## CLINICAL REMARKS ON PERITONITIS.

### CHRONIC PERITONITIS IN THE YOUNG—"TUBERCULAR PERITONITIS"—"TABES MESENTERICA"—CASE OF APPARENT RECOVERY.

By W. T. GAIRDNER, M.D., LL.D.,

Professor of Medicine in the University of Glasgow.

(Continued from page 397, Vol. II, 1884.)

I HAVE for some time had it in view to take up again a subject which occupied us a good deal last summer, by using for your instruction the remarkably contrasted cases of two little patients now in the female ward, viz.:—Jane M., æt. 8, and Mary Jane S., æt. 10.

These two cases, both in their likeness, and in their differences, illustrate in various ways the phenomena (in their clinical aspects) of diseases which form a distinct pathological group under the various names of "chronic peritonitis," "tubercular peritonitis," "tabes mesenterica," &c. Not that these cases are by any means so rare as to makes those now before us very specially worth recording on this account;

but in making some general remarks upon them, I wished to have data to which I could appeal as absolutely within the compass of your own actual experience, and so to proceed not from general statements such as you may easily read in your text-books, but from precisely observed facts in detail leading upwards towards such general statements.

You will find, before we have done, that the study of these cases after this fashion is not without its advantage, and may lead us to modify somewhat the general doctrines, both as to diagnosis and prognosis, which you are apt to derive from the more apparently systematic, and therefore complete, way of looking at the subject. At all events, there is no doubt that the clinical way is the more impressive, and must, if you are careful to follow it closely, leave some definite results or conclusions in your minds which will be of great service to you in the course of general practice; and I may further assure you that you will find such cases as these much more frequently brought under your notice in ordinary practice than they ever can be in the wards of a general hospital.

I ask you, then, for the moment to dismiss from your minds all such ideas of general medical doctrine or nomenclature as I have just referred to, and to look personally into the facts of the case of Jane M. in the first place, as they have been under observation from April 10th, the date of her admission, until now (July 10th); that is, for a period of fully three months. I may mention that during the latter part

of this period Jane M. has been on the whole so well that I have thought it consistent with my duty to submit her, on almost an indefinite number of occasions, to the scrutiny of individual candidates during the clinical examinations; on one day, indeed, fully eight or nine candidates examined her in succession, more or less minutely, in our presence; nor was she at all the worse of so much handling, but took it as a part of her amusements, being as little like a *patient* as it was possible for a little girl in such circumstances to be. With the other case I felt obliged to be much more chary in submitting her to observation; but in both of these typical instances my lips have been sealed, by my position and duties as an examiner, for more than a month; and it is only now that I am free to discourse upon them in such a way as to convey to you the impressions I have been deriving from a lengthened course of study of the details now to be brought before you.

From the father of Jane M. we ascertained that the child had been "always somewhat swollen in the belly"; but it was only towards the end of March (three weeks before admission) that she complained at all of any pain in the abdomen, or that the tension became such as to excite alarm. Her appetite during this period was much diminished, but she never vomited her food, and the bowels were always regular, except, perhaps, in connection with an attack of measles which she had at the beginning of the year, when they tended to be loose. We have every reason to believe that these details (though not under our own observation) are correctly enough stated; for her parents seem not only to be in a general way trustworthy, but have had their attention quickened in this instance by the fact that an elder sister of this girl is under treatment in the country for "consumption of the bowels"; having been removed from the family on this account for about a year. Jane M. had whooping-cough at six or eight months old, and measles, as above reported, within the present year. At two years old her legs bent a little, as from rickets, but soon straightened again. Now and then she would "catch cold" during bad weather, but she never had any permanent or troublesome chest affection, and was always, with these exceptions, regarded as a healthy child. The family history seems good, with the one serious and very notable exception above-mentioned; there are three sisters and one brother, all, except the oldest, regarded as quite healthy.

Now, as to this girl's state since admission, I can tell you quite positively, and without a shadow of doubt about it, that during the fortnight after admission (10th to 25th April) the circumference of the abdomen, evidently much too great from the first, increased from 25 to 28½ inches, and during only eight days of that period the greater part of this increase took place under our observation from day to day, with every sign of the presence of fluid in the peritonæal cavity; the absence of such fluid effusion (or its very small amount) having been carefully ascertained on admission, even although the abdomen was regarded as "much enlarged, and the umbilicus prominent." But that is not all. Not only was this rapid accumulation of fluid very carefully traced, but we were able to make out distinctly, and to demonstrate repeatedly, that although the usual gravitation of the fluid took place to a certain extent, the small intestines, which were at first close to the anterior wall of the abdomen in the recumbent posture, ceased to be so afterwards; their *levitation*, in the same posture, being evidently interfered with, to a more or less considerable degree. For the details (as they are not now under your observation), I must refer you to the journals; but the inference I drew from the whole facts at the time was that this fluid effusion was not a mere ascites, but

some more or less fibrinous exudation which hampered the free movements of the intestinal coils among the fluid, and prevented them from following the physical law which in moderate ascites, or serous dropsy of the peritonæal sac, usually causes them to float up towards the higher levels according to the position of the body at the time; and therefore, in the recumbent position, gives a frankly tympanitic note over the whole umbilical region. Moreover, palpation, though by no means to be trusted alone, concurred in this case with percussion in giving indications of slightly increased resistance, or diminished elasticity in the umbilical as compared with the sub-umbilical regions of the abdomen; as you will easily infer from the details stated under the date of May 6th, when the abdomen had just begun to diminish, after attaining its maximum circumference some time between April 27th and the above date. The abdominal superficial veins, too, were decidedly increased in volume at this date.

