient nourishment or floodings represents the general perversion due to pregnancy, and albuminuria and eclampsia the less common maladies. Probably the nervous system exhibits the greatest frequency, as also the greatest variety of disturbance, from mild headaches to epilepsy, chorea, and mania. Notwithstanding, however, the increased risk to illness which pregnancy renders women liable to, as a cause of death it holds but a low position in the scale. In 1883 there were registered in England and Wales 4,508 deaths from puerperal fever and child-birth, being in the proportion of 5.1 to every thousand children born alive, which is about the same rate that has been maintained for some years past. The mortality in childbed and from such conditions as may supervene within four weeks from delivery has, however, been estimated by Dr. McClintock at nearly 1 per cent.<sup>5</sup> There is a great difference, however, between primiparæ and multiparæ in regard to the dangers of parturition. Dr. Allen, of New York, published in 1872 the following results bearing upon this point. Among 10,382 primiparæ there were 168 deaths, being 1 in every 62, whilst in 26,394 multiparæ there were 213 deaths, being 1 in every 124, or exactly half the risk.

Again, the pregnant and puerperal states exert a powerfully modifying effect upon many diseases which

the patient may have acquired. Speaking generally, the whole groups of specific fevers are so gravely intensified in their severity that recovery is the exception. On the other hand, pulmonary tuberculosis, which may have proceeded to a considerable extent, is frequently in abeyance whilst gestation proceeds, to re-start with accelerated energy within a few weeks after confinement. The liability to death, however, would not seem to be excessive, since only 55 pregnant women were registered in 1883 as having died from other causes than those associated with parturition.

(To be continued.)

## PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,

President of the Health Department, Social Science Association.

(Continued from page 501.)

### DISEASES OF THE RESPIRATORY SYSTEM.

For *Influenza* in India, see vol. for 1884, p. 761. For *Croup* and *Diphtheria*, ib., pp. 625 and 760. For *Pertussis*, ib., p. 761.

*Hay Asthma*, or rather *Hay Fever*. I have already mentioned<sup>1</sup> that this affection does not appear to have been observed in India. I then alluded to the case of an aged civilian, long retired, who told me that he was subject to hay fever before he went to India, and lost it there. In one of his valuable notes on Indian disease the late Dr. Hogg wrote—"At Umballa, quite recently, a young officer, a martyr to hay fever at home, wondered why he enjoyed such entire immunity in India." A lady, a patient of my own, first went to India in middle age; she never had hay fever until she returned to England. On going back to India, the affection left her. Four other ladies of my acquaintance, three of whom were born in India, have become painfully subject to the malady in England. All suffer from coryza, one of them is asthmatic.

*Asphyxia*.—At pp. 645-652 of my "Medical Jurisprudence for India" I combated the then generally accepted opinion that the essential and invariable characteristic evidence of death by Asphyxia is the accumulation of blood in the right heart and in the lungs. I adduced evidence in proof of the fact, which I felt confident would thenceforward be generally accepted, that, although in many cases of asphyxia the muscular power of the right ventricle is overcome, and its cavity is found gorged after death, there is a set of instances in which, the action of the heart continuing after the cessation of respiration, the right ventricle is found well-contracted and nearly empty, the lungs being congested in an extreme degree; and I urged that, unless this fact be admitted, it may, in certain cases, be found difficult to substantiate our opinion that death has resulted from asphyxia.

After my work appeared Dr. Alfred Taylor added his own authority to the principles which I then advanced.

I subsequently noted the following characteristic observation by Dr. Packard, of Philadelphia.<sup>2</sup> It is given as "an instance of pure suffocation by hanging." A very strongly-built and muscular man, ætat. 37, hung himself to a banister with a piece of picture-cord wrapped with soft cotton to give it bulk; it was so

<sup>5</sup> "Death-rates in childbed."—*Brit. Med. Journal*, Aug. 10, 1878.

<sup>1</sup> Vol. i. for 1884, p. 78.

<sup>2</sup> *American Journal of Medical Science* for July, 1870.

short that he could scarcely have had more than six inches fall; he could not have been hanging more than a very few minutes when he was discovered, but death had already occurred. In the autopsy, 48 hours after death, the body having been in ice, it was found that there was strong *rigor mortis*; the upper surface was very pale, but hypostatic congestion of florid hue was present except where the body had pressed on the bottom of the box. There was considerable cerebral congestion with some ecchymosis and slight extravasation of blood. "Lungs, healthy and deeply congested, especially at their posterior parts. Heart, well-developed, *strongly contracted and empty*." [The italics are mine.—N. C.] "On its surface a somewhat unusual amount of fat; valves all healthy. Blood dark-coloured and perfectly fluid. Abdominal viscera healthy. Liver full of blood, although its surface was rather paler than normal."

*Edema Glottidis*, in Syphilitic disease. In a strong European, suffocating apparently from this cause, I waited as long as possible by the bedside, it being the rule of our hospital that surgical cases, occurring in the physicians' wards, should be made over to the surgeon of the day. At last, the patient fell over, and I opened the trachea. I could scarcely adjust the canula when, as frequently happens, the patient, tired out by long-continued dyspnoea and unrest, fell asleep. He recovered without a bad symptom.

*Polypus*.—During convalescence in the above case, the canula, having been long kept in, brought away a growth of mucous membrane about as large as a pea, which had not produced any evident obstruction.

*Laryngitis*.—Sir Joseph Fayrer has placed on record<sup>3</sup> the case of a delicate-looking native man, æt. about 28, in whom he performed tracheotomy at the moment when the patient was on the point of death from acute laryngitis. Writers on tracheotomy will find that the details of this case are replete with valuable suggestions.

I had an undoubted case of *Acute Idiopathic Laryngitis* in a youngish native woman under sentence of death in the jail at Howrah. It yielded to treatment without much difficulty. I had a case of Laryngitis, and more, in the person of a very powerful Greek, whose strength had qualified him to keep a drinking shop in Lall Bazar, the chief resort of sailors in Calcutta. Overlooking the fact that he had become old and fat, this man had a fight with a sailor stronger than himself, was very severely beaten, and fell into ill-health. He was admitted to my ward with very characteristic symptoms of acute laryngitis. Respiration was markedly more interfered with than it usually is in simple laryngitis; and he, with great difficulty, got rid of large quantities of thin mucous froth. I was with him when he suffocated, and did not lose a moment in opening the air passage, but without effect. We found that the laryngitis was caused by an aneurysm of about the size and flattened rounded shape of a child's toy watch, which, arising from the cross of the aorta, grew upwards, and was closely adherent to the bifurcation of the trachea, where it was about to open, having raised a swelling of the mucous membrane very like a small red currant. Under the head of *Mumps*<sup>4</sup> I have described the cases of two little European brothers who were attacked, one fatally, with acute laryngitis [diphtheria?] in the course of that disease.

While in India, I regarded uncomplicated idiopathic laryngitis as one of the rarest diseases of that country. Except in one very questionable specimen, Prep. 719, the condition is not represented in Ewart's

Catalogue of our Medical College Museum. The returns of the Sanitary Commissioner for the four years ending 1883, however, display what must be regarded as a very extraordinary prevalence of this disease. Thus—

*Laryngitis.*

Year 1880	European Soldiers	4 deaths
	European Women	3 admissions
	Native Troops	317 admissions
	with	56 deaths
	Prisoners	46 admissions
	with	16 deaths
" 1881	European Soldiers	3 deaths
	" "	4 invalided
	European Women	1 admission
	Native Troops	105 admissions
	with	8 deaths
	Prisoners	38 admissions
	with	8 deaths
" 1882	No deaths from Laryngitis among the European soldiers, of whom 2 were invalided for this disease.	
	European women, one was admitted and died.	
	Native Troops, 90 admissions, 5 deaths.	
	Prisoners, 22 admissions, 2 deaths.	
" 1883	No death from Laryngitis among the European soldiers; one man was invalided.	
	No case occurred among the European women.	
	Native Troops, 91 admissions, 2 deaths.	
	Prisoners, 38 admissions, 4 deaths.	

As Croup and Laryngitis are taken together in the four years' returns of European Children, I do not cite the figures.

At first sight, it might appear that this disease was laryngeal diphtheria, prevailing in Upper India not only among the sepoys on field-service, but among the inmates of the jails; but this supposition is disallowed by the fact that the returns of the four years give only four admissions for diphtheria among the native troops and prisoners in the three Presidencies, and these only in the years 1880 and 1883.

In 1883 the designation of the disease, as it occurred among the Native Soldiers and Prisoners, is changed from "Laryngitis" to "Laryngitis and Laryngeal Catarrh." This appears to be indicative of a change of type in the malady.

As I think that these statistics can only be satisfactorily explained by medical officers in whose hospitals this disease has been prevalent, I shall refrain from merely speculative comment upon them.

I saw a case of Sir Joseph Fayrer's in which [Syphilitic?] *Necrosis of the Thyroid Cartilage* proved fatal by pyæmic deposits in the lungs, &c. In July, 1881, Dr. McLeod noticed, at the Calcutta Medical Society a case of necrosis of the left ala of the thyroid cartilage in a case of chronic laryngitis in which laryngo-tracheotomy was performed. The necrosed fragment occupied a gangrenous abscess cavity, which communicated with the cavity of the larynx. The patient died of lung disease after a lingering illness.

At the same time Baboo O. L. Mookerjee exhibited a preparation of *Necrosis of the Cricoid Cartilage* from a Hindoo who was admitted moribund, suffering from very urgent dyspnoea. He was unable to speak, but pointed to his throat as the seat of his malady. The cricoid was in a state of necrosis and was surrounded by an abscess. The lungs were hepatized.

In November, the same gentleman reported another very similar case. A Hindoo was admitted with

<sup>3</sup> "Indian Annals of Medical Science," No. 3, p. 427.

<sup>4</sup> Vol. i. for 1881, p. 761.

double pneumonia, from which he recovered. Sponginess of the gums was subsequently noticed. In about three weeks, pain in the throat was complained of, the temperature rose, the voice became laryngeal, and dyspnoea set in. He died a week later. The cricoid cartilage was bare, and lay in a sloughy abscess.

I sent Preparation 727 to the Medical College Museum—"Abscess between the Thyroid and Cricoid Cartilages, and œdema of the laryngeal mucous membrane of the right side, also implicating the glottis."

In my "Medical Jurisprudence" (page 584) I have noticed a case, mentioned to me by the late Dr. Duncan Stewart, in which an aged woman, who was found dead in her bed, had one of the wings of an ossified thyroid cartilage broken and forced inwards, causing suffocation.

Preparation 713 in the Calcutta Medical College Museum represents "Ossification of the epiglottis and all the cartilages of the larynx, and fracture of the anterior portion of the ossified cricoid cartilage. The rings of the trachea are also ossified, and there is calcareous deposition in the elastic ligamentous material connecting the rings to each other; from an aged Armenian woman."

(To be continued.)

## APPOINTMENTS FOR THE WEEK.

*Friday, December 4 (this day).*

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, 8 p.m.—Mr. H. Percy Dunn, "Sac and Adjacent Parts of a Large Omental Hernia," "Pendulous Growths from Mucous Membrane of Stomach," "Tubercular Disease of Testes," "Tubercular Disease of Kidney"; Mr. C. B. Keetley, "Osteotomy of Hip," "Case of Complete Obliteration of One Nostril by Syphilis (Congenital)," "Case of Removal of whole of Lower Lip for Epithelioma"; Mr. Leonard Mark, "Drawing of above Case before Operation"; Mr. J. R. Lunn, "Drawing of a Case of Epithelioma of Lip." Papers: Mr. Dunn, for Surgeon Harold Hardley, I.M.S., "Some Cases of Interest from the late War in the Soudan"; Mr. C. B. Keetley, "Antiseptic Surgery at the West London Hospital"; Dr. Sinclair Thomson, "Suez as a Health Resort, with Notes by the Way."

*Monday, December 7.*

UNIVERSITY OF LONDON, 5 p.m.—Mr. Victor Horsley's First Brown Lecture.

ODONTOLOGICAL SOCIETY, 40, Leicester Square, 8 p.m.—Casual Communications: Messrs. W. St. George Elliott, Felix Weiss, and George Cunningham. Paper: Mr. F. S. Eve, "Some Points in the Pathology of Cystic and Encysted Solid Tumours of the Pelvis."

MEDICAL SOCIETY, 8.30 p.m.—Clinical evening. Living specimens at 8 p.m. Mr. J. Astley Bloxam, (1) "Case of Trephining," (2) "Case of Compound Comminated Fracture of the Skull"; Mr. A. Boyce Barrow, "Cases of Radical Cure of Varicocele"; Dr. C. E. Beevor, "Case of Amyotrophic Sclerosis"; Mr. E. H. Fenwick, "Case of Descending Testis in an Adult"; Dr. Maguire, "Case of Mixed Paralysis of Ocular Muscles"; Dr. J. K. Fowler, "Case of Diffuse Lipoma."

*Tuesday, December 8.*

ROYAL COLLEGE OF SURGEONS, 4 p.m.—Professor John Wood, F.R.S., The Bradshaw Lecture: "On Antiseptics."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 p.m.—Mr. Savory, "A Case of Destruction of a Portion of the Axillary Artery by Sarcoma"; Mr. T. Bryant, "Amputation at the Knee-joint by Disarticulation, with Remarks on Amputation of the Leg by Lateral Flaps."

UNIVERSITY OF LONDON, 5 p.m.—Adjourned debate on the Reconstruction of the University.

ANTHROPOLOGICAL INSTITUTE, 8 p.m.—Mr. H. H. Johnston, "Exhibition of Portraits of Africans"; Mr. W. Seton Karr, "Exhibition of Photographs of North-American Indians"; Mr. E. H. Man, "The Nicobar Islanders."

*Wednesday, December 9.*

UNIVERSITY OF LONDON, 5 p.m.—Mr. Victor Horsley's Second Brown Lecture.

EPIDEMIOLOGICAL SOCIETY, 8 p.m.—E. J. Edwardes, M.D., M.R.C.P., on the "Report of the German Vaccination Commission."

*Thursday, December 10.*

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 8.30 p.m.—Living specimens at 8 p.m. E. Nettleship, (1) "Diabetic Retinitis," (2) "Removal of Chip of Iron from Vitreous by Magnet"; W. A. Brailey, (1) "Case of Haemorrhagic Glaucoma unaccompanied by any Increase of Tension," (2) "Retinitis from Lardaceous Disease," (3) "Peculiar-looking Retinal Detachment relieved by Scleral Puncture"; G. Hartridge, "A Patient with Small Lenses (Congenital)"; W. H. Jessop, (1) "Case of Retinal Haemorrhage," (2) "Case of Detachments of Retina." Communications, &c.: Dr. Samuel West, "A Case of Double Optic Neuritis after a Fall—Perfect Vision throughout—Recovery"; E. Nettleship, "A Case of Fatal Meningitis after Excision of the Eyeball"; C. Higgins, "Neuro-paralytic Ophthalmia"; W. H. Jessop, "Note on the Fields of Vision in a Case of Diphtheria."

PARKES MUSEUM OF HYGIENE, 8 p.m.—Lecture by Mr. Eric S. Bruce, on "Health and the Electric Light."

*Friday, December 11.*

UNIVERSITY OF LONDON, 5 p.m.—Mr. Victor Horsley's Third Brown Lecture.

CLINICAL SOCIETY, 8.30 p.m.—Sir Andrew Clark, Bart., "On a Case of Desquamative Prostatitis accompanied by the Discharge of Hyaline Tube Casts"; Dr. de Havilland Hall, "Aneurysm of the Ascending and Transverse Portions of the Arch of the Aorta, Pressure on the Trachea and Bronchi on the Left Recurrent Laryngeal Nerve and (?) the Vagus"; Dr. Barlow and Mr. Rickman Godlee, "On a Case of Perforation of the Vermiform Appendix treated by Operation." Living specimens: Dr. T. D. Savill, "A Case of Myxœdema"; Dr. Stephen Mackenzie, (1) "A Case of Symmetrical Morphœa," (2) "A Leprosy-like Syphilide."

# Medical Times and Gazette.

SATURDAY, DECEMBER 5, 1885.

THERE has been great execution during the past week amongst the medical candidates for Parliament. Mr. Ernest Hart has been badly beaten in Mile End, and will now, it is to be hoped, return to the management of his journal, which has sorely missed him of late. At Greenwich, Dr. Herbert Watney has gone by the board (no pun intended). In Surrey, Dr.

Alfred Carpenter has been thrown out by a large majority, but, as his successful opponent, Sir Trevor Lawrence, is himself a doctor, and has been very useful to the profession in Parliament, this is the less to be regretted. As we could not have both, and as Dr. Carpenter is as yet an untried Parliament man, there is no reason to regret the result. The same may be said of the result of the election for South Manchester, where Mr. Peter Royle, a local practitioner, was beaten by Sir Henry Roscoe, the distinguished chemist. Professor Roscoe's entry into Parliament is a notable gain. Sir Lyon Playfair and Sir John Lubbock have both been elected without much difficulty, and they, with Sir Henry Roscoe, will form a scientific trio whom it would be difficult to match. Amongst the other medical defeats is that of Dr. Danford Thomas, the Middlesex coroner, who stood for West Islington. Dr. R. D. Lyons, who sat for Dublin in the last Parliament, and whose face and voice are familiar to the rare visitors to the meetings of the General Medical Council, is apparently also left out in the cold, as he was not even nominated for the division of Dublin, for which it was understood that he was standing. Glasgow has succeeded in returning two doctors amongst its Liberal seven, viz., Dr. Cameron and Mr. Mitchell Henry. The contest, however, in which medical men are most interested, that in which Mr. Erichsen is engaged, will not come off until all the other elections have been decided.

AMONGST medical successes we are glad to chronicle those of Dr. Farquharson in West Aberdeenshire and Dr. Balthazar Foster in Cheshire, both of the Liberal persuasion. Dr. Farquharson's easy victory will be heartily welcomed by his many friends. He is aptly described by an evening journal as a physician who has looked after his own health and is of jovial appearance. Dr. Balthazar Foster's success will somewhat make up to the lovers of the British Medical Association for the defeat of their other champion, Mr. Hart. It is a curious, and perhaps not altogether creditable, fact that the greatest number of successes scored by medical candidates will be in Ireland, amongst the Parnellite tail. Of these only Dr. O'Doherty and Mr. Tanner have yet been elected. Dr. O'Doherty has had a chequered career; while yet a medical student, he was arrested for sedition, sentenced to ten years' transportation, and shipped off to Tasmania. Subsequently pardoned, he completed his studies in Paris, and took his diplomas in Ireland in 1857. He practised for some years in Dublin, and then emigrated to Queensland, where he practised at Brisbane, and became a member of the colonial administration. He has only lately returned to his native country. To sum up, the medical practitioners as yet elected to Parliament, including Members who have forsaken medicine after graduating, are as follows:—

Cameron, Charles, M.D. (*Glasgow*).

Farquharson, Robert, M.D., F.R.C.P. (*West Aberdeenshire*).

Finlay, Robert Bannatyne, M.D. Edin., Q.C. (*Inverness Burghs*).

Foster, Balthazar Walter, M.D., F.R.C.P. (*Cheshire*).

Henry, Mitchell, F.R.C.S. Eng. (*Glasgow*).

Hunter, Sir Guyer, M.D., F.R.C.P., K.C.M.G. (*Hackney*).

Lawrence, Sir J. J. Trevor, Bart., M.R.C.S. Eng. (*Surrey*).

Macdonald, R., M.D. Durham (*Ross and Cromarty*).

O'Doherty, Kevin Izod, F.R.C.S.I. (*North Meath*).

Tanner, L. J. N., L.R.C.P., L.R.C.S. Edin. (*Mid-Cork*).

Vanderbyl, Philip John, M.D. Edin., M.R.C.P. (*Portsmouth*).

So far there is a very distinct improvement in the new Parliament, so far as the medical profession is represented.

THE work done at the last meeting of the Clinical Society, although entirely confined to one subject, was of a kind at once interesting and useful. The operative measures for the relief of incurable stricture of the upper parts of the alimentary canal have been considerably added to of late, and the four papers contributed respectively by Messrs. Barwell, Dent, Morgan, and Golding-Bird formed the basis of a discussion in which the relative merits of these measures were keenly criticised. Several points of importance were raised, and amongst them the question of the real efficacy of gastrostomy in prolonging life. Statistical evidence was brought to bear upon this matter, and seemed to show that the average length of life after the operation was but short. It was not, however, made equally clear that the relief to the patient was but slight, and, although it is perfectly well recognised that the operation is only palliative, it is equally probable that patients who are given the choice of death from cancer and death from starvation will unhesitatingly choose the former. The advantages of the cesophageal tube were not universally admitted, only a few cases being mentioned in which the tubes had been well tolerated by the patients.

THE operation of jejunostomy recorded by Mr. Golding-Bird may fairly take rank as a surgical novelty. The idea is not a new one, but no account has hitherto been published in which it has been put in practice. It possesses certain advantages over similar operations upon the parts immediately above the jejunum, but it is attended with certain dangers, as Mr. Golding-Bird's case exemplifies, which can only be avoided by the close personal attendance of the surgeon in charge of the case. Excision of the pylorus, now known by the very cacophonous title of pylorotomy, has not gained for itself in England the reputation which the successes of Billroth and Wölfler have given to it in Vienna, and this operation of "jejunostomy," although merely palliative and not curative, may, not improbably, supplant it in the practice of English surgeons.

THE chief paper of the evening at the last meeting of the Pathological Society was undoubtedly that by Mr. Arbuthnot Lane on the changes which take place in the joints and extremities as a result of pressure. His very careful study in the dissecting-room and elsewhere enabled him to bring out several points of interest, and notably the way in which the dislocations are produced by long-continued impaired range of movement in the joints of the aged, and the

manner in which the extensor tendons are apt to obtain a new insertion into the phalanges. Dr. Hadden showed the joints from two cases of Charcot's disease, and demonstrated the existence of disease of the posterior columns of the cord as well as of certain groups of motor cells in one of them; the changes in the shoulder joint in this case were very extensive. The case was rendered additionally interesting, inasmuch as the patient was already renowned for the severity of his gastric crises, for which he had some years previously been the object of treatment by Dr. Buzzard, and examination of the medulla afforded some support to the theory as to these crises having a central origin on the medulla, which Dr. Buzzard suggested some few years ago. Mr. J. Hutchinson, jun., read a short paper on sub-peritonæal lipomata, drawing attention to the various points of interest in connection with them, the discussion which followed turning chiefly on the relationship of lipomata to the spermatic cord. Dr. Carrington communicated a case of cancer of the thyroid gland, which turned out to be by no means so rare an occurrence as he had supposed. Mr. D'Arcy Power showed two well-marked cases of osteitis deformans, and Dr. Gulliver communicated an interesting case of stricture of the small intestine, in which, however, there had at no time been any symptoms of obstruction.

THE usual monthly meeting of the Obstetrical Society was held on Wednesday evening last. Dr. John Williams presented a specimen, the only one, we believe, ever publicly exhibited, of corroding ulcer of the uterus. A paper by him on the subject was published in the last volume of the Transactions; and in that paper he detailed three cases of that rare disease. One of those patients has since died, and Dr. Williams was thus enabled to exhibit her pelvic organs. All present could thus convince themselves of the accuracy of Dr. Williams' clinical description. Microscopical sections of the diseased structures were displayed upon the table. Some other interesting specimens—ruptured pyo-salpinx, extra-uterine gestation, and conjoined twins—were also shown. The major part of the evening was taken up, first, with a short paper by Dr. Arnold Thomson on a case of protracted pregnancy; then with a detailed essay on the inflammations and strictures of lupus of the female genitals, by Dr. Matthews Duncan, being the last of three papers which complete his description of the clinical character of this disease. To this was appended on account of the histology, by Dr. Thin. This paper excited but little discussion; and the evening was finished with a good account of a case of spurious pregnancy and labour, by Dr. Roxburgh Fuller. Many speakers related similar cases; from which it would seem that the disease is not so rare as the paucity of well-observed cases might make one think.

THE movement for providing a Teaching University for London moves slowly, but still it moves. The Association which has taken the movement under its special charge held its annual meeting on Wednesday, under the Presidency of Mr. John Marshall, and com-

missioned its committee to open communications with the governing bodies of the University of London, University College, King's College, and other institutions. The Association still adopts an expectant attitude with regard to Convocation of the London University, which body again meets on Tuesday next. It looks very much, however, as if that body, by rejecting Lord Justice Fry's scheme, has practically decided that the London University shall not reform itself in such a manner as to meet the aspirations of the Association. Mr. Magnus, who led the majority which rejected Lord Justice Fry's proposals, has drawn up a skeleton scheme which certainly seems little calculated to convert the present university into a Teaching University. If adopted, it may convert it more or less into a Teacher's University, but it does not appear to contemplate any real co-operation of the teaching bodies under the control of the University. What most teachers seem to mean when they talk about a Teaching University is a university in which the teachers shall be able to control the examinations. They are not opposed to the idea of professorships being attached to the University, but that forms a very subordinate part of their proposals. In our view, a university which could not rearrange and economise the teaching of the metropolis, and provide for senior students something higher in the way of teaching than they get now, would not be worth fighting for. The exact constitution of a university, whether it shall have Boards of Studies or Councils of Education or faculties, is an entirely minor matter, which ought to be kept subordinate to the main object of providing London with a central university which shall take in hand and direct the higher teaching throughout the metropolis.

THE deaths in London last week reached a figure, 1610, which has not been attained for many weeks past, but which is still 122 below the average; the death-rate for the first half of the present quarter is more than 2.0 per mille below the average. As regards the zymotic diseases, we find there was a serious increase in the deaths from measles, which rose from 44 during the preceding week to 62 last week; with seven exceptions, the deaths occurred in children under five years of age. There was a slight rise in the number of fatal cases of whooping-cough, which amounted to 47, or 12 more than the average; scarlet fever caused 12 deaths, the average for the week being over 70, and the high death-rate recorded from diphtheria in the preceding week was unfortunately maintained, there having again been 20 deaths from this disease. Enteric fever only claimed 14 victims as against 24 during the preceding week, and there were but two deaths of Londoners from small-pox. A further rise in the deaths from diseases of the respiratory system brought the total number up to 480, which is slightly in excess of the average for the past ten years, but which is not bad when the fact is known that we only had one hour's sunshine and nearly an inch and a half of rain during the week. Ten women died from puerperal fever, and 14 infants from suffocation, facts which show that there is work yet for our sanitarians and—shall we say—humanitarians.

The unusual number of three deaths were attributed to hydrophobia, bringing up the total for the year, so

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eleven weeks.

far as concerns the metropolis, to 25. It is worth noting that neither Glasgow nor Dublin furnished any deaths from measles during the week.

WE are going to say something that may not be quite palatable to some of our readers, but we cannot help that. It seems to us our plain duty to say it. No one can suspect us of any wish to justify the act by which Dr. Heywood Smith has brought down the wrath of the profession on his head, or of any secret sympathy with the *Pall Mall Gazette*, so that we can say what we have to say with less fear of misconstruction than either of our contemporaries. It is this. We fear that the profession, and especially its leaders, are inclined to act towards Dr. Heywood Smith with too little regard to wisdom, justice, or charity. We fear that, led away by their disgust at the theatrical indecencies of the *Pall Mall Gazette*, they are inclined to mete out a punishment to the only victim within their reach out of all proportion to his offence. Dr. Heywood Smith, by a most grave error of judgment, was led to commit an act which no sane man can justify or extenuate. That he should be shown, by the unhesitating voice of its leaders and organs, that the profession utterly reprobates that act, was only natural and proper. But that he should be drummed out of the profession, that he should be turned out of his appointments and expelled from the scientific societies as a moral leper, whom no respectable man can comfortably assort with—that, in a word, he should be utterly broken—is a punishment which will be admitted by all of us, when we are able to think of it coolly, to be ridiculously disproportionate to his offence.

To our minds the solemn words of the judge, supplemented by a censure from the College of Physicians, would have been a fair and equitable punishment; so equitable that there would then have been no prospect of Dr. Heywood Smith's being able to earn that crown of martyrdom which will undoubtedly be pressed upon him by sentimental enthusiasts if the profession does not hold its hand. To a man in Dr. Smith's position the censure of an English judge means a terrible punishment, and that alone almost rendered it unnecessary for any medical body to take further action. We know it has been contended that the profession cannot afford to let it be supposed that it is less tolerant of the irregularities of its members than the laity. That feeling has, no doubt, largely influenced the position of our leaders towards Dr. Smith. In our opinion, however, it is an unworthy motive. We ought to do what we think just and right, without any regard whatever to the opinion which the public may form of our actions. If the medical profession and press had only shown less disposition on previous occasions to close in around their accused brethren, and to support them against public censure through thick and thin, there would have been less need for the present attempt to win a cheap reputation for stainless morality by the casting out of a sinning member. We have this week received a prospectus from the new Medical Defence Union, with some of the objects of which we do not wholly sympathise. If the profession loses its head again as it has done in Dr. Heywood Smith's case, we shall want a Defence Union, not so much for defending practitioners from the attacks of others, as for protecting them against ourselves.

NOTHING could be more prompt than the manner in which the organised troops of Servia and Bulgaria apparently "sprang to arms" on the declaration of war. Fighting began within the first few days, and was continued with a pertinacity worthy of a greater cause; but it appears that very little thought was taken for the care of the sick and wounded, who must of necessity follow in the train of active warfare, especially in the month of November. The example set by England in former years has, however, been followed to some purpose in Vienna, and several ambulance corps have been sent to the seat of war, not only by private enterprise, but also by the Austrian Foreign Office. Great impartiality has been shown in the distribution of this timely assistance, each ambulance being fairly divided between the two belligerents. Professor von Mosetig-Moorhof directs one of the chief companies on the Servian side, from which fact it may be safely concluded that the virtues of iodoform as a field antiseptic will receive a very full trial. The Red Cross Society in Vienna possesses a very fully equipped field hospital, capable of accommodating 200 wounded, but it would appear that it is, for the present, reserved for home service, although at the present moment it would be of incalculable value in a country with so little hospital accommodation as Bulgaria. Meanwhile, we are glad to see that the English Red Cross Society has not been inactive, one of its representatives, accompanied by an English surgeon, having been sent to each of the belligerents.

For the Servians an excellent choice has been made in Mr. F. N. Hume, who was present in the Turco-Servian war, and who has since then resided for a considerable period in Servia. He knows the Servian language well, acted for a short period as American Consul at Belgrade, and is a *persona grata* in the Servian capital.

MEDICAL science has lost another of its younger members from diphtheria, that fatal malady which has already removed so many from the ranks and seriously imperilled the working capacities of others. In the case of Miss Prideaux, whose death we have to record this week, the loss is the more striking, perhaps, on account of the sad ending of a career, which had already been brilliant, at the very moment when the way seemed open for a fresh development of congenial work, full of interest and usefulness. When Miss Prideaux gained the Exhibition and Gold Medal in Anatomy at the Intermediate M.B. Examination of the London University in 1881, even those most sceptical of the fitness of women for medicine could not withhold their applause from this achievement, which exhibited in an unexpected way the serious zeal and earnest work of one of those to whom medical qualifications were being granted so grudgingly. In her subsequent work at the Royal Free Hospital, she came under the admirable guidance of the late Dr. Buchanan Baxter, from whom she imbibed in a marked manner an ardent desire for scientific accuracy. Those who knew her most intimately will realise most fully the loss sustained by her death, for her intellectual powers were the least of her gifts. The real value and extent of her work are not to be measured by any mere enumeration of honours awarded to her, but are to be sought in a more valuable and more enduring direction, namely, in the beneficial influence she exercised over the younger students associated with her, teaching them, by dint of the example of noble work and unflinching self-devotion, how fully she had grasped the highest medical ideal.

THE fact that three more deaths from hydrophobia have been registered in London will do something, perhaps, towards stirring up the Commissioner of Police to take more stringent measures against the spread of rabies. Such measures have become imperatively necessary, as fresh cases of rabies are known to be constantly making their appearance. The badge and collar expedient may be sufficient to keep down rabies in ordinary time, but when it prevails epidemically, or rather epizootically, as at present, the only efficient method of stamping it out is the muzzle. The Commissioner of Police can to-morrow, if he will, issue an order that every dog in the street shall be muzzled or led, the police being empowered to take up all dogs not so guarded. The Granhan wire muzzle is a safe and comfortable appliance, which does not interfere in any way with a dog's breathing or drinking, and is worn without sign of distress. The prejudice against the use of the muzzle is founded entirely on an exclusive experience of the old-fashioned leather-strap muzzle, which is no doubt a barbarous apparatus. The wire muzzle is entirely different. As the advertisements

say, it has only to be known in order to be cordially appreciated.

It is a strange commentary on the inefficiency of Metropolitan government that a Society has had to be formed with a view to check the great increase in the number of deaths from hydrophobia which has lately taken place. The objects of the Society are (1) to enforce existing laws as to the capture and destruction of stray and ownerless dogs; (2) to move Parliament for further legislation in reference to dogs by an increase of the dog tax; by making it compulsory to have the name and address of the owner on every dog's collar, and a ticket denoting that the tax has been paid; (3) to obtain all possible information on the cause, symptoms, and treatment of the disease, and to make the conclusions arrived at known to the public. The offices of the Society are at 64, Jermyn Street, S.W.

#### THE COUNCIL'S APOLOGY.

WE published last week the statement which has been prepared by the President and Vice-Presidents of the College of Surgeons for presentation to the meeting of Fellows and Members which is to be held on Thursday week. The statement is undeniably an able and temperate defence of the policy unanimously adopted by the Council, and we hope it will be treated by the adherents of the Members' Association with the seriousness and the courtesy it deserves. As to the wisdom of the Council in thus formulating the reasons for their action we say nothing, but it will be generally admitted that they have thereby broken once for all with the "sit pro ratione voluntas" attitude which they so long maintained. It is due to their courtesy, we repeat, that the Statement should be courteously received, and it is due, we think, to their intelligence that it should be discussed with all the intellect that those who disagree with it can dispose of. We have never, for our own part, attached much importance to the argument from analogy, on which those who have drafted the Statement lay most stress. We would far rather rest the case for the enlargement of the College franchise on the benefits to the College itself, and to its Members, which might be expected to accrue from an enlargement of the number of those who take a living interest in its prosperity. But, as the Council have elected to base their plea on the argument from analogy, it is there that we must meet them. And, on examining their carefully worded dialectics, we must confess that they prove to be simply a revival of the old argument by which the opponents of an enlarged suffrage have always met its advocates. We are told that in his diploma a Member of the College receives more than the equivalent of his money in the rights, privileges, and immunities which he thereby acquires. Well, exactly the same argument was used against the extension of the political franchise. The unenfranchised were told with wearisome iteration that they received a fair equivalent for the taxes they paid in the rights, privileges, and immunities they thereby acquired.

They bore the glorious title of English citizens, they enjoyed freedom at home and inviolability abroad. Their goods and their chattels and the sanctity of their persons were guarded by the whole apparatus of the law. And so, argued the defenders of privilege, they had no equitable claim to take part in deciding how their contributions to the State exchequer should be expended. Thanks, however, in a large degree to the spirit of our American cousins, that contention was impugned, then sapped, and finally discarded by the nation, and that page of history has been slowly turned and pasted down, never again to be re-opened. So firmly is the political principle that taxation must imply representation established in the English mind that we venture to assert that, if ten thousand of the Members of the College of Surgeons were to petition Parliament not to grant any new charter to the College in which their right to take part in the elections to the Council was not admitted, there is not a single prominent politician who would not heartily endorse their appeal. The Council must know and feel this, and, if it should ever become necessary, which we hope it never may, to request the State to interfere in the struggle between the Council and the Members, the line which it would take is a foregone conclusion. The arguments of the Council would be swept away as the web of sophistry they are.

It ought to have been obvious to the Council that their argument tells just as much against the claim of the Fellows to vote as against that of the Members. If the Members receive a fair equivalent in rights and privileges for the fees paid for their Membership, the Fellows derive a much more than fair equivalent for the fees paid for their Fellowship. A man can take the Fellowship direct for a few pounds more than the Membership, and those few pounds throw open to him hundreds of appointments throughout the country. If the fee for the Membership is fully covered by the privileges which the College has the monopoly of conveying, surely the additional fee required for the Fellowship is fully covered by the higher career which it opens to the surgeon. According to the contention of the Council, the right to vote must be something thrown in above and beyond the fair equivalent for the Fellowship fee. And, if so, there is no equitable reason why it should not equally be granted to the Members. That the concession would not be just to the Fellows is only one of those appeals to vested interest which have always come so glibly from the lips of the defenders of privilege. It may gain a few Fellows over to the Council, but it is scarcely worthy of serious consideration.

As regards the second part of their Statement, we must admit that the officers of the College have made out a good case against the claim of the Fellows and Members to veto every change in the By-laws and Ordinances of the College. And we acknowledge the conciliatoriness of the expression with which the Statement concludes, viz., that on larger questions the Council will be "glad to have an opportunity, so far as practicable, of consulting the Fellows and Members." How much this concession is worth must depend, of course, on the view which future Councils take of two phrases: first, the

precise meaning of "larger questions," and secondly, the exact connotation of "gladness." If gladness is to invariably imply "intention," the Fellows and Members will do well to courteously accept the concession. If it is only a polite phrase for accepting an engagement which is not intended to be kept, because to refuse it would be rude and inconvenient, we hope that the Fellows and Members will not rest until their claim to a right to exercise some control over the larger policy of the College is written on something more durable than an occasional circular.

---

#### THE INTERNATIONAL BRAIN-RACE.

THE rivalry existing amongst savage tribes, and recognised in their case as a struggle for existence, becomes refined into a contest for precedence amongst civilized nations, and is tersely expressed in the idiom of a commercial age as competition. Ever since people took to fighting more with their brains than with their hands, success has naturally inclined to the side of those who were best fitted by mental aptitude and training to command it. The nature and value of these conditions of success was soon appreciated by those who found themselves making but indifferent progress. They observed the methods followed by their neighbours, adopted or imitated what seemed to be of value, and endeavoured, whenever possible, to improve upon it for their own advantage. There has been no attempt to establish anything like patent rights in education. Journals, congresses, reports, commissions, have glorified its aims, formulated the minutiae of its working, and spread the seeming science of it broadcast; until every country which can claim to be marching on the road of Progress has given itself up to the business of vigorously stimulating the perceptive faculties of its sons and daughters while endeavouring to provide the most concentrated forms of intellectual pabulum for their absorption. Under these circumstances, and in an epoch which is remarkable for the brilliancy and variety of its mechanical achievements, it can excite little surprise to find that education is pursued with much the same object and on very similar lines in different lands; or to observe that such differences as do exist are almost wholly dependent upon the nature of the material and the greater or less rigour with which the forces engaged in moulding it are brought to bear. Seeing that the material in question is human, it should be a matter of some interest to enquire what results, so far as they are yet recognisable, have been hitherto attained, and what are promised by the future; so that we may form some estimate as to how far the methods used are of real value for attaining the desired end. Although such an enquiry could not be included within the limits of any single article, certain broad facts may be stated which are not without a grim suggestiveness.

In the first place it is to be observed that, while the higher education of the masses was originally, and rightly, preached as a thing good and beautiful, desirable for its own sake, and carrying with it its own reward, it is now rather the incidental advantage of favouring material prosperity which is put

forward in many quarters as its chief recommendation. We do not mean merely that a knowledge of the dead languages, for instance, though granted a certain social standing as an "acquirement," is spoken of as being practically much below French and German in educational value, because a knowledge of these latter represents a more certain, marketable, and ready-money value to the possessor in his competitive struggle for a clerkship, for example; all of which may, in one sense at least, be true enough. But it is being loudly proclaimed that education is of value because without it a nation has no chance with its neighbours; and, further, that unless it passes as a nation, or at least fully equals the educational standard which has been set up by its neighbours, it must surely be beaten in the international competitions of science, trade, and manufacture. One result is that each nation is anxiously observing the educational standard which has been adopted by its rivals as the minimum requisite for their commercial salvation, and then fixing its own standard at a rather higher point upon the intellectual pressure gauge, so as to be on the safe side as far as possible; with the necessary consequence that stringent efforts are made to force the level of national brain-culture up to the specified point—and as far beyond it as it can be made to go—on the plea that anything less would be a confession of national incompetence and the inevitable forerunner of national ruin.

The natural conservatism of English minds has hitherto prevented the educational machinery of this country from being thus directly prostituted to the apparent exigencies of our merely material welfare. And though the cry is repeatedly raised for further movement in this direction, there is yet time to profit by the results that are apparent in other quarters. In regard to Germany, it appears from a circular issued by the *Provinzial-Schulcollegium* of Westphalia, and officially recognised as valid for Prussia, that the maximum of daily school work considered to be compatible with a due regard for health was fixed at limits rising from 7.2 hours per day for children of 11½ years of age up to 9.3 hours for those of 16½ and over. This standard is still deemed too high by German school-teachers and German doctors. Dr. Emanuel Roth, in his recent treatise on heredity, after contrasting the modern training of children with that pursued by the ancients, says, "We must attribute to the way in which we neglect the training of the body the fact that 64 per cent. of those who should work are found good for nothing, and that a larger percentage of the young men who leave the higher schools are below the normal standard of health." But Denmark exceeds the German maxima by so much that, while children of seven have a little over five hours of daily school work, those of eleven do more than eight and lads of seventeen and eighteen more than eleven hours of school work per day,—the latter amount being two hours in excess of the German limit! It is not surprising that the Danish Government Commission which was appointed after the publication of Dr. Hertel's startling report should, after investigating schools of all grades, have declared that 29 per cent. of the boys and 41 per cent. of the

girls are in a sickly state of health. In Sweden the school-work is a little heavier, but the holidays are longer than in Denmark, and the pupils leave school at a somewhat higher age. The official spokesmen of many Norwegian schools affirm that their pupils are overloaded with work,—several of them working in the highest classes eleven hours daily. Yet the Norwegian School Commission, while admitting the existence of the grievous overpressure exposed by the investigations of the Medical Society of Christiania at the instigation of the school-teachers, gives as its principal reason for not considering the educational demands excessive that "in the Danish schools the prescribed work is much greater." On several hands it has been pointed out that, even where the school hours may not now be longer than they formerly were, "yet, the subject-matter now demanded being much more difficult and requiring more concentrated attention on the part of the learners than was the case thirty years ago, the work is altogether much more exhausting." Such mad attempts at early spurring in the international brain-race are as senseless as they are unnatural. For nature raises the intellectual level of a race by the careful and harmonious culture of successive generations, not by the perilous process of forcing the undeveloped brain of the half-grown individual, keeping it continually at high-pressure, and working each nascent faculty to the utmost limit of endurance during the period of immaturity. And the Nemesis is as sure as it is terrible. The brighter the blaze, the sooner it is over, and the feebler the spark that is left to light the lamps of succeeding generations. Whatever may be said for the simultaneous rational culture of mind and body, there can be no doubt that the exclusive education of only one of the dual elements in man's nature is fraught with ultimate disaster to his race. The parent "all brain and intellect" is only too likely to bequeath what is thoughtlessly called a "splendid example" to his offspring, weighted with a constitution physically too feeble to profit by it. A sudden flight of rockets is impressive, but an inheritance of charred sticks and empty cases is only a poor substitute for the steady flame of the beacon fire. In the long and uphill race of life—so much longer for the nation than for the individual—those who are forcing the pace at the start are by no means those most likely to be in front at the finish. No man, and still more truly no community, can afford, in the long run, to sacrifice physical staying power to temporary intellectual speed. Both grow better and to larger purposes when wisely trained together.

The pessimist will tell us this is no new tale, but rather of a piece with the evolution and decay of nations ever since time began. As peoples grew in culture and in intellectual stature, he will say; as they learned to treat their own bodies kindly, and so gradually lost the hardihood begotten of earlier buffetings; as they cared for their feeble ones and cured their sick, and intermarried with them, favouring the survival of the unfittest; as, in the keen mental competition thus aroused, they began to spur on their intellectual powers in the race, regardless of excess, and careful only for those immediate results from

which they augured still greater successes in the future—they were working out their own reward. The temporary survival of the unfittest only the more certainly ensures their ultimate destruction. As the more intellectual race wanes physically, savage tribes, just issuing from barbarism, press on its track, come up with it in the world's race at a stage when luxury and abuse of intellect have combined to leave it no equivalent for lost brute strength, and so, getting the upper hand, supplant their intellectual superiors, to follow, themselves, in the same steps of intellectual growth, suicide, and supercession by some whilom inferior. We are beginning to realize that certain ages in the world's history are "dark" to us only because the records of that time have been so scantily preserved. The microscopic engraving on old Latin gems; some utterly lost arts of glass and metal working; the surgical instruments which seem only faithful copies of last year's inventions, though they have been disinterred from the ashes of Pompeii; the glass beads discovered from time to time in Abyssinian soil, which no modern art can equal; the vanished power by which the Bushman's ancestors built splendid roadways and "made things to go over rivers"; the marvels of engineering skill preserved in Egypt, and the silent temples of Peru—tell the same story of a succession of civilized cultures which waxed and waned, each slain in the hurry of its own ambition. Is this one of the ways in which Nature makes use of the pride of poor humanity to prevent an over-population of the earth? What will be the language, and what the cult, of European nations ten centuries hence? And will an alien race, then beginning to be myopic, and just adopting the principle of free and compulsory education, dispute over the ruins of Oxford, as we do about Stonehenge, and look upon the grass-grown *débris* of the London Board Schools as indifferently constructed barrows marking the site of some stupendous battle-field? The intellectual struggle between civilized nations is becoming keener every day, and is pressing more and more hardly on the youth of successive generations. Is there no warning of what this may lead to in the history of the past? Is it extravagant to say that nation after nation has forced its culture up to a pitch and with a rapidity which its physical strength was unequal to sustaining, burying in its fall arts and sciences which other peoples have subsequently learned only by toilsome re-discovery; and is this the pathetic secret of the wise king's saying "There is nothing new under the Sun"? If education were merely brain culture, and if it is to be pursued as such, the question is no unreasonable one.

**THE ANTHROPOLOGICAL INSTITUTE.**—At a meeting of this association held on Tuesday week, Mr. Francis Galton, F.R.S., the President, exhibited, on behalf of Dr. Billings, of the United States Army, a collection of composite photographs of skulls. There were in all 20 photographs, forming four series, referring respectively to Sandwich Islanders, ancient Californians, Arapahoe Indians, and Witchitaw Indians, and each composite was the mean of six adult male skulls.

## REVIEWS AND NOTICES OF BOOKS.

### THE SOCIETIES' YEAR-BOOKS.<sup>1</sup>

THE works included in the present article by no means exhaust the list of our societies engaged in the never-ending task of probing the secrets of nature, but the list is sufficiently long to afford some indication of the strenuous efforts that are being made in that direction, and with this preface we will proceed to briefly examine the contents of each of the volumes now before us.

The sixty-eighth volume of the *Medico-Chirurgical Transactions* maintains the traditions of its predecessors as much by the general excellence of what it actually contains as by the inexorable, though not easily determinable, exclusion of much that might have been put in. Dr. Kidd's paper, on the Distribution of the Tubercle Bacilli in the Lesions of Phthisis, will be read with interest. It gave rise to a discussion which occupied not less than three evenings, and has had the effect of establishing beyond any doubt the ætiological significance of these organisms. Dr. Samuel West's paper, on Fatal Hæmoptysis, was another paper which will bear careful study and re-perusal. The paper is a statistical contribution to the opinion, now generally held, that fatal pulmonary hæmorrhage has for its cause, with but few exceptions, some gross lesion of the pulmonary vessels, viz., ruptured aneurysm or erosion. Mr. Lunn's case of cure of an aneurysm of the abdominal aorta by distal compression, but proving fatal on the eleventh day from gangrene of the jejunum, belongs to the greatest of surgical rarities. Dr. Beevor's paper, illustrating the Localisation of Motor Centres in the Braehial Enlargement of the Cord, marks a decided advance in neural pathology, while Dr. Hughes Bennett's case of Cerebral Tumour, which Mr. Godlee removed, shows what may ultimately be hoped for from a careful development of this subject of localisation. Dr. George Johnson's paper on Cholera is among those absent from the volume. It at least served as the basis for an admirable discussion, which gave Fellows the opportunity of learning the weak and the strong points of the most recent views on the nature of this direful malady.

The thirty-sixth volume of *Transactions*, issued by the Pathological Society, contains the record of 229 communications made during the past session, occupying some 560 pages, the longest section being that devoted to diseases of the osseous system. With the enormous mass of facts contained in the volume it is impossible for us to attempt to deal, and it must not be assumed that the papers to which we make no allusion are of necessity in any way inferior to or of less importance than those of which we are able to make a bare mention. Taking them in the order in which they occur in the volume, we find the very full report by Drs. Semon and Payne of their case (unique in this country at any rate) of rhino-scleroma, to which is appended the short report communicated by Dr. Payne at the first meeting of this session on the discovery of bacilli in sections of the growth, their presence having been denied when the communication was originally made. Next we come upon a valuable research by Mr. Arbutnot Lane on the subject of fracture of the larynx, which has caused us to modify very considerably the previously accepted doctrines as to the extreme fatality of certain

*Transactions of the Edinburgh Obstetrical Society*, vol. x., Session 1884-85. Edinburgh: Oliver & Boyd, 1885.

varieties of this accident. Mr. Paul's paper on adenoma and primary carcinoma of the liver, and Mr. Shattock's account of two cases of actinomycosis in man, are certain to be frequently quoted in the future, whilst Mr. Godlee's paper on simple fractures of the skull in the infant, and Mr. Lane's on the changes in the spinal column produced by pressure, constitute real additions to our knowledge. The subject of Addison's disease attracted considerable attention both in communications on that disease itself and more especially from the papers by Drs. Coupland, Barlow, Hadden, and Saundby on atrophy of the adrenals. We have become so accustomed to look for something from Mr. Sutton's pen that the volume would almost seem incomplete did it not contain excellent communications from this gentleman under the head of comparative pathology. As usual, there are a large number of plates, mostly illustrative of microscopical drawings.

The eighteenth issue of the Annals of the Clinical Society presents, among many others, two records which will probably take a prominent position in medical literature for some years to come. Three cases of joint disease in connection with locomotor ataxy were brought forward a year ago by Mr. Marrant Baker, and excited among physicians and surgeons alike a discussion which was carried on for several nights with great vigour. The debate was taken up by some of the leading authorities in medicine, surgery, and pathology, and was illustrated by a valuable series of specimens contributed by Professor Charcot. In the new volume this debate may be studied in its entirety, and will form a standing record of the present state of opinion on the difficult question of chronic inflammation of joints. Although it can hardly be said to mark any great advance in knowledge, it unquestionably lays down with useful accuracy the limits of our ignorance on the subject. Another communication, of even greater practical value, is the report of the committee appointed to investigate the subject of spina bifida. It was rightly described by the President as a report which would do credit to any Society, and might form a useful model for future work of a similar kind. As a record of thorough and painstaking investigation, and as a trustworthy analysis of all previous work upon the subject, it will not easily be surpassed. Scattered throughout the Transactions will be found a considerable number of cases illustrative of recent advances in abdominal surgery, the most remarkable of which are the cases of nephro-lithotomy, an operation which is rapidly taking rank as an ordinary rather than as an extraordinary operation in surgery. A novel procedure, suggested by the late Dr. Mahomed, and carried out by Mr. Symonds under his supervision, was that of removal of a foreign body from the vermiform appendix for the relief of recurrent attacks of perityphlitis. The case was completely successful both in its immediate and its ultimate results. The new volume of the Transactions, containing as it does so many features of especial and remarkable interest, will undoubtedly hold the position, which it deserves, as one of the best of the series, and we are glad to notice that our hint as to cutting the pages before issuing the volume has been adopted.

The Ophthalmological Society enjoys the credit of having had its volume ready for delivery before any of the other Societies. The Society has now weathered five sessions, and with a steadily increasing roll of members and a satisfactory balance-sheet fully demonstrates the wisdom and foresight of its founders. The volume opens with the first Bowman lecture, which was delivered rather more than a year ago by Mr. Jonathan Hutchinson, the President of the Society, and this is followed by a detailed account of the measures taken by the Society in its unfortunately fruitless endeavour to induce the late Government to do something to prevent blindness from ophthalmia neonatorum. There are not many formal papers in the volume, fewer indeed than usual, but it must be remembered that the chief feature of this Society consists in the exhibition of living specimens, and in this respect the work of the past session was quite as good as that in any of the previous ones. The most important communications are, firstly, one by the President on a blood theory in explanation of reflex ophthalmitis, one by Dr. Brailey on the condition of the ciliary nerves in certain diseases of

the eye, a valuable report on amblyopia from bisulphide of carbon, and a further communication by Messrs. Edmunds and Lawford on the condition of the optic nerves in intracranial diseases. The volume closes with three papers by Messrs. Benson, Nettleship, and Jessop, relating to cocaine.

The eighth volume of the proceedings of the Medical Society shows that this Society has made considerable progress in the publication of its proceedings. At first, no volume was issued; then two or three years were included in the same volume; then an attempt was made to report the remarks to which the papers gave rise at the meetings, while in the present volume we only have the papers themselves, readers being referred to the journals for such discussion as took place. We believe it is in contemplation to issue the speeches in an official form, and, if this be so, we must congratulate the Society on its spirited policy. The most noteworthy paper in the present volume is one by Sir Joseph Lister on "Corrosive Sublimate as a surgical dressing." The great interest taken in the subject from the first depended not alone on the personal influence of Lister, but on the efficiency and the many valuable attributes of corrosive sublimate as an antiseptic—its great power, its non-volatility, its inexpensiveness, and its general applicability. Dr. de H. Hall's paper on Surgical Scarlet Fever, and that by Mr. Treves on Intussusception, are specially noteworthy. Mr. Braine's introduction to the discussion on Anæsthetics and their administration should be carefully read by every surgeon. Dr. Lauder Brunton's Lettsomian Lectures must also be again carefully gone through. The volume is edited by the two Secretaries, Dr. Kingston Fowler and Mr. J. H. Morgan.

The third volume of the Transactions of the Academy of Medicine in Ireland is in every way equal to its predecessors. The work done in the different sections is as usual kept separate, the section of Medicine, of course, leading the way. The volume is full of interesting communications from beginning to end, the two most elaborate papers being one by Dr. Grimshaw on the relative prevalence of disease and the relative death-rates in town and country districts in Ireland, and the other by Dr. Jacob on compulsory notification of infectious disease, in which he puts forward and defends his views with much vigour. It is not without interest to notice that the obstetrical and pathological sections have given up the practice of exhibiting specimens by card; we can only suppose that this is owing to the well-known natural loquacity of the Irish refusing to hide its light under a card specimen. Fortunately, at our own Societies there is no tendency for this method to fall into disfavour. The Annual Report shows that the Academy is in a flourishing state, the number of Fellows and Members having increased, and the financial position being quite satisfactory.

The fourth volume of the Edinburgh Medico-Chirurgical Society's Transactions is slightly larger than its predecessor, and in regard to matter fully maintains the reputation which the previous issues have gained. Amongst the chief papers we notice one by Dr. Littlejohn on a case of poisoning by nitrate of potash, which will be read with great interest, not only on account of the rarity of poisoning by nitre, but for the valuable remarks on the duty of the medical practitioner when he suspects during life that he is dealing with a case of slow poisoning. Professor Grainger Stewart's excellent paper on tapping the pericardium will repay perusal, followed as it was by a full discussion, and the same may be said of the contribution from Dr. Clouston on certificates of mental unsoundness, which gave rise to a discussion in which all the leading alienists of Scotland seem to have taken part. Dr. Milne Murray has a long article on the cessation of respiration under chloroform and its restoration by a new method, a paper which demands the attentive consideration of all who have to deal with anæsthetics. We ought to mention, too, an excellent paper by Professor M'Call Anderson on the best means of controlling the febrile state, and one by Mr. J. Macdonald Brown on the ætiology of rickets.

We have to congratulate the Obstetrical Society of Edin-

burgh on another volume of Transactions, containing some excellent work. The most important papers in it are those by Dr. A. H. Freeland Barbour. In one, he minutely describes the mechanism of the third stage of labour, the mode of detachment and expulsion of the fetal membranes from the uterus, and deduces from this some practical points of importance as to the management of this part of the parturient process. In another, he relates a well-observed case of puerperal septicæmia, to which he appends a full and careful *résumé* of our present knowledge of this disease and its connection with micro-organisms. Dr. J. W. Ballantyne contributes some valuable observations made with the sphygmograph in a case of puerperal eclampsia. The whole volume affords gratifying evidence of healthy activity in Edinburgh.

*The History of Cholera in India from 1862 to 1881*; by Dep.-Surg.-Gen. H. W. BELLEW, C.S.I. London: Trübner, 1885. 8vo., pp. 839, with maps, &c. — In 1881, the Government of India appointed a "special Commission to enquire into the recent prevalence of cholera in certain parts of the Punjab." As secretary to this commission, of which he was at the same time the only medical member, the accomplished author of the present work had to deal with a vast amount of information respecting the history of cholera during the last twenty years in all parts of India. That these materials collected with much labour should not meet the usual fate of Blue books, Mr. Bellew determined to collate and publish the substance of these documents, together with a statement of the conclusions to which he had come as to the nature and the mode of propagation of the disease. His own views, with which we shall chiefly concern ourselves, are contained in the last section of the work, and the first is introductory, the rest consisting of statistical and historical matter. The second to the tenth sections deal in order with the geography, population, physical aspects, meteorology, and the history of the cholera, year by year in each of the nine provinces into which our Indian empire is now divided, and contain a mass of information invaluable to every student of the subject, whether he be disposed to agree with the author's conclusions or not; but an attempt to give an abstract or any account of their contents is obviously out of the question. Section xi. consists of meteorological and statistical summaries for the whole empire. In the introductory chapter, after recounting the circumstances that led to the appointment of the commission, Mr. Bellew states very fairly the principal theories previously advanced in this country and in India as to the propagation of cholera, each of which has in it, according to him, sufficient truth to make it plausible, but not enough to stand the test of practical experience or to furnish a satisfactory explanation of all the phenomena of cholera epidemics. The blood poison theory, on which Dr. George Johnson based his eliminatory treatment, he considers well adapted to explain the symptoms, especially of those cases in which the patient is struck down by collapse, and dies in a few hours with or without any diarrhœa; but for a poison received from without, and in his opinion hypothetical, he would substitute a disordered state of the secretions or a poison generated within the body—in fact, Dr. W. B. Richardson's so-called "glandular" theory of specific diseases. Next we have the cholera contagion theory adopted by the Indian Commission of 1861 and the International Sanitary Congress of 1866, that cholera is carried by human intercourse and traffic, a single individual coming from an infected district and himself already infected being capable of setting up an epidemic in a district hitherto free. He admits that cholera *when developed* is "both contagious and infectious," whatever he may mean thereby, but he maintains that Indian experience does not lend much support to this view of its *origin* in any locality, however much it may be intensified and extended by overcrowding insanitary surroundings and human intercourse. The "water contamination" theory which he, certainly on insufficient ground, asserts to have been long since abandoned in England, though prevalent in India, and held by Maenamara to the exclusion of all other explanations, he argues, is the least tenable of all, alleging that Indian

experience does not favour the idea that the drinking of water fouled by cholera evacuations has any influence other than as one of many insanitary conditions. The "germ theory," as he calls it, though the contagion and the water contamination theories alike involve at least in most minds the idea of a "germ" rather than of a chemical poison, "shorn of its germ element and the hypotheses built thereon of reproduction, invasion, dormancy, revitalisation, &c., contains, he says, more of the truth of cholera than all the others put together." To this head he refers the "subsoil water" theory of Pettenkofer and the "earth-generated air-borne" theory of Bryden. He admits the truth of Pettenkofer's facts, but puts his own interpretation on the relation between the fall of the ground water and the renewed activity of cholera pointed out by that observer. In the last section, as we have already stated, we have the author's own conclusions and theory of cholera. According to him, it is neither more nor less than an intestinal catarrh induced by atmospheric conditions, so strictly analogous to influenza or epidemic catarrh of the respiratory passages, that *mutatis mutandis* the statement of the ætiology and pathology of the one will apply equally to the other. He believes that malarial and so-called bilious remittent fevers and even "heat fevers" and cholera pass one into the other, the one essential condition of all being a "chill" or derangement of the function of the cutaneous and mucous areas. In an able and highly interesting argument, he traces the connection between the periodical and local prevalence of cholera and the meteorological conditions of time and place; its endemic character in certain areas, and its epidemic occurrence in others, being due in his opinion solely to the fact that the conditions essential to its development are constantly present in the former and only periodically or occasionally in the others. Thus he explains the triennial waves of cholera on a large scale, and the minor waves within each year, though he admits that an epidemic may be prolonged into a period or season which would in itself be unfavourable to its development. Insanitary surroundings, over-crowding, deficient or unwholesome food, &c., may all act as subsidiary or concurring agents, but the one essential condition is, he insists, a chill: that is, those conditions of temperature and humidity of air and soil which favour rapid evaporation are *per se* causative of cholera. He denies that there is any evidence of cholera having ever been carried by human means into a country where it did not already exist. Against this assertion we must emphatically protest, as against his rejection of the water contamination theory, which has been demonstrated over and over again, as regards another "bowel fever," enteric. What he says of Pettenkofer's ground water theory, we grant, as regards his evaporation hypothesis, *i.e.*, we concede his facts while refusing our assent to his deductions. We stated our opinion some years ago that we in Europe and our neighbours across the Atlantic have, in some respects, better opportunities of studying the mode of propagation of cholera than our Indian friends who have it always present in their midst. We can observe under conditions more resembling those of scientific experiment. They stand to us as regards cholera, much as we do to isolated populations as those of Feejee, with regard to measles, &c. If meteorological conditions alone could develop cholera, why has it never appeared in Australia—in Queensland, for instance, where the climate is identical with that of a great part of India? As to its introduction by human intercourse and its propagation by specifically polluted water, we have abundant evidence of the most crucial character, both positive and negative. We freely admit the influence of meteorological conditions where the disease, the germ, we do not hesitate to say, exists, but we maintain that the facts that cholera may be unknown where every meteorological and sanitary condition known to favour it is present, and that, as Mr. Bellew confesses with regard to India, and we know with greater certainty elsewhere, in Russia, for example, it may be propagated long after the meteorological conditions have become unfavourable, prove conclusively that these are conducive to, not causative of, the disease. To Mr. Bellew's question, why, if transportable, it does not appear every year in England, we reply, just because the conditions, or some of them, are either

absent or are present in so feeble a form that ordinary precautions suffice to keep it at bay; our water supplies are purer and our towns cleaner than those of most countries, and certainly than those of India.

*The Saline Waters of Leamington*; by F. W. SMITH, M.D. London: H. K. Lewis. 2nd edition, 1885, pp. 100.—The first edition of this little unpretending book met, as it deserved, a very favourable reception. Without any extravagant laudation of the waters as a panacea for all the ills that flesh is heir to, the author points out the advantages that Leamington presents over many continental watering-places, not only in the quiet, yet cheerful, English society, but in respect of the waters themselves. He explains their therapeutic action in a number of morbid states of health as due to their influence on the general nutrition and excretory functions, quoting for each constituent from the works of recent investigation in therapeutics, and giving a few illustrative cases. The book is intended for the general public quite as much as for the medical profession, and we heartily wish that it may lead many to seek the restful change and gentle rational treatment of an English spa in preference to those which involve the fatigue of a long journey and the unwholesome excitement of some or the lonesome and comfortless surroundings of others on the Continent, to say nothing of the questionable concomitant of heroic or eccentric "cures."

## ABSTRACTS AND EXTRACTS.

**PAROVARIAN CYSTS AND REMOVAL OF SECOND OVARIES.**—Dr. Goodell exhibited to the Philadelphia Obstetrical Society (*Philadelphia Medical Times*, October 3rd) two specimens of parovarian cysts, which were so detached from the ovaries that they could have been removed without injury to them. He felt tempted to leave the ovaries untouched, but apparently incipient cystic degeneration led him to include them in the ligature. In his experience the removal of parovarian or of broad ligament cysts was one of the most successful of operations. Out of a large number which he had performed he could recall but a single fatal case, and in that the result seemed hardly due to the operation. During the ensuing discussion Dr. Montgomery asked for the opinion of the Society as to the advisability of removing the second ovary when in an operation for removal of an ovarian cyst the other ovary was found to be slightly diseased. In an ovariectomy performed in 1879, although the second ovary was found to contain numerous small cysts, it was not removed. The patient has since been twice pregnant, and there has never occurred any symptom of disease in the other ovary. Dr. Barr also asked if tapping ever cured parovarian cysts, he feeling strongly inclined towards abdominal section in all cases. He also believes that the second ovary should be removed when not healthy, as the idea of a second operation is very depressing to a patient. Dr. Allen considered that, as an ovary somewhat diseased may give rise to a pregnancy, it should be left. We know too little about the probable development of such small cysts into larger ones. Dr. Parish observed, in the same point of view, that he had seen diseased ovaries containing numerous small cysts in many autopsies without there having been any symptoms during life to excite suspicion of their existence. If the second ovary contained a cyst as large as a partridge's egg, he would remove it, but if numerous cysts as large as split peas were present he would not. The possibility of conception must be considered as well as the possibility of the enlargement of a cyst. Dr. Goodell, in reply, acknowledged the truth of this point, and believed that he had repeatedly removed the second ovary unnecessarily. Yet the history of his own ovariectomies shows the return of the disease in the remaining ovary in about 2 per cent.; and he thought that he had erred on the safe and right side. The social condition of the patient would always have a great weight with him. If an

heir were wanted, or the patient were young, he would leave a suspicious-looking ovary, or try to remove the diseased portion. But in the majority of his cases, where there was any doubt, he removed the ovary. Of course, under such a rule, he must remove ovaries which might never give any trouble in the future. But the mental agony of women when informed that the operation must be performed again, and, on the other hand, the great joy and satisfaction of patients, when assured after the close of an operation that both ovaries have been removed, have determined him, other things being equal, to remove the second ovary. As to a cure of parovarian cyst by tapping, his own experience is not sufficient to decide absolutely. He would advise the radical operation; but if the patient, after understanding the liability to return, wished it, he would tap, as there was but little danger. Dr. Goodell referred to some cases in which long periods elapsed after tapping before the cyst refilled.

**AN EXPERIMENTAL RESEARCH UPON THE INFECTIOUSNESS OF NON-BACILLARY PHTHISIS.**—Among the facts which must still be explained before Koch's bacillus can be unequivocally accepted as the sole and direct cause of tubercular disease, none, perhaps, needs elucidation so much as the undoubted occurrence of what may be called non-bacillary phthisis. Reference is not made to those chronic inflammatory conditions of the lungs which are the result of some distinct and thoroughly appreciated irritation, such as nailers' and stonecutters' phthisis, but to the undoubted occurrence, as acknowledged by Koch, and insisted on by Formad, Prudden, and others, of a small proportion of typical phthisical cases whose expectoration during life is found at all times free from bacilli, and in whose tissues after death, though many lesions morphologically identical with tubercular disease are present, the most careful research fails to reveal any of Koch's specific micro-organisms. Dr. E. L. Trudeau, of Saranac Lake, N. Y., has undertaken this task, and he records the results so far obtained in the October number of *The American Journal of the Medical Sciences*. The object he had in view was simply to demonstrate whether non-bacillary phthisical sputum possesses any infectious qualities. If, on the one hand, it were found to produce tuberculosis in the animals operated on, then the bacillus could not be accepted as the sole cause of this disease; if, on the other, no constitutional infection resulted from such inoculations, the evidence thus procured must tend to strengthen the sinister claims of Koch's micro-organisms, and strongly suggest the quality of phthisis. The results of Dr. Trudeau's investigations may be summed up as follows:—(1) Non-bacillary phthisis is a comparatively rare disease. (2) Though clinically almost identical with bacillary phthisis, it differs from it in being non-infectious. (3) Non-bacillary phthisical sputum can be added to the list of agents which have been unsuccessful in producing tuberculosis. (4) All evidence so far tends to prove that the tubercle bacillus is necessary for the production of the disease artificially; and this study brings additional proof to the views expressed by Burdon Sanderson, and insisted on by Sternberg, that, "whenever an inflammation becomes infectious, it owes that property to chemical changes in the exudative liquid of which the presence of microzymes is a necessary condition."

**THE TREATMENT OF ALBUMINURIA.**—There is one prime indication, writes Dr. Andrew, which ought never for one moment to be forgotten throughout the entire course of a case of renal disease. This is that the kidneys are for the time unequal to the function allotted to them, and that they ought to be dealt with accordingly. The indications for this purpose are first to reduce the amount of work they have to perform; to secure this, the patient must be enjoined to refrain from needless effort; rest and external warmth are essential. Lessening the amount of nitrogenous food reduces the strain upon the kidneys, and in this matter the feelings of the patient must not be allowed to exercise any influence over the decision, as he may feel quite well and have a surprising appetite even when his kidneys are hardly able to do any work at all. It is not, however, sufficient to diminish the quantity or alter the quality of his food, we must endeavour to secure as far as possible its more perfect digestion; bitter substances, such

as strychnine, acids, and alkalies, subserve this purpose. Moderate exercise, when it can be taken without risk of chill, is sometimes beneficial. The second indication for treatment is to stimulate other organs to undertake part of the work of the kidneys; the organs which may thus be acted upon are the skin and the intestinal canal. Warmth in bed, daily sponging, and small doses of antimonial wine combined with a simple saline, will best promote the action of the skin. Purgatives and diaphoretics should not be used so as to produce any excessive effect, owing to the exhaustion that might follow, except when uræmic symptoms are threatening; then they must be freely used and their injurious effects counteracted afterwards. A third method of treatment, but one that requires the greatest judgment in its application, is the stimulation of the disabled kidneys themselves to increased action, so that they may earn a period of rest by getting rid of accumulated arrears; but, if the stimulation so used be wrong in amount or kind, it is quite likely that it may be followed by an even fatal exhaustion of the kidneys.—*Practitioner*, November.

**A NEW ANTISEPTIC.**—Those of us who use iodoform in the consulting-room must frequently have been seriously annoyed by its powerful and persistent smell. Drs. Silber and Ciamician of Rome have found an admirable substitute which has all the advantages of iodoform without its odour or, it is said, its poisonous properties. This substance is iodol, which occurs as a dark powder with a slight scent, reminding one of thymol. It is very slightly soluble, and is best used either in substance or suspended in glycerine, or made into an ointment with vaseline. A lotion can also be made by dissolving 1 gramme of iodol in 16 grammes of alcohol and adding 34 grammes of glycerine. Most brilliant results have been obtained by the use of the substance itself on chancres and syphilitic adenitis. In simple indolent ulcers, too, the use of the iodol lotion has been very beneficial. A spot of lupus on the leg was treated by injections of iodol solution into the surrounding subcutaneous tissue with the result of preventing the disease from spreading. Iodol has also proved useful in fungating joint diseases. Over 200 observations have been made, and neither erysipelas nor a diphtheritic condition of wounds has occurred.—*Wiener Medicinisches Blatt*.

**PICHI, A CHILIAN REMEDY FOR CYSTITIS.**—A Chilian plant, called by the natives Pichi (*Fabiana Imbricata*), has long enjoyed a great local reputation in the treatment of urinary diseases, having even been supposed to cure renal and vesical calculi. Although, doubtless, its virtues have been exaggerated, it is believed by a writer in the *Diario Medico-Farmacéutico*, A. Rodriguez, of Buenos Ayres, to be very efficacious in certain maladies of the urinary organs and of the liver. He finds that it is especially valuable in vesical catarrh produced by the mechanical irritation of gravel, calculi, or due to a uric acid diathesis. It allays the irritation, lessens the secretion, and favours the expulsion of the gravel and of calculi which are sufficiently small to pass through the urethra. Its effect on hepatic disorders appears to be due to its climatic action. It has been found useful in Rio de Janeiro in several cases of jaundice, dropsy, and dyspepsia due to deficient biliary secretion. A fluid extract of the plant is prepared, containing 20 grammes to each tablespoonful, and of this from four to six tablespoonfuls are given *per diem* in either hot or cold water. Dr. Demarchi has examined Pichi chemically, and finds in it—1. An essential highly aromatic oil; 2. A resin; and—3. A fluorescent substance resembling esculin, pavin, and fraxin, which crystallizes in needles.

**THE USE OF STRYCHNIA IN NERVOUS DISEASE.**—Dr. Landon Carter Gray, in the October number of the *American Journal of the Medical Sciences*, reports five cases which, as far as they go, demonstrate that strychnia was not well borne by two cases of severe acute myelitis, or by two subacute cases of mild poliomyelitis anterior; that gr.  $\frac{1}{5}$ , continued for four days in a case of transverse myelitis with early extension to the lateral columns, given three months after onset, suddenly induced alarming toxic symptoms; that one chronic case of general myelitis of

traumatic origin was greatly benefited, as was also a case of general myelitis in which the onset had been gradual; that in five cases of progressive muscular atrophy it acted as a remarkable stimulant; that, as Dr. Weir Mitchell has indicated, it was decidedly beneficial in cases of neurasthenia, which, after being treated by some eight to ten weeks of rest and forced feeding, were taken out of bed, although it failed to agree with three cases of neurasthenia treated in the ordinary way.

**SPONGE-GRAFTS IN CARBUNCLE.**—Dr. Grigley states that this method of treatment has been very successful in his hands. As soon as he is sure that there is a carbuncle, he freely cuts away all the implicated tissue, and scrapes the surface clean. He then places pieces of sponge (previously washed in a dilute solution of sulphuric acid and kept in a five per cent. solution of carbolic acid) on the surface, saturating them with an ethereal solution of iodoform, 20 grains to the ounce. A piece of folded iodoform is laid over the sponge, then a thick sheet of absorbent cotton, followed by gutta-percha tissue, and the whole secured by adhesive slips and a bandage.—*Philadelphia Medical Reporter*, September 19.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 27TH, 1885.

THOMAS BRYANT, F.R.C.S., President, in the Chair.

#### *Cases of Gastrostomy.*

Mr. BARWELL communicated the following case of malignant stricture of the œsophagus:—After due precautions exploration with the bougie showed that the stricture commenced  $6\frac{1}{2}$  inches from the upper dental arch, *i.e.*, a little distance below the upper border of the cricoid. Only a bougie, size of No. 14 catheter, could be passed. A good deal of induration without swelling was detected on the left side of the thyroid cartilage; it appeared to be a hardened portion of the gland. A funnel-ended tube, No. 10 catheter gauge, having been procured, was passed and left *in situ*. After a few hours the resultant irritation ceased, and she was so much relieved that she went out at her own request. A week later she returned in much distress. The tube, which had been cleaned only the day before, was clogged with thick muco-pus, and had been ejected during a fit of coughing. She had a rigor the same evening, and the temperature rose to  $103\cdot2^{\circ}$ . Some deep fluctuation was detected on the left side of the thyroid. An exploratory trocar, and then an incision, let out a quantity of very foetid gas and pus. A few days afterwards she was told to swallow a little milk. Very little, if any, passed the stricture, but some came through the abscess opening. A fortnight after re-admission, gastrostomy was performed (1st stage). The stomach was found retracted under the liver. It was drawn down with the finger and thumb, and by means of straight Glover's needles and Chinese silk (an inner and outer ring of the stomach sewn to the abdominal walls. This was followed by neither pain nor fever. Highest temperature  $98\cdot4^{\circ}$ . In three days the stomach-wall was punctured, a No. 7 catheter introduced, and 4 oz. of strongest soup passed into stomach. Ordered that no feed exceed 4 oz. Nutritive enemata to be continued. The allowance of food was slowly increased, and she gained flesh; but the enlargement at the side of the trachea increased, and she had occasional attacks of dyspnoea. Examination with laryngoscope showed the arytaenoid cartilages to be motionless. The dyspnoea became distressing. The house surgeon performed tracheotomy. In consultation, extirpation of the larynx and neighbouring parts was rejected, partly because the disease seemed too extensive, partly because the patient was not in a condition to bear so severe an opera-

tion. She died of bronchitis about five months after the operation. The new growth extended back to the spine, and all but filled the œsophagus from a little below the ericoid cartilage to a level with the tracheal bifurcation; also it had grown into the trachea opposite the fourth cervical vertebra. In both lungs were secondary deposits. Around the gastrostomy wound the parietal peritonæum was firmly adherent to that of the stomach, and to a small extent to that on the left lobe of the liver. There was no trace of peritonitis elsewhere. The stomach-wound, looked at from within, was barely perceptible. Gastrostomy, the author remarked, had been performed very much oftener than appeared to be known in England. A recent article by Dr. Zesas (*Archiv für Klinische Chirurgie*, vol. xxxii., hft. 1) recorded 163 cases—viz., 129 for carcinomatous, 32 for traumatic, and 2 for syphilitic stricture. Of the first category 111 died, of the second 20, and of the third both. But among other cases overlooked by Dr. Zesas was one of recovery from syphilitic stricture (Mr. Colley). In abstracting the results, he was obliged to differ from Dr. Zesas' method, since it appeared incorrect to count such as had died from spread of malignant disease, from phthisis, or other alien cause, three months or more afterwards, among deaths due to the operation. He had also added certain other cases. Thus, of 166 cases of all classes, 107 died chiefly of exhaustion or collapse (43), and of peritonitis 26. Before the period of antiseptics, and before the invention of the two-stage method, 31 cases afforded but 1 recovery; since that epoch 155 cases had yielded 58 recoveries—i.e., 3.22 and 44.5 per cent. respectively. If they took from these numbers the hint that gastrostomy was not so formidable an operation, that it should be postponed until the patient was exceedingly weak, they might save a large proportion of the deaths ascribable to exhaustion, and far more favourable results might be subsequently obtained.

Mr. C. T. DENT mentioned the following case:—The patient, a man, aged 44, had suffered for about four months from symptoms of malignant disease of the œsophagus. When admitted, he could only swallow fluids with difficulty, and had occasional attacks of vomiting. A bougie, passed a long way down, met with an obstruction, and struck against something hard. Gastrostomy was advised, but the patient did not consent to the operation till nearly two months later. The first stage of the operation was performed by means of a curved incision in the left linea semi-lunaris; the stomach was easily recognised, and the part lying beneath the wound was attached to the surface. This part was subsequently proved to be rather near the pyloric end. The stomach was opened on the fifth day. For the first few days subsequently the man improved, but then the stomach became very intolerant of food, and constant thirst was complained of. The patient died on the eighth day after the second operation. *Post-mortem*: extensive malignant ulceration was found seven inches and a half below the thyroid cartilage. A large part of the wall of the œsophagus was destroyed, and the edges adhered to the spine. The right bronchus and lung were involved. Lower down still, a second malignant growth completely blocked the œsophagus. There was no trace of peritonitis. The author remarked that in this case the operation probably neither accelerated nor retarded death. Gastrostomy for malignant stricture was not, in his opinion, justifiable as a "last resource," and could only be advocated in the hope of prolonging life. This it would do if performed very early. The occurrence of vomiting was a very valuable guide, perhaps the most important, as indicating the advisability of gastrostomy. The author cited another case where the œsophagus was affected at two distinct points, and pointed out that such instances were not infrequent, and formed an additional argument against œsophagostomy in cases of malignant stricture. Finally, it would be better to enlarge the abdominal wound if necessary, so as to attach a part of the stomach to the surface remote from the pylorus and near the large curvature.

Mr. JOHN H. MORGAN then described his case as follows:—The patient, on March 1st, swallowed some caustic alkali. The mouth and fauces were burnt at the time, and he vomited phlegm for some weeks following. No solid food could be swallowed for 14 days. Ten

weeks later he was admitted into the Hospital for Sick Children, under the care of Dr. Cheadle, in a poorly-nourished and pallid state. He could then swallow only very small quantities of fluid with difficulty, often followed by vomiting of muco-purulent matter. Though given nutrient enemata from the first, the emaciation increased, and an attempt to pass a catheter down the œsophagus was unsuccessful. For a few days the powers of swallowing improved, but this was only temporary, and the emaciation became so extreme that, after failing to pass a catheter under chloroform, the operation of gastrostomy was performed on August 17th. The stomach was secured with 13 sutures, and was not opened until 31 hours later, when this was done on account of the very feeble condition into which the patient had sunk; some beef-tea and brandy were immediately introduced through an empyema tube. Nourishment was administered every two hours, and on the fourth day he passed a healthy motion. He remained feeble and irritable for the first seven days, at the end of which time he showed a decided improvement, but it was not until three weeks had passed before he began to increase in weight. He had continued to gain weight and strength, looked well-nourished, and weighed the same as at the time of his admission. No attempt had been made to dilate the œsophageal stricture, but coloured fluid had passed from the mouth into the stomach.

#### *Jejunostomy.*

Mr. C. H. GOLDING-BIRD said that the case upon which he founded his remarks was that of a man, æt. 46, who had had symptoms of pyloric obstruction for ten months. When admitted into Guy's Hospital, a tumour could be felt at the seat of the pylorus, and the man's general condition was one of extreme emaciation through the inability to retain the food he took, and his voluntary abstaining from eating on account of the pain he suffered. After three weeks' treatment, under Dr. Carrington, by drugs and washing the stomach out, he passed into the author's hands, and when all the risks had been explained to the patient, and all methods of palliation had failed to improve his condition, arrangements were made to explore the diseased parts, and remove them if expedient. He therefore, on October 25th, 1885, cut down on the pylorus with a view to performing pylorotomy, following the lines laid down by Billroth; but, finding the tumour adherent to the liver, determined to go no further in the radical operation, but to convert it at once into a palliative one of opening the jejunum, in other words, of performing jejunostomy. Having seized the jejunum two inches from the duodenum, it was held up on a pair of tongue forceps, whilst the wound in the parietes was united; to the lower or right end of this wound was the jejunum now stitched by interrupted sutures. The patient suffered in no way as the result of the operation. He was fed partly by rectum, partly by the mouth, until the third day, when the bowel was opened, and food administered solely through the fistula. It was observed that, as long as the meal amounted to a pint, or nearly so, the patient each time he was fed had a severe attack of indigestion, but that this ceased when the meal did not exceed ten ounces. On this the author founded the suggestion that some cases of indigestion were due to the pylorus allowing too free passage of chyme, rather than to anything wrong with the gastric or pancreatic secretions. Everything went on perfectly well till the ninth day, the patient putting on flesh, but on that day, through an error in feeding him, some food passed into the peritonæum, and he died in twelve hours. The post-mortem showed such adhesion to, and infiltration of, the liver, from the cancerous pylorus, that pylorotomy could not have been performed. Except the narrow track made by the probe, and along which the food passed into the peritonæum, the adhesions of the bowel and parietes were perfect. The author then reviewed the operation of pylorotomy, speaking in favour of it in suitable cases, and the operation of gastro-duodenostomy, as performed by Wölfler, and pointed out the great drawback, in this operation, that the stomach was not relieved of its physiological duties at all, the pylorus not being required to act. For the operation of jejunostomy, as he termed the one that

he detailed, he claimed that, whilst it possessed the same disadvantage as gastrostomy, in that the patient had to be fed through the fistula, it was otherwise the best palliative operation for pyloric cancer, inviting less risk than gastro-enterostomy, and requiring less interference in its performance with the other viscera. By duodenal digestion, he also pointed out, full nourishment could be assured, and there was, for physical reasons, less chance of regurgitation of food than after gastrostomy; regurgitation in these cases being a serious drawback to that operation in oesophageal constriction.

The PRESIDENT congratulated the authors of the respective papers, and expressed the opinion that Mr. Golding-Bird's operation was unique in the annals of surgery.

Dr. CARRINGTON related the history of the case from a medical standpoint, and showed, from the early age of the patient, the fact that there was but little emaciation, the tumour being readily felt and freely movable, that there was every reason to believe that no secondary growth existed, and that the diseased tissue might be entirely removed. He believed that there was some dilatation of the stomach, but the condition of the abdomen varied very considerably. There could be no doubt that the washing out of the stomach had afforded a great deal of relief.

Mr. GODLEE exhibited three specimens for Mr. Henry Morris, in illustration of the papers. One of these was a case of cancerous disease of the upper part of the oesophagus, the two others being taken from cases of removal of the pylorus.

Mr. JESSETT, while congratulating the authors of the papers on the success which they had obtained, expressed considerable doubt whether the operation of gastrostomy did in reality prolong life to the extent which it was supposed to do. He thought that statistics rather tended to prove that this was not the case. He quoted a series of figures compiled by various observers, among them those of Professor Gross, showing that the average duration of life after the operation was only 33 days. In the cases which he had himself investigated the average duration had been 26 days; of these cases, however, 8 had died within the first week. He thought that all means to prolong life ought to be resorted to before gastrostomy was undertaken. He related an instance in which Mr. Durham had used the oesophageal catheters and maintained life thereby for four months, in preference to gastrostomy. He did not think that the latter operation would have been equally successful. The statistics of oesophagostomy were worse than those of gastrostomy, and the attendant dangers of the operation were certainly greater. He thought Mr. Golding-Bird's case was unique, but he would prefer to perform gastro-enterostomy under similar circumstances.

Mr. HOWARD MARSH referred to the difference of opinion which existed as to the commonest seat of oesophageal cancer. He thought oesophagostomy was an operation very rarely applicable, and only to be done with any hope of relief to the patient if the disease were seated very high up in the tube. He related a case, in which the innominate vein was exposed during the operation, as an instance of the dangers that might attend it. For himself, he felt unfavourably towards gastrostomy. At the best the operation only enabled the patient to live till his disease killed him. Although it had been improved during late years, and patients had been enabled to exist a little longer, still it was doubtful whether the last few weeks of their existence were really rendered more comfortable. He did not think that the operation should be undertaken unless no other means of relief were available. He advocated the oesophageal tubes suggested by Mr. Durham, and related an instance in which their use had been completely successful, not only as channels for food, but also as dilators, the patient being enabled to swallow fluids or to pour them through the tube, according as their flavour was pleasant or the reverse.

Mr. PEARCE GOULD mentioned a case in which he had operated last September, opening the jejunum in a case of cancerous stricture of the pylorus. In that case the disease was far advanced, and the vomiting was excessive and frequent. He made the incision in the linea alba, attaching the bowel to the lowest part of the wound. Owing to the

great exhaustion of the patient, it was necessary to open the intestine after the first 24 hours, but death ensued on the second day. He had also assisted Mr. Morris in his cases of pylorotomy, but he had no hesitation in preferring jejunostomy to it; indeed, he hardly thought that excision of the pylorus could long survive as a recognised operation in surgery. Duodenostomy might be found to present advantages, but he preferred Mr. Golding-Bird's operation, although it had this possible disadvantage, that the bile might escape from the wound. In the present case, however, this had not occurred. He had performed gastrostomy seven or eight times, and in the result he was inclined to agree with Mr. Marsh's views. His experience of oesophageal tubes had not been altogether satisfactory, having sometimes failed to introduce them, and in other cases found them intolerable to the patient. Gastrostomy should not be attended with any great danger if cases could be carefully selected, but generally the patients were unfavourable subjects for any operation. As a general summary of his opinion, he would say that a late gastrostomy did not prolong life, and in early cases he would prefer to substitute for it the use of oesophageal tubes.

Dr. ANGEL MONEY referred to Mr. Morgan's case from a medical point of view, and called attention to the marked increase of weight which followed the change of diet. He took credit to himself for this, having made the change after a careful consideration of the chemical requirements of the case. He had ascertained that the relative proportion of carbo-hydrates in the previous diet was altogether insufficient, and by more careful adjustment had enabled the child to gain two pounds' weight in one week.

Dr. HALE WHITE mentioned a case in which obstructive disease of the pylorus had proved to be non-malignant, although not believed to be so during life. He thought that, even if a very small proportion only of the cases were of this kind, the surgical treatment should be adopted. Disease of the oesophagus, being generally in close proximity to important vital structures, was usually fatal by spreading to them and causing hæmorrhage or suffocation, but in pyloric disease the natural termination was starvation.

Mr. HOPKINS referred to a case in which pyloric cancer was wrongly diagnosed, the thickening being due to an embolism set up by endocarditis.

Dr. HUGHES BENNETT remarked that the present debate was an extraordinary instance of the change of surgical opinion on this subject. Only ten years previously he had been regarded almost in the light of a maniac for suggesting that the operation should be performed for the relief of a patient who subsequently died of starvation in consequence of a fibrous stricture of the pylorus.

Mr. BARWELL, in reply, stated that he would never perform gastrostomy if the use of oesophageal tubes was possible, but he thought that the surgeon's duty was to prolong life at all risks.

Mr. DENT referred, in his reply, to the danger of passing oesophageal tubes in the later stages of oesophageal cancer.

Mr. MORGAN and Mr. GOLDING-BIRD also replied, the latter stating that, having had abundant opportunities of watching the effects produced by oesophageal tubes, he should much prefer in his own case to undergo gastrostomy.

The following living specimens were exhibited before the meeting:—

Dr. FELIX SEMON—Congenital Malformation of the Larynx, consisting of a Web between the vocal cords, associated with Coloboma of the left upper eyelid, and with Alopecia of the corresponding portion of the right eyebrow.

Dr. C. R. WALKER—A Case of Myxœdema.

---

At the instance of Professor von Nussbaum, Sir William MacCormac has been elected an Honorary Member of the Royal Medical Society of Munich.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 1ST, 1885.

J. S. BRISTOWE, M.D., F.R.S., President, in the Chair.

*Stricture of the Ileum.*

DR. GULLIVER described this case, in which the gut was thickened in all its coats at the stricture one inch above the ileo-cæcal valve; just above it there was a dilatation; below the ileum was quite normal, as also was the large intestine. The stricture was due to a band of adhesion stretching across the ileum at that point. The patient, a boy aged 10 years, had suffered much from pain in abdomen for six weeks, and to a certain extent for a year. There was emaciation and pain, and towards the end vomiting; there was never any intestinal obstruction. After death there was found hæmorrhage into the supra-renal capsule, and also a caseous mass in it. In the dilated portion of intestine a large amount of débris was found. He died from chronic enteritis.

The PRESIDENT recalled a case where death was due to perforation from accumulation of plum-stones, &c., collected in the dilated portion above the stricture.

*Osteitis Deformans.*

MR. D'ARCY POWER showed two specimens of this affection. The first was a femur found in the collection of an old practitioner at Trowbridge, and therefore probably more than forty years old; it was a well developed adult femur, the shaft presenting a marked antero-posterior curvature, and being flattened from before backwards. The shaft of the bone was considerably thickened, measuring six inches in circumference at a point two inches above the adductor tubercle; the lower half of the bone was more affected than the upper portion; the surface was roughened as in chronic periostitis. The increase in girth was due to a deposit of ivory-like bone beneath the periosteum. The medullary canal was enlarged, and the bone immediately surrounding it was porous, as if it had been undergoing a process of rarefaction. The cancellous tissue was much coarser than that usually found in normal bone. The second specimen was an example of that variety of osteitis deformans which usually attacked a single bone. It was the upper half of a tibia of an old man who had neither gout nor chronic osteo-arthritis, and in whose bones, *post mortem*, no other evidence of osteitis deformans could be detected. The bone was characteristically curved, and had undergone very considerable thickening, due in part to the deposit of dense periosteal bone, and in part to a rarefaction of the existing shaft. Microscopical examination showed that the bone had undergone a process of rarefaction; the Haversian canals had become confluent and were filled with embryonic medulla; the concentric arrangement of the Haversian systems had been replaced by a more complex system of curving and interlacing rows of osteoblasts. Numerous osteoblasts were present, forming Howship's lacunæ in the Haversian canals; the lacunæ were small and without canaliculi.

*Malignant Disease of the Thyroid Body.*

DR. CARRINGTON said the specimen was taken from a man, aged 47, whose previous health and history were good. He had an immense tumour at the base of the neck, which was said to have been forming 30 years. It moved up and down with deglutition. The clinical history and symptoms were unimportant. He died from sub-acute nephritis. The tumour had almost the normal shape of the thyroid; the right lobe hard and calcareous, measuring 5 inches; the left soft and pulpy, containing pus, and measuring 7 inches from above downwards; it was continuous, with glands in the same state; the isthmus was about the size of a hen's egg. The carotids passed through the tumours and were healthy; the left internal jugular vein was occupied by a soft thrombus. The kidneys showed subacute nephritis, the right having two secondary growths. Microscopically, the growth was encephaloid cancer. The

case seemed of extreme rarity. This, no doubt, was a true specimen of cancer of the thyroid.

The PRESIDENT asked if there had been disease of the thyroid antecedent to the cancer.

MR. DUNN had seen two cases in women, the disease commencing on the left side. In one case the growth pressed on the trachea and sloughed into the œsophagus; it was a columnar carcinoma, and secondary deposits were found to be of the same character. In the second case tracheotomy was performed.

MR. BUTLIN had no idea the disease was thought to be so rare. There was at that time a case of enormous tumour under Mr. Smith's care at St. Bartholomew's Hospital, the growth extending back- and downwards; the man had much dyspnoea.

MR. SHATTOCK had examined one typical case of cancer of the thyroid; the chief interest was that the patient was one of Dr. Fagge's cases (published) of sporadic cretinism.

MR. SILCOCK referred to a case of Mr. Morris's, of tumours of the scalp, which turned out on investigation by the Morbid Growths Committee to be secondary to primary disease of the thyroid gland.

MR. BOWLBY asked for particulars as to the microscopical characters; any tumours occurring in the thyroid might be alveolar. Not much was known about the sarcomata of the thyroid gland. In some of the cases that had been shown the growths had been found to present only the normal appearance of the thyroid gland.

DR. ACLAND had seen a case of primary carcinoma of the thyroid. The secondary growths in both pleuræ had masked the primary disease; there was also renal disease. The primary growth was a slowly growing fibrous structure with small cells infiltrating the fibrous tissue, and not at all like normal thyroid gland.

DR. HADDEN mentioned a case of myxœdema, where carcinomatous glands simulated enlargement of the thyroid gland.

DR. CARRINGTON briefly replied.

*Pressure Changes in the Joints and Extremities.*

MR. ARBUTHNOT LANE referred to two papers in which he had described the pressure changes which took place in the spinal column, thorax, and pelvis. He now described many of the changes produced by the same cause in the joints of the extremities, several of which had previously received no notice. He first called attention to the changes said to take place in the angle of junction of the neck and shaft of the femur in old age. Though he had examined many old subjects in the dissecting room with the object of verifying these changes, he had failed to find a single instance of them. He did not think the alteration in the direction of the neck at all a necessary factor in intracapsular fracture, as he found that in aged subjects the neck might often be easily broken by rotating the femur inwards, and so bringing the head against the acetabular margin. If a vertical section of the femur of an aged person was examined, it would be seen that, like all the other long bones, it had undergone degeneration, and that the weakest portion of the bone was that portion of the neck in the immediate vicinity of the head, and it was that portion which crumbled away so readily in this fracture. He then showed that in the hip joints of labourers the head and neck of the femur, together with the acetabulum, underwent considerable modification in form and in the extent of articular surface. That of the head was no longer limited and defined, but extended a considerable distance down the anterior and upper surface of the neck. This, with the other changes, was produced by the flexion and adduction of the thigh necessitated by carrying heavy loads on the back. He had also observed a similar condition of extension of the articular surface of the head in the old and infirm, and due there to the continual condition of flexion of the trunk on the thigh habitual to infirm old age. All these changes, he found, were exaggerated by the presence of rheumatoid arthritis, as were all he had previously described. He found no distinct pressure changes in the knees and ankles unless rheumatoid arthritis was present. He had dissected several specimens of displacements of the great toe outwards, but failed to

find the bursa described. He showed two cases of an extreme condition of "hammer" toes due to pressure. The bases of the first phalanges were enormously expanded so as to form very broad bases which rested on the dorsum of the metatarsal bones. The extensor tendons no longer passed over the interphalangeal articulations, but were inserted into the bases and whole length of the first phalanges. He thought this point of very considerable pathological interest, as bearing on the displacement upwards of the head of the humerus when affected with rheumatoid arthritis. All the muscles of the foot had become shorter secondarily to the displacement, and not as its cause. The heads of the metatarsal bones were much altered, having lost their covering of articular cartilage and their original form. Two of them projected through the skin of the sole. He then showed two extreme instances of alteration of the articular surface of the glenoid cavity of the scapula, with consequent change in the relative position of the head of the humerus to the acromion. There were also changes in the inner end of the clavicle and its ligaments, and in the normal relation of the clavicle to the first costal arch. This, he believed, was due to the continual carrying of weights in the hands after the manner of milkmen. He had observed the same change in varying degrees in the bodies of labourers, and it was, as would be expected, found very frequently in them. He described, next, changes he had frequently observed in the upper extremities of aged people, due to the continual and but slightly opposed action of the flexor muscles present in old age. In the shoulder joint the head of the humerus was displaced upwards and partly out of the glenoid cavity, and its articular surface underwent slight consequent modifications. These changes, when exaggerated by rheumatoid arthritis, were much more easily observed, and were then much more common. In the elbow joint, the olecranon fossa became more shallow owing to deposit of bone in its concavity, and there was some thickening of the margin of the olecranon. On account of this the forearm could no longer be completely extended. He next described a condition of adduction of the hand and wrist with changes in the direction of the lower articular surface of the radius, which looked obliquely inwards, and in the fibro-cartilage. At the same time all the digits were much flexed, and the phalanges upon each other. In slight cases the inner two or three fingers were alone affected. In severe cases, as in the specimen he showed, the bases of the phalanges had been displaced upwards so as to rest upon the anterior surface of the metacarpal bones, the heads of these bones forming eminences which projected beneath the skin. In most of the specimens he had examined he had found no rheumatoid changes present in their articulations, but frequently atrophic pits in the cartilage, which, where it covered the ends of the bones, had, from its absence of function, undergone considerable change. There was no primary contraction of the palmar fascia, vaginal sheaths, or any of the fibrous tissues affected in Dupuytren's contraction. The flexor muscles were shortened, as were the fibrous tissues, compensatorily. The causes preventing extension of the fingers were the shortening of the flexor muscles, the displacement upwards of the phalanges, and the consequent shortening of the lateral and anterior ligaments of the joints. He had not found this condition described. He compared it with Dupuytren's contraction, two specimens of which he had dissected and described in the forthcoming number of the Guy's Hospital Reports. He had no new observation to make about this condition beyond that in the fingers in which the vaginal sheaths were affected, besides other fibrous tissues, he had found it very difficult indeed to dissect out the digital nerves, as they appeared to have blended with the sclerosed tissues. Also that, after he had in these specimens divided all the contracted bands of palmar fascia, &c., he found that the thickened and contracted anterior ligament of the joint with the compensatory shortening of the muscles opposed complete extension, and it was not till this ligament had been divided that it was possible to straighten the finger. The distinction between the compensatory contraction of the fibrous tissues in the first deformity described and the primary contraction, causing deformity of Dupuytren's con-

traction, was marked and interesting. To demonstrate this he showed two specimens of Dupuytren's contraction, which he first dissected. He also showed a case of fracture of the neck of the femur, in which there was very abundant callus which formed a strong arthrodiarthral articulation with the anterior inferior spine of the ilium, through which a great part of the weight of the body was transmitted.

Mr. BLACK asked as to the condition of the neck of the femur, and referred to Professor Humphry's views on the degenerative changes consequent upon old age.

Mr. J. HUTCHINSON, jun., thought that Professor Humphry had only contended that it did not always occur; he had certainly seen a very marked instance of the alteration in a case he had recently examined.

#### *Sub-peritonæal Lipoma.*

Mr. J. HUTCHINSON, jun., referred to the difficulty of diagnosis when these growths occurred near the hernial rings. The specimen he showed came through the femoral ring; part of the growth was encapsuled. He referred to other cases which had occurred at the London Hospital, or had been recorded elsewhere. He had collected particulars of 28 cases, two of them having been operated upon, and several had worn trusses. It was twice as common on the left side, and in the remainder was often double.

Mr. STONHAM had brought two cases of the same disease affecting the spermatic cord; the fatty condition extended up into the abdomen, but there was no history in either case.

Mr. LOCKWOOD had recently dissected two specimens in which the fatty tissue was certainly within all the coverings of the cord. He had lately seen a case of subperitonæal fat passing down outside the external ring; this suggested that these cases were perhaps so originated in a certain number of cases.

Mr. JOHN WOOD mentioned a case arising from the external layer of fat, which pressed its way down into the scrotum. These fatty masses might be superficial, or internal, or sub-peritonæal; or, lastly, an accumulation of fatty mass might take place in the cord itself. He thought it was common for sub-peritonæal fat to protrude at the saphenous opening; here such masses might also originate in the fat about the opening. These tumours might also be found in the anterior wall of abdomen, resembling closely small ventral herniæ; they were generally sub-peritonæal lipomata, and they might disappear, leaving room for true herniæ.

Mr. BUTLIN had shown a specimen ten years before, which he now thought might have been a sub-peritonæal lipoma, but he was not disposed to say that such certainly was the case.

#### *Heart with two Aneurysms.*

Dr. HAIG showed this specimen taken from the body of a woman aged 42, who had had rheumatic fever fifteen years before, and who had been under treatment with symptoms of heart disease. The pericardium was adherent, the cavities were dilated, foramen ovale open, mitral valve thickened; the wall of the left ventricle showed two aneurysmal dilatations; the endocardium was thickened and opaque, and at the openings was markedly fibrous. Aorta showed some atheroma; the left branch of the posterior coronary artery was traced into the larger aneurysm. Microscopically, not much change was found in the myocardium near the aneurysms. There was no proof of syphilis. The occurrence in a woman was a noteworthy fact.

#### *Joint Disease with Locomotor Ataxy.*

Dr. HADDEN read the notes of two cases of this association. The first patient was a man aged 52, whose left knee became swollen and painful three years before admission, the swelling later reaching the ankle. A year later an ulcer appeared on the under surface of the right great toe, the toe quite recently having become swollen. For three years there had been difficulty in walking in the dark, and some urino-genital symptoms. On admission, there was ptosis and right external strabismus, the pupils being quite fixed; there was some incoordination, and impaired sensation

in limbs; knee-jerks absent; there was a perforating ulcer of right great toe, the left knee was much enlarged; the femur was displaced forwards and outwards, patella much enlarged; on aspiration, pus was removed from the joint, and ultimately amputation was performed. Numerous bony outgrowths were found along the margins of the articular surfaces, the head of the tibia being also atrophied; a large bony mass was found in the ligamentum patellæ and capsule of the joint. Some doubtful thickening of the perineurium in the internal popliteal nerve was seen on microscopical examination. In the second case, the patient had had severe gastric crises and shooting pains. The left shoulder had been swollen for six years. There was slight ataxy, knee-jerks absent; the pupils were quite fixed. The left shoulder was disorganised and the humerus shortened, the capsule of the joint being much enlarged and thickened; there were many pedunculated growths, partly cartilaginous, partly osseous, springing from the interior, and some were found free in the joint. The head and neck of the scapula and the head of the humerus showed simple atrophy. In the spinal cord sclerosis of the posterior columns was found; some of the postero-lateral group of cells on a level with the eighth cervical nerves on the left side had disappeared, and nearly all the motor cells at the level of the third lumbar nerves had disappeared. The cases seemed to be typical of Charcot's disease, but it was difficult to say whether the atrophy of the motor cells was the cause of the joint lesion or not. The condition of the medulla oblongata lent some support to Dr. Buzzard's theory.

Dr. BUZZARD said that the case was of great interest inasmuch as the patient had had the most severe gastric crises on record. He was especially interested to learn that his surmise as to the existence of a lesion in the medulla oblongata had been verified.

#### Card Specimens.

Mr. SHATTOCK—Perforation of the Plate by Hyper-trophied Upper Incisor in the Rat.

Mr. HURRY FENWICK—Ulceration of the Bladder after Fracture of the Spine.

Mr. BATTLE—Portions of Thumb, with Vessels and Nerves amputated by String.

Mr. BATTLE (for Mr. Croft)—Bullet flattened by Frontal Bone.

## EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, NOVEMBER 11TH, 1885.

WALTER DICKSON, M.D., R.N., President, in the Chair.

### Recent Epidemics at Home and Abroad.

THE PRESIDENT delivered his inaugural address on the above subject. After graceful allusions to the losses which the Society had suffered during the past year in the deaths of several of the most distinguished and respected members, Dr. Dickson turned to the as yet imperfectly worked fields for research presented by a number of epidemic and endemic diseases of tropical regions regarding the ætiology and pathology of which further information was much to be desired. Such was the Verruga of Peru, an endemic exanthem the eruption of which consisted of bleeding warts, lasting for three months, and fatal in 10 per cent. of the cases occurring among natives, but much more severe among fresh arrivals, especially from Europe. It is non-contagious and strictly confined to the narrow gorges on the western slopes of the Andes, between the 9th and 16th degrees of S. latitude, at elevations of 3,000 to 8,000 feet. Another was the Mal de los Pintos, a cutaneous disease, doubtless mykotic, like chloasma, but seated in the epidermis, confined to the coloured races, and indeed to the poorest and dirtiest of them, but extremely prevalent in the hot low-lying regions of Western Mexico, Venezuela, and New Granada, in which the entire surface of the body is variegated with patches of black, blue, red, and white.

Both these diseases were limited to a small area, and the last-named was unattended with danger to life, but it was quite otherwise with Beri-Beri, which, known in Japan 2,000 years ago, and occurring as an epidemic in India and the Malayan Archipelago, was imported in 1864 into South America, where it was now thoroughly established as an endemic disease. But the difference in the characters of Beri-Beri as seen in the New World from those familiar to Indian medical men was very remarkable. In America it spared the young under 15 and the old over 65, but it attacked persons of both sexes, though in India met with almost exclusively among males. Notwithstanding the unlimited opportunities for its observation, little or nothing was known of its ætiology, the experience of medical men in one region negating the conclusions as to the influence of climate, diet, &c., come to by those of others who were guided by local circumstances only. It was even uncertain whether it was contagious or not. There could, however, be no doubt of its transportability, and it first appeared in Brazil at the same ports where cholera and yellow fever effected their first invasions. Dr. Dickson trusted that the Society would before long have some valuable contributions on the diseases of the basin of the Nile, especially on the form of enteric fever that had been so fatal among our troops in the Soudan. He then gave an account of a singular outbreak of fever on board the *Thalia* in 1883, when overcrowded with reliefs for the China squadron, between Columbo and Hong Kong. It did not appear to be contagious, and no deaths occurred. But for the absence of any eruption, it closely resembled relapsing fever and seemed to be the direct consequence of overcrowding and the foul state of the bilge. After a few remarks on the results of the suspension of the Contagious Diseases Act and the prevalence of syphilis in the Army and Navy, Dr. Dickson referred to the recent epidemics of cholera in France, Italy, and Spain. He described the physical characters of the latter country, and dwelt on the remarkable immunity enjoyed last year by Portugal, which was geographically a part of the same country. Physical features and sanitary conditions could not explain it, and he was not disposed to attach any weight to the sanitary cordons or quarantine established on the frontier. At home the most noticeable epidemics of the year were, he said, the outbreak of diarrhœa at Hull, affecting 20,000 persons, in consequence of the pollution of the water supply, and raising an apprehension of cholera happily not realised, though many of the cases were marked by cramps and other alarming symptoms; and the epidemic of small-pox in London, which between October 1st, 1884, and October 1st, 1885, caused 1,920 deaths. He compared this, as regards prevalence and mortality, with those of 1871-2, 1874-5, and 1877-8, and concluded his address by an elaborate statistical account of the various causes of invaliding and deaths among the officers of the Customs, with which department he had been connected for twenty years, and an expression of his hope that, in the political changes looming in the not distant future, the public health might receive the attention it demanded and the position of medical officers of health be made more independent and influential.

## SOCIETY OF PHYSICIANS OF VIENNA.

FRIDAY, NOVEMBER 13TH, 1885.

Professor ALBERT, President, in the Chair.

PROFESSOR SCHNITZLER showed a young girl in whom the vocal cords had grown together. The mucous membrane of the larynx was red and swollen, especially over the arytenoid cartilages, the mobility of which was impaired. On inspiration, the cords separated a little, but two-thirds of the rima glottidis were closed by a membrane, so that only a very small aperture remained for inspiration. The membrane was of a greyish white colour, transparent, and  $1\frac{1}{2}$  mm. thick. This condition was due to a chronic ulcerative process of the vocal cords, which, as in most

such cases, arose from syphilis. Prof. Schnitzler remarked that he would remove this condition by operation. He had been treating the patient for three years, and he gave an account of the different stages of the process.

*On the Sugar of the Blood in relation to Food.*

Prof. SEEGEN read this paper. He had shown on a previous occasion (also at the Society of Physicians) that the liver was a sugar-producing organ and was able to form it even out of peptone. After having combated some of Hofmeister's objections, he discussed the question as to the importance of the function of the liver in the animal economy. He had begun these investigations with the fundamental experiment of Claude Bernard, examining the blood which entered the liver and that which returned from it, in living animals, by means of a new procedure in which he had been assisted by Prof. v. Basch. Blood which had been drawn directly from the portal vein and the hepatic veins respectively was subjected to the method which Hofmeister and Schmidt-Mühlheim had employed for testing the excretion of peptone, and thus rendered free of albumen; it was then examined for sugar by Fehling's method. He found that the blood which returned from the liver contained twice as much sugar as that which had entered it, the proportion being 0.238 to 0.119%, and this was the case in a series of thirteen experiments without one single exception. In order to determine the whole quantity of sugar produced, he first tried to determine the quantity of blood which entered by the portal vein; he introduced a catheter into the splenic vein, ligatured the portal vein, and obtained the average of a series of observations. He remarked that by this procedure one of course obtained only an approximate idea of the amount of blood entering the liver, as the rapidity with which the blood flowed through the catheter was different from the rapidity with which it discharged itself into the capillary system of the liver. Prof. Seegen had found that from 100 to 200 grammes of sugar were poured into the blood by the liver in 24 hours. From this he drew the conclusion that all food, and especially the albuminoids, was capable of being converted into sugar, and that the formation of sugar was for this reason to be looked upon as the most important function of the body. This sugar was probably the sole material by which the heat of the organs was kept up and work done. He had still to find out whether the animal organism really formed sugar out of albumen, and with this view he performed a number of experiments. He first kept the animals without food, and found that during the period of starvation (dogs could live for from eight to ten days without food) the blood still derived a larger quantity of sugar from the liver than was conveyed to it by the blood of the portal vein, or than was contained in the blood of the carotid artery. That this sugar was not derived from the food which had been taken before was evident from the calculation that, if all the glycogen which had been present had been transformed into sugar, it would not have been sufficient for one day's production of sugar, and still less for the production of sugar during from eight to ten days. Hence this sugar had been formed out of the nitrogenous constituents of the blood. This inference had been also verified by the fact that when he had fed the animals with substances which contained a large proportion of hydrocarbons, as rice, potatoes, and starch, the proportion of sugar in the portal and hepatic veins did not change at all; hence, the sugar which was discharged from the liver was not derived from the food, and was not imported into the liver, but was formed in the liver itself. Prof. Seegen observed, in conclusion, that he believed he had succeeded in rehabilitating Claude Bernard's great discovery that the liver actually manufactured sugar.

WE regret to announce the death from scarlet fever, after a week's illness, of Mr. Robert Lawson, one of the house surgeons at St. Thomas's Hospital. He was a very distinguished student and prizeman of the Medical School. He obtained the Cheselden Medal, as well as the Treasurer's Gold Medal last year.

## GENERAL CORRESPONDENCE.

### FORCIBLE DILATATION OF THE SPHINCTER ANI.

[To the Editor of the Medical Times.]

SIR,—I have just been reading in your journal of November 28th an able and interesting clinical lecture by Mr. T. P. Teale, of Leeds, on Spasm of the Sphincter Ani and its treatment by forcible dilatation, and was surprised to find that in it I have been held up somewhat to ridicule as a surgeon who did not recognise the value of the practice advocated.

I read moreover, in the lecture, certain extracts from my book on the "Practice of Surgery," which were quoted to support Mr. Teale's accusation, but which, on reference, I found to be *but parts of sentences*.

These parts were evidently misleading, for, had the whole sentences been given, your readers would have at once seen that the practice advocated by Mr. Teale was one I not only adopted, but taught.

The corrections are as follows:—Mr. Teale states that I condemn "forcible dilatation, as practised abroad, as a barbarous treatment." Had he continued the quotation, he would have added "*though, when a patient is under an anæsthetic, it (the practice) may be followed.*" Your readers will thus have seen that my condemnation of the practice had to do with its adoption, as practised abroad, without an anæsthetic, and nothing more.

Had Mr. Teale also continued reading my article, he would have read, p. 806, under the heading of Treatment of Piles by the Cautery, "The anus is to be dilated forcibly with the view of allowing free manipulation of the piles, as well as of preventing subsequent spasm of the sphincter." Also, p. 808, "When a fissure or painful ulcer co-exists with hæmorrhoids, its base should be divided before the operation for hæmorrhoids is undertaken, or, *what is better, lacerated by forcible dilatation of the anus.*" Your readers will thus see that I and Mr. Teale are fairly in accord in this matter, and not so far apart as might be assumed from the lecture. I feel sure that Mr. Teale will be pleased to read this correction of a serious error by—

Yours, &c.,

THOMAS BRYANT.

[To the Editor of the Medical Times.]

SIR,—I should like to endorse what Mr. Teale has so admirably urged in favour of the operation of forcible dilatation of the Sphincter Ani. I learnt it in Paris many years ago, and it was then not infrequently employed. With respect to that most painful affection, fissure of the anus, I have never found it to fail. I think it is to Recamier, and not to Verneuil, that we owe its introduction into surgical practice. A preliminary dilatation of the sphincter facilitates greatly the operation for piles, and it has the further advantage of diminishing and preventing the distressing straining and tenesmus which not infrequently follows the operation. I have never known any permanent ill effect follow; the muscle usually recovers its full power in five or six days, or at most a week. Mean while the lower end of the rectum remains quiescent, there is no spasm, a fissure will have time to heal soundly, and the processes of repair become far advanced in the stump of the removed pile. Mr. Teale has mentioned other advantages, which I need not repeat. The proceeding is

certainly not a slightly one, but its effects are harmless and beneficent. To stretch fully the Sphincter Ani requires the exercise of a considerable amount of force; imperfect stretching is of no use. The thumb of each hand should be introduced into the rectum, the palmar surface looking outwards towards the rectal tuberosities. Complete narcosis is needful. The stretching should be made steadily and gradually till the resistance of the ischii is felt on each side. In this way the sphincter becomes fully dilated, and there is no risk incurred of over-stretching.

I am, Sir, yours, &c.,  
WILLIAM McCORMAC.

### "THE DANGERS OF COCAINE."

[To the Editor of the Medical Times.]

"Aujourd'hui nous savons que toute suppuration de la cornée est due à une infection de la place."—*De Wecker.*

SIR,—As I was unable to attend the recent meeting of the Ophthalmological Society, whose proceedings are recorded in your columns, will you kindly allow me to add my testimony to Mr. Nettleship's interesting observations on the dangers of cocaine. I have seen two cases, similar to those he describes, myself, and a series are recorded in a recent number of the *Therapeutic Gazette*, an American journal with which you are doubtless acquainted.

All solutions of cocaine are liable to deteriorate by the growth of microscopic organisms, and unless this tendency is checked there is danger that the wound with which they come in contact will become infected. I should not think it was safe to use a simple watery solution that was more than a week old, but such dilutions may be protected indefinitely by the addition of carbolic acid, boracic acid, salicylic acid, and bichloride of mercury. Carbolic acid, unless in infinitesimal proportion, is too irritating to apply to the eye. There is evidence that boracic acid alone is not quite so effectual as other preventives, and salicylic acid, though a first-rate preservative, is, unless in extremely feeble solution, also apt to cause surface irritation. I have, therefore, for some time past used, as a medium for the solution of cocaine, a saturated solution of boracic acid, containing one five-thousandth part of bichloride of mercury, and, although I have used this preparation in a vast number of cases, I have never, since its adoption, seen any ill results. The immense value of the bichloride as an antiseptic in cases of cataract extraction seems amply demonstrated by some statistics recently published by Alfred Graefe. Graefe divides his cases into four categories; in the first he bathed the eye to be operated on, before and during the operation, with a solution of carbolic acid two per cent; of these he lost five per cent. In the second he used carbolic spray; of these he lost six per cent. In the third category, he used a saturated solution of boracic acid throughout; of these he lost four per cent. And in the fourth he used a solution of corrosive sublimate, 1 in 5,000; of these he lost one per cent. Graefe, therefore, concludes that the corrosive sublimate is by far the best antiseptic. "J'en suis absolument persuadé." Lately, however, he has reduced the strength to 1 in 20,000.

I am, Sir, yours, &c.,  
CHAS. BELL TAYLOR, M.D., F.R.C.S.E.,  
Surgeon, Nottingham and Midland  
Eye Infirmary.

---

### AN IMPOSTOR.

[To the Editor of the Medical Times.]

SIR,—I think it right to warn the profession against a person describing himself as Dr. A. Kühnz, Professeur de Prague, who is calling upon medical men, soliciting charity,

and giving the names of gentlemen of high repute in Medicine as references. On enquiry, these references have not borne out his statements, and he appears to be utterly unworthy of belief.

I am, Sir, yours, &c.,  
EDWARD EAST,  
*Hon. Sec. British Medical Benevolent Fund.*

18, Clifton Gardens, W.  
December 1st, 1885.

---

## INVENTIONS AND IMPROVEMENTS.

### NEW AURAL INFLATOR, EVACUATOR, AND INJECTOR,

By J. WARD COUSINS, M.D. LOND., F.R.C.S.,

Senior Surgeon to the Royal Portsmouth Hospital, and to the Portsmouth and South Hants Eye and Ear Infirmary.

THE new aural inflator represented in the engraving is a contrivance designed to fulfil several important purposes in the practice of every-day aural surgery, and it is, in fact, a combination of several instruments, admitting of many useful applications. (1) It serves for inflating the middle ear as an ordinary Politzer's bag. (2) It can be used as an evacuator for the withdrawal of fluid by the Eustachian tube; or as a pneumatic tractor applied to the external auditory canal. (3) It can be employed also for the injection of medicated air charged with the vapour of deodorisers or other volatile fluids.

When the instrument is to be applied for tubal inflation the nasal piece should be adapted to the orifice of the nostrils by means of the wire loop which unites the vulcanite balls. The Eustachian catheter may be substituted for the nasal piece in those cases in which it is desirable to operate upon one ear only.

The hand-ball is especially fitted with very small valves and a central recoil spring. The end of one of the tubes attached to it must be fixed on the nasal piece for inflation, the end of the other tube for evacuation. Very gentle compression of the hand-ball is sufficient for the withdrawal of fluid from the Eustachian tube and tympanic cavity, but the bag must be forcibly and rapidly manipulated for successful inflation. When medicated air is to be injected the fluid selected must be dropped upon the pledget of cotton wool placed in the conical vulcanite receptacle, which should then be adjusted on the end of the injecting tube. By the action of the hand-ball the air is drawn through the perforated lid and so charged with vapour. The instrument is manufactured for me by Messrs. Maw, Son, and Thompson.

Now it has been often asserted, and perhaps not without some truth, that aural surgery is both tedious and troublesome in practice; on the other hand, it must be admitted that there is no class of minor surgical operations which yields in the long run more satisfactory results. The success which follows the early treatment of catarrh of the middle ear by inflation is very gratifying to the practitioner and sometimes astonishing to the patient. Already the timely application of Politzerisation has done much to reduce the frequency of permanent deafness, and this simple and invaluable method of tubal inflation is fortunately serviceable in many forms of aural disease, and also in association with other important methods of treatment. Even in cases of long closure of the Eustachian tube, and collapse of the tympanic membrane, it sometimes succeeds in restoring the normal communication between the tympanum and the pharynx, and this reopening of the tube is soon followed by great improvement in the hearing power. Sometimes the air-douche produces temporary deafness with a sensation of fulness and ringing in the ears, but these symptoms gradually subside as the air confined in the tympanum becomes absorbed. This increased tension is especially liable to occur whenever the inflator is used too frequently or with too much force; it can, however, be relieved at once by using my instrument and evacuating the imprisoned air by simply reversing the action of the hand-ball.

The gentle action of the evacuator is also useful under many other conditions. In young children suffering from ear-ache the bag may be employed for the withdrawal of pent-up fluid into the pharynx. In acute suppurative inflammation of the middle ear, with bulging of the tympanic membrane, evacuation in this way may sometimes succeed, preventing the spontaneous rupture of the drum, and removing the necessity of puncture. In chronic aural catarrh, attended with deafness and tinnitus aurium, the treatment by inflation may often be combined with evacuation, with very excellent results. In many of these cases the Eustachian tube is narrowed and blocked with secretion; at the same time the contents of the tympanum are altered in structure and covered by a layer of thick and tenacious mucus. The air-douche alone is of little service. It aggravates the aural discomfort by increasing the abnormal pressure within the cavity, or else it fails to dislodge the pent-up secretion by the tube, so that the membrana tympani becomes unduly tense, and in this condition a repetition of the operation may cause serious injury.

Now the treatment by alternate inflation and evacuation

not only renders the Eustachian tube pervious, but prevents the accumulation of inspissated mucus in the tympanum." When solutions are employed for this purpose the application of the hand-ball evacuator after the operation will at all times prove of material assistance, for by its action the diffusion of the fluid is secured over the whole mucus lining and its final escape from the cavity promoted, mingled with the elements of secretion. In chronic cases, also, of collapsed and adherent membrane the india-rubber tube may be introduced into the external auditory canal and the instrument used as an exhauster for the purpose of drawing out the drum, and it thus acts as a substitute for the "pneumatic tractor" recently suggested by Dr. Woakes.

The injection of deodorising vapour will be found especially valuable in cases of perforation and chronic otorrhœa—used, of course, in combination with astringent applications and persistent attention to aural cleanliness. By this treatment the patency of the drain tube of the tympanum is maintained; at the same time injected fluids and purulent secretions are blown out through the perforation, which would otherwise be retained in the cavity. It more-

of the tympanum is certainly theoretically sound, and in my hands it has proved of great benefit in many chronic cases. It promotes the discharge of the inspissated secretion into the pharynx, and aids in maintaining the drainage of the cavity. By the injection of air, the mucus is disturbed from its position, and by reversing the action of the hand-ball of my instrument it can then be drawn into the tube and its passage to the pharynx greatly accelerated. This double action is also capable of exerting a salutary influence over the bony chain. The mobility of the ossicles has long been impaired by the morbid condition of the tympanum, but by gently and repeatedly agitating them in both directions their adhesions to each other are loosened, and their normal oscillation is re-established, by which alone vibrations can be transmitted from the drum to the fluid within the internal ear.

But the instrument can be used for many other purposes in aural surgery. The injecting tube can be readily connected with Ker's inhaler for the application of chloride of ammonia vapour in cases of disorder of the mucous passages, attended with profuse secretion. The injection of air charged with volatile vapours, such as carbolic acid, creosote, alcohol, iodine, eucalyptus, and other substances, is suggested as an auxiliary measure in chronic middle ear catarrh, requiring more active treatment than the air-douche, and also as a substitute for the injection of fluids into the tympanum.

After the failure of milder measures, however, in cases of obstinate tubal obstruction and thickening of the nasopharynx, the injection of warm solutions into the tympanum has been followed by considerable and even permanent relief. Mr. George Field expresses a decided opinion upon the value of this treatment, and considers "that the injection of appropriately selected warm fluids

over powerfully aids in destroying the fœtid odour which is constantly emitted with the discharge, and assists in promoting a cleanly state of the aural surfaces, which, after all, is the essential element of the treatment.

All chronic suppurative diseases of the middle ear demand frequent modifications of treatment and the persevering use of some form of antiseptic for a considerable period. In many cases the otorrhœa is soon checked by the regular employment of astringent solutions; but it often happens that, notwithstanding a marked improvement in the secretion, the distressing fœtor continues—kept up by a localised disease of the tympanum, which involves the periosteum and sometimes the bone itself. It is under these conditions that the vapour treatment is suggested as a valuable auxiliary to other remedies. The injection of medicated air causes no aural irritation, and it can be performed by the patient himself many times during the day as a substitute for other local applications.

---

MR. VICTOR HORSLEY, the Brown Professor of Pathology to the University of London, will commence his annual course of lectures in the theatre of the University on Monday next, at 5 o'clock. The first lecture will be, in some respects, a continuation of last year's course, being devoted to the relation of the thyroid gland to general nutrition. In the subsequent lectures Mr. Horsley will deal with the modern pathology of the central nervous system; the functional disorders of that system, produced by loss of function of the thyroid gland and pituitary body; canine chorea, &c. The course will conclude with a demonstration of specimens.

## OBITUARY.

### THOMAS JOLLIFFE TUFNELL, F.R.C.S. IREL., ETC.

This well-known Dublin surgeon died at his residence, 58, Lower Mount Street, Merrion Square, on Friday, November 28th. For some months Mr. Tufnell had been in failing health, and he succumbed to an attack which presented many of the symptoms of organic disease of the stomach and liver. He was born in 1819, his father being Colonel Tufnell, of Lachham House, Chippenham, Wilts. He was educated at Salisbury, under the tutelage of Dr. Radcliffe. In 1836 he was apprenticed to Mr. Lunscombe of Exeter, and subsequently he entered as a student of medicine at St. George's Hospital, London, under Sir B. Brodie and Mr. Cæsar Hawkins. In 1841 Mr. Tufnell became a Member of the Royal College of Surgeons of England, and shortly afterwards entered the Army as Assistant Surgeon of the 44th Regiment, which was then serving in India, and had been just ordered to Cabul. On his arrival at Calcutta to join his regiment, he was ordered to take charge of the troops at Chinsura, and in this way he escaped the massacre of the British forces in Afghanistan in the disastrous retreat from Cabul.

On his return home, Mr. Tufnell was appointed surgeon to the Dublin District Military Prison. He also gave lectures and demonstrations to a large class of candidates for the Army Medical Service. When the Crimean War broke out, Mr. Tufnell once more went on foreign service, gaining amid the horrors of the ensuing campaign an extensive practical knowledge of military surgery. After some time, he returned to Dublin and commenced private practice in that city. He was appointed to the chair of Military Surgery in the School of Surgery of the Royal College of Surgeons in Ireland, to the Fellowship of which body he had proceeded so far back as 1845. Tufnell's success was now secured, and in process of time he became a Member of Council and President of the College, as well as Surgeon, and afterwards Consulting Surgeon, to the City of Dublin Hospital. Among the other distinctions which fell to his lot may be mentioned the Membership of the Royal Irish Academy and the Fellowship of the Medico-Chirurgical Society.

Tufnell's name will be always associated with the subject of the treatment of aneurysm, in which he was rightly considered as a specialist. His plan was to diet the patients strictly, to insist upon absolute rest in bed in the prone position, and to administer iodide of potassium in full and persistent doses. Another topic to which he called particular attention was stricture of the rectum, for the organic cure of which he devised a new form of tubular bougie. In private life and in social circles Mr. Tufnell shone from his genial manner, his soldierly presence, and his frank and generous disposition. For many years he was secretary to the oldest and most celebrated of the many medical dinner-clubs which exist in Dublin as almost an indigenous growth, and to the festive meetings of the club in question his courtly manners and his genuine *bonhomie* lent a special attraction.

### MISS F. HELEN PRIDEAUX, M.B. AND B.S. (LONDON), L.K.Q.C.P.I.

We have to record, with great regret, the death of Miss Helen Prideaux, which occurred on Sunday, the 29th November, after a week of severe illness from diphtheria. Miss Prideaux was one of the most distinguished of the women who have passed the medical examinations of the University of London. She took honours in every examination from the Matriculation upwards, including the Exhibition and Gold Medal in Anatomy at the Intermediate Examination in 1881; and the sixth and the third place in the first class in Medicine and Obstetric Medicine, respectively, in the M.B. Examination, 1884, as well as honours in Forensic Medicine and Surgery. From 1883 to 1884 she was Demonstrator of

Anatomy at the London School of Medicine for Women, where she had received all her medical education. Her fine intellectual powers were combined with a rare and harmonious beauty of character, and with a serene and noble presence. All who knew her looked forward to her taking in time a foremost place in the medical profession, and to her becoming eventually the leading medical woman in England. A month ago she was appointed Honse Surgeon to the Paddington Hospital for Children. On November 21st, she began to suffer with her throat, and on the 22nd she returned to her father's house in Woburn Square. She was attended through the week with the most devoted and untiring zeal by Mr. Cheyne, Mr. Stanley Boyd, and Miss Cock, who were aided during the last three days by frequent consultations with Dr. Broadbent and Mr. Parker. The disease extended early to the larynx and trachea, and death was often imminent from spasm of the glottis. At her own urgent request, and with the view of diminishing suffering rather than with much hope of saving life, laryngotomy was performed on Saturday morning, and for a few hours she was relieved; cardiac dyspnoea, however, set in about 6 p.m., Saturday, and after some hours of great suffering she died early on Sunday. The loss of such a woman at the outset of her career, and after years of patient and conscientious work as a student, is a calamity for those who looked upon her as a future teacher and leader, and will be recognised as a public loss by many beyond the circle of her private friends.

## MEDICAL NEWS.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on Thursday, November 26th, 1885:—

William Frederick Dewsnap, M.R.C.S., 1, Theresa Terr., Hammer-smith; John Simpson Edey, M.R.C.S., 21, Elgin Road, St. Peter's Park, W.; William Gilmore Ellis, M.R.C.S., Banstead Asylum, Surrey; George Stephen Ware, M.R.C.S., Devon Villa, Harrow; Joseph Williamson Winterburn, 12, Cabul Road, Battersea, S.W.

**THE DUBLIN HOSPITALS COMMISSION.**—This Commission met, subsequent to our last report, on Tuesday, November 24th, when evidence was given concerning St. Joseph's Hospital for Children. Founded by private benevolence in November, 1872, the hospital is not at present utilised for the purpose of medical education, but it is contemplated to form a class when the additions at present being made are completed. There are now 30 beds in the hospital, but the new building will accommodate 100. The professional staff comprises one consultant surgeon, two physicians, one surgeon, one assistant surgeon, one apothecary—all visiting. The apothecary alone receives remuneration. There were 275 intern patients and 5,500 extern treated during the year ending 31st March, 1885. Dr. Thos. More Madden, physician to the institution, and Mr. John McEnllagh, the surgeon, were examined, after which Mr. William Perrin, a governor of the Convalescent Home, desired to give evidence as to that institution, but the chairman said that appertained to another branch of the question, which would be dealt with at a subsequent stage. With the exception of Mercer's and Steevens' Hospitals, they had now terminated the general enquiry as to the Dublin hospitals. Concerning the first of these institutions (Mercer's), they would be glad when they met again to hear any additional evidence, but that must be confined within the scope of their enquiry. That done, they proposed to go into the question of the union hospitals; and, finally, to take evidence from distinguished men on the general question of hospital management, both in the United Kingdom and elsewhere—the mode in which they are supported, and in what relation they stand to public authority. The Commission then adjourned *sine die*, public notice to be given of the date of re-assembling.

**BELGIAN ACADEMY OF MEDICINE.**—The following Foreign Honorary Members have just been elected by the

Royal Academy of Medicine of Belgium:—Dr. H. von Bamberger, Professor in the University of Vienna; Dr. S. P. Botkin, Professor of Clinical Medicine in the University of St. Petersburg; Dr. P. Diday, *ex-chirurgien-en-chef* of *l'Antiquaille*, Lyons; Sir Wm. Jenner, President of the College of Physicians, London; Dr. A. Kussmanl, Professor of Medicine and of Clinical Medicine in the University of Strasburg; Dr. E. Leyden, Professor of Clinical Medicine in the University of Berlin; and Mr. J. E. Eriehsen, Emeritus Professor in University College, London. University College, which holds the place of honour in the above list, has unfortunately no longer the advantages of Sir William Jenner's services on the active list of Professors. If our Belgian friends will enquire, too, they will find that, though St. Petersburg possesses both a University and a most important Medical School, the two are unconnected, the University having no medical faculty, and the Medical School being under the Minister of War, so that Dr. Botkin's proper designation is Professor in the Military Medical Academy, St. Petersburg.

THE CASE OF DR. COLLIE.—At a meeting of the Council of the Poor Law Medical Officers' Association, held at their rooms, 3, Bolt Court, Fleet-street, on Tuesday, the case of Dr. Collie, medical superintendent of the Eastern Asylum Hospitals, was again considered, when it was unanimously resolved:—"That this Council, having carefully gone through the evidence that was tendered at the recent official enquiry into the management of the Eastern Asylum Hospitals, fails to discover any sufficient pretext for the suspension of Dr. Collie from his duty as superintendent of such hospitals, seeing that the most that could be brought against him was the neglect of certain clerical requirements which, having regard to the multifarious and onerous duties he was called on to discharge by the Managers, should (as requested by Dr. Collie) have been remitted to some subordinate official; and further expresses its regret that the Poor Law Inspectors to whom was entrusted the conduct of the official enquiry should have failed to recommend to the President of the Local Government Board the removal of his suspension. That the best thanks of this Council be given to the general and medical press, and especially to the *Times*, for the support they have given to Dr. Collie under the trying circumstances in which he has been placed."

VACCINATION SHIELDS.—The following note has been issued from the office of the National Vaccine Establishment. "The Medical Officer of the Local Government Board occasionally hears of cases of Erysipelas following Vaccination, and traceable to the use of old and dirty 'Vaccination Shields.' If in any case, as where a dress is worn dyed with a possibly irritative dye, a Vaccinator thinks some means of 'protection' to a vaccinated arm to be desirable, he had best define the material and the manner of application of such appliance as he judges to be wanted in the particular case; and it appears to the Medical Officer important that every such appliance should be of a kind to be destroyed and replaced whenever it becomes soiled; and particularly that it should not be of a kind likely to be kept for subsequent use. The Medical Officer would, therefore, urge on Vaccinators to discourage the use of the so-called 'Vaccination Shields.'"

CHARITABLE BEQUESTS.—Mr. William Anastus Guy, M.B., F.R.S., F.R.C.P., late of Gordon Street, Gordon Square, has bequeathed 250*l.* each to the Statistical Society, King's College Hospital, and King's College Hospital Convalescent Institution. The moiety of the residue of his real and personal estate eventually comes to the Statistical Society and King's College Hospital Convalescent Institution.

FOREIGN LUNATICS IN GREAT BRITAIN.—According to a recent parliamentary return of the total number of persons of unsound mind, not being British subjects, who were patients on the 1st January last in any county or borough asylum, it appears that in England and Wales the number of sick patients was 434, 287 males and 147 females. There were only four in Scotland.

VEXATIOUS PROSECUTION.—At the York Assizes on Saturday, before Mr. Justice Hawkins, George Henry Heald, M.R.C.S.E., was charged with an indecent assault on a girl between the ages of 13 and 16 years, at Leeds, on September 12th. The girl was a pupil-teacher in the Leeds Board Schools, and the prisoner was police surgeon at Leeds. On the above day the prisoner made a medical examination of the girl, during the course of which it was alleged that the offence was committed. For the defence it was urged that the prisoner merely made a medical examination of the girl, and that she had given an exaggerated account of what had taken place, owing to hysteria. The Jury, after a short deliberation, found the prisoner *Not Guilty*, and he was discharged.

THE "BRADLEY" FUND.—In consequence of the interest which has been taken by the profession in Dr. Bradley's case, and the generous response which has been made to the appeal on his behalf, it has been decided that the proceeds of the above fund shall be presented in such a manner as to give a marked and public expression to the views of those who have sympathised with him. On account of its being the nearest large town to the neighbourhood in which Dr. Bradley practised, Sheffield has been chosen as the most suitable place for the purpose. The presentation, consisting of an address and a purse of four hundred guineas, will be made by Dr. Balthazar Foster, M.P., President of the Council of the British Medical Association, and by Mr. Wheelhouse, of Leeds, at a Medical Dinner, which will take place at the Wharfedale Hotel, King Street, Sheffield, on Friday, December, 11th, 1885, at six o'clock, when it is hoped that as many as possible of Dr. Bradley's friends and supporters will be present. Dr. M. Martin de Bartolomé, Senior Physician to the Infirmary, will preside.

A PERUVIAN MARTYR TO SCIENCE.—Peru is hardly the country to which we should naturally turn in the expectation of finding a martyr to experimental clinical science. It has, however, just produced one in the person of a most promising medical student named D. A. Carrion, aged 26, who, being in his sixth or final year—this country might with advantage take a leaf out of the Medical Regulations of Peru with regard to the length of medical study—was writing a dissertation for his degree on a little-known Peruvian disease called Verruga, and, wishing to study it experimentally, inoculated himself with it last August. The experiment was only too successful, for in 23 days the disease began to show itself, and in 38 days Señor Carrion succumbed to the effects of his mistaken zeal. The Lima Academy of Medicine has announced Verruga as the subject for its prize essay in 1886.

SOME LAY ADVICE TO DOCTORS.—Avoid the society of your patients. Physicians should have no familiars. To be thoroughly respected, they must stand aloof from the gaze of society. A prophet has no power in his own country, neither has a physician in his own circle. Without skill it is impossible to become a flourishing physician; but without good manners all the skill of the most eminent physicians will not avail far in a large capital. A good address is everything to a doctor. Never refuse a fee from any person who is able to give one, in order that you may never have occasion to take one from a man who is too poor to well afford one. It matters not how mercenary you may be accounted by the rich so long as you are merciful to the poor. If you cannot get fees without depriving them of bread, it were better that you had never been a doctor.—*Brooklyn Eagle*.

OBSTETRICAL STUDY AT PRAGUE.—A correspondent of the *Philadelphia Medical News* of October 17th, at present studying at Prague, desirous of giving an exact account of the advantages and disadvantages of Prague as a place of obstetrical study, in consequence of the great discrepancies that have hitherto prevailed on the subject, makes the following statement:—"The *Gebärhaus* is a fine, irregular, and quite modern building, its wards being lofty, well-ventilated, and clean. Since the rupture which took place in the University about three years since, dividing this into a German-speaking and a Bohemian-speaking institution, the lying-in hospital has been divided into three equal

parts, one of these being under German control, one under Bohemian, and the third for the education of midwives, also under Bohemian control. It is to the first of these divisions only that the remarks apply, this being the one that foreign students usually resort to. The total number of births varies from 2,700 to 3,000 per annum, giving from 900 to 1,000 for each division. The vacation months, April, May, August, and September, are usually chosen, as there are then no junior students attending. Dr. Fleischmann, Professor Breisky's first assistant, a very zealous and able teacher, gives two courses, each of four weeks' duration, during each of the vacations. The course consists in digital and external examinations of pregnant women, usually in the last week of pregnancy, combined with external measurements by Baudelocque's pelvimeter, and the various obstetrical operations on the phantom. The fee for the week's course is 25 florins, 16 florins being also paid for permission to live in the maternity and "practise." It is chiefly in relation to this last that discrepant statements have been made. "From extended enquiries and personal experience, I am enabled to define 'practice' as the mere privilege of examining women in labour according to a definite system. Three men are allowed to examine the same case, providing it is a normal one, and only the first man on the list is allowed to make further examinations during the course of the labour. The nurses, who are very efficient, deliver all normal cases, the assistant being sent for only in cases requiring operative interference. This he always effects himself, and no member of the class is allowed to put on the forceps, contrary to the impression that seems generally to prevail. It is deemed quite a stroke of good fortune if one gets an opportunity of supporting the perinæum or passing the catheter once. Strict antisepticism is carried out, to what perhaps may seem a ludicrous extent. After one has handled the 'alcoholic fœtus,' used in the operative course, he must take a tub-bath and change his under-clothing before being allowed to 'practise.' Prior to making a digital examination, the hands and forearms must be well scrubbed, then bathed for five minutes in a sublimate solution (1 to 2,000), rinsed, and dried. The statistics, which are among the best on record (mortality a trifle above  $\frac{1}{4}$  per cent.), seem to justify these precautions. But the assistants and nurses have suffered, for more than once, from slight attacks of salivation. Nature is interfered with as little as possible. The forceps are seldom employed—not more than once, I think, in 50 cases. Every tear, no matter how insignificant, is carefully sewed with catgut; uninterrupted suture. This is done from an antiseptic point of view, so as not to leave any abraded surface which could favour the absorption of decomposing discharges. As may be expected, the number of abnormal cases varies at different periods; but, during a four weeks' course, a couple of turnings, as many forceps applications, a few cases of eclampsia, and a craniotomy may be safely expected. The living accommodation in the hospital is wretched. A large, dirty ward, with beds arranged on either side to the number of 20, is consigned for this purpose. Two long deal tables, with several broken chairs and a couple of wardrobes, comprise the whole furniture of the 'barracks,' as it has been truly named. A single sink serves for all ablution requirements; and organisms, which are not microscopic, with very ferocious appetites, abound in as great numbers as micro-organisms in the object-field of a German microscope. Let ten or twelve men, from all parts of the Universe, with the diverse toilet and other habits which pertain to such a motley collection, occupy the 'barracks,' and fancy the floors covered with a couple of inches of dirt; let dirt meet the eye in whichever direction it turns,—and a fair view will be gained of the 'comfortable residence' provided in the hospital. It is not practicable to live in rooms outside. To a green graduate, who, perhaps, has never made a digital examination, a four weeks' course in Prague, despite the personal inconveniences, will doubtless be of considerable benefit; but anyone coming to the Continent for the purpose of familiarising himself with the various obstetrical operations had better seek another field."

A CORPSE IS NOT "PROPERTY."—The Supreme Court of South Carolina has recently rendered an elaborate

opinion on a question which appears to have been decided for the first time in that case. It was an action brought by an administrator against a railroad company to recover damages for the mutilation of a corpse, caused by the negligent running of a train over it. The referee found for the plaintiff, and fixed the damage at 10,000 dollars. The case went to the Supreme Court on the question whether "there is such property or interest in the dead body of a human being as to sustain an action for its wilful or negligent mutilation; and, if so, whether the right of action belongs to the administrator of the deceased. The Court decided that, while the next of kin have recognised rights touching the dead, there is no such property in a corpse as is claimed in this case. It says, "While the demand of the dead should be tenderly protected, their interment carefully guarded, the mutilation of their bodies and the disturbance of their sepulchre severely punished; and while all laws necessary to that end should be passed and steadily enforced—yet, even for this purpose, to make such remains the absolute property of anyone in the sense of objective appropriation would be abhorrent to every feeling and impulse of our nature." But this view, the Court proceeded to explain, does not apply to the clothes in which the body was clad and the watch on it. There were articles of personal property, to which the administrator had a legal claim, and, as they were destroyed, he was entitled to maintain an action for their value. — *Boston Medical Journal*, November 5th.

THE THERAPEUTIC KNIFE.—Speaking at the annual meeting of the New York State Medical Association (*Philadelphia Medical News*, October 24th), Dr. Pancoast drew attention to certain points of surgical practice: one of these was what he terms "The Antiphlogistic Touch of the Therapeutic Knife." By this he means a very small knife which has the advantage of leaving no scar after its employment. With such a knife he practises tumefactions of almost any sort in numerous places, forming the best means of deep-seated blood-letting of the part; and, if he sees the patient early enough, he can almost assure the patient against abscess occurring. When a bubo or other gathering becomes hard and refuses to yield to local application, he freely punctures it with his little knife, on the point of which he occasionally finds a drop of pus. By this method he has even cured (or, at least, rendered stationary) some cases of goitre, both cystic and fibroid; and many other glandular growths can be successfully treated in the same way. He also gives Donovan's solution or the iodide of potassium internally, with, if the patient's condition requires it, *cinchona* or whiskey.

THE LYONS GIRL SILK WORKERS.—In an article of No. 41 of the *Lyon Médical*, Dr. Augagneur draws attention to the deplorable condition of the girl apprentices who, drawn chiefly from the healthy regions of the Alps and Savoy, are subjected to a life of hard labour under the most sanitary conditions. Overcrowded into small abodes under the *patrones* to whom they have been consigned, they live and sleep in unventilated rooms, passing long hours of labour, even extended sometimes on Sundays, and fed upon a most insufficient diet. The consequence is that the hospital of the Croix Rousse exhibits a greater mortality from phthisis than any other hospital in Europe, a third of its mortality being due to this cause. Against this state of things no legal remedy exists, the laws which supply inspection and control only having power in the large workshops, and not applying to the wretched abodes in which these girls work.

THE STUDY OF LARYNGOLOGY IN VIENNA.—A writer in the October number of the *Canada Medical Journal* points out how well conducted this is in his great school for specialist study. There are four clinics for diseases of the nose and throat, three of which are in the Krankenhaus itself, and the other in the Polyclinic, close by; and the hours are so arranged as not to conflict, so that almost uninterrupted study may be pursued from eight to one. The supply of material seems inexhaustible, this arising to some extent from the encouragement of interesting cases to make frequent visits, so that they are seen over and over again. The class of cases met with is of a more

serious character than occur in Canada, laryngeal phthisis, for instance, being of frequent occurrence. The instruction given is of a most painstaking and practical character, there being almost an entire absence of didactic teaching and a substitution of case-teaching. The Germans possess a facility of illustration almost peculiar to themselves, and one which teachers of other countries would do well to cultivate. The Vienna laryngologists excel in diagnosis and in an intimate knowledge of the pathological condition, but in regard to scientific labour-saving apparatus and treatment they are not superior to the Americans. There is perceptible on the part of the professors and assistants an absence of roughness or violence in handling that is gratifying; and this is a lesson that all laryngologists must learn if they seek success. Education of the parts to tolerate the instruments is generally adopted, and no time necessary for the accomplishment of this is begrudged.

**REMARKABLE CASE OF ASCITES.**—Dr. McDonald reports the case of a woman, about 50, who came to him in December 1880 with ascites. She stated that she had been tapped six weeks before. He now drew off 22 quarts of fluid by means of an aspirate needle, and from that time until now the operation has been repeated at intervals of about two weeks, from 16 to 20 quarts being removed each time. Examination of the urine failed to reveal any cause for the ascites, and neither the liver nor the heart presented any symptoms of disease. Medicinal treatment failed to prevent the exudation or promote its absorption. The patient has now furnished about 500 quarts of fluid, but seems to have suffered in no way from this abnormal excretion, her general condition presenting no change, save that incidental to increasing years.—*New York Medical Record*, November 7th.

**PURE BLACK SILK SUTURES.**—Dr. Pancoast (*Philadelphia Medical News*, October 24th) considers that these are much more satisfactory than those made of white silk, which is commonly coloured by lead and may poison the wound. The black sutures he uses are made of pure black silk which is dyed with iron, which is of service in preventing erysipelas. The silk may be rendered still more antiseptic by dipping it in carbolic acid or chloride of zinc, of which he has a very high opinion. It is the strongest ligature made, and at the same time the most delicate for plastic operations. He always keeps a variety of sizes on hand. Dr. Pancoast also employs diachylon plaster made with black silk, and finds it extremely satisfactory.

**CHEAPNESS OF CREMATION.**—"The cost of cremation by the new Company in this city," the *New York Medical Record*, No. 15, observes, "will be only 25 dollars. The fact that a person dying in New York can have suitable mortuary rites performed for so small a sum is most interesting, and will, we feel sure, do much to rob death of its terrors. The Company, indeed, promises to open up a new era in municipal mortuary history; for, while there has been a great deal said and written about cheap living, we have heard very little of a serious and practical nature about cheap dying. Dying in New York is a luxury, and one about which most people show a strange amount of thoughtlessness and inconsideration. A citizen can live for three years in Arkansas for the price of a conventionally respectable interment in New York. Yet few take such a fact as this into the slightest consideration."

**CHOLERA AND ARSENICAL POISONING.**—The *Philadelphia Medical Reporter* for October 31st states that Dr. Jauney, the late coroner, at a meeting of medical men, made the startling assertion that "no healthy man or woman that is without organic disease and of average strength and vitality ever dies in this climate from cholera." He declared that his experience in, and the records of, the coroner's office substantiate the fact that such a person, when dying with symptoms of cholera, always dies from poisoning, usually arsenical, the case being one of suicide or homicide; and so distinguished an authority as Professor Bartholow declared that he has not the least doubt of the correctness of the assertion.

## APPOINTMENTS.

- BROCKATT, A. A., L.R.C.P., M.R.C.S.—Clinical Assistant in the Skin Department of St. Thomas's Hospital.  
 CALDECOTT, CHARLES, M.R.C.S. Eng., L.S.A. Lond.—Resident Medical Officer to the Eastern Counties Asylum for Idiots, Colchester, *vice* Dr. Coombes, resigned.  
 CHAPMAN, JAMES, L.F.P. & S. Glas., L.S.A. Lond.—Medical Officer to the Hursley District and to the Workhouse, Hursley Union, *vice* Dr. H. C. Selwood, deceased.  
 CROWDY, F. D., M.B. Oxon., M.R.C.S., L.S.A.—Assistant House Physician to St. Thomas's Hospital.  
 GODFREY, A. E., L.R.C.P., M.R.C.S.—Clinical Assistant in the Ear Department of St. Thomas's Hospital.  
 HAIG, F. M., M.R.C.S., L.S.A.—Non-resident Physician to St. Thomas's Hospital.  
 HARRISON, CHARLES, M.R.C.S. Lond., L.S.A.—Medical Officer to the Bitton District, Keynsham Union, *vice* Mr. F. M. Page, resigned.  
 HUTTON, J. S., L.R.C.P., M.R.C.S., L.S.A.—Resident House Physician to St. Thomas's Hospital.  
 JOHNSTON, G. D., L.R.C.P., M.R.C.S.—Ophthalmic Clinical Assistant to St. Thomas's Hospital.  
 KIDD, CAMERON, L.R.C.P., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.  
 LANKESTER, H. H., M.B. Lond., M.R.C.S., L.S.A.—Resident Accoucheur to St. Thomas's Hospital.  
 LAWSON, R., M.R.C.S., L.S.A.—House Surgeon to St. Thomas's Hospital.  
 NEWBERRY, WILLIAM JOHN, L.S.A. Lond., M.R.C.S. Eng.—Medical Officer to the Burton District, Kendal Union, *vice* Mr. R. Whipp, resigned.  
 PLOWMAN, S., L.R.C.P., M.R.C.S., L.S.A.—Clinical Assistant in the Throat Department of St. Thomas's Hospital.  
 RELTON, B., M.R.C.S., L.S.A.—House Surgeon to St. Thomas's Hospital.  
 RITCHIE, E. D., M.R.C.S., L.S.A.—Resident House Physician to St. Thomas's Hospital.  
 ROBERTS, W. LAKE, M.R.C.S.E.—Honorary Surgeon to the Bradford Infirmary, *vice* Herbert Spencer, M.R.C.S.E., resigned.  
 WALTER, ERNEST WILLIAM, M.R.C.S., L.R.C.P., L.M.—Medical Officer to the Fourth District, Havant Union, *vice* Mr. P. Pope, resigned.

## VACANCIES.

- ASHBY DE LA ZOUCH UNION.—Medical Officer to the Fourth District, in succession to Dr. J. N. Watson, deceased. Area, 6,861 acres. Population, 6,393. Salary, £60 per annum.  
 BLYTHING UNION.—Medical Officer to the Second District, in succession to Mr. Fredk. Haward, resigned. Area, 15,329 acres. Population, 5,097. Salary, £75 per annum.  
 CARLISLE UNION.—Medical Officer to the St. Outthbert's District, in succession to Dr. P. Moffatt, resigned. Area, 10,098 acres. Population, 17,276. Salary, £100 per annum.  
 CITY AND COUNTY LUNATIC ASYLUM, STAPLETON, NEAR BRISTOL.—Assistant Medical Officer. (*For Particulars, see Advertisement.*)  
 CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, E.—Assistant Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to be sent to the Secretary's Office, 24, Finsbury Circus, E.C., on or before December 7th.  
 STIRLING DISTRICT ASYLUM, LARBERT, N.B.—Assistant Physician. (*For particulars, see Advertisement.*)  
 TORBAY HOSPITAL AND PROVIDENT DISPENSARY, TORQUAY.—Junior House Surgeon and Dispenser. Salary, £90 per annum, with board, lodging, and attendance. Candidates must be qualified in Medicine and Surgery, registered under the Medical Act, and unmarried. Testimonials to be sent to the Hon. Secretary, W. H. Kitson, Esq., Torquay, not later than January 1, 1886.  
 WESTERN GENERAL DISPENSARY, MARYLEBONE ROAD.—Ophthalmic Surgeon. Applications to be sent to the Hon. Secretary, from whom particulars can be obtained, by December 7th.

## DEATHS.

- ANDREWS, THOMAS, M.D., LL.D., F.R.S., at Fort William Park, Belfast, on Nov. 26th, in his 72nd year.  
 SHERRIN, FRANCIS MARK, M.R.C.S., L.R.C.P., at Vari, Southcote Road, Bournemouth, aged 32.  
 WATERS, JOHN, M.D., at 15, Bedford Square, on Nov. 28th, aged 73.

## NOTES, QUERIES, AND REPLIES.

### MEDICAL KNIGHTS.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—You tell us that you look forward to a long line of Provincial Medical Knights. Few of your readers will, I think, take the same view. During my attendance as a pupil at St. Bartholomew's Hospital—some five-and-forty years ago,—I remember that I once asked an old practitioner some question about Sir James Earle and other gentlemen of title, whose names were known in connection with the hospital. He told me that it had been the custom to knight the Senior Surgeon of the hospitals in London: that, when it came to Mr. Abernethy's turn to receive the honour, he declined it. Mr. Vincent did the same; and the Minister ceased to recommend the Surgeons for the honour. The number of medical practitioners in possession of the honour has been declining for some years. Passing the Baronets, and the Knights of the different Orders, it appears from published lists of Knights Bachelors, to which I

have the opportunity of referring, that there were 33 members of the medical profession among the number in 1849, and 17 in 1871. At the present time there are ten,—which is less than a tenth part of the number of lawyers now on the list.

Your obedient Servant,  
D. R.

November 1885.

"Aqua."—Hime's table, taken from Parkes, gives only such qualitative tests as may serve for condemning offhand or provisionally sanctioning the use of some particular source. Where distillations, maintenance of fixed temperatures for several hours, &c., are required, or when legal proceedings are likely to arise, "Aqua" should refer to a regular analyst. There are, however, a few valuable quantitative estimations that he might advantageously practise, that, for example, for chlorides, either by the ordinary silver chromate or Volhard's method, and we would strongly recommend him to substitute Griess's accurate and delicate test for nitrites for the older ones given by Parkes and Hime. It is this:—To about 50 ccs. of the water, acidulated with dilute sulphuric acid, add a few drops of sulphanilic acid, and ten minutes later a few of chlorhydrate of naphthylamine. Immediately, or after a longer or shorter time, a coloration appears, varying from a pale rose to a deep red, according to the amount of nitrites present. It will indicate 1 in 1,000,000.

Dr. R. White, Trinity, Newfoundland. — Letter and enclosure received with thanks.

## THE TREATMENT OF THE RESULTS OF IRITIS, BEING SOME OBSERVATIONS IN THE COURSE OF A CLINICAL LECTURE DELIVERED AT MOORFIELDS JUNE 20, 1885.

By E. NETTLESHIP, F.R.C.S.,

Ophthalmic Surgeon to, and Lecturer on Ophthalmology at, St. Thomas's Hospital, and Assistant Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

The management of its results is a question that occupies a prominent position in speaking of iritis, and several of the points are well illustrated in the case of the man to whom I am about to draw your attention.

The patient in question, aged 47, was under treatment in July and August, 1884, with severe iritis in the right eye, and slight iritis in the left. He has had several relapses since then, but at present the left eye is quiet, though he cannot see well with it. The most obvious cause of this defect of sight is that lymph has crept into the area of the pupil and formed into a membrane. When this occurs, the pupil is greyish instead of black, and has at first sight somewhat the appearance of a cataract; in this particular instance there is no doubt about the existence of a membrane, but sometimes it is difficult to distinguish between

such a membrane and a true cataract. Sometimes we see a cataract which is the result of iritis, or a cataract and iritic membrane together, causing opacity in the pupil, but such cases belong to a much more serious class than the present one. In distinguishing membrane in the pupil from opacity of the anterior cortex of the lens, the appearances and the plane of the opacity are the points we have to bear in mind, the thickness of the iris being always appreciable in front of the most superficial opacity within the lens-capsule.

Membrane in the pupil is the commonest cause of defect of sight after iritis. Another cause is secondary glaucoma due to occlusion of the pupil from total posterior synechia; the communication between the anterior and posterior chambers being shut off, the fluid behind the iris, being thus unable to escape, causes bulging of the iris and increased tension. The anterior chamber therefore becomes shallower than normal or even is completely obliterated. Such shallowing is distinguished from that caused by thickening of the iris, as the result of old iritis, by the fact that in the latter case there is no alteration of contour, and that the iris is not funnel-shaped; whilst it may be distinguished from that caused by ordinary primary glaucoma in that here the iris seems pushed forward as a whole. The treatment in such a case is as for chronic glaucoma.

In our patient's case, however, there is not much to be done, because there is no glaucoma, and the making of an artificial pupil by removing a small

piece of the iris would not render the eye equal in sight to its fellow. Had there been the same condition in both eyes, I should have felt inclined to make an artificial pupil and thus expose a part of the lens, which would probably be free from adherent pigment and membrane. For in most ordinary cases of iritis the lymph is thrown out only by the pupillary border of the iris, where the capillaries are most abundant. It is of course impossible to remove the iritic membrane and thus clear the pupil, but in suitable cases, free from membrane, single adhesions may be broken down by means of the notched spatula employed for this purpose by Mr. Streatfeild. A small incision is made in the cornea and a thin ivory spatula with a little hook at the end, perfectly smooth and flat, is introduced into the anterior chamber behind the adhesion and gentle force used to separate it.

It is said that when adhesions have been removed in this way there is less liability to a relapse; but surely, if adhesions have much to do with causing relapses, almost every case of iritis should be liable to relapses. Now we know that rheumatic iritis is extremely prone to relapse, whilst in syphilitic iritis, no matter how many adhesions there may be, there is little likelihood of such an occurrence. I have seen many cases of old syphilitic iritis with numerous adhesions and pigment on the anterior capsule of the lens, with no history of the least inflammation since the first attack. Again, there is a class of rheumatic cases in which, though pain and congestion are severe, the actual iritis is slight, and in which no adhesions form, but which are extremely liable to relapse, the subsequent attacks being all like the first. I believe, therefore, that the tendency to relapse has much more to do with the first cause of the iritis than with the adhesions. That iridectomy has in some way the power of preventing recurrences seems, however, well established, though I believe that its influence has been over-rated. The subject is, however, too large a one for the present occasion.

## CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD  
AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the  
Principles and Practice of Medicine and on Clinical Medicine.

### LECTURE VIII.—CASE TAKING.

*Personal History.*

*Sex—continued.*

The relative proportions in which different diseases attack the two sexes may be most conveniently seen by reference to the following table, which I have compiled from various sources. The list makes no pretension to completeness, nor is it submitted with any idea that the figures and proportions set down are to be accepted as being perfectly accurate, since, for many reasons, they are only approximately correct. Thus, by chance or design, the practice of one observer may lie more among our sex than the other; and the records derived from hospitals are subject to the qualification that, whilst more men are, as a rule, admitted as in-patients, the reverse obtains among women, who can less well be spared entirely from their homes. The accommodation for both sexes, also, is not always equal in hospitals, and this in itself would

affect the totals given. But, notwithstanding these and other qualifying circumstances, the general result is, I believe, substantially accurate, and is sufficient to show the broad general distinctions which obtain in regard to the incidence of disease among males and females. Doubtless, as more extended and accurate knowledge is accumulated, some of the conclusions will require to be amended, and you have it in your power by your observations to contribute to so doing. Again and again I shall have occasion to remind you that our science has arrived at that stage in its evolution when the necessity for well attested, carefully recorded, facts are imperatively needed to substantiate or alter hitherto accepted ideas, and for this purpose, and others, a detailed "personal history" is in all cases desirable, even when the value of some of its items is not at once apparent.

The general conclusions which I think may be deduced from a study of this table are the following. First, the far larger number of diseases which prevail in the male sex, and this, although there are, as we have seen, many more females living at every age, to be exposed to illness. It must not, however, at once be inferred that the masculine organisation is in itself in most cases more prone or more easily susceptible to morbid influences, since, without doubt, many of the maladies in the list occur in greater proportion among males from their greater exposure and hence increased risk of contracting disease. Passing to special groups of diseases, it is a noticeable circumstance that the great majority of congenital imperfections (that is, of departures from normal structure which arise at that period of existence when the environment may be regarded as almost identical for the two sexes) occurs in males. The intra-uterine dislocations of the hip offer a marked exception, as well as moveable kidney and lateral curvature of the spine, and we are no more in a position satisfactorily to explain these exceptions than we are to account for the masculine prevalence of congenital deformity. But the prevalence itself suggests an inherent difference in liability to disease.

Among the general diseases, those, that is to say, which are constitutional, or which, if of extrinsic origin, would seem to be primarily affections of the blood, from which the organs suffer secondarily, the difference in their incidence as to sex is but slight; quite insufficient to permit any inference to be drawn as regards the respective proneness of either sex to suffer. Those diseases which cause the greatest mortality, such, for instance, as tuberculosis and cancer, occur with about equal frequency in both sexes. Congenital syphilis, notwithstanding the greater number of male parents affected with the constitutional disease, appears as commonly in infant girls as boys. The zymotic diseases, with but few exceptions, and these probably more apparent than real, affect males equally with females, the slight excess, when it is to be represented in figures, being among males.<sup>1</sup>

Since so many of the differential manifestations between the sexes are connected with the nervous functions, it might be expected that affections of the cerebro-spinal or sympathetic systems would exhibit a very distinct difference in the degree to which they occur in the sexes. This can hardly be said to be the case. For, although all the emotional disturbances comprehended under the term hysteria and its allies are

<sup>1</sup> Thus, Typhoid Fever:—Of 5,988 cases recorded by Murchison at the London Fever Hospital, 3,001 were males and 2,987 females; of 891 cases admitted to the Glasgow Infirmary, 529 were males and 364 females. Leibermeister, at Breslau, gives very much the same proportion—of 2,048 cases, 1,297 being males and 751 females. Measles and idiopathic parotitis are also said to be slightly more frequent in males. And in all epidemics of relapsing fevers a preponderance of males are affected; thus, of 1,164 cases only 431 were females, the remaining 733 being males.

<sup>1</sup> Congenital atresia of small intestine is as frequent in one sex as the other. (Leichtenstern.)  
<sup>2</sup> The defects usually involve other parts of the genito-urinary organs.  
<sup>3</sup> Almost all cases of double hare lip are males.  
<sup>4</sup> Among children there is found a slight excess in females. Of 478 cases recorded at the Children's Hospital, 226 were boys and 252 girls. And Goodhart (Guy's Hospital Reports, xxv., N.S.) gives 44 cases, 26 of which were girls and 18 boys.

<sup>5</sup> Men are much more subject to articular gout than women. Garrod (Reynolds' System, 1866). But irregular manifestations of this morbid inheritance are as frequent in females. Draper (Pepper's System, 1885).  
<sup>6</sup> Mostly seen in men before the middle period of life. Wilks (Reynolds' System, 1879).  
<sup>7</sup> There is no great difference between the sexes. (Senator.)  
<sup>8</sup> Women rarely present typical instances of the disease. The danger to life is infinitely less than in the opposite sex. (Legg, 1872.)

<sup>9</sup> No sufficient reason for believing that one sex is more liable to insanity than the other. At the same time the existing causes of insanity act with different relative frequency in the two sexes, and there are marked differences in the degree in which its several forms prevail among them. (Bristowc, 1884.) On whichever side the difference lies, it is probably inconsiderable. Maudsley (Reynolds' System, 1868).

<sup>10</sup> Unmistakeable preponderance among males. Gull and Anstie (Reynolds' System, 1868).

<sup>11</sup> In children a greater proportion of males. Ross.

<sup>12</sup> All met with more frequently among males.

<sup>13</sup> After the age of 30 years the number of males affected is much greater than that of females. (Ross, 1883.)

<sup>14</sup> Much commoner among males.

<sup>15</sup> Average of twice as many males, due to their more laborious duties, and not to inherent proclivity of sex as such. (Hayden, 1875.)

<sup>16</sup> More frequent in males, from greater exposure to muscular exertion. Gowers (Reynolds' System, 1877).

<sup>17</sup> Pretty equally apportioned between the sexes; though certain forms prevail among males and other forms among females. (Hayden, 1875.)

<sup>18</sup> It is admitted by all that a larger percentage of pericarditis relatively to the number affected with rheumatism occurs in females than in males. (Hayden, 1875. Sibson (1877) says in proportion of 168 to 158.

<sup>19</sup> Fatty degeneration, due to general anæmia, is commoner in women. (Ponfick, 1873.)

<sup>20</sup> Mos' records show a preponderance in the males. (Gowers, 1877.)

<sup>21</sup> Aneurysm of the vessels of the extremities much more frequent among men.

<sup>22</sup> Generally admitted to be more frequent in men, although doubted by some; certainly during gestation and at menopause women are very liable to them. (Bodenhamer, 1884, N.Y.)

<sup>23</sup> Commoner in males. Equal in sexes. Agnew, 1878, N.Y.

<sup>24</sup> In adults is most frequent in women. (Steffen.)

<sup>25</sup> The difference between the sexes as regards frequency only becomes apparent at ages when the occupations of the sexes differ, and when males are more exposed to climatic influences than females. (W. Fox.)

<sup>44</sup> More than twice as frequent in girls, especially after the age of 9 years. (Broadbent, Quain's Dict.)

<sup>45</sup> Although pre-eminently a disease of females, does occur in the other sex. Charcot, in a recent lecture (*Med. Press and Circular*, Dec. 2, 1885), refers to 80 cases collected by Klein and 218 cases by Battault.

<sup>46</sup> Far more frequent in women.

<sup>47</sup> Little of value can be shown as regards the influence of sex in epilepsy. Practically the two sexes appear to be equally affected. (Reynolds, 1868.) The proportion of women affected is greater than that of men; but this is not the case, and in some degree is even the reverse, under 25 years of age. (B. Sequard, Quain's Dict., 1882.)

<sup>48</sup> Has only been seen in females.

<sup>49</sup> Is much more frequent in women. (Ross, 1883.)

<sup>50</sup> Women probably more subject to it than men. Leube (Ziemssen, 1877).

<sup>51</sup> Women are beyond dispute more prone to it than men. (Wardell, Reynolds' System, 1871.)

<sup>52</sup> Commoner among females.

<sup>53</sup> Half were pregnant.

<sup>54</sup> More common in females. (Bristowe.) Comparatively rare in males. (Duckworth.)

<sup>55</sup> The majority of cases are women. (Duhring.)

infinitely more common in the female sex, those graver and more appreciable structural lesions expressed by insanity are about equally frequent among men and women, whilst the inflammatory and degenerative affections of the brain and spinal cord decidedly preponderate among males and are not easily to be accounted for by greater exposure or intemperance on their part. On the other hand, those serious disturbances of nutrition attributable to perverted nervous action, such as exophthalmic goitre and myxœdema, exhibit a decided preference for the female sex, and so far constitute with chlorosis very significant exceptions to what seems to be the general rule of the lessened liability of females to disease. It is probable that rheumatic arthritis should be included in the same group of trophic disturbances prevailing among women. Such maladies are among those for which we cannot at present find any cause in the environment, and are, therefore, to be considered as evidences of mal-nutrition of intrinsic origin.

In respect to the diseases of the digestive, circulatory, respiratory, and excretory systems, their greater frequency among men may in great part be attributable to greater exposure and intemperance of all kinds; but even the special frequency of gastric ulcer among females, and the much greater liability of males to valvular diseases of the heart, of rheumatic origin, although practically both sexes are equally affected with acute rheumatism, are exceptions for which I am unprepared to offer you a satisfactory explanation.

Several of the diseases enumerated on the list, especially acute rheumatism and chorea, clearly show the close relations existing between age and sex in their influence on disease, and how necessary it is to remember that these factors, though here treated of separately, are to be considered as intimately associated when considering any particular case, and that it is the combined result of both that comes before us. Rarely it would seem that locality affects the sexual influence; so, at least, would appear to be the case in regard to endemic hæmaturia, which attacks children of both sexes in Mauritius, but at Port Elizabeth is almost unknown in females. (Dr. W. Roberts, Reynolds' System, vol. v., 1879.)

A branch of the subject, that calls for further enquiry, is the actual effect that sex *per se* determines upon diseases when established, apart from frequency of occurrence; in other words, the differences manifested by the same disease in the two sexes. Two cases of what are regarded as the same illness are not absolutely identical in their symptoms, any more than are the individuals who are the subjects of it, and with such a widespread divergence, even though it be but in minute points, the difficulties of formulating any sexual distinction in this respect become increasingly great. Acute pneumonia seems, among others, to illustrate the question. Occurring less frequently in women, it yet exhibits a higher rate of mortality among them, in the proportion of 14 to 10 among males, although the death-rate is less affected by age than in men (Huss). Further, it appears to be more protracted in the female sex, cases that recover lasting on an average three days longer among them. Their liability to double pneumonia is also said to be greater. And this independently of the very distinct influence exerted by menstruation, pregnancy, or parturition, the effect of which upon the course of disease I alluded to in my last lecture.

It is difficult, I think, from a consideration of all these circumstances, to avoid coming to the conclusion that there is some intrinsic difference in the constitution of the sexes, which shows itself not only in the death tendency, but also in the liability to disease (which are far from being necessarily the same), both appearing in males to a higher degree than they do in

females. In attempting to find any explanation for the difference, we are met with many and great difficulties. True it is that a marked distinction exists between the sexes in the structure of the organs so far as mere size is concerned, with a corresponding difference in extent of function; the composition of the blood differs, and the products of tissue metabolism are less in women; but we seek in vain at present for any definable difference of kind except so far as the function of reproduction is concerned. And yet few will doubt but that at a very early age, long before the generative power is developed, sufficient difference does exist in appearance no less than in manner, habit, modes of expression, tastes, and even in games and amusements, to furnish ample grounds for discrimination. Training and education may play some part in this result, but scarcely all. Later, and especially at puberty, these differences are intensified, and may be grouped as those depending on the organisation of the nervous system, those due to the function of reproduction, and those attributable to habit, education, and pastime. At the extremes of life the distinctions are less apparent; for, although the structural differences in the reproductive organs begin to appear by the fifth day of foetal life, it can scarcely be suggested that, apart from these organs, a distinction can be recognised within the first three or four years after birth; not, in fact, until the mental perceptions derived from the impressions of the senses have acquired precision, after which the nervous sensibility proper to each sex reveals itself.<sup>2</sup> In the later days of advanced life, after all sexual function has long disappeared and the nervous powers have advanced on the road of decay, the sexes are again approximated in the quality of their vitality, and the characteristics dependent upon a mature nervous organisation, intellectual, emotional, and trophic, are no longer to be discriminated. "Woman," says Professor Humphry<sup>3</sup>, possesses "a stronger and more enduring vitality," apart from her greater freedom from exposure and her greater temperance. But we are as yet unable to associate this better "quality of steady, persistent, nutritive force" with any special structural condition. The ganglionic system is said to be developed to a greater extent in the female than the male, both in the size of the ganglia and the distribution of the nerves, and "as a consequence woman possesses a tenacity of life and power of long endurance in resisting the effects of disease greater than that enjoyed by man, but this peculiarity increases the risks of reflex disturbances from ovarian or uterine disorders."<sup>4</sup> Whilst the latter part of this proposition may be unhesitatingly accepted, I am not aware that the greater development of the sympathetic system actually does obtain in the female, or that, even if it be so, such greater development confers a higher degree of vitality, although such may be the case. Indeed, it would seem probable that, apart from the differences clearly attributable to habit, education, and fashion, and those due to the reproductive function (which in both sexes exerts a healthy stimulus to the general nutrition of the body and, only when impaired by disease, reacts unfavourably upon the entire organism), the essential distinction in the power of life between the sexes is connected with that trophic influence which the nervous system exerts. Upon the view that the male organisation is a higher stage of development than the female, it would have to be conceded that in tenacity of life the latter had the advantage. Dr. Braxton Hicks, in his Croonian lectures on the Sexes in relation to Disease, delivered at the Royal College

of Physicians in 1877, after referring to the intimate association of the nervous and sarcoïd elements of the tissues, both in their development and in the perfect state, which causes any change in one to influence the others to an equal degree, argues that "it is neither from testis, ovaries, or uterus alone, nor from the nervous system alone, that the influence springs which makes the difference between man and woman; but rather that this distinction is a consequence of an influence acting before the appearance of either," and adduces in support of his view those individuals possessing neither ovaries, uterus, nor vagina, but presenting the rest of the body and habits essentially feminine. "No doubt," he adds, "the sexual organs react in their influence on the nervous centre, and *vice versa*, and also the impression extends to those parts in sympathy with them, and thus in due course the whole economy is swayed."

### PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,  
President of the Health Department, Social Science Association.

#### DISEASES OF THE RESPIRATORY SYSTEM.

(Continued from page 772.)

##### *Foreign Bodies in the Air-Passages.*

M. NEPVEU has reported<sup>5</sup> the case, forwarded by a military surgeon from Algeria, of a robust Arab who stated that, for a fortnight, he had had a leech in his throat which caused him to spit blood every ten minutes, and induced dysphagia with violent cough, without much dyspnoea. The laryngoscope displayed the leech stretching from the summit of the arytaenoid cartilage to the base of the epiglottis, leaving, however, the glottis pretty free. It was extracted living, by means of the Cusco forceps, and all the symptoms soon disappeared. M. Nepveu refers to six other similar cases which are on record.

Dr. Webb relates the case of an European girl, aged 12, who suffered in an extreme degree from splenic cachexia. She died suddenly, in a fit of coughing. A large worm was found in the pharynx, pressing down the epiglottis, which was very red from irritation. (Page 153, *Pathologia Indica*.)

A similar accident occurred in Madras in 1872.<sup>6</sup> A horse-keeper, in hospital for tetanus caused by the bite of a horse, was talking in monosyllables to the nurse when there was a violent spasm accompanied by extreme contraction of the muscles of the back, lividity of the face, fixed and protruding eye-balls, firm contraction of the flexors of the hands, and cessation of respiration. The spasm terminated as suddenly as it had commenced, and with it the life of the patient. A round worm was removed from the mouth about a quarter-of-an-hour before death. It occurred to Mr. Brockman that probably a worm had entered the wind-pipe. There was found lodged there a round worm about seven inches long. Its head extended far into the left bronchus. Its tail lay just below the true vocal cords.

Preparation 737 in our Calcutta Museum shows three round worms in the bronchial tubes. "There is

an ulcerated communication between the œsophagus and the trachea, near its bifurcation, through which the entozoa have gained access to the air passages."

At page 619 of my "Medical Jurisprudence for India" will be found a case which I saw admitted in 1865 to the surgical wards at the Calcutta Medical College Hospital. A native boy of 4 appears to have placed a Coie fish, which is very tenacious of life out of water, in his mouth. In its struggles, its head passed the glottis and caused suffocation, as all attempts to draw it out were prevented by the catching of its gill-plates anchor-wise below the vocal chords. Other similar cases of laryngeal choking by fish will be found in the above-named work.

The following appears in the "Lady's Magazine" for September, 1771, p. 143: "On the 5th of this month, as a fisherman of Whitstable was pulling a small sole out of the mesh of the net with his teeth, it slipped into his throat. His companions saw the tail, but could not get hold of it, and, the fish insinuating itself into his windpipe, he was suffocated in a few minutes."

A case has lately been reported<sup>7</sup> in which the death of a boy, æt. 15 months, was caused by the presence of a *shrimp's head* at the bifurcation of the trachea. Mr. Macnamara<sup>8</sup> was successful in removing a *cowrie shell* by tracheotomy in a native child ætat. 4½ years.

For cases of impaction of living fish in the gullet, see *Foreign Bodies in the Pharynx*.

*Bronchial Glands.*—Preparation 743. "Tuberculosis of the bronchial and cervical glands, and obliteration of the left pulmonary artery from pressure caused by a bronchial gland greatly enlarged by strumous infiltration. The yellow tubercular matter is also seen in the small portion of lung preserved."

Preparation 744. Part of the trachea, bronchial tubes, and lungs. There is a ragged orifice, as large as a sixpence, at the bifurcation, and a smaller one in the right bronchus, caused by the breaking down of bronchial glands infiltrated with tubercular material.

I met with a case in which a calcareous mass, which had formed in a tubercular bronchial gland, was making its way through an ulcerated opening large enough to admit the point of the little finger, in the trachea, just at its bifurcation.