What was the general state of the patient during these local changes?—which, it may be remarked, were limited to the abdomen throughout. There was little or no obvious suffering; but (our report adds) "the ward sister has occasionally heard her complain of pain on handling. There is now (May 6th) no fretfulness nor acute suffering; but it is quite evident that although she is not too weak to sit up for three or four hours every day, there is none of the usual playfulness proper to a child. She sits quietly with her picture-book and doll, not complaining, and not seeming to feel the want of more active employment. It is rather remarkable that even during the period when the changes mentioned have been going on, there has been an increase in the weight of the body, which, on the third day after admission, was three stone three-and-a-half pounds, at nine days three stone four-and-a-half pounds, at sixteen days three stone seven pounds; and at or about this point, according to latest evidence, it has continued." [This increase in weight we regarded as purely factitious, depending upon the fluid effused, and probably coinciding with a real loss of tissue-weight, or relative emaciation.] The appetite was, on the whole, well preserved; the diet being chiefly milk and farinacea, but also beef-tea, and occasionally small quantities of minced collops. The urine, relatively scanty during the period of active effusion, increased from a daily average of seventeen ounces to twenty-four ounces after the close of this period. The temperatures indicated only slight febricula (max. 100·4° F.). "The period most characterised by these slightly abnormal temperatures was from 19th to 26th April, when the morning temperature during eight days averaged 98·6°, and the evening 99·6°." Both before and after this period the differences were insignificant, and, after the 1st May, no abnormal temperatures at all were noted.

I ought perhaps to add in general terms that the lungs were throughout entirely devoid of râles, and even on the most critical examination could not be said to give any positive physical signs of disease. The heart sounds, and the percussion signs were alike normal. The liver and spleen were normal in volume. The bowels were regular throughout the period of observation, and the tongue was absolutely clean, the only fact noted being a slight increase in the size of the papillæ during the most active period of the disease.

Here, then, is the exact history of this little patient, so far as known to us, up to the date (July 10th), at which you have her now under your observation. Bear in mind that not only has there been a very considerable effusion of fluid, but that the physical signs of this were so manifest and typical, that up to nearly the beginning of the present month, not one of the clinical examiners, nor, so far as I know, of the

candidates who were found competent in other respects, and who were examined on this case, had the slightest difficulty or doubt in detecting it. Yet if you examine this girl now according to exactly the same methods, and with every possible precaution, you will find it to be almost doubtful if there is any gravitating fluid at all. [Details here demonstrated and reported.] In other words, the fluid, which at one time since her admission amounted at least to several pounds, influencing the whole body-weight of the little patient, and which we know to have been scarcely, if at all, recognisable on admission, has been for the most part, if not entirely, absorbed again during the last fortnight. And throughout a much longer period than this, probably since the very end of April or beginning of May, Jane M. has been gaining in flesh, in colour, in cheerfulness, in childish vivacity, so that in the course of June she quite ceased to think of herself as ill at all, and during the whole month she played in and out of the ward, and came up with a smiling face for the mere fun of being repeatedly examined, returning to her play again as contentedly as ever. These are the little indications which, especially in children, ought always to be most carefully observed, because although the question—*What the disease is?*—is most often and best decided upon the physical signs commonly so called; the questions of *worse or better*, to *die or to live*, aye, even the diagnosis in the first instance of *the presence of disease at all*, depend upon those commonplace details which a young man, proud of his special knowledge recently derived from the schools, is, perhaps, rather apt to overlook. Observe too, that in this instance the circumference measurement of the abdomen is to some extent a misleading fact, because the absorption of bulk depending on fluid and perhaps also on gas, has been counterbalanced by an increase of muscular flesh and fat in the abdominal wall, so that this child is now only  $\frac{7}{8}$ ths of an inch less in girth than when admitted on the 10th of April with an only too obviously enlarged and tense abdomen, for which she came to us to be treated. Her extreme abdominal circumference then was 25 inches; it increased from fluid effusion to  $28\frac{1}{2}$ , and has now declined to  $24\frac{1}{2}$  inches; yet no one now would think of calling the abdomen "much enlarged," as on the 10th of April. It is now almost, if not quite, in due proportion to the rest of the body. The *note* most characteristic of these cases in infancy and early childhood is the *swollen abdomen with shrunk limbs and face*; sometimes along with these you have a relatively large head, which, though not absolutely *per se* characteristic, is strongly suggestive of tubercular meningitis, or still more of congenital chronic hydrocephalus. This child has been absolutely free from this last suspicion.

But is she, however well in appearance, cured? No, she is not cured; if by "cured" we are to be taken as meaning that she is physically and organically, *i.e.*, pathologically as well as clinically, sound. Although she has gained  $2\frac{3}{4}$  lbs. in weight since the latter part of June, when the absorption of the fluid ceased to be a counterpoise to the putting-on of flesh: although her temperatures have for many weeks together been altogether normal, her functions well-performed, and her sensations those evidently of health in the main, I am able to show you physical facts in the abdomen which, taken in connection with those which have preceded, are still quite typical of the disease from which our little patient has been suffering. She is not, therefore, "cured"; only we trust she is *being cured*. But, after all, if her disease is to be called by any of the names I gave you out of the Nosology at the beginning of this clinical lesson, it must be admitted that the facts of this case tend to qualify considerably the ordinary book-descriptions of the prognosis, and to cast a ray of hope into the dark

regions occupied by "tabes mesenterica" in the older nosologies, and by "chronic" or "tubercular peritonitis" in works from the time of Louis downwards. It is well that you should learn this lesson of hope in the first instance, if possible, from a case which leaves no kind of doubt as to the essential facts. I therefore abstain from comment of a more general kind in the meantime, and ask you simply to observe with me the points which bear now upon the diagnosis of *thickening of the great omentum*, the most obvious, and often the only, physically discoverable fact which, in the absence of fluid effusion, makes it certain that the peritonæum has been the subject of a morbid process. I shall have more to say as to the general questions, both of diagnosis and of prognosis, here involved on another occasion.