*Foreign Body in the Left Bronchus.*—Two young medical men, whom I shall designate as T. and S., were passing some stone-masons at work in Moorgate Street. T., while laughing heartily, felt something strike his soft palate sharply. The pain was so great as to confuse him, but he immediately spat some blood and felt certain that a fragment of stone had passed into his left bronchus. T. and S. entered the Indian Service; S. died early of phthisis. T. was, at about the same time, suffering from most distressing symptoms which much resembled those of phthisis. He was much emaciated, was very weak, and had cough with expectoration. I attended him for some time. There was considerable sub-clavicular dulness on the left side, with small moist sounds. He was positive that the stone was still lodged in the left bronchus. There was no sound to prove this; and, if a stone was really there, the case was exceptional, as foreign bodies usually lodge in the right bronchus. I counter-irritated very strongly. His health improved, and he accepted an appointment up country. He did not live many months. I was unable to obtain particulars of his last illness. The body was not examined.

I was at Guy's Hospital when Mr. Key was engaged upon the most interesting case of Mr. Brunel, who had a half-sovereign lodged in his *right bronchus*; and I was present at some of his trials upon the dead body,

<sup>5</sup> To the Paris Société de Chirurgie, cited in the *Medical Times and Gazette*, vol. i. for 1884, p. 463.

<sup>6</sup> *Madras Monthly Journal of Medical Science* for March of that year, p. 190.

<sup>7</sup> *Medical Times and Gazette* for September 5th, 1885.

<sup>8</sup> *Indian Medical Gazette*, vol. viii., p. 295.

to reach a similar coin with curved forceps through an opening in the trachea, &c. There was, nearly at the same time, a poor fellow in the wards, in whom there was clear evidence of the presence of a sixpence in the right bronchus. He was a turnpike keeper in the west of England, and met with the accident in shouting to a driver while the coin was in his mouth. Dr. T. A. Wise records<sup>9</sup> a remarkable, but not perfectly demonstrative, case of an English gentleman serving in India, in which severe pulmonary symptoms appear to have been excited by the presence of a fish-bone in some part of the air-passages—apparently the right bronchus.

At pages 617-18 of my "Medical Jurisprudence for India" will be found various Indian cases of *suffocation from the presence of foreign bodies in the air-passages*. In addition to these, Surgeon-Major William Curran has alluded, in his interesting paper on Sudden Death,<sup>10</sup> to three cases of soldiers in whom vomiting, while they were lying drunk, caused suffocation.

In October, 1881, it was reported in the London papers that a perfumer, whilst sitting with some friends, suddenly quitted them. He was found insensible in the garden. He was taken to the Middlesex Hospital, but was found to be dead. There were evidences of suffocation in the trachea and lungs. It was believed that he had retched, had taken a sharp inspiration, and had drawn the vomited matter into the trachea.

*Water and foreign bodies may enter the air-passages in submersion and drowning*—vide my "Medical Jurisprudence," pp. 643-44, especially an important case of a young boy found drowned in a tank. I found small portions of green vegetable matter in the fauces, larynx, and trachea. The right bronchus was almost completely filled with a portion of an aquatic weed so large that it was astonishing how such a body could pass the rima. No weed of the kind grew in the tank where the body was found; but it was discovered that the boy's body had been discovered by a woman in a tank, near his home, in which the weed grew abundantly. This female had conveyed the corpse to the more distant tank, which belonged to a person against whom she bore a grudge.

At pages 223-24 of the same work I have cited cases by Dr. James Wise and others of *Aphonia* resulting from Indian hemp intoxication in confirmed *gunja*-smokers.

*Glottidis Spasmus*.—See Tracheotomy in "Hydrophobia," vol. i. for 1885, p. 742.

*Death from Spasm of the Glottis in the First Paroxysm of Tetanus*.—At the time of the trial of Palmer, it was rumoured that a negro servant in Edinburgh cut his hand with a broken decanter while waiting at table, fell, and immediately died in a tetanic spasm; but a record of the case could not be discovered. Dr. A. Webb told me that a little boy at La Martiniere School was having an ulcer on his leg dressed when he fell back in opisthotonos and immediately died.

*Tracheotomy*.—I opened the air passage six times in India: in three Europeans, in two natives, and in an East Indian infant;—in two cases of diphtheria, and in one each of syphilitic laryngeal disease, whooping-cough, aortic aneurysm, and hydrophobia. Two of these cases did well, as far as the operation was concerned. In five the opening was made at the instant of apparent death; in one of these the patient recovered. Here I must repeat a surgical platitude, so important have I found it in practice; *the canula can hardly be too large*. I saw a case many years ago in London, in which it was clear that suffocation had been promoted by the use of a small canula. The fatal error in more than one ingenious instrument, strongly

recommended by its inventor, has been that it did not leave an opening equal in size to the rima glottidis. The external incision should be free. It is to be borne in mind that the veins of the neck, from which troublesome hæmorrhage is to be apprehended, are most engorged when we operate late. Ample deliberation in making the incisions is always allowable. If the patient be dead, a few seconds can make no difference; if not, he will either recover immediately or may be restored by Sylvesterism. In one of my cases, where the neck was enormously fat, I hurried, and there was great venous hæmorrhage. Mr. R. W. Parker's advice to remove the exudation in tracheotomy for diphtheria should never be lost sight of.

*Bronchial Catarrh and Bronchitis* (vide "Influenza," vol. i. for 1884, p. 761) are common throughout India whenever the damp air becomes chilly, especially at the commencement of the Rains, and still more so at the setting-in of the cold season. Then asthmatics, the phthisical, and the aged get severe chronic bronchitis. From time to time we hear of isolated cases of *capillary bronchitis* or *acute pulmonary œdema*—a medical officer; a European lady lately married; the young wife of a wealthy native—attacked in the cold early morning with difficulty in breathing and dying suffocated in a few hours.

Under the head of Influenza, I have given some account of the *capillary bronchitis* which was extremely and very destructively prevalent among children in Bengal in 1828.

Dr. Macpherson, of Bauliah, remarked, with regard to the climatic condition at that time, that the wind, which during the rainy months in Bengal blows almost invariably from the east or south-east, was then (August and September) generally southerly and easterly, "*with hot sultry days and strong gales at night*." The sentence which I have here italicised tells us as much in explanation of the causation of nine-tenths of the acute disease which occurs in India as many elaborate treatises do.

One morning, when I was unable to visit my wards, a European was brought in from a burning house. He was suffocating from a draught of hot air, against which his epiglottis did not close, drawn into his lungs, probably when shouting. My colleague bled him freely to relieve the terrible asphyxiating congestion, but he rapidly sank.

I know of only two cases of *Bronchitis with tube casts in India*, both in medical officers, who upon retirement have enjoyed active health and are now aged men. I think that, in these cases, there was also malarious asthma.

For *Malarious Spasmodic Asthma*, see remarks on this disease in the section on "Malarious Cachexia," vol. i. for 1884, page 76.

My friend, Dr. Robert Bird, now of Virginia, has recorded<sup>11</sup> the following markedly typical case. An engine driver, at Howrah, near Calcutta, began to suffer from well-marked intermittent fever in the cold weather of 1863, having been previously strong and healthy. These attacks were always complicated with cough. Fever returned again and again, until, at last, the accompanying cough degenerated into chronic bronchitis. But the most interesting feature in this process was that, as the feverish symptoms became less marked, the symptoms of bronchitis became more so, until, at last, the fever entirely disappeared and the asthma became, for the time, established. After this he suffered from a fully developed attack of asthma about once a month, and each attack lasted from two to five days. The disease resisted every kind of treatment, and Dr. Bird had quite despaired of doing the sick man any good, when, in July 1865, he was attacked

<sup>9</sup> *Calcutta Medical and Physical Transactions*, vol. ix., p. 162.

<sup>10</sup> *Indian Annals of Medical Science*, No. xxxii., p. 361.

<sup>11</sup> "Remarks on Malaria and some of its Effects," *Indian Medical Gazette*, vol. i., p. 56.

with fever and ague. From this time up to March of the following year, when the report was made, with the exception of two very mild attacks, he was exempt from the tortures of asthma. He became perfectly healthy, the bronchitis disappeared, appetite and strength were restored, and he grew stout.

I am happy to be able to say that my brother officer, whose case I noticed 23 months ago (vol. i. for 1884, p. 76), appears at length to have completely shaken off his malarious asthma; but, some time ago, an attack was excited on passing, by rail, a tract of sea marsh between Bournemouth and Southampton.<sup>12</sup> He and I steadily avoid residence by the seaside.

I have not been so fortunate as to receive any reply to my question (*vide* vol. i. for 1884, p. 77). *Are any seaside resorts, in the United Kingdom or on the Continent, absolutely exempt from marsh influence?*

Dr. Hogg<sup>13</sup> found that, in the jails of Lower Bengal, 129 died out of 3,415 treated for asthma. But what diseases were here comprehended under the designation "Asthma"?

#### PNEUMONIA.

In speaking of *Idiopathic Pneumonia*, in the chapters on Paludal Cachexia,<sup>14</sup> I have mentioned that very few cases occurred during my long experience in civil practice in Lower Bengal. A very observant man, Mr. J. Murray, writing in the Bombay Presidency<sup>15</sup> observed that, during eight years, he had not met with a single case of pneumonia in a European, or with an idiopathic case of the disease among natives.

When pneumonia does occur in Bengal Proper it is very apt to attack the *upper* lobes of the lungs of ill-fed cachectic subjects. Morehead shows that "Pneumonia is a rare disease in Europeans in Bombay"; but that, in natives, pneumonia of asthenic type is common.

Hugh Macpherson found that, in the eight years 1853-54, Inflammation of the Lungs gave half per cent. of admissions in the European army serving in Bengal, and fifteen and a half per cent. of deaths to treated; which, compared with Col. Tulloch's columns, shows this disease to have been only half as common, but twice as fatal to those attacked, in India as in England.

The Sanitary Commissioner's Returns give the following statistics of Pneumonia throughout the three Presidencies.

Year 1880	European Soldiers	143 died
	" "	3 invalided
	European Women	12 admitted
	" "	4 died
	European Children	12 admitted
	" "	7 died
	Native Troops	3,370 admitted
	" "	1,222 died
	Native Prisoners	1,669 admitted
	" "	1,222 died
Year 1881	European Soldiers	86 died
	" "	10 invalided
	European Women	6 admitted
	" "	1 died
	European Children	16 admitted
	" "	9 died
	Native Troops	2,007 admitted
	" "	593 died
	Native Prisoners	1,082 admitted
	" "	398 died
Year 1882	European Soldiers	1 died
	" "	9 invalided

<sup>12</sup> My friend Dr. Eatwell tells me that a very delicate lady, advanced in life, has suffered from a return of her Indian intermittent fever whenever she has crossed Pevensy Marsh, near Eastbourne, by rail.

<sup>13</sup> *Indian Medical Gazette* for 1875, p. 314.

<sup>14</sup> Vol. ii. for 1883, p. 654.

<sup>15</sup> *Indian Journal of Medical Science*, vol. ix., O.S., p. 523.

European Women	4 admitted
" "	1 died
European Children	14 admitted
Native Troops	1,560 admitted
" "	384 died
Native Prisoners	1,018 admitted
" "	349 died

In the above years, the average strength was, European Soldiers, 58,571; European Women, 3,741; European Children, 6,784; Native Troops, 118,630; Native Prisoners, 100,556.

Just before going to press, I have obtained the following statistics for the year 1883:—

European Soldiers	32 died
" "	9 invalided
European Women	9 admitted
" "	1 died
European Children	9 admitted
" "	3 died
Native Troops	1,541 admitted
" "	380 died
Native Prisoners	1,084 admitted
" "	351 died

#### Epidemic Pneumonia in India.

At page 106\* of Webb's *Pathologia Indica* is a report by Dr. Green, which shows that, between February, 1844, and May of the following year, an epidemic or endemic of pneumonia, frequently complicated with pleurisy, attacked the prisoners at Midnapore, in Bengal Proper, which stands on a laterite soil outside the Gangetic delta. In the sixteen months under report there occurred a total of 175 cases of pneumonia, 14 of phthisis, and 10 of bronchitis. In the several months the cases of pneumonia occurred in the following numbers—0, 2, 7, 2, 7, 1, 3, 15 (September, a very hot month), 22, 13, 37 (December, the coldest month), 24, 19, 21 (March, hot weather), 8, 4. Dr. Green's paper is well deserving of study, especially in connection with Mackinnon's remark upon epidemic pleurisy. I do not think that any such outbreak has occurred in a jail of *Lower Bengal*, within my experience, since 1848. Webb cites (p. 100a) a report by Dr. Edward Goodeve upon the prevalence at Cawnpore of pneumonia and of other pulmonary disease simultaneously with the Midnapore outbreak in 1844-45. Writing in 1848 of a low type of pneumonia, Webb says, "About two years ago this form of pneumonia, terminating in "[pulmonary]" oedema, was epidemic at Delhi, and very fatal." Mackinnon says, writing at Cawnpore in 1848, "Pneumonia is common in this part of India, at least as a complication in fever, and as an idiopathic affection." My own sensations while in the keen northerly winter air on two nights at the Patna and Allahabad railway stations, and again, on arriving before dawn, also in a cold season, at Cawnpore, fully enable me to understand that the cold-weather climate of the North-Western Provinces, following abruptly a season of great heat, tends to the causation of acute pulmonary disease.

With reference to Mackinnon's remark upon the occurrence in the North-Western Provinces of pneumonia as a complication of fever, I have already cited, in the section on Malarial Cachexia, a striking observation on this subject by Mr. Oldham. Of 103 cases of pneumonia in natives, treated by Morehead, 76 were of primary pneumonia and 27 of pneumonia complicating intermittent (4) or remittent (23) fever.

Pneumonia has always been recognised, in its epidemic form, as Influenza; and we have several records of the endemic and epidemic occurrence of this disease in old times. Of late, its tendency to assume the epidemic character has been rather closely

investigated. Dr. G. B. Longstaff has published<sup>16</sup> some important suggestions in reply to the question "Phthisis, Bronchitis, and Pneumonia: are they Epidemic Diseases?" Mr. Henry E. Armstrong, Medical Officer of Health, has recently observed<sup>17</sup> that the increased prevalence of pneumonia in Newcastle during the third quarter of 1883 was much greater in certain districts of that city than in others; thus, in Westgate, the deaths were equal to an increase of 85 per cent., whereas in St. Andrew's and St. Nicholas', there was a decrease from this cause. This circumstance, he held, cannot be explained on the ordinary grounds of coldness of season, &c., but may be due to local circumstances, possibly in the form of sanitary defects. He adds that it is considered by some that "certain kinds of pneumonia are the direct expression of the effects of zymotic poison rather than a condition of simple inflammation of the lungs; and that the relatively increased prevalence of the disease in certain parts of Newcastle would appear to support this view."

I do not know how it may have been of late years in London, but, fifty years ago, *herpes labialis* was a very frequent attendant of pneumonia; and, quite within my recollection, pneumonia attended with "typhous deposit," occasioning extensive lung consolidation, was so marked a feature of the great London outbreak of maculated typhus of 1838 that the pulmonic complication was, to say the least, the most prominent feature in the disease.

A most useful work will be accomplished by those who may succeed in tracing the geographical spread of the very marked epidemic of pneumonia which prevailed in New York and, at least, England, Scotland, and Ireland, late in the spring of the present year. I note the following in a South African report for August—"Inflammation of the lungs has been very bad at Kimberley—quite an epidemic, in fact; and it is said to have proved more fatal to the white population than the small-pox last year." There was a marked decrease when the report was made.

The following scattered notes suggest the advisability of compiling from the records a full history of the *Epidemics of Pneumonia* which have occurred in Northern India within the past fifty years.

Mr. R. H. A. Hunter, of H.M. 57th Regiment, gave<sup>18</sup> the following account of an outbreak which occurred in 1839. It appears that very little pulmonary disease occurred until the army, having crossed the Indus, penetrated the high mountain districts of Afghanistan. At the termination of the first campaign, on the descent of the troops through the different passes, what appears to have been regarded as fever with pulmonary complication for a short time assumed a most malignant character, and, in a milder form, followed the several corps for months afterwards. Not only did the 2nd and 17th Regiments suffer much from the time of their emergence from the Gundana Pass in the beginning of December 1839 (see Transactions of the Bombay Medical and Physical Society, vol. 3), but so also did the Bengal column on their descent into Tezeen. The most destructive epidemic of this kind which came to the reporter's knowledge was that which occurred some years later in H.M. 40th at Kwettah. The annual return gave a death-rate from pneumonia of no less than 50 in the 1,000 of strength. The disease is described as "pleuro-pneumonic fever." An idea of the character of the pleurisy is suggested by the use of the word "empyema." It was added that, within the Indus, the pulmonary complication

seldom exceeded that of a bronchitis, except at the most northern stations, as at Deesa near the borders of Scinde, where pneumonia of a lower lobe in the cold season was by no means uncommon.

I have referred above to Dr. Edward Goodeve's report on the prevalence of pneumonia at Cawnpore in 1844. Within the last sixteen years, at least, Epidemic Pneumonia has, from time to time, been reported as prevailing, in the cold weather, in Northern India. Dr. J. Kelly observed<sup>19</sup> that, since the cold season of 1869-70, pneumonia had been a frequent complication of the very prevalent remittent fever at Kohat, Bunnoo, and various other parts of the Punjab. In the cold season of 1870-71 Dr. Kelly observed 25 cases of secondary pneumonia in the 1st Punjab Infantry. I have spoken above of the tendency to pneumonia of the upper lobes which I observed many years ago in poor and ill-fed natives of Lower Bengal. Dr. Kelly found that in six, or nearly one-fourth, of his cases the disease was limited to the upper lobes. These cases presented many of the local and general characteristics of phthisis; but only one patient became phthisical (how far may this have been a case of intercurrent pneumonia?). Hence Dr. Kelly entitled his paper "Phthisis simulated by Pneumonia of the upper Lobes."

Mr. Joshua Duke made<sup>20</sup> a valuable report on the pneumonia which prevailed in the cold season of 1874-75 among native troops marching, on the triennial relief, to the stations of the North-West Frontier of India. There were 35 admissions, with 6 deaths, all in sepoy.

What appears to have been the earliest of Dr. G. M. Giles's now famous reports on pneumonia as observed on the Punjab Frontier appeared at pages 235 and 272 of the *Indian Medical Gazette* for 1883. Dr. Giles heard from Dr. Kelly, whose observations are cited above, that he was convinced that the pneumonia of the Punjab Frontier was "a disease almost specific, and distinct from the croupous pneumonia met with in Europe." Dr. Kelly was also strongly of opinion that the disease was, in many if not in all cases, propagated by contagion. He found, on proceeding to Dera Ismael Khan to take medical charge of the 4th Punjab Infantry, at the end of the cold season of 1882, that an epidemic outburst of pneumonia appeared to be ending. Other medical officers of the station held nearly Dr. Kelly's opinion. Dr. Giles then made examinations of the blood which are reviewed side by side with the observations of Dr. Mendelsohn in the first volume of the *Medical Times and Gazette* for 1844, page 261. It is there shown that Dr. Giles gives five cases of pneumonia occurring on the Punjab Frontier. The disease appears to be broncho-pneumonia, always attended with pleurisy. The pneumonia of that locality is, in the opinion of good observers, infectious. In all Mr. Giles's cases a peculiar micro-organism was present, both in the blood and sputa, during the whole of the illness; these organisms were similar in all the cases in which they were looked for; and, when the sputa containing these were injected into rabbits, they too were attacked by pleuro-pneumonia, to which they succumbed; and the blood, pleuritic effusions, and lungs of the rabbits were found to be crowded with similar organisms. Dr. Mendelsohn firmly believes that the European form of pneumonia is infectious, that it depends on the presence of bacteria, and that one form of bacterium is constant in all cases. He shows that numerous cases often occur simultaneously in small districts among troops

<sup>17</sup> "Report on the Recently Increased Death-rate of Newcastle-upon-Tyne, 1883."

<sup>18</sup> "Statistical Remarks upon some of the Principal Diseases among European Troops in the Bombay and Madras Presidencies." *London Medical Gazette* for 1847, vol. i., p. 7.

<sup>19</sup> *Indian Medical Gazette*, vol. vii., p. 270.

<sup>20</sup> *Indian Medical Gazette* for July, 1875; vide also Surgeon-Major Jessop, at p. 232 of the same vol., and Surgeon-Major Curran, on "Croupous Pneumonia and Gangrene of the Lung," *ibid.* for 1877, p. 281.

stationed at one place, in private houses and prisons (*vide* my note upon an outbreak of pneumonia which occurred eighty or ninety years ago in a Russian squadron at Spithead, Vol. 2 for 1883, p. 654), and that these outbreaks can often be referred to miasmatic influences, especially in connection with bad sanitary arrangements and deficient ventilation. He produces evidence to show that not only are those in immediate association with the sick in danger of taking the disease, but also that it appears capable of being carried from the sick to others by persons who do not themselves contract it. He contends that the prevalence of pneumonia is independent of changes of temperature, but that it varies with the amount of rain and the consequent rise and fall of the subsoil water. He considers that the cause of the disease is probably the *monas pulmonale* of Klebs, which Leyden and Günther obtained by puncturing the living lung. These are egg-shaped and generally occur in pairs, but also in chains of three or four. Similar, but larger, forms are found in the pleuro-pneumonia of horses. He states that the time of incubation appears to be about twenty days. He places pneumonia in that class of infectious diseases one attack of which predisposes to a second. In infected places, strangers are more liable to be affected than natives. Drunkards are peculiarly liable. Exposure to cold is a favouring, not an exciting, cause. The reviewer remarks of these two sets of independent observations, "It is noteworthy how similarly these bacteria have been depicted by both observers—egg-shaped bodies occurring singly or in short chains."

Lately, Dr. Klein and Dr. Sternberg, of the U.S. Army, have been led, by separate courses of research, to consider that such of the micrococci of croupous pneumonia "as are really infective in the sputa are accidental." Dr. Klein "implies that they have access to the sputa during expectoration."<sup>21</sup>

I should be glad to learn whether pneumonia has occurred epidemically in Lower Bengal in the past ten years. I am inclined to attribute the rarity of pneumonia and pleurisy in Lower Bengal in a measure to the freedom of the inhabitants from tuberculosis and strumous cachexia, to which a very large proportion of these cases are due in Europe.

For *Passive Congestion* and *Œdema*, see *Pneumonia*.

I only know of one unexceptional case of *Idiopathic* (pneumonic) *Abscess of the Lung* occurring in India. I shall have to recur to it in the section on Diseases of the Liver, as it was, with good reason, supposed to be a case of hepatic abscess.

*Gangrene* of the lung has been frequently noticed in the pneumonia of cachectic ill-fed native patients.

*Pulmonary Emphysema*, which, in its highest development, is especially a disease of muscular European labouring men, subject to winter cough, poorly fed, lodged, and clothed, addicted to intemperance and overworked, is not essentially an Indian disease; but traces of pulmonary emphysema are observed, particularly in cases of obstructive cardiac disease, in Indian *post-mortem* rooms. Preparations 746 to 748 in our museum are good specimens of pulmonary emphysema in natives. In the second of these, at the lower third of the upper lobe, and on its anterior aspect, is "an irregular opening about three quarters of an inch in diameter and an inch in depth, through which a direct communication was established with the pleural cavity."<sup>22</sup>

I had one noteworthy case of *Atelectasis* in the infant

of an English lady. The pulmonary artery had only two healthy well-formed cusps.

In the Sanitary Commissioner's Reports for the three years ending 1882 solitary examples of this condition appear only in the two later years among the soldiers' children.<sup>23</sup>

*Malformation*.—Dr. Lewtas has recorded<sup>24</sup> a case of *Congenital Hernia of the Lung* in a Hindoo, æt. 30. "When he took a deep inspiration, a soft tumour was seen to develop itself just outside the left nipple."

I treated a few miserable cases of *Phthisis Laryngea* imported from home, but never saw an indigenous case.

(To be continued.)

<sup>23</sup> For other cases of Atelectasis, see *Indian Medical Gazette*, vol. i., No. 9, and vol. v., No. 2.

## APPOINTMENTS FOR THE WEEK.

Friday, December 11 (*this day*).

UNIVERSITY OF LONDON, 5 p.m.—Mr. Victor Horsley's Third Brown Lecture.

CLINICAL SOCIETY, 8.30 p.m.—Sir Andrew Clark, Bart., "On a Case of Desquamative Prostatitis accompanied by the Discharge of Hyaline Tube Casts"; Dr. de Havilland Hall, "Aneurysm of the Ascending and Transverse Portions of the Arch of the Aorta, Pressure on the Trachea and Bronchi, on the Left Recurrent Laryngeal Nerve and (?) the Vagus"; Dr. Barlow and Mr. Riekman Godlee, "On a Case of Perforation of the Vermiform Appendix treated by Operation." Living specimens: Dr. T. D. Savill, "A Case of Myxœdema"; Dr. Stephen Mackenzie, (1) "A Case of Symmetrical Morphœa," (2) "A Leprosy-like Syphilide."

Monday, December 14.

UNIVERSITY OF LONDON, 5 p.m.—Mr. Victor Horsley's Fourth Brown Lecture.

MEDICAL SOCIETY OF LONDON, 8.30 p.m.—Dr. Samuel West, "On the Treatment of Hæmoptysis."

Tuesday, December 15.

PATHOLOGICAL SOCIETY, 8.30 p.m.—Dr. Silcock, "Syphilitic Ulcerative Tracheitis"; Mr. J. Poland, "Internal Anthrax"; Mr. Sutton, "Diseases of the Circulatory System in Animals"; Mr. D'Arcy Power, "Endosteal Sarcoma of the Upper End of Femur"; Dr. Samuel West, "Aneurysm of Mitral Valve"; Mr. G. Stoker, "A Rhinolith"; Mr. Swinford Edwards, "Round Cell Sarcoma of Skin of Thigh"; Dr. Hale White, "Melanotic Sarcoma of Liver"; Mr. Lane, "Multiple Sarcomata"; Mr. E. H. Fenwick, (1) "Tuberculous Ulcers of Bladder" (Card); (2) "Contracted Bladder supervening on Atony" (Card).

Wednesday, December 16.

UNIVERSITY OF LONDON, 5 p.m.—Mr. Victor Horsley's Fifth Brown Lecture.

Thursday, December 17.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 3 p.m.—Meeting of Fellows and Members.

Friday, December 18.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 p.m.—Dr. E. C. Seaton on "The Recommendations of the Royal Commission on the Housing of the Working Classes as they affect the Status of the Medical Officer of Health."

<sup>21</sup> *Lancet*, vol. ii. for 1885, p. 1018, in a review of the recently published Report of the Medical Officer of the Local Government Board.

<sup>22</sup> *Vide* case, by Dr. G. S. Sutherland, of Emphysema in Double Pneumonia, in a middle-aged native, *Indian Medical Gazette* for December, 1877.

# Medical Times and Gazette.

SATURDAY, DECEMBER 12, 1885.

SINCE we last wrote, another medical candidate for Parliament, W. B. Gordon Hogg, M.D. Edin., has been defeated, while Dr. (?) J. F. Fox, who is stated to have once practised medicine and surgery in the United States, though on what qualification we are not told, has been elected, as a follower of Mr. Parnell. Another medical Parnellite has also been elected in the person of Dr. J. E. Kenny, who is a licentiate of the two Edinburgh Royal Colleges and of the Dublin Apothecaries' Hall. So that we may expect that the medical wrongs of Ireland, if it can be imagined that any have been left unexposed by the Irish Members of the Medical Council, will be denounced with sufficient vigour in the new Parliament. We fell into error last week with regard to one of the Parnellite doctors. The Member for Mid Cork is Dr. C. K. D. Tanner, who, besides being a son of the notorious Dr. Tanner, of Cork, is a graduate in Medicine and Surgery of the Queen's University in Ireland, and was lately Demonstrator of Anatomy in Queen's College, Cork. Leaving out Dr. Fox, the new M.P.s with medical qualifications now amount to twelve, and these, we still hope, are destined to be headed in every good word and work by Mr. Erichsen. It is not likely that anything we can say in favour of Mr. Erichsen will influence voters whose minds are already made up, but in every speech that he delivers Mr. Erichsen shows what an admirable University representative he would make. He gave an excellent speech at St. Andrews on Wednesday week, from which we cull one paragraph, because it embodies a view which we have often insisted on. So far as the Universities themselves were concerned, said Mr. Erichsen, he could not think but that they would be strengthened by widening and broadening the base of the institution in the interest and affections of its graduates. They would be enabled to be more useful in improving all their branches of learning by keeping in touch with the body of young men who had gone out into the world, and who were better acquainted with the requirements than those who were now sitting on the benches could possibly presume to be. That is the great plea which, whether writing of the reform of the London University or of that of the College of Surgeons, we have always put in the forefront of our argument, and we are glad to have it backed by an ex-President of the latter body. Mr. Erichsen, we may add, has followed Mr. Hart and Dr. Watney in pledging himself to vote for the total repeal of the Contagious Diseases Acts, but at the same time he would "feel it incumbent on him to urge upon the Legislature the pressing need for the enactment of measures, equally applicable to both sexes, that would strike at vice and check those gross evils, physical as well as moral, that are its direct outcome."

At the Royal Medical and Chirurgical Society, on Tuesday, Mr. Savory related an unusual case of malignant disease, involving both the axillary artery and vein. Very little discussion took place. The surgeons

present seemed to reserve themselves for Mr. Bryant's paper, on which a most instructive debate ensued. Mr. Bryant advocated disarticulation at the knee-joint in preference to amputation through the shaft of the femur. For the former he claimed a broader basis of support, less risk, and more strength in the resulting stump than for the latter, whatever method were adopted. The various modes of operating were reviewed, and preference given to that of Stephen Smith by "lateral hooded flaps." All the speakers agreed as to the admirable stump which resulted in really successful cases. Mr. Holmes thought that the operation ought nevertheless to be sparingly applied on account of certain risks present, due to the fact that, whatever method of operating were adopted, the flap consisted chiefly of skin, that it must be very long, and was very liable to slough. Dr. Hardie, of Manchester, described his own flap, the so-called "oblique circular," and pointed out that, being in one continuous piece, there was less risk of its sloughing. Mr. Bryant has introduced a new feature, that of leaving the semi-lunar cartilages *in situ*, thereby lessening the tendency to retraction of the flaps.

FRIGHTENED, no doubt, by the fact that three more deaths from hydrophobia had been registered in one week, the Commissioner of Police issued on Friday last a Muzzling Order under Section 18 of the Metropolitan Streets Act, accompanied by some very sensible advice to dog-owners; and all that remains now is for the police to see that the order is faithfully carried out. We trust that the authorities will vigorously insist on the use of efficient as well as comfortable muzzles, samples of which are on show at the police stations, so that no dog-fancier can plead ignorance as to the proper muzzle to employ. Of course there have been protests against the Order. No sanitary measure was ever issued and enforced without evoking the resistance of selfishness and folly. But the question as to the necessity and efficiency of universal muzzling in the presence of an outbreak of rabies has been thoroughly threshed out by the experts and decided in the affirmative. Anyone who wishes to make acquaintance with the arguments on both sides will find them fully stated in Mr. Fleming's "Rabies and Hydrophobia." One of the protestors founds his argument on the fact, which no one denies, that many cases of biting which have terminated fatally have occurred indoors. To this we may reply—(1) That an equal number of cases have occurred in the streets, and (2) That the object of the Order is to prevent the spread of rabies quite as much as the communication of hydrophobia, and that, as there are probably a hundred people who keep a single dog for every person who keeps more than one, it is evident that rabies is almost invariably communicated out-of-doors. If we can only prevent the dogs at present rabid or about to become rabid from biting other dogs, we shall soon put a stop to the deaths from hydrophobia. Against indoor danger we must trust to sounder knowledge and greater vigilance on the part of private dog-owners.

THE deaths in London last week numbered 1,544, being 66 less than the week before and 208 below the

average for the week during the last ten years. The death-rate accordingly fell to 19·7. The falling off in the deaths was most marked in those between the ages of 40 and 80, the deaths of those under 20 being, no doubt, kept up by the slightly increased number referred to the zymotic disease group. In the latter, measles resulted fatally in 69 instances, and whooping-cough in 58, whilst diphtheria and enteric fever caused 16 deaths each, and scarlet fever, which usually proves decidedly more fatal than measles, only claimed 12 victims. There was one death from small-pox, but

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past twelve weeks.

not one from hydrophobia. The weather was favourable to those affected with chest complaints, as there was a decided fall under the head of diseases of the respiratory system and an even greater reduction in the deaths from phthisis. The chief provincial towns, on the whole, show the same tendency to a low rate of mortality that is found in London, but Bolton had a general death-rate of 31·3, and Liverpool a zymotic death-rate of 5·1, due almost entirely to the large number of deaths (24) from measles. Glasgow and Dublin were both again without a fatal case of this complaint.

THE remarkable immunity of Gibraltar during the recent cholera epidemic in Spain has been the subject of two interesting letters to the *Times*, and is a matter of such importance as to be worthy of a passing notice. In all, there have only been 33 cases of cholera and 24 deaths; this result contrasts so strikingly with what took place during the last epidemic in 1865 that even the most prejudiced person could not but admit that the sanitary and other measures which were adopted in consequence of the fatal results of that outbreak have been the cause of saving the town from a similar occurrence.

But it is probable that, notwithstanding the improved sanitary condition of the town, the cholera would have been enabled to obtain a footing, had it not been for the energetic measures at once adopted by Sir John Adye, the Governor, and the police authorities. Directly the possibility of an invasion of cholera became known, the supply of drinking-water from Spain was stopped, and the condensing machines erected by the foresight of a previous Governor were ordered into active use, and arrangements were made for supplying the public with six gallons of distilled water for a penny, 52,000 gallons per week being produced. The strictest watch was kept over the fruit and fish markets; in the barracks, the closets, and in the town the smallest sewers were flushed twice a day; the dustbins too were emptied twice daily, and disinfectants were thrown down every manhole, gully, and sewer at intervals. The quarantine and stagnation of commerce of course caused a good deal of distress amongst the poorer classes, to meet which a fund was raised and supplemented by a contribution from the Mansion House Fund; a camp was extemporised on a portion of unused land belonging to the War Department, where cooking could be carried on on a large scale, and in a short time the wants of some 4,000 people were thus provided for, with the additional advantage of rendering them personally less predisposed to cholera, and of affording an opportunity for their homes to be thoroughly disinfected whilst they remained in camp; for in all the houses where a case of cholera occurred, regardless of the possibility of a charge on the ground of the illegality of the proceeding, the inhabitants of the house were turned into camp whilst the premises underwent a thorough cleansing. One family of Jews refused to turn out, and, as the police had no warrant, they could not compel them to go in the ordinary way, but the gentle persuasion of a process of fumigation soon effected the removal of the obstructives. Although Gibraltar has thus shown itself fully able to grapple with so dangerous a foe, it would appear that the sanitary authorities are not thus keenly on the alert at all times, for the average death-rate is decidedly high, and diphtheria and typhoid fever are of far more frequent occurrence than they should be in a well-managed community.

THE fourth and fifth ordinary meetings of the Liverpool Medical Institution have been chiefly occupied by a discussion on Syphilis. Dr. Barron read a paper on the pathology of the disease, describing in an able manner the symptoms and the microscopical appearances met with both in the early and the remote stages. From the structure of syphilitic growths he classed the disease with tubercle, leprosy, and glanders, syphilitic deposit being in some cases only known from tubercular deposit by its increased vascularity and slighter tendency to caseation. This similarity of deposit naturally led to the search for the syphilitic bacillus which was discovered some four years ago by Aufrecht, afterwards described by Klebs, and shown by Lüstgarten to be similar to those of tubercle and leprosy. Dr. Barron showed under the microscope a section of an indurated papule where the cells of the part con-

tained many micrococci, and where the lymph spaces were filled with a hyaline coagulum which contained numerous organisms of the same kind as the cells. Although much yet remained for elucidation, Dr. Barron believed syphilis to be a germ disease similar to tubercle and the eruptive fevers. The tertiary stage, occurring as it sometimes does many years after the secondary stage, he explained by ascribing its onset to an injury that determined further action on the part of "resting" spores that had formed when the supply of pabulum died out at the end of the secondary stage. Dr. Oxley's paper was largely devoted to the consideration of social questions in connection with syphilis. He thought the subjects of syphilis should be treated as openly and carefully as those who suffer from pneumonia or any of the eruptive fevers are treated. The disease in all its stages should be treated by one class of surgeons or physicians, and not by several as at present, when it is considered scarcely respectable to treat the primary lesion, and the subjects of this phase of the disease are shut up in scarce and badly supported hospitals. The advanced lesions are, on the other hand, generally treated by grave and most respectable physicians and surgeons, and the subjects of these tertiary lesions are allowed to herd with their fellows. Dr. Oxley also strongly expressed his belief in the analogy syphilis presents to an eruptive fever, and advocated the advisability of classifying it as an exanthem. Dr. J. Wilson devoted his attention to lauding the value of the inunction of blue ointment in the disease. He is a strong advocate of the course of treatment adopted at Aix-la-Chapelle, where the disease is treated systematically by professional rubbers; the diet, baths, and whole course of life being regulated with an amount of success rarely attained in this country.

MR. R. H. LOWNDES opened the discussion at the adjourned debate. In ten and a half years at the Lock Hospital he had only seen one death, and that was from purpura hæmorrhagica. Syphilis differed from the exanthemata in the one being contagious and the others infectious. The enormous duration of the period of incubation in syphilis contrasted strongly with the shorter periods of incubation in the exanthemata. The induration of the inguinal glands also confirmed him in the belief that syphilis should not be classed with the exanthemata; mercury and time were the chief agents in curing the disease. Dr. Bernard said the initial lesion was not always a papule; sometimes it was merely an erosion. Mercury was fairly successful in his practice, but he thought its administration should be occasionally relaxed for a time, to be resumed again with greater effect. Inunction was too dirty and too tedious a process to be used, except by the well-to-do or in hospitals. It should never be left to the patient. The advantages of Aix arose as much from the change of scene, rest, and diet as from the more specific treatment. Mr. Rushton Parker thought mercury the antidote to syphilis; when its failed, iodide of potassium should be tried. Grey powder was very useful in syphilitic disease of the nostrils, and he described its effect on a case of syphilis which had been allowed to run a natural

course under homœopathic treatment. Dr. Waters referred to syphilis in the medical wards and as met with by the physician. Mercury was *the* remedy, and in the adult was most conveniently given internally. Inunction could, however, be adopted in the case of children. As to Aix, he rarely sent patients abroad. He believed they could be treated quite safely at home. At Aix the success met with depended as much on the mode of life, regimen, rest, and pure air as on anything else. Dr. Hope called attention to the inadequate accommodation in Liverpool for venereal cases. Dr. Alexander mentioned an exception to the statement of Dr. Barron that it was rare for syphilis to directly affect children *in utero*. A child was born a few days ago in the wards of the Liverpool Workhouse and died a few minutes after birth. A well-defined scaly rash was found on each loin and a gumma in the lung. Whilst admitting that, generally speaking, mercury and iodide of potassium were the remedies for syphilis, he thought with Dr. Bernard that both remedies should be sometimes relaxed if the patient became depressed and cachectic, and the disease ceased to respond to them. Compound decoction of sarsaparilla and good diet with alkaline baths were the means then to be adopted. He strongly recommended alkaline baths in syphilitic skin eruptions. Dr. William Carter also spoke highly of the value of the decoction of sarsaparilla in the cachexia of syphilis. In syphilitic brain tumours 20 to 30 grain doses of iodide of potassium were most effectual. He agreed with Mr. Lowndes that syphilis did not closely resemble the exanthemata. Mr. Edgar Browne said we must not forget the natural history of the disease. Some cases were slight, and the symptoms soon disappeared under any treatment, and these cases would seem to impart virtue to any remedy. In many of these, however, the disease reappeared long after, to the consternation of the patient. Mercury was *the* remedy for syphilis. The waters of Aix were, however, useful because the simultaneous ingestion of sulphides by the system produced a greater tolerance of mercury. The Aix treatment could be carried out at Harrogate, and by giving sulphide of calcium, potassium, or sodium with the mercury it could also be carried out nearly as well at home. Dr. Archer and Mr. Steele both criticised unfavourably the inunction method of treatment. Drs. Barron and Wilson briefly replied, and the discussion terminated after having attracted good audiences on both nights.

MATTERS have at last reached a turning point in the Aberdeen Royal Infirmary scandal, and we may fairly hope that the controversy is now at an end. Not convinced by the numerous unfavourable reports that they had received on the state of the Infirmary, the authorities resolved to invite Dr. J. B. Russell, of Glasgow, and Dr. W. J. Simpson, of Aberdeen, to make a thorough enquiry into the state of the present building, and also to report upon some plans that had been submitted for improving the buildings on the existing site. The report of these gentlemen is now before us, and, as regards the first point of their investigation, viz., the present state of the Infirmary, they say that "in every particular we find it opposed to the now universally accepted principles of hospital

construction, and in several violates the primary conditions of health which are necessary in ordinary house construction, and which are sought to be enforced under the Public Health Act in the dwellings of the people." Stronger condemnation than this it would be difficult to find, and we need not further allude to this section of the report. The plans for altering the existing buildings which were submitted for their approval do not come up to the standard that should be required for a hospital, though they admit that probably more could not be done on the site than these plans foreshadow. It results, therefore, that the reporters strongly urge that a fresh site should be selected and a new hospital built on the pavilion system, instead of making any attempt to patch up the present institution. If the managers wish to retain that share of public confidence which it is most desirable they should possess, they will lose no time in taking steps to give effect to this report.

THE intelligence that Dr. Collie has been reinstated in the office which he held so long, and in which, as his contributions to scientific journals show, he did such excellent work, will have been received with pleasure by his fellow-practitioners, and all must hope that the reinstatement will be ratified by the Local Government Board. The managers of the Asylums Board acted with both justice and wisdom in restoring him to office, though justice and wisdom only prevailed by one vote in a division list of 45. As to the justice of the decision, we have already spoken by anticipation, and so long as justice does prevail it matters not greatly, perhaps, whether it prevails by one vote or twenty. At any rate, Dr. Collie, in having behind him the sympathy of the whole profession and the formal support of its organisations, has little reason to repine at the narrowness of his victory. That the decision of the managers is a wise one, everybody who knows Dr. Collie and his work will agree. He has won for himself the position of a leading authority on the class of cases which he has been and is again to be called upon to treat, and it would have been the height of folly in the managers to have replaced such a man by untrained and untried officers. To the public and to the profession alike the disuse of Dr. Collie's tried faculty of practical treatment and scientific observation would have been a most serious loss. We say nothing of the ill effect which an unjust and unwise decision in this particular case would have had on the loyalty and contentment of hundreds of medical officers in the employment of the State. Our gratification at the result so far as it affects an able and honoured member of the profession is sufficient for the day.

DR. BRIEGER, of Berlin, who has for some years been engaged in the investigation of ptomaines, has just given to the world, in a pamphlet of 83 pages, the results of his latest researches. These have been directed to the determination of the ptomaines which make their appearance in the human body after death, in order that he might the better distinguish such as are the product of pathogenic bacteria. He has added

to those already known, viz., neuridin and cholin, no fewer than five hitherto undescribed. His observations show that in each successive stage of the decomposition of the body new basic bodies are formed, that some ptomaines disappear, others taking their place, while some found at first very sparingly become more abundant as putrefaction proceeds. So soon as life is extinct, lecithin begins to break up into its proximate constituents, and by the third day neuridin appears, always accompanied by some cholin, but neither of these have any great toxic power; only after they have disappeared do the highly poisonous bases come into existence. The later ptomaines which Dr. Brieger has identified he calls cadaverin, saprin, putrescin, trimethylamin, and mydalcin, which, however, are far from exhausting the whole series of cadaveric ptomaines. Dr. Brieger believes that pathogenic bacteria like those of simple putrefaction generate ptomaines out of the organic fluids in which they multiply. He conducted observations on the typhus (enteric) bacillus of Koch and Eberth, and was repeatedly able to isolate a ptomaine which was extremely fatal to guinea-pigs; and, turning to septicæmic poisoning, he was in like manner able to connect the origination of the toxic substances in the pus of a psoas abscess in a girl of 19 years, which ended fatally, with an organism described by Rosenbach as the *Staphylococcus pyogenes aureus*, the poison in this case being a hydrochlorate of a ptomaine. Dr. Brieger's are the first researches of the kind conducted on strict scientific methods, and it is to be hoped that he will, before long, indicate some practical application of his results in the field of forensic medicine no less than of pathology.

WE are glad to see that it is proposed to commemorate the work, ability, and character of the late Miss Prideaux by the foundation of a scholarship or prize. Lady Stanley of Alderley has placed herself at the head of the movement, and in her appeal dwells on Miss Prideaux's great distinction as a student, and on her elevation of character, good judgment, and personal grace. We hope that Miss Prideaux will not be the last, as she has not been the first, medical woman to evince these qualities. But it is right that everything should be done to hold them up as an ideal to her successors, so that, in competing for any prize which shall bear her name, they may be reminded that it is not by talent alone, though of that Miss Prideaux had enough and to spare, that the medical woman can best overcome the difficulties of her peculiar position.

THE appeal which Dr. Stretch Dowse has been obliged to make to the law courts—unsuccessfully at present, on account of his neglect of certain technicalities—in order to prevent a certain firm from making an unwarrantable use of a testimonial he had given in favour of a preparation of Messrs. Battle, should serve as a warning, not only to himself, but to all other practitioners. It may be admitted in Dr. Dowse's favour that he has been at considerable pains to prevent Messrs. Battle from advertising his name and with it their own merchandise, but it is obvious that he would have saved himself the trouble

if he had followed the wise unwritten rule, which should be considered binding on all practitioners, not to lend one's name to the dealers in proprietary medicines. This law is far too often broken nowadays, especially in America, and it is high time that it should be enforced and its disregard reprobated with all the authority of the profession.

It may be well to remind Fellows and Members of the Royal College of Surgeons that a *conversazione* will be held in the theatre of the institution on Thursday afternoon, at which the Council will present a statement containing the reasons which have led them to refuse to extend to the Members the privilege of voting in elections to the Council. It is expected that the reading of the statement will be followed by an animated, if not altogether amicable, debate. For our part, we trust it will be both.

---

### CONSERVATISM AT THE LONDON UNIVERSITY.

THE Conservative forces in Convocation of the London University have conquered, and, unless the Senate itself should initiate some measure of reform, the University will remain, as it is and always has been, a cosmopolitan examining body, leaving a free field for Sir George Young's Association to start a real Teaching University. It is true that Convocation at its meeting on Tuesday last appointed a new special Committee to consider the question of re-constituting the University, but the general feeling is that the subject has passed into farce-land, and any new scheme that amateur constitution-makers may devise will be politely received by Convocation and as politely set on one side. Mr. Magnus's Committee will only waste its time. The wisest and most influential members of Convocation have come to the conclusion that reform is at present either hopeless or needless, and the two attitudes will combine to give the Conservatives an overwhelming majority whenever Convocation is called upon to take a serious decision. Dr. Weymouth, in his contention that the time is not yet ripe for action, expressed, we believe, the present feeling of a large majority of the graduates, who, having rejected Lord Justice Fry's scheme, are not very likely to accept one elaborated by Mr. Magnus and his Committee. A mere glance at the names of the representatives of the medical faculty on this Committee is sufficient to sap all confidence in the result of their deliberations. The medical representatives are these: Dr. M. P. M. Collier, Dr. W. J. Collins, Mr. Victor Horsley, Mr. Edmund Owen, and Dr. Pye-Smith. The majority of them are hardly out of their studentship, and there ought not to be a single grey hair amongst the whole five. We have the greatest possible sympathy for youth, with its courage, its hopefulness, and its blindness to difficulty. We have no doubt that Dr. Collins and his colleagues could draw up a beautiful scheme of reform. But that is not the difficulty. Anyone can devise a scheme; the point is to get it accepted, and it is at that stage, we think, that the young and eager graduates who have taken the

destinies of the University under their arms will realise the influencelessness of undegenerating tissues.

As was pointed out by a drily humorous speaker on Tuesday, the London University could convert itself into a Teaching University to-morrow if it really wished. It could institute courses of lectures on those higher subjects now almost entirely neglected in the organized teaching of the metropolis. Half-a-guinea a year subscribed by every graduate of the University would suffice to set on foot a series of lectures such as could be heard nowhere else. But it is pretty clear that such a scheme would not satisfy those who are most anxious to reform the University. What the reformers want is not a teaching, but a teachers' university. They want to control the examinations, partly, no doubt, with the view of improving their teaching, but partly also, we fear, with a view to protecting certain teaching institutions in which they are interested against the competition of less fortunate bodies and the army of private teachers. Thus, between those members of Convocation who wish the teachers to control the University, and those who wish to leave that control in the hands of the graduates, it does not seem very likely that any working alliance can be formed. There will no doubt be much talk, but we shall be very much surprised if anything comes of it. The more distinguished of the medical graduates, no doubt, feel this, or they would have accepted a place on Mr. Magnus's committee, and they are turning their eyes to the Teaching University Association, in the hope that there they may find a body which shall be able to organise the medical teaching of the metropolis and found an accessible degree for their students. The action of Mr. Magnus and his party has given a fresh momentum to that body, and rendered it for the first time possible for a new university to be founded in London which may eventually prove a serious rival to the old one. Lord Justice Fry and his late colleagues are amply avenged.

---

### A NEW DEPARTURE IN WATER ANALYSIS.

THE growing belief that all communicable diseases are directly or indirectly connected with the vital actions of bacteria, and the facilities for the observation of the latter afforded by the method of pure culture on gelatin films, suggested to Dr. Robert Koch and others some five or six years ago the idea of estimating the potability of waters by the number of living organisms in a given volume, and this method has been systematically employed for several years in connection with the sewage irrigation works of Berlin, and the effects of the effluent on the rivers and on the water supply of that city. Dr. Angus Smith, after having familiarised himself with Koch's procedure, commenced a line of investigation somewhat different, viz., to endeavour to discover some relation between the activity of bacterial life and the oxygenation of the water; his labours were unfortunately cut short by death, but Dr. Dupré was, at the time, engaged in like researches, though following a method differing in some respects from that

of Dr. Smith; and in the last report of the Medical Officer to the Local Government Board he has given the first published account of his experiments. The bacterioscopic examination of water has, as we have said, been employed for some years in Germany, but it is only within the last few months that its value has been recognised in this country. Dr. Percy Frankland began by reading a paper on the subject before the Royal Society on the influence of filtration and of Clark's process on the number of bacteria in water, and in it he expressed his intention of undertaking such an examination of the waters of the several metropolitan companies. This promise has now been fulfilled, and there appeared a report thereon, signed by Sir F. Bolton and Dr. P. Frankland, in the daily papers last week.

The unsatisfactory character of all purely chemical examinations has long been tacitly admitted. Frankland's combustion process was an attempt to apply the ordinary method of "ultimate organic analysis" to the residue, and to estimate the amount of carbon and of hydrogen contained in the organic matter, and from their relative proportions to infer the nature of the pollution. Wanklyn, by his ammonia process, sought to estimate the organic matter by converting it into ammonia after having eliminated the ammonia already present as such, believing, as he did, that, if not the whole, a constant proportion of the organic matter was thus converted. The significance of the nitrates and nitrites as products of the oxidation of ammonia, and of the presence of chlorides, phosphates, and sulphates, have always been recognised by chemists, though some have attached more importance to each of these constituents than others. More recently attention has been directed to the aëration of the water or the quantity of free oxygen in it, and conversely to the quantity of oxygen consumed in the oxidation of the organic matter present, as estimated by a modification of Schutzenberger's permanganate of potash method. All chemical processes, however, deal with dead matter only, or rather they fail to draw any distinction between the living and the dead, and, judged by these standards, the water in which vegetables have been boiled, or a cup of meat broth or coffee, would rank far worse than water containing a small quantity of enteric or of choleraic stools, or even than the anthrax-bearing waste from a mohair factory. Herein lies one great advantage of bacterioscopy, which enables us to learn the actual number of *living* bacteria in a cubic centimeter. Koch has long ago shown the relation between this and the purity of waters, as well as the effect of filtration, when he announced that the numbers were for Berlin sewage 38,000,000, the water of the Spree 118,000, the effluent from the sewage farms 87,000, the Rummelsberger See 32,000, the Stralau waterworks, before filtration, 125,000, and after, 120! In the best well waters 30 to 60, and in boiled distilled water 4 to 6, probably from the air. Whence it appeared that any number under 100 indicated an irreproachable water, under 200 a potable one, while polluted rivers count their thousands and sewage its millions. Judged by this standard, our London waters leave nothing to complain of, and, whatever may be urged against the Thames as

a source, the process of filtration seems to be most efficiently performed. Thus the New River and the West Middlesex water contains but two germs in a cubic centimetre, though Dr. P. Frankland found 1,600 in the Thames at Hampton in October, and Mr. Bischof, at the end of November, estimated the number at Sunbury, near the intake of the Companies, at 8,000. At London Bridge he found 45,000, and in the Lea at Tottenham Bridge, where the stream is, as we have often said, little less than diluted sewage, no fewer than 4,200,000. At the intake of the East London Waterworks, however, there were not more than a third of the number found in the Rummelsberger Lake, whence Berlin gets its supply. Even the Kent Company's wells contained 18.

But, though this method serves to distinguish between living and dead matter, it fails to do so between innocent and pathogenic organisms. We know, however, that some, at least, of these can be identified by their mode of growth in tubes of nutrient gelatin, by their behaviour with colouring reagents, and otherwise, even when in themselves morphologically alike and indistinguishable under the microscope. But Dr. Dupré suggests an easier and speedier plan in the fact that some can and others cannot survive exposure to certain degrees of heat, and that, while dead matter rapidly absorbs oxygen from permanganate of potash, it does so to a very slight extent, if at all, from the water itself, at least within a limited space of time. We cannot here enter into a description of his apparatus or procedure, but must content ourselves with a statement of his aims and conclusions, referring our readers for details to the paper in the appendix to the Report. The points to which he is directing his attention are that—“(1) The amount of oxygen taken up from the aërated water may be contrasted with that taken from permanganate. (2) The amount of oxygen taken from the aërated water in its natural condition may be contrasted with that taken up after any living organisms present in it have been killed by the application of heat. (3) A degree of heat may be applied sufficient to kill developed organisms or certain germs and spores, but insufficient to kill other kinds of germs and spores; and, if this degree of heat be known for the several kinds of germs and spores, a judgment may be formed as to the nature of the germs and spores present. (4) Some substances, sterile in themselves, but capable of nourishing any living organisms contained in the water, may be added, and the increase in the amount of oxygen absorbed may be noted.”

The practical results to which he has come at present may be thus summed up—“(1) A water which does not diminish in its degree of aëration, or, in other words, which does not consume any oxygen from the dissolved air, may or may not contain organic matter, but presumably does not contain growing organisms. Such organic matter, therefore, as, on analysis, it may be found to contain need not be considered as 'dangerous organic impurity.' (2) A water which, by itself or after the addition of gelatin or other appropriate cultivating matter, consumes oxygen from the dissolved air at lower temperatures, but does not consume any after heating to 60° C. for three hours, may be regarded

as having contained living organisms, but not of a kind able to survive exposure to that temperature. (3) A water which, by itself or after the addition of gelatin or the like, continues to consume oxygen from its contained air after the water has been heated to 60° C. is to be regarded as containing spores or germs of organisms that can survive that temperature." Whether the power of resisting a given temperature affords any clue to the innocence or malignity of an organism is a question for future investigation by biologists, and must be decided by separate observations on each known species. Dr. Dupré found more bacteria in the Trafalgar Square well than in the Chelsea Company's filtered water, but the former were all killed by a temperature that only partially destroyed those in the latter; a fact which is at least suggestive.

## ESSAYS ON MEDICAL CLASSICS.

### XIV.—SIR GEORGE BAKER AND THE DEVONSHIRE COLIC.

In the history of medical progress during the last two or three centuries there is in all probability scarcely any instance of a scientific induction more remarkable for the brilliancy of its conception, or more valuable for the practical benefits which it conferred on the public health, than that suggested by the heading prefixed to our present article. One eminent authority, indeed, goes even so far as to place the observations of this great President of the Royal College of Physicians on the lead colic of this country and of the Continent second only to Harvey's discovery of the circulation of the blood. Yet the symptoms of lead colic, with its attendant neuroses, had been described with minute precision, long before Baker's day, both by Citois, of Poitou, and by Dr. Huxham, of Plymouth. The toxic influence of lead, as the primary cause of the Devonshire disease, was, however, altogether unsuspected, and the presence of lead in the wine or cider was in consequence entirely overlooked. For more than a century and a half the symptoms of plumbism had been recognised and clinically pictured by many observers under the various local names of Colic of Poitou, *Colica Pictonum*, *dolor colicus apud Pictones*, and Devonshire Colic. These terms were, in general, applied to certain more or less circumscribed outbreaks of an obscure intestinal disorder, which was accompanied by certain definite nervous symptoms, either paralytic or epileptiform. It is obvious, however, from the accurate records handed down to us from the older writers, that the disease was in all these instances some form of accidental lead-poisoning, and Huxham appears to have been the first to entertain some slight suspicion that a common cause was at work in the various outbreaks in Devon and on the Continent, although he failed to detect what its exact nature really was. In these endemics, as Baker afterwards proved, the poison had found an entrance into the system through the medium of the leaden presses and vats which were used in their respective localities for the manufacturing either the cider or the wine.

As the mineral poison was unrecognised, the beverages which contained it gained for themselves a widespread and evil notoriety; and previous to Baker's investigations the term *Colica Pictonum*, which had at first a purely local and provincial significance, as indicating the disease originally described by Citois in

Poitou, came to be generally applied to the whole group of symptoms which we now recognise as plumbism or lead-poisoning. *Colica Pictonum* in its primary sense literally signified the colic of the Pictones or Pictair, the ancient inhabitants of that part of Gaul known subsequently as Poitou. In the present day the term is not unfrequently used in a looser sense, as if it indicated the lead colic of house-painters. It so happens that the wine colic of Poitou (*Colica Pictonum of Citois*) was really lead colic, as we shall have occasion to show in referring to the accurate and unconscious description of it given by Citois, but this was not known until Baker drew attention to the fact in 1767 in his celebrated essay on the endemical colic of Devonshire. Etymologically, therefore, the *Colica Pictonum* has nothing whatever to do with the lead colic of painters (*pictores*), but, pathologically, they were, by a common coincidence, proved by Sir George Baker to be the same condition, induced by accidental poisoning by lead. Baker's great merit lay in the circumstance that he saw that the diseases in Poitou and in Devon were precisely identical, and that the symptoms in both cases were those of plumbism. To the mode in which he worked out the subject further attention will be drawn when we have occasion to speak later more in detail of his investigations.

François Citois, who in later editions of his works is described as physician to the King and to Cardinal Richelieu, and *decanus* of the medical faculty of Poitiers, first published his account of the wine colic of that district in 1616, under the title of *dolor colicus biliosus apud Pictones*. The malady spread far and wide throughout the province, and was marked at its onset by violent abdominal pains. These were followed by loss of motion in the wrists and hands, in the tibiæ and feet, but sensation at the same time remained unimpaired. The paralysis was in many cases accompanied by epileptiform convulsions, but Citois appears to have entertained no suspicion that the disease might be in any way connected with lead poisoning.

At the beginning of the next century the production of cider in Devonshire had enormously increased, and a similar disease broke out there. It infected the country nearly every autumn and was observed to be most prevalent in good apple seasons, when large quantities of cider were made and drunk. Hence the colic came to be popularly ascribed to the use of this beverage in a crude and unfermented condition, and Dr. Husgrave, of Exeter, who incidentally refers to the outbreaks in his work on Rheumatism in 1703, merely adopts this popular explanation, and gives no further details concerning the nature or symptoms of the malady.

In later years the epidemics increased greatly in virulence, and in 1738 Dr. Huxham, of Plymouth, to whose writings reference has been recently made in our columns, published a graphic account of the complaint in his *opusculum de morbo colico Damnoniorum*. As a native of Devon, and a practitioner at Plymouth, he had paid great attention to the therapeutics of cider-drinking, and ascribed the disappearance of many of the scorbutic affections formerly prevalent along the coast-line of Devon and Cornwall to the largely increased use of this beverage. He highly extols its beneficial influence in sea scurvy. At Plymouth he saw many severe cases entirely recover by the use of apples and cider alone, and further states that many captains of ships carried cider with them even on voyages to the East Indies. In these observations Huxham showed himself to be far in advance of his age. The ravages of scurvy in the British Fleet during the 18th century were only equalled by those of the ship or typhus fever, yet the general distribution of lemon juice as an antiscorbutic did not take

place in our Royal Navy, as the result of the writings of the elder Lind, until 1796.

Huxham was entirely unaware of the accidental presence of lead in the Devonshire cider, and, in this connection, it is interesting to note, as bearing on the later researches of Dr. Garrod, that he attributed the great prevalence of gout in that county to the increased production and consumption of this drink. His description of the Devonshire colic, particularly founded on the outbreak of 1724, and other seasons, is an admirable instance of accurate clinical observation, and exactly describes the various symptoms which we now recognise to be due to lead poisoning. The affection commenced with violent pains in the stomach, with vomiting and extreme constipation. Later the abdominal symptoms might abate, but severe neuralgic pains were experienced in the spine and in the bones and joints of the upper and lower limbs; loss of use of the hands, often accompanied with epileptic convulsions, then supervened, the "power of feeling" only remaining, but palsy of the legs was almost unknown. These latter various symptoms Huxham grouped together as rheumatic, and in some cases they might either come on before the colic itself, or alternate with it. In children the disease was less common—a fact which Huxham attributes to the greater looseness of their bowels. He perceived that the symptoms he had described were those of the *Colica Pictonum*; but in both instances he attributed the outbreak to the excessive acidity of the unfermented fruit juices in certain seasons.

That the course of a disease, so well recognised, should have escaped discovery until Baker threw light on the subject, may well excite our surprise, but explanations of this apparent shortsightedness are not far to seek. All the writings of the older physicians prove them to have been excellent clinical observers of the outward manifestations of disease, but the names of the great masters of the medical art still overshadowed them: all symptoms, pathology, and treatment were referred to their *dicta*, and made to square with their incontrovertible doctrines. The classic literature of the Renaissance had doubtless much to do with this servile deference to ancient authority. The fashion of writing scientific treatises in Latin still held its sway, and a scholarly style came to be far more highly esteemed than either a correct inference or a well-considered experiment. Sense was sacrificed to sound, and truth often to the rounding of a sentence or the construction of an epigram in a dead language. Much of the obscurity of even Sydenham himself may be traced to this tendency, and he is held by many learned commentators to be in some passages almost untranslatable.

Again, the theory of the epidemic constitution was still dominant in pathology, and all epidemics were referred to some unknown atmospheric or telluric influences. A minute and undue attention was, in consequence, directed to endemic or purely accidental conditions. Racial idiosyncrasies, peculiarities in the diet or habits of a neighbourhood, even the prevalent direction of the wind or the amount of moisture in a particular locality, were deemed sufficient to explain what could not be comprised under any more plausible hypothesis. Diseases were tabulated rather on their geographical or local distribution than on their common pathological affinities, and a copious terminology of medical synonyms came into vogue. This system of local nomenclature, which is often at the present day so extremely perplexing, caused the otherwise accurate clinical descriptions of many of the older observers to be of comparatively little practical value at the time they were written.

Although much of Huxham's work was still coloured by the prevailing theories of his time, he may be said

to have been almost the first of the great medical writers of the 18th century who attempted to free himself from the intellectual trammels of the previous age. He wrote in a simple and flowing style, and his observations in consequence proved to be of far more lasting value than those of many of his more scholastic predecessors. Indeed, Sir George Baker, in his own investigations, appears to have been greatly indebted to the accurate record of the symptoms of the *Colica Damnoniensis* which had been written by his eminent countryman some thirty years before. Baker was himself a native of Devon, and was born in a part of the country which had been long celebrated for its apples and cider. His attention was in consequence strongly drawn to the colic, which was still very prevalent there even up to his day, and in his *Essay on the Endemical Colic of Devonshire*, read before the College of Physicians in 1767, he gives statistics of the cases which had been admitted into the Exeter Hospital for five years previously. The majority of these cases were, on admission, only suffering from palsy of the hands, many of them being subsequently transferred to Bath for the benefit of the waters, which at that time enjoyed a high repute in the treatment of the malady, and Baker was struck by the fact that the cases in the Bath Hospital from Devonshire were eight times as numerous as those from the other cider counties, Hereford, Gloucester, and Worcester.

A complaint, very similar to the Devonshire colic, had been frequently epidemic, at the end of the seventeenth century, in Germany, in the Rhine and Moselle countries, and this was then generally recognised to be due to the adulteration of the acid wines with litharge, which was added to prevent their acetous fermentation, and stringent laws were in consequence enforced to suppress this practice. Sir George Baker, after carefully comparing these outbreaks with those of Devonshire, inferred that the disease was, in all cases, due to the same cause, and concluded that the Devonshire colic did not depend on the pure cider, but more probably on some accidental contamination of it. He perceived, also, that the symptoms of the *morbus colicus Damnoniorum*, which had been so accurately described by Huxham, were the same as those produced by preparations of lead; and he proceeded to compare the method of cider manufacture in Devon with that of other cider countries, where the Devonshire colic was almost unknown. He found that, in Devon, the trough in which the apples were ground was composed of pieces of moor-stone, and their interstices were usually filled up with large quantities of melted lead. Consequently, the apples, during the process of crushing, came in contact with a considerable surface of the metal. The cider presses, also, were commonly lined with lead to prevent leakage, and the juice was conveyed from the presses in leaden pipes. Lead was thus not only largely used in the apparatus for cider-making, but it was also a common practice for farmers to put a leaden weight in the casks to arrest too rapid a fermentation, and to prevent the cider from becoming sour. In other cases the cider was sometimes racked off into leaden cisterns, with the same object, but the deleterious effects of the metallic poison taken up by the cider as a result of these methods appear to have been quite unsuspected. Baker continued his enquiries into the process of manufacture in other counties, as in Hereford, Gloucester, and Worcester, where no bad effects were attributed to cider, and found that there no lead was used in any part of the apparatus for grinding or pressing the apples, or during fermentation. To put the matter entirely at rest, he, in 1766, while near Exeter, tested the apple juice as it flowed from a cider press lined with lead, and satisfied himself that the must contained an appreciable quantity of the metal. This fact he subsequently confirmed in many

other instances, and even found distinct traces of lead in Devonshire cider from his own cellar. Sir George Baker's "leaden theory" was at first received with much opposition. Its truth, however, became rapidly recognised, and lead has now, for many years, been entirely discarded from the Devonshire cider-making apparatus, and the *Colica Damnoniensis* from this cause has altogether disappeared. Thus, Sir George Baker, to quote the words of Lisson, "by the acuteness of his observation discovered the cause of a most afflicting and fatal disorder; and, by his perseverance in recommending the discontinuance of a long and generally prevailing usage, he was the fortunate means of preserving the health and lives of thousands."

F. W.

## REVIEWS AND NOTICES OF BOOKS.

### BRITISH ETHNOLOGY.<sup>1</sup>

It is not often that we are called upon to notice an important work on one of the outer circle of the natural sciences on which medicine is based, by an author actually engaged in the practice of his profession. The belief is far too prevalent, both inside and outside our ranks, that the practice of medicine is like shoemaking, and that "the cobbler must stick to his last," but, as the prejudice is being slowly, but surely, broken down by the more general culture of all classes, we may hope to see many more works like Dr. Beddoe's *Races of Britain* produced in future. It might be thought, indeed, that anthropology would form the very foundation of medical science, or, at any rate, that it would be the branch of natural science which would be most interesting to medical men, and with which they are most competent to deal, and it is for this reason that we now call attention to the subject.

Dr. Beddoe has been engaged for upwards of thirty years in collecting materials for the differentiation of the racial elements of our population, much of which he has from time to time published in the journals of the English and French Anthropological Societies; and the book before us is the result of the re-arrangement of those papers, together with much new matter. Dr. Beddoe has directed his attention to some of the chief physical characters of our present population, such as colour of hair and eyes, head-form, stature, bulk, &c., by the numerical method which he was the first to employ, and which has been adopted by other British and Continental anthropologists; and he has compared the results of his observations with the records of history as far as they relate to the conquests and immigrations of Roman, Anglo-Saxon, Danish, and Norman stocks. He attaches most importance to complexion, as he believes "that the colour of hair is so nearly permanent in races of men as to be fairly trustworthy evidence in matters of ethnical descent, and that nearly as much may be said for the colour of the eyes," and because complexion is the character most easily observed and recorded. The head-form is not largely available in this country on account of the scarcity of measurements of modern English skulls, and the difficulty of obtaining measurements of living heads. The values of stature and weight as racial distinctions have been treated of by him in a separate essay, and also by the Anthropometric Committee of the British Association, and the statistics are not therefore republished in the present work.

For the purpose of securing uniformity of observation and comparison, Dr. Beddoe has adopted what he calls an "index of nigrescence" based on the colour of the hair. Having classified the hair as red (R), fair (F), brown (B), dark (D), and black (N), "the index is gotten," he says, "by subtracting the number of red- and fair-haired persons

from that of the dark-haired, together with twice the black-haired. I double the black, in order to give its proper value to the greater tendency to melanosity shown thereby, while brown (chestnut) is regarded as neuter, though most persons placed in Class B. are fair-skinned and approach more nearly in aspect to the xanthous than the melanous variety:

$$D + 2N - R - F = \text{Index.}''$$

Dr. Beddoe's classification differs somewhat from that of Virchow, Broca, and other Continental anthropologists, and form that of the Anthropometric Committee, which is primarily arranged on the distribution of pigment in and on the surface of the iris, as the best adapted for getting uniform results from a large number of observers. The personal equation of the observer, and the difficulty attending the use of the names of colour of hair and eyes, does not interfere with the results of Dr. Beddoe's observations, as they were chiefly made by himself. By means of this ingenious formula or index, the author has reduced the apparently homogeneous inhabitants of our islands to certain definite groups, which he shows closely correspond in their distribution with the historic races which conquered and settled the different parts of the country, a record of which conquests he gives at considerable length and with great impartiality. Of the races which occupied the country at the time of the Romans—and, as the latter added little to the ethnical character of the people, at the time of the Anglo-Saxon invasions—Dr. Beddoe remarks:—"The natives of South Britain consisted mainly of several strata, unequally distributed, of Celtic-speaking people, who in race and physical type, however, partook more of the tall blonde stock of Northern Europe than of the thick-set, broad-headed, dark stock which Broca called Celtic . . . . Some of these layers were Gaelic in speech, some Cymric; they were both superposed on a foundation principally composed of the long-headed dark races of the Mediterranean stock, possibly mingled with the fragments of still more ancient races—Mongoliform or Allophylian. This foundation-layer was still very strong and coherent in Ireland and the north of Scotland, where the subsequent deposits were thinner, and in some parts partially or wholly absent . . . . No Germans, recognisable as such by speech as well as person, had as yet entered Britain." Of Dr. Beddoe's analysis of the racial elements of the present population of the British Isles it is impossible to give here an adequate idea, and the student must consult the work itself, where he will also find some illustrations of the physical types existing at the present time in various districts. Among the tables will be found some statistics of the colour of hair and eyes in relation to diseases, notably to phthisis and cancer, which have a direct practical interest for medical men. *The Races of Britain* will, no doubt, long remain the chief authority on the subject of the racial constituents and their distribution in our islands. Year by year the questions which Dr. Beddoe has discussed will become more difficult to answer on account of the movements and mixture of the labouring and peasant classes, who alone possess distinctive racial characters, by the introduction of railways and the fluctuations in trade and labour centres. There will remain, however, the wider, and for medical men the more important, questions of the influence of what the French call *media*, that is to say, of social and sanitary surroundings, on the development of the people, many efforts for the solution of which questions have already been begun by the Anthropometric Committee of the British Association and a few individual observers in our own country and in America.

*A System of Practical Medicine by American Authors; edited by WILLIAM PEPPER, assisted by LOUIS STARR, M.D., Vol. iii. London: Sampson Low, Marston, Searle, and Rivington, 1885.*—The regularity with which the successive volumes of this important work make their appearance is as praiseworthy as it is exceptional. The volume now before us is devoted to diseases of the respiratory system, of the circulatory system, and of the blood and hæmopoietic system. Commencing with the diseases of the larynx and trachea, including a chapter on tracheotomy, we

<sup>1</sup> *The Races of Britain: a contribution to the Anthropology of Western Europe.* By John Beddoe, M.D., F.R.S., &c. London: Trübner, 1885

come to diseases of the bronchi, asthma, hay-asthma, and then to emphysema. The article on croupous pneumonia is by Dr. A. L. Loomis, who discusses the ætiology in a very clear manner, and, whilst not denying that cold may to some extent be an exciting cause, is strongly inclined to deny that it is the principal cause. The points of resemblance between pneumonia and the acute general diseases he puts as follows: It has an initiatory chill, an orderly pyrexia, a somewhat typical course, and the symptoms follow in regular sequence. The article is well written, and gives a faithful picture of the disease, but we are not quite prepared to agree with all he says about croupous pneumonia in children. The editor has written the article on catarrhal pneumonia, of the symptoms and physical signs of which he has given a full and excellent description. Dr. Austin Flint is the author of the article on pulmonary phthisis, and he fully accepts the recent doctrines which have followed on the recognition of the bacillus of Koch, though even before its discovery he with many others subscribed to the doctrine that all phthisis is tubercular. If we do not misunderstand him, he is not assured of the communicability of phthisis; the clinical proof of this doctrine, he says, must be based on a number so large that mere coincidence would be excluded; "A collection of isolated instances gathered from medical literature or reports from different physicians does not establish the doctrine." We must confess to some surprise when we read of his belief that those who have had scrofulous disease in early life are not likely to become phthisical in after years, and that contraction of the chest from deformity diminishes the likelihood of the disease. There is, as he says, a current belief to the exactly opposite effect, but any statement made by a practitioner of such enormous experience deserves the utmost attention, and we hope that our readers will bear these points in mind. Diseases of the pleura are very fully treated of by Dr. Frank Donaldson, who in the concluding section on the history of thoracentesis points out very clearly the part played by Dr. Wyman and Dr. Bowditch in originating the method of treatment by aspiration. To the second portion of the work Dr. Osler contributes two articles, one on diseases of the substance of the heart, including therein myocarditis, acute and chronic, fatty heart and hypertrophy, and a most careful article on diseases of the blood and blood-making organs, in which progressive pernicious anæmia, leukæmia, Hodgkin's and Addison's diseases, amongst others, are fully considered. Dr. Loomis deals with endocarditis, whilst Dr. Longstreth writes on the congenital anomalies of the heart, and Dr. J. B. Roberts on the operative treatment of pericardial effusions, the subject of pericarditis having been allotted to Dr. Da Costa. These articles are fully up to date and quite maintain the high standard shown by those to which we have referred at greater length.

*The Preservation of Health as it is affected by personal Habits, such as Cleanliness, Temperance, &c.*; by CLEMENT DUKES, M.D. Lond., M.R.C.P., &c. Pp. 222. Rivingtons. —This is the essay to which the Council of the Statistical Society awarded the "Howard Medal" in 1884. Dr. Dukes is to be congratulated upon the manner in which he has, within the limits assigned to him, brought down to the altered circumstances of to-day those admirable rules for the preservation of health which Howard drew up more than a hundred years ago; and he shows us incidentally how far the old writer on "Prisons" and on "Lazarettos" was in advance of his own age, and how nearly abreast of the boasted sanitation of the present time. Cleanliness, Temperance, the Prevention of Disease, and Personal Health form the principal headings of the essay; and the teaching is throughout sound, plain, and always practical. Dr. Dukes objects to the supply of water by meter, lest it should be scantily used. In practice, however, a rule permitting the cistern which supplies the drinking-water of the house to feed the cisterns of the watercloset is liable to misconstruction and open to abuse, and a "housemaid's sink or slop receiver," if provided with a four-inch pipe "syphoned immediately beneath the sink," is not likely to remain sweet for long in many houses. The section on Temperance is especially good,

though all medical men are not disposed to endorse our author's indiscriminate condemnation of condensed milk as a food for infants, "its only use being that it is better than starch food when no other milk supply can be obtained." The golden "rule of not too much" finds in Dr. Dukes an able and eloquent exponent: "To my mind the virtues of temperance far exceed the virtues of total abstinence." But the most important part of the book is the sub-section on "Temperance in relation to Sex," especially that portion dealing with the vitally important question of the causation and prevention of juvenile immorality—"a question usually discussed only in a whisper; a subject which, as a rule, is only dealt with when all the evil has been committed by quacks, the victim swindled by charlatans, and the sinner compelled to endure intolerable mental anguish." This subject—the delicacy of which is too generally allowed to over-ride its importance—is admirably handled. It is simply impossible to estimate the good which would accrue to future generations if parents would only take to heart and faithfully carry out the duty which is here so clearly set before them—a duty which it is theirs alone rightly to discharge, and the neglect of which no efforts of the schoolmaster and no warnings of the clergyman, and, we may add, no sensationalism in literature, can repair. A book like this, dealing so emphatically with the *personal* (but not the selfish) basis of hygiene, is all the more to be welcomed amidst signs which indicate a popular tendency to look upon sanitation as a matter of "traps" and "cowls" and sanitary patents. In utility of weighty precept and in simple directness of language, Dr. Dukes' essay is a worthy commentary on the preaching of a great and wise philanthropist.

*Chirurgische Erfahrungen in der Rhinologie und Laryngologie*; von Dr. med. MAX SCHAEFFER, Bremen. (Surgical Experiences in Rhinology and Laryngology.) Wiesbaden: J. F. Bergmann, 1885.—A record of ten years' experience of the surgical treatment of affections of the nose, nasopharynx, and throat. The author puts his facts in plain and straightforward terms, giving his figures in simple order without any statistical manipulation. With a short introduction, under each heading, of the principal features of the affections as presented by his cases, he gives an account more or less precise of his mode of treatment, and then presents a list of his principal cases with short notes on each. In some of the more debateable questions, such as the production of asthma by chronic hyperplasia of the mucous membrane of the nose, he enters at some length into controversy with other observers. In the section referred to, he does good service by showing that asthma is only *sometimes* curable by the destruction of the hypertrophied tissue, and that the treatment, like every other form of treatment for asthma, is successful only in special forms of the disease. His recorded cases, however, on which he operated for the most part with the galvanocautery, give remarkably good results. Sixty cases are recorded of phlegmonous pharyngitis treated by incision, the results fully justifying the author's recommendation of it. For the relief of granular pharyngitis he recommends immediate resort to the galvanocautery, and herein he is in accord with all practical observers of that troublesome affection. Of adenoid vegetations in the posterior nares and vault of the pharynx he treats at considerable length, and his experience forms a useful contribution to the literature of a subject which has been strangely overlooked by general practitioners and others until quite recently. After experience of all the ordinary methods of operating, he gives the preference to the curved forceps with sharp-spoon blades, a choice which quite accords with the very few expressions of opinion on the subject which have been heard in this country. In operations for the removal of mucous polypi from the larynx it is somewhat surprising to find that the author advocates the use of Voltolini's sponge-tipped probe. The method was amongst the earliest of endolaryngeal operations for the destruction of small tumours, but was very generally regarded as insufficient, and was, by most operators, discarded in favour of forceps or guillotine. Dr. Schaeffer's cases would lead

to the supposition, however, that it has been too hastily thrown aside, and it must certainly claim one standing advantage, that it is by far the safest method in unskilled hands. As a plain and trustworthy history of a considerable experience in special surgery, Dr. Schaeffer's work deserves every recognition.

*Diseases of the Larynx*; by Dr. J. GOTTSTEIN, Breslau. Translated and added to by P. McBride, M.D. Edinburgh. Edinburgh and London: W. & A. K. Johnston.—The human larynx, like the human eye, is a very small organ, but the amount of study which may be brought to bear upon its diseases, and the amount of literature to which such study may give rise, seems inexhaustible. The English translation of Dr. Gottstein's work may perhaps be regarded by some as a superfluous addition to this literature, coming so shortly after the publication of Dr. Mackenzie's text-book. We think, however, that in some respects it will be found to be a valuable adjunct to the more elaborate work, dealing with its subjects, as it does, from a more purely clinical standpoint. As we noticed the German original of Dr. Gottstein very fully when it first appeared a year ago, it is not necessary to enter here into the particular features of the work, and it will suffice that we record that a faithful rendering has been presented by the translator, supplemented in many points by useful notes and comments which the most recent knowledge on the various subjects could supply. The chief characteristic of the book, and the one which most fully appeals to the practical reader, is the perfectly straightforward tone taken by the author, who leaves no doubt upon his reader's mind as to the relative value of the statements which he makes. Ascertained facts are not confused with quasi-scientific speculations, and the author always makes it clear when his positive statements are backed by personal experience. The work has been handsomely prepared and excellently printed.

*Acne, its Ætiology, Pathology, and Treatment*; by L. DUNCAN BULKLEY, A.M., M.D. London: J. and A. Churchill, 1885, pp. 280. A monograph on so familiar a subject as Acne, extending to the number of 280 pages, may appear at first sight somewhat of a superfluity. When it is considered, however, that all disorders of the sebaceous glands are included under this term, in accordance with the most modern nomenclature, as well as an important disease not primarily affecting the sebaceous system at all ('acne' rosacea), the length of the work receives its explanation and perhaps its justification. The major portion of the book is occupied by a full description of the various recognised forms of the disease, based upon an analytical study of 1,618 cases, and by a recapitulation of well-known facts and well-worn arguments in support of the theory of its reflex causation. Many of the links in the chain of evidence on this point are a-wanting, and the acceptance of the theory leaves us entirely in the lurch when we meet with acne in persons otherwise perfectly healthy. It would seem more logical merely to state that acne in its various forms is a frequent concomitant of certain disturbances of the digestive or generative organs than to assert a causal relation between them. Nor would such a statement in any degree tend to diminish the amount of attention paid by a careful physician to the treatment of any digestive or other disturbances present in any given case of acne. Throughout the work no allusion is made to the not infrequent cases of comedones of the hairy scalp in robust children before the age of puberty. From them the ingenious explanation of the prevalent occurrence of comedones in sebaceous glands attached to imperfectly developed hairs (*e.g.*, on the face), and consequently furnished with small or no muscoli arrectores pilorum, receives at least partial refutation. Nor does the common non-contagious form of follicular sycosis receive any notice from the author, although it is undoubtedly as much an affection of the sebaceous glands as of the hair follicles, to which they are appended. The book ought to prove of valuable service to the practitioner, as it furnishes an excellent list of formulæ for the treatment of this frequent and often

obstinate affection, with full directions for the application of the remedies. There is also an excellent and interesting historical chapter upon the nosology of the disease, with a very exhaustive bibliographical index. The paper, letter-press, and general get-up of the book are excellent.

*Veterinary Pharmacology and Therapeutics*; by J. B. GRESSWELL, M.R.C.V.S. London: H. K. Lewis, 1885, pp. 206.—The plan of this little work is based mainly upon the "Extra Pharmacopœia" published by Mr. Martindale, from which many of the descriptions of drugs and formulæ have been taken. Having said this much, our readers will readily understand the scope and character of the work. If there be room for criticism, it would take the form of suggesting a little more veterinary and a little less human therapeutics. We gladly draw attention to the book, and believe that it will be found both reliable and convenient to the veterinary practitioner.

## ABSTRACTS AND EXTRACTS.

THE TREATMENT OF PLEURISY IN THE BELLEVUE HOSPITAL.—Dr. S. Mitchell, writing in the *Therapeutic Gazette* for November, states that about 150 cases of pleurisy are treated annually. It is rare to meet with true cases of acute pleurisy, except when they occur in patients while in the hospital. When a case, however, is seen within the first few hours, opium is given, usually as Dover's powder or as Majendie's solution, and hypodermically, which, besides relieving the pain and nervous manifestations, to some extent checks the determination of blood to the pleura. The bowels are opened by salines, and mustard or turpentine applied to the chest. The pain caused by the movements of the chest is greatly relieved by strips of adhesive plaster. Tincture of aconite is given in half-minim doses every fifteen minutes for two hours, and afterwards every two hours until the pulse shows signs of becoming feeble. Quinine in doses of 10 grains every six hours is given during the first twenty-four hours. When the state of effusion occurs the patient is made to take freely of a bitartrate of potash solution as a diuretic, the saline cathartics are continued, and iodine is applied locally. Another form of local application, which is a favourite with some, is the punctuated cauterisation with Paquelin's cautery every other day. Tonics are given and continued into the third stage, the following formula being that usually prescribed: Strychniæ Sulph. gr. i, Liq. Pot. Arsenit. ʒ ij, Cit. Ferri et Quiniæ ʒ iv, Glycerinæ Aq. Cinnam part. equal. ad ʒ viii; a dram after meals. With this is often given an ounce of whiskey three times a day. A dram of the following mixture is also given occasionally to allay the cough: Morph. Sulph. Pot. Cyanidæ gr. ij, Syr. Solut. Syr. Prun. Virg. part. equal. ad ʒ ij. Blisters are seldom employed. When the effusion is great enough to cause much dyspnoea paracentesis is performed at the mid-axillary line of the sixth interspace, the fluid being withdrawn slowly and arrested at the moment when the patient begins to cough or feel other unpleasant symptoms. In the chronic form of the disease the patient is put on diuretics, tonics, and mild cathartics, and counter-irritation is kept up by Corson's paint, made of Ol. Tiglii ʒ ij, Aetheris ʒ iv, Tr. Iodin. Co. ad ʒ ij. This painted on every morning produces a crop of pin-head blisters with very little annoyance. When absorption does not occur, this has seemed in many cases to become stimulated by aspiration, a few drams of liquid being removed by means of a hypodermic syringe, this often rendering paracentesis unnecessary.

THE CAUSAL RELATION OF OBSTRUCTED CARDIAC CIRCULATION TO LYMPH STASIS.—In a learned article in the October number of the *American Journal of the Medical Sciences* Dr. S. C. Busey points out that retardation or arrest of the current of the fluid in the thoracic duct at or near its outlet into the subclavian vein may produce dilatation, distension, and rupture of lymphatic vessels, and consequent effusion of chyle and lymph into the serous cavities.

The remoteness of the effects from the obstacle interrupting the current of the fluid may depend upon various concomitant conditions, especially upon the anatomical integrity and the tensibility of the vascular walls. When the impediment to the flow of chyle and lymph occurs at or near its outlet, the area of stasis and ectasis would necessarily depend upon the duration and extent of such obstacle; and, hence, when the area of ectasis is extensive, the manifest inference is that the cause has been one of gradual development and protracted duration. The influence of partial obliteration or stenosis of the thoracic duct at or near its termination in the causation of dilatation or rupture of some part of the lymph vascular system cannot be doubted. The evidences of experimentation must be accepted as conclusive. The effects of stenosis, produced by the gradual encroachment from disease of the duct or of surrounding and contiguous tissues and structures, are shown by clinical and *post-mortem* citations. In this latter class of cases the ectasis is gradual in its development and more extensive in its field. In those cases where the lymphangiectasis was consequent upon the slowing or interruption of the venous blood-current in the left subclavian vein, the relation of cause and effect seems equally well established. Dr. Buscy shows that such diseases of the heart as slow, impede, or stagnate the venous blood-current in the left subclavian or innominate vein may also produce lymph-stasis.

**PROGRESSIVE PRIMARY MYOPATHY.**—It is the object of a paper which appears in the October number of the *Revue de Médecine*, by Drs. Marie and Guinon, to demonstrate that pseudo-hypertrophic paralysis, Erb's juvenile form, and the hereditary infantile atrophy of Duchenne are not three distinct diseases, but merely different forms of the same disease. Between the infantile hereditary form of Duchenne and the juvenile form of Erb there are several points of close resemblance, and notably that the muscles attacked or respected by the disease are identically the same in the two affections; in both too electrical contractility is modified quantitatively, but not qualitatively; there are no fibrillary twitchings, though muscular retractions are common. The chief point of difference is that in one the muscles of the face are affected, and in the other they are not. Comparing next the hereditary form of Duchenne with pseudo-hypertrophic paralysis, they show that in the former the changes in the muscles are essentially of the same nature as in the latter disease, though differing considerably quantitatively. Further the atrophy, which is often a marked feature of cases of pseudo-hypertrophic paralysis when present, affects precisely the same muscles as are affected by it in the juvenile form. The condition of the face, which might at first sight be supposed to cause a distinct line of demarcation between the hereditary form and the other form which we are considering, does not in reality do so, for it is evident on close investigation that the face is often affected in pseudo-hypertrophic paralysis, and that such is the case was recognized by Duchenne, who attributed to it the dull and stupid look which the subjects of pseudo-hypertrophic paralysis often have. The authors believe that a slight degree of affection of the face is sometimes to be found in cases of the juvenile form of Erb. The last point they insist upon is that all these diseases are hereditary, and that they may be met with combined in the same family; the only combination which has not as yet been recorded being the co-existence amongst blood relations of pseudo-hypertrophic paralysis and of the hereditary form of Duchenne.

**SALT-WATER BATHS IN ENTERIC FEVER.**—A Russian physician has made a number of observations on the effects of baths consisting of solutions of common salt of various degrees of concentration on the temperature of patients with enteric fever as compared with those produced by fresh-water baths. He finds that in every respect the saline baths are the more effectual, but that 4 per cent. solutions are not materially superior to 2 per cent. or 2½ per cent. solutions. The maximum reductions of temperature with salt baths were, at intervals of ½-an-hour, 1 hour, 2 hours, and 3 hours, 1.9°, 1.4°, 1.4°, 1.1°C. respectively, and after fresh-water baths of the same temperature and

duration 1.5°, 1.2°, 1.2°, 0.6°C. The minimum reductions in the case of the saline baths were similarly 0.8°, 0.4°, 0.2°, 0.1°C., and in the case of the fresh-water baths 0.6°, 0.3°, 0.1°, 0.1°C. The pulse, too, is further reduced by saline than by fresh water, the maximum reductions obtained being 34 with salt and 26 with fresh water, and the minimum reductions 14 and 10 respectively. There was also a difference in the respirations, amounting to from 2 to 6 per minute, and it was noted that they became deeper and more regular after the saline than after the fresh-water baths.

**ACUTE RHEUMATISM.**—In a clinical lecture on acute rheumatism, delivered at the hospital of the University of Pennsylvania, Dr. Pepper described a typical case of rheumatic fever. Speaking of the morbid principle to which the symptoms were probably due, he said it was held by many that this was lactic acid; his own belief was that it was some complex organic acid substance which had not as yet been, and perhaps never would be, thoroughly isolated. The great danger of hyperpyrexia from a sudden failure of the heat-controlling centre was one that ought always to be before their minds. In his experience it had generally been associated with a marked tendency to nervous exhaustion, either from the prolonged course of the disease with considerable febrile action, or from worry, anxiety, and depression of spirits. The treatment of hyperpyrexia was of the utmost importance. If salicylates and antipyrine failed to bring the temperature down, the patient must be put into a cold bath. His plan was to put the patients into a bath-tub, and rub them with blocks of ice until they were cool, and the symptoms had passed off, when they were put to bed; he had never seen any injurious results from this plan, and believed he had saved life by it in five instances.

**A CONTRIBUTION TO THE STUDY OF DIPHTHERIA OF THE ŒSOPHAGUS; WITH THE REPORT OF A CASE.**—In the October number of *The American Journal of the Medical Sciences* Dr. H. D. Fry, of Washington, contributes an interesting study of this rare affection, and reports a case which occurred in his own practice. The diagnosis of diphtheria of the œsophagus is extremely difficult. In most cases it is absolutely impossible to recognize the disease. This difficulty is met with not only when the œsophageal mucous membrane is primarily the seat of diphtheritic inflammation, but also when it is implicated by extension of the false membrane from the pharynx or larynx. In the vast majority of the reported cases its presence was not suspected until revealed by *post-mortem* examination. Symptoms, at most, only warrant a suspicion of the existence of the affection. An important indication is the expulsion, by the mouth, of bands of false membrane, provided no symptoms exist to indicate that the air-passages are involved. The expectoration of a membranous cast of the œsophagus is the only positive sign of the disease. The obscurity which accompanies nearly all affections of the œsophagus is well illustrated by the experience of Steffen. Out of 44 cases, including diphtheria, hyperæmia, catarrhal inflammation, ulceration, ecchymosis, and gangrene, the diagnosis was made in only three; the remainder were found on *post-mortem* examination. Dr. Fry concludes his paper with a careful analysis of the symptoms which were observed in the 12 cases which he has been able to find fully reported in literature.

**DEATH FROM ROUND WORMS.**—The *Deutsche Medicinische Zeitung* gives an account of a unique case of what was supposed to be an infectious disease which appeared simultaneously in two brothers, the symptoms being of a gastro-intestinal character. One of them, aged seven, at last died. On examination, a reddened, inflamed looking coil of intestine attracted attention, lying superficially in the right inguinal region. It appeared to be tense and distended by something, and when opened was found to contain a huge quantity of ascarides lumbricoides, all matted and entwined together, completely blocking up the lumen of the gut. No peritonitis existed, and the rest of the intestine was healthy enough. After this, of course, there was no difficulty in devising a treatment for the survivor, who under a brisk vermifuge passed some 20 worms and before long was convalescent.

**APPLICATION OF COLD TO THE LEG FOR SLEEPLESSNESS.**—A writer in a German journal devoted to mental diseases advises bandaging the leg with a cold water compress covered with gutta-percha tissue, dry bandage and a stocking for sleeplessness, especially in cases where there is more or less cerebral congestion. It has been found that the temperature taken in the ear becomes 0.4° C. lower fifteen minutes after the application of the compress, and remains an hour or two below normal. The writer says he has employed this plan for two years with great success.—*Allgemeine Zeitschrift für Psychiatrie*.

**PLEURISY IN PERTUSSIS.**—Dr. Zabala, writing to the *Bulletin de Thérapeutique*, Aug. 15, states that during a recent epidemic of pertussis, in which about 30 cases came to his share, he met with two cases of pleurisy in children nine and ten years of age, in which the presence of fluid was ascertained by aspiration. In one of these cases the effusion disappeared after the application of two blisters; while vesication proving of no avail in the other, he succeeded in producing abundant sweating and disappearance of the liquid by means of two hypodermic injections of a centigramme of the nitrate of pilocarpin.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, DECEMBER 8TH, 1885.

BERKELEY HILL, F.R.C.S., Vice-President, in the Chair.

#### *A Case of Destruction of a Portion of the Axillary Artery by Sarcoma.*

MR. SAVORY contributed this paper, which recorded the case of a man, æt. 33, who was admitted into St. Bartholomew's Hospital with a large tumour beneath the pectoral muscles. The mass was soft, and manifestly increased in size during the fortnight the patient was under observation. An attempt was made to remove the growth by a free incision along the lower margin of the pectoralis major, where it presented, through the fat of the axilla, a well-defined outline. That part of the tumour which lay below the vessels was easily removed, but no attempt was made to detach the portion which was found, during the operation, to have grown around those structures. Whilst securing some insignificant arteries, which had been divided in the lower part of the axilla, the hæmorrhage, which up to that stage had been but slight, began to be exceedingly copious. In searching for the seat of the bleeding, it became evident that it proceeded from where the axillary artery should have been, though that vessel could nowhere be found. The hæmorrhage was afterwards arrested by means of pressure forceps. The patient lived for a week after the operation, when there was suddenly a violent gush of blood, and before it could be arrested he died. *Post-mortem* examination showed that the part of the axillary artery involved in the tumour was completely broken up. A detailed account of the *post-mortem* state of the other vessels was added. A note by Mr. D'Arcy Power on the histological appearances of the artery at a point immediately below the rupture was also appended.

The VICE-PRESIDENT enquired as to the original starting-point of the growth, and as to the condition of the pulse.

MR. BRYANT thought the author of the paper was fortunate in having been able to watch the ease from its commencement. He quite agreed with him as to the power of resistance which arteries possess against the inroads of such growths as this present one. He referred to cases in his own practice, in which they had nevertheless ultimately become occluded.

Sir WILLIAM MACCORMAC referred to the fact that both vein and artery were occluded in this case, and enquired

what effect this had had on the circulation in the limb below the seat of the disease.

MR. SAVORY briefly replied.

#### *Amputation at the Knee-joint by Disarticulation: with Remarks on Amputation of the Leg by Lateral Flaps.*

MR. BRYANT commenced his paper by saying that the operation of removal of the leg by disarticulation at the knee-joint was first practised in England by Mr. S. Lane, and had been advocated by Messrs. G. D. Pollock, Pick, Stephen Smith, Markoe, Brinton, Staples, and himself. It was still regarded with some suspicion and not frequently resorted to, amputation through (or just above) the condyles being generally preferred. The operation by disarticulation required for its success that the disease or injury should be confined to the leg, the condyles of the femur uninvolved or very slightly affected, and a sufficiency of healthy soft parts below the knee for the formation of a good flap. If these conditions were not present, some other method of amputation would have to be adopted. The author gave tables of his thirty cases, with the results. Where there was no sloughing, no trouble was experienced with the articular cartilage on the condyles of the femur, and after healing the soft parts moved freely over the end of the femur. The cicatrix was always placed well behind the femur. The patella was preserved, its removal being found to be quite unnecessary. The steps of the operation, after three different methods, were then described, viz., that of Pollock by the long anterior flap, Pick's plan by lateral flaps, and Stephen Smith's method by lateral hooded flaps; and illustrations of the steps of the latter operation were shown. The author endorsed completely the remarks of the American surgeon upon the value of this method of procedure, and strongly urged its application to cases of amputation in the leg also. The muscle substance was generally included in the flap in thin subjects, but not in others. The resulting stumps in the leg thereby obtained were excellent. The method of Stephen Smith for amputation at the knee-joint was to be preferred to either of the two other plans already mentioned, as it gave a better covering to the condyles of the femur, and the flaps were less prone to slough than in the long anterior flap of Pollock. One case in five of the former sloughed, and rather more than half of the latter class of cases. Smith's method also placed the cicatrix entirely behind the condyles and out of harm's way, whereas by Pick's method the cicatrix came to lie in the intercondyloid notch. Moreover, Smith's plan permitted no bagging of fluids, the stump being in the best position for drainage. The author advocated the leaving of the semilunar cartilages *in situ*, as of great advantage to the case, the soft parts being thereby all held well in place and the fascial relations preserved. Dr. Brinton, as early as 1872, had advised this point of practice. Finally, the author summarised the advantages of this form of operation over amputation through the thigh in the following words:—(1) The lessened shock of operation. (2) The lessened section of tissues and the non-exposure of the muscular interspaces of the thigh. (3) The escape from the necessity of sawing the femur, with its attendant risks. (4) The preservation of the attachments of the thigh muscles, and consequently the greater mobility of the stump. (5) The useful character of the resulting stump.

The VICE-PRESIDENT, in proposing a vote of thanks to the author, referred to the excellent suggestion to leave the semilunar cartilages. He should himself certainly follow that practice for the future.

MR. PICK was pleased that the subject had been brought forward, for he felt that the operation was still unpopular, and that preference was given to cutting through the femur, with its attendant dangers. He preferred lateral flaps; in his earlier operations he had made long anterior flaps, and sloughing had frequently resulted; on one occasion he had practised a long posterior flap, but had found that it dragged open the incision during repair. The making of lateral flaps was, so to speak, an accident, they were necessitated by the condition of the skin in a traumatic case. He rather disagreed as to leaving the patella; he thought it was liable to be displaced, and that it might interfere with the fitting of an artificial limb.

Mr. MARSH commented on the leaving of the articular cartilage; it was not only not followed by any untoward results, but it seemed to act in some measure as a barrier against absorption of wound products. He did not think that any strong prejudice against this operation existed at St. Bartholomew's. It was very important to cut the flaps long enough.

Dr. HARDIE (Manchester) spoke in favour of the operation. He had read a paper at the Liverpool meeting of the British Medical Association, advocating its utility, but he preferred what he there called the "oblique circular" method. He said there was no other stump, except that of a Syme's operation, which could compare with it, the anatomical conditions being just those favourable for a good result. He thought the circular method lessened the chance of sloughing, as the skin flap remained a single piece. He left the patella, and had never seen harm follow. He was favourably struck with the idea of leaving the semi-lunar cartilage; it was of course a matter of great moment to secure, if possible, primary union.

Sir WILLIAM MACCORMAC had been much struck with the amount of retraction which took place in the posterior flap.

Mr. POLLOCK referred to the question of leaving the patella; there were decided advantages, less dissection was needed, and few muscular insertions; he had never seen inconvenience result, not even as regarded the fixing of artificial limbs; on the contrary, the patients walked firmer, and with less throwing of the limb. He preferred Dr. Hardie's flaps to the lateral one advocated by Mr. Piek.

Mr. TIMOTHY HOLMES agreed that the results were very excellent when an operation was successfully carried out, but the method was more dangerous, and less often successful than amputations of the thigh done in any one way. Such flaps, wherever and however obtained, were chiefly skin, and there was danger of their sloughing. He approved of leaving the patella. The danger of leaving a surface covered with cartilage was antiquated and exaggerated. Nevertheless, the operation was one to be done sparingly and only after very mature consideration. The plan of leaving the semi-lunar cartilages was a great improvement on the old plan.

Mr. BARWELL spoke in favour of the operation.

Mr. BENNETT quoted some statistics from the registers of St. George's Hospital which tended to show the association of sloughing of the flap and of secondary hæmorrhage; something, he thought, must be attributed to tension on the flap by its distension with synovial fluid secreted by the sub-crural pouch of synovial tissue from the joint. Surgeons, fearing sloughing, often increased the danger by making the flaps too short.

The Society then adjourned until January 12th, 1886.

---

## WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

NOVEMBER 6TH, 1885.

W. B. HEMMING, M.R.C.S., President, in the Chair.

Dr. ALDERSON showed three patients, victims of scirrhus of the breast, who had been under his observation and care more or less for a long series of years.

CASE I.—M. P., aged 50, was shown as a typically successful result of operation; the cicatrix now, after several years, being perfectly smooth and very pale, evidently fading. Dr. Alderson diagnosed this case very early, when it had only been noticed a fortnight and was but the size of the kernel of a nut, but it grew rapidly in the interval of two or three weeks that elapsed before operation, and was then about the size of a small egg. The breast was removed by Mr. Hulke in the Middlesex Hospital in 1878.

CASE II.—A. B., 68. Large scirrhus cancer of right breast, of twelve years' duration; has frequent attacks of pain and bleeding (relieved by leeches). Large cancerous induration of left side and commencing cancer of left breast; now in good general health. A. B. refused operation years ago.

CASE III.—M. H., 70. Lived all her life at Queen's Street, Hammersmith, the high autumn tides coming a considerable distance up the street. About four years ago there was a cancerous induration in a straight line, like a small cord which the finger could roll, about two inches below breast and to the left of the sternum; there was a slight ulceration in the centre of this induration, and subsequently that ulceration extended about four inches along the cancerous seam, which became a raw surface half an inch in width and with everted edges; it inflamed, and then gradually contracted and healed coincidently with the formation of a cancerous lump in the breast, and, as it healed, it fixed the breast to the sternum. The glands in the axilla are now enlarged, indurated, and tender. There is but slight discharge and little bleeding; a year or two ago the bleeding was frequent and copious. This case was shown as an example of the slow growth and comparatively little danger to life of cancer in elderly people, and Dr. Alderson thought that they did best without operation. He then proceeded to give some interesting particulars as to ten cases, the patients having been under his care and observation for several years. In seven of the ten the cancer was in the left breast. He asked if this proclivity to the left breast was accidental; he thought not. Five were spinsters, five married, two had no children, the remaining three six between them, and only three of these were living. Whatever influence child-bearing might have on the production of uterine cancer, he believed it had none in the production of cancer of the breast; as an obstetrician, he spoke as to this with some confidence. There was no history of rheumatism in any; he thought rheumatism and cancer vicarious; cancer patients had frequent premonitory pains, but did not develop cancer. Five had their breasts removed, one lived seven years after operation with four years' complete health, and then came recurrence *excited by injury*. One derived but doubtful benefit from operation, the cancer quickly reappearing in the cicatrix, and was subsequently developed in the right breast; the patient died just two years after operation. The third (shown) after several years was perfectly successful, the cicatrix so pale and smooth that Dr. Alderson thought the patient might prove an example of what has been considered "one of the rarest successes of operating surgery, *i.e.*, when it is cut out and never returns." The fourth recurred, and death occurred in two years. The fifth was too recent to speak as to results, which were at present favourable. Dr. Alderson mentioned that all his cancer patients, uterine and mammary, lived very near the river, some at only an altitude of ten to twelve feet above the mean level of the sea. This question of locality, he thought, was something more than a theory.

Mr. HAVILAND had observed that cancer fields were situated along rivers that occasionally overflowed their banks, and it was impossible to argue that, because the mortality from cancer showed no abatement in fine seasons as compared with humid, the damp surroundings of rivers had no influence on the causation of cancer. The increase in the mortality was gradual, only because the result and the cause did not follow in quick succession as in acute rheumatism after exposure to damp or cold. Death from cancer did not result for a long period after the dampness of soil might have produced the first germ of this fatal disease, which, though latent, might have existed for some time.

### *The Theory of Cancerous Inheritance.*

Mr. DUNN read a paper under this title. Prefacing his remarks by a quotation from Bacon's Essay on Innovation, viz., "As the births of living creatures at first are ill-shapen, so are all innovations which are the births of time," he proceeded to say that he believed that the pregnancy, so to speak, of the non-identity of heredity with cancer had begun; that the metaphorical embryo was satisfactorily

developing; that time would enable us to chronicle a new birth in the history of a foul disease; and that, in the future, we should be able to show, unequivocally, that there was no such thing as the hereditary transmission of cancer, and the facts, in his opinion, were accumulating to this end. Weighing calmly the direful results to which cancer as a disease gave rise, upon the grounds even of humanity, it was right that every particle of evidence bearing upon its supposed hereditary transmission should be sifted and exposed to the pyralinistic effect of scientific research for the purpose of proving its value. Cancer was said to be hereditary. Upon what grounds? This demanded full investigation. The laws governing inheritance, as Darwin observes, are, for the most part, unknown. Heredity, nevertheless, was operative as a fixed principle in accordance with three definite and unvarying laws—there was direct, indirect, and atavic heredity. Cancer was held to be hereditary because it occurred consecutively amongst the members of certain families, and because its occurrence has been considered to be consonant with the principle of the hereditary transmission of structural peculiarities. Sir James Paget's statistics, which place the hereditary influence of cancer as high as one person in three with cancer, are well known. But, apart from and beyond the consecutive appearance of the disease in certain families, cancer fulfils in no sense whatever the characters of an hereditary disease. Does cancer become an agent of variation? Is there such a thing as a cancerous diathesis, equivalent to what we understand by the gouty diathesis, the tubercular, or the syphilitic? In the midst of a disease which is active, is it not natural to expect some impress of it, if nothing more, to be visible in the offspring? But are we able to say—Oh, here is a child who will become cancerous, or, because this child's parent was cancerous, therefore it will suffer in this way or that? No. Therefore the conclusion was obvious and indisputable, that, whilst syphilis, gout, and tuberculosis, which were correctly described as constitutional diseases, permanently modify the structure and functions of the body, cancer could not be included in that category, for, commencing as a local disease, its effects, it was true to say, were never transmitted. There was no such thing, even in the most recent text-books of medicine, of, say, a cancerous stomach, a cancerous neuralgia, a cancerous ache or pain, without cancer. A person was either cancerous or he was not, and he was not so until he became so by exhibiting in some organ or part the disease in its primary form. It is clear then that, if he had inherited cancer, he had not inherited much. For, obviously, cancer must be an exceptionally benign disease before it becomes cancer in those cases, indeed, in which it is believed to be inherited. For a man with an inherited cancerous taint must patiently wait until the near approach of the last scene of all, which ends his strange eventful history, before his morbid patrimony can become an accomplished fact. After discussing various other points in relation to the hereditary theory of cancer, Mr. Dunn concluded:—"In bringing these facts and opinions before you this evening,—and I must freely admit that the latter predominate,—I have not endeavoured to exhaust the subject to which they relate. But rather my object has been to extract the most salient features of the case, and appear before you as a counsel with his brief, urging the claims of a client in whom he has more than ephemeral interest. The advocacy of a cause of this nature involves the discussion of many complex topics; it necessarily deals with problems of science, of which the solution cannot be too frequently essayed; it leads the enquirer into many a *cul-de-sac* of pathology, from which it is often a difficult matter to effect a graceful retreat. But whether or not we shall ever determine the influence of heredity upon cancer depends, confessedly, upon whether or not we are prepared to sink the belief which has been bred of unsupported facts, and to struggle onwards, patiently seeking for, hopefully expecting, some gleam of light to disperse the obscurity of the pathology of the disease."

Mr. BUTLIN said that, since he had left the West London Hospital, great changes had taken place there, so much so that upon this occasion he felt like a Rip Van Winkle. With regard to the subject under discussion, he had listened with great interest to the cases described by Dr.

Alderson, with whom he agreed in many of his remarks in regard to the influence of locality upon the disease. Upon the theory of inheritance, he did not think Mr. Dunn had left him anything to say. The memorandum which he (Mr. Butlin) had drawn out for the collective investigation committee, in which, among other things, certain questions were asked in regard to the inheritance of cancer, was not intended to convey the expression of any decided opinion upon the matter. It was merely for the purpose of eliciting facts. Of course he had his own views upon the subject. Speaking personally, he did not agree with the adoption of the hereditary theory of cancer. Amongst the upper classes it was looked upon as a great calamity if a case of cancer occurred in the family. He was of opinion that the locality in which the person resided was most important, and that residence had a most powerful influence over the disease. But he also considered that there were other factors of great moment which predisposed to cancer, such as, amongst others, smoking, diet, good or bad, anxiety or worry; that it was from a combination of these, rather than from any single cause, that predisposition arose. In addition to the above influences, he would also mention that important factor in health, viz., the soil of the locality, and the way in which it was drained and manured.

Mr. KEETLEY said that in the investigation of cancer, as to its causation, hereditary or otherwise, great care was required, as it was an exceedingly complex question. In a collective investigation of the predisposing causes of cancer he considered that the enquiry in each district and in each neighbourhood should be considered separately.

Mr. LLOYD was of opinion that locality was an important factor in the causation of the affection under discussion.

Dr. ALDERSON, in reply, said that he thought that the importance of the heredity of cancer was considerably overrated, inasmuch as, whilst many families were undoubtedly tainted with the disease, it nevertheless occasionally never manifested itself in any way. It was of the utmost importance that the predisposing causes should be fully investigated.

Mr. DUNN, in reply, thanked the members of the Society for the kind attention they had given to his paper. He also showed a collection of specimens of Sarcoma and Carcinoma from patients who had died in the West London Hospital during the last fifteen months.

Dr. WELLS showed a specimen of Colloid Cancer of the Colon.

Mr. KEETLEY showed a case of Gritti's operation.

---

## MANCHESTER PATHOLOGICAL SOCIETY.

WEDNESDAY, NOVEMBER 11TH, 1885.

DR. H. ASHBY, President, in the Chair.

Dr. S. MORITZ showed several specimens of the *Anchylostoma (Dochmios) duodenale* which had been sent him by Professor Leichtenstern of Cologne. This form of nematoid worm was first described by Dubini, of Milan, in 1838, afterwards by Griesinger in Egypt, and later still it was found to infest the workers in the St. Gothard tunnel; and more recently it has been observed by Leichtenstern among the workers in the brickfields about Cologne and in the mining population of Belgium. The male anchylostoma averages 7—11 mm., and is slender, bent in the form of a hook at its tail, and white in colour. The female is 7—16 mm. in length, straight, fusiform, of a brownish or blood-red colour, due to the fact that it extracts blood from the patient's intestine. It fixes itself to the intestine by means of a sucker and six teeth. The principal symptoms caused by the presence of these worms in the small intestine consist in a feeling of fulness and pressure in the abdomen, diarrhoea, marked anæmia, and the presence of the ova in the fæces completes the diagnosis. The number of the ova may be very large; as many as 2,700 have been counted in 1 c.cm. of fæces. The worms do not

regenerate themselves in the intestine, but probably develop into some larval form outside the body, which is swallowed in the drinking-water. Male fern, in large doses, seemed to be the most effective anthelmintic.

Mr. F. PAUL, of Liverpool, related the clinical histories of seven cases of carcinoma of the nasal mucous membrane and antrum. These cases had occurred in patients who were past middle life, and were often preceded by polypi; they often caused stoppage of the nasal duct, and growing into the orbit displaced the eye. The sections showed carcinoma formed of columnar cells.

Dr. ALEXANDER, of Liverpool, exhibited a heart with several masses of sarcoma occupying its walls. The specimens were taken from a sailor, aged 31, who presented himself with a pharyngeal tumour which gave rise to both dyspnoea and dysphagia; there were no abnormal sounds on auscultating the heart; the tumour, which was sarcomatous and appeared to grow from the pharynx, was removed without difficulty. The patient died apparently of exhaustion some ten days after the operation. The *post-mortem* showed the left lung and mediastinum to be infiltrated with a sarcomatous growth, the heart had several nodules on the surface, and on opening the ventricles nodules were seen attached to the chordæ tendineæ; there were also nodules in the pancreas, liver, and kidneys. The structure of the nodules showed them to be lympho-sarcoma.

Dr. GEORGE HAMILTON, of Liverpool, showed microscopic sections of the heart, from a case of lardaceous disease. In several similar cases examined by him the only naked-eye appearances on treating the heart with iodine were a few black specks beneath the endocardium. On microscopical examination the waxy material was present, infiltrating the endocardium, the fibrous tissue beneath the endocardium and in the intermuscular tissues, no trace being found in the muscular fibres, though they appeared to undergo atrophy. The vessels supplying the tissue of the heart were unchanged, though, on examining the liver, the small vessels had undergone degeneration especially of their middle coats.

Dr. DRESCHFELD stated that in some cases which he had examined the muscular fibre itself had undergone degeneration.

Dr. A. GRIFFITHS showed a specimen of abscess of the frontal cerebral lobe, communicating with the orbit. Some six months before, the patient had presented herself with slight ptosis and prominence of the right eye with diplopia, and discharge of muco-pus from the nostril of the same side. Later the eye became more prominent, and there was a discharge of glairy fluid from a sinus which made its appearance by the side of the orbit. On passing the probe into this, it passed directly backwards and upwards, some four inches evidently, into a cavity in the frontal lobe of the brain. Finally vomiting, incontinence of urine and faeces, came on, and death quickly ensued. The *post-mortem* showed a large abscess containing greenish pus in the frontal lobe. The patient had probably suffered from a periostitis of the orbit, and a cerebral abscess had formed secondarily to this.

Dr. A. BARRON, of Liverpool, showed a double monstrosity consisting of two fetuses joined together by the sides of the thorax (*Thoracopagi*), resembling the "two-headed nightingale." The monster had been delivered with much difficulty, and the heads and legs were separate, the sides of each trunk being attached as low as the umbilicus. There was one common liver and one peritoneal cavity, one pericardium containing a six-chambered heart, two gall-bladders, two alimentary canals, four lungs.

Dr. H. BRIGGS showed various specimens of solid ovarian tumours.

The PRESIDENT showed a series of hearts taken from cases of scarlatinal nephritis, showing dilatation of the cavities and endocarditis.

CHARITABLE BEQUESTS.—Mrs. Mary Blackden, late of Norfolk Crescent, Hyde Park, has bequeathed 300*l.* to the Convalescent Institution, Walton-on-Thames, and 200*l.* to St. Mary's Hospital, Paddington. Mrs. Louisa Brooke Blake, late of Sunnylands, Torquay, has left by her will 100*l.* to the Torbay Infirmary and Dispensary.

## SPECIAL CORRESPONDENCE.

### INDIA.

(From our Own Correspondent.)

*The Health of Bombay Presidency—The Proposed Hospital for Women and Children in Bombay—The Burmah Expeditionary Force.*

November 13th.

MR. T. G. HEWLETT, C.I.E., Sanitary Commissioner with the Government of Bombay, has just issued his annual report for 1884, on which a Government *resolution* has been published. He calls attention to the defective system of registration of vital statistics, which, he states, will never be satisfactory until it is rendered compulsory by law. But it would appear that in Bombay, and all other municipal towns where omission to give information of births and deaths is now punishable, the registration is most defective. The Government evidently think that, unless the importance of accurate registration is recognised by those responsible for municipal administration, the law can scarcely be effectual. This view, I am inclined to think, is virtually correct. It is gratifying to learn that, though cholera prevailed throughout the Presidency, there was a considerable decrease in the year under report. The proportion of deaths reported to attacks was 52.93 per cent. as compared with 47.76 per cent. in 1883. The ratio in Bombay was 78.13 per cent., which, with the exception of Ahmedabad, gave the largest mortality. According to Mr. Hewlett, the principal cause of this high mortality is "the long distances which the patients have to be carried to hospital." The Government, however, do not seem to look upon this as a satisfactory explanation, for they say "it must not be overlooked that in the rest of the Presidency most cholera patients are not treated in hospitals and dispensaries at all, and that the theory did not meet with the support of other medical officers whose opinions on the subject were called for. The high apparent mortality of deaths to attacks in Bombay is probably in great measure due to the circumstance that many attacks which do not terminate fatally are not reported at all." The deaths from small-pox show an increase. One case of inoculation is reported. The quality of lymph obtained from England was found to be generally good. In the city of Bombay vaccination is carried on with animal vaccine. In some of the districts both animal and human lymph is used, and in all others only human lymph. Mr. Hewlett, who, like Dr. Cunningham, is a non-contagionist, brings forward some evidence of the "non-contagiousness of cholera," which the Government hold to be undoubtedly very strong, but they wisely "refrain from expressing any opinion how far Mr. Hewlett has succeeded in indicating the true origin of cholera, and in proving that the disease is not contagious, as these questions are still subjects of controversy among experts, but it is admitted on all sides that the disease is fostered by filth, and, if this fact is persistently impressed on the people, sanitary improvement will be facilitated." An interesting contribution on the "Cause of Cholera" has appeared in the September number of the *Indian Medical Gazette* from the able pen of Mr. W. J. Moore, C.I.E., and to this I would invite the attention of those of your readers more especially interested in the subject.

The Municipal Corporation of Bombay had recently under consideration a Government *resolution* anent that body contributing towards the cost of the proposed new hospital for women and children, for the erection of which a native gentleman has generously made a gift of a lakh of rupees. At this hospital it is intended that clinical instruction shall be given to the students of the Grant Medical College. I regret to have to report that the action of the Municipal Corporation in this matter was by no means commendable, a disposition being displayed on the part of some of its medical members, not belonging to the Indian Medical Service, to obtain for themselves or their friends appointments to its staff, by the Municipality, instead of Government, having the management, contrary to the

stipulation of the donor. Dr. Khory moved the ill-conceived resolution that the Government be informed that the Corporation is not willing to contribute on the condition noticed above. Mr. Cowasjee, a medical practitioner, remarked that there was a great and crying necessity in Bombay for a good obstetric hospital. He pointed out that Mr. Parakh, who some time back had acted as obstetric physician in the Jamsetjee Jeejeebhoy Hospital, had pronounced the opinion that the present institution was unsuited for the purpose of giving obstetric instruction, and was wanting in proper sanitary arrangements; and that the latter accounted for the high rate of mortality. Mr. Parakh, he said, was also of opinion that the present obstetric hospital was dark and damp to a degree in the rains; moreover, it was situated in the midst of a crowded, noisy, malarious, and unhealthy locality, and that, farther, there was no operation room, no office, and no visiting and consulting room. Such, we are told, are the views expressed by Mr. Parakh, L.R.C.P., M.R.C.S., in a paper recently read by him before the Grant College Medical Society of Bombay. It does strike one as certainly strange that Mr. Cowasjee, L.M., after indicating by the above the urgent need that there is for the establishment of a new obstetric or lying-in hospital, was led away to support Dr. Khory's proposition which asked the Corporation to refuse to make any sort of grant. Some very wise observations fell from Colonel Merewether, who stated that the Surgeon-General had informed the Government of the necessity for constructing a new hospital, and that Dr. Cook had only recently urged the same point at a meeting of the Town Council. He accordingly moved "that the Town Council be asked to report as to how the one lakh of rupees might best be provided during the years 1886-87 and 1887-88." Mr. Waters, L.R.C.P., L.R.C.S., seconded this, and said that it would be rather an undignified proceeding on the part of the Corporation to refuse a grant, the object of which they well recognised, simply on the score of injured pride. He thought there was nothing very unreasonable in the stipulation that the Municipality should have no voice in the management of the proposed hospital, and that it should be maintained and conducted by Government, which had at its command the most perfect medical machinery for the purpose of supervision and administration. The Corporation, he added, did not possess such a machinery, and, although there might be some medical members in the Corporation, they had not the executive and administrative experience possessed by Government officers. Several native members who spoke after this opposed the amendment. Mr. Kemp, a local chemist, said that no hospital could be obtained on more favourable terms, and therefore the Corporation should not miss the opportunity which had now presented itself. On a division the amendment was lost by a large majority, and Dr. Khory's motion was unfortunately carried by 15 votes against 5.

Several months since, an allegation of professional neglect was laid against Surgeon Thomas, of the Madras Medical Service, by the Government of Madras, who, it appears, had censured him, and, as the result of suspension, and without appointment, he was for several months on "unemployed pay." The alleged neglect was in respect to the case of an officer who succumbed to cholera. It is said that the case was in appeal submitted to the Supreme Government, who have now officially recorded their dissent from the opinion and decision of the Local Government, with the result that Mr. Thomas has been reinstated to his former post and receives his arrears of pay. This is satisfactory.

At the Colonial and Indian Exhibition in London, I learn, medical works and publications and appliances, peculiar to India, are to be exhibited. Surgeon-General W. J. Moore, C.I.E., is at some pains, it seems, to get these collected and placed at the disposal of the Bombay Committee.

Deputy Surgeon-General Donnelly is appointed Principal Medical Officer to the Burmah Expeditionary Force, and the following are the names of some of the medical officers proceeding therewith:—Surgeon J. Hoey, 1st Madras Pioneers; Surgeon-Major R. V. Power, 12th Madras Infantry; Surgeon-Major J. C. Lawrenson, 21st Madras Infantry; Surgeon G. M. E. McKee, 23rd Madras Infantry; Surgeon-Major F. H. Blenkinsop, 25th Madras

Infantry; Surgeon J. W. Evans, Madras Sappers and Miners; Surgeon-Major H. W. MacKinnon, Hampshire; Surgeon C. Williamson, Q/1 Royal Artillery; Surgeon M. W. Kerin, 4/1 Royal Artillery; Surgeons-Major D. F. Bateman, C. Sibthorpe; Surgeons A. D. Adams, D. F. Dymott, J. Kernan, and R. E. S. Davis with the General Hospital to be established. Some of the troops with the Head Quarters Staff have already left, but no serious opposition is expected.

## GENERAL CORRESPONDENCE.

### "FORCIBLE DILATATION OF THE SPHINCTER-ANI."

[To the Editor of the Medical Times.]

SIR,—Allow me to thank Mr. Bryant for his courteous correction of what might appear to be a misinterpretation, or rather an inadequate interpretation, of his meaning. In speaking of "dilatation of the sphincter ani, as practised in France, as a barbarous operation," he had given me the impression, and others also, that he was condemning "dilatation," whereas he was evidently "intending to condemn the absence of an anæsthetic" in such an operation. In this, I am sure, we shall all agree. The object of my lecture was to strike a clear note on the subject of "dilatation," as a mode of operation which ought to supersede the knife in dealing with spasm of the sphincter ani, and, in the second place, to enforce the principle that "dilatation of the sphincter" ought to be a preliminary step in nearly every operation on the rectum, a rule laid down in some special works on the rectum, but, as it seemed to me, not adequately insisted upon in the general works on surgery which I find most commonly in the hands of medical students.

I am, Sir, yours, &c.,

T. PRIDGIN TEALE.

Leeds, December 7th, 1885.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN Ordinary Meeting of the Council was held on Thursday, the 10th inst. The minutes of the Extraordinary (last) Meeting on the 24th ult. were read and confirmed. The Examiners in Elementary Physiology were re-appointed, and Mr. McCarthy was appointed *vice* Mr. Gerald Yeo, an Examiner in Physiology. A letter was received from Mr. Marshall, as Chairman of the Statistical Committee of the General Medical Council, enclosing a report on the subject of statistics in relation to what becomes of medical students. A letter was read from Mr. Marshall, as representative of the College in the General Medical Council, reporting the proceedings of that Council at their late session; it was ordered to be entered on the minutes, and a vote of thanks to Mr. Marshall for his services was passed unanimously. Mr. Berkeley Hill was added to the Committee on the "Doctor" question. The delivery of the Bradshaw lecture by Mr. Wood was reported, whereon the Council voted him their thanks and requested him to publish it. Mr. Hutchinson, on being called upon to move his resolution, by permission of the Council, was allowed to substitute the following: "That a Committee be appointed to consider, and report to the Council, whether it is desirable in any way to widen the basis on which the Fellowship is obtained, and, if so, by what methods." This was seconded by Mr. Bryant, and carried *nem. con.* The Committee to consist of Sir James Paget, Mr. Marshall, Mr. Lund, Mr. Hutchinson, Mr. Cadge, Sir Joseph Lister, Mr. Bryant, Mr. Hulke, Mr. B. Hill, besides the President and Vice-Presidents *ex officio*.

Mr. Macnamara's motion, seconded (*pro formâ*) by Mr. Pemberton, was brought on, discussed, and not carried, inasmuch as the Court of Examiners have already taken steps to increase the time of the practical examination from twenty minutes to half-an-hour. The Council then adjourned.

UNIVERSITY OF EDINBURGH.—The following gentlemen have passed the final examination for B.Sc. in the department of Public Health:—

Philip Cockburn, M.B., C.M.; James M'Lintock, M.D.; L. Goodall Nasmyth, M.B.; Caleb Terrey, M.B., C.M.; John Warnock, M.B., C.M.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, December 3rd, 1885:—

John Kingdon Frost, Dunhered, Saltash; Sydney Blake Jolly, M.R.C.S., Home Lea, Lansdown, Bath; Alfred John Stethorn, M.R.C.S., 1, Wetherby Terrace, South Kensington, S.W.

The following gentleman passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise:—

William Henry Cossens, 37, St. Mary's Terrace, Paddington.

The following gentlemen also on the same day passed their Primary Professional examination:—

William Frederick Brook, St. Thomas's Hospital; William Gostwycke Sargent, The London Hospital.

EDINBURGH UNIVERSITY — FACULTY OF MEDICINE. — The following bursaries have been awarded: 1. The Thomson Bursary, for the preliminary examination, has been awarded to George M. Cullen, a preferential candidate. 2. The Grierson Bursary, for the same examination, to W. B. Drummond. 3. The Neil Arnott Prize, for experimental physics, to David Traill, M.A. 4. The Grierson Bursary, in the subjects of chemistry, botany, and natural history, to Robert Muir. 5. The Grierson Bursary, in the subjects of anatomy and institutes of medicine, to J. H. Ross Garson. 6. The Grierson Bursary, in the subjects of materia medica and pathology, to Joseph Tillie.

It is reported from Montreal that the small-pox epidemic has almost come to an end, though cases of the disease continue to occur.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY AND PROVIDENT DISPENSARIES.—We are requested to publish the following letter: Sir,—I have to acknowledge the receipt of your note enclosing the two resolutions passed at the meeting of the Council of the West London Medico-Chirurgical Society, held 20th November. In consequence of these resolutions, I must ask you to remove my name from the list of members of your Society. I take this step with the less regret for the following reasons. *Firstly*.—That at the last meeting of your Society a matter seriously affecting the professional status of a member was allowed to be discussed without any notification having been given that his conduct was to be called in question. *Secondly*.—That the resolution passed, neither being on the agenda paper nor arising from the minutes of the last meeting nor being proper business for an ordinary meeting of the Society, was out of order and should not have been allowed to have been put. *Thirdly*.—That a member of your Society, an official, I believe, sent to the *Lancet* what purported to be an account of the proceedings, in which he suppressed the statement of the President to the effect that the Council had already decided that the West London Medical Aid Institute was not a private dispensary, and in addition so misquoted the rule of your Society as to make it appear that the Society had some show of reason for their conduct in referring the matter again to the Council. *Fourthly*.—That the Council, without making any attempt to find out the true facts of the case, have reversed their previous decision and have declared that the West London Medical Aid Institute is a private dispensary carried on for the personal gain of the medical staff. That this decision is purely capricious, the following resolution unanimously passed by our Committee will show—"That the appointment of the medical staff shall rest with the Committee alone, who shall have power

to regulate the duties of, to add to, or remove any member from, according as the duly considered interests of the Institute shall require. That the services of the medical officers shall remain *gratuitous* until, in the opinion of the Committee, the finances of the Institute will satisfactorily allow some remuneration to be begun, and the Committee shall then decide upon the amount and plan of such remuneration." I note that your Council refer in their resolution to the arrangements we make for the treatment of non-members. I beg to enclose the circulars of the South London Medical Aid Institute and of the Hammer-smith and Fulham Sick Clubs, on the staffs of which you will find the names of several members of your Society. You will see by the advertised rules that they each arranged for the treatment of non-members, the first-named on precisely the same lines as the W.L.M.A.I., the two latter by charging an entrance fee of 5s. and admitting the patient at once on payment of the usual weekly payment of  $\frac{1}{2}d.$  or  $1d.$  The weekly payments to be kept up throughout the illness, at the end of which the patient may, if he chooses, of course, retire from the club. The medical officers see the patients at their (the medical officers') own houses, or visit them, if necessary, and supply them with medicines. Perhaps the Council, if these facts are laid before them, will declare that each of these gentlemen carries on a private dispensary for his own personal gain. I need scarcely say that I do not admit for one moment that I have broken Law II. of your Society either in the spirit or in the letter. I resign my membership simply because I consider that I have received neither the courtesy nor the justice which every member of our profession has a right to expect from his fellows. I must beg of you to lay this before the Society at its meeting on Friday next, and to let it form a part of any account you may think it proper to send to the medical press of the proceedings. Failing this, I shall exert my right of publishing the whole proceedings.—I am, Sir, yours faithfully, PHILIP BIRCH, 2, Tretower Road, West Kensington, December 3, 1885. —To the Hon. Secs., West London Medico-Chirurgical Society.

EDINBURGH HEALTH LECTURES.—The series of weekly lectures promoted by the Edinburgh Health Society was continued on Saturday evening in the Free Assembly Hall by Dr. P. A. Young. There was a large attendance, presided over by Councillor Cox. With "Milk in Relation to Public Health" for his subject, Dr. Young set out with the observation that his chief object was to enforce the importance of milk as an article of diet, and the consequent necessity for the proper arrangement and supervision of the milk supply of large towns. With this view, he in the first place explained the composition of milk, and, enlarging thereafter on its dietary prominence both in health and in disease, and pointing out, also, that no single article of diet could in any way approach it as a nutrient agent, he said it could not be too frequently urged upon mothers and upon all concerned in the rearing of children that, till infants were six months old, they should be fed entirely on milk. Some years ago, he said, he went into the house of an intelligent, steady, and hard-working man, and found his family of young children at tea. On his pointing out the danger of tea for children, and the superiority of milk, the man demonstrated to him that with his small wages he could not possibly afford the quantity of milk his family would drink. This he (the lecturer) believed to be quite true; and what he would suggest would be the use of skim milk or butter milk, which were cheaper, and which, where new milk could not be obtained, were excellent substitutes. Having in this same connection expressed regret at the falling-off in the use of "halesome parritch," the lecturer went on to urge the necessity of the milk supply of large towns being properly arranged and supervised. First he noticed the various methods by which good milk might be known; then he called attention to the ingredients with which it was often adulterated, and also to the diseases which might be communicated through it; and, lastly, he considered the precautions which should be taken and legally enforced, in order that milk supply might be pure and uncontaminated. Regarding precautions against adulteration, he urged that, for the ends of justice

and for the sake of the public, some recognised standard as to what constituted good milk should be declared by the authorities, so that medical officers of health and analysts might have some grounds for recommending prosecutions. Mr. Falconer King told him, he said, that three-fourths of the milk sold in Edinburgh, sent to him for analysis, was adulterated. This surely was not as it ought to be. Desiderating certain precautions in the distribution of milk, the lecturer said he could not too sharply condemn the practice which obtained in Edinburgh of having milk carried in open cans, where the lid was taken off at every door when milk was handed in, exposing it to dust and other impurities. Above all, he could not speak too strongly against the custom of dipping the measure into the can each time milk was given out, causing the hand of the distributor to be introduced into the milk. The danger of communicating skin diseases and other forms of malady was very evident. To obviate this, cans with taps at the bottom, or wooden barrels with taps, as they had in the west country, would be preferable. At the close, Dr. Young was heartily thanked for his lecture.

**CONVICTION FOR ILLEGAL PRACTICE.**—At Southwark Police Court on Thursday week, Henry Clifford, *alias* Professor Clifford, described as of the Medical Institute, 68, St. George's Road, Borough, was charged on remand with representing himself to be a physician at the above address. Mr. Washington, who appeared for the defendant, said he never pretended to be a medical man, but employed a physician in all cases that required attention. Mr. Bridge said he had read a bill which had been circulated by the defendant, and was of opinion that it was so worded as to make the public believe that the defendant was a qualified physician. He, therefore, had no hesitation in convicting the defendant. He fined him 20*l.*, the alternative being two months' imprisonment.

**A LARGE TURPENTINE FARM.**—The largest turpentine farm in the world is located at Live Oak, Florida. The owners run eight stills, over 25,000 acres of well-timbered land, employ over 300 hands (chiefly convicts), work 100 crops of boxes (1,200,000 tons), and turn out annually nearly 30,000 barrels of rosin and 6,000 (300,000 gallons) spirits of turpentine.—*Philadelphia Medical Reporter*, November 7th.

**PROPRIETARY MEDICINES IN THE UNITED STATES.**—According to the last United States' census there are 563 establishments there devoted to the "proprietary medicine" business, employing 4,015 operatives, with an aggregate investment of capital amounting to 10,620,000 dollars, and the annual produce is valued at 14,682,000 dollars.—*Boston Medical Journal*, November 19th.

**PHOTOPHOBIA.**—Dr. Wecker recommends the following for relief of photophobia and orbicular spasm antecedent to the removal of foreign bodies from the conjunctiva:—Distilled water, ʒ iij, Hydrochlorate of Cocaine, gr. iv, Corrosive Sublimate, gr.  $\frac{1}{10}$ ; two drops in the eye.—*Philadelphia Medical Reporter*, November 7th.

**EATING GLASS.**—The *New York Medical Record* (Oct. 17th) states that "Dr. Burke, of Texas, sends us the following curious account, for the authority of which he vouches:—'I witnessed the other day what seemed to me to be an impossibility, a human being eating glass, I might say, by wholesale. I had heard of the negro before he reached our town, and I, like all others, disputed his ability to eat glass without its doing him serious injury. When he arrived I witnessed his exhibition both in private and public, and I am now thoroughly satisfied, from careful examination of his mouth and throat, before and while eating the glass, that he eats it fairly and squarely. He is not very particular to chew it very fine. I saw a piece in his mouth, after he had chewed it, a quarter by half-an-inch long, made into all kinds of shapes and sizes by crushing it with his teeth. He informed me that he had been at it for 20 years, and had never had the least discomfort from its effects, and that he has daily passages of glass through the bowels. He eats it in any quantity, from a small piece to a whole lamp-chimney at a time, and keeps

it up during the day, making his living by exhibiting his extraordinary power.'"

**THE BAROMETER AS A GUIDE TO HEALTH.**—Dr. Veeder (*New York Medical Record*, Nov. 7th) observes that the fact is familiar that many persons liable to rheumatism, headache, and similar ailments are liable to reproduction or aggravation of their pains when barometrical changes take place, and are enabled by means of these pains to foretell changes in the weather. This he attributes to difficulty in the adjustment of the volume and rate of the circulating blood to the varying atmospheric pressure on the surface of the body. Ordinarily the results are not serious; but Dr. Veeder believes that there are cases in which barometrical movements are of prognostic value. He has noted several deaths from apoplexy at times when there were excessive fluctuations of atmospheric pressure, and he believes that at such times over-excitement, over-eating, improper clothing, and the like may induce most disastrous consequences in those who are predisposed to apoplexy, the weakened blood vessels being already subjected to unusual strain by unfavourable atmospheric conditions. He recommends, therefore, that those who are advanced in years, or are subject to indications of an apoplectic tendency, should be warned to exercise great moderation in all things whenever mercury is seen to be unusually active in its movements.

#### APPOINTMENTS.

- BOSTOCK, JOHN, M.R.C.S., L.S.A.—Assistant Medical Officer to the Shoreditch Infirmary.  
 CLARKSON, HERBERT GEORGE HAROLD, L.R.C.P. and S. Edin.—Medical Officer to the Eastern District, Pateley Bridge Union, *vice* Mr. F. H. Saunders.  
 COTTON, CHARLES, M.R.C.P. Edin., M.R.C.S. Eng., L.M.—Medical Officer to the Ramsgate District, Isle of Thanet Union, *vice* Mr. W. Curling, resigned.  
 GOSSE, HOPE WILKES, M.R.C.S. Eng., L.R.C.P. Edin., L.M.—Medical Officer to the Eccleshall District, Stone Union, *vice* Mr. J. W. Hopkins, resigned.  
 KING, ERNEST E., M.R.C.S. Eng., L.S.A. Lond.—Assistant Medical Officer and Dispenser to the Central London District Sick Asylum, *vice* Dr. G. L. Galpin, resigned.  
 SAVILL, T. D., M.D.—Resident Medical Officer to the New Infirmary at Paddington.  
 SIDNEY, H. C. M., M.D. Lond., B.Sc., M.R.C.P.—Physician to the Dispensary for Foreigners.  
 SPREAT, F. A., M.R.C.S.—Registrar to the North-West London Hospital.  
 TRATMAN, FRANK, M.B. Lond., L.R.C.P., M.R.C.S.—House Surgeon to the London Hospital.

#### VACANCIES.

- BLACKBURN AND EAST LANCASHIRE INFIRMARY.—House Surgeon. (*For particulars, see Advertisement.*)  
 BOROUGH OF OLDHAM.—Medical Officer of Health. (*For Particulars, see Advertisement.*)  
 MALTON UNION.—Medical Officer to the Rillington District, in succession to Mr. J. Hindle, resigned. Area, 22,970 acres. Population, 2,677. Salary, £30 per annum.  
 THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO BRIDGE ROAD, S.E.—Physician. Candidates must be Graduates in Medicine of one of the British Universities, and Fellows or Members of the Royal College of Physicians. Applications, with testimonials, to be addressed to the Secretary on or before December 16th. Also, House Surgeon. Honorarium of £70 per annum, with board and lodging in the Hospital. Candidates must be Fellows or Members of the Royal College of Surgeons of England, and Licentiates of the Society of Apothecaries or of the Royal College of Physicians, or Graduates in Medicine of any recognised University. Applications with Testimonials to be sent to the Secretary on or before December 16th.  
 THE VICTORIA HOSPITAL FOR CHILDREN, QUEEN'S ROAD, CHELSEA, AND CHURCHFIELDS, MARGATE.—Senior Surgeon, also a Second Surgeon. Candidates must be Fellows of the Royal College of Surgeons of England, not practising Midwifery or Pharmacy. Applications, with copies of testimonials, &c., to be sent to the Secretary on or before December 21st.  
 TORBAY HOSPITAL AND PROVIDENT DISPENSARY, TORQUAY.—Junior House Surgeon and Dispenser. Salary, £90 per annum, with board, lodging, and attendance. Candidates must be qualified in Medicine and Surgery, registered under the Medical Act, and unmarried. Testimonials to be sent to the Hon. Secretary, W. H. Kitson, Esq., Torquay, not later than January 1, 1886.  
 WANDSWORTH AND CLAPHAM UNION.—Assistant Medical Officer to the Infirmary, in succession to Dr. J. Wilson, resigned. Salary, £120 per annum.  
 WEST DERBY UNION.—Medical Officer to the West Derby South District, in succession to Mr. J. Newton, resigned. Salary, £125 per annum.

## DEATHS.

CARPENTER, WILLIAM GUEST, F.R.C.S., at 105, Fernlea Road, Balham, on December 3rd, aged 70.  
 EATON, J. C., M.R.C.S., L.S.A., at Ancaster, on December 7th, aged 41.  
 GILCHRIST, JAMES, M.D., at Linwood, Dumfries, on December 7th.  
 JOYCE, WILLIAM, M.R.C.S., L.S.A., at Ashby-de-la-Zouch, on December 5th, in his 54th year.  
 JULIUS, GEORGE CHARLES, M.D., at Claremont House, Tilford, Farnham, Surrey, on December 1st, aged 81.

## NOTES, QUERIES, AND REPLIES.

## APPENDIX TO THE MEDICAL DIGEST.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—The time draws near when the MSS. of the 1st Appendix to the "Medical Digest" must pass into the printer's hands. Dr. Walshe has very kindly accepted the dedication of the work, therefore it is all the more necessary to render it worthy of his name. Will you, therefore, allow me again to beg of your readers to send me at once notice of any errors discovered, and also allow me to return my thanks to those, I regret to say comparatively few, gentlemen, who have up to the present time acceded to my request.

I am, Sir, yours, &c.,  
 RICHARD NEALE, M.D. Lond.,  
 60, Boundary Road,  
 South Hampstead, N.W.

December 5th, 1885.

## COMMUNICATIONS RECEIVED—

Sir VILLERS LISTER, London; Dr. NEALE, London; THE REGISTRAR-GENERAL, Queensland; Messrs. J. H. PECK & Co., Liverpool; THE SEC. OF THE PARKES MUSEUM OF HYGIENE, London; THE EDITOR OF THE "NEW BEDFORD MERCURY," New Bedford, U.S.A.; Dr. ALLCHIN, London; THE SEC. OF THE SOCIETY OF APOTHECARIES, London; THE REGISTRAR-GENERAL, Brisbane; THE SEC. OF THE LONDON SOCIETY FOR THE ABOLITION OF COMPULSORY VACCINATION; THE SANITARY COMMISSIONER FOR THE PUNJAB, Lahore; THE SEC. OF THE MEDICAL SOCIETY OF LONDON; Mr. T. PRIDGIN TEALE, Leeds; THE SEC. OF THE ROYAL INSTITUTION OF GREAT BRITAIN, London; THE SEC. OF THE YOUNG MEN'S CHRISTIAN ASSOCIATION, London; Mr. H. P. DUNN, London; OUR VIENNA CORRESPONDENT; THE SEC. OF THE STATISTICAL SOCIETY, London; THE REGISTRAR-GENERAL, Edinburgh; THE REGISTRAR-GENERAL, London; OUR LIVERPOOL CORRESPONDENT; Messrs. WILLIAMS & Co., London; THE HON. SEC. OF THE SOCIETY OF MEDICAL OFFICERS OF HEALTH, London; Dr. PRINGLE, London; THE SEC. OF THE PATHOLOGICAL SOCIETY, London.

## BOOKS RECEIVED—

Remarks on the Treatment of Urethral Stricture, etc., by Reginald Harrison, F.R.C.S.—Notes on Books, by Messrs. Longmans & Co.—Correspondence respecting the International Sanitary Conference at Rome—Transactions of the Pathological Society of London, Vol. 36.—Transactions of the Clinical Society of London, Vol. 18—Manuel de Technique des Autopsies, par Bourneville and P. Bricon—Fagge's Principles and Practice of Medicine, Vols. 1 and 2—The Inertia of the Eye and Brain, by James McKeen Cassell.

## PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—The Hospital Gazette—Revue Médicale—Journal of the American Medical Association—The Medical Chronicle—The Zoophilist—The Birmingham Medical Review—The Glasgow Medical Journal—The Australian Medical Gazette—The Boys' Own Paper—The Leisure Hour—The Girls' Own Paper—The Sunday at Home—Friendly Greetings—The Practitioner—Scienze Mediche—Revista de Medicina.

## HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.; Chelsea Hospital for Women, 2.30 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the Principles and Practice of Medicine and on Clinical Medicine.

LECTURE IX.—CASE TAKING.

*Personal History.*

*Sex—concluded. Civil State.*

THERE yet remains, for brief consideration only, another aspect of the sexual influence on disease, viz., the limitation it exercises in hereditary maladies. The exact share that each parent takes in the fashioning of the offspring is very uncertain. Even as the boys structurally resemble the father, in physiognomy and manner they frequently are more like the mother, and the same may be seen in the girls of a family. But, inasmuch as the embryo results from the fusion of the two sexual elements, it must be considered as deriving a portion of its structure from each parent, though which part is to be attributed to each, or whether indeed such a statement of the question is

allowable, is wholly unanswerable. Some have suggested that the male parent is largely responsible for the organs developed from the epiblast, the skin, and its appendages with the nervous centres, as the hypoblastic structures were particularly related to the female ancestor; whilst another view, and one that appears to have much to recommend it, is that the feminine share in reproduction and development is conservative, being to preserve and hand on all the parts that belong to the race, whilst the male confers the tendency to variation and stamps the impulses to higher development on the common product of organisation.<sup>1</sup> "The limitation of heredity by sex cannot yet be regarded as established," wrote Mr. Herbert Spencer in 1864<sup>2</sup>, "while in many cases it seems clearly manifested; it is in other cases manifested to a very small degree, if at all. In Mr. Sedgwick's essays will be found evidence implying that there exists some such tendency to limitation, which does or does not show itself distinctly, according to the nature of the organic modification to be conveyed. But more facts must be collected before any positive conclusions can be reached." I do not know that we can go much beyond this position today. Mr. Sedgwick's articles<sup>3</sup> still remain the most elaborate contribution to a knowledge of the subject,

<sup>1</sup> "The Law of Heredity," by W. K. Brooks, Baltimore, 1883.

<sup>2</sup> "Principles of Biology," vol. i., p. 253.

<sup>3</sup> *British and Foreign Medico-Chirurgical Review*, 1861, vols. i. and ii.; 1863, vols. i. and ii.

and I would recommend you to refer to them for illustrations of the most varied diseases which in the course of hereditary transmission are for the most part limited to one or the other sex. As a result of his extended investigations, Mr. Sedgwick is "disposed to think that sexual limitation in the transmission of diseases is more common in females than in males," and gives numerous examples showing the occurrence of an imperfection in an illness in the males of successive generations, being transmitted through the female line. In a previous lecture I referred to atavism as contrasted with direct transmission, and gave you an illustration selected from Mr. Sedgwick's records. It would seem that diseases of the skin and its appendages with the organs of the senses are more prone than other organs to exhibit a sexual limitation in propagation; that is, affections of those structures when appearing in successive generations tend to be limited in their occurrence to the members of one sex, with rare exceptions appearing in the other. If such limitation comes hereafter with increased knowledge to be strictly defined, it will help a good deal to a clearer comprehension of the comparative influence of the male and female parents on the offspring. "So far there is abundant evidence to show the occurrence of the restriction is neither infrequent nor capricious, but in some diseases is constant and regular, whilst in others, in which it is only occasionally observed, it is so evidently the result of a strong controlling influence that it may safely be referred to some law of their development, which, absolute in the one case, has to struggle, as it were, to express itself in the other. Although, why the limitation occurs in connection with some diseases, and not others, it is impossible to say, any more than why some diseases are hereditary and others not, or why some diseases only occur once in a life-time." (Sedgwick.) The influence of age in this sexual limitation has also to be taken into account, just as it has in the actual transmission of disease and in the prevalence of certain maladies in one or the other sex. The characters which appear late in life in one sex, observes Darwin, are transmitted exclusively to the same sex.<sup>4</sup>

This is not the occasion to indulge in the speculations that the foregoing observations suggest, but enough will have been said to show the influence that sex exerts in the causation and manifestation of disease, furnishing thereby data for diagnosis that may not be disregarded. I would again remind you, before passing to other matters, that the three factors which I have been concerned in explaining to you, age, sex, and hereditary predisposition, are inextricably interwoven in their operation, and, though treated of separately by me, must be remembered as combining to bring about the results that will come before you, and hence exists the necessity on your part for the most careful and accurate enquiry if you are to discriminate the part which each plays.

*Civil State.*—The next subject to which you direct your attention in investigating your patient is to ascertain if he or she be single, married, or widowed, and the number of the family, if any.

The effect of marriage upon the individual as regards the general health and the liability to disease would seem to be of a twofold character. First, there is the improvement in the circumstances and surroundings which should reasonably be expected to accompany the state; the "settling down" of the man, as it is popularly spoken of, and the cessation of those excesses, slight or great, which as popularly are supposed with varying grounds of reason to characterise the bachelor existence. Equally, for the woman, marriage means in the majority of cases a protection

from many untoward influences, mental and bodily. Beyond these indefinable, yet none the less real<sup>7</sup> circumstances, which differ within the widest range in both sexes and among individuals, there are the direct sexual effects which exercise a most definite effect upon the health power of both men and women. It should not be forgotten that the function of reproduction, attended with risks of its own though it be, contributes, when properly carried out, to the healthy life of the individual, and the non-performance of it *per se* confers a liability to disease.

The actual facts in support of the view that the married state is the healthiest are not easy of acquirement, but yet some statistics on the subject have been prepared by M. Bertillon, and presented by him to the Academy of Paris in November, 1871,<sup>5</sup> which are sufficiently illustrative of the assumption. Thus the mortality per 1,000 living of the married, single, and widowed at different ages he reckoned as follows:—

	25-30 years.		30-35 years.		35-40 years.	
	Males.	Females.	Males.	Females.	Males.	Females.
Married ..	6	10.5	7	9	7.5	—
Single ..	10	11	11	11	13	—
Widowed ..	22	17.5	19	17	17.5	—

Beyond 45 years of age, the death-rate among married women was still lower than among the spinsters and widows, and the table shows, with all allowance being made for accidental circumstances, the more favourable condition of the married state. The same is also to be noticed when special diseases are considered. Insanity is more frequent among the unmarried, and in the recent epidemic of cholera in Paris M. Bertillon showed, in the official report, that of 1,338 deaths among men, at all ages from 25 to 75, 936 were unmarried. The influence of marriage upon women in respect to diseases peculiar to them is not less marked. "The female who has passed the age of 30 unmarried is more liable to suffer from the development of a fibrous tumour of the uterus than the sterile woman or one who has borne children, and the sterile more likely than the fruitful woman. At the same time the woman who has borne children is not exempt from these growths, but, as a rule, only suffers after she has been rendered sterile from some other cause."<sup>6</sup> A preference is also exhibited by different diseases for the single or married state; thus sarcoma of the uterus rarely occurs in the woman who has borne children, whilst epithelioma usually attacks healthy women who have had families. Mammary cancer is met with far more frequently among married women. Of 160 cases recorded by Nunn, only 22 were single women, and of the 138 married 51 were sterile, whilst 87 had an average of 5 children each. Marrant Baker observed among 260 cases that 23 per cent. were single, 74.4 per cent. were married, and 4.6 per cent. widows, and the more extensive records collected by Gross show an even greater risk to the married state in this disease. Of 688 cases only 81 or 11.7 per cent. were single, leaving 88.3 per cent. married.

<sup>5</sup> Quoted by Dr. Southey in his lectures on Personal Hygiene, *Lancet*, 1876, vol. i., p. 340.

<sup>6</sup> "Principles and Practice of Gynaecology," Dr. Emmett.

<sup>4</sup> "The Descent of Man," Part ii., chap. 8.

Next should be ascertained the ages at which marriage took place. If we consider that the capability of bearing healthy children has not reached its maximum aptitude until the age of 22 (Southey), we shall be in position to estimate the ill effects of too early marriages in tending to impair the health of the individual and raise the rate of mortality. Bertillon has also given figures in support of this statement, for he showed that among 8,000 men the death-rate of those unmarried under 20 years of age was only 7 per 1,000, but that it rose to 50 per 1,000 among those married before the age of 20.

In enquiring as to the number in family, it is most necessary to ascertain the lengths of intervals between the successive pregnancies. Should the births of the children have quickly followed each other, it may help to explain the debilitated state of health the mother may present in the puny, ill-nourished, condition of the children, and this more particularly if the period of lactation have been prolonged, a circumstance that should always be noted. It is a rule, to which few, if any, exceptions should be made, that a child should be suckled until it is 8 or 9 months old, that is, until the first teeth are cut, and should then be weaned. Suckling continued beyond this time is often the cause of much ill to mother and child. You will find it excessively difficult in practice to insist on this rule, for parents can always point to exceptions that have occurred within their own knowledge, and that they will not recognise as the exceptions which they are, preferring to consider them as an example which should be followed. A record of frequent miscarriages should be carefully noted, as, apart from pelvic deformities or uterine disease, it is a frequent evidence of a syphilitic constitution, and thus may put you on a line of enquiry most helpful towards a diagnosis.

---

## PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,

President of the Health Department, Social Science Association.

### DISEASES OF THE RESPIRATORY SYSTEM.

(Continued from page 810.)

#### *Struma and Phthisis in India.*

THERE is certainly exceedingly little "scrofula," as expressed by the ordinary joint and glandular disease, in Lower Bengal. Allan Webb and Kenneth Mackinnon, writing at about the same time, differed in opinion with regard to the prevalence of struma in different parts of India. Mackinnon, speaking mainly from experience of localities at least 400 miles north of Calcutta, says (p. 46) that he has often seen scrofula in the form which Webb states that he has rarely met with—swelling and ulceration of the glands of the neck. Webb enters (p. 125) very carefully into this question in reply to a statement made in the *British and Foreign Medical Review* for July, 1846, that "In India, consumption is rare; scrofula rife." He asserts that, taking Mr. Phillips's test, the existence in the glands of the children's necks of scrofulous swellings, or of the characteristic cicatrices, he has never seen such swellings or ulcerations, nor, consequently, had he occasion

to open them. Dr. Webb held for many years the charge of two charity schools in Calcutta, with an aggregate strength of 561 children, Europeans, East Indians, and Armenians of all ages. Of the boys, only two presented marks. The only girls having marks of scrofula belonged to one family, and were European-bred. The orphan school children were always carefully examined on admission; but, in four years, Webb never saw marks of scrofula. Here there were between four and five hundred admissions to hospital annually, "yet not one entry for scrofula." Dr. Webb had travelled throughout the length and breadth of India. He says, "Among the natives of India inhabiting the lower range of the Himalayan Mountains" (a temperate region, upon which one of Mackinnon's centres of observation, Tirhoot, verges—N. C.) "I have certainly seen scrofulous swellings and ulcers in the neck common; but in no other part of India do I know this disease to prevail generally." So also we are told, in the Madras Report upon the medical topography of the mountainous region of Coorg, the lowest part of which is elevated not less than 3,000 feet above the sea, that there "phthisis is often met with, and is said usually to occur between the ages of 20 and 40." "Scrofula is very common, usually making its appearance at the age of puberty in the form of swellings in the neck, to which ulceration succeeds."

Dr. Webb, and another able authority, Dr. W. A. Green, were agreed in thinking that the most common form of strumous lesion with the natives is "bone disease of an asthenic character." I cannot pretend to offer a valid opinion upon the question of the frequency of bone disease of tubercular origin; but it is certainly noteworthy that my Indian experience of twenty-seven-and-a-half years leaves in my memory only the solitary case of a young lady, reared in a northern temperate district, the child of a highly strumous father, who was deformed by hip-disease. I never saw a case of strumous cervical glands in the plains of India, a great part of which I have traversed, always keeping my eyes wide open. The result of Morehead's twelve years' experience, in the charge of the large Bombay schools, is less full than could be desired; but, as coming from so accurate an observer, it may be regarded as strongly confirming Bengal experience. He says (p. 653), "I do not know what might be the result of the application of the test suggested by Mr. Phillips in his work on Scrofula—viz., "enlarged cervical glands discoverable by touch"; but I believe that I am correct in saying that scrofulous disease of the joints and suppurating lymphatic or tubercular mesenteric disease are of infrequent occurrence." These observations stand out in very strong contrast with the statistics of struma in Europe, and with one of those incisive axioms which were studied like gems throughout Thomas Addison's teaching. I was present when a fellow student, who soon afterwards died of a strumous malady, consulted him upon his case. In answer to a question, Mr.———drew himself up and said—"There is no struma in my family, Sir!" "No," was the reply, "certainly not—it is a remarkable fact that my family and your's stand alone in the United Kingdom as being absolutely free from all taint of struma; but, as a secret, I assure you that everybody else's family is rotten with scrofula!"

Mr. J. Murray, writing on the influence of the climate of India on children,<sup>25</sup> stated that we have the testimony of Sir Astley Cooper,<sup>26</sup> of Alison,<sup>27</sup> and other experienced observers to the fact that children sent from India to England are exceedingly liable to scrofulous disease. This was probably the case under

<sup>25</sup> *Indian Journal of Medical Science*, vol. ix., O.S. p. 525.

<sup>26</sup> *Lancet*, vol. iv., p. 400.

<sup>27</sup> "Outlines of Physiology and Pathology, p. 474.

a system of therapeutics which is now discarded, but I think that the observation is not largely applicable in the present day. With thirty-seven years' knowledge of a multitude of children sent to England, I can only recall the solitary case of a boy,—lodged at an atrociously miscondacted school in a London suburb, where, to my own knowledge, boys of 8 or 9 were wrapped in the rags of womens' garments,—who became the subject of empyema.

In his invaluable commentary on the Diseases of Burmah,<sup>28</sup> Dr. Waring observes, "Scrofula, in any form, is very rare amongst the Burmese."

Fully admitting the fact that nothing is more dangerous than to lay down positive rules in questions of disease, I must state confidently my belief that, *if an individual lands in Lower Bengal with perfectly healthy lungs, and lives well, prudently, and carefully, he will, residing there, never be attacked with phthisis, although he may be a member of a phthisical family.* Against this I may cite Joseph Ewart's observation that people who would probably have become phthisical at home are very liable to dysentery in India, and the fact noticed by several authorities that strumous subjects are especially liable to hepatic abscess in India.

The opinion given in italics above is the outcome of my personal experience of non-military Europeans throughout my Indian Service, and of much enquiry. Thirty years ago, I heard of one case; but as, there, the patient had been cooped up in the fore-castle of a small vessel, my honoured friend, Dr. Henry Mac-Cormac, would doubtless consider that the tuberculosis was artificially produced. As the effect of removing a case of phthisis from Europe to Calcutta is, in the large majority of cases, nearly that of burying a dead body in a hot-bed, there is a great deal of pulmonary consumption, especially among sailors, in the European wards of the Calcutta hospitals. So also, in the cold season, many cases occur among natives; but, in a rough way, this fact is very significant. The London hospitals formerly used, as rigidly as possible, to exclude cases of phthisis, as I believe they still do, seeing that special aid is now afforded to these cases; still, during the many years in which I frequented it, the *post-mortem* room at Guy's was rarely without a case of pulmonary tuberculosis. In Calcutta, it was a standing rule that all phthisical applicants should be admitted to my wards, which, although sometimes nearly filled with cases of consumption, were never overcrowded. Seeing that my own share of beds for native men was only sixteen, this must be regarded as representing no great prevalence of the disease in a city numbering about half-a-million of inhabitants, and in its thickly-populated vicinity.

To me the arguments contained in Morehead's, chapter xxiii., do not appear to bear so directly as could be wished upon the very important question—*to what extent does phthisis ORIGINATE in India?*

His remark, immediately following the heading *Causes*, that "the erroneous opinion at one time entertained of the rarity of phthisis pulmonalis in tropical countries has been long since corrected by the medical statistical reports of the British army, and information from other sources," would be a direct and accurate reply to the mischievous idea, formerly entertained at home, that the climate of India is favourable to phthisical cases, but it must be apparent that the prevalence or rarity of phthisis in our European force in India in no way illustrates the *causation* of phthisis in that country, seeing that, in all probability, a very large proportion of the men who succumb to phthisis in India were the subjects of tuberculosis before they reached that country. I feel little doubt that the

records in the Director-General's Office would supply materials for a return showing the number of men first attacked with phthisis after five years' service in India. This would go directly to the point at issue. Morehead says, "If the history of these" [Byculla] "children be traced after they have grown up and left the schools, it will be found that phthisis pulmonalis is a cause of death sufficiently common. I can bring to my recollection several cases in proof of this." He shows that the number of natives suffering from phthisis admitted to the J. J. Hospital, Bombay, during six years was 445, not many out of so large a population as that city has.

We are told in the Medico-Topographical Report, p. 47, that, in Madras, phthisis "has been frequently met with in Indo-Britons," and that it "has also been seen in European subjects about the age of puberty, and within the first two or three years after arriving in India, but is of rare occurrence after that period; and, in natives, true tubercular phthisis has comparatively been seldom met with."

My friends, Dr. T. W. Wilson<sup>29</sup> and Dr. Joseph Ewart,<sup>30</sup> offer us, in monographs which are replete with facts of the greatest importance to Indian practitioners, a large view of this class of diseases as they have prevailed of late in India. Dr. Wilson shows that, formerly, a great deal of tuberculosis and phthisis was overlooked, especially in native jails; and that cases of phthisis with colliquative diarrhoea were frequently registered under the heads of "Diarrhoea" and "Dysentery." At the Medical College Hospital I always bore this observation in view, and it repeatedly occurred to me to find that an emaciated native, who complained of nothing except an alvine flux, was, in reality, dying of pulmonary consumption. Dr. Ewart shows that, in the decennium 1857-67, 454 cases of phthisis occurred in natives treated in the Calcutta C. M. C. Hospital.

[We have seen that 445 cases of phthisis in natives were treated in the less capacious Jamsetjee Jeejeebhoy Hospital, Bombay, in six years.]

Ewart shows that, in the six years 1871-76, the ratio per 1,000 of strength treated for phthisis amounted to 9.0 among the soldiers of the European army in India. In the native army of the Bengal Presidency, the corresponding ratio amounted to 2.5. In the jail population, it varied from 1.5 in the Central Provinces to 8.9 in that of the Gangetic Provinces and Oude. In the aggregate of the jails of the Bengal Presidency the ratio was 4.2 per mille. He further demonstrates that, according to Aitken, the ratio of admission for phthisis in the British army, from 1861 to 1862, ranged from 9 to 10 per 1,000; and, in the American army (1862-63), from 8 to 10 per 1,000. Consequently, the prisoners in the jails of the Gangetic Provinces and the soldiers of our European army throughout India were then scarcely less prone to phthisis than soldiers at home were. He draws the same deduction with regard to the women and children in European barracks.

In happening to take the statistics of the six years 1871-76, *i.e.*, in showing that the admissions for phthisis in our European army in India were 9.0 per mille, Dr. Ewart places the matter in its worst aspect. Thus Mr. Macpherson found that, in the four years ending 1853-54, in the Bengal Presidency, "pulmonary consumption brought under treatment  $\frac{2}{5}$  per cent. of strength, less than one half the number in England, and of deaths to treated  $44\frac{9}{10}$ , or 30 per cent. less." "Spitting of blood contributed to the admissions  $\frac{1}{7}$  per cent. of strength, or one-third fewer than in Eng-

<sup>29</sup> "On Tubercular Disease in the East," "Indian Annals of Medical Science," No. 3, p. 182.

<sup>30</sup> "On Scrofula, Tuberculosis, and Phthisis in India," "Transactions of the Epidemiological Society," vol. iv., Part iv., p. 597.

<sup>28</sup> "Indian Annals of Medical Science," No. 1, p. 101.

land; and of deaths to treated  $\frac{7}{10}$ , or  $1\frac{1}{2}$  per cent. less."

The Returns for the whole European Force in 1881 give an admission rate of 7.1. In the native army it was 2.9.

The Returns for 1881 show that only one *child* of a European regiment was admitted (in Bombay) for "scrofula" in the army of India, the strength being 6,548. There were, during the same term, 43 admissions of children for phthisis and 24 deaths. The admissions for tabes mesenterica were 15, with 1 death. Among the *women* there was one case of scrofula, which was fatal; among them, the admissions for phthisis and hæmoptysis were at the rate of 11.2 per mille of strength.

I think that, undoubtedly, the great prevalence of phthisis in European barracks in India points to the necessity for an enquiry as to whether these buildings, or, at least, those of them in which a large amount of phthical disease occurs, are properly ventilated and are not overcrowded. Then a plain suggestion offers itself. A regiment, 1,000 strong, is drawn up on a wharf just before embarkation for India. We know that, healthy as their appearance is, some 9 or 10 of these men will be admitted to hospital for phthisis within the next twelvemonth. Ought not these and more to be eliminated from the draft, seeing that, in all probability, all in whom the disease is latent will die in India within their first year's service, and would, almost certainly, wear on much longer at home?

The most extreme case of miliary tuberculosis I ever saw occurred in a prisoner in the mud jail at Purulia. Wherever I was able to trace fully the history of a native phthisis case, I found that its subject had inhabited an ill-ventilated brick or mud building. I never succeeded in tracing a case to a bamboo hut. Upon Dr. MacCormac's doctrine, I believe that the immunity from phthisis of well-to-do Europeans in Lower Bengal is mainly due to the free ventilation of their sleeping-rooms. I regard this very remarkable immunity as a strong argument against the heredity of phthisis.

I think that I may say confidently that none of the many phthical European sailors whom I treated lived, after their arrival in India, so long as five months. I cannot recall a single case of "Discharged Relieved," although there were many of these in the native wards. The picture of a European dying of phthisis in Calcutta is one of the most painful in hospital experience. The bowel complication usually takes on a dysenteric character and occasions extreme distress. The heat of the climate induces and greatly aggravates colliquative sweating. Every one who thinks of sending a phthical patient to a hot climate should look at Severn's masterly sketch of the face of Keats in his death sweat at Rome. In India, I never saw the disease borne with that cheerful hopefulness which characterises many of these cases at home. The phthical European in India is generally so despondent, irritable, and captious that I used often to approach the beds with an uneasy doubt,—what new grievance is to be adjusted to-day? Hectic is usually very pronounced. If these unfortunates arrive in the cold weather, the next hot season will be fatal; if in the hot weather, and they survive it, the change of temperature at the beginning of the cold season will probably excite intercurrent pneumonia and kill them. In nearly all European cases the destructive process is exceedingly rapid. A young gentleman who had suffered from hæmoptysis in Scotland came to my house soon after landing. He appeared to be in fair health. Shortly afterwards, I attended him in an attack of hæmoptysis from the left apex. The hæmorrhage readily passed off, and there remained no evidence of lung disease anywhere,

save a little increase of sub-clavicular vocal resonance (which is frequent in healthy persons) on the affected side. I did not see him afterwards. A week or two later, an accomplished brother officer, having carefully examined his lungs, remarked that, but for the history, he should have considered the chest perfectly healthy. From this time "decline" was rapid and he died in about three months. His lungs were brought to me. Tubercle had proliferated to so enormous an extent that the organs were solid. He must have died suffocated. There was no history of intercurrent pneumonia.

Morehead was inclined to subscribe to the opinion that "phthisis runs a more rapid course in warm than in cold climates," on the ground that "in all diseases which include destructive degeneration of structure and co-existing hectic fever the rapidity of the course will bear relation to the number and degree of the debilitating influences to which the individual is exposed." Among such influences he enumerates Heat, Malaria, a greater proclivity to intestinal ulceration, and, as causes of intercurrent pneumonia and bronchitis in natives, weak constitution, insufficient clothing and lodging.

At p. 128\* of his great work, Webb draws a most striking picture of the misery caused by the fatal impression, then prevalent in England, that the climate of India is favourable to the strumous and consumptive. He says, "I have seen medical men, clergymen, officers in the service, &c., who have told me, when surprised with the fatal turn of these cases, that they expected to *get well here*. I have seen young and beautiful European ladies carried off with appalling celerity. I have seen quite young soldiers who, if they do not quickly die, are sent home wholly unfit for this or for any other service."

The question, "*Is the climate of Indian Hill Sanitaria beneficial in Scrofula, Tuberculosis, and Phthisis?*" has been most thoroughly argued out by Dr. Joseph Ewart.<sup>31</sup> I believe that all medical men of Indian experience will agree in the validity of his conclusions, (1) that the hill sanitaria of India are beneficial to persons afflicted with scrofula only; (2) that they are useful in the warm months of summer, (a) in uncomplicated and simple tubercular consolidation, (b) in tubercular affection in which previous inflammation of the adjacent lung and the bronchial mucous membrane has subsided, and (c) where this is proceeding in the direction of repair by absorption, cicatrization, or cretification; and (3) that they are injurious, probably at all seasons, but in an aggravated degree in the cold season and rains, to all cases of active and advancing pulmonary consumption."

I have the following very scanty evidence tending to show that the climate of the East and West Indies is not *certainly* fatal to European consumptives. A London surgeon who was phthical spent some months in Jamaica. He appeared improved in health on his return; and, subsequently, his case proved to be remarkably chronic. A strong-looking middle-aged gentleman told me in Calcutta that, having, when young, suffered very severely from hæmoptysis, that excellent man and physician, Thomas Hodgkin, sent him to Jamaica, where he recovered. A young medical officer who arrived in Calcutta *circa* 1858 was attacked with hæmoptysis almost immediately upon landing. When he was convalescent, the head of our department, Sir John Forsyth, whose secretary I was, said to me, "What can we do with W—? We can neither send him home nor to the Upper Provinces. He shall go with that detachment to Dibrughur in Upper Assam. He

<sup>31</sup> "Transactions of the Epidemiological Society," vol. i. for 1881-82, p. 26.

will have a pleasant voyage of some days up the Bramapootra, and the climate is temperate." Dr. W— had no return of his disease. Most of his service was at the above station, and he has lately retired with the appearance of a remarkably powerful and healthy man. The climate of the mountain sanitarium of India is inimical to consumptives. I have seen Dibroghur, and certainly do not consider that the stream of consumptive patients ought to be directed thither; but there, and in the hills of Jamaica, there is a moderate climate which may probably agree with some consumptives. These three exceptional cases do not appear to bear upon the rule, denouncing hot resorts in phthisis, laid down above. I had some experience of recovery from incipient phthisis in natives of India. I need hardly say that hard-working students often suffer from transient hæmoptysis. Sir Astley Cooper did, and directed that those who examined his body should look for the traces. I had very slight hæmoptysis, and long afterwards coughed up an earthy concretion. Several of my military class students, Mahomedans, had severe attacks of hæmoptysis from which they so completely recovered that when, upon the completion of their three years' term of study, it was my duty to examine them, I did so with especial care and could not find any evidence of pulmonary lesion. In examining the body of a dakoit (professional robber) who had been hung, I found a cavity, about as large as an orange, in the upper lobe (below the apex) of the right lung. It was neither a dilated bronchus nor a pneumonic abscess, but clearly a phthisical vomica in process of recovery. There were no tubercles. He was of middle age, gaunt, but wiry, and his history showed that his habits were only too active.

I lately heard of the very sad, but interesting, case of an officer who, before he went to India, was considered to be so much predisposed to tuberculosis that he was strongly advised not to marry. After some years' Indian service, he became and continued to be a very strong and healthy man. He married; two of his children, having arrived at adult age, have died of phthisis, and three others are threatened.

In recent conversations with my friends, Brigade-Surgeons J. Barclay Scriven and Dr. William Palmer, who are equally experienced in the diseases of the North-Western Provinces and in those of Lower Bengal, I learnt that, although they fully agree in considering that the climate of the latter is most inimical to sufferers from phthisis, they had cases in which the dry atmosphere of the plains of Upper India, say Lahore and Ghazee-pore, stations of which they respectively long held medical charge, appeared to be decidedly beneficial. Further observations on this point are very desirable. I saw and carefully examined, not long before his death, a military officer who, I was informed on good authority, had suffered in Upper India from unmistakable phthisis for ten years.

#### *Treatment of Phthisis.*

I have always held to and acted upon the conviction, expressed in one of my earliest publications,<sup>32</sup> that bronchitis is not essential to and is separable from phthisis, and that, consequently, the leading indication of treatment in this disease is to free the lungs from bronchitis, and to keep them free. Cough does not, of necessity, attend phthisis. Several of my native phthisical patients come into hospital without cough. Edward Goodeve made an excellent observation upon this point in his Cawnpore Dispensary Report for 1845.

<sup>32</sup> "Observations on the Treatment of Phthisis," *London Medical Gazette*, vol. ii. for 1840, p. 782.

"We make it a rule to examine the condition of the chest in all cases of chronic diarrhoea, dysentery, and so-called remittent, but frequently hectic, fever, and in continued fevers in the cold season. The patients often make no complaints of chest disease themselves, their attention being concentrated on the symptomatic fevers and diarrhoeas, or failure of strength. It is necessary to question them closely, to watch the general symptoms of lung affections, and generally to resort to auscultation before coming to a conclusion as to their real complaints. Within twelve months, we have met with every form of pulmonary disease, except the malignant ones." . . . "Tubercular phthisis we have had an abundance of."

This absence of bronchial complication in phthisis has also been observed in England, but here bronchitis is so common that phthisical lungs rarely escape it. A *Hem* is all that is requisite for the expectoration of blood and pus from vomica. If I had a phthisis ward, I would write above the entrance COUGHING IS NOT PERMITTED HERE. In every case that I have treated, this indication has been constantly borne in view. I cannot boast of marvellous success, but I have had many favourable cases, especially in natives, whom I have treated from the first attack of hæmoptysis onward. I relied greatly upon extensive counter-irritation, long continued. As a general rule, neither Europeans nor natives in Calcutta could digest cod-liver oil in phthisis.

In India, the condition induced by tubercular ulceration of the intestines in phthisis is, in many cases, not diarrhoea, but dysentery, and the suffering from this cause is often very great. In reports of the recent case of King Alphonso of Spain, the intestinal complication of phthisis, which caused death unexpectedly, is described as "dysentery." This is one of the forms of dysentery in which the ipecacuanha treatment is inadmissible. My chief reliance was upon opium (a valid anti-dysenteric) and demulcent food. In chronic cases, I have sometimes staved off bowel irritation by dealing very carefully with the troublesome constipation which is its usual precursor. The patients are often most urgent for purgatives, but I never allowed more than the very smallest doses of castor oil. In the last case that I treated, there was constipation for a year before the patient's death, and the bowels were never allowed to become loose. In several miserable cases of excessive ulceration of the rectum some relief was obtained by small enemata of pure opium rubbed up in mucilage of acacia, and the application of warm anodyne poultices externally. I repeatedly noticed that, on a chilly gusty morning in the rains, two or three patients would be attacked with hæmoptysis. This was always commanded by ergot.

I had several cases of phthisis in which *Pneumothorax* occurred. Mine were ordinary typical cases, except that of a middle-aged native who was walking about the ward with no signs of thoracic distress. I was surprised when my house physician called my attention to the splash and the metallic tinkling.

I saw a case of *Primary Medullary Cancer of Lung* many years ago in London. I did not meet with this condition in India, and I do not find notice of any specimen in Ewart's Catalogue. Assistant-Surgeon Dr. Jayakar has recorded<sup>33</sup> a case (encephaloid or melanotic) occurring in a native aged 35 years. I have already cited, under the heading of Cancer, the case of a native, related by Allan Webb at p. 1 (one) of his *Pathologia Indica*, in whom there was melanosis of the lungs and heart.

*Pleurisy*.—Placing aside cases in which pleuritic inflammation was caused by wound or occurred inter-

<sup>33</sup> *Indian Medical Gazette*, vol. v., p. 79.

currently in phthisis, acute rheumatism, or Bright's disease, or where liver abscess made its way into the chest, I only recollect to have seen one case of acute idiopathic uncomplicated pleurisy in Lower Bengal. This occurred in a European who did well. I repeat that my observation applies only to the Delta of the Ganges.

Mackinnon says, "I have seen pleuritis prevail in an epidemic form"; but I can only find one other notice of this disease in his works. "Pleuritis I have seen prevailing among prisoners in jails at certain seasons." In the chapter on Pneumonia I have mentioned that Dr. W. A. Green recorded [Webb's *Pathologia Indica*, p. 106\*] a remarkable prevalence of *Pleuro-Pneumonia* among the prisoners in the Midnapore jail in 1844 and 1845.

In one of his latest publications, Mackinnon barely repeated the fact<sup>34</sup> that he had "*seen pleuritis prevail in an epidemic form.*" A few details would have been most valuable. This probably occurred in his up-country experience.

The Sanitary Commissioner's Returns for 1880, in which year we have seen that pneumonia was remarkably prevalent, give 599 admissions for pleurisy with 61 deaths in the native army. In 1881 there were 377 admissions with 17 deaths. In 1882 there were 266 admissions with 14 fatal cases. The average strength of Sepoys during these three years was 118,630. In these three years, the deaths from this cause of European soldiers, with an average strength of 58,571, were five, two, and four.