[Demonstration in detail followed, with results as recorded, in a condensed form, in the report.] "At present (July 10th) it cannot be said that the abdomen is absolutely normal, inasmuch as there is distinct, though not very great, dulness to superficial percussion, easily penetrated by a slightly stronger stroke in the umbilical region, and especially to the right side of the umbilicus. Following up this line of enquiry, Dr. G. succeeds in demonstrating (1) the *stomach region* nearly, if not absolutely, normal to percussion; (2) *transverse colon*, slightly obscure, but still quite definitely distinguishable to the right, just over the costal cartilages, and  $2\frac{1}{2}$  inches from the insertion of the xiphoid; (3) *small intestines* on both sides, but more distinctly on the left, between the umbilicus and Poupart's ligament, quite superficial in the lower part of these areas and in the hypogastrium. Between the various points indicated above (*i.e.* in the middle region of the abdomen, verging toward the epigastric and hypochondriac regions) lies an area of distinctly more dull percussion superficially, easily definable on the left side, not so easily on the right, and extending to about  $2\frac{1}{2}$  inches above and  $1\frac{3}{4}$  inches below the line of the umbilicus. As this area exactly corresponds anatomically with the probable position of a thickened omentum, Dr. G. invites several members of the class, as well as Dr. Middleton (clinical tutor) to perform palpation of the abdomen, with the result that although there is no change which, apart from the percussion, could be securely reported, there is a very general coincidence of opinion that on the left side (perhaps not on the right) a slight relative loss of elasticity, corresponding with the region above indicated as dull to percussion, can be made out by the most delicate handling. At the same time it is only right to remark that the abdomen, although still inclined in the direction of undue fulness, might easily enough pass for a normal abdomen, on a rapid examination without knowledge of the previous incidents."

[On July 14th, Jane M. left for a stay in the country, looking and feeling perfectly well.]

The treatment was exceedingly simple; it consisted mainly of inunction with cod-liver oil, the use of extr. hordei, pancreatic emulsion, and careful regulation of the diet, as above indicated. Cold compresses were employed up to April 25th, but were then found to be unnecessary, and the oleaginous application was substituted. Gastric tonics, &c., did not appear to be required at any time.

(To be continued.)

---

COTTAGE HOSPITAL, LLANDUDUO.—Lady Penrhyn has opened in the Pavilion a fancy fair in aid of the funds of the Hospital, which has been erected on a site given by Lord Mostyn.

## CLINICAL LECTURE ON A CASE OF SYPHILITIC OPTIC NEURITIS.

GIVEN AT THE MOORFIELDS OPHTHALMIC HOSPITAL ON  
JUNE 13TH, 1885.

By E. NETTLESHIP, F.R.C.S.,

Ophthalmic Surgeon to and Lecturer on Ophthalmology at St. Thomas's Hospital; Assistant Surgeon Royal London Ophthalmic Hospital, Moorfields.

GENTLEMEN,—The patient whose case we will discuss to-day is a man of 30, pale, nervous, with a stutter in his speech, by trade a hair-dresser. He comes for an opinion on his left eye which, he says, went nearly blind, for some time, several years ago, but recovered almost completely. At present his right eye is normal in every respect; the left sees  $\frac{6}{9}$  partly, the pupil is natural, the optic disc shows signs of having been inflamed some time ago, for it is not so pink, its texture not so transparent, and its border not so clear as in the other eye; the veins also are larger, and are bordered by white lines; all the other parts of the eye appear healthy. The movements of both eyes are perfect.

He says that when in New Zealand in 1879 he had gonorrhœa. About a year later he had a chancre, followed by a bad sore throat, but without rash; he was treated with "mercury," and soon got, as he supposed, quite well. Within four or five months, however, of the primary sore, the sight of his left eye failed, and he again (in March, 1880) put himself under Dr. Wilkins, of Dunedin, whose notes of the state of the eye he is fortunately able to show us. Dr. Wilkins states that on March 7, 1880, there was "optic neuritis" in the left eye, the disc "quite obscured," and sight "nearly gone, cannot see  $\frac{20}{200}$  or 12 J. at any distance;" the state of the vitreous is not noted. There is no actual statement that the disc of the other eye was unaffected. We find that Dr. Wilkins prescribed iodide of potassium and bichloride of mercury; that in a few days the sight of the defective eye began to improve and the disc to clear, and that on April 19th (six weeks from the commencement) Dr. Wilkins notes that the vision was  $\frac{20}{20}$ . He had no pain from beginning to end, nor any "head symptoms." About this time the man says he had an "abscess" in one leg which was soon well, and which need not concern us. Several weeks later he suffered from some degree of weakness, with numbness and tingling, in the lower extremities, probably due to a mild, but acute, syphilitic lesion of the cord. This symptom, whatever its meaning, soon passed off, the vision of the left eye reached in time its present state, and he continued quite well till October last (1884). Then he "lost power over the right eye," and, being in England, came to this hospital, and was treated by one of my colleagues for paralysis of the right third nerve. The notes state that there was ptosis and diplopia, and that the visual acuteness was (as it is now)  $\frac{6}{6}$  with the R. and  $\frac{6}{9}$  with the L. The nerve soon and completely recovered under anti-syphilitic treatment. At the present time therefore he has no symptoms; his left eye is well, his right third nerve is well, and his legs are strong. But as he wants to return to New Zealand he is anxious to know whether his sight is safe, or whether it is likely to fail again as it did 5 years ago. The case therefore is worth a retrospective examination, particularly as to the precise cause of the optic neuritis which for a time almost blinded the left eye in 1880.