Macpherson's tables give 688 cases of pleurisy, and 33 deaths, as occurring during the 8 years ending 1853-54, among the European soldiers in the Bengal Presidency. The percentage of sick was  $\frac{2}{5}$ —twice as large as in England—and the percentage of deaths to treated  $4\frac{1}{5}$ , one-fourth larger than at home.

*Pleurodynia* is very common in Lower Bengal, and is often so acutely painful as at first sight to resemble this disease. My European male ward was so ill-placed that the beds stood in a thorough draught. One damp windy morning, I found the three patients nearest to an open window complaining of pleurodynia on the windward side.

I never saw a case of *Idiopathic Empyema* in a native of Lower Bengal. Prep. 608 in the Calcutta Museum, however, represents "displacement of the heart of a native of Bengal from empyema." A very few other cases are on record. One was reported at the Calcutta Medical Society in 1880, and my friend, Dr. W. Burns Beatson, now of Bath, reported<sup>35</sup> one occurring in a native of Azimghur, who contracted the disease at Dacca, where he had been for some time resident. In 1882 only 4 cases, one of which was fatal, occurred in the native army throughout India—all in the Bengal Presidency—most probably up-country. There can be little doubt that the rarity of this condition is due to the great immunity of the natives of the plains of India from strumous disease.

I knew two gentlemen, a member of the Civil Service and a tea planter, in whom there was great falling in of the thorax consequent upon empyema in youth. In the former, the deformity and the deficiency of lung expansion were more extreme than I have seen in any other case, yet he was a good cricketer. Both enjoyed good health in India, but were accidentally killed early in life.

I had various cases of *Hydrothorax* arising from ordinary causes. In one of these, my diagnosis could have done me but little credit with my class. A northern sailor, from whom I could obtain very little information upon the history of his case, was brought

to my ward in considerable dyspnoeal suffering. He was a muscular square-built man, over 30 years of age, his face and neck were much congested, and the veins of the neck extremely full. Great bulging of the right thorax. Absolute dulness extending over the right pulmonary and hepatic and the cardiac regions. Absence of respiratory and vocal sounds on the right. The edge of the liver was felt below the ribs. A soft systolic aortic bruit extending upwards. I considered this to be aneurysm of the ascending aorta, filling the right thorax, pressing the collapsed lung upwards and the congested liver downwards. This was all wrong. When he sank, it was found that the right pleural cavity was distended with clear serous fluid, apparently an inflammatory product, as the pleural surfaces bore traces of pleurisy. It was evident that the bruit was caused by outward pressure on the artery. Few of my cases have caused me so much after-thought as this has done; but, if I had another like it, I am not at all assured that I could judge it better. I have seen enormous aneurysms of the ascending aorta, none certainly as large as this would have been; still the size of aortic aneurysms can hardly be said to have a limit.

Prep. 780. "Extraordinary lenticular vegetations projecting from the costal pleura like small buttons. Some of these are globular, others more or less elongated. They arise by a broad base, and are covered by a smooth membrane continuous with the pleura, which is greatly thickened. They vary in size from a millet-seed (or small point) to those of a kidney-bean. From a native of Bombay, who died of dysentery."

I saw cases, in Europeans, of *Abscess* and *Non-malignant Tumour* of the *Anterior Mediastinum*.

---

## ON THE REPRESENTATION OF THE MEMBERS ON THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.<sup>1</sup>

By WALTER RIVINGTON, M.S., F.R.C.S.,  
Surgeon to the London Hospital.

As an independent Fellow, unconnected with any Association, and untrammelled by the weight of office at the College, I am unwilling to give a silent vote on the present important and, it may be, historical occasion. For many years it has been obvious to me that this College possesses too close and exclusive a constitution; that the Fellows and Members ought to enjoy the right of meeting annually within the College for the discussion of collegiate and professional affairs; that, looking solely to the present constitution, the Fellows have no sufficient voice in the conduct of the business of the College, partly by reason of the small number of Councillors who vacate office every year, or, in other words, by reason of the length of time, an average of eight years, for which Members of the Council are usually elected; and partly by reason of the practical disfranchisement of the country Fellows, owing to the Charter denying the privilege of using voting papers at the election of Councillors; and lastly, and this is the main point which is before the meeting for discussion, and the point to which my remarks will be confined, that the Members of this College ought to be represented in the Council of the College. In declining to accede to what many believe to be the reasonable claims of Members of the College,

<sup>1</sup> Being a speech delivered on the occasion of the meeting of the Fellows and Members of the Royal College of Surgeons, December 17th, 1885.

<sup>34</sup> "Indian Annals of Medical Science," No. 5, p. 128.

<sup>35</sup> *Indian Medical Gazette*, vol. i., p. 60.

the Council, who are said in their Report to be unanimous, though I trust sincerely that the unanimity is greater in appearance than reality, base their opposition on several grounds. The first ground of opposition is not openly alleged, but rather is insinuated, in an early paragraph in the report. It is contained in the following carefully worded sentence. "With reference to the first resolution of the meeting, the Council have carefully considered the question which *some* Members of the College have recently raised, and it does not appear to the Council that the main argument which *these* Members advance to support their claim, that all the Members should be entitled to vote in the election of Members of the Council, is a valid one." From the use of the phrases "some Members" and "these Members," it is evident that the Council believe that this movement has very little vitality in it, that it has originated from, and is supported by, a small minority, possibly a minority of wirepullers and demagogues who make up by empty clamour for what they lack in inherent strength. If this is the kind of belief which is prevalent in the Council, I would take the liberty of doubting whether it has any solid justification. On the contrary, there can be little doubt that the present agitation is a *bonâ fide* movement, begotten of intrinsic injustice to the Members of the College, and that it must gather fresh strength until success crowns the work.

In the interest of all parties concerned in this controversy, I would earnestly invite the Council to poll the constituency and ascertain the numbers of Fellows and Members in favour of, or adverse to, the representation of the Members of the College in the Council, and by the result of such an appeal let both the Council and the promoters of this movement be prepared to abide. On the one hand, it would be a pity to continue the agitation if only a small minority of the 18,000 constituents of the College favoured the proposal, and, on the other hand, it would be a serious error for the Council to continue to resist the change if they are mistaken in the belief which the wording of their report undoubtedly implies.

The second ground of opposition is comprised in an attempted refutation of the argument that the Members of the College are entitled to representation because they have been taxed, and taxed heavily, for the maintenance of the Institution. The abandonment of this argument altogether would do little to weaken the case of the Members, but, in point of fact, it is not destitute of considerable cogency. The diploma of Member of this College was actually the very dearest single-barrelled licence to practise in the three kingdoms. It was dearer by 6*l.* 5*s.* than the licence of the Royal College of Physicians of England, which entitles its holder to practise both Surgery and Medicine, and it was dearer by 1*l.* than the conjoint licences to practise, granted by the Scotch Colleges in combination. What may be the special rights, privileges, and immunities, and the professional and social advantages, conveyed by the Membership as an equivalent for this extra tax, I have been at a loss to discover, for, beyond the privilege of admission to the Museum and Library, of which comparatively few can avail themselves, and beyond recent eligibility to examinerships and lectureships, which not 1 in 1,000 can ever attain, I know of none, and the lavish way in which the Council spreads all these rights, privileges, and immunities, and social and professional advantages, before the bewildered and incredulous reader inclines one to say, in the language of Shakespeare—

Are such things here as we do talk about,  
Or have we eaten of the insane root  
That takes the reason prisoner?

I had always supposed that the Members of the College were neglected and left out in the cold, and that, from the time of their obtaining the diploma of Membership to the time of their death, they might never receive an official communication from the College unless they had been guilty of some offence which demanded erasure of their names from the Register.

In the third place, the Council shelter themselves behind the Charter of 1843, by which a constituency of Fellows was provided, and to any argument for extension they simply replied, "non possumus," or "Nolumus leges Collegii Anglicani mutari." Now, Sir, I am not one of those who find retrospective fault with the Charter of 1843. That Charter at least abolished an intolerable and effete *régime*, viz., a Council which was a close borough, entirely irresponsible to any body of their professional brethren, and whose Members could only be removed by their own sign-manual or by the hand of death. The Council appointed themselves examiners for life, and the examiners became responsible to themselves on the Council. The oldest Fellows were elected and re-elected Members of the Council, the oldest Members of the Council were elected Examiners, the oldest Examiners President and Vice-President. Whatever injustice may have been done to individuals in the selection of the 250 to 300 Fellows prescribed by the Charter, let it not be forgotten that the Charter recognised the representative principle as the basis of election to the Council, and, by opening the Fellowship to all Members of the College by examination, gave every Member, at all events, a chance of belonging to the constituent body. So much must in fairness be admitted, but practical experience of the working of the Charter shows that this plan of forming a constituency is a failure. The Fellows are a diminishing constituency, and new Fellows are mostly young men fresh from the schools, who cannot be regarded as better qualified to elect Surgeons on the Council than the potent, grave, reverend, and distinguished seniors who would be an honour to any constituency, and who are shut out from the franchise. The fact is that it is a mistake to elevate a merely academic distinction, obtained after an uncertain and occasionally capricious examination, into a test of political capacity and competency.

Lastly, the Council urge that the Members of the College must be excluded from the franchise in order to keep up the attraction of the Fellowship, and in the interests of the Fellows themselves. Can the Council prove that any single Member or person passes the Fellowship, for the purpose of obtaining a vote in the election of Councillors? Surely the Fellowship attracts candidates almost entirely on account of its being a professional honour, and because it carries with it certain conspicuous professional advantages in the competition for public appointments and in the estimation of professional brethren. And then, as to injustice to the Fellows themselves, there can be no injustice to Fellows if an act of justice has to be done to the Members, any more than an injustice to the old parliamentary constituencies was inflicted when the Legislature admitted 2,000,000 fresh voters to the franchise. Exclusive privileges, which can only be maintained by ignoring the just claims of our professional brethren, as worthy and as competent as ourselves to exercise the franchise, so far from being valued, are a source of regret, dissatisfaction, chagrin, and mortification to a large number of Fellows, probably as enlightened, though possibly less distinguished than the illustrious Members of our unanimous Council.

And now, having replied to the arguments adduced in the report of the Council, allow me a few moments

to formulate the grounds on which it is desirable to allow the Members to elect a proportion—a small proportion, if you please to have it so—but still a proportion, say not less than one-fourth, of the 24 Members of the Council. Whatever may be said, the Members are an integral portion of the Corporation; they are the backbone of the College, they are not mere Licentiates, and by the Members the College is alone able to exist. Without them, the College would sink into a Surgeons' club in its present flourishing condition. The Members of the College are generally well-educated gentlemen, fitted to uphold the dignity and honour of the profession in the eyes of the public. And the culture of the great body of the profession improves every year.

The enfranchisement of the Members would place the College on a broader basis and a more stable foundation, for it would rest on a united profession and be upheld by the cordial sympathy,—aye, and on that which the Council can never secure but by generous concession, the affection—of its magnificent constituency.

The measure is absolutely necessary in the interests of the profession at large. The Members, being generally engaged in general practice, are more fully acquainted than most of the Fellows with the wants and requirements of the ordinary practitioner, and better able to appreciate some of the defects of our present system of education and examination. A few representatives of the Members sitting in Council would be a valuable and important addition to that august body, and some needed improvements might be expected as the practical outcome of the enfranchisement.

Our profession is a disunited body, and needs organization. It may fairly be asked what, under the present condition of things, is the advantage to the College of possessing so magnificent a constituency as 18,000 Members of our profession, and what is the advantage to the 16,800 Members of the College in their connection with the College of Surgeons of England? All the great advantages which might accrue to both are scattered to the winds. The only organized body which the profession possesses is the British Medical Association, but the number of Members is several thousands less than the constituency of the College of Surgeons. Moreover, it is not altogether satisfactory that the only organized body possessed by the Profession should be a voluntary Association. A Royal and Chartered College under the immediate guidance of the recognized leaders of the Profession, backed by the suffrages of 18,000 medical practitioners, must necessarily carry a weight and influence, with the public and with the Government of the country, with which a voluntary Association like the British Medical Association could not pretend to compete.

I am not a Radical or a Revolutionary, but a Conservative. As a Conservative, I am extremely anxious that this question should be settled by the existing Council. Surely it is better that a boon of this kind should be gracefully conceded from above than forced on an opposing Council from below. Better that it should drop as the gentle rain from Heaven upon the place beneath, blessing both him that gives and him that takes, rather than that the surging waves of professional Democracy should rush in and burst the artificial barriers which are being erected to stay its progress, and perhaps sweep away in its headlong course much that it would be desirable to retain. It rests with the Council to determine whether they are content to remain at the head of a body distracted by controversy, torn asunder by dissension, disaffected to the existing régime; or whether, by a timely concession which can do no possible harm to anyone or anything in the College, but which must be fruitful of good in the time to come, they will place themselves at the

head of their magnificent constituency, united in one common bond of professional sympathy and brotherhood, instinct with one common spirit, animated by one common aim and hope—the advancement and elevation of the great profession to which we are all proud to belong.

REPORTS OF  
HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY

ST. BARTHOLOMEW'S HOSPITAL.

CASE OF ENTERIC FEVER COMPLICATED  
WITH PAROTID BUBO—RECOVERY.

(Under the care of Dr. GEE.)

(The notes by Dr. OSWALD BROWNE.)

In the *Medical Times and Gazette* of June 28th, 1884, Dr. H. Lewis Jones reported the notes of two cases of enteric fever complicated with parotid bubo, noticing that the appearance of this complication had been regarded both by Murchison and Trousseau as a most unfavourable symptom, and in a very large majority of cases portending a fatal termination.

It has seemed to me that it may be of interest to add the notes of a further case, in which, as in one of those reported by Dr. Lewis Jones, the occurrence of the complication was associated with great dryness of the mouth and tongue, and marked and long-continued deafness, and terminated in the complete recovery of the patient.

Edward B., aged 18, was admitted on February 5th, 1885. He had been feeling weak and languid, and complaining of vagrant pains in the belly since the 18th of January. On the 29th he began to suffer from diarrhœa, and on the next day gave up work and took to his bed.

On admission to the hospital, he was dusky and slightly deaf. Much sordes on lips. Tongue dry and parched, and somewhat tremulous. Abundant rose spots on belly and chest. Temperature 104°. Urine contained a well-marked trace of albumen.

For the next two days, as one crop of the eruption faded, others appeared. Temperature ranging from 102°·2 to 104°·4.

February 8th.—Very deaf. Slightly delirious. Tongue parched and tremulous.

February 9th to 11th.—Continuing very deaf. Tongue very parched and tremulous. Temperature ranging between 102° and 103°.

February 12th.—Temperature 104°·8. A fresh eruption of rose spots.

On February 15th proceedings were varied by the visit of the patient's aunt, and the prompt administration of an emetic gave ocular demonstration of an undigested meal of pork-pie, pastry, apple, and currants as the cheering results of her visit! Temperature morning, 99°. Evening, 102°.

February 16th–18th.—Temperature ranging between 99° in the morning and 101°–102° at night.

February 19th.—Some pain and tenderness, with swelling of left parotid region. Temperature 99° morning, 99°·6 evening.

February 19th to 22nd.—Increasing fever. Much increased pain and swelling of left parotid region.

February 23rd.—Left parotid incised, a little pus escaping.

February 24th.—Increasing pain, with high fever.

February 25th.—Much swelling over gland and behind left ear, with distinct fluctuation. Free incision made and drainage tube inserted. At least ten ounces of sanious pus escaped.

From this time pain rapidly ceased and fever abated, and the patient continued to make steady and uninterrupted progress. Recovery complete.

---

### APPOINTMENTS FOR THE WEEK.

*Friday, December 18 (this day).*

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 p.m.—  
Dr. E. C. Seaton on "The Recommendations of the Royal Commission on the Housing of the Working Classes as they affect the Status of the Medical Officer of Health."

*Saturday, December 19.*

VACCINATION OFFICERS' ASSOCIATION, 2.30 p.m., at the Charing Cross Hospital Medical School.—Surgeon-Major R. Pringle, M.D. (late Bengal Army), "State Vaccination."

*Monday, December 21.*

MEDICAL SOCIETY OF LONDON.—Dr. B. W. Richardson, F.R.S., "A Case of Aneurysm of the Innominate Artery"; Dr. W. B. Hadden, "Chronic Poisoning by Bisulphide of Carbon."

---

## Medical Times and Gazette.

SATURDAY, DECEMBER 19, 1885.

THE polling for the parliamentary representation of Edinburgh and St. Andrew's Universities has been busily proceeding for the past three days, and we trust that, before these lines are published, Mr. Erichsen may have been declared duly elected. So far, to use a somewhat objectionable phrase, the betting has been against him, the Conservative candidate having been so much longer in the field. But, latterly, Mr. Erichsen's prospects have somewhat improved, and it is just possible that those who have been so confidently promising the seat to the Government may find their anticipations falsified. Both candidates have expressed themselves in favour of the admission of women to the degrees of the Scottish Universities, and Mr. Erichsen is not averse to their receiving the necessary instruction from the University professors.

At the meeting of the Ophthalmological Society on Thursday sennight the subject of pemphigus of the conjunctiva again came up, and occupied a considerable portion of the evening. It was started by two cases of essential shrinking of the cornea shown by Messrs. Anderson, Critchett, and Juler, who agreed that the disease was not true pemphigus, a view subsequently expressed also by Messrs. Nettleship and Malcolm Morris. Dr. Samuel West contributed a

case of double optic neuritis after a fall without any affection of vision, and Mr. Higgins sent a short paper on neuro-paralytic ophthalmia. Several living specimens of interest were shown, that which excited most attention being a case of diabetic retinitis of Mr. Nettleship's, the point being whether the appearances were wholly due to the diabetes, or whether, as was contended by some, they were only the results in a very advanced stage of albuminuric retinitis. Those who held the former view appeared to us to have the best of the argument.

OWING to the temporary indisposition of Sir Andrew Clark, a paper by him on the subject of Desquamative Prostatitis, which had been announced for presentation to the Clinical Society on Friday last, was deferred until the author could be present. The disappointment doubtless felt by the large number of members present, many of them attracted by the novelty of the subject, no less than by the eminence of its exponent, was, however, tempered by the excellence of the other papers provided for discussion. An account of a case of laryngeal obstruction due to sudden paralysis of the abductor muscles of the larynx was related by Dr. de Havilland Hall, and gave occasion to Dr. Felix Semon to put once more before the Society a concise account of his views, now very generally adopted, with respect to the peculiar proclivity of the abductor muscles to become paralysed before the adductors in all cases of organic lesion of the nerve trunks and nerve centres supplying the muscles of the larynx. The views of Dr. Krause, who has endeavoured to prove that the apparent paralysis of the one set of muscles is in reality due to spasm of their antagonists, were made the subject of severe adverse criticism.

THE latest achievements of abdominal surgery were once more under discussion at the same meeting, the subject being introduced in a paper by Dr. Barlow and Mr. Godlee, on a case of abdominal abscess treated by the simple method of evacuation and drainage. The patient was exhibited in apparently perfect health. In the course of the debate several useful facts were elicited, perhaps the most remarkable being that contributed by Mr. Barker, proving that abdominal section and peritonæal investigation might be safely undertaken in the presence of acute peritonitis. The advice given by the President that exploratory incisions should in all cases of doubt be made in the region of the cæcum is most valuable, and will probably be largely adopted in the future. In this debate, as in many previous discussions, it was made very clear that the present means of diagnosing obscure abdominal affections are altogether insufficient, many of the most important signs and symptoms being common to such widely differing conditions as mechanical obstruction and acute inflammation.

THE last meeting of the Pathological Society before Christmas was held on Tuesday, and was the occasion of a large number of communications. Mr. Sutton was again to the front; this time with the results of a very extensive study as to diseases of the heart and

blood-vessels in the lower animals, about which he had much to say that must have been new to many of his hearers ; the varieties of pericarditis, the peculiar compression of the heart in some rickety monkeys, vermiform aneurysms, and arterio-capillary fibrosis were the diseases he chiefly dwelt upon and illustrated with a large number of specimens. The only point on which perhaps we should feel inclined to disagree with him would be in reference to the absence of arterial strain in animals. Surely beasts of burden subject their arteries to a very considerable degree of strain in performing their daily task. Mr. Poland reported a case of internal anthrax, the chief interest in the case being that the organisms had presumably entered the body through the trachea, that the man had only worked with hides on one single occasion, and that the symptoms had set in on the same day ; the chief lesions *post mortem* were hæmorrhagic infarctions in the lungs, scattered sloughing ulcers in the stomach and small intestines, and hæmorrhage into the pia mater ; no micro-organisms were found in the blood or tissues, but the failure to discover them was attributed to the amount of decomposition that had taken place. Mr. Silcock showed a good specimen of syphilitic ulceration of the trachea, the stage of the disease constituting the most noteworthy feature of the case, as the ulcers have usually healed before the patient reaches the *post-mortem* table. Mr. Swinford Edwards showed a case of round-celled sarcoma of the skin, which led to some interesting remarks from Mr. Butlin, and Dr. Hale White had a probably unique case of primary melanotic carcinoma of the liver, whilst Mr. D'Arcy Power and Mr. Lane added to our store of recorded instances of the occurrence of malignant disease in bone.

THE constituents of the Metropolitan Hospital Sunday Fund have done wisely in endorsing the conclusion of their General Purposes Committee, "that matters relating to the internal administration of Hospitals are beyond the jurisdiction of the Fund." If the principle supported by some of the hotter-headed friends of the Fund had been admitted, and pressure had been put on University College Hospital to change its system of nursing, it would have been difficult to see what limits could be placed on the interference of the constituents of the Fund. Probably King's College Hospital would have been the next to be threatened with a stoppage of supplies, because the medical teachers connected with it are required to sign themselves *bonâ-fide* members of the Church of England.

WE hear with great regret that a member of the Asylums Board intends to move that the resolution of the Board re-instating Dr. Collie in his appointment at Homerton be rescinded. Such a proposal, if successful, or even if unsuccessful, would be as cruel as it is unusual. But we trust that the Board will not consent thus to play with the interests and feelings of those who are, unfortunately, dependent upon it.

EVERYONE must sympathize with the sanitary aspirations of Mr. Edwin Chadwick, and hope that his

letter in Monday's *Times* may attract some interest among the convalescents from election fever. Whether it will ever be possible to reduce the general death-rate throughout the country to "prairie value," as Mr. Chadwick hopes, it is difficult to say. There are deaths enough at present from preventible disease, in all conscience, and there is no doubt that the conditions under which the mass of the population live are very far from satisfactory. But the conditions under which the work of the world has to be done can never be ideally healthy. We cannot all be inhabitants of well-drained and well-watered villages, or even of suburbs with go-ahead Local Boards of Health, and we can never expect their health and long life. We can cut down the mortality from zymotic disease—the doubtful zymotic whooping-cough, perhaps, excepted—we can diminish the deaths from the effects of drink and debauchery, but there are many diseases whose causes we cannot touch without reforming our whole civilization. And we strongly suspect that, as the old gross diseases die out, other more subtle ones will take their place, to vindicate Nature's law that only the fittest shall survive. One question to the ardent sanitarian. Can he ensure the average middle-class mother a full breast of milk ?

THE returns of the Registrar-General for the past week again show a fall in the death-rate in the metropolis, the total number of deaths having been 1,474, or 351 less than the corrected average. Of

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past thirteen weeks.

these, 57 were due to measles and 58 to whooping-cough, the high mortality from these ailments during the two preceding weeks being thus fully maintained. Diphtheria caused 20 deaths, 14 of the victims being under 5 years of age ; scarlet fever was the cause of

death in 14 cases and enteric fever in 7, and 3 deaths were due to small-pox. The deaths of 264 persons were referred to bronchitis and of 100 to pneumonia. The mean temperature for the week reached the low figure of 32.7°, a fall of 12° as compared with the previous week. In the provincial towns Bolton again had the highest death-rate, viz., 31.8, Plymouth coming next with 27.5. Liverpool and Nottingham suffered rather severely from measles. The death-rate in Dublin rose to 31.0, owing to the increase in the deaths from whooping-cough and fever.

OUR Paris correspondent writes:—The eminent veterinarian, Henri Bouley, whose death the scientific bodies of France have so deeply regretted, was of all the members of his profession the one who attained the highest dignities. He had been President of the Academy of Medicine; he was President of the Academy of Sciences, and filled the Chair of Claude Bernard at the Museum. His funeral, which was celebrated with almost princely splendour, elicited more than the usual amount of eloquence, and his praises have been sounded in the whole scientific press of France. Yet he was better known as an eloquent expounder of the views of others than as an original labourer in the field of science, and it is chiefly to his uncompromising adhesion to the views of Pasteur that his great celebrity is due. The Faculty of Medicine have unanimously elected M. Mathias Duval to succeed Professor Robin in the chair of histology. The result was foreseen, since Professor Ranvier had withdrawn from the lists. The talents of the new professor will secure him a legitimate popularity, both among students and scientific men, although he has laboured more in the cultivation of normal and comparative anatomy and embryology than in that of histology, properly so called.

THE last meeting of the Paris Academy, being the "*Séance Solennelle*," was chiefly devoted to the proclamation of prizes and the "Eloge" of the celebrated surgeon Chassaignac, by M. Rochard. There occurred, however, an interesting communication by M. Hermann Fol, of Geneva, upon the microbe of rabies. The author takes it for granted that M. Pasteur's experiments have proved conclusively that this disease is produced by a microbe which hitherto had not been found. He professes to have discovered in the brain and spinal cord of animals affected with hydrophobia a micrococcus of small dimensions, viz.,  $\frac{1}{50000}$ th of a millimetre, which chiefly lies in the neuroglia, but is also found in some other parts of the nervous centres. Some portions of the brain of mad dogs, having been subjected to regular cultivation in sterilized broth, produced a deposit which precipitated in the space of four days, and which, when subjected to microscopical investigations, exhibited similar micrococci. The deposit, being inoculated in animals in sound health, sometimes produced hydrophobia. This result is no longer attained after the sixth day. The author, therefore, claims to have discovered the specific living organism of rabies. M. Hermann Fol is a naturalist of great talent and his assertions deserve the greatest attention. It may, therefore, be true that

we have attained the solution of one of the most important problems of medicine. In the meantime, M. Pasteur's patients are constantly increasing in number. Unfortunately, some of them have died, but this might of course have been foreseen, and the event has by no means acted as a damper upon public enthusiasm.

THE dinner given to Dr. Bradley at Sheffield, on Friday last, formed a fitting close to an episode which does not reflect much credit upon the law. The evidence upon which Dr. Bradley was convicted was of such a nature that we doubt if any other jury could have been got together to agree in convicting him; but, notwithstanding this, when once the sentence had been passed, it took months of agitation on the part of the medical profession to obtain a reversal of it. The dinner in question was arranged for the purpose of affording Dr. Bradley some tangible proof of the wide-spread sympathy which his case has aroused, in the shape of an address and a purse containing four hundred guineas. Dr. de Bartolomé occupied the chair, and the presentation was made jointly by Dr. Balthazar Foster, M.P., and Mr. Wheelhouse, whose speeches were received with great applause, and were well worthy of the important occasion on which they were delivered.

MEETINGS to promote the formation of a Medical Volunteer Corps in connection with the various schools of medicine in Dublin have been held during the past week or two. At a largely attended meeting for this purpose, held in the School of Physic in Ireland, Trinity College, Dublin, on Friday, the 11th instant, the Rev. Dr. Haughton presided, and the objects of the movement—which is extensively promoted by the London Medical Schools, and in Edinburgh and other parts of Scotland—were explained by Surgeon-General Evatt, of the Army Medical Department, Woolwich, and Mr. Cantlie.

THE offence for which a student was sentenced to six months' imprisonment with hard labour the other day at Belfast may not be so rare as people would be disposed to believe. The charge was that of uttering a forged certificate of matriculation in the Royal University, and the forgery would probably have been completely successful, had it not been for a want of attention to detail, which, curiously enough, is by no means uncommon in frauds of this class. The certificate purported to show that the holder of it had passed the examination in November, and, as that examination is never held in November, this attracted the attention of the Registrar, who on a little investigation had no difficulty in arriving at the conclusion that the whole document was a forgery. That some one should have thought it worth his while to go to the trouble and expense of forging a lithograph of this certificate looks as if a large business in that particular line could be safely calculated upon, and it will be necessary for the authorities in future to scan with unusual care the certificates handed in by would-be students. Meanwhile it is some satisfaction to know that no other certificate belonging to the issue the existence of which has thus been made known will be able to do duty on any subsequent occasion.

WE notice with much regret that the publication of Squibb's "Ephemeris" is discontinued with the number issued in November last. The disappearance of a periodical conducted, as this has ever been, with so much public spirit and with a single object to advance knowledge on subjects relating to materia medica, pharmacy, or therapeutics, is a real loss to our profession, and we would fain hope that the possibility hinted at in the parting notice, that its publication may some day be resumed, will be realised.

#### THE MEETING AT THE COLLEGE OF SURGEONS.

WE looked forward with some apprehension to Thursday's meeting of Fellows and Members at the College of Surgeons, fearing a repetition, if not an aggravation, of the painful and indecorous exhibition of animus which characterised the last meeting. We are bound to confess that our apprehensions have been falsified by the event, and that, save for a brief scene of disorder, for which Mr. Brudenell Carter, the main advocate of the policy of the Council, has alone to thank himself, the meeting passed off as pleasantly, and the discussion was, on the whole, as serious and statesmanlike, as could be expected from men for the most part untrained in the arts and amenities of the forum. Certainly the discussion reached a higher level on Thursday than it did at the previous meeting. The speakers were of higher rank, both in the College and in the Profession, three of the four chief spokesmen for the Members being themselves Fellows, and two of them, if we may use the expression, men of Council rank. The Members' Association had immensely strengthened their position by coming to terms with the Association of Fellows and restricting their claims on behalf of the Members as conditioned by the alliance. Their willingness to accept an instal of reform, instead of pressing for the immediate enfranchisement of every newly-fledged Member, has not only secured for them the influential support of men like Mr. Holmes and Mr. Rivington, and, we presume we may add, Mr. Pollock; but ought both to conciliate the Council and, to some extent, disarm the hostility of Mr. Carter and the Junior Fellows.

When we reviewed the statement prepared by the officers of the college for presentation to the meeting, we expressed our surprise at the argument from analogy between the Members and the citizens of a State. At best, a weak and inconclusive plea, it should not have been brought into such undue prominence by the apologists for the Council. And we are glad that the speakers on Thursday showed as little regard for the argument as for its contravention, basing their contention on much larger and more valid considerations. For these arguments we must refer the reader to our report of the meeting and to the ably reasoned speech of Mr. Rivington, which we give in full in another column. As to the arguments on the other side, mainly formulated by Mr. Brudenell Carter, we need say little.

The plea that personal knowledge of the candidates constitutes the best claim to the privilege of voting for Members of the Council lost what little force it may have had when the Council accepted the principle of proxy voting. If it is a valid argument, it would restrict the Parliamentary franchise

to the *habitués* of the London clubs. Besides, even under the present system any individual Fellow cannot have a personal knowledge of all the candidates for the Council, and, if he has not, it is impossible for him to compare their relative competency. He may know A. and feel sure that he possesses all the shrewdness and common-sense and business-like habits that Mr. Carter panegyricized, but how can he assure himself that B., whom he does not know, has not greater shrewdness and better business habits? The fact probably is that no man can attain rank and recognition as an able surgeon who does not possess these qualities, and we are very sceptical as to their presence or their absence influencing to any tangible extent the votes of the present Fellows. Mr. Carter's argument, that with a large electorate the chief places on the Council would fall to the surgeons connected with the larger schools, sounds more forcible than it really is. The votes of the Members, we imagine, would go mostly to the men with whom they were most brought into contact in practice, *i.e.*, with the men who had the greatest success as consultants, and, though the surgeon to a large school is perhaps more sure of a consulting practice than the surgeon to a small one, the experience of the school which Mr. Carter quoted shows that this fact does not prevent the surgeons of small schools from rising to pre-eminent positions as consultants. Sir Prescott Hewett, for instance, would probably have gained quite as many votes from Members of the College as any of his contemporaries at the over-grown schools further east. Of course the extension of the College franchise would bring with it a much larger infusion of country Fellows into the Council, especially if the personal knowledge lauded by Mr. Carter were to have much influence with the electors, but we do not know that this would be a consummation greatly to be deplored. Indeed it is inevitable if the College is to take that position as a national institution which the reformers desire. One word in conclusion as to the unfortunate remark of Mr. Carter about the part played by the medical press in this agitation. We must leave the two gentlemen specially selected by Mr. Carter for the honour of being named by him to speak for themselves; but, for ourselves, we must candidly confess that for some months after the foundation of the Members' Association we looked on it with much distrust, and scarcely thought its proceedings worth mention in our columns. Even after the October meeting we expressed the opinion that the Association was still on its trial, from which we are now glad to admit that it is emerging with something not far short of success. Everyone connected with and loyal to the press of this country must deeply regret that Mr. Carter should have allowed himself to speak in such disparaging terms of two members of that profession with which he has himself been so long and so closely connected.

#### MR. JOHN WOOD'S BRADSHAW LECTURE.

THE memory of the pious founder of these lectures will long remain fresh and green if the successive orators, chosen to commemorate the anniversary, be as well selected in the future as they have been in the

past. And, while the sister College has selected from their entire body younger, but married, men for the task, the Surgeons have hitherto only chosen from the narrow, but very select few, who constitute the Council of the College, and who have occupied, or are about to occupy, the highest position to which surgeons can aspire. Each plan has its advantages. The one gives the junior Fellows the all-important opportunity of showing what is in them, while the other secures for the listeners, and the profession at large, the matured judgment and the sober truths which age and experience alone can bring. It is probable that few men could have spoken with greater weight and authority than Mr. John Wood on "Antiseptics in Surgery." Well versed in both the art and science of a near, but bygone, surgical era, Mr. Wood is now associated at King's College with the man who has revolutionised surgery, and has given his name not only to a method of dressing, but to a principle which in future ages will be known and taught as "Listerism." He has thus the opportunity of judging, by a comparison of the near past with the practice of the actual present, how far and in what way Listerian antiseptic surgery answers the ends and purposes it professes to serve, and in what respect it is superior to other methods of surgical dressing then or now in use.

Although Mr. Wood devotes himself chiefly to the external application of antiseptics to the exclusion of theories of causes and origin of diseased processes (which belong to pathology rather than to surgery), it is impossible in the consideration of such a theme to altogether avoid theoretical points; nor does he. For he begins by a brief consideration of "the agencies which more or less accelerate or retard the healing of wounds." In doing so, he says, "every method of treatment has some basis of fact or theory which enables it to resist immediate extinction." This is the *vis medicatrix nature* of Cullen, and Mr. Wood places it "first in order and in importance." The vigour and intensity of vital force which pervades all the tissues, from the highest nerve-structure to the lowest forms of protoplasm, endow an individual with the means of resisting disintegrating influences. "But a great degree of this power is sometimes found in those who are by no means examples of perfect health, and a scrofulous subject will frequently undergo severe operations, long suppuration, and tubercular infection without showing symptoms of either pyæmia, erysipelas, or other forms of blood-poisoning, to which others, stronger than they, succumb." Here Mr. Wood is plunging into rather debateable ground, and we cannot quite follow him without some misgiving. In the first place, what is a scrofulous subject, and in what respect does such an one differ from a healthy subject? In the second place, what is the explanation of "long suppuration" of "tubercular infection"? Are they not themselves examples of blood-poisoning? Then, are the scrofulous alone able to withstand long suppuration, and do others, "stronger than they," always succumb? Finally, does the condition of perfect health—the possession of a large supply of vital force—always suffice to ward off disintegrating influences, and, if so, how are we to explain the onset of acute diseases, like diphtheria or fevers, in persons of robust

health, as is so frequently seen in practice; or, when overtaken by accident the occurrence of suppuration, of pyæmia, erysipelas, or other form of wound complication? That the weakly and the strong should both suffer from the effects of evil surroundings appears to us an incontrovertible argument in favour of extraneous agencies—germs—as the real source of surgical calamity.

The variety of answers which the foregoing questions would probably give rise to is a proof how little we know of the subtle influences and of the agencies which everywhere surround us. It is all very well to say that germs are floating in the atmosphere we breathe and move in, that they "lie latent in all the tissues, even of the healthiest animals" and "seem to cause no mischief." For, the germs notwithstanding, vital operations are now every day undertaken without regard to vital force, perfect health, or even the scrofulous habit, with results that leave nothing to be desired, provided always that suppuration can be avoided. The doctrines of antiseptic surgery point out how this can be accomplished with almost absolute certainty, and thus we are led to the conclusion that more depends on the surgeon than on the patient, more on the application of scientific teaching than on vital force, and that, when patients "succumb" after accident or surgical operation, it is that the patient, for some reason or other, has not had the full benefit of the knowledge which every surgeon has, or should have, at his fingers' ends. Of course, a patient may be killed outright, or vital organs may be injured past recovery, by accident; or he may delay consulting a surgeon until disease is too far advanced. Such cases are not now under consideration.

Given a surgical operation, or injury, what is the best antiseptic, and what is it capable of doing? Such is really the gist of Mr. Wood's lecture. The reader will find the questions answered with all the clinical acumen that Mr. Wood possesses. He does not appear to have any prejudices, but says plainly what each one can do, and how it may most effectually be used. We need not here follow him into details; the following points must, however, be carefully heeded: "In the choice of an antiseptic agent, it must be borne in mind that a much weaker solution suffices to prevent putrefaction than to destroy it when it has once commenced," and again, "solubility, a degree of volatility, no irritative property when applied to the living tissues, and no effect upon the system by absorption, seem to be the criteria of a good antiseptic." There is an entire absence of the disparagements of Listerian dressings, which have so disfigured previous utterances by eminent surgeons when dealing with "antiseptics," nor is any attempt made to under-rate or minimise the immense changes which have been introduced into surgical practice since "antiseptic surgery," in its modern sense, has come to be generally practised. Mr. Wood wisely emphasises the value of drainage; this, he thinks, has "prevented many of the disastrous results, such as tension, abscesses, and burrowing of matter, which formerly were common in hospital wards," and we feel with him that it is quite as important as the use of carbolic acid, iodine, chloride of zinc, or other chemicals. Indeed, Mr. Wood might

shortly have described successful antiseptic surgery as careful co-aptation of parts, free drainage, and absolute cleanliness.

We will conclude this brief notice of Mr. Wood's interesting lecture by the following extract:—From the foregoing, among many other considerations, it appears to me that the relative efficiency of antiseptics in different hands, and under varying circumstances, is very difficult, if not impossible, to estimate by the statistical method. Cases vary much; scarcely two are exactly alike. The influences which surround, and act, directly or indirectly, upon them, in other ways than by dressings, render the comparison apt to be variously determined by different minds and from different points of view. Each surgeon will do best, I believe, with the means at his disposal, to compile his own statistics for his own guidance, from his own experience, and from his own standpoint. He may be confident that the wisest questioning will bring the wisest and most direct answer; that his results will depend most upon the care bestowed upon his patient, the exactitude of his record, and the accuracy of his judgment; and that his time will be better spent upon these things than by wrangling over his comparative statistical success with his fellow-labourers upon the same lines.

#### ALLOPATHIC TEMPERANCE.

A SCHEME, put forward in all seriousness, to diminish drunkenness by making public-houses more attractive is something to make even a moderate temperance advocate stand aghast. That men do enter public-houses, and that they do so almost invariably for the purpose of drinking intoxicating liquors, are admitted facts, bad enough in themselves surely. But that men should be allowed to stay there by an increase of comfortable accommodation and greater facilities for snugly enjoying the society and conversation of their neighbours seems, at first sight, a needless aggravation of temptations which are already more than strong enough. And to expect by such means to seriously lessen the evils of drinking to excess sounds like a preposterous dream. Yet, a careful examination of the arguments advanced will serve to show that they are reasonable and weighty, and a candid consideration of the whole question, viewed by the light of common sense, must go far to convince the impartial philanthropist that some such plan as that sketched by a recent writer in *Macmillan's Magazine* is far better suited for general and lasting adoption by the great bulk of mankind, and so far more practical than the extreme measures advocated by the non-alcohol reformers; while the results, immediate and remote, of its operation are likely to be at least as satisfactory as any which can be expected to follow an attempt "to absolutely prohibit the employment of alcoholic beverages."

There is too much truth in the assertion, and too much risk to sobriety in the fact, that the public-house is, despite its title, less a house for the public than for the publican. It must be, under the present condition of things, to the interest of the publican

(i.e., to the interest of his landlord, the brewer or distiller) that his "guest" should pay for as much drink as possible. It is not to his interest that customers should find in the public-house comfortable seats, good ventilation, newspapers to read, ample room in which to talk quietly and comfortably to friends, with the minimum of temptation to do nothing but drink. A very slight acquaintance with the interior arrangements of the public-houses, whose gleaming casements attract the city wayfarer with the promise of warmth, if of no other comfort, is sufficient to make clear the fact that the "refreshment" offered is almost entirely restricted to the single item of strong liquors. The central, usually the only, attraction is the "bar"—bright with the glare of gas on glass and burnished metal. Here the customers most do congregate, not only because the counter is of a convenient height to lean upon, but also because sitting accommodation is utterly inadequate, even if not totally lacking. The cubic space is small out of all proportion to the number crowded into it. The atmosphere is soon made close and unhealthy, impregnated with the mingled fumes of tobacco-smoke, humanity, beer, spirits, and gas. Ventilation, as the sanitarian understands it, does not exist, for to open a window would be to create a formidable draught, and the large class to whom comfort means mainly a sense of warmth, however acquired, will stand no such intrusion of the chill external air. All these things, the heat, the light, the glitter, the sight and sound of drinking, the buzz of orders and of conversation, the outwardly jovial impression of the scene, all conspire to drinking and lure the drinker only too easily to have the emptied glass filled again. Such a description does not, of course, fairly apply to the small roadside inn or to the primitive village alehouse, where the public room with its sanded floor is fairly large, if low, and the long table is furnished with a tolerable accompaniment of forms or even chairs. But it is no exaggeration of the conditions which obtain in the gin-palaces that crowd the populous thoroughfares of a large city, and it applies also in its degree to the less ambitious public-houses of smaller towns. In all of them the main object is to provide drink, and in almost all, by providing no other possible means of amusement or employment, to tempt to repeated and continuous drinking, and to make everything except drinking an absurd impossibility.

Enthusiastic teetotalers have caused scores of public-houses in various parts of London to be carefully watched by the day together; and temperance orators have quoted statistics, showing the number of hours which each customer on an average spends within their doors, as evidence of the inherent and acquired depravity of alcohol-consuming humanity. But it has been aptly pointed out that such figures suggest a very different interpretation,—one quite as rational in itself and more hopeful for the future. Man is a gregarious animal in all walks of life. But the poor man has none of the facilities possessed by the rich for receiving and entertaining his friends and neighbours in his own home; and too often, for other reasons, it is the place where there is, above all others, least entertain-

ment for himself. The public-house is the only place where he can do this with comfort and under cover; his father and his grandfather went there for the same purpose before him; and the only fee demanded, nominally, is the not unpleasant duty of drinking a glass himself. If men and women went into public-houses *merely* to drink, they might be expected to leave so soon as they had consumed all that they wanted or all that they could pay for. The very fact that they do stay so much beyond the time which can be spent in this way merely is in itself a very cogent proof that one of the strongest motives that takes them there, and probably the strongest which keeps them there, is that hungering for fellowship and society which is deeply implanted in every human breast, and which so many of us have scarcely any other place and scarcely any other opportunity of gratifying. It is no fault of the poor man that the management and structural arrangements of the "poor man's club" have been developed so far in the direction of subordinating everything else to fostering and gratifying the passion for drink.

If such reflections are not very novel, there is novelty in taking them as arguments for making the public-house less noxious by making it more comfortable. We are not yet all agreed that men should be prohibited from drinking beer and spirits altogether; but we are practically unanimous in the opinion that many men drink too much; and it is reasonable to look for a diminution of this excessive, needless, and demoralising drinking, if only the accessories which tempt to and encourage it be done away with. Let us, in short, try the experiment of public-houses arranged and conducted upon rational principles—making them places where people who need rest and comfort and refreshment of both mind and body may obtain these things in all reasonable fulness, instead of being, as is now the case, debarred from what is reasonable, while they are powerfully tempted to what is both needless and debasing. The coffee-palace is good in its way, but it does not empty the public-houses or appeal strongly to their frequenters. It is an open question whether a moderate daily consumption of sound malt liquor is injurious to the healthy man. But it is certain that no other place for social gathering can successfully compete with the public-house unless beer is included amongst its attractions. Why, then, should not the public-house retain this attraction while improved accommodation is made to lessen the risk of its abuse? Let the cubic space be ample and ventilation good, let comfortable seats and tables be provided, and a reasonable supply of newspapers; diminish the size and the obtrusive glitter of the bar; if possible, let the use and shelter of such a place be allowed for a small weekly sum to those willing to pay for it, without exacting any other tribute; in other words, while drinking is allowed, lessen as far as possible the moral and physical temptations to it, and make it a distinctly subordinate object of the establishment. The success of the better class of working-men's clubs is a proof that such institutions can be made to pay, even when conducted in the face of opposition and under the difficulties of individual

isolation. But their success and the good which they can achieve does not the less necessitate an improvement of public-houses as they at present exist.

The establishment of one public-house arranged and conducted in this manner, providing good sound liquor, but providing also for the gratification of those other and higher wants which must at present be drowned in beer or gin, would soon compel others in the same neighbourhood either to close or to follow its example; and would eventually lead to a considerable reduction in the number, and a great improvement in the standard, of such places throughout the country. It is an experiment which a really philanthropic brewer, for example, could easily and might well test.

There is a class of zealous reformers who regard the muzzle as a panacea: who would make the gratification of a natural appetite impossible and call it self-control. We believe the creed—whatever its value in certain special circumstances—to be fallacious and impracticable in its application to the general mass of humanity. We might term total abstinence a homœopathic remedy for drunkenness; for alcohol is so universally distributed that even ordinary drinking-water is held to contain it—and that in a degree of tenuous dilution which should satisfy the most fanatic of the avowed followers of Hahnemann. But, putting all the foolish controversies of fading "schools" aside, it may be asserted that the most hopeful cure for drunkenness lies in the better physical and moral care of those who drink; that it is to be sought for by elevating the tastes, improving the food, brightening the surroundings, lightening the cares, and lessening the temptations of those around us—not by any futile attempts to fasten a padlock on men's mouths, or to banish from the world all familiarity with a substance which would, in that case, only be hailed by the next generation as a beneficent discovery, and wrested, by the experiments of ignorance, to still greater abuse.

---

## REVIEWS AND NOTICES OF BOOKS.

---

*Handbook of Diseases of the Skin*; edited by H. v. ZIEMESSEN, M.D. New York: William Wood and Co., 1885, pp. 658.—This handsome book constitutes the eighteenth and last volume of Ziemessen's *Cyclopædia of Medicine*. Its tardy appearance is no subject for wonder when the immensity of the original undertaking and the difficulties arising from the necessary incorporation of our daily increasing knowledge in a "standard" work are taken into consideration. The number of volumes issued having already surpassed the original estimate, that now before us has been most generously presented to original subscribers by the publishers, who are undoubtedly deserving of a tribute of gratitude. Turning to the book itself, it cannot be denied that, despite the immense amount of thought and labour expended upon it, resulting in a work of sterling worth, its perusal is to some extent accompanied by a feeling of disappointment. Apart from the obvious objection that the various articles must have varying values, certain other defects are necessarily inseparable from a work representing the collaboration of a considerable number of authors whose views by no means invariably coincide. The adoption of an uniform classification and nomenclature would have greatly facilitated the task

of comprehension to the ordinary medical reader, although admittedly variety in these matters often recalls many an interesting historical point to the expert and the erudite. All classifications are necessarily arbitrary and artificial, especially perhaps in dermatology, where connecting links abound, but probably none more nearly approaching scientific truth has hitherto been suggested than that elaborated by Professor Auspitz in his excellent chapter upon the general pathology of skin diseases, founded, as it is, upon carefully digested anatomical, physiological, and pathological considerations. No portion of the work more thoroughly repays study, even if the reader's gratification is occasionally marred by some of the composite names which the author has thought it necessary to fabricate in order to express his views as to the essential nature of various lesions. Despite the marked individuality pervading the chapter, but little objection can be made to any of the statements therein. Probably, however, few will agree with Professor Auspitz that the papules of prurigo consist merely, or even mainly, of hypertrophied *musculi arrectores pilorum*, and that psoriasis and lichen ruber are "paratypes of the cornification process, the hyperæmia and fluxion being secondary and due to pressure on the base by the accumulated scales," not inflammatory processes, as is generally taught. Professor v. Ziemssen's article on the physiology of the skin is commendably brief, as no new facts of importance have been elicited by recent experimentation. It may be as well to indicate his opinion that only gases and substances which become easily volatile at low temperatures are absorbed by intact epidermis, and that substances dissolved or suspended in fats are absorbed only when mechanical pressure is employed, so as to introduce them into open glands. Dr. Veiel, under the heading of "dermatitides superficiales," treats, *inter alia*, of such widely dissociated conditions as eczema, impetigo herpetiformis, and lupus erythematosus. Apart from the curious statement that only nine cases of impetigo herpetiformis have been placed on record, the affinity, amounting almost eerily to identity, of this disease with herpes gestationis should relegate its description to a class far separate from eczema. Nor can we assent to the close relationship claimed to exist between eczema and lupus erythematosus, the points of resemblance being only very superficial, whereas the border line between the latter and lupus vulgaris is clinically and pathologically often indefinable. In regard to the treatment of eczema, we cannot but think that tarry preparations are far too freely recommended, our own experience having led us to use this class of remedy very sparingly, very dilute, and always tentatively, over a limited portion of the disease, in the first instance. Professor Schwimmer writes with authority upon scleroderma, justifiably including morphea under the title, but he omits all mention of rheumatism among the ætiological factors, and appears to us to give too gloomy a general prognosis by under-estimating the chances of spontaneous cure. His observation that a fatal termination frequently occurs by general amyloid disease is new to us, nor are we inclined to place much confidence in the treatment he warmly recommends by "galvanisation of the sympathetic." Professor Schwimmer's acceptance of the rôle played in its causation by *filaria sanguinis hominis* is very half-hearted, only Dr. Lewis's paper published in 1874 being referred to. This is not the only instance throughout the book of the neglect of recent work by English observers. Lupus and other chronic infectious diseases of the skin are undertaken by Professor Neisser and handled with special discretion. The evidence as to the tubercular nature of lupus is very carefully sifted and a decision in the affirmative finally arrived at, Schüller's successful inoculation experiments being unhesitatingly accepted, and serofuloderma, the tubercular nature of which is said to be easily demonstrable, being regarded as a connecting link with visceral tuberculosis. Difficulties in accepting the view are met by the theory that the tubercular organisms are less virulent because located in a situation unfavourable for their growth, and that they do not easily find their way from the skin into the general circulation. Were any series of cases or even any single case on record in which a lupus was indisputably the starting point of a general tuberculosis, any

doubt on the subject would be dispelled. It is impossible in the time and space at our disposal to enter more fully into the merits and shortcomings of this remarkable work. The task would be a fascinating one as in the case of almost every article one cannot but feel that one is criticising the work of a master. The volume forms a fitting conclusion to one of the most remarkable series of medical works ever submitted to the profession.

*Hirsch's Handbook of Geographical and Historical Pathology*; translated by CHARLES CREIGHTON, M.D. London: New Sydenham Society, 1885.—Some time ago we had the pleasure of speaking in the highest terms of the first volume of this work, and, now that we have carefully perused the second volume, we can only repeat our congratulations to the Sydenham Society that it should have undertaken to bring it out in an English dress, and that it was so fortunate as to secure the services of so excellent a translator as Dr. Creighton. Anyone who turns over these pages cannot fail to be struck with the magnitude of the work which Dr. Hirsch has accomplished, and we can confidently recommend it as an almost never-failing work of reference on the subjects of which it treats. The present volume deals exhaustively with some diseases regarding which we should search for such information elsewhere in vain; leprosy, yaws, pellagra, ergotism, beriberi, and others, which are usually, but superficially, referred to in text-books, are fully discussed in its pages, and copious references are furnished as to all the subjects. There is an excellent summary of the literature of animal parasites, and especially of the parasites of tropical and sub-tropical regions; the chapter on guinea-worm, for example, is a model of careful work, and the summary of our knowledge of the *Filaria sanguinis hominis* is the best we have seen. The reader cannot help being struck with wonder at the number of out-of-the-way periodicals and pamphlets which the author has consulted, and many a writer will find notices of observations which he has made and published in distant parts, which he little expected would have found their way into such a classical volume as this. We had made copious notes of several of the articles in this volume—such as those treating of syphilis, scurvy, erysipelas, scrofula, and puerperal fever—with a view of drawing special attention to some of the more striking passages contained in them, but have found it so difficult to make a selection which would adequately represent the author's views in the space at our disposal that we have been reluctantly compelled to omit them altogether. We, however, cordially recommend our readers to consult the volume for themselves, and would specially recommend it as worthy of the careful attention of writers of handbooks on medical subjects. They will find that Dr. Hirsch is particularly careful in giving all the information available, and that he takes broad, common-sense views of the subjects which he discusses. Of Dr. Creighton's work, both as translator and editor, we have nothing but praise to offer. He has placed at the disposal of the Sydenham Society a volume written in such vigorous English that it would be hardly possible to imagine it was of German origin; whilst the accuracy with which the innumerable references have been reproduced testifies to the labour which he must have expended in seeing the proof-sheets through the press.

*Transactions of the American Gynæcological Society*. Vol. ix., for the year 1884. New York: D. Appleton & Co., 1885.—When Mr. Herbert Spencer visited America, the thing that made the most unfavourable impression upon him was the low moral tone which he found prevalent. There is the most hope of reformation when those who need reforming are conscious of that need. Whether Mr. Spencer's opinion as to the public morality of America be well founded or not, we shall not presume to judge. If it be, then the address of the President of the American Gynæcological Society, with which this volume opens, shows the promise and potency of improvement, for the occupant of that high position has not hesitated to speak plainly about certain articles that have appeared in a well-known

American journal. There is no need for us to dwell on this topic, for it is to be hoped that Dr. Albert Smith's severe rebuke will prevent future errors of the kind; and the volume before us contains articles which are themselves the proof of progress towards a higher and better standard. Dr. J. C. Reeve, of Dayton, Ohio, discusses certain moot points with regard to inversion of the uterus. These are four; viz., (1) Can inversion of the uterus occur entirely independently of pregnancy, of polypus, or even in the nulliparous organ? (2) Does inversion of the uterus always begin at the fundus? (3) Does puerperal inversion of the uterus ever occur except at, or immediately after, delivery? (4) May inversion of the uterus take place without sufficient symptoms to attract attention or to indicate that anything has gone wrong? As to each of these questions, Dr. Reeve brings forward facts and arguments which, even if they should not be thought sufficient to warrant a confident affirmative answer, yet at least ought to prevent hasty dogmatism on the opposite side. Dr. H. P. C. Wilson, of Baltimore, has collected some cases in which foreign bodies were left in the abdomen after laparotomy. He relates a marvellous case of his own, in which a sponge was left inside the belly, the patient recovered, and nearly six months afterwards the sponge escaped through the abdominal walls. Dr. C. D. Palmer, of Cincinnati, writes on abdominal section as a means of exploration and treatment. His paper is valuable, because it shows that an exploratory incision is not quite so free from danger as some would have the profession believe, more especially in cases of malignant disease. Dr. Palmer writes to recommend, not to dissuade from it, and his temperate conclusions cannot but carry weight. Dr. Paul F. Mundé contributes a valuable paper on interstitial cervical fibroids as a cause of dystocia, and their removal by vaginal enucleation. The paper is described by its title, and it seems to us that Dr. Mundé has done a useful service in showing the feasibility of the method of treatment in question. Dr. Thomas communicates six cases of extra-uterine pregnancy. Three are instances of supposed cure by electricity, but the diagnosis was unverified, and they may have been cases of ordinary pelvic peritonitis. One was treated by laparotomy at the time of rupture and died; another by secondary abdominal section, the placenta being in great part removed, with success. Dr. Maury reports an unverified case of the same disease, and argues against immediate laparotomy. Dr. Mundé tries to make out a case in favour of extirpation of the cancerous uterus; but we cannot say that his essay exhibits that judicial temper which is necessary for it to be convincing. Dr. Sawyer, of Chicago, writes an excellent paper on occipiti-posterior position in vertex labour, based on 38 cases. In proportion to the amount of thought and work in it, it is brief, therefore it must be carefully read to be understood and appreciated. Dr. Engelmann describes some exceptional cases of septicæmia in which the symptoms were less marked than usual; he terms them "insidious septicæmia." Readers of the English journals will remember that Dr. Priestley recently brought before the British Medical Association some similar cases. Dr. Isaac E. Taylor describes changes in the appearance of the vulva which he has noticed in cases of fissure of the anus. The attention and industry which the author has given to his subject deserve recognition, but we are inclined to think that he estimates a little too highly the utility of diagnosis of the alterations which he describes. Dr. Lush furnishes a most important contribution to the anatomy of the pregnant uterus. He has examined the uteri of two pregnant women and failed to find any trace of the ring of Bandl. Dr. Stansbury Sutton supplies an essay on non-malignant tumours of the uterus, but it does not contain anything very new. Lastly Dr. Bozeman writes on the clamp-suture in relation to the injuries incident to parturition. His object is to vindicate his own originality, and to remove the idea that he was a copyist of Marion Sims. In concluding this brief survey of the contents of this volume, we may give ourselves the pleasure of saying that we think it one of the best volumes of "Transactions" that we have seen, and that it shows unmistakeable signs of improvement in American Gynecology.

*A Handbook of Therapeutics*; by SYDNEY RINGER, M.D. Eleventh Edition. London: H. K. Lewis, 1886. It has been said, not unaptly, that Dr. Ringer's well-known handbook comes as a boon to the general practitioner as being the sole modern substitute for the old apprenticeship system. It is like a vessel in which the latest scientific improvements are employed to convey an assortment of old guns, cast-off uniforms, and American notions to certain artless aborigines. The cargo is admirably suited for its destined purpose, but it is a little incongruous to find it in a steel vessel driven by the newest thing in engines. Dr. Ringer's book is a standing testimony to the truth of a favourite saying of Dr. Wilks' that what we want is not so much new drugs as better knowledge how to use the old ones (or in many cases how *not* to use them). Dr. Ringer certainly gives us a greater number of empirical facts, a richer series of therapeutic "tips," than any known author. His book teems with directions for innumerable therapeutic experiments, the only objection to which is that, in other hands than Dr. Ringer's, as often as not they fail to come off, a result which again brings us back to Dr. Wilks' dictum. In short, to apply Dr. Ringer's teaching with success, we must have Dr. Ringer's diagnostic skill. In the present edition the author, with the aid of some of the younger men of his school, has done his best to bring his book up to date. It contains an excellent account of cocaine by Dr. Dudley Buxton and a short notice of anti-pyrim and of the new substitutes for digitalis; but Dr. Ringer is commendably cautious in speaking of drugs of which he has not had adequate personal experience. In fact, the one great merit in the work has always been admitted to be its personal character, teaching by authority being essential in an empirical art like therapeutics, as taught by Dr. Ringer. This is perhaps a sufficiently valid excuse for the omission of certain drugs, such as guaiacum, and its relative, serpentary, so much trusted by some physicians. Of the former, considered by many as a specific in the early stage of quinsy and in rheumatic sore throat, the only mention we have been able to find is in a short footnote, describing its purgative action. In conclusion, we are sorry to notice that the present edition has been rather carelessly revised, small errors in proper names and in punctuation being plentiful in some of the chapters. The hurry necessary in following up the publication of the British Pharmacopœia may, in some measure, be an excuse for this, but whether that or modesty account for the omission to record on the title-page the well-won honour of F.R.S. accorded to Dr. Ringer last spring we forbear to enquire.

*A Reference Handbook of the Medical Sciences*; edited by ALBERT H. BUCK, M.D., vol. i. New York: William Wood & Co., 1885.—Our American colleagues seem never tired of startling us with the magnificence of their literary projects. The bulk and elaborateness of the volumes of the Index Catalogue of the Surgeon-General's Library, the admirable execution and rapid production of the new American System of Medicine, the loving labour spent by Professor Dalton on his exquisite series of brain photographs, all testify to a largeness of conception and boldness of enterprise amongst American authors and publishers not common on this side of the water. And the large and beautiful volume before us, called, by a perhaps pardonable abuse of language, a "handbook," witnesses the same thing. Over here we produce with labour and sweat a Dictionary of Medicine, and our American rivals at once cap it with a handbook in eight volumes, copiously and beautifully illustrated. To descend to particulars, the Reference Handbook is the joint production, under Dr. Buck's editorship, of some of the best-known and ablest practitioners in the United States and Canada. The articles vary in length, some being long enough to constitute a book in themselves, like Dr. Ransohoff's profusely illustrated article on Amputation, which occupies more than 80 closely printed columns, and the series of articles on the Brain, which take up 140 columns. We think that the editor has acted wisely in giving fairly exhaustive articles on important topics in preference to filling his space with brief and comparatively useless notices of a larger

number of subjects. In this volume he has shown much judgment in choosing the articles to be treated liberally, these being mostly connected with the diagnosis and treatment of disease. The practitioner, therefore, who wants help, who desires to have at his hand in a small space the latest and best of the knowledge that is likely to be of value to him in practical emergencies, will find in the Reference Handbook a most valuable ally. If he uses it, however, as an exhaustive medical encyclopædia, he may possibly be disappointed. It is only fair to add, however, that many subjects apart from purely practical ones find a place in the volume, many of the articles dealing with the facts of botany, climatology, medical jurisprudence, &c. The articles, of course, vary in excellence, as they necessarily must do, in a volume reckoning so many contributors, but we can strongly recommend the publication to every practitioner who likes to have the facts of his science and art in a reasonable compass. The volume is well illustrated by woodcuts and coloured plates.

*A Treatise on Amputations of the Extremities and their Complications*; by B. A. WATSON, M.A., M.D., Surgeon to the Jersey City Charity Hospital, &c. Philadelphia: Blakiston, Son, and Co., 1885, pp. 762.—In the preface Dr. Watson tells the reader that he has been nearly a quarter of a century unceasingly devoted to the study of the topics treated of in his book; ever since, indeed, the war of the Rebellion, during which he served as medical officer. It may be at once conceded that the author has succeeded in making a very admirable work, bearing throughout an evidence of large personal experience, and of a carefully cultured appreciation of the labours of other workers in the same field. The work is dedicated to Sir Joseph Lister, "the father of antiseptic surgery, whose labours mark a new era in the treatment of wounds." The first chapter is chiefly retrospective, and gives a general history of amputations. It helps to make the work complete, but otherwise has little right to the 61 pages which are devoted to it. Chapter 2 deals with a consideration of all those conditions which go to form the personal element of each case—the moral, mental, physical, and hereditary influences which come into play—as well as the patients' surroundings, as affecting the results of amputations. These are followed by chapters on the general and the special features of amputations, and on their after-treatment, the latter being a powerful appeal in favour of strict Listerian precautions. Chapter 8 relates to the selection and application of artificial limbs. It occupies some 150 pages, including many illustrations, and contains a large mass of information not otherwise so accessible to the surgeon as in its present form; we know of no better account of this often neglected portion of the subject; its careful study and discriminate assimilation by those who are called upon to advise in such matters can be confidently recommended. The chapter on the "complications of wounds," as our author designates it, deals with the nature and causes of shock, the management of accidental hæmorrhage, traumatic delirium, an experimental enquiry into the ætiology and distinctive peculiarities of traumatic fever, finishing up with an account of the causes and treatment of secondary hæmorrhage. In our judgment, this last-named subject alone can be regarded as a wound complication, and we should have included it under pyæmia and other septic conditions (which the author has dealt with separately), to which it is so frequently due. Shock and traumatic delirium depend on causes apart from the wound, though due to the accident, and may be present notwithstanding that the wound is thoroughly healthy and free from those septic conditions, which are included under the now restricted term of "complications." We can congratulate the author on his work, and the publishers on the manner in which it leaves their hands.

*Clinical Lectures on Diseases of the Liver*; by CHARLES MURCHISON, M.D., LL.D., F.R.S. Third edition, edited by Dr. Lauder Brunton, F.R.S. London: Longmans, Green, & Co., 1885. Seventeen years have elapsed

since these lectures first made their appearance, and eight years since a second edition underwent revision at the hands of the author. Notwithstanding the march of knowledge which has taken place in the interval, these lectures will, we believe, retain all their old popularity, and that because they are eminently clinical, for, as a clinical teacher and writer, Murchison had no superior and but few rivals. It would be superfluous to say anything in praise of a work which has become so renowned as the series of lectures that are now before us, but we must congratulate the editor upon the great judgment he has shown in handing on the lectures to us in as nearly as possible the form in which they were left by their distinguished author. Here and there additions and slight alterations have of course had to be made to keep the work up to date with the most recent teachings of science, but Dr. Brunton has managed to do this without destroying its original character. The chief alteration he has made consists in the addition of a section on the action of toluylendiamine in producing jaundice. This substance with the unpronounceable name possesses the formula  $C_6H_3(NH_2)_2CH_3$ , and it appears that it so alters the blood as to cause it on reaching the liver to supply the hepatic cells more readily with material for the formation of bile. The section on tropical abscess has been entrusted to Sir Joseph Fayrer, who has been rather more liberal in the matter of alterations than the editor, but he has added several cases of great interest, derived either from his own experience or from that of Professor Maclean at Netley.

*The Vegetable Materia Medica of Western India*; by W. DYMCK, Surgeon-Major, Bombay Army. Second edition, Part ii. London: Trübner & Co., 1885.—This is a continuation of the work we recently noticed. The nomenclature adopted is that of the Flora of British India, and the author has availed himself of Mr. G. Watts' catalogue of the economic products of India. Much that is of general interest will be found in this work; for instance, we are told of the Indian fruit *mango* that, when ripe, it is invigorating and refreshing, fattening, and slightly laxative and diuretic; that the rind and fibre, as also the unripe fruit, are astringent; that unripe mangoes pickled and dried in the sun, and known as *amchar*, are largely used as an article of diet, and form a useful antiscorbutic; and that a fluid extract can be made of the bark or rind: *Ext. Fl. Mangif. Ind.*, 10 grammes; water, 120 grammes; dose, one teaspoonful. The information respecting domestic remedies is both useful and interesting. A systematic research into the physiological and therapeutic properties of some of the indigenous drugs touched on in this treatise might well be conducted by competent observers. Besides the lack of accurate knowledge in respect to the major portion of these indigenous drugs, there are some, more strictly speaking, Indian in their habitat, the nature of which is enveloped in utter obscurity; such, for example, as *gaozaban*, *galeep*, *talispatra*, &c. The drugs which have hitherto been employed in native practice have been given in a more or less crude condition. By properly made extracts, liquid extracts, tinctures, and infusions, the properties could be tested more accurately. We would suggest to the author that on revising a future edition he should excise much extraneous matters and mould his work more in accordance with standard books on *Materia Medica*, so as to render it useful to the profession.

*Die Diphtheritische Allgemein-Erkrankung und deren Behandlung*; von Dr. ED. SCHOTTIN, in Dresden. Hirschwald: Berlin, 1885. (General Diphtheritic Disease and its treatment.)—The author of this monograph, who brings an extensive practical experience to bear upon his subject, has set himself the task of proving the distinctions and relations between the purely local manifestations of diphtheria and the wider and more important changes in the internal organs which may follow as a consequence upon them. He believes that the disease must be regarded as a general infective malady entering the system by certain channels upon which it may or may not exert a specific

influence. That in cases where local changes are induced these are in direct proportion both in severity and duration to the subsequent systemic disturbances, and that in many respects the disease bears a strong clinical resemblance to erysipelas. He lays much stress upon the great variety which is to be noted in the mode of onset when the disease attacks internal organs and its tendency to show spurious signs of recovery after the first effects of local disturbance have passed away. In the succeeding chapters the author reviews systematically the clinical features of diphtheria as affecting the various organs, quoting cases which have come under his own observation wherever possible. In his description of diphtheritic disease of the lungs he records the fact that he has never yet seen a case in which the disease, being primary in the lungs, has spread by continuity to the upper air passages, although, like many other observers, he has seen the converse taking place, a form of disease presumably diphtheritic in nature, spreading to the lungs from a diphtheritic larynx. With respect to the disease as affecting the cerebral membranes, he is not able to adduce any pathological evidence, but quotes a case in full which would appear to have been an undoubted instance of meningeal inflammation occurring in association with typical diphtheria. In his notes upon the affection of the kidneys he points out the singular disposition which diphtheria shows to attack only one at a time of the paired organs of the body. Hardly any mention is made of diphtheritic paralysis, and the whole tone of the work is more clinical than pathological, but it presents many interesting, if not actually new, points for consideration. In his opening sentences Dr. Schottin refers to our conception of diphtheria, as a whole, as that of a veiled picture. The veil can only be lifted by means of pathological investigation, but it may fairly be said that in the work before us many indications are given which will serve to render its obscurity less dense than it has hitherto appeared.

*The Extra Pharmacopœia*; by WILLIAM MARTINDALE, F.C.S., and W. WYNN WESTCOTT, M.B. Lond. Fourth edition. London: H. K. Lewis, 1885.—This, the most invaluable of pocket and table companions, still keeps up its reputation for accuracy and completeness. In the present edition considerable alterations have been necessitated, as a consequence of the recent publication of the British Pharmacopœia. Mr. Martindale's work may be regarded as a sort of satellite of the official publication, revolving for the most part faithfully around it, but, on occasions where that leading luminary fails to enlighten us, ready both to criticise it and to supply its place. The brief review of the changes made in the B. P. of 1885, with which Mr. Martindale opens his volume, will be found extremely useful. Another new feature of the present edition is the list of secondary drugs, or drugs "on promotion." The medical editor has brought his references in the body of the work well up to date; and altogether the publication is one of which, in its limited sphere of usefulness, it would be difficult to speak too highly.

*The Physicians' and Surgeons' Visiting List for 1886* London: John Smith & Co.—This admirably arranged visiting list is entering on its 40th year of publication. It is so largely used by the profession that it needs little recommendation from us. This we must say, however, that, having tried many of its rivals, we have never found one quite as satisfactory. The tables prefaced to it we have always found extremely useful, and their value is increased this year by the addition of tables of "Expectation of Life" and of "Average Heights and Weights" of man in his various stages of growth. The posological table has not yet been altered in accordance with the new edition of the Pharmacopœia, but the necessary changes are so slight that we can well wait until next year for this revision.

*Clinical Studies on Diseases of the Eye*; by Professor VON ARLT. Translated by Lyman Ware, M.D. Edinburgh: Young J. Pentland, 1885.—This volume deals with diseases of the conjunctiva, cornea, sclerotic, iris and ciliary body, that is, it includes those diseases for his knowledge of which

Professor Arlt is so widely and so deservedly famous, and it is hardly necessary for us to add that the lectures are worthy of his reputation. Except for the frontispiece, representing a horizontal section of the eye, there are no illustrations: a wise decision, for the cost of coloured drawings sufficiently life-like to be of any use would have added so much to the expense of the book as to have placed it beyond the means of many of those to whom it is addressed. The translator is to be congratulated on his share in the work, and the general get-up of the book is worthy of commendation and imitation.

## ABSTRACTS AND EXTRACTS.

### THE CURE OF EXTRA-UTERINE FŒTATION BY ELECTRICITY.

—It may be regarded as an accomplished and proven fact that electricity in some form is a specific cure for extra-uterine pregnancy. It arrests the growth and destroys the vitality of the embryo and cyst, and its use is followed by a truly remarkable disappearance of all or the greater part of the growth in a short time. This at least is true when the electricity is used during the first half of the pregnancy. As we approach the period of viability in the child, the risk of rupture of the cyst diminishes, and the propriety of surgical interference at or near term becomes greater. The great advantage of the Faradic current over all other forms of electricity has been shown, but opinion is not yet settled as to whether we should use a local current for a long time or a strong current briefly, and how many repetitions of the application are necessary. To determine these points, Dr. Henry G. Landis has conducted a series of experiments which are published in the October number of *The American Journal of the Medical Sciences*. They are based upon the supposition that success is achieved by the death of the embryo; the *specific* value of the method being that the fœtus will surely be killed if it gets a large enough dose of the current. The experiments are also based upon the supposition that the fœtus is in the matter of vitality to be compared with some of the lower forms of life. Dr. Landis draws the following conclusions:—(1) In using the Faradic current in extra-uterine pregnancy, the applications should be protracted for an hour if the patient can bear it. (2) The current should be repeatedly applied, in order that the vitality of the fœtus may be finally exhausted. (3) The current should for at least one sitting be used in great strength. (4) The current probably acts, not only by destroying the fœtus, but by its action upon the placental circulation; an additional reason for a long application.

TREATMENT OF SUNSTROKE.—During the hot weather of July and August of the present year, Dr. Horwitz states that a very large number of cases of sunstroke were treated at the Pennsylvania Hospital on an almost uniform plan. The patient was at once put into an ice-water bath, digitalis, antipyrin, and morphia being administered, and, where convulsions occurred, ten-grain doses of musk were given every half-hour by the rectum. The employment of musk in thermic fever is a novelty, and its effect in subduing the convulsions has been extremely pronounced. Antipyrin, which has also been advantageously used in New York, has been very satisfactory, as in only one case did it fail to keep back the rebound of the temperature which is so apt to follow the fall produced by the cold bath. There is one point of treatment to which earnest attention should be given. Many years ago, Dr. Horatio Wood found that, if a dog or rabbit was immersed in the cold bath, as soon as it became unconscious, it recovered; but, if it were allowed to lie for a few moments, the withdrawal of the heat almost always failed to bring about recovery. Often the animal would become conscious; but paraplegia and other paralytic symptoms would remain, and death soon followed. Clinical experience abundantly confirms this. It is certain that minutes, and even seconds, are of the greatest importance in sunstroke. With covered ambulances there would be no difficulty in stripping the patient, at least to his underclothing, and rubbing him with ice,

and administering antipyrin hypodermically, &c., whilst *en route* for the hospital. In this way, we believe that many lives would be saved. A case of sunstroke treated immediately would very seldom prove fatal.—*Therapeutic Gazette*, November.

**GRAFTING OF TENDONS.**—At the Société de Biologie M. Assaki made known (*Gazette des Hôpitaux*, November 3rd) the results of a series of researches on grafting of tendons, which he and M. Fargin had been carrying on. In these experiments they transplanted portions of tendon on animals of different species, such as from the sheep or the dog to the rabbit, and from the rabbit to the dog—the grafts uniting by primary intention. Extending the sphere of these experiments, they found that they could graft tendons from birds or mammalia, as from the duck or the turkey to the rabbit, and from the rabbit to the fowl. The tendons so grafted preserved their mobility and their normal resistance. These observers are of opinion that these facts are of a nature to induce surgeons to have recourse to grafting in cases in which simple tendinous suture is impossible. They also found that the portions of catgut interposed between the two divided ends facilitated the work of reparation.

**THE LIMITATIONS OF COLOTOMY IN DISEASE OF THE RECTUM.**—Dr. Charles B. Kelsey, in an elaborate paper in the October issue of *The American Journal of the Medical Sciences*, defines the following as the indications for colotomy. (1) In congenital malformations of rectum or anus in children, in which a tentative operation in the perineum has failed to reach the rectal pouch. (2) In intestino-vesical fistulæ. (3) In tumours occluding the rectum which cannot be relieved by any other means—dilatation, division, hot water, or electrolysis. (4) In non-cancerous, simple, or specific stricture and ulceration of the rectum (with or without fistulæ), where the disease cannot be relieved by proctotomy or dilatation, or division of the fistulæ and local treatment of the ulceration. (5) In cancer where the disease can neither be removed nor the passage re-established, and where death is probable from obstruction—except in cases where the immediate dangers of the operation more than counterbalance any good likely to be gained by it. (6) In volvulus or intussusception of the colon or sigmoid flexure, where reduction by the aid of laparotomy has been found impossible.

**TREATMENT OF VARICOCELE.**—Dr. Pancoast states (*Philadelphia Medical News*, October 24th) that he has successfully treated varicocele in more than 400 cases by a method which he regards as much superior to the removal of a portion of the scrotum, now in vogue in New York, or the operation advocated by Mr. Henry Lee of London. In his own operation, too, the patient is cured in three or four days instead of in as many weeks. It consists in transfixing the scrotum with a sailmaker's needle (which has a good point, but no sharp edges) and passing between the vas deferens and the veins a strong silk ligature, which, having been carried around the veins, is then brought out at the point of insertion. The ends are tightly secured over a button of German silver or zinc, and, the veins being thus strangulated, the ulcerative process goes on rapidly.

**RESORCINE IN EPITHELIOMA.**—Dr. Rubino Antonio has successfully applied resorcine to an epitheliomatous tumour on the side of the nose of an elderly man. The tumour was itself only of the size of a pea, but was apparently attached to the bone, and was surrounded by an extensive area of reddened skin which was evidently infiltrated to a considerable distance. Under the circumstances, Dr. Antonio did not advise an operation, and at first feared that nothing could be done. He, however, remembered some observations of Drs. Pascal and Manino, and decided to apply resorcine locally. An ointment was prepared containing 15 parts of resorcine to 20 of vaseline, and after the tumour had been washed with permanganate of potash this ointment was applied twice a day. The discharge began almost immediately to diminish, and the growth became gradually smaller and smaller, till, after five months of this treatment, nothing was left except a small white circular cicatrix.—*Giornale Internazionale delle Scienze Mediche*.

**SOLUBILITY OF BIN-IODIDE OF MERCURY.**—M. Mehu, in a note read at the Brussels Academy of Medicine (*Presse Belge*, October 18th), stated that castor oil is one of the most powerful solvents of the bin-iodide, one gramme of which to 50 of the oil satisfying every therapeutical requirement. The iodide of potassium adds to this solubility. Lard will only take up  $4\frac{1}{2}$  grammes to 1,000, and vaseline 1 gramme to 4,000. Carbolic acid, warmed to about  $100^{\circ}\text{C}$ ., dissolves a little more than 20 grammes of the bin-iodide in 1,000 grammes, half of this being precipitated on cooling. At the ordinary temperature benzine retains 4 grammes in 1,000.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, DECEMBER 11TH, 1885.

THOMAS BRYANT, F.R.C.S., President, in the Chair.

THE PRESIDENT announced that, owing to temporary indisposition, Sir Andrew Clark was unable to be present, and that the reading of his paper on a case of desquamative prostatitis would therefore be deferred.

*Aneurysm of the Ascending and Transverse Portions of the Arch of the Aorta—Pressure on the Trachea and Bronchi, on the Left Recurrent and (?) Left Vagus—Paresis of the Crico-Arytenoidei Postici.*

Dr. F. de HAVILLAND HALL communicated this case. The patient was a barrister, aged 61. When seen on October 5th, he was found to be suffering from great dyspnoea, and there was some lividity. He had a brassy ringing cough with purulent expectoration. There were no respiratory excursions of the larynx, the breathing was equally stridulous on inspiration and expiration, voice quite clear. Examination of the chest showed rhonchi and stridulous breathing. Doubtful impairment of resonance across upper part of sternum. Heart sounds clear. Pulse in radials equal; pupils equal. Laryngoscopic examination revealed paresis of the crico-arytenoidei postici. There was a history of shortness of breath for two or three months, much increased the last week. The patient had been previously seen by Sir Andrew Clark and Dr. Semon, and a diagnosis of pressure on the trachea with implication of both recurrents or of one vagus was arrived at independently. As regards the nature of the pressure, the absence of the usual physical signs of aneurysm seemed to exclude that affection, and it was thought probable that the pressure was due to a malignant growth. The patient at first improved under the influence of iodide of potassium, but died quietly on October 8th. The *post-mortem* examination disclosed an aneurysm on the posterior aspect of the ascending and transverse portions of the arch, about the size of an orange, pressing upon the trachea, right and left bronchi, left recurrent laryngeal nerve, and possibly also the trunk of the left vagus. There was a second aneurysm just above the diaphragm, fusiform in shape, and about two inches in length. The lungs were in a state of pneumonic consolidation, and there was some recent pleurisy. Inspection of the larynx showed the cords to be in the position of semi-adduction (*i.e.*, nearer the middle line than the usual cadaveric position). The muscles appeared healthy to the naked eye, but on microscopical examination, though the striation was good, there was deposit of pigment beneath the sarcolemma. He had brought the case forward as illustrating the difficulty in diagnosing aneurysms springing from the posterior aspect of the arch of the aorta in cases in which all the physical signs of aneurysm were absent. He was of opinion that in the case under consideration there were at least two factors to account for the dyspnoea, as the paresis of the abductors was insufficient to explain the great shortness of breath. Moreover, the absence of respi-

ratory excursions of the larynx pointed to the chief impediment being below the glottis. He accepted Dr. Bristowe's theory that in cases in which the trachea was compressed accumulation of mucus took place just above the constriction in consequence of the mechanical impediment existing to the performance of an effective cough. In such cases of mixed obstruction to the respiration the justifiability of tracheotomy at once arose.

Dr. FELIX SEMON observed that the case related by Dr. Hall was important as illustrating two special points. The first of these was the pathogenesis of the disease, and the second the performance of tracheotomy in such cases. With regard to the first point, it would naturally be asked, how came the vocal cords to occupy this position of complete adduction? He had placed before the profession, some years ago, a series of observations, many of them original, and others quoted from previous writers, to prove that any organic pressure exercised upon the vagus, spinal accessory, or recurrent laryngeal nerves, if slowly applied, had the effect of paralysing the muscles of abduction before those of adduction. Since that time his statements had been frequently criticised adversely, and often perverted to a meaning which they were never intended to convey, but, having invariably submitted his cases to the judgment of competent observers and to the investigation of one or other of the medical societies, he did not feel disposed to change his views unless their error could be demonstrated in an equally full and satisfactory manner. An attempt in this direction had been made by Dr. Krause in Berlin, who had endeavoured to prove by experiment that slight pressure brought to bear upon the trunk of the recurrent laryngeal nerve would produce, not paralysis of the abductor muscles, but spasmodic action of their opponents, the adductor muscles. He had tied small pieces of cork loosely on the trunks of the nerves and then observed the effects upon the vocal cords. Fibrillary tremors were at first produced, shortly followed by the adduction of the cords to the middle line. In the trunks of the nerves, however, it had been found that neuritis was set up, thereby constituting an irritative lesion such as is known to produce the so-called neuropathic contracture of muscles supplied by acutely inflamed nerves. This contracture, however, only lasted for a very short time. In Krause's case the source of pressure had been removed after 5 days, but even in that time degenerative changes had been found to have begun in the posterior crico-arytænoid muscles, thus proving the truth of his (Dr. Semon's) observations. It was no doubt possible that in some very acute cases there might be produced a sufficient degree of irritation to set up this neuropathic contracture, just as it might be artificially produced by section of the nerve and irritation of the cut end. He thought that Dr. Hall's case must therefore be received with caution as an instance of paralysis, pure and simple, since the short history gave good grounds for believing that some such irritative lesion had at first been at work. There could be no doubt that pressure upon one recurrent nerve alone was not capable of producing bilateral paralysis. With regard to tracheotomy, it was always necessary to consider the possibility that a slowly increasing stenosis from abductor paralysis might at any time remain stationary, although it was generally progressive; also the possibility that the adductor group of muscles might become paralysed, thus bringing the cords to the cadaveric position in which there was less danger to life. The decision must be made by the patient or his friends, after fully comprehending the chances of success. The operation in most cases afforded the greatest relief to the patient, saving him from the constant danger and dread of suffocation.

Dr. OGLE inquired as to the state of the pupil in Dr. Hall's case, and advocated the use of palliative remedies, such as the bromides and chloroform, to combat the spasm.

Dr. LONGHURST also referred to the state of the pupils. He had seen many cases of aneurysm, but none requiring such an operation as tracheotomy. He thought that the laryngeal difficulty was due to nerve irritation and commented severely upon surgical interference in such cases.

The PRESIDENT expressed his opinion that, in some

cases, tracheotomy was not only advisable, but necessary. He had seen two cases in which life had been prolonged thereby for a great length of time.

Dr. HALL, in reply, expressed his agreement with Dr. Semon's view that the spasm of the glottis might sometimes be due to nerve irritation. The pupils, as stated in the report of his case, were equal. As regards other treatment than tracheotomy, his case had been so acute that the operation was imperative in the first instance.

*Suppuration around the Vermiform Appendix, treated by Abdominal Incision.*

Dr. THOMAS BARLOW and Mr. RICKMAN J. GODLEE read a paper relating to a man, æt. 20, whose previous history was unimportant, except that for the last two years he had been subject to attacks of diarrhoea and vomiting. His illness began rather acutely on September 12th, 1885, with loss of appetite, severe abdominal pain, and later, vomiting and absolute constipation. He was admitted into University College Hospital on the 15th, with a temperature of 102.4°, intense abdominal pain and tenderness, intermittent bilious (not stercoraceous) vomiting, and tight distension of the abdomen. There was a small patch of slight redness in the right iliac fossa. The diagnosis appeared to be between mischief about the appendix and constriction of the intestine by a band high up. He was given opium and iced beef-tea, and ice was applied to the abdomen. The temperature fell to normal, and the pulse was about 90, full and soft, the tongue dry and the colour good; but, as the symptoms were unrelieved, an exploratory incision was made in the middle line on the night of the 16th. General early peritonitis was found, but lymph only in the neighbourhood of the cæcum, surrounding a collection of fœtid pus. The vermiform appendix was much thickened. A second incision was made over the right iliac fossa, and a large drainage tube was inserted through it, reaching down to the appendix, a smaller one being placed in the median incision, which was closed with sutures. The peritonæum was first washed out with a solution of corrosive sublimate (1 to 500). The patient made an excellent recovery, the temperature remaining normal, and the pulse about 90. He was fed principally by the bowel for some time; beef-tea and arrowroot were allowed on the 20th day, and minced meat a fortnight later. No drugs were given except morphia for the first two days. Thirst was allayed by means of warm-water enemata. He had slight albuminuria a day or two after the operation, and a little later a parotid bubo occurred which did not suppurate. It was claimed that the uncertainty of the diagnosis justified the exploration, and that the early evacuation of the putrid pus rescued the patient from a condition of very great danger and prevented the matting together of the intestines which would otherwise have occurred. The freedom with which the peritonæum might be treated was pointed out, and the advisability of withholding food from the stomach for a prolonged period in such cases was insisted upon. Remarks were also made upon the absence of peritonitis and the presence of albuminuria as points in the diagnosis, and upon the relation between inflammation of the parotid and diseased states of the peritonæum.

Mr. MORRANT BAKER related a case under his own care, in which an abscess in the neighbourhood of the cæcum had been evacuated by operation, but which had recurred with a fatal issue at a later date, the cause being found in the presence of a needle projecting through the vermiform appendix and held in its position by hard concretions on the inner side, thus forming a permanent source of irritation.

The PRESIDENT described a case in which, with all the signs and symptoms of peritonitis, an abscess was discovered and evacuated through a lumbar incision with perfect success. Acute peritonitis was rare without a local cause, and this was very frequently to be found about the cæcum. He suggested that exploratory incisions should always be made in that region. Mr. Baker's case was remarkable as proving beyond all doubt that foreign bodies might sometimes lodge in the vermiform appendix, a possibility which had been denied on the highest authority.

Mr. C. J. SYMONDS remarked upon the fact that in Mr.

Godlee's case the escape of the pus into the peritonæal cavity had not prevented the success of the operation. Such a fact was very encouraging and would lead to more active treatment in this class of cases, which were sometimes impossible to diagnose. The ordinary signs and symptoms were not always sufficient to indicate the nature of the attacks of intestinal obstruction or peritonitis which appeared at times to come on absolutely suddenly. There could be no doubt that foreign bodies in the vermiform appendix were very rare.

Mr. BARKER considered that more decided action would in future be taken in dealing with these cases. He related the particulars of a case in which he had operated for the relief of strangulation by volvulus in the presence of acute general peritonitis. Although the coils of intestine were in places matted together with lymph, he had been able to search the greater part of the course of the small intestine and also the cæcum, to wash out the cavity and the coils of intestine, and to return them without difficulty and with perfect success. The case had done well since the operation. He thought that such a case, with others similar to it which were now accumulating, proved that the inflamed sac of the peritonæum might be dealt with in the same way as that of an ordinary abscess.

Dr. BARLOW confessed to a feeling of relief that no adverse criticism had been advanced to the early surgical interference in this case. He was aware that many physicians of experience were not in favour of it. The result of the case had been perfectly satisfactory, and the patient had recovered without any of that thickening round the wound which was apt to become a source of future danger. The really important element of the case, after the operation, was the feeding. The abdomen had to be kept at absolute rest, and hence nutrient enemata had been employed. The rectum, however, was not usually tolerant of ordinary enemata after the first day or two, and hence arose a serious difficulty which was only partly to be overcome by the use of peptonised meat extract and peptonised milk. He related the method adopted in the preparation of these enemata. Thirst was almost always a serious feature in these cases, the mouth and tongue often getting very dry and coated. By giving the tongue something to do, however, this difficulty could be got over, and in this case, by causing the patient to chew the meat without swallowing it, the desired result had been obtained.

Mr. R. J. GODLEE observed that he should bear in mind the remarks of the President with respect to making exploratory incisions in the neighbourhood of the cæcum. He related his own personal experience to the effect that the pain in inflammatory affections of the cæcum is often felt on the left side of the abdomen. He thought that the patients' own history of very sudden onset of the attack was not always trustworthy.

Mr. JONATHAN HUTCHINSON remarked upon the importance of deciding whether an abscess was really situated within the peritonæum. In his own experience, although he had often opened foetid abscesses behind the peritonæum, he had never opened one within it.

#### *Living Specimens.*

Dr. SAVILL—A Case of Myxœdema.

Dr. STEPHEN MACKENZIE—(1) A Case of Symmetrical Morphea; (2) A Leprosy-like Syphilide.

Mr. ROBERT PARKER—A Case of Congenital Deformity of the Upper Extremities.

Mr. STONHAM—Removal of Anterior Part of Lower Jaw, with the adjacent Floor of the Mouth, and the whole of the Tongue, for Epithelioma.

THE Madrid Medico-Chirurgical Academy offers prizes of 250 pesetas and 750 pesetas respectively for dissertations on the under-mentioned questions, to be sent in by the 15th of September, 1886, and written in either Spanish, Portuguese, French, Italian, English, or German. 1. What modifications has the pauperist doctrine introduced into the treatment of internal diseases recognised as or supposed to be parasitic? 2. A critique on improvements made in operations on bones.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 15th, 1885.

J. S. BRISTOWE, M.D., F.R.S., President, in the Chair.

### *Syphilitic Ulcerative Tracheitis.*

Dr. SILCOCK said that in this case numerous small ulcers were found in the larynx and throughout the air-tubes. The symptoms were those of chronic bronchitis. Several similar cases had been recorded, and one in the 20th volume of the Society's Transactions by Dr. Payne. The case suggested the desirability of using anti-syphilitic remedies more frequently. The man was aged 32, and there was a well-marked history of syphilis, and a gumma in the liver, and the microscopical appearances confirmed the diagnosis.

Dr. GOODHART thought it was comparatively common to see scars, but not so common to meet with active ulceration.

Dr. PERCY KIDD had met with a case in which the lower part of the trachea was solely affected, leading to considerable narrowing and difficulty of diagnosis.

Dr. LONGHURST asked how long it was since the man had contracted syphilis.

The PRESIDENT had exhibited a specimen which he then thought was tubercular, but now believed might have been syphilitic; in it there was extensive ulceration, the cartilages exposed and much destroyed.

Dr. SILCOCK said the man had syphilis in 1877 in India, and added that a large number of cases were mentioned in Ziemssen's Cyclopædia.

### *Internal Anthrax.*

Mr. JOHN POLAND said the specimen was taken from the body of a man, aged 23, who had worked at the river-side landing Chinese hides. When admitted, there was marked fever, soon after there was great restlessness, vomiting, unconsciousness, followed by a series of convulsive seizures. The fever increased, and he died comatose, Cheyne-Stoke's breathing having been well marked. At the *post-mortem* very extensive hæmorrhage into the pia mater was found, especially over the right hemisphere, the spinal cord was soft, and at the lower part posteriorly there was hæmorrhage. Hæmorrhagic infarctions were found in the lungs, also some hæmorrhagic erosions on the surface of heart. The blood was not clotted. The peritonæum contained four pints of dirty fluid; the posterior wall of stomach showed sloughing ulcers; an inch below the pylorus there was a similar slough, and four similar ones in the jejunum; the mucous membrane was elsewhere œdematous; mesenteric glands swollen. Large intestine natural. Spleen soft, liver normal. The skin over one scapula showed a hæmorrhagic area similar to that in the lungs. No characteristic bacilli could be found; this he attributed to the rapid decomposition. There was no external point of inoculation, and the disease had therefore entered through the air-passages. He had only worked one day at the hides. The symptoms came on the same day.

### *Diseases of the Circulatory Organs in Animals.*

Mr. J. BLAND SUTTON made a communication on this subject, prefacing his remarks with the observation that lesions of the heart and vessels were by no means so common in animals as in the human subject, and indeed were comparatively rare. (1) *Pericarditis*. Inflammation of the pericardium arose from much the same causes and presented much the same characters as in that disease in man; it might be of traumatic origin, or be due to extension from pleurisy, simple or tubercular, or result from *perlsucht*, parasites, or (?) rheumatic fever. It was well known to veterinarians that horses suffered from rheumatic fever, and that pericarditis was a frequent complication, and he was strongly of opinion that mammals which frequented the water, such as the hippopotamus, beavers, otters, and

the like, suffered from this disease. It was in these animals that most of the uncomplicated cases of pericarditis occurred, and many days before death they would lie about, abstain from entering the water, and when moved manifest evident signs of pain. He showed specimens of pericarditis from a lizard and a peacock (parasitic), from a beaver, an antelope, and a monkey (rheumatic?), from a tiger, coati-mondi, &c., arising from extension, and one specimen from a monkey, where the pericardium was enveloped by a mass of lympho-sarcoma, giving rise to effusion into the pericardial cavity. It was interesting to note that, according to Rayer, Galen had described the first case of pericardial effusion, and that it occurred in a monkey. The most interesting cases of traumatic pericarditis were chiefly found in cows, who frequently, when chopping grass, would take up foreign bodies, such as pieces of glass, wire, or needles, &c. Such articles were checked by the psalterium, and, being diverted from their course, they might pass through the coats of the stomach and diaphragm, and enter the pericardium, giving rise to violent inflammation; this mode of origin was well known to veterinarians. (2) The milk-white patch was very frequent in some birds and monkeys as a consequence of pressure from rickets, but the deformity induced by the latter disease led to a very serious condition of the heart, which might best be named "flexion." If the body of a young monkey that had recently died from rickets was frozen and bisected vertically, it would be found that the spinal column presented a high degree of curvature; when this was well-marked the sternum was also apt to become flexed, so that a knuckling-in took place which caused the heart to be squeezed between the sternum and the spine, and thus it became flexed. This led to atrophy of the wall of the right ventricle, which in some cases was so thin that the outer boundary of the cavity of the ventricle consisted only of the visceral layer of the pericardium. He thought that a similar condition would perhaps be found in children in extreme cases of rickets. (3) Affections of the valves, endocarditis vegetations and calcifications, occurred occasionally, leading to incompetency and its chain of consequences; specimens were exhibited from sheep, coypu, rats, deer, antelopes, buffalo, and a bear. (4) Diseases of the vessels were excessively rare, atheroma was found with tolerable frequency in the posterior aorta of the horse, and verminous aneurysm occurred probably in 90 per cent. of adult asses; excluding these examples, diseases of the vessels were very rare. In wild animals he had only twice discovered atheroma, viz., in a buffalo and in a zebu. The result was that true aneurysm was very rare in wild animals, he only knew of three genuine instances. (5) Verminous aneurysm, although so common in asses, and fairly frequent in horses, was, so far as he knew, confined to domesticated animals. The disease was of little interest to them, inasmuch as man was not liable to it, but the presence of these worms in the tunic of an artery was known to Ruysch as far back as 1665. (6) Arterio-capillary fibrosis, which was the last affection he had to deal with, affected the medium-sized arteries of the horse and cattle, and, as in man, was associated with chronic interstitial nephritis. He thought that the most interesting point that arose out of his communication was the rarity of atheroma, which he supposed might be due to the absence of alcoholism, syphilis, and arterial strain.

Mr. SHATTOCK mentioned a specimen of verminous aneurysm in a dog, in University College Hospital.

Mr. EVE knew of a specimen of worm in the mesenteric artery of a horse. If the animals came from the Zoological Gardens, they would not so much have been exposed to strains.

Mr. CRIPPS doubted whether aneurysms were so rare. In two out of a pack of hounds that had died, he had discovered aneurysms of the aorta. A well-known greyhound, Master McGrath, twice a prize-winner, had died from aneurysm of the aorta.

Mr. SUTTON, in reply, said the temperature had in some cases been found elevated. The aneurysms in the dogs might have been verminous. No doubt these did occur in horses, especially in the mesenteric artery, the vertebræ becoming eroded until suddenly the animal broke its back. His material was derived from very wide sources and not solely from animals confined in the Zoological Gardens.

#### *Central Sarcoma of the Femur.*

Mr. D'ARCY POWER showed this specimen, the limb having been amputated in a man, of 28, in consequence of spontaneous fracture. Pain had been felt in the limb for four months, and an oval tumour had been observed. The bone was very greatly expanded, a mere shell of bone being left, except on the external surface, where the bone had been thickened by a new deposit in such a manner as to form an oval swelling. The new growth was a tapering mass five inches long and an inch and a half in diameter at its thickest part. It was very loosely inserted into the shaft of the femur. Microscopically, it was a round-celled sarcoma which appeared to be undergoing calcification. The chief points of interest were the locality and its localisation, and the slight amount of expansion which the femur had undergone, compared with the large amount of absorption which had taken place in the bone.

#### *A Rhinolith.*

Mr. STOKER showed this specimen. It had given rise to no symptoms; it was chiefly composed of phosphate of lime arranged in concentric lamellæ. He thought it might have originated in a blood-clot. The disease appeared to be somewhat rare.

Mr. CLUTTON said that his case was reported in the "Transactions." There was a cavity containing a powder which might have originated in a blood-clot. It was larger than the present one.

#### *Round-celled Sarcoma of the Skin.*

Mr. SWINFORD EDWARDS showed this specimen, taken from the body of a woman, aged 45. It had begun ten months previously as a small pimple on the right thigh, which rapidly spread and became ulcerated. There was a large ulcer on the upper and inner part of the right thigh; the skin around was pigmented, the subjacent tissues indurated, several nodules surrounded the ulcer, a few papular spots were to be seen over the hypogastric and right iliac regions. Typhoid symptoms supervened, leading to death. The internal viscera showed no secondary growths. Köbner had recorded two cases of this nature, and similar ones had been described by Hardaway and Hyde. There was no reason to suspect syphilis, the patient had had 11 children, 10 of them being then alive, and anti-syphilitic treatment did not arrest the disease at all. On examination of the skin, the subcutaneous tissue was also affected and the skin was somewhat undermined.

Dr. CROCKER had seen the case and thought it must be one of sarcoma. It belonged to the class called by the French *mycosis fungoides*; the tumours in these were localised and ran a rapid course; the French called them lymphadenomas, the Germans called them sarcomas. Many names had been given to it.

Mr. EVE said that Dr. Alexander, of Liverpool, had published a very similar case. He thought there was more intercellular structure than was usual in such cases.

Mr. MAKINS had seen a similar case in a man between 50 and 60 years, with several nodules scattered about his trunk. The case resembled one of keloid. The tumours were removed.

Mr. BUTLIN had been much interested in this specimen, but he was inclined to think that the case was one of parasitic disease of the same nature as lupus or tubercle rather than a sarcoma. The reasons for this were that all the tumours were limited, and that there was a good deal of ulceration, and further that there were no secondary tumours. Death occurred from symptoms not consistent with the amount of local mischief, except on his hypothesis.

Dr. CROCKER said that Rindfleisch and Auspitz had found micrococci in one of their cases, but they had not succeeded in their inoculation experiments.

Mr. EVE said that this tumour had been very thoroughly examined for micro-organisms, but none had been found.

#### *Primary Melanotic Sarcoma of Liver.*

Dr. HALE WHITE showed this specimen, taken from the body of a man, aged 66, who had been admitted into Guy's Hospital with emaciation and a large liver. It weighed 122½ ounces, the left lobe and the greater part of the right

being enlarged and completely replaced by a firm new growth of greyish-green colour, with several black foliaceous bands running through it. Scattered throughout the organ were several round black masses of new growth, whilst there were also two white masses, each of them umbilicated, and looking like an ordinary carcinoma of the liver. The lymphatic glands in the portal fissure, and those on the upper surface of the liver, contained black pigment. The diaphragm was slightly adherent to the liver. The body was otherwise healthy, save that two moles and two warts were found in one orbit, from which the eye had been previously removed for simple glaucoma. Microscopically, the growth was a genuine carcinoma, the cells and alveoli being distinct. In parts the fibrous tissue amounted to scirrhous, especially near the old portal canals; pigmentation was very marked in the large bands and their small alveoli. In the white parts the growth stained well with hæmatoxylin. The gland showed chronic inflammation, and contained black pigment granules. No similar case was on record, though three of primary melanotic sarcoma of liver had been recorded. This case disproved Schuppel's statement that melanotic tumours in the liver were melano-sarcomata. This was a genuine carcinoma and not a malignant adenoma.

Mr. SHATTOCK said that, if the colour was greenish, the case might have been of biliary origin, and would then have belonged to the same category as some shown by Mr. Paul on a previous occasion.

Dr. GOODHART had not thought that the specimen at all resembled Mr. Paul's cases.

#### *Multiple Sarcomata.*

Mr. ARBUTHNOT LANE read the notes of a case of multiple sarcomata occurring in an aged woman, who appeared to have died from old age. In each innominate bone there was a central sarcoma as large as a walnut placed in the middle curved line two inches below the crest of the ilium; the tumours were exactly symmetrical in form and position. In the left ischium, immediately above and in front of the tuberosity, there was another tumour of the same size as those just described. In the ninth, tenth, and eleventh ribs were three other tumours arranged in a vertical line. In the body of the seventh cervical vertebra there was a growth which occupied the whole centre of the body of the bone, it had a well-defined margin anteriorly, where it encroached on the anterior surface of the body, and posteriorly it had destroyed a part of the posterior surface of the body with part of the upper articular processes; it did not extend along the sixth pair of nerves, nor did it appear to compress the cord. No other growths were found. Microscopically, they consisted of round and spindle cells, and were rapidly undergoing osseous changes.

#### *Card Specimens.*

Mr. E. H. FENWICK—(1) Tuberculous Ulcers of Bladder; (2) Contracted Bladder supervening on Atony.

Mr. J. H. MORGAN—A Siren Monster.

Mr. SHATTOCK—Woody Tumour on Branch of Pine, bearing out Cohnheim's theory of the origin of tumours.

Mr. BARKER—(1) Cancer of both Breasts (patient shown); (2) Arrest of Development of Humerus following upon Dislocation (?) in Childhood; (3) Arrest of Development of Femur from Disease of Upper Epiphysis.

### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, DECEMBER 10TH, 1885.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair

Mr. NETTLESHIP showed a patient suffering from diabetic retinitis. Scattered over the fundus were a large number of white patches and spots. He considered that they differed in position, mode of arrangement, and colour from those of

albuminuric retinitis; he had noticed differences of this kind in a few other cases of diabetic retinitis. The yellow-spot region of the right side was occupied by a dense irregular mass of the white deposit; there was no tendency to radiate arrangement round the yellow spot. The general tint of the spots was, he thought, yellower than in albuminuric retinitis. The patient was a man, aged 50, with cataract on the left side. The appearances had remained unaltered since January, 1885.

Dr. STEPHEN MACKENZIE pointed out that Lebert had shown that, though the majority of early observers had assumed that retinitis in diabetes was due to albuminuria, retinitis might occur in connection with diabetes independently of albuminuria. He did not think the appearances characteristic; anæmia, cerebral tumour occasionally, and lead-palsy all produced retinal changes closely resembling those of albuminuric retinitis. In a case reported by Lebert, and in another reported by himself, there were hæmorrhages in the vitreous. He enquired whether the combination of hæmorrhage into the vitreous with retinitis could be considered characteristic of diabetic retinitis.

Mr. NETTLESHIP agreed that retinitis with retinal hæmorrhages and white patches, combined with hæmorrhage into the vitreous, pointed very strongly to diabetes. The arrangement of radiating rows of spots in the retina was different to what occurred in albuminuric retinitis. The question on which he felt doubtful was whether an eye, in the state seen in the patient, was a later stage of the same condition, and whether the changes were characteristic of diabetes, as he was inclined to think.

Dr. S. WEST was inclined to agree with Mr. Nettleship. He did not think the appearances bore any close resemblance to albuminuric retinitis.

Mr. ADAMS FROST suggested that the condition of the retina in the patient resembled that seen in albuminuric retinitis in the late stage, and probably it appeared to be unusual, because patients with albuminuric retinitis seldom survived long enough.

Mr. McHARDY suggested that diabetes was sometimes over-looked, owing to this resemblance.

Mr. NETTLESHIP showed a patient from whose eye a chip of iron had been removed with the electro-magnet. No reaction occurred, but the retina became detached; and it was, therefore, very doubtful whether the eye would ever be useful.

Dr. W. A. BRAILEY again showed the patient exhibited at the last meeting; the retinal detachment had been treated by scleral puncture, and had disappeared.

#### *Essential Shrinking of the Conjunctiva.*

Mr. ANDERSON CRITCHETT and Mr. JULER showed two patients, the subjects of essential shrinking of the conjunctiva (so-called pemphigus of the conjunctiva). One case—that of a farmer, aged 53—was of special interest, as it had been under observation from its commencement. He came under Dr. Felix Semon's care in September, 1884, on account of an affection of the right nostril, which resembled syphilitic perichondritis and periostitis. In June, 1885, he was transferred to Mr. Nettleship's care, on account of epiphora and conjunctivitis, with partial obliteration of the lower *cul-de-sac*. The conjunctiva of the upper lid was marked by scars parallel to the free border. The affection went progressively from bad to worse in the right eye; and in August, 1885, slight conjunctivitis of the left eye was noticed. The right eye had finally become almost blind. Both eyelids were thickened, and partly adherent to the globe. Both *cul-de-sacs* were obliterated; and, though the globe moved pretty freely, the lids moved with it. The lashes were inverted, and the cornea opaque and vascular. Similar shrinking of the conjunctiva had commenced in the left eye; the lashes were turning inwards; and the *cul-de-sacs* were so much diminished that the lids could not be everted without difficulty. The conjunctiva was red and velvety, but showed no scars. Vision was still fairly good. The man gave a distinct history of syphilis ten years earlier. No sign of pemphigus could be discovered on the body, though the man stated that he had seen bullæ on his palate. Mr. Critchett expressed the opinion that the condition had no relation to pemphigus, but was an essential shrinking of the conjunctiva, similar to that

described by Gräfe (*Arch. Oph.*, vol. xxiv.) and Bäumler (*Monatsblätter f. Aug.*, August, 1885).

Dr. F. SEMON said that the patient came under his care in September, 1884, suffering from a muco-purulent discharge from the nose, which was sometimes streaked with blood. Beyond slight superficial ulceration of the mucous membrane there was nothing to account for the symptoms. At that time the only part affected was the left nostril. Mercury and iodide of potassium, given separately and in combination, produced no improvement; but, while under this treatment, on one occasion several large bullæ appeared, and the skin of the face was in a branny condition, resembling erysipelas. This subsided after the withdrawal of the drug. Conjunctivitis soon afterwards appeared, and some small serpiginous ulcerations of the mouth. He had been impressed by the infective character of the malady, and had suggested that it might be a case of very slowly advancing glanders.

Mr. LANG quoted a case recorded by Schweigger, which agreed closely with the patient shown by Mr. Anderson Critchett. Cases of the disease had been seen at all ages, and in many of the cases there was no suspicion of a specific history.

Mr. JULER was struck by the exceedingly localised nature of the disease in Mr. Lang's cases. In a certain proportion of the cases no pemphigus was ever observed; while in others, where bullæ were seen, the amount of shrinkage of the conjunctiva was more extensive.

Mr. NETTLESHIP said that, even if the disease were allied to pemphigus, there was a good deal more extensive inflammation than mere conjunctivitis, for there was great thickening of the lid.

Mr. MALCOLM MORRIS thought that the use of the term pemphigus required justification. The presence of a syphilitic history in certain of the cases suggested that the disease was a late syphilitic lesion. The slow progress of the case, and the occurrence of new growth, probably inflammatory, in the skin, seemed, however, to show that the disease was more allied to rhino-scleroma.

#### *Compression of Optic Chiasma.*

Mr. SILCOCK showed a specimen of sarcomatous tumour, springing from the pituitary fossa, and compressing the optic chiasma. The chiasma was elongated and flattened. The patient was a needlewoman, aged 25, who was admitted into St. Mary's Hospital in a comatose condition; she had been able to do her work up to two days earlier. There had been, so far as could be ascertained, no defect of vision. The optic nerves were inflamed, but there was no evidence of degeneration.

#### *Double Optic Neuritis after a Fall.*

Dr. SAMUEL WEST related the case of a girl, aged 11, who was admitted into hospital with the history that, one month before, she had fallen and struck her head, that two days later she had a fit, and subsequently, on several occasions, short attacks of unconsciousness, and that she had gradually grown feebler. There was no paralysis and no objective symptoms beyond double optic neuritis; vision was good, I. J. being read with facility. Under treatment by iodide of potassium and mercury, for about ten weeks, the optic neuritis finally completely disappeared. There was no evident hypermetropia.

Mr. WARREN TAY asked at what date the optic neuritis had been noticed. He had on a previous occasion brought forward three cases of optic neuritis after injury without disturbance of vision. He thought such cases were very rare.

Dr. STEPHEN MACKENZIE asked why the patient had come under observation, as there seemed to be few or no symptoms. He also asked as to the state of the knee-jerks.

Mr. JULER asked if there was any error of refraction, as in such cases slight injuries were often followed by optic neuritis.

Dr. WEST, in reply, stated that he did not see the child until three or four weeks after the injury, and then the neuritis was present; the child was brought on account of having had a fit. He had no note as to any abnormality of the knee-jerks, and he therefore assumed they were

natural. There was certainly no marked degree of hypermetropia.

#### *Contraction of the Field of Vision in Diphtheritic Paralysis.*

Mr. W. H. JESSOP had examined the field of vision in a child suffering from diphtheritic paralysis when she first came under treatment, and had found considerable contraction of the field; this contraction of the field disappeared as the other symptoms improved.

Mr. LANG had recently examined one case of diphtheritic paralysis where there was no limitation of the field of vision. He added that Professor Uthoff had examined the field of vision in several cases, but had not recorded any limitation of the field. In his own case there was loss of accommodation and inability to converge; these pointed, in his opinion, to a central lesion.

#### *Neuro-paralytic Ophthalmia.*

The Honorary Secretary read for Mr. CHARLES HIGGINS the history of a case of paralysis of the fifth nerve with corneal ulceration. The patient was a woman, aged 19, who had a large central corneal ulcer, small superficial ulcers on the skin of the temple and forehead, and total anaesthesia of the conjunctiva, and all parts supplied by the right fifth nerve; wasting of the muscles of mastication occurred later. The eye was brought under the influence of atropine, and carefully covered; the patient was sent to the seaside, and the ulcers of the skin healed within six weeks; the corneal ulcer healed in eight months, leaving a dense leucoma; the anaesthesia still persisted, and there was some ulceration of the nostril and styes on both eyelids; but the patient was otherwise in good health, and the eye on the affected side appeared to be, with the exception of the leucoma, quite normal.

#### *Retinitis.*

Dr. BRAILEY showed a girl, aged 12, the subject of congenital specific disease, in whose left eye were numerous white, opaque, striated retinal patches very similar in appearance to opaque nerve-fibres. Since, when first seen, she had albuminuria, he regarded these as due to a retinitis, probably of renal origin; in addition, there were a few minute spots of choroiditis disseminata. The vision of each eye was defective, the left the more so; each was hypermetropic about 7.D, and astigmatic 1.5.D; glasses, however, produced no material improvement. There was long standing extensive suppuration of the bones of the left forearm and of both tibiae; no visceral enlargements could be detected. The case was accompanied by an ophthalmoscopic drawing.

#### *Card Cases.*

Mr. W. H. JESSOP—(1) Large Semi-circular Retinal Hæmorrhage, near the Yellow Spot; (2) Detachment of Retina (living patient).

Mr. JULER—Gunma of Iris (living patient).

## NOTES ON FOREIGN HEALTH RESORTS.

### THE CAPE COLONY.

THE favourable climatic conditions which served to make the Cape the sanatorium of our Eastern Empire were not lost on the completion of M. de Lesseps' great waterway. And, although no longer distinguished as the health recruiting station for Indian invalids, the Colony has for some years past attained to a position of considerable importance as a health resort especially beneficial to those suffering from various forms of pulmonary disease. The reputation thus generally bestowed really requires, however, something more definite in the way of an analysis of local conditions if it is to be made practically useful. When the Colony was founded by the Dutch in 1652 its limits lay within gunshot of the Fort of Good Hope (the

progenitor of the present Castle at Cape Town), and at night the lions sometimes "scemed as though they would take the Fort by storm." Since that date its boundaries have been continuously pushed onwards, until at the present day the Colony may be said to extend from the Orange River on the north and Natal on the east to the coasts washed by the Atlantic and Indian Oceans, including a total area of more than 250,000 square miles. There are necessarily considerable varieties of climatic conditions to be found within an area so vast and so varied in its conformation. In general terms the climate of the Colony may be described as fine, healthy, warm and dry, and so forth; but the man who speaks less vaguely of "the Cape climate" in set words is really only describing his own experience of some particular portion of the country. We shall here endeavour to give such information on the subject as will enable anyone, with the help of a good map, to distinguish the chief climatic attributes of the different districts; and at the same time to comprehend some of those other conditions of local existence which are so important to the invalid who purposes making his home for health's sake in a strange and distant land.

The prevailing winds of Southern Africa are southerly; the air being sucked northwards towards the vast heated surface of the interior of the Continent. Since these winds blow from the cold and ice-bound southern seas, they are but slightly charged with moisture, and tend generally to give a character of rainless drought to the lands over which they sweep. But in the Cape Colony itself the prevailing winds correspond pretty closely to the Trades, blowing from the south-east during the summer months, *i.e.*, from early October until March, and from the north-west from April to September. Here we are at once met by a striking distinction between the two provinces—Eastern and Western—into which the Colony is primarily divided. The south-easterly winds which blow towards the Eastern Province, and so much of the Western Province as lies east of the Gauritz River, come laden with watery vapour from seas comparatively warm; and, striking the elevated and cooler coast-line and the inland plateaus, this watery vapour is partially condensed and precipitated. Thus, in the Eastern Province, summer is the season of fertilizing rains. But the south-east winds which blow over the Western Province have either come from the colder region of the South Pacific or (as regards the Karroo and Great Bushmanland, for instance) they have been already robbed of their moisture while traversing the cooler mountain ranges of the east; hence the summer of the Western Province is dry. Again, the north-westerly winds, which blow during the winter months, come to the western shores of the Colony saturated with vapour from the Tropic ocean. The rain thus deposited falls for the most part, however, only along the coast and in its vicinity, the air becoming rapidly dried as it passes inland, so that Bushmanland and the major part of Little Namaqualand and of the Karroo are almost rainless the whole year long; and the Eastern Province thus also enjoys a dry winter season, in contrast to the Western Province, which receives most of its rain during that period. We can, therefore, at once divide the Colony into three portions which present certain broad climatic distinctions. A wide belt of country bordering the coast is divisible into an eastern and a western portion by the Gauritz River, or by an imaginary line running northward from Mossel Bay. In the west the seasons are about a month earlier than in the east; and, during the winter, the prevailing north-west winds carry regular and plentiful rains as far inland as the Karroo. In the east, on the contrary, the rains fall during the summer months, being deposited by the south-easterly breezes which blow, laden with moisture, from the ocean. The eastern coast too is climatically affected by the warm current of the Mozambique Channel, much as North-western Europe is by the Gulf Stream. Thirdly, between the belt of country just described and the Orange River—south, therefore, of the great Kalihari desert—lies the elevated region of the Karroos and Bushmanland, arid plateaus, for the most part, where the rainfall is scanty, irregular, and limited, and chiefly dependent upon those electrical conditions which form one of the most striking atmospheric peculiarities of this portion of the country.

The physical feature which is most important in determining the more strictly local conditions of climate throughout the country is the arrangement of its mountain-ranges. South Africa is essentially a land of mountains. From no spot along the coast, from the mouth of the Kei to that of the Great Berg River, can the traveller journey "up country" into the interior without crossing a mountain range; and at no spot within the Colony is he out of sight of mountains, even if they do not surround him, as is frequently the case, on every side. The distant peaks, often more or less snow-clad in winter, relieve the greatest stretch of plain from monotony. And the views obtainable from the mountain-passes, the panorama of kloof and precipice, deep rifts and wind-worn buttresses, are grand and beautiful in the extreme. The general level of the ground rises from the sea towards the interior, attaining its greatest altitude towards the North and East. The principal mountain-ranges run like a series of curvilinear barriers one within another in a direction which may be described as a parallel with the coast-line; they are separated, not by valleys, but by plateaus which stand like broad terraces arranged one above another in successively increasing altitude, and it is thus, in great part, that the different zones of climate are determined.

Beginning at the north-west corner of the Colony, we may recognise a district which corresponds pretty closely to the coast region of Little Namaqualand, extending from the Orange to the Olifant's River and inland to the foot of the mountain ranges. This cannot be recommended to invalids as a place of residence. Rain is rare on the coast, but heavy sea-fogs, extending for more than 50 miles inland, are common in the early morning. Amongst the mountain peaks thunderstorms are frequent, yet little rain actually falls, and the main characteristic of this barren and shelterless waste of sand is protracted drought. Even during the hottest season the nights are cold; at sunrise the thermometer often registers 40° or 50° F. in the middle of summer, and will stand at 100° or more in the shade between the hours of 11 and 4 in the same day. At Ookiep are the famous mines of the Cape Copper Mining Company, employing about 1,500 people, including a large number of Welsh and Cornish miners. A railway some 90 miles in length connects them with Port Nolloth on the sea-coast. But although, with due precautions, Europeans may maintain a passable existence, difficulties of travel, lack of comforts, monotonous surroundings, and a trying climate will close this part of the country against the ordinary health-seeker.

Running south and then eastward, from the Olifant's River to the Gauritz, lies a tolerably broad tract of coast country, of which the inland boundary is fringed by the mountains forming the eastern and southern borders of the Great Karroo. The climate of this region corresponds generally to that described as typical of the Western Province. It is within the invigorating influence of the south-east trade wind; while westerly winds, charged with plentiful supplies of rain, blow for more than six months of the year. The "South-easter" is a very strong, but dry and healthy wind; and thunderstorms are less frequent and more mild than in any other part of the Colony. Certain portions of this district deserve special mention. To the north-west, and behind the second range of hills from the coast, lies the "Warm Bokkeveld"—a circular plain 1,700 feet above sea-level, possessing a rich and well-watered soil, and a climate at once warm and equable. The mean temperature is about 66° F., but the mercury seldom falls lower than 50°. Tulbagh, an old-fashioned village still primitively Dutch, and famous for its vineyards, lies in a deep valley, and is about 80 miles by rail from Cape Town. Ceres, a few miles further to the east, is a pretty and well laid out little town of more modern type, occupying a high and healthy situation. It too is on the Cape Town and Kimberley line, but it can also be easily reached from the former place by the road which runs through the grand scenery of Mitchell's Pass. North and west of the Warm Bokkeveld, between the Karroo and the Olifant's River Mountains, lies the Cold Bokkeveld, at an altitude of 4,000 feet. The climate is fine and dry, but cold. Ordinary English fruits are grown to perfection. It is enjoyable and bracing during the summer season, but the

cold is severe in the winter, when it is quite deserted by the flocks and snow lies on the ground for weeks.

Not far from Ceres, on the same line of rail and road, and about 80 miles from Cape Town, is the thriving town of Worcester, with some 4,000 inhabitants, 780 feet above the sea. It possesses the advantages of charming scenery and a pleasant climate. The mean temperature is about 62°, but the range is considerable, from 28° to 106°, and invalids generally will find summer to be the most agreeable and most healthy period for staying there. Perhaps the most grievous charge that can be laid against the climate is the frequency of heavy thunderstorms. Provisions are good, plentiful, and very reasonable in price.

The valley of the Table range, which also lies within the geographical limits of the Western district now under consideration, presents certain local peculiarities which merit notice, if only from the fact that it is this part of the Colony with which the vast majority of visitors first become acquainted. At the outset it may be stated that Cape Town is, in all respects, inferior to its suburbs as a place of residence—especially for invalids. Putting the coarser aspect of sanitation on one side, it must be admitted that the beneficent “Cape Doctor,” which sweeps away smells that would otherwise demand investigation, has an over-boisterous manner of working, and dispenses heavy charges of red dust with a reckless freedom very trying to his patients. A full South-easter will sweep a street exposed to its force clear of all light movables, and the writer has seen the tin lining of an empty packing case, four feet high, merrily trundling along the road like a schoolboy’s hoop. The visitor who makes his first landing in one of these winds, blowing at the rate of fifteen miles an hour and more, expresses only a qualified surprise at the sight of a city of flat-roofed houses with conspicuously absent chimney-pots. Strictly speaking, the term “South-easter” is here a misnomer, the prevailing winds during the summer being from the South and West, occasionally S. by E.; while easterly winds are rare throughout the year, and that from due E. is quite unknown. The mean temperature of Cape Town for the year is about 65°; but for the months of December, January, and February in summer it averages over 73°; while for the same months the mean in the Table valley is 68·7, the dew point 57·5°, and the mean humidity of the air 66·4 per cent. Cape Town, in fact, lies, as it were, in the focus of the great horse-shoe face of Table Mountain, from which it receives reflected heat by day and radiated heat by night. Hence all its business men, if possible, make their homes in one or other of the villages which stud the line of railway running through the Table valley to Simon’s Town, on the opposite side of the peninsula. Most of these are delightfully placed beneath the wooded slopes of the Table range itself or on the borders of the “flats,” which stretch northward like a vast sheet of sandy common covered with heaths or carpeted with flowering bulbs, dotted with small farms and sparkling vleis, towards the Blaauwberg Mountains, whose peaks in early spring are still white with the remains of scanty snows. Local peculiarities of exposure and of rainfall, &c., also allow a fair variety of choice. Cape Town has an average rainfall of 24 inches—about half that of Sydney, in the same latitude. At Mowbray the rainfall is about 19 inches, and at Wynberg, close to the famed Constantias, 36 inches. At Rondebosch, five miles from Cape Town, and midway between that place and Wynberg, the rainfall is about 20 inches or less; while groves of oak and pine protect the dwellers on the Camp Ground from a too violent incidence of the refreshing breezes which, during the hottest day, sweep across the flats between False and Table Bays. Christmas-tide—hot, but bright and clear, and with none of the oppressiveness often felt during summer weather at home—suggests to the newly arrived Englishman a strangely pleasant combination of iced roses and mulled holly. During January and February, when the heat is apt to be most felt, a general exodus takes place to the seaside watering-places of Kalk Bay and Somerset Strand, on the shores of False Bay; Green Point, also, is a pleasant and healthy place of residence in the summer months. Occasionally, during the rare “Black South-easter,” a *Table-cloth*—darker than that which rolls over the mountain brow above the Capital

when the ordinary summer wind is most violent—projects over the southern side of the mountain and deposits slight showers in the neighbourhood of Rondebosch and Claremont. A damp north-west breeze, which sometimes blows through the kloof near Cape Town, is considered to be responsible for the malaise, sore-throats, and respiratory oppression which are apt to affect those who have been subjected to its influence. During the winter months, from April to September, the prevailing winds are from the N., N.W., and W., and the major part of the rainfall is deposited in and about Wynberg. But rain is rarely continuous for more than two days together, and the rain-free days are beautifully clear and exhilarating. Moreover, the soil is so porous and absorbent that within half-an-hour of the cessation of the heaviest down-pour the pedestrian can always enjoy a walk in comfort. The mean temperature of the three coolest months, June, July, and August, is 55·1° F., the humidity 80·6° per cent., and the temperature of the dew point 49°. The beginning of each winter and summer season is inaugurated by slight thunderstorms which play at intervals for two or three days over the summits of the Blaauwberg and Table ranges like distant discharges, more visible than audible, over some huge prime conductor. “At the Cape there is probably less thunder and lightning than in any other part of the world”; and, in fact, lightning is only observed, on an average, twelve times throughout the whole year. This part of the country has been described as too warm and relaxing for phthisical subjects during the summer; and it must be admitted that the average healthy Englishman, after two or three years’ residence there, is conscious of a need for a more bracing environment. This can be amply met by a visit to some of the higher lands, such as those of Fort Peddie, Grahamstown, or Murraysburg; to the Alpine farms of the Cold Bokkerveld, or the delightfully cool valleys of Post Retief and the Great Winterberg. But there are many professional men, for whom existence in England is impossible, who live and work in comfort at the Cape without finding any such change of residence necessary to their continued physical welfare.

The district of George, east of the Gauritz River, is one where the summer heat is tempered by gentle showers from the south-east. The climate is a very pleasant one, and frost is unknown near the coast, where the scenery presents a striking combination of mountains, forests, and lakes, unusual in South Africa. A fair amount of sport is obtainable, but the small, yet numerous, torrent beds make travelling rough and difficult. The town is 6 miles from the coast and 290 by road from Cape Town; it is pleasant and well-watered, and very fair accommodation is obtainable. In the neighbouring Knysna district, which lies lower and has a much damper climate, are fine forests affording cover to herds of elephant and buffalo, which are strictly preserved.

In the districts east of the Gamtoos river the very hot days of summer are usually terminated by heavy thunderstorms which materially help to reduce the average temperature. Port Elizabeth, the second port of the Colony, should not detain the invalid. Despite recent improvements in the water-supply, its sanitary reputation is not of the best; it is much exposed to high winds, and the air is exceptionally humid. Uitenhage, eighteen miles inland by rail, is a town of well-watered gardens; provisions are good, living reasonable, and the district is considered a very healthy one. But the precaution, always advisable, of drinking only filtered water is especially necessary in this locality, since the neighbourhood has furnished a considerable number of sufferers from the too notorious *Bilharzia hæmatobia*. Grahamstown, which may be reached by rail from Algoa Bay, about 90 miles, or from Port Alfred (25 miles), is the capital of the Eastern Province, and has considerable pretensions as a residential health resort. It contains a population of some ten thousand, and contrasts with other settlements in being exclusively English in the composition and tone of its society. It stands at an altitude of 1,728 feet, and has an annual rainfall of about 32 inches. The town is admirably laid out, and has a plentiful water supply, with numerous churches and other public buildings, including a good library. Great care is bestowed upon the sanitation of the town,

and its health reputation is of the best. The winters are often cold, but the air is clear, dry, and invigorating. Among the other advantages of Grahamstown may be mentioned the opportunities which it gives to the botanist, the angler, and the sportsman; and, not least, the facilities now afforded by its railway communication for rapid removal to the warmer and moister district of the Kowic, or to the keen mountain air of the high plains north of the Katberg and Winterberg, three to seven thousand feet above the sea. In this region the air is rendered cool and pleasant during summer by the thunderstorms which break continually among the mountain summits; the winters are sharp, but clear and bracing. Close to the high ranges snow lies on the ground for three or four months of the year. In the possession of a climate admirably adapted to the treatment of pulmonary complaints, the plateau of Cradock and Queenstown can well rival the Free State, while in accessibility by road and rail, in the greater comfort obtainable, and the vastly more varied character of the surrounding scenery, it may reasonably claim to be superior. In striking contrast to the cooler air of these highlands are the deep and sweltering valleys of the Great Fish and Great Kei Rivers, which they border.

The Great Karroo extends eastward from the Hantam River between two nearly parallel mountain ranges to Graaff-Reinet, at an average of 3,000 feet above the sea; almost rainless, except just under the mountains, with a summer of intensely hot days and cold nights, and a winter where, between very sharp nights and mornings, come four hours of high temperature after 11 a.m., this *Barren Plain* will scarcely tempt the invalid even if the difficulties of transport were less stupendous. What has been written of the Karroo applies with even greater force to the almost waterless wastes of Great Bushmanland. In both cases the aridity is due to water-starvation; and it is probable that judicious planting and well-boring might do much towards restoring its former aspect to a country which is, in itself, potentially most fertile.

As regards means of communication throughout the Colony, it may be said that, until recently, mule or bullock waggons formed the only means of transport available for long distances and for heavy goods. Passenger carts, taking a moderate and variable allowance of luggage, run between all the principal towns and villages, and the post or mail carts are also available to a limited extent for passengers who have more regard for expedition than for their toilet. The first short railway was opened in 1863, but little was done in the way of extension until after the diamond rushes of 1870. Now, however, the Cape Railways System has assumed something of the complexity and extent which its title implies. Three main trunk lines connected by communicating branches are in existence; and, as they do not yet appear on any ordinary map, we may be allowed to indicate here their general arrangement so far as they are at present completed or in process of construction. The Western line runs from Cape Town, by Beaufort and Victoria West, to Hope Town on the northern border of the Colony, and thence to Kimberley, thus bringing passengers within less than a hundred miles of Bloemfontein. The Midland trunk line runs from Algoa Bay, by Cradock, as far north as Colesberg. It also has branches to Graaff-Reinet and to Grahamstown. The Eastern line runs from the port of East London, through Queenstown, as far as Aliwal North, thus tapping the immense coal-bearing region of the Stormberg. The branch connecting the Western and Midland lines runs from De Aar to Naauw Poort, and the traveller from Cape Town to Port Elizabeth is compelled to make a very considerable *détour*. The journey, at present, occupies no less than three days and two nights, thus comparing unfavourably with the steamer as regards both time and comfort, unless the passenger be a hopeless victim to *mal de mer*. Food is provided by the Company, at an extra charge, during the longer journeys. The standing details of the sea voyage from England to the Cape were given in a recent article on the Orange Free State. It may be added that, while travelling in the remoter and less settled districts of the interior is still tedious and uncomfortable, communication is very fairly easy between all the more important towns,

and the difficulties and delays inseparable from transport in a country of this character are being continually modified. A good supply of warm clothing should be provided; even near Cape Town there are many occasions on which the value of an "ulster" will be proved during the nights of winter.

The cost of living in the various towns and villages of the Colony need be little, if at all, in excess of that experienced at home, even for the invalid. In some places it will even be less. It would be impossible to give all the variations in price for different localities, but the average will not differ much from those prevailing in Cape Town and Port Elizabeth, although local conditions may considerably lessen the price of fruit and poultry, for example, or raise that of butter and fuel. Thus in the Cape district ordinary vegetables cost much the same as in England, except potatoes, which are about twice as dear. Butcher's meat is cheaper than at home; but the beef is usually poor, and in country districts the choice is only one between the different joints of mutton and strips of sun-dried venison known as "biltong." Fowls are sold at 3s. to 5s. per pair, and along the coast fish is excellent in kind and variety, abundant, and inexpensive. Fresh butter costs about 3s. a lb. Fruits which are looked upon as luxuries in England are plentiful and cheap—grapes, strawberries, peaches, apricots, loquats, oranges, lemons, citrons, guavas, bananas, figs, pomegranates, and quinces flourish in the warmer districts. Cucumbers and all varieties of the melon tribe abound. A few years ago fine bunches of grapes were considered rather dear near Cape Town at a penny a-piece; and the basket which held half-a-crown's worth of grapes could be filled for a like sum with apricots or peaches. Many of the Cape wines are sound, pure, and wholesome; some of the lighter varieties, possessing a Hock character, are very agreeable summer beverages. Hotel life is all the world over the most expensive of its kind. A bachelor can generally secure board and lodging for a term at from 12*l.* to 15*l.* a month and upwards. Where the popular boarding-house is available, and they are common in and near the larger towns of the Western Province, he will obtain similar advantages for about 4*l.* per month less. Although big game must now be sought for beyond the limits of the Colony, there are many districts easily accessible which still afford good buck-shooting; and there is probably no place where the wanderer who combines something of the scientist and the sportsman will have to complain of a blank day. Paterfamilias would find good educational advantages afforded by the various schools and colleges which flourish beneath the fostering regard of the University of the Cape of Good Hope, and in which work is carried on under conditions which have hitherto served to prevent "over-pressure" from striking root—or, at all events, from bearing fruit—amongst the rising generation.

The intending visitor is advised so to time his departure from England as to reach Table Bay during the early weeks of September. Then, unless it is imperative that he should lose no time in making his way to the more elevated regions of the interior, he will do well to take up his abode, for a time at all events, in one of the villages on the Wynberg line. He will live, by preference, on the borders of the Flats rather than close under the wooded mountain slopes, and will thus escape the dust of the high road, while securing all the benefits of the light play of winds across the peninsula. Until nearly the end of October he will be reminded, throughout the hours of sunlight, of the best part of a perfect English summer's day, say that between 7 and 9 a.m. Vegetation visibly grows under his eyes, and the lovely spring flora of the Flats, the clear air and cloudless sky, the quiet beauty of the lower slopes and the splendid definition of each scar and crevice in the topmost thousand feet of mountain wall, give an inexpressible charm to the scene around him. Football will be over with the winter, but the cricket and lawn-tennis season will be in full swing. There are several rowing clubs in Cape Town; and the jackals very creditably supply the place of English foxes to the sportsmen who regularly hunt over the neighbouring downs. With the advent of hotter weather, towards and after Christmas-tide, a change may be profitably made to Kalk Bay, Simon's

Town, or "The Strand," where pleasant lodging and good fishing are obtainable. And the traveller will be all the better equipped for a longer journey, if such should be desirable, by the opportunities which will have been afforded to him for picking up a colloquial acquaintance with Cape or "Kitchen" Dutch, a bastard *patois* that forms the speech of the descendants of the old settlers, and a knowledge of which serves as a most useful passport throughout the country. He will also have had time to learn something practical about the dress and mode of life suitable to the country, with numberless other important details which can only be acquired on the spot. There is, however, a large class of phthisical cases which are doomed only to go from bad to worse in England, and who yet find all the conditions necessary to them for health, with a minimum of the evils of expatriation, in the neighbourhood of the Cape itself; learning to combine an undiminished patriotism with a loyal acceptance and a physical appropriation of the Colonial legend *Spes Bona*. If house-keeping be decided on, a cottage of five rooms with offices can be secured at a rental of about 5*l.* a month, and larger houses in proportion. Furnishing is a much less serious matter than at home, since the open-air kind of life, and perhaps the more genial tone of society, greatly restricts the number of necessaries and tends to kill any passion for internal display. Fires are, as a rule, needed only for cooking purposes. Wood is the fuel employed, and a load of this, costing 12*s.* to 16*s.*, will provide an ordinary kitchen fire for about a month. Taxes are light, and servants are obtainable upon terms much more reasonable and with results far more satisfactory than are possible in the less settled districts. The drawbacks inseparable from the exchange of English for Colonial home life are here least noticeable; and such discomforts as there are receive a large balance of compensating pleasures. Even the exile scarcely feels expatriated where the sun-set shadow of the mountain simulates a northern twilight; where the wild-rose and the blackberry greet him with indigenous familiarity; and where, from the lips of the oldest settled colonists about him, he hears England always alluded to as "home."

## MEDICAL NEWS.

### MEETING OF FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

THE theatre of the College of Surgeons was again filled to repletion, on Thursday afternoon last, to hear read a Statement which had been prepared by the President and Vice-Presidents in reference to the resolutions carried at the meeting held on the 29th October, 1885. (Those resolutions were duly reported in our columns.) The President, on taking the chair, explained the silence of the Council at the former meeting. They were desirous, he said, to carefully consider the resolutions which had been brought forward, and they believed that an authoritative statement was better than personal and indefinite views. This statement was the more authoritative, inasmuch as it was the unanimous feeling of the Council. He assured the meeting that it would have been more agreeable to them to have granted the demands than to be obliged to withstand them.

Mr. Trimmer, the Secretary, then proceeded to read the Statement, copy of which appeared in our issue last week.

Mr. K. Cornish's resolution, seconded by Dr. Rogers, that a petition to the Queen in Council, signed by a large number of Members, be now read, was put to the meeting, and negatived.

Mr. Holmes thereupon moved:—"That the answer of the Council is not satisfactory, and that the Council be respectfully requested to reconsider the subjects—(1) Of the Representation of Members of the Royal College of Surgeons. (2) Of submitting for approval any alterations proposed to be made in the constitution or in the relations of the College, or in any of its by-laws, to a meeting of the Fellows and Members." He said that, from a long acquaintance with the College and with the Council, he was sure that any well-considered

resolutions, which could be shown to be beneficial to the constituents of the College, were certain to receive an impartial consideration at the hands of the Council. He, and those with whom he was acting, felt that the matters at issue had not yet been placed before the Council in their proper light, and they felt that the answer which the Council had made was not satisfactory; for the arguments they had used were but a summing-up of the imperfect arguments which had been brought forward at the previous meeting. The Council had not taken any part in the discussion. It was perhaps a wise resolve on their part, for, like other bodies of men, they were not agreed, and it would have been very inconvenient to have tried to come to an understanding at a public meeting of the entire body corporate. The real truth was that the matter was not yet thrashed out. He differed from the Council's interpretation of the resolutions. The Members had not advanced any claim that all Members should vote unconditionally in the election of the Council; they felt, however, and he felt too, that it would be greatly to the advantage of the College and the profession if Members, under some circumstances, could vote as to whether the Members got an equivalent for their 2*l.* diploma; he would not discuss; the real question was whether the College got an equivalent from the possession of a constituency of 16,000 of the most energetic men in England. They never would until there was a more intimate connection between the College and the Members, and that connection would only commence when they obtained a vote. It was largely on this argument that he voted with the Members. That the College had been very successful in its career was no argument in favour of the present system; it was to make it still more successful that he would urge the Council to avail themselves of the great reserve force to be found among its Members. The College had three chief functions to subserve: the collection and care of its library; of its museum; and the arrangement of its examinations; and each one was a splendid monument of the skill and success with which the Council discharged their functions. The College, thanks to the liberality of the late Sir Erasmus Wilson, had come almost into possession of an enormous property. This fact would probably attract other properties. So that within a brief time the College would become the patron of professional research and the arbiter of professional conduct. Would the 16,000 Members stand aside and let 24 of their body manage all this for them? Besides, would a College, managed by hospital and consulting surgeons, stand? What about the general bulk of practitioners? Did the Fellows fear that they would be swamped? A scheme could be formed which would not upset existing privileges. Such a scheme might be sketched as the following Members should only be entitled to vote after some years had elapsed. Members wishing to vote would have to be put on a Register, and either vote personally or by voting-paper. The right of the Members to sit on the Council was even more important than a vote, for it was essential that there should be some who were cognisant of the requirements of the general practitioners. When he was serving as a member of the Conjoint Scheme, and while the matter was under discussion, he had been struck with how little they (the Council) knew of the wants of the general practitioners. He would hesitate to support any scheme which would upset the present Council: either the Council could remain as it was, and add to their number some few Members; or a proportion—a fourth, say -- of the Council should consist of Members. He would not rush these changes on, but bring them about only after a thorough discussion of them had been made. As regarded the second resolution, he admitted that the wording was unfortunate. The Members meant that no considerable changes should be made in the By-laws without submitting them to the Fellows and Members. He referred to an instance, known to the President, in which they (he and the President) had influenced the Council by obtaining an expression of opinion of Fellows adverse to the views held by the Council, which showed that the Council were not *always* the best judges of what was best for their constituents. Further, he questioned whether the Council *could* effect any important alterations, should the Fellows and Members really oppose it.

Mr. Gangee seconded the resolution (in an able speech, which was marred in its effect by being read). He reiterated many of the arguments used at the former meeting; he criticised, and much in the same spirit, the Council's interpretation of their former resolutions; if they had not properly formulated their views and their requirements, he hoped the Council would take the two large meetings as an indication of what was the real feeling of the body at large on the matters at issue. He concluded by suggesting an informal meeting of some Members of Council with delegates from the two Associations.

Mr. Brudenell Carter (in a speech which produced considerable and long-continued uproar) upheld the view propounded by the Council. He disapproved even of extending voting by proxy to the Fellows, believing that a personal knowledge of candidates seeking election to the Council was the surest means of securing the best men. It would be unfortunate for the College to be governed by tumultuous assemblies such as the present; and, before the old regulations of our predecessors, who were in favour of a small constituency, were revived, it would be well to hesitate and be sure that some better plan could be suggested. He believed the Associations were largely got up by the medical journals, and were kept going at their behest.

Dr. Ward Cousins supported the resolutions. He appealed to the Council to come from behind that old wrapper—the Charter, and meet the Associations with a view to readjustment.

Mr. Haughton spoke against the resolution, and in favour of the *status quo*. He deprecated Mr. Carter's personal allusions.

Mr. Rivington (in a powerful speech, which we print elsewhere) supported the resolution.

The President, in answer to calls "Vote, vote," although other gentlemen appeared wishful to speak, put the resolution to the meeting. It was carried by an overwhelming majority.

After a vote of thanks to the President for his conduct in the chair, proposed by Mr. Holmes, seconded by Dr. Collum, and carried by acclamation, the meeting broke up.

**UNIVERSITY OF CAMBRIDGE.**—The following candidates have been examined and approved for the degree of Bachelor of Surgery:—

Messrs. Castle, Pembroke; Fox, Cavendish; Ingle, noncollegiate; Lund, Trinity; Skelding, Caius; Thornton, Christ's; Trott, Caius; Walsham, Caius; C. Yeoman, Pembroke.

Third Examination for M.B. Degree. Examined and approved:—

Ds. Andrews, John's; Daniels, Trinity; Dudfield, Trinity; Evans, John's; Facey, John's; Magr. Haig, Trinity; Ds. Havilaud, G. D., John's; Jones, H. C. W., Downing; Musgrave, Magdalen; Nichol, Caius; Niven, Caius; Piggott, Emmanuel; Ritchie, Trinity; Rushbrooke, Christ's; Spicer, Caius; Magr. Tayler, Clare; Ds. Wishaw, Cavendish.

**UNIVERSITY OF DUBLIN.**—At the Michaelmas Term Examination for the degree of Bachelor of Medicine (M.B.), held on Monday, November 30th, and following days, the successful candidates passed in Order of Merit as follow:—

Robert G. Patteson; Henry C. Earl; Reginald W. Studdert; Foster R. Newland; Richard B. McCausland; James Craig and Benjamin D. Dickson (equal); Henry M. Brabazon; Henry F. Phillips; Ross V. B. Smyth; Richard C. Bolton; George Paris; Samuel G. Edge; George Hilliard; Henry F. Kingston; James C. Weir; Gardiner W. Trouton.

Passed provisionally—  
Kenneth Frazer.

At the Michaelmas Term Examination for the degree of Bachelor of Surgery (B.Ch.), held on Monday, December 7th, and succeeding days, the candidates who passed were arranged in Order of Merit as follow:—

William S. Dobbin; Robert G. Patteson; Reginald W. Studdert; Henry M. Brabazon; Henry J. Hadden; Henry F. Phillips; Foster R. Newland; Henry F. Kingston; Gardiner W. Trouton; James Craig; Edward Wolfenden A. Gray; Alexander Fiudlater.

**UNIVERSITY OF DURHAM, FACULTY OF MEDICINE.**—The following candidates have satisfied the Examiners:—

*Examination for the Degree of Doctor in Medicine for Practitioners of Fifteen Years' Standing:*

George Fowler Bodington, F.R.C.S., M.R.C.P.; Edward Eustace, L.R.C.S., L.R.C.P.; Allen Pennings, M.R.C.S., L.S.A., L.R.C.P.

(Edin.); John William Hembrough, M.R.C.S., L.S.A.; John McGee MacCormac, L.R.C.S., L.R.C.P.; Thomas Stephen Maguire, L.K.Q.C.P.; Whitfield Perkins, M.R.C.S., L.S.A.; Robert John Shepherd, M.R.C.S., L.S.A.

*Examination for the Degree of Doctor in Medicine (Essay):*

Gold Medal, 1885:—Frederick Spicer, M.B., M.R.C.S. Pass List:—David Henry Barley, M.B., M.R.C.S.; Thomas Elisha Gordon, M.B., M.R.C.S.; Herbert Ryding Mosse, M.B., M.R.C.S.

*Examination for the Degree of Bachelor in Medicine (Essay):*

Auburn Wilkinson, L.M.

*Examination for the Degree of Master in Surgery:*

Philip Boobbyer, M.B., M.R.C.S.; George Rome Hall, M.B., College of Medicine, Newcastle; Arthur Herbert Hart, M.R.C.S., L.R.C.P., Queen's College, Birmingham; Alexander Yates Reily, M.R.C.S., Middlesex Hospital.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following Members, having passed the Final Examination for the Fellowship on November 26th, 27th, 28th, and 30th, were at a meeting of the Council held on the 10th instant admitted Fellows of the College, viz:—

Henry Dawson Farnall, L.S.A., The Goffs, Eastbourne; Francis Henry Weekes, L.S.A., 3, St. Leonard's, York; James Thomas James, L.R.C.P. Lond., Llwynfack, Llandoverly, South Wales; John Bowring Lawford, L.R.C.P. Lond., 73, Lambeth Palace Road, S.E.; John William Batterham, M.B. Lond., General Hospital, Birmingham; Henry Waytes Pomfret, L.R.C.P. Lond., Hollingworth, Manchester; Alfred Ernest Hind, St. Bartholomew's Hospital; Robert Jones, M.D. Lond., 11, Mecklenburgh Street, W.C.; Charles Edward Henry Cotes, M.B. Cantab., The Mall, Hammersmith; Sidney Plowman, L.R.C.P. Lond., The Residence, St. Thomas's Hospital; Henry Robert Woolbert, M.B. Lond., Royal Albert Hospital, Netley; George Adlington Syme, M.B. Melbourne, 36, Albany Street, N.W.; Jasper Jewett Garmany, M.D., Bellevue, Savannah, U.S.A.

Two other candidates passed the examination, but, not having attained the legal age (twenty-five), will receive their Diploma at a future meeting of the Council. Nine candidates failed to reach the required standard, one candidate was referred to his professional studies for six months, and eight for twelve months.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on Thursday, December 10th, 1885:—

Charles Hotham Evans, M.R.C.S., Winchmore Hill, N.; George Hope, M.R.C.S., 8, Spring Gardens, Ventnor, Isle of Wight.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the usual monthly Examinations for the Licences of the College, held on Monday, December 7th, and following days, the under-mentioned candidates were successful:—

*For the Licence to practise Medicine—*

Alfred Ernest Jaffray Barcroft, Kingstown, Co. Dublin; Jeremiah Behan, Lixnaw, Co. Kerry; Henry Theodore Bewley, M.B. Univ. Dubl., Booterstown, Co. Dublin; Thomas Browning, Limerick; Alban Butler, Dublin; William George Chute, Tralee, Co. Kerry; Thomas Paul Codd, Dublin; Arthur Richard Thomas Craig, Dundrum, Co. Dublin; Albert Edward Davis, Rainhill, near Liverpool; John Joseph Davoren, Ennis, Co. Clare; Cuthbert Eccles, Drogheda, Co. Louth; Henry Leslie Finny, Howth, Co. Dublin; Edward Heard, Carrigtwohill, Co. Cork; John Keatly, Dublin; Arthur Foster Keyworth, Bath, Somersetshire; Walter Kiddle, M.B. Univ. Dubl., Dublin; Henry Thomas Knaggs, Dublin; Martin Bernard Lyster, Athlone, Co. Westmeath; Frank Parry, Kildermister; John Rogers, Elphin, Co. Roscommon; William Whitlaw Scott, Kingstown; Joseph Samuel Sergeant, Brigg, Lincolnshire; Edward Russell Wawn, Redcar, Yorkshire.

*For the Licence to practise Midwifery—*

Thomas Browning; John Paul Cavenagh, Dublin; William George Chute; Thomas Paul Codd; Arthur Richard Thomas Craig; Albert Edward Davis; John Joseph Davoren; Cuthbert Eccles; Henry Leslie Finny; Edward Heard; Arthur Foster Keyworth; Henry Thomas Knaggs; Martin Bernard Lyster; Edwin Graves Newell, M.B. Univ. Dubl., Dublin; John Rogers; William Whitlaw Scott; Joseph Samuel Sergeant.

The following Licentiate in Medicine of the College, having complied with the By-laws relating to Membership pursuant to the provisions of the Supplemental Charter of December 12th, 1878, has been duly enrolled a Member of the College—

James Emerson Reynolds, M.D. (*honoris causa*), Univ. Dubl., Professor of Chemistry in the University of Dublin.

**UNIVERSITY OF OXFORD.**—At a congregation held on the 3rd inst., a number of amendments upon the very

important statute for the reorganisation of the medical faculty and studies in Oxford were approved of, by which, among other changes, there are to be established the degrees of bachelor of surgery and master of surgery. The latter is now given in many other Universities, and it may be observed that it will be the only master's degree in the University which at present involves a qualification of intellect or acquirements. The statute will of course be powerless to confer the membership of Convocation upon these newly constituted masters of surgery, but it may be presumed that the necessary powers will be applied for to carry out this change in the constitution of the University. The amendments proposed to-day and carried without dissent were an embodiment on the part of the Hebdomadal Council of the suggestions of members of the medical faculty both in London and Oxford, and the Regius Professor of Medicine expressed his general approval of the statute. Dr. Bruce Clarke stated that he was requested to thank the Vice-Chancellor and the Hebdomadal Council in the name of the medical graduates of London for the entirely satisfactory and liberal spirit with which they had met and accepted their suggestions, and to say that all the provisions of the statute met with their entire approval.

**HOSPITAL SATURDAY FUND AWARDS.**—The Board of Delegates met on Saturday, when the report of the Distribution Committee, recommending that 9,500*l.* of the 11,300*l.* already realised be distributed among 71 hospitals, 40 dispensaries, and 19 convalescent homes and other institutions, was adopted. The largest awards to hospitals are as follows:—London, 684*l.* 15*s.* 2*d.*; Consumption and Diseases of the Chest, Brompton, 578*l.* 18*s.* 4*d.*; City of London, for Diseases of the Chest, 277*l.* 2*s.* 10*d.*; Middlesex, 262*l.* 18*s.* 2*d.*; St. George's, 260*l.* 13*s.* 6*d.*; St. Mary's, 219*l.* 16*s.*; North London or University College, 197*l.* 15*s.* 6*d.*; Westminster, 193*l.* 17*s.* 10*d.*; Royal, for Diseases of the Chest, 189*l.* 17*s.* 2*d.*; King's College, 177*l.* 3*s.* 10*d.*; Royal London Ophthalmic, 171*l.* 7*s.* 4*d.*; Royal Free, 169*l.* 2*s.* 8*d.*; North London, for Consumption, 169*l.* 1*s.* 2*d.*; Charing Cross, 150*l.* 5*s.* 6*d.*; West London, 128*l.* 8*s.*; Sick Children, 121*l.* 15*s.* 6*d.*; Seamen's, 119*l.* 0*s.* 10*d.*; Royal National, for Consumption, 109*l.* 18*s.*; Male Lock, 101*l.* 16*s.* 10*d.*; German, 101*l.* 3*s.* 10*d.*; Cancer, 100*l.* 3*s.* 8*d.*. The other awards to hospitals range from 90*l.* 10*s.* 10*d.* for the Hospital for Diseases of the Throat to 15*l.* 16*s.* 8*d.*, the amount given to the British Lying-in Hospital.

**HELEN PRIDEAUX MEMORIAL FUND.**—We stated last week that it is proposed to raise a sum in memory of Miss F. Helen Prideaux, M.B. & B.S. (Lond.), sufficient to endow a Prize or Scholarship bearing her name. Subscriptions may be sent to the Treasurer, the Dowager Lady Stanley of Alderley, 40, Dover Street, W., or to the Hon. Secretary, Mrs. Garrett Anderson, M.D., 4, Upper Berkeley Street, W. The following sums, with others, have been already received:—Dowager Lady Stanley of Alderley, 25*l.*; Mrs. Garrett Anderson, M.D., 25*l.*; Louisa, Lady Goldsmid, 10*l.* 10*s.*; Sir William W. Gull, Bart., M.D., 10*l.* 10*s.*; The Earl of Derby, 10*l.*; G. Hanbury, Esq., 5*l.* 5*s.*; Dr. Allen Sturge, 5*l.* 5*s.*; Mrs. Thorne, 5*l.*; Miss Alice G. Smith, B.A. (London), 5*l.*; J. C., 5*l.*; Mrs. Holland, 5*l.*; Mrs. N. Montefiore, 3*l.* 3*s.*; Professor Bentley, 2*l.* 2*s.*; Dr. Cheadle, 2*l.* 2*s.*; Bowen May, Esq., 2*l.* 2*s.*; Miss R. Martin, 2*l.* 2*s.*; G. R. Clarke, Esq., 2*l.* 2*s.*; Dr. Matthews Duncan, 2*l.* 2*s.*; Madame Bodichon, 2*l.* 2*s.*; Mrs. Westlake, 2*l.* 2*s.*; William Shaen, Esq., 2*l.* 2*s.*; Dr. Ford Anderson, 2*l.* 2*s.*; Miss Holland, 2*l.*; Dr. Curnow, Dr. Elizabeth Blackwell, Mrs. Atkins, M.D., Thomas Bond, Esq., F.R.C.S., and Miss Buss, 1*l.* 1*s.*; Mrs. G. S. Gibb, H. Ede, Esq., and Miss Barker, M.D., 1*l.*

**CHARITABLE BEQUESTS.**—Mr. Joseph Stevens, late of Stapleford, and Nottingham, and Sandiacre, Derbyshire, has bequeathed 1,000*l.* to the Nottingham General Hospital, 500*l.* to the Midlands Institution for the Blind, Nottingham, and 100*l.* each to the Nottingham and Midlands Eye Infirmary, Nottingham, and the Nottingham Dispensary, Broad Street, Nottingham, all free of legacy duty.

**WEST LONDON HOSPITAL.**—A very successful meeting,

presided over by the Marquis of Lorne, was held at the Town Hall, Kensington, on Monday, on behalf of this hospital, and subscriptions were promised during the evening to the amount of 1,150*l.* Much larger sums, however, must be raised if the hospital is to be placed on an assured footing of prosperity.

**HEALTH OF THE CITY OF LONDON.**—Dr. Sedgwick Saunders, Medical Officer of Health, reported to the meeting of the City Commission of Sewers, held on Tuesday last, that during the previous week the almost unprecedentedly small number of seven deaths had been registered in the City, including that of a man executed at Newgate. No death from zymotic disease had occurred.

**ST. JOHN'S AMBULANCE ASSOCIATION.**—Certificates of proficiency were, a few days ago, presented to 57 gentlemen cadets of the Royal Military College, Sandhurst, who had been instructed in "First aid to the wounded" by Brigade-Surgeon Alfred Clarke.

**SANITARY ASSURANCE ASSOCIATION.**—At the monthly meeting of the Council last Monday arrangements were completed for the series of free lectures to be given by the Association at the Parkes Museum during January and February next. The first lecture is to be by Professor Roger Smith on "A Damp House" on Wednesday evening, January 20th, and on the following Wednesday Mr. F. B. Jessett, F.R.C.S. Eng., will lecture on "Preventible Diseases."

**A COMMITTEE** has been formed with Sir Edwin Saunders as Chairman and the following gentlemen as Members:—Mr. H. Royse Bell, Mr. Edward Bellamy, Mr. Thomas Gaddes, Lord Alfred Paget, Mr. W. Rose, Dr. Brodie Sewell, Mr. Henry Smith, and Mr. J. S. Turner, in order to present Mr. Oakley Coles with a testimonial from his old friends and colleagues on his retirement from the Dental Profession. Contributions should be forwarded to the Treasurer, Mr. Charles Vasey, 5, Cavendish Place, W., before the end of December, 1885.

**DEATH OF PROFESSOR BOULEY.**—M. Henri Bouley, President of the Académie des Sciences, late President of the Académie de Médecine, and Professor of Comparative Anatomy at the Muséum d'Histoire Naturelle, died on the 30th November after a prolonged and painful illness.

**MR. FREDERICK AUGUSTUS DIXEY, M.A. and B.M.,** Demonstrator to the Professor of Physiology in the University of Oxford, and formerly scholar of Wadham College, has been elected to a medical fellowship in that Society.

**AN IMPORTANT RAILWAY CASE.**—The case of Huxley *v.* the West London Extension Railway Company, which was tried last week, is of some interest, inasmuch as the plaintiff was a medical man. It was an action for injuries sustained by the plaintiff, as he alleged, by the negligence of the company's servants in May, 1884, in getting out of one of their carriages at their station at Chelsea. The defence of the company, who denied the alleged negligence and also denied the injuries, was in substance that, even assuming contributory negligence or their liability for some slight injury, the case of the plaintiff was in reality a sham. Lord Coleridge, in summing up the case to the jury, said it was for the plaintiff to make out his case, which in substance was that the train was taken beyond the platform, and that there was no light or not sufficient light, and that, therefore, he could not see the distance of the ground from the foot-board, and so, while getting out, fell down and injured himself. Much of this was admitted, but there was cogent evidence that the lamp at the spot was lighted, and, probably, the plaintiff, if he had taken care, might have seen that the train was beyond the platform, and, even if he had got out before the train had absolutely stopped, yet there was not enough to deprive him of his right to an action, and the real question in the case was as to the nature and extent of the injury. The plaintiff, in his case, made it out to have been very serious, but how far was it sustained by the evidence? If there had been only a slight injury, the damages would be small, and, even if the jury believed there had been an attempt to exaggerate the injury, still he would be entitled to such damages unless they thought

that the exaggeration had been so gross as to deprive him of credit as to his evidence as to the accident itself. The plaintiff described himself as having suffered from "dull, aching pain" ever since the accident, which was in May, 1884, and that he was confined to his house for three months and had to take to crutches, and had become unable to attend to business, and was even affected by loss of memory, which he traced distinctly, he said, to the accident. Now, it was a maxim (not always perhaps perfectly true)—*ex uno disce omnes*—judge of the whole case from a particular instance. His own medical attendant said he never believed in this loss of memory. His counsel said this was exaggeration, but it was a very serious symptom indeed, if true, as it indicated injury to the brain. And it was remarkable that it was only in railway accident cases these curious symptoms arose. Here the man had only slipped and fell on the ground. And, if the jury believed that the plaintiff had not really lost his memory and knew he had not lost it at all, then the jury might regard that as discrediting the rest of his evidence. On the other hand, did the jury believe the evidence of the two witnesses, porters of another company, from the Walham-Green Station, who had seen the plaintiff daily for six months and said that they had seen him "tuck his crutches under his arms and run downstairs?" (Laughter.) If the jury believed those witnesses (and he did not see why they should not), how could they credit the rest of his story? Then, again, there was his own letter, written on the 15th of May, in which he stated that he was "full of rheumatism," and was in anxiety about "a practice he had purchased at Battersea," where he had no practice at all. It was for the jury to consider how far there was any foundation in fact for the statements in his letter. Then, in June, came the letter of the plaintiff's solicitor, stating that he felt that he had suffered a severe shock to his nervous system. This was the favourite topic of complaint in railway accident cases—a shock to the nervous system from merely falling on a platform. The letter described the most serious symptoms, which must have been derived from the plaintiff himself, and it spoke of injury to the business of his surgery, &c. And in a subsequent letter the solicitor wrote of "terrible loss of memory." Yet his own medical man said he did not believe in this; and then there was the evidence of Mr. Bond and Mr. Barnard Holt, the result of whose evidence was that they could not say that a man so falling might not have suffered some slight injury, but that the joint certainly had not been injured, and the injury was only slight, and there was no necessity for crutches at all, and no evidence of any serious injury at all. On the whole case the jury must judge whether the plaintiff had made out a case at all, and, if he had, what were the damages; as to which they were bound to consider the character of the evidence he had given, and, if they thought that he had attempted to mislead them, then they would probably give very small damages. The jury, after a few moments, gave a verdict for 50*l.*

**THE LAICISATION OF THE PARIS HOSPITALS.**—The *Gazette des Hôpitaux* of December 3rd publishes a list of the Physicians and Surgeons of the Paris Hospitals who have attached their names to a petition addressed to the Minister of the Interior, couched in the following terms. "The undersigned Physicians and Surgeons of the Paris Hospitals have the honour to request of you to maintain the *religieuses* in the hospital services to which they are attached. In addressing this request to you, they believe themselves to be acting in the interests of the patients entrusted to their care, as well as for the good order and maintenance of the hospitals and hospices of Paris." The signature amounts to more than a hundred in number. Of the total number of 163 of Physicians and Surgeons of Hospitals, 108 signed the Petition, and 55 did not sign it.

**A COLLECTION OF SKULLS.**—The Natural History Museum at Vienna has just been presented with 708 skulls collected through a series of years by Dr. Weissbach, who was for a long time director of the Austro-Hungarian hospital at Constantinople, and was a very distinguished anthropological investigator. Of the collection 195 are pure

Turkish skulls, 131 Greek, 96 Servian or Croat, 48 Hungarian, 43 Armenian, 29 old Byzantine. There are also skulls of Maronites, Albanians, Koords, Asiatic Jews, &c.

THE Vestry of St. Luke's has resolved to erect a set of mortuary buildings in Warwick-place, Whitecross-street, at an estimated cost of 990*l.*

THE Library of the Royal Medical and Chirurgical Society will be closed on Friday, December 25th, and reopened on Tuesday, December 29th.

THE BRITISH PHARMACOPŒIA.—The page of *Errata* is now ready, and can be obtained on application.

## APPOINTMENTS.

- CHAPMAN, PAUL M., M.D. Lond., M.R.C.P.—Physician to the Hereford General Infirmary, *vice* H. G. Bull, M.D., deceased.  
 MATHESON, F., M.B., C.M.—Honorary Surgeon to the Scottish Hospital Corporation.  
 NASH, WILLIAM GUNNER, M.R.C.S., L.S.A.—Medical Officer to the Third District, Brixworth Union, *vice* Mr. C. Hedley, deceased.  
 PHILLIPS, E. W., M.R.C.S., L.R.C.P., L.S.A.—House Surgeon to the Windsor Royal Infirmary.  
 RUSSELL, W., M.D., M.R.C.P.E.—Tutor in Clinical Medicine in the Royal Infirmary, Edinburgh, *vice* G. A. Gibson, M.D., F.R.C.P., resigned.  
 VICKERY, GEO., M.D., M.Ch., Q.U.I., L.A.H. Dub.—Medical Officer to the Kinsall Dispensary, *vice* Dorman, resigned.

## VACANCIES.

- ASHBY-DE-LA-ZOUCH UNION.—Medical Officer to the First District, and to the Workhouse, in succession to Mr. W. Joyce, deceased. Area, 6,381 acres. Population, 7,465. Salary, £35 per annum. Salary for Workhouse, £25 per annum.  
 BLACKBURN AND EAST LANCASHIRE INFIRMARY.—House Surgeon. (*For particulars, see Advertisement.*)  
 BOROUGH OF OLDHAM.—Medical Officer of Health. (*For Particulars, see Advertisement.*)  
 NANTWICH UNION.—Medical Officer to the Audlem District, in succession to Dr. W. R. Tough, resigned. Area, 11,045 acres. Population, 2,705. Salary, £30 per annum.  
 ROYAL ALBERT HOSPITAL, DEVONPORT.—Assistant House Surgeon, Board and lodging, but no salary. Candidates must be possessed of one qualification, Surgical or Medical, and be registered. Applications, accompanied by not more than three testimonials of recent date, to be addressed to the Chairman of the Managing Committee not later than December 23rd.  
 SLEAFORD UNION.—Medical Officer to the Wilsford District, in succession to Mr. J. C. Eaton, deceased. Area, 14,140 acres. Population, 1,908. Salary, £21 per annum.  
 THE VICTORIA HOSPITAL FOR CHILDREN, QUEEN'S ROAD, CHELSEA, AND CHURCHFIELDS, MARGATE.—Senior Surgeon, also a Second Surgeon. Candidates must be Fellows of the Royal College of Surgeons of England, not practising Midwifery or Pharmacy. Applications, with copies of testimonials, &c., to be sent to the Secretary on or before December 21st.  
 TORBAY HOSPITAL AND PROVIDENT DISPENSARY, TORQUAY.—Junior House Surgeon and Dispenser. Salary, £90 per annum, with board, lodging, and attendance. Candidates must be qualified in Medicine and Surgery, registered under the Medical Act, and unmarried. Testimonials to be sent to the Hon. Secretary, W. H. Kitson, Esq., Torquay, not later than January 1, 1886.

## DEATHS.

- CASTLE, M. A., M.D., late of 2, Chapel Street, Park Lane, London, at Lucerne, on December 9th.  
 DUFFY, Dr. BERNARD, F.R.C.S.I., at Florence, Italy, on Dec. 8th.  
 MCCLINTOCK, CHARLES, M.D., F.R.C.S., at Richmond, New South Wales, on October 27th, aged 36.  
 MILNE, CHARLES, M.R.C.S., at 6, Brunswick Place, Brixton Hill, on December 13th, aged 46.

## NOTES, QUERIES, AND REPLIES.

### "CEREBRAL RHEUMATISM."

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—The following case might be given as an instance of so-called "Cerebral Rheumatism." Mrs. W., age 36, first attack of acute rheumatism. Nov. 15.—General malaise, wandering pains, rigor at night. Nov. 16.—Sent for medical advice; condition when first seen: left ankle and knee swollen; intensely painful and full of fluid; right wrist joint ditto; temperature 103° 2' F. Pulse 98, full, bounding. No cardiac murmur. Ordered Sodii Salicylatis, gr. xv,

every three hours. Nov. 17.—No pain, fluid in joints diminished, T. 101.4°. A slight blowing systolic murmur at apex.

From this time improvement went on, and the salicylate was gradually decreased. On Sunday 30th, at 4 a.m., I was called to see the patient, was told she had been delirious throughout the night, not knowing anyone, and had suddenly relapsed into stupor. Respiration stertorous, 12 per minute. Pulse 45, very full and bounding. Temperature by rectum 110.2°, at which I was quite taken aback. Cold wet sheet packing was tried, and ice to the head. Calomel, gr. v, put at back of tongue, but without any good effect, the patient dying one hour and a half after my arrival. The patient had an interview with her sister the evening before, with whom she had not been on good terms for three years, and had never seen her during that period, but I should think this incident could hardly have had anything to do with the sudden and alarming rise of temperature.

I am, Sir, yours, &c.,  
CASPAR R. LAURIE, M.R.C.S., L.R.C.P.

6, Eaton Villas, Loughton, Essex.  
December 10th, 1885.

## CLINICAL REMARKS ON A CASE OF MYDRIASIS WITH IRITIS, AND ON CASES OF MYDRIASIS FOLLOWING A BLOW ON THE EYE.

(Delivered at the Royal London Ophthalmic Hospital.)

By E. NETTLESHIP, F.R.C.S.,

Ophthalmic Surgeon to, and Lecturer on Ophthalmology at, St. Thomas's Hospital, and Assistant Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

THE patient to whose case I am about to draw your attention is a man above fifty years of age, who came here three days ago for inflammation of the left eye, the result of a blow from the cork of a lemonade bottle five days previously. His pupil was noticed to be partly dilated, although the only application had been a bread poultice, and on examination, after atropine had been dropped in, we found several well-marked iritic adhesions.

Iritis following a contusion of the eye, such as this patient received, without any wound, is not common; a much more usual result of such an accident being mydriasis and paralysis of accommodation. In the present case we have an inflamed iris and a dilated pupil, a combination which, as the result

of injury, is certainly rare. The mydriasis must in this instance be put down as an accidental, not an essential, accompaniment of the iritis, for in almost all cases of iritis the natural tendency is towards contraction of the pupil. An exception to this rule is often seen in cases of so-called "serous" iritis, where, along with some increase of tension and deepening of the anterior chamber, we find a rather enlarged pupil; but the case before us has no affinities with that disease. (It may be observed that even in "serous" iritis, when posterior synechiæ form, as they often do after a time, the pupil becomes small again.)

The most common form of traumatic iritis is that following a penetrating wound of the eye-ball; after a simple blow iritis is, as I have already stated, of much less frequent occurrence. The question arises as to the cause of this latter variety (contusion iritis). It is often due, no doubt, to direct squeezing of the iris, between the cornea and the lens, caused by the sudden indenting of the former. At St. Thomas's Hospital some time ago, a young man came to me about three hours after he had received a blow on the eye from a blunt instrument; the cornea at one part was scratched and rather cloudy, and the iris just behind this spot, which of course marked the point of impact of the projectile, was already adherent to the capsule of the lens, and there was some haziness of the corresponding part of the lens. Well-marked iritis came on in this eye.

In the case we have seen to-day, the patient's age

may have acted as a contributory cause of his iritis, for advanced age always predisposes the iris to inflammation. This fact receives daily illustration in cases of ulcer of the cornea and of cataract extraction, iritis being a more common complication of these states in the old than in the young. Even in the common acute catarrhal ophthalmia, if the patient be middle-aged or elderly, the iris is often notably discoloured, whilst in the same disease in children we scarcely ever find the iris altered. There is nothing particular to be said as to the probable course of the iritis in this case; it is likely to be a long, but not severe, attack, and it does not call for any heroic treatment.

In respect to the other factor in the case, the mydriasis, which, with paralysis of the ciliary muscle (cycloplegia), is such a frequent result of contusions of the eyeball, some further remarks may be made. The iris is more easily affected by blows than the ciliary muscle, as it seems to be by all mydriatics and miotics; hence, after the slighter blows on the eyeball, we get mydriasis without any demonstrable cycloplegia. Against this statement, however, we must set the fact that a little weakening of the ciliary muscle is less easy to detect than a slight change in the size of the pupil. The pathology of mydriasis-cycloplegia has not, so far as I am aware, yet been made out; the symptoms have been attributed to rupture of the ciliary nerves within the eye-ball, but it is more likely that they are due to suspension of function from bruising of the iris fibres, or of the nerve endings in the iris; probably to both combined.

The course of these cases of traumatic internal ocular paralysis is usually long; it is always a matter of weeks, sometimes of months, and some cases never get well. In October (1884) I was consulted by a lady about thirty-five years of age, who, five weeks previously, had been struck in the right eye by a lawn-tennis ball. Her pupil measured 6 mm., and her accommodation was weakened, as evidenced by her inability to read small print, and the type that she could read required to be held further from this eye than from the sound one. When seen on May 7th (1885), there was decided improvement both as to the condition of the pupil and the accommodation, the pupil measuring 4 mm. and the accommodation being partly recovered. In another instance, a gentleman, aged 27, was struck in the left eye, two months before I saw him, by a Lacrosse ball; the pupil was somewhat dilated (3.5 mm.), but it acted well to light and accommodation. I saw him again six months later, and there was no improvement. In another instance which came under my notice, some fifteen years after the injury the pupil was always smaller than its fellow. The case was a little complicated by the presence of some superficial choroidal change near the yellow spot, with pallor of the disc, the result of acute changes caused by the blow. The patient, who was 25 years old when I saw him at the Queen's Square Hospital, said that, when a boy, he had had a severe blow on the right eye from a stone, and that the eye had been defective ever since. On trial, he could read print almost as well with this eye as with the other (equivalent to about 2 J.), and the near point was not removed at all in the injured eye. The pupil, which acted well to light and accommodation, and dilated when shaded, was always decidedly smaller than that of the sound eye. Dr. Beevor was kind enough to try the effects of eserine and atropine, and found that the iris of the injured eye reacted quite well to both these substances. There was no reason whatever to connect any of the eye changes with the disease for which he was under treatment at the Queen's Square Hospital.

The mydriasis which occurs in these cases of blows is, like that seen in paralysis of the third nerve, never complete, as it is in atropine mydriasis; the pupil is

usually about 4.5 mm. in diameter, and not 8 or 9 mm. as in the latter form. Immediately after the accident it often happens that the fibres of the iris do not act fully either to atropine or eserine, as if the tissues of the iris were actually damaged. In some cases, after a time, there is partial atrophy of the iris in places. This was well illustrated in the following case. Mr. S. H. received a severe blow on the eye from a racquet ball at the age of about 17, and the sight of that eye was permanently damaged. He was told soon afterwards that partial cataract had formed. When I saw him he was 33 years of age, and during the interval the opacity in the lens seemed to have remained stationary; it was in the form of spokes radiating from the anterior and posterior poles, each spoke reaching about half-way from its pole to the equator. The sight ( $\frac{20}{50}$  and 6 J.) was too much interfered with by the lenticular opacity to permit of accurate measurement of the accommodation; the pupil, however, was always larger than that of the other eye, though acting well to light. On carefully examining the iris, its pupillary border was found in parts to be slightly crenated, and the structure of the iris at these points was thinned and looked wrinkled. I may add that I have seen at least one other case of this atrophic appearance of the iris after a blow. Though it may be said that this atrophy of the iris is due to paralysis of the nerves, yet we never find such a result in cases of long-standing idiopathic paralysis of the third nerve, a fact which seems to suggest that in the contusion cases the mydriasis is due to actual damage of the fibres of the iris.

No treatment does any good in these cases; the miotics, pilocarpine and eserine, affording only temporary help.

---

## THE OPERATIVE TREATMENT OF CANCER OF THE CERVIX UTERI.

By JOHN WILLIAMS, M.D., F.R.C.P.,

Obstetric Physician to University College Hospital.

L. H., AGED 39, married, was admitted into University College Hospital, December 10th, 1883, with the following history: About September, 1882, she noticed a yellow discharge from the vagina, and she had for the same time been gradually getting thinner. She attended as an out-patient in June, 1883, and was ordered some medicine and vaginal injections, containing Condyl's fluid. About a fortnight later, when using a vaginal injection of warm water, she noticed some blood in the discharge. Blood appeared frequently afterwards, and varied in amount at different times; it also appeared independently of the use of injections. For nine months there has been bleeding and pain on coitus. For five weeks before admission, the blood had increased in quantity, and the discharge had been offensive.

The patient began to menstruate when 11 years old, and had always been regular till nine months before admission. The flow was not excessive. She was married at 18, and had one child 17 years ago, and a miscarriage one year later. She has not been pregnant since. She has had several of the acute specific fevers. She had rheumatic fever when young, and again, nine years ago, with "pleurisy at the heart" and "inflammation of the bladder." Since that time she has had some difficulty in, and slight

scalding sensation during micturition. She has had "inflammation of the womb" three times.

The patient, when admitted into University College Hospital, was then fairly healthy-looking; she weighed 6 st. 1 lb.; had been getting much thinner lately. External examination of the abdomen revealed nothing abnormal. On vaginal examination, there was found an ulcerated surface on the cervix uteri. It was raised about one line at the edge, and it involved the whole of the posterior and about one-third of the anterior lip. There was a small strip of healthy mucous membrane on the left side and posterior lip, and a strip about three-quarters of an inch in width running around the anterior lip of the uterus. The ulcerating surface had the diameter of a florin. Four days before (Dec. 7th), it was not bigger than a shilling, and involved chiefly the posterior lip. On the left side there was a fissure of the cervix running into the insertion of the vagina. The urine was normal.

Owing to the rapid extension of the disease, the patient was operated upon at once. She was placed under ether, in the lithotomy position. A Sims' speculum was introduced into the vagina and a sharp hook passed into the cavity of the body of the uterus to drag the organ down to the outlet of the vagina. The sound was passed into the bladder to indicate the limits of that viscus. An incision was then made through the anterior vaginal wall near its insertion into the cervix, and the bladder dissected from the uterus by the fingers and blunt-pointed scissors. The posterior vaginal wall was divided in a similar manner and the peritonæum dissected from the uterus, the broad ligaments were also divided, and the vessels secured with Spencer Wells's forceps. After reaching the level of the inner orifice or thereabouts the wall of the uterus was cut in a conical manner to within half an inch of the fundus, and then divided with a Paquelin cautery. The vessels in the forceps were then burnt off. The vagina was plugged with a "kite tail" of iodoform wool and a morphia suppository administered. There was very little bleeding, and the operation lasted 20 minutes. Pulse after operation, 72.