Optic papillitis is very uncommon in secondary syphilis, except as a complication, and probably a result, of choroidal and retinal inflammation. In many such cases all the hinder intraocular tissues, choroid, retina and vitreous suffer, and the disc suffers too, sometimes badly, sometimes mildly. But, as you are aware, cases of syphilitic choroido-retinitis run a very long course, are liable to recur, usually leave permanent changes in the choroid, retina and vitreous, and often cause lasting damage to sight; whereas the attack in our patient ran a quick course, and has left no ophthalmoscopic traces except at the disc, where we know that violent changes took place. We may therefore put away the suggestion that the papillitis was consecutive to disease of any other part of the eye; and may assume that it was the result of inflammation of the optic nerve. The question then arises was this optic neuritis dependent upon acute intracranial mischief (syphilitic meningitis), or was it from beginning to end a purely local affair? Our patient never had a symptom of intra-cranial inflammation, and besides, acute meningitis in secondary syphilis is, of course, exceedingly rare; moreover, had meningitis been the cause, it is most unlikely that the other optic nerve would have escaped.

By exclusion, therefore, we are obliged to assume that the disease was primary in the optic nerve or its immediate surroundings, and that the starting point was somewhere between eyeball and skull. The complete absence of pain, both before and during the attack, though it does not entirely negative acute gummatous periostitis limited to the bony optic canal, makes that diagnosis improbable, and the escape of the second eye precludes us from appealing to the morbid state of the blood as a possible cause of the optic neuritis. I think, therefore we shall be right in supposing that a true syphilitic inflammation, a gumma if you will, occurred in the optic nerve between the eye and the apex of the orbit, and that it was rapidly resolved by treatment, leaving a little, though very little permanent damage.

Perhaps you will ask why, as syphilitic inflammation of other cranial nerves is so common, it is necessary in the case of the optic nerve to beat about the bush so long, instead of taking you straight to the point? Simply because, if you go carefully into the cases in which disease of the optic nerves is a consequence of syphilis, you will not find many which can rightly be spoken of as "syphilitic optic neuritis" in the same direct sense as the present one; and this is almost as true of the later periods, as of the secondary stage of syphilis. This being so, it is worth noting that the patient seems to have a strong tendency to early syphilitic disease of his nerve tissues, as shown by the previous occurrence, at intervals, of slight paraplegia and of paralysis of one third nerve. If we have found the true explanation of his optic nerve attack, we may safely assure him that his prospect, so far as sight is concerned, is very good indeed; neither relapse nor progressive failure are at all probable.

---

THE IDENTIFICATION OF THE DEAD.—Hitherto, the course adopted by the Police authorities has been to issue a written description of the body, and have it pasted up outside some of the police stations, but instead of this, or in addition to it, it is proposed to photograph each unclaimed body prior to decomposition setting in, and have the likeness circulated, and placed outside each station. The many unclaimed bodies which are continually being found in the rivers, and canals, and in the streets of London and its suburbs, render some further endeavours to procure identification necessary.

## NOTES OF A CASE OF BLACKWATER FEVER,<sup>1</sup> WITH REMARKS.

By J. FARRELL EASMON, M.D.,

Acting Chief Medical Officer, Gold Coast Colony.

CASE of J. H. N., Foreman of Works, Accra.—*Diagnosis*.—Fievre bilieuse melanurique de moyenne intensité.

*Result*.—Cured.

*Previous History*.—This is his second tour of service on the Gold Coast, and he has been out six months; was invalided last time to Europe in consequence of anæmia and general debility, resulting from several attacks of endemic fevers. Since his return to the Colony, six months ago, his general health has been far from satisfactory; has had slight attacks of fever. A fortnight before his present illness, he broke out in boils all over the head and face, one of which assumed a carbuncular character, and gave him much pain. His general health gradually, but steadily failed, and although he was taking quinine daily in small doses, he fell ill on the morning of the 3rd June, 1885, with fever. A dose of purgative pills (pil. hydr., pil. coloc. co. aa, grs. v) administered the previous night, had acted satisfactorily, his tongue was only slightly coated and skin acting gently. Mist. diaph,  $\bar{z}i$  every two hours ordered. Seen later at 5 p.m., he had had two stools since the morning. Skin was acting freely; temperature 101.6°, pulse 85; to continue mixture every three hours and a dose of quinine mixture early in the morning.

June 4th, 1885, 9 a.m.—Temperature 99.2°, pulse 82. Patient slept well last night; bowels acted twice this morning; has had 12 grs. quinine. Urine passed this morning = 8 ozs.; highly febrile in colour, but calls for no other remark. His conjunctiva and face and skin are slightly bile-tinged. To repeat quinine at 11 a.m. Beef-tea diet, rest in bed.

*Onset of Melanuria*, 3.40 p.m.—Temperature 100°, pulse 106. Half-an-hour ago, the patient passed "black" urine for the first time, and I was sent for. Up till then he was feeling all right. At sight of it, however, he became considerably alarmed. Urine =  $\bar{z}iiss$  dark port wine colour; strongly acid. Albumen by precipitation =  $\frac{1}{5}$ th. Specific gravity not noted, quantity being insufficient. The patient is in a high state of excitement. No local pains or tenderness over abdominal organs. Neither spleen nor liver enlarged; pulse quick and slightly irregular. Says he feels certain he must die. He had not taken his second dose of quinine mixture; the jaundiced tint of conjunctiva and skin generally has deepened; has vomited twice.

To have beef tea, weak brandy and soda. Carnick's beef peptonoids *ad lib.*—7 p.m.—Temperature 104°, pulse 102. Has had only two doses of pills, both of which he has retained as well as a dose of mixture: vomited after the quinine draught and once since; pale clear green fluid with particles like chopped spinach floating in it; intensely acid; says he felt better after second vomit. Does not like brandy and

soda, to have champagne instead. Urine passed =  $\bar{z}iij$  darker than last note. Alb. =  $\frac{1}{4}$ th roughly.—12.45 p.m.—Temperature 104°, pulse 110. Has been perspiring freely since last note; had one copious stool and passed much flatus; no vomiting; has not had any more quinine pills since 9 p.m., has had two doses of mixture since last note. The pulse is still weak and irregular; slight ringing in ears; has had one tin of Brand's chicken essence since the afternoon; jaundice deepens. To continue mixture and pills as before.

June 5th, 4 a.m.—Temperature 101°, pulse 110 (?105). Has had a dose of pills and mixture since last note and snatches of sleep. The pulse is better in strength and not so irregular. Just now after vomiting on taking a cup of tea, it is 110; vomited matter, characteristic; no headache, no backache, no local tenderness; Urine =  $\bar{z}iv$ ; not so dark as last quantity passed. To continue as before.—7 a.m.—Temperature 102.2°, pulse 108. Had one stool since last note. Skin had been acting till half-an-hour ago, when he again vomited; now feels dry and parched. To have fifth dose of mixture at once and R Quin. Sulph. grs. L Colomel grs. x, Pulv. Opii grs. iss., Ft. pil. xxiv; every hour till cinchonised, jaundice deeper, and tongue more furred, but moist: no pains or local tenderness; can retain teaspoonful doses of chicken tea, any larger quantity brings on vomiting.—10.15 a.m.—Temperature 102°, pulse 112. Had a stool shortly after last note, and two others since. Passed some urine each time with the stools, colour of which is less marked; had sixth dose of mixture, and has been sweating; had one dose of pills; no vomiting since last note; seems more cheerful. Passed just now urine =  $\bar{z}ij$ , Continue

1.15 p.m.—Temperature 100.2°, pulse 111 (after vomiting). Has just vomited; had one stool since last note, had two doses of pills and one dose of last mixture; feels sick and sleepy, and deaf; pulse is rather weaker than heretofore. To take only two pills every two hours and continue mixture as before.—6 p.m.—Temperature 100.8°, pulse 108. Had two stools since last note; has been quiet, but feels sick; urine passed is much lighter in colour.

Applic. Emplast. Sinapis Epigastric.

11 p.m.—Temperature 99.8°, pulse 110. Has been quiet since last note, and had two hours' sleep (from 8 to 10), after waking up from which he began to feel sick, and has since vomited twice the characteristic vomit. Skin feels cool and is acting gently; no headache, no tenderness over liver, but pressure in pit of stomach increases nausea.

June 6th, 1 a.m.—Temperature 99.8°, pulse 106. Nausea has increased since last note, and now he is unable to retain anything. To take nothing by mouth, keep as quiet as possible.

Empl. Sinapis Epigas. Applic.

The urine passed two hours ago, shows a brownish red deposit =  $\frac{1}{5}$ th.—6 a.m.—Temperature 99.8°, pulse 105. Skin gently acting. Nausea still marked. Urine much improved in colour, light claret =  $\bar{z}vi$ . Strongly acid. Specific gravity 1032. Brown mucoid deposit =  $\frac{1}{5}$ th; albumen  $\frac{1}{10}$ th; tongue moist, lightly coated, no headache or local aches of any kind. Bowels have not acted since 7 p.m.

R Enema Simplex c Quin. grs. xx.

and whiskey  $\bar{z}ij$  statim. To keep quiet, take nothing by mouth except teaspoonful doses of Brand's essence of chicken.—11 a.m.—Temperature 99.8°, pulse 105. Has been very quiet since last note; slept a little; one stool after action of enema; passed urine on both occasions; now  $\bar{z}vi$  much lighter in colour simply

highly febrile, but with a decided reddish tinge; tongue is more coated, but the patient feels altogether better; nausea less.

℞ Pil Quin (Simplex) grs. iiss — ij om horâ.

Begin mixture as before. Stop brandy and champagne. Patient to have some still hock and water in small quantities occasionally.—6 p.m.—Temperature 100·8°, pulse 108. Has been doing very well since last note. Nausea all gone; one stool; no abdominal tenderness. The quality of urine continuing to improve; he has had two little snatches of sleep; tongue more coated than in last note; no local aches or tenderness.

June 7th, 8 a.m.—Temperature 100°, pulse 102. He has had a very good night. Slept twice, once for three hours consecutively. Since mid-day yesterday he has had 40 grains of quinine, two stools since last note. The fur on tongue is deeper, and on the whole he seems more yellow about the body and face, but the pulse is decidedly better in strength and volume, and has lost its irregularity. He says he feels better—he certainly looks better—no longer despondent. Skin acting gently.

℞ Q. grs. iiss Cal. grs. ss. Ft. pilula, ij om horâ.

Continue chicken-tea and Hock.—1 p.m.—Temperature 100·2, pulse 98. Has had three doses of pills, now about to take fourth. One dose of mixture—two stools, now being about to have third. Seems clearer in skin generally, and certainly the icteric tint of conjunctiva is less marked. Skin acting gently. Urine,  $\frac{5}{5}$  v (exclusive of the quantity passed with stools). Strongly acid, s. g. 1,027, dark amber colour, clear, alb. =  $\frac{1}{10}$ th (roughly). Continue as before.—6.40 p.m.—Temperature 99·8, pulse 75. Has had two or three stools since last note. Complains of hunger. Skin and conjunctiva much clearer. Urine of ordinary febrile tint, breath foul. His gums are tender and sore. Has had two more doses of pills and one of mixture. To stop calomel pills and continue. Simple quinine pills grs. iiss, ij every two hours, and next dose of mixture at 2 a.m. Borax and alum wash for mouth. Beef tea.

June 8th, 8 a.m.—Temperature 99·4°, pulse 80. Had a very good night. Slept from 11 to 3, and 4 to 6. Had two doses of pills and one of mixture during the night. Since 6 a.m. has had five pills = 12½ grs. quinine. Bowels acted once. Mouth still sore. To continue quinine pills.—6.50 p.m.—Temperature 99·6°, pulse 78. Has been sitting up during the afternoon. Feels weak and exhausted, bowels have acted twice. Has had altogether 35 grs. quinine since 6 a.m. Character of urine continues satisfactory.