A week after the operation the patient had two attacks of hæmorrhage, and the wound was plugged with lint soaked in a solution of perchloride of iron. Then she had an attack of pelvic peritonitis during which the temperature rose to 104.2° F. She recovered from this, and then an abscess formed in the remains of the uterine cavity, arising from closure of the canal, or sinus leading up to it. This was opened twice. Ultimately, it opened into the rectum, and the patient has not been troubled with it since. The patient has reported herself from time to time, the last occasion being the end of November, 1885. She was then quite well, and gaining flesh. The scar in the vagina as well as the uterine stump was perfectly healthy.

This is a favourable instance of the cases in which a much less severe operation than total extirpation of the uterus is undertaken for cancer of the cervix. The reasons for the operation are the following: the tendency of cancer, commencing at the external uterine orifice, is to spread superficially towards the vagina, and not deeply towards the body of the uterus; under such circumstances the chances of removing the whole of the disease by this operation are quite as great as they are by total extirpation, for the recurrence would be expected to appear, if it appeared at all, not in the uterine stump, but in the edge of the vaginal wound; and there is just as good an opportunity for making the vaginal wound wide of the disease in the less as in the more severe operation. Then the mortality from supra-vaginal amputation of

the cervix is much less than from total extirpation, while the results are just as good.

Many improvements in the operation as described have been carried out since. The vessels in the broad ligaments are secured with ligatures, and the risk of secondary hæmorrhage is reduced to a minimum; and the stump of the uterus is stitched to the lip of the wound in the vagina. This does away with the causes of closure of the wound and damming up of the uterine secretion in the remains of the uterus, leading to abscess.

---

## NOTES ON PRACTICE IN ITALY.

By JOHN GASON, F.K.Q.C.P.I. and F.R.C.S.I.

SHORT practical remarks are often useful to the busy practitioner, and if such have reference to diseases frequently met with they are the more acceptable.

*Cod Liver Oil.*—The difficulty of finding this valuable medicine is daily becoming greater. In fact, I believe it is rarely found pure, and fish oil more or less refined is sold for cod-liver oil. I believe it is to be found pure at a few chemists' in London, as Mr. Bell's, Messrs. Savory and Moore, and at Mr. Squire's, but the price of pure cod-liver oil is so great that it cannot be generally employed. Messrs. Savory and Moore showed me the means of detecting its purity, which I invariably follow when requested to administer it, and I say positively that no one sample of it in Italy that I have tried shows any proof of purity. Some years since I was led accidentally to observe the quantity of cod-liver oil that can be absorbed by patients, and I found from many examinations that the English system cannot absorb more than one teaspoonful taken three times a day. To prove this, let persons who have been taking it defæcate into a pôt-de-chambre, pour some hot water over the action from the bowels, and, if more than the quantity above stated has been taken, the oil will be seen floating pure and clear on the surface of the water. Russians and other fat-eating nations may be able to absorb more. Let them do so.

*Polypus of the Ear.*—Last summer, at the Baths of Lucca, an Italian woman called on me. She had been to me in the preceding summer with a polypus in the right ear, but which was so low down, and so soft, that, failing to detach it, I tried to destroy it by means of the liquor ferri perchloridi fort. During the past summer she called on me again. The polypus had then reached the exterior of the meatus externus. I seized it with a dressing forceps, and twisted it until I completely detached it from its origin on the tympanum, to which it was adherent by a pedicle. The polypus was of a semi-cartilaginous consistence, of white colour, and one inch and a half long. There was some hæmorrhage after its extraction, which soon ceased.

*Intermittent Fevers.*—Many cases of this disease came to me at the Baths of Lucca last summer. These cases originated in the Island of Sondegna, in the Tuscan Maremma, and in other malarious parts of Italy, and, as many of the inhabitants of the Baths of Lucca go to those places for work in the winter, they frequently return home with these fevers. Such cases I invariably treat with arsenic, but in much larger doses than are generally given, and with the most decided benefit. I never find any bad results from the arsenic. The dose I generally give is ten drops of Fowler's solution three times a day, or, if there is much

anæmia or that yellow waxy colour so frequently met with in that disease, I find one grain and a half of the arseniate of iron three times a day a most useful remedy. Whenever it produces puffiness of the under eyelids, or the patient complains of pain in the stomach, I suspend its use, but these symptoms I rarely meet with. Most of the patients who came to me had been treated by Italian medical men with quinine alone, that being the only treatment which they adopt.

*Neuralgia of the Face and Head.*—In the treatment of this disease, which is frequently of a malarious character, I find the use of arseniate of iron in doses of one grain and a half three times a day a most valuable measure. Where the neuralgia is of a purely neuralgic character, the use of valerianate of zinc in two-grain doses three times a day I have found very beneficial.

*Asthma and other Nervous Affections.*—The use of nitrite of amyl produced the most wonderful effects in the relief of asthma and many nervous affections. Patients would come to me hardly able to breathe and leave quite relieved. The dose for inhalation, ten drops on cotton, inhaled by the nose and expired by the mouth. I repeated it generally in the same dose three times. No bad effects were produced in any case.

*Heart Affections.*—Such affections were very frequent among the poor in the mountainous districts of the Baths of Lucca, and appeared to me to be produced by carrying weights up the mountains. The affections which I saw consisted of palpitation of the heart, and in some cases decided hypertrophy. They were generally very much benefited by the use of bromide of potash and extract of belladonna, which I found far more efficacious than the extract of digitalis. The doses I used were eight grains of the bromide and  $\frac{3}{4}$  gr. of extract. belladonnæ twice a day.

*Moxas in Rheumatic and Neuralgic Affections.*—For some time I have been trying in my hospital and in private practice in Rome, and with marked effect, the use of Moxas. I know the prejudice against this treatment both in England as well as in Italy. I have suffered in my own person for six weeks from that obstinate affection, so frequently met with in the deltoid muscle. To so great a degree was I suffering from it that I could not put on my coat without assistance. I resolved to try the moxa. I applied it in four places over the deltoid muscle of the left shoulder, and let it burn until I smelt strongly the odour of burning flesh. The skin was deeply burnt in four places and vesication produced. I did it late at night, when I was suffering very much; the next morning I rose from my bed perfectly well, and, though that happened more than ten years ago, I have never felt the pain since. Two years ago a poor woman was brought to my dispensary in Rome, supported by two women. She attended regularly for a month, almost always twice a week. At the end of that time she said to me, "Doctor, I have been coming here for a month and do not feel the least better." I said to her, "I have tried everything for your sciatica that I could think of, except one thing, which is, using fire to your thigh; will you submit to it?" She agreed, and she came supported by two women on the following dispensary day. I used the moxas in four places, as I have described in my own case. She was helped home by her two assistants; that was on Tuesday. On the next day she began to walk about her own house without assistance. On the following Thursday she went downstairs for a can of water, and on the next day, Friday, she came to my dispensary without any assistance, and nearly quite well. Last winter I had in my hospital in Rome a young person suffering from sclerosis of the spine. I had used with her electro-galvanism,

belladonna, bromide of potash, &c., without any benefit. I then used moxas over the spine, as described in my own case. She felt so much better in a day or two that she was able to leave the hospital quite cured ten days afterwards. She called a few days since at my dispensary to report herself, and was then quite well. At the present time I have a patient in my hospital of 55 years of age. She has been suffering for a considerable time from chronic and fixed rheumatism in both her knees, which caused her much pain, stiffness in the joints, and much lameness in walking. Last week I applied moxas in four places on both knees, as described in my own case. In three days she was able to walk about without any pain or lameness. She will leave the hospital quite cured on Saturday next.

*Hæmorrhoids.*—I have had many operations for the removal of external piles in women in my hospital, which I have always done simply with curved scissors, stopping the hæmorrhage, which has been sometimes severe, by means of application of several folds of linen soaked in the liquor ferri perchlorid. fort. — which invariably stopped the bleeding in a short time. I have never been obliged to use clamps, merely holding the piles with a pair of forceps. In some cases the piles have completely surrounded the anus.

I cannot close this paper without calling attention to the great amount of rickets, marasmus, and glandular affections occurring in children, apparently the result of their parents' unfaithfulness. To my mind it calls for more strict and watchful attention on the part of the Governments of every country to pass laws for the arrest and examination of prostitutes, who are the cause of the ruined health of thousands of children, innocent victims of ill-placed sentimentality. The mothers of these children state without reserve that they have been infected by their husbands, and in Rome it is now considered almost a necessary result of marriage. Venereal affections, both in men and women prevail to a great extent in Rome.

THE BACTERIA OF EYE DISEASES.—Some interesting observations are recorded by Dr. Widmark in "Hygiea," a Swedish journal (also presented in a summarized form in French as an appendix), on the bacteriology of dacryocystitis, hypopion-keratitis, blepharadenitis, and phlegmonous dacryocystitis. From ten cases of dacryocystitis he has isolated three micrococci, *Staphylococcus pyogenes albus*, *Staph. pyog. aureus*, and *Streptococcus pyogenes*, also a bacilliform bacterium. He examined these by means of cultures and grafted them on the corneæ of rabbits, and found that they were all capable of producing keratitis with hypopion, which frequently presented characters resembling the serpiginous ulcer of the human cornea. The author, Dr. Widmark, believes that microbes are not the original cause of eye inflammations, but that, if the lacrimal canal is obstructed and the contents of the lacrimal sac thus caused to be stagnant, they develop abundantly and set up inflammatory changes in the walls. When little abscesses appear in the hair follicles in blepharadenitis as a complication of dacryocystitis, they are due to the migration of *Staph. aur.* or *Staph. alb.*, or both, which, after developing in the lacrimal sac, are carried back by a reflux of the lacrimal secretion into the conjunctival sac and thus are able to penetrate to the ciliary roots. Phlegmonous dacryocystitis is due as a rule to the entrance of *Streptococcus pyogenes* into the anterior subcutaneous tissue. Dr. Widmark's observations are in perfect correspondence with clinical facts, for it is well known that abscesses in the ciliary roots are nearly always circumscribed, producing but little effect in their *entourage*, whereas phlegmonous dacryocystitis is very apt to set up erysipelatous inflammation, and Ogston and Rosenbach found that *Staph. alb.* and *Staph. aur.* produced circumscribed abscesses, while *Strept. pyog.* gave rise to abscesses of a more erysipelatous character.

## SEVENTEEN CASES OF SYPHILIS TREATED WITH THE TANNATE OF MERCURY.

By J. INGLIS PARSONS, M.B., M.R.C.S.E.

WHILE acting as house-surgeon to Guy's Hospital, I treated the following cases of syphilis at the out-patient department with the tannate of mercury. It was prescribed, quite alone, in the form of a pill taken three times a day, one hour before meals, the reaction of the gastric mucous membrane being alkaline at that time. No opium or tonics were ever given

with it, nor were they required. It seemed possible to continue its administration for any length of time without disturbing the patients' systems. Most of the cases, as soon as the symptoms disappeared, refused to attend any longer, so that I was unable to give it for any lengthened period of time. This salt contains 50 per cent. of mercury, is insoluble, and is precipitated by dilute alkalies in so minute a form as to show molecular movements under the microscope. The extracts from my notes will show how the drug acted. In only one case had there been previous treatment. It is needless to add that local treatment was also employed whenever a case required it.

Name and Age.	Period of time from onset of disease to commencement of treatment.	Principal Symptoms.	Period of time from commencement of treatment to disappearance of symptoms.	Dose.	Duration of treatment.	Effect on Bowels, Gums, and General Health.
H. L., 36 ...	4 months	Hard chancre on penis, ulcer on both tonsils, small maculæ on back and chest; inguinal, cervical, and sub-maxillary glands enlarged.	Rash 3 weeks; all symptoms in 5 weeks.	gr. ij ...	2 months	Never had appetite better; bowels open once a day; gums a little tender; felt much stronger.
H. D., 22 ...	2 months	Chancre on penis, squamous syphilitide on arms, trunks, legs and face; throat ulcerated, enlarged glands.	Rash partially in 5 weeks; other symptoms better.	gr. i½ ...	5 weeks; never came again.	Appetite good; no looseness of bowels; no tenderness of gums; felt a little weak.
J. T., 39 ...	10 months	Papular rash on trunk, some places pustular; throat ulcerated, submaxillary and post-cervical glands enlarged.	4 weeks ...	gr. i½ ...	7 weeks	Gums slightly tender; no relaxation of bowels; appetite and general health better.
A. B., 25 ...	1 month ...	Large maculæ, some squamous, on arms, legs, and trunk, ulcer on both tonsils, glands, &c.	3 weeks ...	gr. i½ ...	3 weeks	Felt stronger; bowels a little loose.
S. S., 35 ...	6 months...	Squamous and papular rash all over arms and chest and back, ulcers on both tonsils, pains in limbs, submaxillary and inguinal glands enlarged.	5 weeks; all symptoms quite gone; pains went in 14 days.	gr. i½ ...	5 weeks	Bowels open twice a day; appetite good; feels much stronger; no tenderness of gums. Was under a medical mau for three months.
R. G., 24 ...	3 months...	Now has large squamous, and in places eczematous patches on arms and legs. Chancre healed.	Symptoms a little better in 5 weeks.	gr. i½ ...	5 weeks	Bowels constipated; feels better; history of old eczema before onset of specific symptoms.
G. B., 25 ...	1 month ...	Two hard chancres on frænum. After a week some maculæ appeared on chest, arms, and legs, and an ulcer on left tonsil; right inguinal glands enlarged.	Chancres in 4 weeks; rash in 2 weeks.	gr. ij ...	7 weeks	No looseness of bowels; appetite good; feels stronger for medicine.
F. M., 22 ...	4 months...	Papular and squamous rash all over body, arms, and legs. Both tonsils ulcerated. Ulcers on side of tongue. Papillomatous excrescence on dorsum of tongue; mucous tubercles.	All gone in 6 weeks	gr. ij ...	10 weeks	Bowels a little loose; no soreness of gums; feels better.
A. J., 25 ...	2 months...	Maculæ on chest, arms, and face, ulcer on tonsils, chancre on vulva.	Rash 2 weeks; ulcers better.	gr. ij ...	2 weeks	Bowels open once in two days; no tenderness of gums.
J. L., 34 ...	12 months	Extensive squamous patches on both legs.	Slight improvement.	gr. ij ...	3 weeks	The same.
T. D., 47 ...	5 months...	Small maculæ on forehead, arms, and legs, squamous in places. Ulcers appeared on tonsils in 2 weeks.	Rash 2 weeks; ulcers in 3 weeks.	gr. i½ ...	5 weeks	Gums a little sore; appetite better; bowels regular.
G. H. M., 27	3 weeks ...	Small indurated chancre on frænum; in 14 days some maculæ appeared; in 5 weeks two small ulcers on tonsils.	Chancre almost healed; maculæ gone in 2 weeks.	gr. ij ...	5 weeks	Slight tenderness of gums; appetite good; no looseness of bowels.
S. A., 23 ...	3 months...	Indurated spot on frænum, no sore, ulcer on tonsil, inguinal glands enlarged.	Induration much less; ulcers nearly healed.	gr. ij ...	3 weeks	The same.
J. T., 56 ...	3 weeks ...	Large cartilaginous chancre on dorsum of penis; in 14 days ulcer appeared on both tonsils; no rash.	All healed in 5 weeks.	gr. ij 2 weeks gr. iij 3 weeks	5 weeks	Bowels regular; gums a little tender; appetite good.
M. H., 17 ...	3 months...	Large diffused chancre on right labium; ulcers on tonsils; roseola on chest, back, and legs.	Rash and ulcers in 14 days; chancre less induration.	gr. i½ ...	4 weeks	Missed medicine one week; bowels normal; appetite better.
C. C., 38 ...	1 week ...	Large hard chancre at base of penis; one large inguinal gland; no rash.	Gone in 1 month	gr. ij ...	4 weeks	Bowels a little loose; no tenderness of gums; appetite good.
H. G. H., 19	1 month ...	Chancre on glans penis; maculæ on trunk; enlarged glands in both groins; in 3 weeks ulcer appeared on tonsil.	Chancre and rash in 3 weeks.	gr. i½ ...	4 weeks	Bowels constipated; gums tender; felt much better for medicine.

## SOME CASES OF INTEREST FROM THE LATE WAR IN THE SOUDAN.<sup>1</sup>

By HAROLD HENDLEY, M.R.C.S.  
Surgeon, Indian Medical Department.

As surgeon in charge of a large field-hospital for followers of all nationalities, much of my work was of the most interesting character, much medical work was done, but the following cases are all surgical:—

**CASE I.—Bayonet Wound.**—H. Abdi, aged 23 years, camel-driver, admitted April 4th for a bayonet wound received during a quarrel. The patient walked from near his camp, where he received the wound, to the hospital, a distance of 200 yards, without any difficulty or discomfort. Examined by the apothecary on duty, he was detained in hospital, more from the situation of the wound than its apparent danger to life. In the left arm over the body of the biceps two small wounds, two inches apart in a horizontal direction, were found connected by a passage between the skin and muscle, through which a gunshot probe could be passed with little difficulty. Corresponding to the inner of these wounds, when the arm was brought to the side, was a small wound in the mid-axillary line just below the seventh rib, apparently superficial. There were no symptoms of penetration, no cough, hæmoptysis, emphysema, or difficulty of breathing. There was a slight wound of the scalp, and this, with the others, was dressed with wet lint and bandage. After remaining about an hour in the hospital, the patient absconded, returning to his own tent. On arriving there, he began to experience some difficulty in breathing; three hours from the time of the accident, he was again seen and found dying of asphyxia.

*Post-mortem*, 16 hours after death. On examination the wounds described above had scarcely altered, there was slight emphysema around the chest wound, and this, when probed, seemed to be quite superficial. On opening the thorax, a large quantity of inoffensive air escaped from the left pleural cavity. Both lungs had collapsed, occupying on either side one-fifth of their usual space. Four ounces of venous blood were found in the left chest. The lower lobe of the left lung was bound to the chest wall by old adhesions which encircled a small roughly triangular wound having a slightly thickened, rounded, congested edge, through which a large gunshot probe could be introduced with ease for two inches. Left bronchus stained with blood. Heart contracted, no blood in the cavities. Abdomen normal. Diaphragm uninjured. Tracing the wound in the chest wall from without, it was followed in an oblique direction over the eighth rib, through the lower border of which it passed, causing a triangular opening with sides and base formed of bone, the latter slightly detached from the main portion. The wound was then found to extend into the pleural cavity and became continuous with that in the lung. Owing to the position of the adhesions, the wound of the lung was held firmly in a patent condition within about half-an-inch of the chest wall; blood escaped, but not to a large extent probably at first. The air, profiting by the man's exertions, began to find its way into the pleural cavity, the fatal pumping action went on until the lung, continuing this suicidal process, began to affect its companion; pressure within equalled pressure without; the chest walls failing in their duty, the lungs collapsed. The absence of lung symptoms, the presence of adhesions, and their effect upon the results, together with the opening in

the rib, giving the exact shape of a triangular bayonet, are worthy of notice.

**CASE II.—Bullet Wound (Remington Rifle).**—Rajab Ram, Indian mule-driver, aged 28, admitted on May 5th. Whilst asleep on night of April 26th, he was wounded by the enemy. Two small superficial wounds on the right thigh, connecting which a slight thickening of the subcutaneous tissue could be felt; the one situated slightly external to the middle line of the front of the thigh and near its vertical centre, the other five inches from it and on a rather higher plane on the inner side of the limb, constituted respectively the entrance and exit wounds of a Remington bullet. The bullet had then passed into the left foot, just in front of the astragalo-scaphoid articulation; here it had been searched for previous to admission without success. Under chloroform on May 6th, digital examination showed the scaphoid to be in a condition of disintegration, and the two internal cuneiform bones much injured. Nelaton's probe was used with but little success, the earthenware was slightly marked, due probably to particles of lead adhering to the bones. Again the finger was introduced, the limbs having been carefully placed in the position they were supposed to have been in at the time the injury was received; palpating with the disengaged hand over the sole of the foot, an oblong mass was detected lying deep between the two inner metatarsal bones just in front of their bases. There could be no reasonable doubt that this was the missing bullet; it was cut down upon and removed; there was no direct communication between the small cavity in which it lay and the original wound; a little bloody serum escaped.

A drainage tube was forced through from above and the wound dressed with carbolic lint, iodoform, tenax, and a splint. By May 19th the superficial wounds in the thigh had healed. In the foot small pieces of bone had separated, and the remainder were satisfactorily granulating. An extra counter-opening was made in the sole, the other having been found to be too far forward. On May 21st the patient was invalided to India.

The position of the patient at the time of receiving the wound was one often adopted by natives when resting, viz., reclining towards the right side, the right leg and thigh being slightly flexed, and the opposite foot being drawn up into the fork with the toes turned out. The bullet was very little damaged, two or three small pieces of bone were adhering to a grazed surface near its apex. It would be difficult to find a case similar to this in character amongst Europeans; the exit on the inner side and higher up the thigh than the entrance, yet with the bullet—having met with little resistance—passing into the opposite foot with a general direction from above downwards, as shown by skin and bone. There was no trouble with the thigh wound, it healed very rapidly.

**CASE III.—Suture of tendons and of the median nerve.**—E. Matoesey, aged 30, a Greek. Transferred March 26th from one of the field-hospitals, where, in consequence of a deep horizontal sword-cut across the front of the right wrist, extending from the radial side of the ulna round to the dorsal surface of the radius, and then becoming superficial, it had been considered necessary to resect the lower end of the radius. On admission, the major portion of the wound had healed, leaving unfortunately complete loss of sensation in the thumb and adjoining two fingers and a half, and but slight power of movement in the hand. By April 6th I had lost all hope of any improvement without an operation. Deciding to reopen the wound, a vertical incision was made through the cicatrix and prolonged upwards along the course of the median nerve. After some dissection, the

<sup>1</sup> Read by Mr. H. Percy Dunn before the West London Medical-Chirurgical Society on December 4th, 1885.

ends of the palmaris longus and flexor carpi radialis tendons and median nerve were discovered much separated; the central end of the latter, superficial and bulbous, the peripheral, deep and apparently normal, were both embedded in the cicatrix.

After cutting off the bulbous end and paring the opposite side the parts were brought together, slightly over-lapping and secured by three catgut sutures. The tendons were treated in like manner, care being taken to keep the hand flexed. The wound was now closed with silver wire sutures and dressed with carbolic lint, iodoform, and tenax; the flexed position was maintained by means of a splint and starch bandage. On the 18th the wound was dressed and found to be doing well. By the 23rd a small portion of the cicatricial tissue had commenced to slough, also there was a considerable discharge from the wound; a good result therefore seemed very doubtful. On May 1st, however, the wound looked healthy, sensation to a modified degree had returned to the middle and radial side of the second finger, the hand was still kept slightly flexed, the fingers moved fairly well. On 26th, wound healed. June 5th, patient discharged with complete sensation over the whole of the hand except for two small patches of skin upon the dorsal surface of the metatarsal bones of the thumb and index finger, immediately above the superficial portion of the sword-cut; the power of movement in the hand under the influence of shampooing and passive motion is increasing daily. The importance of joining all structures in recent wounds of this description cannot be too much insisted upon; the results generally more than repay the trouble taken, even often under the most unfavourable circumstances.

CASE IV.—*Ununited Compound Fracture of the Radius and Ulna* (middle third) right arm.—D., aged 20, native of India. The patient was admitted March 25th, suffering from the effects of the bite of a camel. There was an open, profusely granulating, pus-discharging wound situated over the middle third of the dorsal surface of the ulna, communicating with a fracture of that bone, and indirectly with one of the radius, over which bone also there was a recent cicatrix. With a good permanent splint, there was hope that the parts would unite; this treatment was carried out, but, although the discharge diminished and the granulations became healthier, union seemed as far off as ever. On April 22nd an examination was made under chloroform; the ends of the bones were found necrosed and partly separated by soft tissues, no callus had been thrown out, and there had been no attempt at union. After enlarging the wound over the ulna and re-opening that over the radius, the ends of the bones were resected obliquely so that corresponding surfaces might be applied to one another; holes were then drilled through the fragments, and the latter were closely approximated with silver wire, the ends of which were left projecting from the wound. Dressing consisted of drainage tubes, carbolic lint, tenax, and iodoform; on the 28th, on which day he was invalided to India, the wounds were healing fast, the discharge was slight, and there seemed to be every prospect of union taking place. This was one of several cases of camel-bites treated in the hospital, with all of which I had a good deal of trouble. In one it was found necessary to resect the end of the tibia, in another (an Austrian) a large part of the head of the tibia necrosed. Where the bones escaped, the soft tissues suffered in like manner; large sloughs came away, leaving unhealthy-looking ulcers. With broad teeth and strong jaws a camel's grip is not to be despised. In the case referred to above the man was held suspended in the air by the lower part of his knee for the space of three minutes in spite of a violent

assault on the animal by upwards of a dozen men armed with thick sticks.

CASE V.—*Removal of Epithelioma*.—K., single, aged 30, native of India, admitted April 11th for a malignant-looking ulcer over the pubes, of 180 days' duration, and measuring  $3\frac{1}{2}$ " in a vertical and  $2\frac{1}{2}$ " in a horizontal direction. Its edges were irregular, raised, rounded, and indurated; its base was partly covered with blue cicatricial tissue, partly with new tissue, between which ran tortuous channels of ulceration, leading to a central deeper ulcer with a firm indurated base. The inguinal glands were slightly enlarged on both sides. On the 17th, under chloroform, I removed the whole mass, allowing a fairly wide margin; the central ulcer gave some trouble, as it was firmly adherent to the linea alba. A flap of skin was brought down from the right side to the middle line, twisted at its base and attached by its free end to the loose skin of the penis; the sides and under-surface were also secured, leaving only a small portion on the left of the wound still uncovered; dressing, carbolic-oiled lint, tenax, and iodoform. The skin of the abdomen was brought towards the middle line by means of strapping, and the legs were tied together. On the 18th the man was sent on board ship for a passage to India; the skin had already adhered, and the whole promised well. I afterwards heard that the patient did remarkably well, returning to his home, after a short stay in the hospital in India, quite convalescent.

With the exception of cases complicated by disease, such as ague or dysentery, all wounds, both in Europeans (from the Mediterranean) and Asiatics, did well. It was not so, however, with Africans; their wounds healed very slowly, after resulting in unhealthy-looking ulcers, aggravated by their own treatment. This consisted of a copper coin, pressed firmly over the wound, to be substituted for another—a larger one—when the ulcer appeared beyond its margins. I never saw any good result follow this treatment; nevertheless, their faith in it seemed to be unbounded. Though fine-made men, their flesh was deficient in healing power, owing chiefly, I think, to overfeeding, preceded by bad living. Amongst the Indians many wounds healed wonderfully well—sword wounds, minor operations, and others, such as castration and hæmorrhoids.

The dressings already referred to were those most commonly used, carbolic oiled lint, iodoform, tenax; combined or otherwise, the three made an excellent dressing; the iodoform sprinkled on the wound, then the small strip of lint, covered by the tenax bound on by a gauze bandage, rendering it completely aseptic. Although flies abounded, they only gave trouble in two or three cases; the following powder, used sparingly outside the bandages, I found very useful in keeping them off a wound:—

R.—Iodoformi, ʒi.  
Zinci Oxidi, ʒij.  
Pulv. McDougall, ad ʒiv.

On the whole, the followers kept exceedingly healthy; the percentages of sick, invalids, and deaths from disease were low. When sick, the heat affected them but little, and often bad cases made good recoveries, and returned to work.

---

CHARITABLE BEQUESTS. — Mr. Henry Aste, late of Castle Hill Lodge, Norwood, has bequeathed 200*l.* to University College Hospital; 100*l.*, each, to the North London Consumption Hospital, the Royal Hospital for Incurables, Putney, and the Asylum for Idiots, Earlswood; and 20*l.* to the Margate Sea Bathing Infirmary. Miss Heald, late of Didsbury, near Manchester, has bequeathed 100*l.* to the Stockport Infirmary.

REPORTS OF  
HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY.

EAST LONDON HOSPITAL FOR CHILDREN.

TWO CASES OF CIRRHOTIC LIVER IN  
CHILDREN IN ASSOCIATION WITH  
TUBERCULOSIS—CASE OF NON-TUBER-  
CULAR MENINGITIS.

By Dr. G. N. PITT, Late Assistant-Physician.

CASE I.—G. C., æt. 3, admitted under the care of Dr. Eustace Smith. No history of exanthems. Has been ill and pining away for three months; appetite capricious; complains of abdominal pains; bowels are relaxed, motions often offensive, sometimes containing blood and mucus.

On admission, the abdomen is distended, no fluctuation, no marked tenderness, but some increase of tension on the right side. The liver extends four fingers' breadth below the costal margin. No enlarged glands to be felt. Lungs healthy; venous hum over upper part of sternum when head is retracted. The child is drowsy and looks ill. Some broncho-pneumonia developed. The child gradually emaciated and remained drowsy until its death  $3\frac{1}{2}$  weeks after admission.

*Post-mortem*, 24 hours after death. A few caseous nodules were found in the lungs with diffuse broncho-pneumonia. There were tubercular ulcers in the intestine, and the mesenteric glands were caseous. In the brain there was general tubercular meningitis, the brain tissue being very soft, especially that bounding the lateral ventricles. The liver, extending four fingers' breadth below the ribs, was much enlarged, and there were a few adhesions on its surface. There was no ascites. The liver was quite free from any trace of tubercle; but was so tough and dense, it could not be broken down by the finger. Microscopically, the capsule showed thickening, and there was a general well-marked increase of fibrous tissue along the portal canals, together with an infiltration with small deeply-stained cells which picked out the portal canals to the naked eye. The cells are not distributed between the liver cells, but were confined to the portal canals. The coats of the arteries and veins seemed thickened. There were no collections of cells forming tubercles to be discovered, and no caseation. The case was one of small-cell and fibroid changes thickening the capsule and running along the portal canals.

CASE II.—J. H., æt. 7, admitted under Dr. Donkin. His mother died of phthisis. He had scarlatina, measles, and whooping-cough when quite young. Well till 6 weeks ago, since when he has been languid and has emaciated. Has had diarrhœa. On admission, the child was extremely emaciated, with a furred tongue. There was some dulness with deficient breathing at the right base, further signs gradually developed over the lungs.

He developed diarrhœa, and a tumid abdomen and some enlarged abdominal glands were felt before his death, which took place in 2 weeks from exhaustion. Neither liver nor spleen were enlarged.

*Post-mortem*, 17 hours after death. Skin very rough. Abdomen: the omentum was matted to the intestines and the abdominal walls crammed with tubercles and

in places thickened. The intestines were universally adherent, their serous surfaces contained numerous caseous tubercles  $\frac{1}{16}$  to  $\frac{1}{8}$ -inch in diameter. The mucous surfaces were healthy. The mesenteric glands were enlarged and caseous. There was extensive involvement of both lungs in a not very acute tubercular process. Pleuræ more or less adherent. Blood-stained serum in the pericardium. The upper surface of the liver was adherent to the diaphragm, and on its under surface were several caseous nodules. On section, the liver looked fairly normal, but was so dense that the tissue could not be broken down. On microscopical examination, an increase of nucleo-fibroid tissue limited to the portal canals was observed.

In neither of these cases was there any evidence that the children had drunk alcohol previous to admission, and the small amount they may have had while in the hospital would have been administered only towards the end. These two quite bear out my experience in other cases, that tubercular lesions, more especially of the peritonæum, may be a *causa vera* of a cirrhotic condition of the liver in children as well as in adults. In many, if not in most, of the cases no tubercles are found in the liver tissue. Several authors have drawn attention to the frequent association between tubercular peritonitis and cirrhosis of the liver, and in some cases the combination has made the diagnosis doubtful. M. Moroux, in his Thesis at Paris in 1883 on this subject, collected 13 cases which he discussed at length, but the only notice of tubercle being a cause of cirrhotic liver in a child, which I have seen, is in France, Méd. Par. 1881, by Bruté fils, who relates a case.

*Non-tubercular Meningitis—Persistent Retraction of the Head and Neck.*

A. T., æt. 3, admitted under Dr. Donkin. Has always been well till 9 weeks ago, when she was taken sick and had a fit. Her eyes were fixed and her arms rigid. Since this time there has frequently been vomiting without any definite cause. She has had convulsions 5 or 6 times, and has not been able to stand. She often cries, has hallucinations of sight, and has lately become blind. Bowels constipated.

On admission, she lay on her left side with her head retracted, eyes wide open, but blind. Some rigidity of legs, which were painful when moved. Skin inelastic. Takes food well. *Optic discs*—*Left*, reddish, blurred, and swollen, but vessels not obscured. *Right*, becoming atrophic, with a whitish, filled-in look. Inequality of the pupils, nystagmus and conjunctival ecchymoses developed, and the child died in 4 days. The head remained retracted the whole time, and the child cried if an attempt were made to move it.

*Post-mortem*, 48 hours after death. The body was fat and well-nourished. There was great distension of the lateral ventricles, about 5 ozs. of fluid escaping. There was lymph at the base near the 7th and 8th nerves on the left side and at the apex of the temporo-sphenoidal lobes, 2 patches of softening were found in the temporo-sphenoidal lobes just in front of the optic commissure. The optic tracts seemed normal. After floating out the membranes, and after staining them, no evidence of tubercle could be discovered in them. The temporal bones were not carious, but one of the middle ears was filled with an almost muco-purulent fluid, but quite sweet, but I doubt whether this was the cause of meningitis. Both tympana were complete. Sinuses of skull normal.

This case is only one of four or five this year in which persistent retraction of the head has been associated with non-tubercular meningitis, an observation to which Drs. Gee and Barlow drew attention a few years ago.

# Medical Times and Gazette.

SATURDAY, DECEMBER 26, 1885.

## NOTICE.

*We regret to announce that the MEDICAL TIMES AND GAZETTE will cease to appear after this number.*

THE medical profession in general, and the medical graduates of the University of Cambridge in particular, will have read with peculiar pleasure an announcement contained in the daily papers on Saturday last, to the effect that Her Majesty has been pleased to confer upon Dr. G. E. Paget, of Cambridge, the distinction of a Knight Commander of the Bath (Civil Division). The name of Paget, however, has for so long been associated with the highest and most worthy aspects of medical science and medical practice that it would seem to claim for itself a measure of respect *greater* than that which any titular distinction can command. Very few, indeed, are the instances in which two brothers have so successfully climbed to the topmost rung of their life's ladder, unsullied by the least suspicion of any false step or doubtful action. Throughout his long tenure of the office of Regius Professor of Physic in the University of Cambridge, Dr. Paget has maintained with all the force of his precept and example the standard and dignity of his medical school and its medical degrees. To attribute to his influence alone the remarkable advances which of late years have raised the school to one of the most important in the kingdom would be neither true to him nor fair to others, but we shall probably be rightly interpreting the feelings of the large number of graduates whose privilege it has been to be associated with him in any capacity when we say that their school and their respect for its degree are inseparably associated with sentiments of affectionate respect for their leader. But it is not alone in the University of Cambridge that Dr. Paget has done knightly service for the cause of medical education. For eleven years he represented his University on the General Medical Council, over which he presided for the last five years of his tenure, from 1869 till 1874. His former and latter colleagues on that august Board will join with the University of Cambridge in a unanimous expression of satisfaction at the honourable distinction with which Her Majesty has been pleased to crown the later years of a distinguished and honourable career.

It will, we think, be universally admitted that the titular honour which has been conferred on Dr. William Roberts, of Manchester, has been well won. Dr. Roberts is almost the only living provincial physician who is recognised as the leading authority in this country on his special subject. His book, thumbed by every advanced student of medicine, stands on a level with the best treatises on special branches of

medicine, and should serve to other writers as a model of careful clinical research. As we said a short time back, we hope to see a long train of provincial medical knights and baronets. We believe that medicine could get on quite as well, perhaps better, without any of these gewgaws, but if they are to be given it is only right that provincial practitioners, many of whom are quite of the same calibre as our London court-physicians and surgeons, should have some share in them.

WE are sure that there has been a very general feeling of regret in the medical profession at Mr. Erichsen's failure to get into Parliament. He conducted his canvass in a manner which contrasted very favourably with the line taken by his opponent, and it is scarcely denied by any but party politicians that he would have made out-and-out a better University representative than the Lord Advocate. The result of the election may have an effect on the future of University seats which the majority of the electors can hardly contemplate with pleasure. The Universities are safe for a time, but they will be disfranchised to a certainty by the next strong Liberal Government if their representatives are chosen without regard to special fitness as the spokesmen of science and culture.

THE correspondence recently issued respecting the Sanitary Commission held at Rome, on the subject of Cholera, confirms the impression that the Continental superstition as to the efficacy of quarantine has been considerably weakened, and that, in the words of Sir J. Fayrer, "One may almost foresee the time when quarantine will give place to sanitary regulations duly and carefully enforced." Although the majority of the delegates still adhered to the principle of quarantine, yet concessions of no small moment were obtained from them as to its application. All land quarantine and sanitary cordons were unanimously declared to be useless. Quarantine on vessels arriving from infected ports was recommended to be reduced from seven days to five, and this regulation was subsequently mitigated by a further reduction to twenty-four hours in the case of all vessels in which there had been no cholera for ten days. At the fourteenth sitting of the Sub-Commission, the British delegates gave a detailed account of the system of sanitary administration existing in this country and the results obtained, and these results were contrasted with those obtained under the system of quarantine. Here the Indian delegates chimed in with corroborating evidence to such effect that a number of propositions affirming the principles of the English system were unanimously adopted by the Sub-Commission.

THE annual meeting of the Pathological Society will be held on Tuesday, January 5th, when the following list of officers and Council for the new year will be submitted to the meeting:—President—John Syer Bristowe, M.D., F.R.S. Vice-Presidents—Henry Charlton Bastian, M.D., F.R.S., William Cayley, M.D., \*Thomas Henry Green, M.D., George Johnson, M.D., F.R.S., \*William Marrant Baker, John Whitaker Hulke, F.R.S.,

\*Sydney Jones, Thomas Pickering Pick. Treasurer—John Wood, F.R.S. Honorary Secretaries—\*Sidney Coupland, M.D., Henry Trentham Butlin. Council—\*Robert Edmund Carrington, M.D., \*David White Finlay, M.D., \*James Frederic Goodhart, M.D., \*Walter Baugh Hadden, M.D., Arthur Edwin Temple Longhurst, M.D., Norman Moore, M.D., Felix Semon, M.D., Seymour J. Sharkey, M.B., Francis Charlewood Turner, M.D., Samuel West, M.D., Arthur E. J. Barker, \*Anthony Alfred Bowlby, William Watson Cheyne, Henry Hugh Clutton, Frederic S. Eve, Cuthbert H. Golding-Bird, \*John Hammond Morgan, Henry Morris, Samuel G. Shattock, \*Charters James Symonds. And on the succeeding Friday, January 8th, the annual election of officers and Council of the Clinical Society will be held, the following being the list of those suggested by the Council:—President—Thomas Bryant. Vice-Presidents—James Andrew, M.D., William Cayley, M.D., \*Samuel Wilks, M.D., F.R.S., \*Sydney Jones, Thomas Pickering Pick, \*Sir Henry Thompson. Treasurer—Christopher Heath. Council—\*Robert Edmund Carrington, M.D., Sidney Coupland, M.D., \*F. G. Dawtrey Drewitt, M.D., Arthur W. Edis, M.D., William Ewart, M.D., David W. Finlay, M.D., \*Walter Baugh Hadden, M.D., F. de Havilland Hall, M.D., Felix Semon, M.D., \*William Joseph Tyson, M.D., John Williams, M.D., Henry Hugh Clutton, J. N. C. Davies-Colley, \*William Harrison Cripps, Clinton T. Dent, A. Pearce Gould, J. Warrington Haward, Henry Morris, \*Walter Rivington, \*John Wood, F.R.S. Honorary Secretaries—Stephen Mackenzie, M.D., Rickman John Godlee, M.S. In each case the gentlemen whose names are marked with an asterisk were not on the Council or did not hold the same office during the preceding year.

THE next General Meeting of the Medical Officers of Schools Association will be held at the rooms of the Medical Society, Chandos Street, on Tuesday, January 12th, at 3 p.m. Dr. G. Fletcher, medical officer of Highgate School, will read a paper on the subject of "Athletics in Public Schools." It is hoped that there may be an attendance of headmasters on the occasion, as it is very desirable to elicit their views and the results of their experience as to many of the details of this important matter.

THE deaths in the metropolis last week were 1,725 the highest figure of the present quarter, and the death-rate jumped up to 22.0 per 1,000, but, even with this rise of 250 above the record of the previous week, the total falls short of the average by 139. To infants under one year, and to those between the ages of 5 and 20, the week, as compared with its predecessor, was not a particularly fatal one; at all other ages the increase was very marked, and it became greater progressively with advancing years, so that the increase between the ages of 60 and 80 was just 100. Of the infectious diseases, whooping-cough showed a decided advance, the total number of fatal cases being 72, whilst measles and diphtheria remained tolerably stationary with 58 and 21 deaths respectively, and scarlet fever was content with a modest 10 victims.

Enteric fever caused the rather large number of 17 deaths, the average, however, being nearly 22, and, for the third time this quarter, there was no death from small-pox. Respiratory diseases carried off 503 persons, and 65 people met with a violent death. Thanks to the variability of our climate, the mean temperature was 10° higher than during the preceding week, but there were only seven hours of sunshine registered. Measles ran riot at Nottingham, Plymouth, Birmingham, and Liverpool, and its attendant satellite, whooping-cough, had a large share in the mortality at Liverpool and at Bolton. Plymouth heads the list with a general death-rate of 41.2 and a zymotic rate of 6.2, whilst Nottingham comes next with 33.8 and 5.7.

THE Report to the Clinical Society on Spina Bifida is now before us in a separate form. We have already alluded to its general excellence, and only refer to it again to approve the action of the Council in presenting a copy of the Report to everyone who, by contributing cases, by the presentation of specimens, or by other means, has assisted the Committee in the accomplishment of their task. It is but too common to issue circulars, asking for information for such Committees as this one, and to subsequently ignore those who furnish it. The presentation of a copy of a Report to those who have in any way contributed to its preparation is one of the surest methods to secure the co-operation of those who can help, and we heartily wish that the example set by the Clinical may be adopted and acted on by the other learned Societies.

IN a recent number of the *Pharmaceutical Journal*, Professor Atfield undertook the task of replying to the numerous critics who have given vent to their feelings anent the new Pharmacopœia in that journal, or elsewhere, during the last two months. Commencing with the preface, he goes through the whole volume *seriatim*, noticing even the comments on the appendix. Throughout his remarks Prof. Atfield treats his opponents with great courtesy, in many instances contenting himself with merely pointing out how widely the critics differ amongst themselves, in others showing that the matter was fully considered and the alternatives suggested rejected after due consideration, and in others again either acknowledging that the suggestion is worthy of future consideration or holding that it is immaterial which view is adopted. In conclusion, he contends that the pharmacists have really very little to complain of, seeing that for the past eighteen years every pharmaceutical discovery made by pharmacists, every improvement of processes or tests, every comment, in short, every contribution to the construction of the Pharmacopœia which has been deemed by the author worthy of publication, has been fully considered by the authorities responsible for the publication of the book, and that whenever the contribution has been considered worthy of incorporation, and it usually has been, it has been incorporated.

IN a note in a recent number, referring to the immunity that had been enjoyed from cholera at

Gibraltar, we alluded to the prevalence of other diseases there as indicative of a not altogether satisfactory sanitary state. The chief grievance appears, from another letter of the same correspondent of the *Times*, to be over-crowding. In former days this always brought its own remedy in the shape of an epidemic which reduced the numbers to a safe proportion, but of late its ill effects have not been declared quite so plainly, and the evil has continued to grow. Seventy years ago the population was under 10,000, now it is about 24,000, and the number of houses has in the same time decreased by more than one third; of course those that do exist are larger than they were then. The over-crowding tells most on the Maltese, who now infest the colony in considerable numbers, and whose habits are of the worst description, and it was amongst them that the cholera succeeded in getting a footing in Gibraltar. Prices have gone up so tremendously that no one is willing to build fresh houses, which is the only available remedy against over-crowding, and this notwithstanding that the Government have offered fifteen sites on 99 years leases. It appears probable that the present state of affairs will not be overcome until the houses are built by the Government and sub-let by them instead of by some third or fourth party.

It is stated that the Queen is about to issue a Royal Commission to enquire into the working and results of the Education Acts, and that the Commission, in the wide scope of its reference, will, amongst other matters, take into account the subject of over-pressure. Medical experience of Royal Commissions is not very encouraging, for, the more they substantiate the need for reform, the greater seems the disinclination to introduce it. They tend, too, to lessen the sense of Ministerial responsibility by shifting it on to other shoulders. But in a case, like that of educational over-pressure, where the views of the permanent officials are so obstinately opposed to the best scientific opinion, the only way of giving due effect to the latter would seem to consist in the appointment of an impartial body like a Royal Commission, to thresh out the evidence and give a decisive ruling thereon.

THE last act in the persecution to which Dr. Collie has for several months been subjected has at length been played, and the Local Government Board have grudgingly consented to the removal of his suspension and his resumption of his duties. They recognise, they say, the exceptional services which, irrespective of his office at the Homerton Asylums, he has rendered to the managers, but they contend that "he failed in matters which were of great importance to the proper administration of the establishment under his charge, and he cannot be allowed to divest himself of responsibility for the very grave abuses towards the growth of which his laxity contributed." The Board accompany their sanction of the removal of his suspension with the following conditions:—(1) That his tenure of office shall be considered probationary for six months, at the end of which time the Local Government Board request that they may be furnished with a report from

the managers as to the manner in which his duties have been discharged. (2) That it is distinctly understood that no claim for salary or allowances shall be preferred by Dr. Collie in respect of the period which has elapsed since his suspension. And, in order to deprive their act of any semblance of grace, they add that they have come to this conclusion with considerable hesitation, and they desire now to state that, if any further cause of complaint is given, it will be impossible that Dr. Collie should continue to hold the important office which he now occupies.

THE College of Physicians and the Obstetrical Society have taken exactly the same action in respect to Dr. Heywood Smith. They have resolved to censure, but not to expel him. In another column we publish the text of the reprimand which has been addressed to Dr. Smith by the President of the College of Physicians, and which we think the authorities of the College have done wisely in publishing. For it will now not only serve its own immediate purpose, but as a sort of State document will have a wide influence in crystallizing the somewhat fluid ethics of the profession, and especially of its obstetrical section, on the points with which it deals. The censure of the Obstetrical Society is to be kept hanging over Dr. Heywood Smith until the annual meeting, a delay which we think is to be regretted. We are very glad that both the Physicians and the Obstetricians have refused to be led away by the hotter-headed and more violent of their bodies, and have followed the line we suggested a short time back. We suggested it then in some fear and trembling, but we have since had the satisfaction of hearing that our remarks were widely appreciated, and we have now the singular pleasure of seeing them endorsed by what we think we may justly call the first court of medical ethics in the world.

THE close of another year involves the melancholy duty of calling the roll to see who has fallen out of the ranks during the past twelve months, and we regret to find that so many good men and true have passed over to the great majority. Some, no doubt, like the late Mr. Moncrieff Arnott, had exceeded the years usually allotted to man; others, like Buchanan Baxter, were in the very prime of life. Next in point of public standing to Mr. Arnott, who in his day had filled the highest positions in the profession, having twice been President of the College of Surgeons, and having also for a short time presided over the deliberations of the General Medical Council, come Dr. W. B. Carpenter, C.B., and Dr. W. A. Guy, both widely-known and respected in and out of the profession, though not practising members of it. Mr. John Gay, Dr. Herbert Davies, and Dr. Francis Harris had but just reached the time of life when men retire from hospital work and look forward to spending the evening of their life in well-earned, but by no means idle, rest. Sir W. Mure Muir, K.C.B., and Dr. Shepherd complete the tale of prominent Londoners who have disappeared. In the Provinces, Birmingham has had to mourn the loss of Dr. Heslop and Dr. James Russell, whilst Manchester has lost, all too soon, Dr. John

Thorburn and Dr. Morison Watson, and Liverpool Mr. Shadford Walker. Scotland is the poorer by the deaths of Dr. William Walker, and Dr. W. A. F. Browne, of Dumfries, whilst Dublin has lost two of her most distinguished ornaments in Tufnell and B. G. McDowel. On the Continent we have had to record the deaths of such world-renowned men as Henle and Frerichs, and more recently the hardly less well-known name of Robin, whilst from the north and south the deaths of Panum and Pantaleoni help to make up a list which marks 1885 as a year singularly fatal to men of the highest eminence in science.

#### A YEAR OF GOOD INTENTIONS.

THE history of the year that is passing away provides an excellent illustration of the inconvenience of summing up at stated intervals the progress of our science and profession. Science, we know, has no last words to say; each gain, final as it may seem at the time, being but the prelude and stepping-stone to fresh discoveries. But even science in the past year has been singularly inconclusive. In respect to most of the researches of the day, she is at this moment in the very middle of her sentence. And, as for the politics of medicine, uncompleted change meets us on all sides. The year has been one of restlessness and discontent. There is scarcely an institution connected with the profession of medicine that has not been threatened with reform, and in the case of some the threats have been so loud and general as to warrant the belief that they will lead to some practical result. But the past year gives us no clue towards determining whether these various movements of reform are the work of earnest and determined spirits or merely represent good intentions on the part of reckless busybodies. The movement in connection with the existing University of London is the one which has shown the nearest approach to finality—the finality of failure. There is still a sort of fifth act going on, but the climax has been passed and the general attention has been diverted elsewhere. The prospects of the Teaching University Association, which has attracted to itself the hopes once squandered on the existing University, are still in the clouds, and have not arrived at even the fluid state. The new University is as yet an airy nothing, without either local habitation or name. The questions now agitating the College of Surgeons, though important, are upon an altogether lower platform. In the case of the University question the main motive of the reformers is, we hope, a wish for the improvement of education, individual advantage being only a secondary object. In the attack on the College of Surgeons, the welfare of the College itself is only the ostensible object, the chief incentive being the more or less selfish desire for an extension of privilege. At the present moment the contest between the Council of the College of Surgeons and the Associations of Fellows and Members is more undecided than ever. The refusal of the Council to grant the demands formulated at the

October meeting has precipitated an alliance between the two Associations and led the Members to whittle down their programme to such an extent that no reasonable Fellow can now take exception to it. The fact that at the meeting last week not more than thirty Fellows at the outside could be brought to vote against the proposal of the allied Associations shows how little the Council can rely on the present privileged class for the maintenance of those privileges. The majority of Fellows begin to see that they are quite as much interested in the reform of the government of the College as the Members, and, if the two classes will only work loyally together in spite of the attempts of the Council and its self-appointed advocate, Mr. Brudenell Carter, to set them by the ears, a large measure of reform is certain to come sooner or later. This movement, indeed, already promises to pass beyond the stage of a good intention. As a result of the failure of the Medical Bill of 1885, the General Medical Council has this year entered on a new lease of life, but has shown no falling off in the excellence of its intentions or the ineptitude of some of its decisions. In the autumn it published a new edition of the "British Pharmacopœia," but, to the regret of many, declined the opportunity thereby afforded it of introducing the decimal notation into official pharmacy. The long-expected issue of the official drug-list determined the precipitation of a shower of books on materia medica, good, bad, and indifferent. The year, indeed, has been prolific in publications, some of the most important of which, however, are, like other events of the year, as yet incomplete. Amongst these we may mention the English edition of "Ziemssen's General Therapeutics" in seven volumes, four of which have been published in rapid succession; the American "System of Medicine" in five volumes, three of which have already appeared; and the American "Reference Handbook of the Medical Sciences," of which only the first of the eight volumes has yet come upon the scene. The posthumous work of the late Dr. Fagge, which we notice in another column, may, we think, be justly described as the book of the year. The medical politics of America have, during the year, eclipsed those of this country in turbulence as well as in indecisiveness. It is left to 1886 to bring together the disunited fragments of a sorely wounded profession.

Science, as we have already stated, knows no finality, but the year that is now expiring has been singularly devoid of new work as well as guiltless of much progress in the way of expanding knowledge already gained. The outbreak of cholera, which caused such terrible ravages in Spain throughout the summer months, afforded Dr. Ferrán ample scope for demonstrating the value of his much vaunted preventive inoculation, and it also afforded decisive proof of the utter worthlessness of his claims, a matter in which the true believers were already satisfied by the unscientific character of his work. Klein's report of his proceedings in India, and the discussions, official and unofficial, which have arisen out of that report, have sufficed to show that the great question of the causation of cholera must still be considered as *sub judice*, though

the opponents of Koch's doctrines have decidedly lost ground. The international sanitary conference, of which great things might have been expected, met in the early part of the summer at Rome, and after several sittings arrived at the absolutely colourless conclusion that no good was likely to result from a continuance of their labours then, but that probably a session in November would be more fruitful. But the second session has not taken place, and, for aught we know, never will.

Should M. Pasteur's treatment of hydrophobia prove that it can do all that its distinguished progenitor believes that it will do, he will undoubtedly be the scientific champion of the year, but the method is only just entering on its real trial, and no one can foretell what may be its outcome. It must, however, be remembered that, so long ago as the Copenhagen Congress, M. Pasteur was at work upon it, and had then made such progress as to justify him in speaking hopefully, if not confidently, of its results, and he has now given it to the world at a time when nothing remains to demonstrate its reliability but actual experiment on human beings. The subject has derived additional interest from the fact that at no previous time has hydrophobia been anything like so fatal in the metropolis as at the present. The report of the German Vaccination Committee has come at an opportune moment, and will, we hope, serve to reassure those weak minds which are apt to believe the blatant agitator rather than the unassuming voice of science. The tubercle bacillus has certainly made way in public estimation, and since the debate at the Royal Medical and Chirurgical Society has assumed a position which is practically unassailable and unassailed; whilst cocaine still remains our last new friend and has not suffered appreciably from the rather too lavish encomiums which were poured upon it soon after its introduction. It has even survived the crucial test of being recommended for sea-sickness, and has deservedly found a place in the new pharmacopœia, and, if practitioners will only use it fairly—take care, that is, that their solutions are freshly made—it will no doubt retain the high position it has won.

Dr. Hughes Bennett's and Mr. Godlee's case of removal of a cerebral tumour by trephining, though the operation was not actually performed during the current year, may nevertheless be claimed as one of the surgical triumphs of the year, notwithstanding the death of the patient; there can be no doubt that it has paved the way for the successful treatment of scores of similar cases. And in the matter of abdominal surgery, too, the surgeons may claim to have made distinct advances, the treatment of acute peritonitis by free incision and the removal of foreign bodies from the vermiform appendix constituting the chief additions to operative procedures that have been brought within the range of practical surgical procedure during the year.

---

#### MR. HORSLEY'S BROWN LECTURES.

THE lectures which were delivered last year before the University of London in pursuance of the bequest of Mr. Brown may be said to have centred in interest

around the subject of Myxœdema. Not only was that disease much before the profession at that time, but Mr. Horsley was able, by his strikingly original work in the region of experimental pathology, to rivet together the then scattered facts concerning the pathogenesis of myxœdema, and to bring home to our minds the close association subsisting between that disease, cretinism, and cognate states. In the lectures of this year Mr. Horsley may be said to have continued his researches upon the thyroid body and rendered more complete the evidence he last year adduced for considering that portion of the human frame not the least important among metabolic glands. The claims the thyroid gland possesses to be thus raised from comparative insignificance rest upon its supposed powers as an elaborator of mucin, and secondly of blood corpuscles. It cannot be denied that Mr. Horsley's experiments prove that the thyroid possesses in some way or another a mucinogenous function, and that in diseases affecting the thyroid tissue huge and unruly production of mucin obtains. The experimentalist, however, would travel a step further, and, in instituting a comparison between the involution of old age and the morbid involution following ablation of the thyroid, would seem to shadow forth some, at present, indefinite connection between it and the trophic co-ordination of the organic metabolism of the human frame. One very striking point in this relation is the marked effect upon the heat regulation of the body when the thyroid body is removed. In the earlier experiments, after ablation was performed, the monkeys rapidly died, that is, after a few weeks. However, when these creatures were maintained in a temperature of 90° Fahr., their life was considerably prolonged. Upon the hæmatopoietic function of the gland Mr. Horsley insists, and finds that the actual number of red corpuscles issuing from the gland is considerably more than in the entering blood.

In developing his subject, we find the Brown Professor entering upon the tortuous paths of the pathology of the central nervous system. How far his conclusions can at present be accepted it is difficult to say. The mass of experimental work spoken of in his lectures is very great, and there is no doubt that the extreme care which was taken to avoid indefinite spreading of a traumatic lesion, such as must occur when antiseptics is not actually obtained and inflammation is produced, invests Mr. Horsley's results with especial value. Much of Schiff's work and Schiff's results are called in question. Thus, Schiff (we are quoting the lecturer) maintains that the paralysis following excision of the sigmoid gyrus is the same as that consequent upon section of the posterior column of the cord. And further, he maintains that the posterior column is concerned with the conduction of tactile sensation directly to the excitable area. Hence paresis, in his idea, is due to sensation gone wrong. The sigmoid gyrus, Schiff contends, may be excised, and so anæsthesia be established. Now this is, of course, opposed to Ferrier's well-known and carefully executed work in the same connection. Mr. Horsley has also shown that, when Schiff's well-known experiment is repeated and the utmost care taken, a

transverse myelitis always results with effusion into the central canal of the cord. As a sequence, pressure upon the motor paths occurs and a block to the transmission of motor impulses results. It is hence taken as proven that Schiff's result was due to unintentional traumatism on his part, and that neither his "ataxia" nor the anæsthesia nor paretic posture of the foot was caused by section of the posterior column of the cord.

Dealing with the questions of the fundamental rate of nervous discharges, the mode of such discharges, and the nature of the muscular contractions following upon them, Mr. Horsley enunciates views which are novel, although in a way foreshadowed by the communications already made by him and Professor Schäfer. Under certain circumstances it would appear that stimulation of the cortex produced waves upon the tetanic curve, giving, as Professor Horsley puts it, "a typical epileptiform seizure." When, however, the corona radiata is stimulated such epileptiform movements are never or rarely seen. Mr. Horsley finds that the spinal cord is excitable, but in that case the epileptiform movements are wanting. And further evidence is advanced in support of the contention that, whatever rate of stimulus be applied to the cortex, the motor cells discharge at a fundamental rate of eight per second, and that all higher rates are multiples of eight. It would be wholly impossible for us to follow in detail the elaborate arguments adduced by Mr. Horsley in dealing with this most difficult theme, or to attempt a criticism of the steps by which he arrives at his main contention that the cortical cells liberate energy at the rate of eight muscular contractions per second, and that the path of afference is along the pyramidal tract to the motor cells in the anterior cornua and thence by the motor nerves to the muscles. We think that the facts brought forward would have stood out more boldly and have been more likely to carry home conviction, had they been marshalled apart from theories, however inviting these last may be. The true and careful experimentalist can well afford to leave theory alone, and often the best work is marred by a too obvious bias in research, and a dominating idea replacing a simple logical statement of facts seen. Mr. Horsley's work has been so thorough and so earnest that one views with respect all positions advanced by him and almost regrets any departure from the most perspicuous method, especially when he is dealing with so intricate a subject as the morbid physiology of the brain.

In the course of his investigations concerning the functions subserved by the pituitary body, Mr. Horsley is led to believe that it, like the thyroid body, is largely, if not wholly, concerned with the regulation of trophic and metabolic processes. Although the experiments in which successful ablation of the pituitary body was performed were very limited in number, yet the lecturer appears confident that the uniformity in his results warrants him in saying that the pituitary body is largely concerned with the nutrition and vigour of the nervous tissue of the brain. Canine-chorea, or, as Mr. Horsley prefers to call it, disseminated sclerosis, received careful attention in the concluding lectures. The distinction which was therein shown to exist between chorea, as it is revealed in the man and in the dog, deserves careful study, as reasoning

from dog to man is in this case liable to mislead us in any attempts made to elucidate the pathogenesis of the human complaint. The seat of the nervous discharges which produce the choreiform movements is said to be the spinal cord, a conclusion strongly evidenced by the facts brought before us. And, further, the fundamental rate was found in the experiments performed to correspond with the rate of cortical discharges mentioned above. In conclusion, one is impelled to admit that Mr. Horsley, while ploughing up fresh ground, has worked with well-sharpened implements, and with the utmost care and acumen. Much of what is brought before us is so new that one needs time and further experience before giving full adhesion to conclusions, the outcome of premisses which *primâ facie* show no flaw or second interpretation. It can hardly be supposed that the conclusions are submitted as final, but rather as tentative, while further facts and experimental evidence are being collected. The value of this species of work is not easily over-estimated, especially when, as we hinted above, theory is steadily subordinated to experiment, and experiment not allowed to become the slave of theory.

---

#### THE TURN OF THE TIDE.

THERE are no actuarial tables in existence whereby the life-expectations of a medical theory may be even approximately gauged; and this uncertainty is increased tenfold in the case of the medical fashions which such theories serve to animate. The various systems, schemes, and principles which have dominated the reason of mankind in matters medical seem at first sight to have been only less remarkable for their failure in securing permanent acceptance than they are bewildering in their variety. Yet a somewhat closer examination of their nature and comparison of their claims shows that humanity has been presented with very few real differences, and reveals the same idea, returning time after time, disguised only in some slight alteration of form or treatment, assured of the same welcome, and, in due course, of the same neglect. The same obscure truths, shrouded in various errors; the same specious errors, more or less successfully impugned by truth—meet us in the theories of succeeding schools. This fact, observed from a new point of view, is hailed as a new truth, subversive of its long accepted self. That error, already recognised as such in its nakedness, reappears clothed with plausible adjuncts, and now serves to bolster up a fabric of mistakes which, thus fortified, still bars the high-road of discovery. Like the tiny streamlet at its source, young science is baffled and obstructed by trivial obstacles, of which the full flood takes no heed, and must at first meander in a devious course, often seeming to flow back upon itself, in order to make any progress at all. But, if variety fascinates the philosopher hardly less than it tickles the frivolous, it is remarkable upon what flimsy disguises variety frequently depends, and how often the same *motif* is repeated even in the music of the spheres; how, too, the very weariness and doubt begotten of long usage recoil as interest and faith. Enthusiasm for novelties and forgetfulness, the common overgrowth

of familiarity, will generally secure the ready acceptance of new lamps for old, though the source of light remains the same in both. So, as the common saying has it, the pendulum swings, and the tide alternately ebbs and flows. But those who watch these things only forget the even revolutions of the wheels of Time, and do not heed how steadily the river runs, broadening, to the ocean.

The micrococcus is a child of yesterday, and the science of pathogenic organisms is yet young. But, in the remoter districts of modern Greece, there still survive wise women who are commonly resorted to for the cure of all diseases, which depend—they say—upon the operation of various sorts of parasitic worm-like organisms which invade and prey upon the human body; which, surely, is but the germ-theory writ large. The witch in a Swazie kraal practises the cure of minor ailments according to a form of faith-healing which would not seem out of place in a Boston drawing-room. And, to take cases of a more modern type and nearer home, the world has seen the cold baths lauded by Cullen rescued from a subsequent obscurity by the enthusiastic commendation of German physicians. Alcohol, over-trusted by one generation of practitioners, has been decried by their successors, and is perhaps only now beginning to attain its rightful therapeutic rank. Even port wine claims rehabilitation, and refuses to be banned by gout. So with bleeding; so with mercury. "He who knows the healing power of herbs and plants is an ordinary man," wrote the Sanscrit sage; "he who can impart the benefit of fire is a demon; he who can exercise the force of prayer is a prophet; but he who knows the power of mercury is a God." So with countless other good (and bad) remedies "out of fashion." Men expect too much, or do too much with them, and are disappointed or hurt accordingly. The burnt child dreads the fire, and shuns it, but the cold child is again attracted by its warmth; and the wise man learns in time to value it at its true worth and to manage it as a useful servant. So the excursions of the pendulum become gradually shorter and shorter until at last it hangs motionless in the plumb-line of truth.

There is then much of hopefulness as well as a measure of disappointment for those who note the tidal ebb and flow of medical thought and practice. There are always those about us who show pretty plainly which way the stream is setting for the time. Light shallows, lately launched, perchance, and ballastless; chips and straws, loose wreckage, severed weeds—float rapidly and easily enough with the current and may make holiday progress for the while. Lucky for them if the ebb do not leave them stranded as jetsam, showing the high-water mark of an exploded theory or the extreme of some abandoned fashion. Others, again, securely anchored, sway with the stream, it may be, but do not shift their moorings, which they know are to be trusted, whatever tide may run. And still recruited by countless streamlets of investigation and discovery, their waters purified by trial and experience, the rivers of science run with ever-increasing volume into the fathomless sea of truth; where, like a huge Nilometer upon its shore, the records

of a lessening death-rate, and of longer, happier, and purer lives, show that, despite apparent ebb and flow, the sea-level is always and continuously rising. If we doubt more than our forefathers did, we probably know more thoroughly what we have learnt, and the extent of our cautious doubting is not to be taken as the measure of our assured knowledge. To recur once more to a former simile; the swing of the pendulum and the click of the escapement may serve to indicate the rate at which time is being measured; but it is only by studying the clock-face of humanity that we can ascertain how far the world has advanced towards the noon of perfect knowledge. As regards our own profession, those who are fond of satirizing "fashion in medicine" forget all that a change of fashion implies. The healthy sceptic is himself an unwitting proof of the real progress of a science whose seeming vacillations he derides.

## REVIEWS AND NOTICES OF BOOKS.

---

### FAGGE'S PRINCIPLES AND PRACTICE OF MEDICINE.<sup>1</sup>

THIS magnificent work, which cost the author twelve years of unremitting labour, and probably had much to do with his premature and deeply regretted death, is at length in the hands of the profession. For years the book has been eagerly expected in medical circles, and, now that it has actually arrived, we have no hesitation in asserting that even those who had formed the most favourable anticipations regarding it will not be disappointed. To the younger generation of practitioners hailing from Guy's it will constitute an abiding, and indeed almost living, memorial of their revered teacher, whilst those to whom was denied the privilege of instruction from his lips, as they read the concise clinical descriptions of disease in these volumes, or the learned summing up of opinions on questions of ætiology, will feel that Fagge was well worthy of the great name which he enjoyed in his school, and that he has more than maintained the traditions of that school as the home of pathology and medicine.

In accordance with a previously expressed desire on the part of the author, soon after his death, Dr. Pye-Smith was requested to undertake the publication of the work, and at once set about his task. Fortunately Dr. Fagge had completed the manuscript of the whole, except the portions on valvular diseases of the heart, on aneurysm, and on thrombosis and embolism, which have been kindly written by Dr. Wilks, and the subject of skin diseases, which had apparently not been commenced, and which has been supplied by the editor. With these exceptions, the manuscript was finished, but the labours of the editor have been by no means light, for he has had to verify all the references to authors quoted, a matter of considerable difficulty, seeing that Dr. Fagge was probably one of the greatest readers of current and ancient medical literature of his day.

In a work of this kind the manner in which the author deals with the questions of general morbid processes affords an excellent criterion of his ability to grapple with his task, and it will therefore be worth while to notice very briefly the views which the

<sup>1</sup> "The Principles and Practice of Medicine," by the late C. Hilton Fagge, M.D. 2 vols. London: J. & A. Churchill, 1885.

author holds on some of the most difficult and complicated problems of the day. But, first, certain definitions have to be laid down, such, for instance, as that of the term pathology, to which he attributes a thoroughly comprehensive meaning, and which, according to him, includes the best attainable knowledge on the origin, course, and termination of the disease, as well as mere morbid anatomy. Speaking of symptoms, he holds that the distinction between symptoms and physical signs is quite untenable; symptoms, he contends, are part of the disease to which they belong, no less than the lesion or specific cause, or whatever else is taken as its main characteristic; in Dr. Fagge's view, there can be no such thing as a symptom until the disease of which it is a symptom is discovered, and he goes on to say, "so far from hesitating to classify clinical phenomena as diseases when we are unable to trace them to their causes, I only wish that we had a more complete supply of suitable names for them." As an instance of the uncertain and arbitrary nature of the distinction between symptoms and anatomical signs, he quotes tubercle of the choroid as a case in point; some, he says, would call it a symptom, and, if so, why has not tubercle of the lung an equal right to the same term? He therefore concludes that all morbid changes, whether of structure or function, which are recognised during life, may properly be called symptoms.

Speaking of the modes of death, he rejects the so-called death from coma as always capable of being referred to one of the two main causes, viz., death by the lungs or death by the heart, and he gives a short account of the different modes of death from these, adding a third, viz., death from gradual asthenia, where the failure of the vital powers proceeds so slowly and gradually that it is impossible to assert that either the heart or lungs were the first to fail.

From these general preliminaries he passes on to ask what we understand by specific diseases, his own definition being that they are those "which have a definite cause arising from without, but acting within the body, distinct from the causes of all other diseases"; that overcrowding, starvation, or even the inhalation of sewer gases not contaminated by any specific virus, can give rise to specific disease, he stoutly denies. The reason why a person does not have a specific fever a second time he believes to be connected with the fact that the blood or tissues undergo such a change that they no longer afford, and never again afford, the requisite conditions for the development of the corresponding microzymes. The immunity which some people enjoy, he thinks, may be due to inherited protection, though he is only able to give this as an impression and not as an opinion supported by well-authenticated facts. He would fear, he says, to stamp out infectious diseases altogether, lest the consequences of their re-introduction should be terrible, and would rather rely upon protective inoculation, but we suspect that, were he now living, he would place more reliance on the muzzling of dogs than on Pasteur's inoculations as a preventive of hydrophobia. He accepts Nägeli's view that contagia are probably transferred by means of dust.

On the general subject of fever, Dr. Fagge accepts the now usually received doctrine, first propounded by Liebermeister, that pyrexia is due to a change in the normal function of heat regulation, by which the production of heat and its loss are so balanced as to create and maintain, while the pyrexia lasts, a higher temperature instead of the normal one. His views on inflammation may be very briefly given as follows: when a part is at all severely injured, the removal of the damaged tissue elements is an essential preliminary to the work of reconstructive repair; the leucocytes, he says, probably have the power of re-

moving the damaged cells or fibres. Gangrene always arises from an inflammatory process, excluding its immediate or instantaneous occurrence.

On the subject of tubercle Dr. Fagge was probably somewhat in advance of his time, and the two years that have elapsed since he wrote would not have necessitated his making any alteration on this subject, had he lived until now. "All phthisis is tubercular" is a doctrine which is much more readily accepted now than it was when he penned the words. The current ideas as to the histology of tubercle do not satisfy him; he believes that tuberculosis is a modification of the inflammatory process, so that, whereas the circumscribed irritation of a minute area of connective tissue results in forming a granulation made up mainly of leucocytes; the same kind of irritation applied to an epithelial area results in a granulation consisting of epithelial cells; the two bodies may differ completely in their histological characters, and yet the same name may rightly be given to both. Caseation, he says, may safely be set down as tuberculosis. He includes fibroid phthisis under the head of tubercular phthisis, and he explains it by stating that sometimes tubercles, instead of undergoing the caseous change, become fibroid. As to the mode of production of tubercular processes, he says that the cases attributable to infection from non-tubercular lesions are so scarce that it is impossible to attach any importance to them, and his theory of the origin of tubercle is that under certain unknown conditions the occurrence of what is at first a simple inflammatory process may cause microzymes already existing in the body to acquire specific properties which they did not previously possess, and convert the simple into a tuberculous inflammation.

On the subject of new growths he argues that the histological characters indicate the true relations of tumours, and are fundamental characters in their case, but he admits that in the case of tubercle he had expressed an opposite opinion. In the hereditary propagation of cancer he declares himself unable to see more than a part of a widely-spread diffusion of new growths of various kinds in certain families rather than in others. The possibility that micro-organisms might play any part in the origin of cancers or sarcomas had not even been broached when the author was at work on this part of his book, and it is still true, as it was then, that no one has yet explained how a fragment of tissue after lying dormant so many years can produce a sarcoma or cancer. The chapters devoted to the infectious diseases are admirable, but the subject does not admit of so much originality of handling as do other portions of the work.

The descriptions of the various diseases of the nervous system are throughout excellent, and we would especially call attention to the chapters on peripheral paralysis and on cerebral hæmorrhage as presenting the subject in a more comprehensive manner than has been achieved by any previous writer. Here and there are just a few points on which we should hardly be prepared to agree with him; for instance, he recommends calabar bean in the treatment of spastic paraplegia; but in the cases which Dr. Gee recorded, and to which he refers, this drug was administered without any benefit. In the treatment of infantile paralysis he says that shampooing and friction with stimulating liniments may sometimes be of service; whereas we should say that they formed an essential part of the treatment of such cases. Nor were we quite prepared for the statement that progressive muscular atrophy in its most typical form is sometimes really the result of chronic plumbism; we should be more inclined to think, in any case in which this appeared to be the case, that we had to do with a coincidence. Dr. Fagge strongly inclines to the belief that pseudo-hypertrophic paralysis owns a central origin, notwithstanding the

complete failure hitherto to demonstrate any disease in the central nervous system, and he quotes Charcot at some length on the subject of joint affections in locomotor ataxy, but expresses no opinion himself on this recently much debated point. We have been unable to find any account of ophthalmoplegia interna or externa, which is the more remarkable as Dr. Fagge has elsewhere shown himself quite familiar with the writings of Mr. Hutchinson.

The subject of diseases of the respiratory system, with which the first volume concludes, gives Dr. Fagge the opportunity of expressing his views on the difficult question of the nature of membranous croup. It will be remembered that he was one of the committee appointed some years ago by the Royal Medical and Chirurgical Society to consider the relationship between membranous croup and diphtheria, and that in an appendix of his own cases to the Report of that Committee he foreshadowed his misgivings as to their identity. He has now thrown all doubt aside and arrived at the opinion that there may be a simple non-specific membranous laryngitis due to cold, and that, even if membrane should appear on the fauces in such a case, the disease is not necessarily diphtheria, though how we are to distinguish between diphtheritic and non-diphtheritic laryngitis we are nowhere told. Nor can we quite reconcile this view with the statement he makes, when speaking of diphtheria, that it would be natural to expect that in a case of diphtheria, when the disease spread to the larynx, the symptoms, apart from the mechanical difficulties superadded, would not be very grave; that is, that we are not to look for marked blood-poisoning in laryngeal diphtheria. Dr. Fagge does not look with much favour on the view that pneumonia is an infective disease, but the evidence on this point has probably increased considerably since he wrote. As we have already said, he regards all phthisis as tubercular, and fully accepts the doctrines resulting from Koch's discovery. He is very sceptical as to the bronchiectatic origin of cavities in the lungs, because he has never been able to see the process in an early stage. On the subject of the inheritance of phthisis he says that family predisposition means little more than vulnerability, and he holds that the consumptive tendency, however strong, could be kept in abeyance by vigorous hygienic measures.

And, here, circumstances to which it is unnecessary to allude compel us to take farewell of this most important work without even mentioning the contents of the second volume. It will doubtless be said—indeed, the editor assumes as much in his preface—that there is too much reference to Guy's Hospital in this work. We do not think so. It was part of the author's scheme to write a work based on his experience at Guy's, and it is inevitable that constant reference should be made to the case-books and *post-mortem* records of the hospital. But this work is in no sense a compilation; it is true that Dr. Fagge's reading has been most extensive, and that he has assimilated his material from a very wide field, but the book is nevertheless stamped on every page with its author's individuality in a most unmistakeable manner. We have no doubt that it will exercise a very considerable and beneficial influence on medical thought in the future, and do not hesitate to prophesy for it an immediate and lasting popularity amongst practitioners of all classes.

Dr. Pye-Smith is to be congratulated on the judicious arrangement of the subjects, for there were no indications as to the author's intentions in this respect, and the remarkably few and trivial errors which we have found testify to the care which he and Dr. Carrington have bestowed upon the proof-sheets.

### CASSELL'S CLINICAL MANUALS.<sup>1</sup>

WE have already drawn attention, in terms of commendation, to some of the foregoing volumes in this series, the object of which is to present to the practitioner and student of medicine original, concise, complete, and illustrated monographs on all the principal subjects of medicine and surgery, both general and special.

Of Mr. Owen's work on the "Surgical Diseases of Children," in the words of the preface, it may be said that, "in the endeavour to compress within an allotted number of pages an account of the entire subject of the surgery of infancy and childhood, theory has not been unduly sacrificed to practice, nor clearness to condensation." The latter point especially stands out, for in all his statements the author is clear and precise, not to say epigrammatic. Of the former point, theory, it may be said that Mr. Owen troubles his reader with very little indeed; while, as regards practice, the student will find short concise statements what to do in the various diseases discussed; very little choice is given him, the author probably relying on the means which he has himself most knowledge of, and not caring to burden the probably inexperienced reader with the responsibility of selecting. If we were disposed to be critical, we might in the first place take exception to the order, or rather the want of order, in the arrangement of the subjects, which seem to follow each other without any definite plan, either as regards nature of disease or region affected. Thus, after some introductory remarks in chapter 1, we find croup, diphtheria, and laryngitis in chapter 2, tracheotomy in chapter 3, and certain diatheses in chapter 4. Surely it would have been wiser to deal with the diatheses of childhood—the constitutional peculiarities, in other words—before speaking of such very special and comparatively rare conditions as diphtheria and tracheotomy. And this brings us to the second (and last) criticism which we venture to make, viz., that throughout the work the special peculiarities of childhood, the features which distinguish the practice of surgery among children, do not stand out with that prominence which they deserve and call for. We know how difficult it is to determine what should or should not form part of such a work as the one before us, especially when the author's space is strictly limited; notwithstanding the points we have criticised, we heartily congratulate Mr. Owen on the completion of his task.

Mr. Henry Morris' work on the surgical diseases of the kidney is one of more restricted interest than the foregoing; but for surgeons, and especially for operating surgeons, it will prove acceptable as an able exposition of the forms of renal disease in which they may legitimately interfere, in many cases with the most gratifying results. The author discusses the diseases very fully, collecting together the published cases to an extent not hitherto attempted. We regret that the purely operative details are not gone into at greater length; the whole chapter dealing with this part of the subject only occupies about eighteen pages out of a total of more than 500, while abdominal nephrectomy is disposed of in about one and a half pages, Mr. Knowsley Thorntou's experience and marvellous success not being even mentioned. Mr. Morris has not seized the unusually good opportunity, which the publication of his work afforded him, of assuring for Marchetti the credit of having been the first surgeon to perform nephrolithotomy, as recorded by Charles Bernard, formerly Surgeon to Saint Bartholomew's Hospital. On the contrary, Mr. Morris says that nephro-lithotomy "had remained a mere name until it was performed on Dr. Coupland's patient in October, 1880." It is probably quite true that "none had accepted the operation as a veritable nephro-lithotomy," although *there can now be no doubt* (as Mr. Herbert Downes showed in a learned article published in

<sup>1</sup> Clinical Manuals for Practitioners and Students of Medicine. Illustrated by original chromo-lithographs and woodcuts. Messrs. Cassell and Co., London, 1885. (1) Surgical Diseases of Children, by Edmund Owen, M.B., F.R.C.S., pp. 518. (2) Surgical Diseases of the Kidney, by Henry Morris, M.A., M.B., F.R.C.S., pp. 548. (3) Fractures and Dislocations, by T. Pickering Pick, F.R.C.S., pp. 524.

these columns in the early part of the present year) that Marchetti anticipated Mr. Morris by upwards of 200 years in cutting into and removing a calculus from a kidney "not dilated into a tumour or perforated by a fistula." The opportunity of authoritatively vindicating Marchetti's priority is thus lost, and Mr. Morris' work is by that much deficient in historical detail and scientific accuracy. The work will prove useful to all who are interested in renal surgery.

Mr. Pick's work on "Fractures and Dislocations" will appeal to almost every practitioner as dealing with a class of cases of general interest, which occur with considerable frequency. The work is illustrated with numerous woodcuts, many of them copies from antecedent works on the same subject. Some are of secondary interest, such, for instance, as those representing reduction of the dislocated hip joint by means of pulleys. It is very improbable that in these days of chloroform and manipulation pulleys will be wanted by "practitioners and students of medicine." On the other hand, a few anatomical diagrams, representing muscles and ligaments "after" Gray, would probably have been highly appreciated by the readers. Hamilton's work is no doubt so popular partly on this account; it is graphic as well as accurate in the text. Mr. Pick's descriptions are clear and to the point, and the work cannot fail to become popular among those to whom it is addressed.

*Vital Statistics. Selections from the writings of the late Wm. Farr, M.D., D.C.L., C.B., F.R.S.;* edited for the Sanitary Institute by NOEL HUMPHREYS and published by E. Stanford. London: 1885. Large 8vo., pp. 563.—All who take an interest in the health and wealth of the people will hail the appearance of this volume, containing in a small compass and admirably arranged most that is of permanent value in the scattered writings of Dr. Farr, his official reports, papers in the Transactions of the Statistical Society, &c. Though Graunt and Petty, Halley and Neumann, Steuart, Godwin and others, may justly be described as the fathers of Vital Statistics, and did good work with the very imperfect materials at their command, the honour of raising the study to the rank of an exact science belongs to Dr. Farr, who, a born mathematician, though almost self-educated, and endowed with indomitable perseverance and hopefulness, steadily evolved out of the most defective beginnings our present comparatively perfect system of registration and census reports, and trained a number of disciples, among whom is the able editor of this volume, to worthily carry on the work after his retirement. The contents are divided into six parts—I., almost complete in itself, on Population. II. Marriages. III. Births. IV. Deaths. V. Life-tables. And VI. Miscellaneous. In each of the first four divisions we have a historical account of the progress of our knowledge of the facts, a clear exposure of fallacious doctrines founded thereon, an exposition of the natural laws which govern these phenomena, and of the inferences to be drawn from them, especially the remarkable interdependence of the increase of population, or the reverse, with prosperity and the demand for men, and the insensible, but powerful, influence exerted by the production of subsistence on propagation. He refutes the fallacies of Malthusianism, and of the doctrines broached by Dr. Price, and more recently by Dr. Letheby, as to the hypothetical evils consequent on a too rapid increase of population, and the necessity for epidemics and other causes of mortality as natural checks, by showing that generally population increases or decreases as the means of subsistence, and that the law which holds good of the lower animals, who are dependent on the natural fruits of the soil, does not apply to man, the products of whose industry are always convertible by exchange into means of subsistence; that, so long as markets can be found for our manufactures, and fields are open for emigration, no fear need be entertained of over-population, the productive power of a country being directly dependent on its population, and men themselves having a money value as instruments for the creation of wealth.

The marriage-rate he calls the barometer of national prosperity, and he contends that without the intervention of epidemics or a constant slaughter of the innocents, or even enforced celibacy and so-called moral, *i.e.*, artificial, restriction of births, a redundant population would soon adjust itself to the means of subsistence by the natural postponement of marriage for a few years only, which would result from scarcity of employment. There are always, as he shows, thousands of couples ready to marry so soon as they see a prospect of a competence, and by anticipating or postponing the date of marriage by five years, *i.e.*, by making the mean age of marriage 20 or 30 years respectively, the rate of increase would at once be doubled or halved as the case might be; not only would the population increase or decrease in consequence of the greater or less number of children which would follow each marriage, but by the shorter or longer interval which would elapse between each generation, even if the cohabitations should be equally prolific. As to the relation between a high birth-rate and a high death-rate, he shows that, though the former follows the latter, the converse does not hold good; a sudden increase in the number of young children may indeed for a short time appear to affect the death-rate unfavourably, but, if continued for a number of years, it must lower it by increasing the proportion of young adults and reducing that of aged persons, whose preponderance in a population, like that of France, with few children, gives a delusive semblance of general longevity. On this question of the connection between the constitution of a population as regards age and the birth- and death-rates Dr. Farr is very clear, and, so far from laying himself open to the criticisms of Dr. Rumsey, nearly all the sources of fallacy insisted on by the latter are plainly indicated in this work. Dr. Farr, too, shows that on account of immigration the mortality of towns is really higher than would appear from the death-rate; and that, as we have repeatedly urged, all estimates of infant mortality, whether on the population or the total deaths, are absolutely useless, the only rational basis for calculating the deaths at any age being the number living at that age, which for infants is equivalent to the births.

His history of each epidemic of cholera in this country will be found useful for reference, compiled as it is from documents now out of print and otherwise inaccessible. The part dealing with life-tables is, like everything else in the book, full of wisdom and instruction, but of less purely medico-sanitary interest. Should another edition be called for, as we trust it will, of a work which must ever remain classic, we would suggest that the editor should add the actual date to the expression 4th, 19th, and annual reports, which, like the legal reckoning by the years of the reigning sovereign, necessitate a mental translation into common language. There is one statement in the life of Dr. Farr which must be a slip of the pen or a printer's error. He is said to have attended in 1832 "the lectures of Grant, Carswill (*sic*), Jenner, Elliotson, and others." Probably *Liston's* name should be substituted for Jenner's. Carswill should be Carswell, and elsewhere Dr. Brittan's name is spelt Brittain, and once Parkes' is written Parko's.

*The General Pathology of Infective Diseases;* by Prof. S. STRICKER. Vienna: Alfred Hölder, 1886.—This important work opens with an elementary introduction containing the definitions of the different pathological terms. These definitions are given in exact and philosophical language, as, for instance, the differences between normal and abnormal appearances, the differences between normal and pathological processes, and the definition of the class "disease." After having spoken of the disposition to disease, and of the different characters of the disposition, the author arrives at the chief part of the book, *viz.*, at the doctrine of the infective diseases. The discussion on tuberculosis, which forms one of the most interesting chapters in the book, is divided into three parts, one treating of the history of the affection, the second of tubercle-bacillus, and the third of the infectiveness of tubercle. The author is of opinion that tubercle bacilli have not hitherto been proved to be genuinely infective; he refers to several experimental and clinical data which show that

the virulence of the bacilli, in the sense that the inoculation of tubercle-bacilli on healthy individuals who were affected with a tubercular disposition caused general tuberculosis, has not yet been proved. He further declares that tuberculosis has not yet been proved to be contagious. He first refers to historical data, stating that neither Hippocrates nor the great clinical physicians of modern times considered phthisis a contagious disease. As far as he remembers, neither Skoda nor Oppolzer taught that phthisis was contagious. The idea of the contagiousness of tuberculosis arose in the laboratories, and even Buhl, who was the first physician to accept this idea, did not state that he had met with any observations in support of it in his practice. Prof. Stricker, speaking of the value to be attributed to the evidence of transmission of phthisis from husband to wife, or *vice versa*, says:—It is a generally known fact that phthisis usually begins to flourish after puberty, at about the twentieth year of age. Now, in the female sex this age coincides in our climate with the time of marriage, and this in a considerable proportion of females. Whether the coincidence is accidental, or whether the activity of the sexual functions, pregnancy and lactation are conditions which favour phthisis, is a question yet to be decided. Hence those rare cases which seem to point to contagion may be equally well explained in another way, viz., the wife, who falls ill after marriage, might equally have fallen ill when living with a healthy husband, because, having a disposition to phthisis, the new functional activity gave her an increased tendency to acquire such an inflammation of the lungs as was likely to result in a caseous and tubercular process. The author further says, when we consider what an immense number of persons affected with phthisis have been accurately observed since Auenbrugger and Laënnec, since the invention of percussion and the auscultation; when we remember how freely physicians expose themselves to the exhalations of the sick, how nurses occupy themselves with them, and how constantly students of medicine, who, as we all know, are very liable to infectious disease, and practitioners, come into constant relation with the subjects of phthisis—it is difficult to understand how it should have escaped our great clinical teachers that tubercle is contagious—if in truth it be contagious. The book, on the whole, is most readable, instructive, and interesting, and it may be confidently recommended to the medical reader.

*Von Ziemssen's Handbook of General Therapeutics*, Vol. iv. *The Treatment of Disease by Climate*; by Dr. HERMANN WEBER. *General Balneotherapeutics*; by Prof. OTTO LEICHTENSTERN. London: Smith, Elder, & Co., 1885.—As we only received this volume a day or two ago, and this is our only opportunity of noticing it, we cannot pretend to do it justice. Of all the volumes of the Handbook, this is the volume that will probably be most popular, partly owing to the deservedly great reputation of Dr. Weber in this country, and partly to the intrinsic interest and importance of the subjects treated therein. We have already several good works on Climate in our language, but we think that Dr. Weber's monograph is likely to take the first place, and to be regarded as the standard work on the subject until the rapid growth of the science of climatology renders it old-fashioned. The elements or factors of climatology are treated in a most thorough, exact, and scientific manner in the first chapter, and in the second we have a very complete and, as far as we have been able to test it, impartial account of the various health resorts. The third chapter is the most important of all, giving, as it does, Dr. Weber's mature views on the indications for treatment by climate in different diseased states. The fourth and last chapter is a short one, containing hints on home climatic treatment. It is, we think, to be regretted that Dr. Weber has not followed the example of most of his collaborators in giving a list of his authorities. The translator of this part of the present volume is Dr. Henrich Port, and he appears to have done his work excellently well, which is more than we can say for Inspector-General Macpherson, the translator of Dr. Leichtenstern's article.