June 9th, 8 a.m., temperature 98·8°, pulse 80. Did not rest well during the night, which was a very close and stifling one. Bowels have not acted, and he complains of sense of fulness in abdomen which is slightly tympanic. Frequent eructations. Pulse is slightly excited and skin dry. ℞ hst. salina purgans statim to be repeated at 2 p.m., if at least two stools have not been obtained. Quinine grs. v. every hour till fully cinchonised.—2 p.m.—Bowels acted twice. First time copiously, no necessity for second draught.—7 p.m.—Temperature 100°, pulse 84. I find the patient sitting up and having some soup. Seems much stronger and altogether better than this morning; lost the dusky hue of countenance he then had. Has taken altogether 30 grs. quinine since last note. To take 10 grs. more by 10 p.m.

June 10th, 8 a.m.—Temperature 98·8°, pulse 76. The patient had a very good night, and the prolonged sleep has been productive of much good. He seems altogether clearer. The gums are still tender. To continue liquid diet and hock and take quinine in five gr. doses every two hours till cinchonised.—7 p.m.—Temperature 99·2°, pulse 75. Has had 30 grs. quinine,

and is slightly deaf. Has been sitting up for a short time during the afternoon. Had one stool during the day. To take a dose of effervescent citro-tartrate of soda early to-morrow morning.

June 11th, 8 a.m.—Temperature 99°, pulse 78. Not such a good night as the previous night. Has had the saline, which has acted once, since when patient has been feeling more comfortable. To continue quinine as yesterday, and repeat dose of saline at 2 p.m. if a second stool has not been obtained before.—7 p.m.—Temperature 99·2°, pulse 74. Has had 25 grs. quinine. Three stools without second saline draught. Able to leave his room and walk about his parlour in an overcoat.

June 12th, 8 a.m.—Temperature 99°, pulse 82. Night close and sultry, patient did not sleep well. Sense of fulness in the stomach, very irritable. Pulse slightly irregular. Tongue cleaner than heretofore, and soreness of gums very slight. His skin has a dusky hue which it is difficult to describe. To continue his quinine as yesterday, and to go on again with the mist. potass. nit. c digitalis.—7 p.m.—Temperature 99·8°, pulse 76. Has had 20 grs. quinine, and three doses of mixture, been perspiring freely. Felt very unwell about mid-day, but this feeling disappeared as soon as the skin began to act. He is now perspiring freely. Pulse is more regular and steady. To take 10 more grs. quinine by 9 p.m.

June 13th, 8 a.m.—Temperature 98·5°, pulse 72. Patient has been up and out of bed, as he was feeling so well when he woke up at 6 a.m. Says he feels hungry. He has lost that duskiness of the skin, and is in very good spirits knowing that I have invalided him to Europe for a change of air. To continue mist. *ter die* and quinine grs. v every four hours.—7 p.m.—Temperature 99°, pulse 74. Has had 20 grs. quinine, and been able to pick the bone of a broiled chicken.

June 14th, 8 a.m.—Temperature 98·6°, pulse 75.—7 p.m.—Temperature 99°, pulse 75. Took 20 grs. of quinine this day.

June 15th.—Left for England. To continue quinine 15–20 grs. daily till he has passed Sierra Leone, and then to continue in 5–10 gr. doses daily till a week after his arrival in England. A tonic of arsenic, strychnia and calumba also ordered.

Remarks.—This case illustrates several features of interest characteristic of this form of malarial poisoning. In attacking an individual whose health had been gradually but steadily declining; in being preceded by attacks of intermittent fever; in its rapid onset, and with this a train of symptoms which at once modified the clinical aspect of the case into one of the greatest gravity; in the peculiarity of the urine and vomit; the uniform diffusion of a rapidly developed icterus, and in the absence of conjunctival injection, this case agrees with all the others that have come under my personal observation.

The total absence of reference to this peculiar form of endemic fever in all the works of English writers on diseases of tropical climates is, as pointed out in my official *brochure*<sup>2</sup> on the subject, worthy of note, for its clinical features are sufficiently marked to distinguish it from the ordinary bilious, remittent and other malarial fevers of tropical climates. The error has been in regarding this form of fever as simply a bilious remittent with hæmaturia as a complication, a nephritic form of pernicious intermittent; or, lastly, a malignant bilious remittent in which the colour of urine and the jaundice have been wrongly attributed to some primary organic mischief in the liver.

As regards the pathology of this fever, the clinical history, its being invariably preceded by attacks of

<sup>2</sup> "The Nature and Treatment of Blackwater Fever." Printed for the Government of the Gold Coast, London, 1884.

intermittent fever, and its occurrence only in malarious districts or in subjects affected with malaria—and in this it offers an important point of diagnostic difference from that form of hæmoglobinuria known as intermittent hæmaturia,<sup>3</sup> and also the undoubted utility of quinine in its treatment, point strongly to its malarial origin. From this point of view it might be regarded as a *pernicieuse* “*hemaphéique*,” as distinguished from a *pernicieuse* “*icterique*,” “*néphretique*,” &c., *i.e.*, in which the malaria poison expends itself not only primarily but chiefly upon the blood itself, and causes in it those sudden changes characteristic of the manifestation of its action. And if we bear in mind the facts which physiological chemistry has recently thrown upon the digestive process and the contents of the intestinal canal generally, it is not difficult to conceive how a process of *autochthonous* infection resulting from perverted secretions in the subjects of this form of fever, may so modify the quality of the blood, as to render it unusually, peculiarly susceptible to the influence of the malarial poison, which, finding here the *nidus* and *pabulum* for its growth and support, expends its malignant energies upon and destroys the vital qualities of this fluid. And this is borne out by the clinical fact so well recognised in this form of fever, *viz.*, the great tendency to that form of toxæmia generally, but erroneously described as uræmia. And here, also, the clinical relations which have been observed to subsist between ague, rheumatism, oxaluria, and intermittent hæmaturia may be noted. But the associated disturbing or pathogenetic element need not necessarily be *autochthonous*, for under the very conditions in which the malarial poison, whatever that may be, is evolved, are developed septic elements of various kinds, the ingestion of which, we have every reason to believe, is capable of producing serious results in the human system. And it is not in this particular form of malarial poisoning alone that such a possible association may occur; intermittents, non-bilious, and bilious remittents may equally so be modified, hence such expressions as *typho-malarial*, *bilious typhoid*, *malarial yellow fever*, &c. Elsewhere<sup>4</sup> I have pointed out that Sternberg<sup>5</sup> in his observations, undertaken to confirm the researches of Klebs, and Tommasi-Crudeli, found septic organisms invariably associated with the so-called malarial germs. Bérenger Férand<sup>6</sup> assuming the malarial origin of the disease, attributes its specific symptoms to a primary organic change in the liver, especially in drunkards, although this is controverted by his own *post-mortem* observations. According to Pellarin<sup>7</sup> and Barthelemy Benoit,<sup>8</sup> and on equally insufficient data, it is the kidneys that are at fault. Corre<sup>9</sup> avers that the disease is a mixed form of malarial fever evolved under conditions “*qui permettent de supposer une rupture d'équilibre soudaine, entre l'organisme impaludé, en possession d'une sort d'accoutumance, relative et habituelle, plus ou moins constatée, au poison palustre, et le milieu météorologique.*” Letona<sup>10</sup> observes, “*elle réunit les symptômes les plus redoutables de l'intoxication palustre dus à une altération profonde du sang.*”

The idea that this form of fever may result from the abuse of quinine, as suggested by Tomasselli and Karamitzas, appears to me utterly untenable. The fever which results from the abuse of quinine is essentially of a nervous type, characterised by great nervous

excitability at the onset, which is rapidly succeeded by marked prostration of all the bodily powers, death being preceded by an interval, of varying duration, of coma. It has been supposed by some to be a form of yellow fever, so-called *malarial* or *sporadic* yellow fever; but the clinical history and association and the influence of quinia in its treatment negative this idea. And it is well that this fact should be insisted upon, because in West African communities, especially among the European residents, any fever having anything “black” about it, is at once called “Yellow Fever,” and a panic ensues, the consequences of which may be—indeed, have proved—most disastrous. In the worst forms of blackwater fever the vomit assumes a bluish black colour, but this is as distinct as possible from the “coffee grounds” of true yellow fever. I have seen typical “coffee grounds” vomit in cases of bilious remittent and other forms of malignant malarial fever on this coast, which could not for a moment be mistaken for yellow fever. The prognosis in this fever is always grave.

As regards treatment, while all are agreed as to the utility of quinine, Pellarin<sup>11</sup> perhaps excepted, much difference of opinion exists as to the quantity required. My experience is decidedly in favour of large doses persistently administered till its physiological effects are manifest, and this, not only in the acute stage of the disease, but also during convalescence to prevent relapse. With reference to Calomel opinions are at variance regarding its utility. Bérenger Férand<sup>12</sup> rejects it absolutely. According to Bourse,<sup>13</sup> Guergil,<sup>14</sup> Corre,<sup>15</sup> and others it is certainly beneficial. In my experience its utility is decided. “It would appear to act not only as is well known, upon the liver, but also as a sedative to the stomach, and as an antiputrefactive upon the contents of the intestinal canal, thus minimising that amount of *auto-infection* which, in fevers of this kind, is extremely likely to occur and the possibility of which is often lost sight of.”<sup>16</sup>

I have never been able to detect bile in all the specimens of urine I have examined. Microscopy has invariably revealed a few blood corpuscles more or less altered, amorphous granules, a few epithelial casts, glomerular epithelium, triple phosphate, and acid urates. Heat and HNO<sub>3</sub> give a variable proportion of albumen. The urine treated with sodium chloride and strong acetic acid exhibited the characteristic crystals of hæmatin. In the case reported the urine passed the day before the patient left for England showed not a trace of albumen. In none of my previous successful cases has kidney mischief been subsequently developed.

As regards prophylaxis, convalescents should be sent away as soon as possible to some temperate and healthy climate to prevent relapses, which are otherwise certain to occur.

## ON THE ECZEMATOUS DIATHESIS.

By TOM ROBINSON, M.D.

THE words temperament, idiosyncrasy and diathesis are used by us all, I fear, without attaching to them anything approaching to a definite significance, and if we think for a moment we shall not be surprised at this, because they, in a certain sense, have a similar meaning. It will be well before I enter on my special

subject, to define these terms, and in so doing, it is right that I should acknowledge my indebtedness to Professor Laycock, Sir James Paget, and particularly to the lectures of Mr. Hutchinson, who treated the subject in his masterly style in the lectures which he gave on the pedigree of disease at the College of Surgeons.

I should define temperament as a state of the organism which spreads throughout the life of an individual—for instance, we have the nervous, the sanguineous, and the bilious temperaments. These states are always present, and go with a man to his grave. By idiosyncrasy, I should indicate an organism which is influenced in a manner peculiar to itself by ordinary influences and without reference to temperament—for instance, iodide of potassium will in some patients produce a violent coryza, or a copious eruption, which will, in some instances, be an acne, and in other cases a bullous rash. Common articles of diet will produce all the symptoms of a virulent poison in certain individuals. I may allude to hay fever, to the influence of mercury, the action of the balsams as parallel examples of a peculiarity of constitution which at present we are unable to discover by any outward sign, such as peculiarity of structure.

By diathesis, I should indicate a tendency to a certain and fairly regular series of manifestations, which is coloured by the bias of a morbid state—for instance, we speak of a scrofulous diathesis, or a gouty diathesis, by which terms we mean a sequel of morbid states which we recognise readily, and we are able to associate certain peculiarities of structure which accompany these well-marked constitutional states. I have ventured to attach the words eczematous diathesis to a group of patients which constitute such a very large number of those who come before us for aid. The following picture will indicate the type which I have before me.