Dr. Macpherson's English is such as a schoolboy ought to be ashamed of. One instance will suffice to illustrate his idea of the duty of a faithful translator, viz., he translates Kochsalz, culinary salt, so that when one comes across the heading "Culinary Salt Drinking Cures" one has to retranslate it into German before one catches the author's meaning. We fear that this unfortunate inefficiency on the part of the translator will prevent Dr. Leichtenstern's article from receiving that amount of attention which it deserves. It is very thorough and very German, and contains a large amount of information on the subject with which it deals, but it does not appear to be of the same rank of article as its fellow, the excellent essay of Dr. Weber.

*Student's Atlas of Bones and Ligaments*; by C. W. CATHCART, M.D., M.B., F.R.C.S. Eng. and Edin.: and F. M. CAIRD, M.B. London and Edinburgh: W. and A. K. Johnston, 1885, fol.—This atlas consists of 30 plates and the necessary letter-press explanation. The representations of the individual bones are somewhat larger than those in Holden's well-known Osteology; the origins and insertions of the muscles being marked in the manner which Holden was the first to introduce. Of these we can say that they are accurate and clearly marked out. The explanatory text has been written, so the authors say, "to help the student to understand the plate, rather than to explain fully all that it illustrates. This would have necessitated writing an additional treatise on the bones and ligaments, which is not the purpose of the present work." The plates dealing with the ligaments are not quite as well done in our estimation: and students, if we mistake not, will fail to grasp the subject without considerable help from dissected preparations. The work is exceedingly well published. We question, however, whether the folio form is the one best adapted for students' use—such works are ill-suited for dissecting-room purposes. With one or two unimportant exceptions, the illustrations could have been arranged on an octavo page, and the large margins of the present volume could then have been utilised for letter-press. We think also that the model student's book should be complete in itself, and should deal fully with the subject-matter. Our present atlas is hardly good enough to dispense with the bones themselves, still less with the dissected ligaments, while the descriptive portion has been purposely curtailed. The practitioner who has once thoroughly mastered all these details will find the work handy to refer to in the case of fractures, or dislocations; but we think English students, at least, will prefer their "Gray" or their "Holden" to the present work, if for no other reason, on account of their more handy size.

*A Text-Book of Medical Physics for the use of Students and Practitioners of Medicine*; by JOHN C. DRAPER, M.D., LL.D. London: J. & A. Churchill, 1885.—This excellent text-book contains the substance of the lectures delivered by Professor Draper in the medical department of the University of the City of New York. It therefore escapes the besetting sin of most teachers of physics, who always assume in their pupils a considerable familiarity with mathematics. There can be no doubt that, if physics is to be taught successfully to medical students, it must be taught from the experimental and not from the mathematical standpoint. For our part, we believe that a short laboratory course of physics would prove as interesting to the intending medical student as it would undoubtedly be useful; and in time we hope that such a course will be obtainable at every good school. For those who have not and cannot have this advantage we can cordially recommend Professor Draper's text-book as far and away the best work on the subject for the purposes of the medical student or practitioner. Everything is treated from the practical standpoint, and, though the student may find some difficulty in grasping the facts of physics without practical work at it, we have no hesitation in saying that Dr. Draper's book will be of the greatest use to him. The chapters on optics and on the construction of the microscope are especially excellent.

*The Mother's Manual of Children's Diseases*; by CHARLES WEST, M.D. London: Longmans & Co., 1885. This manual is intended to give in a small compass, and without any technical detail, such an account of the diseases of infancy and childhood as will help an intelligent mother to understand something of their nature and symptoms; it will save her from all needless anxiety as to their issue, and enable her to second the doctor in his endeavours for their cure. Dr. West is not one of those who think that children's diseases can be treated without the aid of the medical man, and he especially draws attention to the fact that his book is not intended as a handbook for the nursery, while bearing testimony to the excellence of the many such manuals which already exist. We can best commend this work by saying that it is written with the same care and in the same style as his well-known treatise, and it is equally well adapted, as regards subject-matter, to the class to whom it is specially addressed. The work should be studied diligently by all young mothers; they will find a fund of information of the greatest value, such as will help them to understand the laws of health and to appreciate those departures therefrom which constitute the beginnings of disease in their children.

*A Text-book of Operative Surgery and Surgical Anatomy*; by A. T. NORTON, F.R.C.S., based on the original work of Professors Claude Bernard and Ch. Huette. 2nd edition. London: Bailliere, Tindall, and Cox.—The second edition of a book so well known to operating surgeons as the above needs but a short notice. The profusion, the artistic character, and the general accuracy of its illustrations, most of them coloured steel engravings, render it almost unique as a medical work. Since its first production many important changes have been introduced in operative surgery, and it is necessarily difficult to represent these changes in plates, the original cost of which must have been prodigious. Mr. Norton has done his best to bring the letterpress up to date, and he gives an excellent account of those operations on the kidney which constitute perhaps the most important of recent advances in operative surgery. But the chapter suffers in comparison with others from want of illustration, and we wish that the publishers could have seen their way to introducing a special plate in explanation of a series of operations admittedly difficult. The same criticism applies to other novelties described in the letterpress, but on the whole the work is a most valuable one both to the operator and to the candidate for the higher surgical examinations.

*The Insane in the United States and Canada*; by D. HACK TUKE, M.D. London: H. K. Lewis, 1885.—In this little volume Dr. Tuke records the impressions received during a visit to North America last year, when he had many opportunities for familiarizing himself with the management of the insane, both in the States and in Canada. Dr. Tuke has the merit of being able to see things and to write about them with perfect impartiality; and we accordingly find the various points in which they manage on the other side of the water these things better or worse than ourselves each recorded with an evident freedom from exaggeration. Asylums are conducted on the same principles over there as they are here, though in a few in Canada restraint was used more frequently than we should consider necessary. Those who are anxious to reform our present procedure in regard to the admission of lunatics will find in America every variety, from the mere statement by a medical man to the effect that So-and-so is insane to public trial before a jury of six. Altogether it is a pleasantly written book, and should be read by all who are concerned in the welfare of the insane.

*Insanity; Modern Views as to its Nature and Treatment*; by W. T. GAIRDNER, M.D., I.L.D. Glasgow: Maclehose, 1885. This pamphlet contains an address delivered at Glasgow in the spring, together with some interesting notes.

We have not space to enter into the many important points raised in it, but we cordially recommend it to the perusal of the reader as a most suggestive and scholarly essay.

*Manuel de Technique des Autopsies*; par BOURNEVILLE et BRICON. Paris: Librairie du Progrès Médical, 1885. The authors have divided their work into two portions—the first, dealing with the historical, public, and official aspects of the subject, so to speak; the second, with the technical details of a *post-mortem* examination. The latter, which is most systematic and minute, though due attention has been paid to conciseness, ends up with a chapter on the mode of hardening specimens for microscopical work. It is an extraordinary thing that no one has taken the trouble to write a guide for the *post-mortem* table in this country.

*Chemistry, General Medical and Pharmaceutical*; by JOHN ATTFIELD, F.R.S. Eleventh edition. London: Van Voorst, 1885. This popular text-book has been rendered, by the addition of a chapter on organic chemistry, a complete and reliable manual for the medical student. The reputation of the author, both as a scientific worker and teacher, is a guarantee for the accuracy and appropriate arrangement of his facts. The book has a singularly copious index, which renders it admirably adapted for a place in the practitioner's reference library.

*Illustrations of Unconscious Memory in Disease, including a Theory of Alteratives*; by CHARLES CREIGHTON, M.D. London: H. K. Lewis, 1886. This is a thoughtful and suggestive essay which, if it does not tell us anything very new, yet invites us to view old friends in a somewhat new aspect. Dr. Creighton has done good service in reminding us of the many uses of alteratives in treatment, a class of remedies which in these days of minute physiological treatment have been far too much neglected.

## ABSTRACTS AND EXTRACTS.

AFFECTIONS OF THE PAROTID FOLLOWING OPERATIONS ON THE FEMALE GENITALS.—At the late meeting of the American Gynecological Society, Dr. Goodell (*Philadelphia Medical Times*, October 3rd) read a paper on "Inflammation of the Parotid Glands following Operations on the Female Genital Organs," in which he referred to the close relation which is known to exist between the salivary glands and the genital organs in the adult. He had seen the parotid suppurate after a posterior incision of the neck of the uterus, and had met with parotid bubo once in 153 ovariectomies, this occurring in a woman who had died on the 22nd day, and who was at the time of the operation suffering from septic poisoning, following tapping of the cyst. He had also met with three cases in which there was transference to the parotid gland, in which there were no symptoms of septic poisoning. Two of these cases followed ovariectomy, and one oophorectomy. None of these terminated fatally, and the speaker regarded the affection as sympathetic rather than symptomatic. In the discussion, Dr. Sutton referred to a case in which one gland after the other began to swell during convalescence after ovariectomy, the patient dying during the third week. Dr. Johnson reported a case of swelling of both parotids after ovariectomy, which terminated fatally on the ninth day; and Dr. Mann related three cases. One of these terminated fatally after ovariectomy with septic symptoms, and another recovered after ovariectomy; the third, after a penetrating wound of the abdomen, recovering. Dr. Emmet had met with two cases, once after operation for lacerated cervix, with recovery, and once after operation for a small vesico-vaginal fistula, which ended fatally. Dr. Baker reported a fatal case of suppuration after Tait's operation; and Dr. Reamy described two cases, one fatal, after Tait's operation, and one with recovery after hysterectomy.

**VOMITING OF PREGNANCY.**—Dr. Chadwick finds that in cases of moderate vomiting in pregnancy, chewing of spruce gum gives relief. He thinks also that in these cases patients often go too long without food because of the nausea it occasions. A late supper is often successful.—*Cincinnati Lancet*.

**HÆMORRHAGES INTO THE SUBSTANCE OF THE BRAIN IN WHOOPING COUGH.**—A case of this description is recorded in the *Progrès Médical*, No 41, by M. Fernand Vidal. The patient in question was a child five years old, who died of whooping cough; during the last two days of her life she suffered from epileptiform convulsions. On examination of the brain the grey matter was everywhere found congested, but the white matter was perforated with small hæmorrhagic clots varying in size from a pin's head to a grain of wheat. In the occipital lobe they were especially numerous, being arranged in clusters, and they were met with in the white substance of the cerebellum medulla and spinal cord. Microscopically each clot was found to have in its centre a capillary blood vessel, the lymph sheath round it being distended with blood which had extravasated into the surrounding brain tissue. There were thus the dissecting aneurysms which have been described by Cornil and Ranvier. M. Vidal is unable to decide whether to attribute the cerebral condition to mechanical causes or to the fact, which he says is well known, that the infectious diseases often determine the formation of miliary aneurysms with consecutive hæmorrhages.

**PERMANENT ANÆSTHESIA FROM DIVISION OF A NERVE FOR NEURALGIA.**—In a case of severe headache following a blow on the forehead, Professor Wurfbain divided the supra-orbital nerve some months ago subcutaneously with a fine tenotomy knife, and since then sensation has been entirely lost over a surface equal to the breadth of the hand above the seat of division. The headache was almost cured.

## REPORTS OF SOCIETIES.

### EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, DECEMBER 9TH, 1885.

WALTER DICKSON, R.N., M.D., President, in the Chair.

DR. E. J. EDWARDS read a paper on the Report of the German Vaccination Commission. This Commission was appointed by the German Government to make a physiological and pathological enquiry into the present aspect of vaccination, especially as regards any attendant evils, to frame rules for the general introduction of animal vaccine lymph into general use in public vaccinations, to draw up a scheme for the institution of an effective supervision of public vaccination, and to arrange for Imperial statistics of the small-pox mortality. The Commissioners' conclusions on the present status of the vaccination question, viewed physiologically and pathologically, were answers to eight questions propounded by the Imperial Board of Health. They are as follows:—

- (1) With rare exceptions, one survived attack of small-pox confers immunity against future attacks.
- (2) Vaccination exerts a similar protection.
- (3) The duration of the protection afforded by vaccination varies within wide limits, but is about ten years on the average.
- (4) At least two well-developed vesicles are necessary to ensure efficient protection.
- (5) Re-vaccination is necessary ten years after primary vaccination.
- (6) A well-vaccinated condition of the *community* increases the relative protection which the *individual* has acquired against small-pox, and thus vaccination is not only individually, but generally, useful against small-pox.
- (7) Vaccination may under certain circumstances be injurious to the health. In the case of human lymph, the danger of transferring

syphilis, although extremely slight, cannot be entirely excluded. Any other injurious effects are apparently due only to accidental wound diseases. All these dangers may, by precautions in the performance of vaccination, be reduced to such a minimum that the benefits of vaccination infinitely outweigh any possible injurious effects.

(8) Since the introduction of vaccination no scientifically proveable increase of any special disease or of the general mortality has occurred, such as might be regarded as a consequence of vaccination. The statistics brought forward by the Imperial Board of Health to show the effect of the law of 1814, introducing compulsory re-vaccination throughout Germany at the age of twelve, have been already published. Other valuable statistics were now produced, in particular the Bavarian statistics of Dr. von Kerchensteiner, the Leipzig statistics of Dr. Siegel, and the elaborate army statistics of Dr. Grossheim. In the last case accurate particulars were known as to 1,005 small-pox cases, with 61 deaths amongst them. Of these 1,005—

	Deaths.	Mortality per cent.
4 = not vaccinated ;	with 1	= 25
109 = successfully re-vaccinated ;	with 2	= 1.8
224 = unsuccessfully ,, ;	with 10	= 4.5
531 = not re-vaccinated ;	with 46	= 8.6
In 130 = result of re-vaccination unknown ;	with 1	= 0.7
In 7 = ,, ,, ,, doubtful ;	with 0.	

The whole number of cases in the German field army during the epidemic of 1870-1 was 4,991, with only 297 deaths = nearly 6 per cent. of the cases.

Whether the number of cases in the French army, given by some French writers, was absolutely correct or not, it was impossible to say. That number for the field army was 23,439. But in the Paris army alone, numbering 170,000, the cases were 11,500, and the deaths 1,600 (nearly 14 per cent.). Again, the French prisoners in Germany were 372,918, the small-pox cases 14,178, the deaths 1,963, *i.e.*, over 13 per cent., while the immobilized German army, on the other hand, numbered 300,424, the small-pox cases 3,472, and the deaths only 162, *i.e.*, 4.6 per cent. This was a striking instance of the protective power of vaccination, for Dr. Grossheim amply proved that the French army was far less thoroughly vaccinated than the German. The following were the conclusions of the Commission upon animal lymph:—

(1) Since the dangers to health and life (vaccination syphilis, vaccination erysipelas, &c.), occasionally connected with the use of human lymph can be avoided by the use of animal lymph so far as any direct transference of syphilis or of accidental wound-diseases is concerned, and since vaccination with animal lymph has been recently so perfected that it may now altogether supersede the use of human lymph, the latter is to be replaced by animal lymph.

(2) This is to be effected gradually, and (by the help of experience already gained) institutions are to be established for the provision of sufficient supplies of animal lymph. When the supply is thus secured, public vaccinations will be performed with animal lymph exclusively.

Other conclusions followed. The arguments for and against animal lymph had been previously ably summed up in a memorandum emanating from the Imperial Board of Health. On the side of human lymph were: certainty of effect, simplicity of operation, and costlessness; while against it were the proved dangers of imparting syphilis and erysipelas, the theoretical possibility of imparting tuberculosis, and lastly the occasional difficulty of obtaining it. The advantages of animal lymph were: security against syphilis, the advantages connected with large supplies (*viz.*, uniformity of character and subjection to test-inoculation), simplification of the public vaccinator's work, and lastly, the advantage of obtaining it under antiseptic precautions, to the certain exclusion of "early erysipelas." Its only disadvantages were a somewhat less certainty of direct effect, a slightly more complicated operation in using it, and lastly its cost. But Koch

maintained that compulsory vaccination could only be justified by their making it as absolutely safe as possible. It had been conclusively proved that syphilis could not be communicated to animals. Dr. Edwardes said that one point seemed to have escaped the notice of the Commission. If it was a fact, as stated, that the syphilitic virus could not subsist outside the human body, except for a short time, certainly not more than a few days, then human lymph was as safe as calf lymph, if only arm to arm vaccination were done away with. The use of charged points or capillary tubes should be imperative in every case. But for this again the supply would never be sufficient, so that, after all, animal lymph was the only effective solution of the problem. The report teemed with valuable information.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 2ND, 1885.

J. B. POTTER, M.D., F.R.C.P., President, in the Chair

### *Case of Protracted Pregnancy.*

DR. ARNOLD THOMPSON (Amphill) read the following case:—The patient was a delicate woman, not long married, who had had a miscarriage previously, occasioned by a shock. After this menstruation recurred, and the last period ended June, 1884. Her husband left home a week after, and returned on Monday, June 16th, for one night only, on which coitus took place. He left home the next morning, and was away for four months. Soon after the husband's departure signs of pregnancy appeared. Delivery took place April 13th, 1885, 317 days after the end of the last menstruation, or 301 days from the last coitus. The dates were absolutely certain. The child was not weighed or measured; it was a female, and appeared of full average size and weight. According to Prussian law, the child would be legitimate; according to Scottish law and the French code it would be illegitimate; in England its legitimacy would be determined by circumstances.

DR. GRAILY HEWITT enquired whether anything was known as to the duration of the menstrual interval in this case. The late Dr. Tyler Smith was of opinion that a relation subsisted between the duration of pregnancy and the menstrual interval. In Casper's work it was stated that Cederschjold had observed cases of excessive prolongation of pregnancy in cases where the menstrual interval was unusually extended.

### *On the Inflammations of Lupus of the Pudendum.*

DR. MATTHEWS DUNCAN read a further paper on this subject. In this paper the peculiar inflammations occurring in the course of the disease were described, as well as the strictures which also occurred. These conditions were contrasted with such as occurred in connection with malignant disease. Their treatment was also entered upon. The histology of the disease had already been briefly described by Dr. Thin, and would be found in the reports of the October meeting of the Society.

DR. HERMAN had seen two cases of stricture of the female urethra, due to general fibrous thickening of the wall of the canal. In neither of these was there any evidence of lupus or history of any inflammation or ulceration. Dr. Flectwood Churchill, in his work on diseases of women, described under the title of "Spasmodic Stricture" two cases which seemed to him to be of the same class.

DR. MATTHEWS DUNCAN said that the subject was far from being exhausted. He entertained some hope of entering upon and laying before the Society the bibliography of the disease, its nomenclature, and, still more important, its alliances.

### *A Case of Spurious Labour.*

MR. H. ROXBURGH FULLER communicated this case. The patient, a short spare woman aged 31, became, as she sup-

posed, pregnant, for the fifth time, in 1882. She had been married over 11 years, had borne four children, and had never miscarried. Her last child was born August 31st, 1881, and she suckled it until August 3rd, 1882. On that day she noticed a pink discharge "like a birth-show," and felt the movements of a child. She at once weaned her child. She had never conceived before while suckling, and she had suffered from morning sickness since April, but did not think herself pregnant till she "quickenened." From this date the sickness ceased. On cross-examination, it was found that the sickness was irregular and occurred at any time of day; also that the catamenia, absent from the birth of the child till the "show" in August, returned naturally in September, scantily ten days later, and at irregular intervals in October and November. In December ordinary morning sickness began, and persisted till "labour" began. In December the catamenia were absent. On January 1st, 1883, "labour" began with "niggling" pains in the stomach and thighs, which continued during the second and third, but on the fourth true labour came on, the pains becoming strong, frequent, and forcing; the "waters" soon broke, and she sent to St. George's Hospital for assistance. Nine hours later the student in attendance sent for Mr. Fuller, as Resident Obstetric, reporting that the labour was making no progress, and that the patient was becoming exhausted. The patient remarked to Mr. Fuller that she thought it was a cross-birth, as she missed the pressure of the child's head. The author found all signs of advanced pregnancy absent. The pains occurred every three to five minutes, and the bearing-down forced the small cervix uteri nearly to the vaginal outlet, while at the same time urine escaped. The pains were typical of the second stage of labour. Dr. Champneys was called to the case, and diagnosed a pregnancy of six weeks, which proved to be correct. He also succeeded in convincing her that she was not pregnant, her belief in her pregnancy having been mistaken till then. Mr. Fuller remarked on the belief in pregnancy, which persisted, in the absence of all signs and of all symptoms except "foetal movements," on the occurrence of true conception during the progress of the case, which was not disturbed by the "labour." He also alluded to the two classes of spurious pregnancy: (1) in which all symptoms except foetal movements are absent, and (2) the class in which the mammary and other sympathetic signs are more or less marked. The latter class, as Harvey had pointed out, was noticed in animals.

DR. PHILIP JONES referred to a case in which a patient suffered from morning sickness with cessation of menstruation for four months and enlargement of the abdomen. At the end of the seventh month a severe attack of bronchitis occurred, and a week later the abdomen began to diminish, and at the end of three weeks all signs and symptoms of pregnancy disappeared and the menses returned.

DR. GERVIS alluded to two cases of spurious labour, in one of which an elongated cervix was mistaken by the attendant for the foot of a child; in the other the attendant had diagnosed a head presentation; the uterus was quite small, though the pains were active.

DR. CAMPBELL POPE related a case in which a patient suffered from morning sickness, felt movements, and increased in size, and had strong labour pains at supposed full term. The uterus was not enlarged. She was not anxious to have a child, and was with difficulty persuaded that she was not in labour.

DR. ROUTH said that most obstetricians had seen cases of spurious labour. He referred to two cases, in one of which the pains were regular, strong, and characteristic in locality and regularity. During the pains the uterus was nearly forced out, and the os seemed to give slightly to the finger. The pains continued for several hours. It was thought that a miscarriage might be impending, but, as no progress was made, a full dose of opium was given, and the "labour" ceased. Both patients were hysterical.

DR. HERMAN said that it was quite certain that spurious pregnancy was not simply a hysterical affection (as Dr. Routh said), for it occurred in the lower animals. The question of the labour pains which occurred was interesting, for the uterus had been seen to contract in cases treated by abdominal section, and it was reasonable to suppose that

these pains were of this nature. Cases related that evening showed that in labour-pains occurring in spurious labour there were uterine contractions.

Dr. CHAMPNEYS said that well-recorded cases of spurious labour were very rare, and Mr. Fuller's seemed to him the best yet recorded. The patient, who was the mother of several children, did not seem at all hysterical, but merely to be possessed by a false idea. An offer on his part to adopt the child if born within four months brought the pains to a standstill; he dared not name a longer time on account of the signs of early pregnancy. In this case (as in Dr. Gervis') a malpresentation, in this instance a face presentation, was diagnosed by the first attendant. He thought that evidence as to true uterine contractions must be entertained with great caution, and it must be remembered that the true uterine contractions in extra-uterine pregnancy, referred to by Dr. Herman, concerned a uterus which, if not truly pregnant, was that of a pregnant woman.

Dr. GALABIN related a case illustrative of the fact that spurious labour might be misleading to the diagnosis. In this case pregnancy seemed to have been protracted some weeks beyond term, and fetal movements were said to have ceased. There was a firm irregular abdominal tumour extending into the pelvis behind, and pushing the uterus forwards and upwards. The part behind the uterus was suspected to be the fetal head, and Dr. Braxton Hicks and he diagnosed extra-uterine gestation. The case had been sent up as one of extra-uterine gestation or missed labour. One evening labour pains came on, the vagina was relaxed, glairy secretion in quantity, the os was within reach and appeared to be slightly dilating. Exploration of the uterus found it empty. The diagnosis was thought to be rather confirmed by the spurious labour. As matters were quiescent, the patient was sent home. Three years later she returned, stating that the tumour had at first diminished, then grown. Part of it fluctuated, the sound mass behind the cervix remained. It was thought that fluid might have been effused into the gestation, &c., or that it might be complicated by ovarian tumour. Symptoms of collapse suddenly set in; he performed abdominal section and removed two unruptured ovarian tumours. Recovery followed.

The following specimens were shown:—

Dr. LEWERS—Pyo-Salpinx.

Dr. JOHN WILLIAMS—Corroding Ulcer of Uterus, with Microscopical Sections.

Dr. WALTER GRIFFITH, for Mr. STRUGNELL—Early Extra-Uterine Pregnancy.

Dr. CAMPBELL POPE—Pregnancy in Bicorned Uterus.

Dr. GALABIN, for Dr. LEWIS JONES—Double Monster.

SOCIETY OF MEDICAL OFFICERS OF  
HEALTH.

NOVEMBER 20TH, 1885.

W. H. CORFIELD, M.D., M.A., President, in the Chair.

*Koch's Cholera Bacillus.*

Dr. G. A. HERON read a paper on "Koch's Cholera Bacillus," and he and Mr. J. Moore exhibited stained and mounted specimens, under the microscope, of Koch's, Finkler's and Prior's, Flügge's or Deneke's, and Miller's bacilli: tube gelatin cultivations of all, except Miller's, and plate gelatin and potato cultures of Koch's and Finkler's. Dr. Heron began by expressing his utter inability to explain the ignorance that prevailed in this country generally as to the real facts and issues of the question after so much had been talked and written about it. The eagerness with which the statements of a single observer, unconfirmed as they were by anyone else, had been accepted as furnishing a complete refutation of Koch's arguments bespoke an amount of prejudice which he could not understand, unless it were traceable to the strong

determination in high quarters to listen to nothing which might be supposed to conflict with a commercial policy to which we were committed. He described the procedure followed in Koch's laboratory, where he had himself undergone a course of instruction in bacterioscopy, as had no fewer than fifteen hundred German medical men and a large number of foreigners, all of whom, as well as other observers of the highest authority, had over and over again verified all the essential points in Koch's position, whereas Klein, almost the only practical observer who had disputed Koch's theory, had simply evaded them. Koch maintained that in the intestines and evacuations of persons the subjects of cholera, and in water recently polluted thereby, he had detected an organism, whether we preferred to call it a bacillus or a spirillum, which he had failed to find under any circumstances elsewhere; that, in short, it was always present in cholera, and in cholera only. He, therefore, felt justified in asserting that it was the cause or part of the cause or the effect of cholera, and, in either case being invariably associated with cholera and never occurring without that disease, it had a diagnostic value which could scarcely be over-estimated. Koch did not rest his belief in the specific identity of his bacillus, on its form as seen under the microscope; he admitted that there were several, perhaps many other, bacilli morphologically indistinguishable, as Finkler's, Flügge's, and Miller's, but not one of these would stand the test of cultivation. In tubes the form assumed by the colony of Koch's bacilli was quite characteristic and totally different from that of Finkler's and Flügge's, which were by no means easily distinguished the one from the other, while Miller's had as yet refused to grow at all. On potatoes Finkler's flourished, covering the whole surface with a mouldy film visible to the naked eye, whereas Koch's could scarcely be said to vegetate, probably owing to the acid reaction. Deneke's or Flügge's bacilli were found in old cheese, and Miller's, so called after a well-known dentist in Berlin, occurred in the mouths of most persons. They were therefore of less importance, but Finkler's, like Koch's, had its home in the intestine, especially in diarrhoea and similar states. It was no answer to Koch to urge that bacteria, identical in appearance and in their behaviour towards reagents with his, had been discovered in healthy evacuations, in the mouth, and elsewhere. No one was more ready to admit this than Koch himself, but he did deny that anyone had yet found a bacillus which would stand what he, Dr. Heron, would call the triple test, for some, which grew not unlike Koch's in gelatin, could be distinguished under the microscope. There was not a sentence in Klein's report to show that he had cultivated those which he alleged to be indistinguishable from Koch's. This he must do, and his success must be publicly confirmed by others before he could be held to have proved his case. Dr. Heron then described Koch's experiments on animals, in which, after failing to induce choleraic symptoms in guinea pigs in consequence of the acidity of the chyme mass always present in the stomach, and the rapid movements of the contents of the small intestine, which was the only part of the canal where the reaction was alkaline, he had obviated the former difficulty by doses of carbonate of soda and the latter by opium, and thus succeeded in nearly every case, between thirty and forty in number, in inducing symptoms, depression of temperature, cramps, &c., and *post-mortem* appearances closely resembling those of cholera, though control animals treated with soda, laudanum, or both, were entirely unaffected, beyond dozing for half an hour, like the others, after the opiate. In short, as Dr. Heron insisted with much warmth, no one had yet disproved Koch's facts, facts which had been confirmed by hundreds of competent observers; all that his opponents had done was to assume the identity of various "comma bacilli" on the ground of morphological resemblance, which, as Koch had shown, was, taken by itself, perfectly useless, while as to experiments on animals they had failed to achieve his success because they either neglected to take precautions against the destruction of the bacilli or had performed violent operations which interfered with the result. In conclusion, Dr. Heron pointed out the practical importance of the connection, whether causative or not, between cholera and Koch's bacillus. The early cases in an epidemic, those through which it established itself in any

locality, were rarely fatal, and were indistinguishable by any known means from cases of severe summer diarrhoea, but we now knew that the bacilli in the former would be found by tube cultivations, &c., to be those of Koch, and in the latter those of Finkler, an observation by which the medical officer would be forewarned of, and forearmed against, an invasion of cholera.

In the discussion that followed the reading of the paper, Mr. MOORE remarked that it had long been known that many micrococci, &c., identical to the eye, were distinguishable by cultivation.

Professor LANKESTER urged that Koch's conclusions were open to question, that his acquaintance with bacteriology was but of recent date, that it was to the German botanists rather than to the pathologists that we owed most of our knowledge of bacteria, and that Koch had shifted his position within the last year and a half, having been at first unaware of the existence of any other commas in the human body, and having described this as a straight rod-like body when in Egypt. From what we knew of the influence of surroundings on plant life, he doubted the value of growth as evidence of specific difference, and he refused to believe that the connection of this bacillus with cholera was in any way established.

Mr. WYNTER BLYTH entirely agreed with Dr. Heron, and considered that Koch's bacillus, whether causative or not, was diagnostic of cholera, and would be of the utmost value to medical officers of health in distinguishing between those mild cases of cholera, with which epidemics mostly began, and severe cases of diarrhoea, there being hitherto absolutely no feature by which we could distinguish them. He found, however, some difficulty in understanding how so perishable an organism could be the actual cause of such results.

Dr. CORFIELD lamented the want in this country of such a laboratory as that at Berlin, where medical officers of health could, or, as he believed, were now compelled to study these subjects. He thought that all were agreed as to the evidence of specific difference between commas identical in form, afforded by their mode of growth, and maintained that all arguments based on their microscopic appearances were beside the mark. In this respect the Report and Inquiry were most unsatisfactory. Whether the bacillus were the cause of cholera or not was of no importance to medical officers of health; what really did concern them was whether it was evidence of cholera.

Dr. HERON, in reply, criticised the composition of the Commission, which contained but one or two members who had any acquaintance with bacteriology, and was chiefly composed of men pledged to certain views on ætiology and prophylaxis. Their references to "tubercular diarrhoea" and "cholera nostras," if they had any meaning, were meant to discredit Koch's statements. Dr. Heron would accept no man's evidence without independent confirmation. Koch's observations had received ample confirmation, but neither Klein's nor Emmerich's had as yet. In reply to Dr. W. Blyth, he remarked that the cholera bacillus was not so perishable as some might think, it could be easily grown in Agar-Agar for five months; indeed, some of the cultivations on the table were made from a tube which had been laid by, forgotten, for 243 days. In conclusion, he maintained that Koch's bacillus was perfectly and easily distinguished from every other known organism, and he defied anyone to prove the contrary.

SOUTH LONDON SCHOOL OF PHARMACY, 325, KENNINGTON ROAD, S.E.—The following prizes were awarded to the successful competitors at the School Examinations held from the 2nd to 5th December, 1885:—Senior Chemistry: Medal, Thomas C. Barkas. Junior Chemistry: Medal, Alfred H. Evans; Certificate, John P. Ellerington. Botany: Medal, Thomas C. Barkas; Certificate, W. R. Wheeler. Materia Medica: Medal, Albert G. Atherton; Certificate, J. Askew. Pharmacy and Dispensing: Medal, John P. Ellerington; Certificate, A. H. Evans. The Pridmore Prize (Botany) *in abeyance*. Secretary's Prize (Gold), for General Good Studentship, J. A. Nuroe.

## SPECIAL CORRESPONDENCE.

### AUSTRIA.

(By our Vienna Correspondent.)

*The Society of Physicians of Vienna — Pathological Specimens — Demonstration with Prof. Stricker's Electric Microscope.*

Vienna, December 18th, 1885.

At a recent meeting of the Society of Physicians, November 20th, Prof. Kundrat showed a very interesting specimen, viz., a false circumscribed aneurysm of the right thigh. The patient from whom it had been taken was a young man, aged 23, who had suffered from epilepsy from childhood, and who, probably during an epileptic attack, fell from a bench and broke his right femur just below the lesser trochanter. Six weeks later, a pulsating tumour was felt at the spot. This increased gradually, so that on the death of the patient, which occurred three months later from hæmorrhage, the thigh was fusiformly distended and measured nearly 30 inches in circumference. The swelling proved to be due to a false aneurysm lying under the muscles. The orifice in the posterior wall of the femoral artery, by which the artery communicated with the aneurysmal sac, lay at some distance from the point of fracture, but it could only have been caused by the point of a fragment of the fractured bone. The second specimen which Prof. Kundrat showed was taken from a man of 40, who died of pulmonary tuberculosis. At the *post-mortem* examination the left thigh presented a united fracture with a slight formation of callus, and opposite the seat of fracture were two plates of bone united with the muscles, one of them being as large as the palm of the hand, and the other smaller. The case was, no doubt, one of parostal callus which had taken its origin in the connective tissue and the adjoining muscles. The connections between the point of fracture and the parostal callus which had once been present had become loosened owing to the movements of the muscles, and thus the plates of bone had become almost free, so that at last a kind of pseudarthrosis was formed between the fractured bone and the parostal callus.

The next meeting of the Society of Physicians took place, not in the usual room, but, at the instance of Professor Stricker, in his lecture-room. Professor Stricker wished to bring under the notice of the Society the improvements and modifications introduced in the electric microscope which he showed the Society some time ago. He first drew the attention of the audience to the new method of writing kymographic curves which he had been compelled to adopt, because, owing to the enlargement of his lecture-room and the increase in the number of his students, the various kymographic diagrams could not be seen distinctly by those who sat at a distance. Chiefly encouraged by his assistant, Dr. Gärtner, he arranged the matter thus. For the paper which is moved in the kymograph by clockwork he substituted an accurately cut plate of glass, about 80 cm. in length. On this plate the curves were written in the usual way, with red ink. When the whole kymograph was placed in the focus of the electric microscope, one saw not only the sharply defined images of the table, the animal on which the experiment was being performed, &c., but also the image of the pen, and, of course, also of the curves traced by it, all doubly magnified. For many experiments this degree of magnifying was quite sufficient, the image being thrown on a gypsum-plate fixed to one of the walls of the room and visible from all parts of it.

But in those experiments in which one wished to show the pulsations of the heart this method was not sufficient when the pulse became very frequent. In these circumstances Prof. Stricker placed a large condensing lens behind the pen, by which means the pulse-curves were magnified twenty times and became easily visible to all present. At the beginning of the demonstration, Prof. Stricker showed with the electric microscope a glass-plate on which two sorts of curves were to be seen, one obtained

from the aorta, the other from the pulmonary artery; by this one was enabled to determine the different conditions of blood-pressure in the systemic and the pulmonic circulation. When the vagus was irritated in the neck, the blood-pressure in both systems diminished considerably. Prof. Stricker also showed how reflex irritation on the cessation of the respiration led to a rapid increase of the pressure in the systemic circulation, whereas this was in a much less degree the case in the pulmonic circulation. The most important part of the whole curve was its terminal portion, which showed how, when the venous blood increased, the pressure of the blood diminished in the systemic circulation, whereas it gradually increased in the pulmonic vessels, as had been first shown by Opencowski and Julius Wagner. As the blood-pressure in the aorta increased with the cessation of respiration, the left ventricle had to work against a greater resistance, and at the same time, the oxygenation of the blood diminishing for the same reason, the ventricle gradually lost the power to overcome the increased blood-pressure, and could not sufficiently discharge itself, as might be noticed on inspecting the heart. As a result of the same condition, the pulmonic vessels and the left auricle did not sufficiently discharge their blood, the resistance in the pulmonic circulation increased, and hence also the pressure in it.

The second part of the programme of the evening consisted in the demonstration of a transverse section of the spinal cord of a monkey with an immersion-lens, Hartnack, No. 15, or Seibert, No. 8, the distance of the image being 6 metres. The section was thus magnified 4,000 diameters, and all the details of the spinal cord, the transverse sections of the nerves, their axis-cylinders, and the neuroglia could be quite distinctly seen by the audience, which filled the lecture-room to overflowing. Another transverse section of the spinal cord, which had been coloured with carmine, gave images which were still more striking, each ganglion cell appearing as large as the palm of the hand. Professor Stricker next performed an electric experiment intended to show how greatly the new methods of instruction were aided by the objective microscope. The microscope was replaced by a skioptikon in which Professor Stricker had inserted an apparatus for decomposing water by the electric current. When the lens was introduced one saw on the gypsum plate two large rods, the electrodes of the apparatus, and when the electric circuit was closed one could distinctly see the development of the gas, innumerable bubbles running along the electrodes. Professor Stricker remarked that those who began to study the subject of electricity might obtain a very clear idea of it by this method of instruction, and that the quantity of electricity could in this way be weighed, as it were, before those present, as, according to Faraday's principle, the quantity of gas developed might be looked upon as a measure of the quantity of electricity produced. After performing some other experiments of the same kind, Professor Stricker showed some specimens by reflected light. One of these specimens was the ethmoidal bone, all the details of which were clearly seen. Afterwards a frog with its heart exposed was put into the electric microscope, and the pulsations were seen most admirably. One saw it becoming pale with each systole, and flushing again and filling itself with blood with each diastole. Professor Stricker remarked that the electric microscope would be found of great utility in the clinical department, as, for instance, in dermatology. Every successive demonstration of Professor Stricker's was followed by a burst of applause, and the whole was followed by enthusiastic cheering.

#### UNITED STATES.

(From Our New York Correspondent.)

*A proposed Pilgrimage to Paris—Veterinary Medicine in America.*

*New York, December 7th, 1885.*

IT was to be expected that the announcement of M. Pasteur's intervention on behalf of poor Joseph Meister, together with the fame of his supposed success in saving the lad from a

horrible death from hydrophobia by means of his elaborate system of protective inoculation, would shortly give rise to a demand on the part of the laity for the benefit of the plan in any suspicious cases of dog-bite. This expectation, it appears, is already being realized, for we read that the great Frenchman even now has on his hands a number of victims whose protection he is confidently expected to accomplish. Perhaps the most noteworthy of the occurrences thus far brought to light in this connection is the project of sending to M. Pasteur a number of children who were bitten last week in Newark, a considerable New Jersey city, not far from New York. When, several weeks ago, the newspapers began, in their blundering way, to occupy themselves with the Pasteur system, one of them professed that a member of its reporting staff had "interviewed" a well-known New York physician on the subject, and that the doctor had patted Pasteur on the back, so to speak, adding that, should he be applied to in a case of suspected infection, he would at once "cable to Pasteur for a supply of his virus." It seems never to have crossed the worthy man's mind that possibly those little dried spinal cords might prove no more obedient in his hands than the strings of a Cremona under the touch of a backwoodsman. Not so conceited is the Newark practitioner, Dr. O'Gorman, who was called upon to minister to some of the six or more little children in question. He is evidently enthusiastic over the Pasteur process, but has not the "continental" assurance to suppose himself competent to carry it out. Instead, therefore, of cabling to Paris "for virus," he wires the French *savant*, asking if he will take charge of the children in case they are sent to him. The reply comes promptly, "Yes, send them at once." The doctor then puts his hand into his pocket, brings forth fifty dollars, and proceeds to take prompt measures to induce the benevolent to add to the fund for sending the little ones to Paris. Thanks, primarily, to the doctor's enthusiasm, which has proved infectious, an ample fund has already been raised, and it is thought that the children will be sent by Wednesday's steamer—all but two of them, whose parents refuse to allow them to be sent.

It is said that the children are to be accompanied by Mr. Frank S. Billings, who has investigated the case of the dog, and stated his unqualified belief that it was suffering from rabies. As Mr. Billings is one of the ablest pathologists in the country, and beyond question its most accomplished bacteriologist, while his practical training has been that of a veterinarian, it will be seen that the gravity of the situation, as regards the children, is probably not overdrawn, and that no better observer of M. Pasteur's management of the cases could possibly have been chosen than Mr. Billings, albeit he has the reputation of being so pronounced an admirer of Koch's as to take everything French *cum grano salis*.

This mention of Mr. Billings, who, by the way, disdains the title of doctor of medicine, and, in his determination to raise veterinary medicine in this country to its proper dignity without extraneous aid, has persistently refused to take the degree of M.D., although urged to do so by no less a person than his friend Virchow, leads me to a few remarks on the position of veterinarians in America. Until quite lately, they were held in little higher esteem than farriers, and, even so recently as in the trial of Guiteau, President Garfield's assassin, the lawyers ventured to speak of them as "horse-doctors." Even now, save by a few owners of fast horses, the veterinarian is scarcely regarded by the community as having any well-founded pretension to be classed as a scientific man. In the medical profession, however, I am glad to be able to say, his status has been rectified, and the general Government, together with several of the States and at least one of the academic colleges, Cornell University, has publicly recognised the importance of veterinary medicine by appointments which are well calculated to give dignity to its practitioners. Indeed, they would soon have forced themselves into the foreground in any event. Already the services of Professor Law, of Cornell University, are widely acknowledged, and Dr. Salmon, the Government veterinarian, is generally credited with being the author of the most ingenious theory yet advanced to explain the *modus operandi* of protective inoculation. Two excellent journals of comparative

medicine are published in New York, one of them edited by Professor Liautard, and the other jointly by Mr. Billings and Dr. Conkling, of the zoological staff of the Central Park. Until lately Mr. Billings was the lecturer on pathology at the New York Polyclinic, a school for practitioners of medicine, and his appointment to that position was in itself a token of the increased appreciation of veterinary medicine felt by members of our own craft, who but a few years ago would have scorned to take instruction from a "horse-doctor." On the whole, the outlook for comparative medicine in America is at last exceedingly good.

## GENERAL CORRESPONDENCE.

### THE CORRECTIONS IN THE PHARMACOPOEIA.

[To the Editor of the Medical Times.]

SIR,—In consequence of the recent publication of numerous corrections in the "British Pharmacopœia," certain alterations have been found necessary in the new edition of "Garrod's Materia Medica." Will you kindly announce that a printed list of these can be obtained from the publishers, Messrs. Longmans and Co., or from myself?

I am, Sir, yours, &c.,  
NESTOR TIRARD, M.D.,  
Editor of "Garrod's Mat. Med."

28, Weymouth Street, Portland Place, W.  
December 22nd, 1885.

## DIARY OF THE YEAR.

### JANUARY.

- 4th.—Death of Dr. Herbert Davies.
- 5th.—Dr. Lauder Brunton's First Lettsomian Lecture on Disorders of Digestion.
- 6th.—Appointment of a Committee of Convocation of London University to consider the proposal for establishing a Teaching University.
- Annual Meeting of the Pathological Society. Dr. Bristowe, F.R.S., elected President.
- 7th.—Debate on Dr. W. A. Duncan's Paper on Extirpation of the Uterus, at the Obstetrical Society.
- 9th.—Annual Meeting of the Clinical Society. Mr. T. Bryant elected President.
- 10th.—Extraordinary Meeting of Fellows of Royal College of Surgeons in Ireland—Decision to admit Women to Examinations for the Diploma.
- 12th.—Dr. Poore's First Cantor Lecture on Climate and its Relation to Health.
- 13th.—Dr. Kidd's Paper on Tubercle Bacilli at the Royal Medical and Chirurgical Society.
- 14th.—Death of Dr. Buchanan Baxter.
- 27th.—Appointment of two Examiners in Surgery by the Society of Apothecaries.

### FEBRUARY.

- 2nd.—Sir James Paget distributes the Prizes at Netley Hospital.
- 11th.—Annual Oration at the Hunterian Society by Dr. Charlewood Turner.
- 13th.—Meeting at the Mansion House in support of the Parkes Museum.
- 14th.—Hunterian Oration at the Royal College of Surgeons by Mr. John Marshall.
- 24th.—Extraordinary Meeting of Convocation of London University on the Teaching University Question.
- 26th.—Dr. Osler's First Gulstonian Lecture on Endocarditis.

### MARCH.

- 2nd.—Annual Meeting of the Medical Society—Dr. W. M. Ord elected President.
- 6th.—Meeting of the Metropolitan Counties Branch of the British Medical Association on the Question of a University Degree for London Students.
- 7th.—Anniversary Dinner of the Medical Society.
- 10th.—Defeat of the Anti-Vivisectionists in Convocation at Oxford.
- Dr. Herman Weber's First Croonian Lecture on Phthisis.
- 14th.—Death of Professor Frerichs.
- 19th.—Sir Andrew Clarke's First Lumleian Lecture on Dry Pleurisies.
- 24th.—Debate on Cholera at the Royal Medical and Chirurgical Society.
- 26th.—New Lunacy Bill introduced into the House of Lords.
- 30th.—Sir W. Jenner re-elected President of the Royal College of Physicians.
- 31st.—Farewell Dinner to Professor Maclean at Netley.

### APRIL.

- 1st.—Volunteer Medical Staff Corps enrolled.
- 6th.—Meeting of the French Congress of Surgery in Paris.
- 8th.—Congress of the German Society for Surgery at Berlin.
- 29th.—Deputation from the Metropolitan Counties Branch of the British Medical Association to the Senate of the University of London.

### MAY.

- 3rd.—Death of Professor Panum at Copenhagen.
- Death of Dr. Pantaleoni at Rome.
- 4th.—Conference between the Teaching University Association and the Metropolitan Medical Schools.
- Professor Humphry's Oration at the Medical Society.
- Opening of a Cholera Conference in Berlin.
- 8th.—Debate on the Lunacy Act Amendment Bill at the Medico-Psychological Association.
- 12th.—Session of General Medical Council opens.
- Annual Meeting of Convocation of London University.
- 13th.—Death of Professor Henle.
- 15th.—Deputation from the Ophthalmological Society to the Local Government Board on the Prevention of Blindness from Ophthalmia Neonatorum.
- 20th.—Meeting of the Association of Fellows of the Royal College of Surgeons.
- International Sanitary Conference opened at Rome.
- 22nd.—Report of Committee on Spina Bifida presented to the Clinical Society.
- 23rd.—Session of Medical Council ends.
- 27th.—Death of Mr. J. Moncrieff Arnott, F.R.S.

### JUNE.

- 1st.—Annual Meeting of the Irish Medical Association.
- 2nd.—Death of Sir W. Mure Muir, K.C.B.
- Mr. John Wood's First Hunterian Lecture on the Radical Cure of Hernia at the Royal College of Surgeons.
- 5th.—Dr. Bristowe's Cavendish Lecture.
- 14th.—Hospital Sunday.
- 15th.—Opening of the Holloway Sanatorium.
- 17th.—Death of Dr. Heslop of Birmingham.
- 19th.—Meeting at the Mansion House in support of the Volunteer Medical Staff Corps.
- 27th.—Dr. Gairdner's Address on Medical Education at Dundee.
- Outbreak of Cholera in Spain.

### JULY.

- 1st.—Conversazione at the Royal College of Physicians.
- 2nd.—Election of Council of Royal College of Surgeons.
- 4th.—Opening of the New Buildings of the National Hospital for the Paralysed and Epileptic.
- 9th.—Mr. Savory elected President of the Royal College of Surgeons.

- 13th.—Statue of Pinel unveiled in Paris.  
 15th.—Hospital Saturday Street Collection.  
 16th.—Conference of Health Officers on Cholera Prevention.  
 22nd.—Release of Dr. Bradley by order of the Home Secretary.  
 26th.—Death of Dr. A. B. Shepherd.  
 28th.—Meeting of the British Medical Association at Cardiff.  
 Meeting of Convocation of London University—Presentation of Scheme of Reform by Lord Justice Fry.

## AUGUST.

- 1st.—Address by Professor Greenfield on Medical Education at Edinburgh.  
 4th.—Annual Meeting of the Medico-Psychological Association at Cork.  
 18th.—Dr. Goodhart's Bradshaw Lecture at the College of Physicians.  
 26th.—Medical Congress at Antwerp.

## SEPTEMBER.

- 9th.—Meeting of British Association at Aberdeen.  
 10th.—Death of Dr. W. A. Guy, F.R.S.  
 15th.—Death of Mr. John Gay, F.R.C.S.  
 22nd.—Congress of the Sanitary Institute at Leicester.

## OCTOBER.

- 1st.—Opening of the Winter Session at the English Medical Schools.  
 Death of Lord Shaftesbury, Chairman of the Board of Commissioners in Lunacy.  
 5th.—Death of Dr. James Russell of Birmingham.  
 6th.—Death of M. Chas. Robin of Paris.  
 8th.—Discussion on Dr. Matthews Duncan's paper Lupus of the Vulva at the Obstetrical Society.  
 14th.—Dr. Burdon Sanderson's address at University College Medical Society.  
 19th.—Dr. Quain's Harveian Oration at the Royal College of Physicians.  
 Dr. Ord's Address on Hyperpyrexia at the Medical Society.  
 20th.—M. Pasteur on the Cure of Hydrophobia at the Academy of Sciences, Paris.  
 24th.—First Sitting of the Dublin Hospitals Commission.  
 27th.—Opening of the Winter Session in the Scottish Universities.  
 29th.—Meeting of Fellows and Members of the Royal College of Surgeons.

## NOVEMBER.

- 2nd.—Opening of the Medical Session in Dublin.  
 Discussion on the Deep Reflexes, at the Medical Society, introduced by Dr. Gowers.  
 3rd.—Meeting of Convocation of the University of London—Rejection of Lord Justice Fry's scheme.  
 10th.—Death of Dr. W. B. Carpenter, C.B., F.R.S.  
 13th.—Dr. Hughlings Jackson's Bowman Lecture at the Ophthalmological Society.  
 17th.—Meeting of the General Medical Council.  
 Dr. Wilks' Address at the Midland Medical Society, Birmingham.  
 19th.—Dr. Buzzard's first Harveian Lecture at the Harveian Society.  
 21st.—Session of General Medical Council ends.  
 27th.—Discussion on Gastrostomy at the Clinical Society.  
 Death of Mr. Joliffe Tufnell.

## DECEMBER.

- 2nd.—Annual Meeting of Association for promoting a Teaching University in London.  
 7th.—Mr. Victor Horsley's first Brown Lecture.  
 8th.—Mr. John Wood's Bradshaw Lecture at the Royal College of Surgeons.  
 Extraordinary Meeting of Convocation of London University—Appointment of new Committee to consider the Reorganisation of the University.  
 17th.—Meeting of Fellows and Members of the Royal College of Surgeons.

## LETTERS TO UNDISTINGUISHED PERSONS.

## 5.—TO THE EDITOR OF THE MEDICAL TIMES.

SIR,—I have been pained to hear of the approaching extinction of the *Medical Times*. No man of sensibility can watch the last flicker of the taper that has cheered his loneliness, or draw the last fragrant breath of the pipe that has soothed his perturbation, without some slight tremor of regret, and I, who for years have enjoyed the sober companionship of your journal, have contemplated its last delirious splutterings with more of sorrow than of anger. I bent over its cradle, I sympathised with it in its boisterous and unruly boyhood, I was present at its marriage to its serious and gentle mate, I rejoiced in the self-contained force of its honourable manhood, and now, as I follow at its funeral, the pain with which I have witnessed the delusions and vagaries of its decrepitude is merged in grateful memories of its pure and faithful life. I see now that its mission was done, and that it was hopeless to revivify it. If audacious and heroic treatment could have done it, success would have been yours. With a light heart you remodelled its every feature, till its old friends scarcely knew it. You changed its form, its type, its price; for plain straightforward common-sense you substituted paradox and speculation and untimely jocosity; you dissected its articles so that one found one's self suddenly thrown into a crevasse midway between premisses and conclusion; and, worst sin of all, you travestied and made a common thing of that most solemn function of our lives, the consultation. You ignored this one fact, that our profession is conservative to the back-bone, inveterately conservative. Your medical reader likes to take his journal as he takes his breakfast, with one eye on the duties of the day before him. He looks to it for sustenance and utility, and not for the excitement of disturbing thoughts and unsatisfiable aspirations. Forgetting this, you peppered his sugar, salted his milk, and flung handfuls of spice over his bland and unstimulating rasher. Poor man! he knew not what to be at. All day through his peace was disturbed and his work injured by the fermenting of crude and flatulent ideas. Watch your successful rivals. See with what consummate skill they feel their reader's pulse, assess his digestive power, and gauge his emotions. He is ever in their thoughts, and how to soothe him and feed him with a sustenance suited to his strength is the one preoccupation that guides their weekly labours. Has he fads, they shall be flattered; has he prejudices, they shall be propitiated; has he appetite for facts, nay even for gossip, it shall be met. By dint of prolonged and laborious exploration they have mapped out his territory and laid down routes which must be strictly followed by all who would not lose their way therein. They have investigated his mind, and arrived at a series of inductions which every medical writer who would succeed in his calling is bound to obey. He, the journalist, may venture, on occasion, to animadvert on the College of Physicians; he may—nay, he must—abuse the College of Surgeons and the Universities; and, as for the Medical Council, he will fail in his clear duty if he empty not out the vials of his concentrated wrath on all that it says, does, and leaves undone. But you, why, you have had the hardihood to pat the Medical Council on its polyglot back, you have made excuses for the College of Surgeons and spoken well of the Physicians. On the other hand, there are matters on

which the medical journal may only roar like a sucking-dove. Remember: every corporation connected with the profession, bar one, is corrupt, but every individual in it is of the highest probity and of stainless reputation. If a man with friends amongst the mightiest commits, well, an error of judgment, he is sacrosanct, and is to be defended with all the rhetoric and sophistry of the trained special pleader. If he has no friends in high places, and is not popular even in low ones, the journalist need be at no pains to put a curb on his righteous indignation. If it gallops him into a law-court, has he not behind him the sympathy of a united profession, banded together to hound out of their ranks an unworthy member? In all these matters individual opinion of right and wrong has no logical ground for existence. It is not for the journalist to arrogate to himself the privilege of private judgment. He is there to register, not to dictate; to re-echo the voice of the profession and of its leaders, not to trouble us with his own. And now read your own conduct by the light of these simple principles. You have not done what you were expected to do; what, in fact, you were paid for doing. To use a literary expression, your whole career has been one continued *ἀπροσδόκησις*, an expedient, I may remind you, which should only be used sparingly even by the most trained judgment. You have persistently and habitually disappointed expectation, and so,—with sorrow I say it,—“Good-bye.”

SILAS PHANTOM.

## MEDICAL NEWS.

UNIVERSITY OF LONDON.—M.B. Examination.—Examination for Honours:—

Medicine:—

*First Class.*—Henry Betham Robinson (Scholarship and Gold Medal), St. Thomas's Hospital; Edward John Cave (Gold Medal), St. Bartholomew's Hospital; John Elliott, B.Sc., St. Bartholomew's Hospital; John Walter Carr, University College.

*Second Class.*—James Harry Ernest Brock, University College; Charles Joseph Arkle, University College; Arthur John Jefferson, St. Thomas's Hospital; Mary Elizabeth Pailthorpe, London School of Medicine and Royal Free Hospital; James Swain, Westminster Hospital.

*Third Class.*—Walter Pearce, B.Sc., St. Mary's Hospital; Thomas Sydney Short, King's College; William Tusting Cocking, University College; Charles Barclay Innes, St. Bartholomew's Hospital; Philip Percival Whitcombe, St. Mary's Hospital.

Obstetric Medicine:—

*First Class.*—Philip Dymock Turner (Scholarship and Gold Medal), University College; John Elliott (Gold Medal), St. Bartholomew's Hospital; Edward John Cave, St. Bartholomew's Hospital; Frank Hinds, University College; John Walter Carr, University College; James Berry, St. Bartholomew's Hospital.

*Second Class.*—William Tusting Cocking, University College; Henry Betham Robinson, St. Thomas's Hospital; Patrick Watson Williams, Bristol Medical School; James Calvert, B.A., B.Sc., St. Bartholomew's Hospital; Arthur Frederick Davenport, University of Edinburgh and University College; Arthur William Dingley, University College.

Forensic Medicine:—

*First Class.*—Ed. Wilberforce Goodall (Scholarship and Gold Medal), Guy's Hospital; Philip Percival Whitcombe (Gold Medal), St. Mary's Hospital; Henry Betham Robinson, St. Thomas's Hospital; Edward John Cave, St. Bartholomew's Hospital; Willmott Henderson Evans, B.Sc., University College; James Harry Ernest Brock, University College.

*Second Class.*—Charles Barclay Innes, St. Bartholomew's Hospital; Frank Hinds, University College; Reginald Maurice Henry Randell, Guy's Hospital; John Walter Carr, University College; James Swain, Westminster Hospital; James Calvert, St. Bartholomew's Hospital.

*Third Class.*—William Alfred Wills, Westminster Hospital; Frederick Lever, B.Sc., Guy's Hospital; George William Hill, B.Sc., St. Mary's Hospital; James Berry, St. Bartholomew's Hospital; Charles Joseph Arkle, University College; John Elliott, St. Bartholomew's Hospital.

M.D. Examination:—

George Elliott Caldwell Anderson, B.S., William Henry Bowes, B.S., Albert Martin, Charles Hartvig Louw Meyer, B.S., Maurice

Parry-Jones, B.S., Guy's Hospital; Frederick William Bennett, Manchester Royal Infirmary and Owens College; Robert Black, London Hospital; Samuel Buckley, John Hervey Jones, Ernest Septimus Reynolds, Owens College; Harry Campbell, B.S., Ernest Clarke, B.S., Bernard Rice, Tom Henry Sawtell, Thomas William Shore, B.Sc., Henry Smith, St. Bartholomew's Hospital; William Wriothesley Colborne, John Roberson Day, William Ayton Gostling, B.S., B.Sc. (Gold Medal), Frederick Knight, Arthur Hamilton Nicholson Lewers, Francis George Penrose, Thomas Wilson, B.S., University College; Rolla Edward Rouse, St. Thomas's Hospital; Robert Henry Scanes Spicer, B.Sc., St. Mary's Hospital; William Thorburn, B.S., B.Sc., Owens College and Manchester Royal Infirmary; Clement Bernard Voisey, Manchester and St. Mary's Hospital.

Logic and Psychology only:—

Charles Frederic Bailey, Joseph Langton Hower, B.S., St. Bartholomew's Hospital; Frederic Haycraft Berry, Edward Hargrave Booth, George Ryding Marsh, Guy's Hospital; Paul Frank Moline, Frederick Walker Mott, B.S., University College.

B.S. Examination:—

*First Division.*—James Berry, St. Bartholomew's Hospital; James Harry Ernest Brock, University College; John Walter Carr, University College; Alfred Edward Price, Guy's Hospital; Henry Betham Robinson, St. Thomas's Hospital; James Henry Targett, Guy's Hospital.

*Second Division.*—Rayner Derry Batten, St. Bartholomew's Hospital; Richard William Brogden, Guy's Hospital; Charles David Green, St. Thomas's Hospital; Joseph George Harsant, Guy's Hospital; Frank Hichens, London Hospital; Frank Hinds, University College; Arthur John Jefferson, St. Thomas's Hospital; Robert Jones, M.D., St. Bartholomew's Hospital; Frederick Lever, B.Sc., Guy's Hospital; Walter Pearce, B.Sc., St. Mary's Hospital; Richard Thomas Williamson, Owens College.

Examination in subjects relating to Public Health:—

Arthur Newsholme, M.D., St. Thomas's Hospital.

M.S. Examination:—

William Job Collins, M.D., B.Sc., St. Bartholomew's Hospital.

UNIVERSITY OF DUBLIN.—At the Winter Commencements held in Michaelmas Term, on Thursday, December 17th, in the Examination Hall of Trinity College, the following Degrees in Medicine and Surgery were conferred by the University *Caput* in the presence of the Senate, the Right Hon. the Earl of Rosse, K.P., Chancellor of the University, presiding:—

*Baccalauri in Chirurgiâ:* Henricus Moore Brabazon, Jacobus Craig, Guilelmus Sinclair Dobbin, Eduardus Wolfenden Gray, Henricus Johaunes Hadden, Georgius Hilliard, Henricus Freeland Kingston, Foster Reuss Newland, Robertus Glasgow Patteson, Henricus Fitzmaurice Phillips, Reginaldus Waller Studdert, Gardiner Guilelmus Trouton. *Baccalauri in Medicinâ:* Ricardus Carolus Eduardus Bolton, Henricus Moore Brabazon, Jacobus Craig, Benjamin Devonsher Dickson, Samuel Georgius Edge, Georgius Hilliard, Henricus Freeland Kingston, Ludovicus Maxwell Mackintosh, Guilelmus Vere MacMahon, Foster Reuss Newland, Robertus Glasgow Patteson, Henricus Fitzmaurice Phillips, Ross Vincent Beatty Smyth, Reginaldus Waller Studdert, Gardiner Guilelmus Trouton, Jacobus Christophorus Weir. *Doctores in Medicinâ:* Arturus Montfort Archer, Guilelmus Ambrosius Ardagh, Samuel Josiah Barton, Augustus Eduardus Dixon, Robertus Ker Johnston, Leonardus Henricus Kellett, Guilelmus Leah, Johannes Carolus Martin, Henricus Pollen, Johannes Jacobus Carl Watson.

The following Honorary Degree was also conferred:—

*Doctor in Medicinâ:* Daniel Johannes Cunningham.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, December 17th, 1885:—

Frederick William Nielsen, Nordby, Stockton-on-Tees; Alfred William Thompson, 67, Queen's Road, Aston, Birmingham; Vidal Gunson Thorpe, 46, Talfourd Road, Camberwell.

The following passed the examination in the Science and Practice of Medicine, and received Certificates to practise:—

John Arthur Rigge, M.R.C.S., The Grammar School, Grays, Essex; Robert Trimble, Hill Top, West Bromwich; Nathaniel Henry Turner, M.R.C.S., 13, Redcliffe Gardens, S.W.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners, held on the 7th December and following days, the under-named gentlemen, having passed their final examinations for the Letters Testimonial and taken the declaration, and signed the roll, were admitted Licentiates of the College, viz:—

Charles R. Battersby, Thomas M. Bellew, Pollonjs P. Bhedwar, James G. Boyce, Campbell Boyd, William R. Chambers, Harold D. Davenport, Robert Elliott, Edward J. Goode, Ignatius P. Hartford, Connell Hoyer, William A. Johnston, Richard J. Leeper, Martin B. Lyster, Patrick T. Morressy, Michael J. Ryan, Alfred T. Smith, William E. Waters, and David T. Wylie. Sixteen were stopped.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Mr. John Benjamin Story, F.R.C.S.I., has been elected after a sharp contest of votes to serve on the Council of the College in room of the late Mr. Jolliffe Tufnell, F.R.C.S.I.

CORRIGENDUM.—In the pass list for Degrees in Medicine and Surgery of the University of Dublin, published last week, the name of "G. W. Trouton" should be the eighth in order of merit, instead of seventeenth, as printed.

THE ROYAL COLLEGE OF PHYSICIANS AND DR. HEYWOOD SMITH.—Sir Henry Pitman writes, as Registrar of the College of Physicians, to inform us that, at a general meeting of the College held on Friday, the 18th instant, specially summoned to receive the report of the President and Censors on the case of Dr. Heywood Smith, the following resolution was adopted:—"The College, having considered the statements made by Dr. Heywood Smith, and his apology through the Censors' Board, while acquitting him of deliberate intent to do evil, desires to put on record an opinion that he has committed a grievous error in connection with the Armstrong abduction case, which has brought discredit on himself and the profession to which he belongs. The College, therefore, regards his conduct as deserving the severest censure, and requests the President to express the views of the College, and to reprimand him accordingly." The following is the text of the Reprimand:—"The College has most carefully considered your conduct with reference to the girl Eliza Armstrong, your written explanation of your actions and motives, and your written answers to the questions asked by the President and Censors. Speaking generally, and without regard to this special case, or to cases involving medico-legal questions before, or about to come before, Courts of Law, it is, in the opinion of the College, a grave professional and moral offence for any physician to examine physically a young girl, even at the request of a parent, without having first satisfied himself that some decided medical good is likely to accrue to the patient from the examination, and also without having first explained to the parent or legal guardian of the girl the inadvisability of such examinations in general, and the special objections that exist to their being made. Moreover, the College feels that a young girl should on no consideration be examined excepting in the presence of a matron of mature age, and, so far as the physician can know, of good moral character. The College, therefore, condemns your conduct—(1) In examining girls of tender age, without the consent of their parents or legal guardians. (2) In making such examination without there being the least grounds for anticipating any medical benefit to the children to follow from your examination. (3) In examining these children in the sole presence of women whom you believed were till not long before prostitutes or procuresses. As to your having examined the child, Eliza Armstrong, as described by you in the evidence before the Court of Law, for the purpose of clearing the character of one who had, well knowing the consequences, voluntarily placed himself in an equivocal position in relation to the child, the College has a difficulty in conceiving how such a perverted view of professional morality could have arisen in the mind of a Member of this College. By failing to conform to rules that should regulate professional conduct, rules founded on concern for the public good, and on sound moral principles, you would, had the College not taken its present action, have brought dishonour on the College of which you are a Member, and discredit on the profession to which you belong. Having regard, however, to the motives that influenced you in your actions, to the fact that you were misled by others, to your full acknowledgment of the wrong you did, and to the promise you have given to the College in reference to your future conduct, the College has determined not to erase your name from the list of its Members, but has desired me as their mouthpiece to reprimand you and to admonish you that any deviation in the future from strictly honourable professional conduct will be followed by the severest punishment the College can legally inflict."

BRITISH MEDICAL ASSOCIATION.—The British Medical Association will hold its 54th annual meeting at Brighton, under the presidency of Dr. W. Moore, on August 10th,

11th, 12th, and 13th of next year. Out of compliment to the American medical profession, Dr. Austin Flint has been invited to deliver the address on medicine, and he has consented to do so. An address on surgery will be delivered by Mr. Frederick Abell Humphry, F.R.C.S., surgeon to the Sussex County Hospital; and an address on public medicine will be given by Mr. E. D. Mapother, M.D., consulting medical officer to the City of Dublin. The scientific business of the meeting will be conducted in nine sections, of which the presidents are as follow:—Medicine.—W. H. Broadbent, M.D. Surgery.—John Eric Erichsen, F.R.C.S., London. Obstetric Medicine.—Alfred Meadows, M.D., London. Public Medicine.—Richard Patrick Taaffe, M.D., Brighton. Psychology.—Thomas Smith Clouston, M.D., Edinburgh. Pathology.—Julius Dreschfeld, M.D., Manchester. Therapeutics and Pharmacology.—Thomas Lauder Brunton, M.D., London. Ophthalmology.—Charles Oldham, F.R.C.S., Brighton. Otology.—G. F. Hodgson, M.R.C.S., Brighton.

M. PASTEUR AND HYDROPHOBIA.—It is said that M. Gomot, the Minister of Agriculture, is so well satisfied with his visit to M. Pasteur's laboratory that he will ask the French Chambers to enable him to practise inoculation against rabies on a large scale, and to treat human beings suffering from that malady in a special hospital. About 40 persons were under treatment when M. Gomot was at M. Pasteur's. One was a Hungarian sent by his Government, another a captain in the Russian Imperial Guard, whose hand a mastiff had bitten. There were several children who had received bites in the face, and other patients are being sent from America to be placed under Pasteur's treatment.

THE Executive Committee of the Mile-end Liberal and Radical Association have passed a resolution conveying to Mr. Ernest Hart their sincere thanks for the energetic, and self-sacrificing manner in which he, at the invitation of the Liberal party, contested the division at the recent election.

MESSRS. CHRISTY & Co. request us to mention that the fire on the premises they occupy at No. 6, George Yard, Aldgate, on the night of the 12th, has not caused any interruption to their business, as all orders for drugs, &c., are being supplied from their warehouse at No. 2, George Yard.

PAYMENT OF MEDICAL WITNESSES.—At the Munster Winter Assizes at Cork, on Friday, December 11th, in the course of a case of infanticide, Mr. Justice O'Brien said he had received a letter from Dr. Peirce, of Newcastle, county Limerick, who complained of having received but 6*l.* odd for his attendance at the assizes. He stated that he claimed three guineas a day and 15*s.* a day expenses, and that he had been allowed but two guineas, without any expenses, so that he had received but half of what he claimed. It was his (his lordship's) intention to reply to him, stating his opinion that two guineas a day to a professional man, who came from a distant place, was a wholly inadequate remuneration. The Treasury were, no doubt, very great people, and, of course, it was the duty of any person holding an official position not to sanction undue extravagance and expense; but he could cause the Treasury to understand that he would not require the services of any medical man from the country at two guineas a day. He would not sanction it, and he would treat as contempt of court any attempt to dispute the carrying out of his orders by the Crown Solicitors.

ANOTHER ARGUMENT IN FAVOUR OF VACCINATION.—Among the many queries which the present extensive revival of vaccination has raised, is the one relating to its effect upon those who have already undergone small-pox or varioloid. We have been somewhat surprised to find that vaccination "takes" with those who have had small-pox, two or three of such cases having come under our notice. Upon enquiry of a physician, whose position at the Board of Health has given him a wide opportunity for observation, he assured us, without hesitation, that after small-pox vaccination will take always, and in the primary form. Moreover, that vaccination is a surer safeguard from small-pox than small-pox itself, for he knew of instances where

unvaccinated individuals have had the disease two or three times. This information is, therefore, of great importance, for most people who have had small-pox feel that they are sealed with an immunity greater than a life-time of continued vaccination could purchase for them.—*New York Medical Record*, November 21st.

**HICCUP DUE TO NEEDLES.**—Hiccup came on suddenly in a woman after an emotion, and persisted for 24 days. She could take milk and broth, which were not vomited. After bromide and ether had been tried in vain. Dr. Liégois was called to her on the 24th day, and ordered strong doses of chloral and hyoscyanine. These procured sleep, during which the hiccup ceased, only to return again when she awoke. After some days it ceased for some time, but again came back whenever the patient was irritated or attempted to swallow food or drink. Some months later an abscess formed on the right side of the epigastrium, from whence issued a needle 3 centimetres long, and Dr. Liégois extracted six other shorter needles. From this moment the hiccup finally stopped, the patient pretending ignorance as to how the needles penetrated her body.—*Revue de Thérapeutique*, November 15th.

**STRAMONIUM IN HYDROPHOBIA.**—A correspondent of the *Morning Post* relates the following:—"While I was residing at Chettespore, in Ganjam, not far from the cantonment of Berhampore, I was one night awoken by my head-servant, who came to tell me that three of the stablemen had been bitten by a mad jackal. He begged me to send at once for a Brahmin residing in Ganjam, about four miles off, who was known to have saved the lives of many persons attacked with hydrophobia. The Brahmin came at daylight, and administered a green pulp, which from its smell and its effects proclaimed itself as *Datura*; he warned us to expect the paroxysm of delirium and stupor during 24 hours, and enjoined abstinence from certain meats, but he would not divulge the nature of his remedy, nor was he willing to sell the secret. He assured me that the medicine was equally efficacious during an attack or as a preventive taken beforehand, and it is certain that he was universally believed to have cured numerous cases. The persons bitten were in my service for a year at least, and none of them were attacked."

*Errata.*—In our last issue, on page 844, line 2, for 'married' read 'marked'; and on page 861, line 21, for 'revived' read 'reversed.'

### APPOINTMENTS.

BARON, B. J., M.B., C.M.—Demonstrator of Practical Pathology in the Bristol Medical School.  
LITTLEWOOD, H., M.R.C.S.—Senior Demonstrator of Anatomy at University College, London.  
MACREADY, J. F. C. H., F.R.C.S.—Surgeon to the City of London Hospital for Diseases of the Chest, Victoria Park.  
NEWHAM, W. H. C., M.A., M.B. Cantab., M.R.C.S.—House Surgeon to the Bristol General Hospital.  
NICHOLSON, H. G., M.R.C.S., L.S.A.—House Surgeon to the Middlesex Hospital.  
SHAW, L. E., M.D. Lond., M.R.C.P., M.R.C.S.—Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria Park.

### VACANCIES.

BOROUGH OF OLDHAM.—Medical Officer of Health. (*For Particulars, see Advertisement.*)  
DERBYSHIRE GENERAL INFIRMARY.—Resident Assistant House Surgeon. No Salary, but a bonus of £10 is given with board and washing. Candidates must possess a qualification, and they will be eligible for re-election. Applications, with testimonials, to be sent to the House Surgeon not later than December 29th.  
FRENCH HOSPITAL AND DISPENSARY, 10, Leicester Place, Leicester Square, W.C.—Resident Medical Officer. Salary, £60 per annum, with board, furnished rooms, and attendance. Candidates must be qualified and speak French. Applications, with particulars of professional qualifications and testimonials, to be sent as early as possible in the beginning of January.  
SUNDERLAND INFIRMARY.—House Surgeon. Salary, £60 per annum, increasing £10 annually, with board and residence. Candidates must possess registered double qualifications. Applications, with testimonials, to be sent to the Chairman of the Medical Board on or before January 4th, 1886.

TORBAY HOSPITAL AND PROVIDENT DISPENSARY, TORQUAY.—Junior House Surgeon and Dispenser. Salary, £90 per annum, with board, lodging, and attendance. Candidates must be qualified in Medicine and Surgery, registered under the Medical Act, and unmarried. Testimonials to be sent to the Hon. Secretary, W. H. Kitson, Esq., Torquay, not later than January 1, 1886.

### DEATHS.

DYER, S. S., M.D., at Ringwood, Hants, on Dec. 20th, aged 61.  
JEWELL, THOMAS WILLIAM, Staff Surgeon, R.N., at Rocquettes, Guernsey, on December 19th, aged 32.  
MILLER, J. R., M.D., Surgeon-General, at Meran, on December 7th, aged 65.  
PHILBRICK, JAMES, F.R.C.S., at Toronto, on December 2nd, aged 69.  
SMYTH, LUKE DOWEL, M.D., late of Bingham, Notts, at 21, Parliament-Hill Road, Hampstead, N.W., on December 21st, aged 74.

### NOTES, QUERIES, AND REPLIES.

#### COMMUNICATIONS RECEIVED—

Prof. GAIRDNER, Glasgow; Dr. DRYSDALE, London; Dr. TRARD, London; Mr. J. CLARK, Edinburgh; OUR VIENNA CORRESPONDENT; THE SEC. OF THE UNIVERSITY OF LONDON; Messrs. HODGE & Co., London; THE SEC. OF THE SOCIETY OF APOTHECARIES, London; THE SEC. OF THE ROYAL INSTITUTION OF GREAT BRITAIN, London; THE REGISTRAR OF THE ROYAL COLLEGE OF PHYSICIANS, London; THE REGISTRAR-GENERAL, Edinburgh; THE REGISTRAR-GENERAL, London; THE SANITARY COMMISSIONER OF THE PUNJAB, Lahore; THE PROPRIETORS OF GRAND VIEW HOUSE, Wernersville, Pa., U.S.A.; OUR NEW YORK CORRESPONDENT.

#### BOOKS RECEIVED—

Report of Spina Bifida Committee, 1885—Die Bakterien-Aetiologie der Infections-Krankheiten, von Dr. Hugo Mitteleur—Die Physiologische und Therapeutische Wirkung des Schwefelwasserstoffgases, von Dr. H. Stiff—A Plan for erecting a Health City on the South-West Gulf, Coast of Florida—The Mammalia, by Oscar Schmidt—Vital Statistics, by Noel A. Humphreys.

#### PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—The Hospital Gazette—Revue Médicale—Journal of the American Medical Association—Société Médicale—The Journal of the British Dental Association—The Canada Lancet—The Detroit Lancet—The New Orleans Medical and Surgical Journal—The Ophthalmic Review—The Canada Lancet—Annales Médico-Chirurgicales—Caslon's Circular—The Canadian Practitioner—Night and Day.

### SUMMARY OF CONTENTS, DECEMBER 19.

#### LECTURES, &c.:

Dr. W. H. Allchin: Clinical Lectures on the Method and Data of Medical Diagnosis. Lecture IX.—Case Taking.  
Dr. Norman Chevers, C.I.E.: On Strumia and Phthisis in India.  
Mr. Walter Rivington, M.S., F.R.C.S.: On the Representation of the Members on the Council of the College of Surgeons.

#### HOSPITAL REPORTS:

St. Bartholomew's Hospital.

#### EDITORIAL NOTES.

#### LEADING ARTICLES:

The Meeting at the College of Surgeons.  
Mr. John Wood's Bradshaw Lecture.  
Allopathic Temperance.

#### REVIEWS:

Minor Notices.

#### ABSTRACTS AND EXTRACTS.

#### NOTES ON FOREIGN HEALTH RESORTS:

The Cape Colony.

#### MEDICAL NEWS, &c.

Meeting of Fellows and Members of the Royal College of Surgeons.

## INDEX.

## A

- Abdomen, removal of tumours from walls of the, Dr. Sanger on, 265  
Surgical Treatment of Tumours of the, Part I., Dr. Keith on, notice, 645
- Aberdeen University, Faculty of Medicine, pass lists, 200  
programme for 1885-86, 366  
Royal Infirmary, charge of mismanagement against the, 189, 258, 399, 436, 636  
proposed re-organisation of, 655  
report of Drs. Russell and Simpson on, 813
- Acne, Dr. Bulkley on, notice, 821
- Actinomycosis, acute tubercle of the liver resembling, Dr. J. Harley's case of, 747
- Adonis vernalis, therapeutical properties of, 581
- Adynamia, hypodermic use of ether in, 197
- Air-passages, foreign bodies in the, Dr. Chevers on, 806
- Albumen, the picric acid test for, Dr. Johnson on, 107  
a new test for, Dr. Harris on, 455
- Albuminuria (cyclic) in the apparently healthy, Dr. Pavy on, 529  
scarlatinal, Dr. S. Thomson on, 671, 685  
treatment of, Dr. Andrew on the, 782
- Alcoholism, acute, pilocarpin in, 581
- Alderson, Dr., cases of schirrus of the breast, 824
- Alexander's operation, fatal case of, 112
- Allbutt, Dr., on Scrofulous Neck, notice, 485
- Alleluia, Dr., clinical lectures on the method and data of medical diagnosis, 531, 569, 603, 629, 661, 701, 767, 798, 831
- Amaurosis, an unusual cause of, 685
- Amblyopia, hæmorrhagic, dilatation of sphincter ani in, Mr. Hartley on, 733
- Ambulance-work, Dr. L. Roberts' Lectures on, notice, 645
- American System of Medicine, review, 819
- Ammonium chloride, utility of, 211
- Amputations, Mr. Dobson's practice in, 566  
Mr. Bryant on (with discussion), 823  
Dr. Watson on, notice, 849
- Anæsthesia, the modes of, Dr. Buxton on, 251
- Anæsthetics, administration of, to children, Dr. Willard on, 580  
as employed at Souakin, 631
- Analysis, Practical Organic, by Ellis, notice, 158
- Anchyllostoma duodenale, specimen of, 825
- Anderson, Dr. L. B., on ice in congestive chills, 60  
Dr. James, curious case of hemianopia, 545
- Andrew, Dr., treatment of albuminuria, 782
- Andrologists, a plea for, 17
- Aneurysm, popliteal, compression in case of, 330  
circumscribed pulse, 888  
causation of "true," Dr. Chevers on, 497  
as observed in India, Dr. Chevers on, 498  
femoral, ligature of external iliac, Mr. Rivington's cases of, 715  
of internal carotid, 619
- Ani, sphincter, dilatation in, Mr. Teale on, 729, 827  
Mr. Bryant on, 789  
Sir Wm. MacCormac on, 789
- Antipyrin in continued fever, Dr. W. Wilson on, 248  
in sunstroke, Dr. Westbrook on, 410  
properties of, Dr. Zitzeke on the, 484
- Antiseptic ointment, Dr. Thayer's, 411
- Antiseptic system in obstetrical practice, Dr. Priestley on (and discussion), 92  
Mr. Wood on the, 843
- Antiseptic Treatment, Mr. Cheyne's Manual of, notice, 126  
in midwifery, Dr. Gervis on, 160
- Aorta, rupture of the, case of, 234
- Aneurysm of the, Dr. Oswald Browne on, notice, 515  
Dr. De Haviland Hall's case of, 851  
aspiration of the, Mr. Dacres' case of, 684
- Apocrypha of evil, 322
- Apothecaries' Society, regulations for the examinations at the, 344  
pass lists of the, 29, 65, 98, 132, 168, 200, 236, 267, 300, 334, 417, 450, 486, 520, 553, 586, 655, 688, 726, 759, 792, 828, 881, 892  
discussion at the Medical Council on surgical examinations by the, 723, 752, 754
- Apothecaries' Hall of Ireland, regulations of the, 368
- Arlt, Prof., Diseases of the Eye, notice, 850
- "Armstrong Case," comment on the results of the, 675
- Army Medical Department, analysis of the report of, for 1883, 121, 261  
successful candidates for the, 300  
efficiency of the, in the Soudan, 300
- Army Medical School, successful competitors at the, 201
- Arsenic, detection of, in presence of anti-mony, 271  
poisoning by, through mother's milk, 60  
and supposed cholera mortality, 795
- Arterial tension, morbid, Dr. Goodhart on, 241, 260
- Arteries, the Ligature of, Sir Wm. MacCormac on, notice, 58  
atheroma of the, tabetic contracture in association with, 328  
*vide* Carotid, Iliac
- diseases of, in animals, Mr. Sutton on, 853
- Artigas, Dr., *Les Microbes Pathologiques*, review, 403
- Ascarides lumbricoides, death from, 882
- Ascites, a remarkable case of, 795
- Asphyxia, Dr. Norman Chevers on, 770
- Association, British Medical, report on the meeting of the, 146, 184  
observations on the, 153  
British, for the Advancement of Science, meeting of the, at Aberdeen, 396
- Asthma—  
pyridine in, Professor Germain Sée on, 411  
malarious spasmodic, Dr. Chevers on a case of, 807
- Attfield, Prof., Chemistry, notice, 834
- Austria, statistics of medical practitioners in, 590
- Axillary artery, destruction of, by a sarcoma, Mr. Savory's case, 823

## B

- Bacteria of eye disease, 868
- Baker, Marrant, and Bowlby, Messrs., on diffuse lipoma, 621  
Sir George, as a medical classic, 817
- Baillière, J. B., obituary notice, 701
- Barbour, Dr., A. H. F., Spinal Deformity in relation to Obstetrics, notice, 89
- Barker, Mr., on the bacillus of malignant pustule, 746
- Barlow, Dr., and Mr. Godlee, case of suppuration of vermiform process
- Barnsley Hospital, cases treated at the, 396
- Barometer as a guide to health, 829
- Barrett, Dr. A. W., Dental Surgery, notice, 515  
Dr. J. W., on homatropine, 73
- Bartholomew's (St.)—  
Hospital cases treated at, 839  
Medical School, history and present state of the, 344  
award of prizes and scholarships at the, 301, 554
- Barwell, Mr., cases of gastrostomy, 783
- Bateman, Dr., case of scurvy in a child, 60
- Bath, sanitary state of, 269
- Baths, how to give in typhoid fever, 454
- Bauduy, Dr., on cocaine in diseases of the nervous system, 579
- Beddoe, Dr., Races of Britain, review, 819
- Belfast School of Medicine, condition of the, 674
- Belgium, professional status in, 520
- Bellew, Dep. Surgeon-General, History of Cholera in India, review, 781
- Belugou, Dr., on causes of locomotor ataxia, 685
- Bengal, deaths from tigers and snakes in, 135
- Bennett, Prof. E. H., on the study of fractures on the skeleton, 159  
Drs. Hughes and Campbell, case of brachial monoplegia, 329
- Ben Rhydding, as a health-resort, 333
- Berlin Hygienic Institute, account of, 485
- Bert, M. Paul, opposition to experiments on the decapitated, 83
- Bettany, Mr., Eminent Doctors, their Lives and their Work, review, 542
- Betz, Dr., on chloroform as a hæmostatic, 485
- Beyer, Dr., influence of cocaine on the heart, 296
- Billing, Archibald, as a medical classic, 405
- Biniodide of mercury, solubility of, 851
- Binz, Prof., *Vorlesungen über Pharmakologie*, notice, 90
- Bird, Mr. Golding, case of jejunostomy, 784
- Bishop, Mr. S., on enterorrhaphy, 446
- Birch, Mr., note on Provincial Dispensaries, 828
- Birmingham, health returns of, 487  
School of Medicine at, account of the, 359  
Queen's College, distribution of prizes at the, 521
- Bladder, defective development of the, Mr. Morgan on, 43  
perforating ulcer of the, Dr. Oliver on, 77

Bladder, nervous affections of the, in children, 106  
 tubercular disease of the, in children, 106  
 tumours of the, Mr. R. Harrison on, 142  
 in children, Mr. Morgan on, 213  
 cancer of the, Mr. Shield's case of, 648  
 extra-peritoneal rupture of the, specimen of, 648  
 inflammation of, *pichi* in, 782  
 Blood, sugar of the, in relation to food, 789  
 Blood-letting, Professor Jurgensen on, 444  
 therapeutical value of, Dr. James Robinson on, 667  
 Bloemfontein as a health resort, 330  
 Boddart, Professor, testimonial to, 50  
 Bombay, letters from, 27, 95, 163, 234, 299, 415, 446, 549, 623, 742, 826  
 the Goculus Tejpál Hospital at, report on the, 163  
 registrars' reports of, 416  
 Bone, malignant disease of, Dr. Knight's case of, 669  
 Bonnafont, Dr., on insensibility of decapitated heads, 203  
 Books, reviews and notices of, 22, 57, 89, 125, 158, 194, 228, 262, 294, 327, 408, 443, 481, 514, 542, 616, 645, 680, 713, 745, 779, 819, 846, 879  
 Boot, Cook & Townshend's model, 97  
 Borated Petrolasoline, M. Vigier on, 410  
 Boroglyceride, value of, Dr. MacSmith on the, 297  
 Botany, position of, in the medical curriculum, Professor Bower on, 608  
 Bottles made of paper, 33  
 Bouchard, Dr., on the nature of cholera, 253  
 Bouley, Prof. Henri, obituary notice, 842  
 Bournemouth, Mont Dore Institution, account of the, 552  
 Bowditch, Dr., case of traumatic linear atrophy of the skin, 412  
 Bowman Lecture, by Dr. Hughlings Jackson, 695  
 observations on the, 743  
 Bradley, Dr., release of, from prison, 115, 189  
 the fund raised for, 793  
 Bradshaw Lecture, Mr. Wood's, 843  
 Bradshaw Lecture, Dr. Goodhart's, 241, 260  
 Brain, heat-centre in the, Dr. Ott on, 233  
 nomenclature, Prof. Wilder's views of, 238  
 extravasation into, from rupture of the pons, Dr. West's case of, 45  
 Diagnosis of Diseases of, Dr. Gowers on, review, 223  
 abscess of the, specimen of, 826  
 following disease of the ear, Mr. Parker's case of, 395  
 cysticercus of the, specimen, 582  
 tumours at base of the, specimen, 647  
 Brain race, the international, 777  
 Breast, tumours of the, Mr. Dobson on his cases of, 598  
 scirrhus of the, Dr. Alderson's cases of, 824  
 Brehmer, Dr., *Aetiologie der chronischen Lungenschwindsucht*, notice, 326  
 Breisky, Prof., on kraurosis vulvæ, 25  
 Brieger, Dr., on the ptomaines, 814  
 Bright's disease, delirium in, Dr. Quinquaud on, 337