A patient usually springing from parents who are the subjects of one of the forms of constitutional skin disease is in early life prone to chilblains, to a catarrhal condition of the mucous membranes, and to the advent of some form of irritation of the skin during cold weather; sometimes the skin is also irritated by excessive heat. Their skins are also made very pruriginous by the bites of insects, by east wind, by coarse soaps, and even by hard water; in point of fact, there is not a limit to the trivial irritant which will not be sufficient to bring out the proclivity which they possess. I know of an instance where the skin of the face is so exquisitely impressionable that the rays of light will bring out a copious vesicular eruption on exposure. It is not, however, the cutaneous area alone which so easily loses its physiological balance, but the mucous membranes are just as easily disturbed. It will be found, I think, that these patients take cold easily, they are prone to gastritis, and enteritis, and cystitis. They often present a severe form of conjunctivitis, and as age advances they become arthritic. Their physical peculiarities are a tendency to turn grey and become bald early in life, to have teeth which degenerate early; sometimes the incisors are pitted, or marked transversely; they wear down, and fall out in some instances in a most unexpected way. The nails are also of great interest in these patients, and present many forms of malformation—in some instances they are marked by white spots, or white transverse lines, or they are pitted with small circular depressions, or they are marked by transverse furrows; the longitudinal flutings are exaggerated in others. The shape of the nail is also of importance: it is often flat, sometimes even concave on its upper surface, and is frequently shaped like a shield; and they are often the subjects of early fatty degeneration of the cornea constituting

the state which we recognise as arcus senilis. A moment's reflection will enable us to recognise at once that all the manifestations which I have enumerated are due to a physical peculiarity in the structures of epiblastic origin. It is not possible to indicate with any precision what this morbid state exactly is; we can only say the epithelium is not capable of resisting external influences. Fortunately there are many human beings who pass through life with epithelial structures which are not vulnerable to the influence of such an irritant as the east wind; on the other hand, there are very many whose skin and mucous membranes assume a pathological state on the least provocation. Is it not strange that ordinary chicken-pox will, in some children, leave behind it ulceration of the vesicles which may last for many months, and some cases are on record where a gangrenous process has been established in these spots and the patient destroyed by the morbid process? Is it not a striking but well-known fact that in some skins a mustard plaster, or the rubbing in of a linament, will establish an eczema, which will spread with great rapidity to the opposite limb, and spread in a manner which is certainly not by continuity of tissue?

It is this difference in structure which accounts for the fact that in some children ringworm has a vesicular edge, whilst in other cases it is most certainly not the case.

There are many degrees of this tendency to break down in the epithelial structures, and this is why eczema presents so varied a canvas, and this is why we have such names as eczema impetiginosum eczema siccum, eczema rubrum, and pityriasis rubra—each one of these are precisely similar in their ætiology. They are all due to a badly-formed and brittle epithelium.

If we examine our patients carefully I believe we shall find that all the cases of obstinate ulcers of the legs, and many other equally troublesome affections, such as chronic discharges from the urethra, pruritus ani and pruritus vulvæ, ulcers of the os and cervix uteri, occur in those who present other evidences of an unstable epidermis.

I have been seeing during the last few weeks several cases of an affection of the face which is usually known as relapsing erysipelas, which displays an erythematous condition of the bridge of the nose spreading with more or less symmetry over the malar bones and going to the ears, is associated with a good deal of œdema of the parts and much smarting pain; the redness occurs in patches which are quite separated from each other, and which are not in all cases blistered, neither is the line clearly marked between the sound and diseased tissue, and what is most important there is very little, sometimes not any, elevation of temperature. These cases relapse very many times, and they often leave behind them for a long time a clumsy look about the features which constitutes a state differing in no way from elephantiasis. The point of interest to me is that all these patients present other evidences of badly built-up epithelial structures. A case I saw the day I wrote this page has deep clefts behind each ear, very badly formed nails, and a most susceptible bronchial mucous membrane. I may add that on two occasions a visit to Cromer has apparently induced an attack.

It is of importance, in treating of this diathesis, to recognise the fact that eczema has some peculiarities worthy of note. I should say my notes would indicate that anything approaching to a general eczema is only found in young children or in those who have passed the middle period of life. This fact is probably due to the feeble resisting power which the skin and mucous membranes have during the period of growth and the period of degeneration. Is it not true that the young and the aged are those who are the most liable to bronchitis?

During the middle period of life in those who have an eczematous tendency the disease is much more local. The patches of eczema which we see, especially about the hands and wrists, but not by any means confined to these positions, do not assume large proportions. The forms of eczema which we see on the scalp, on the outer aspects of the arms and legs or between the scrotum and thigh, or in the flexors, do not become universal, probably because the epithelial structures are more stable; and does not this help us to understand how it is that epithelial cancer occurs at the latter end of life when degeneration of tissues is going on?

The eczematous process has always a tendency to perpetuate itself, and the longer the time which has elapsed since its origin so much the more will our difficulty be in stopping the action.

We must not omit to allude to the power which some drugs, notably mercury and opium, have to induce an eczema in those who have the diathesis we are discussing. Some articles of diet have the same influence, notably malt liquors and port wine. A patient of mine in the British Museum assures me that salt beef will invariably produce an eczematous process in the clefts of his fingers, where I have treated him many times for an acute eczema. This is an example of the habit which tissues have of taking on an eczematous action which have before been similarly affected. I think there is a great deal in the doctrine that the epithelium throws off morbid products. All the exanthemata are associated with manifestations in the skin and mucous membranes. Syphilis, one of them, in no way breaks the law. Mercury produces stomatitis because the cells break down under the strain of endeavouring to throw off the drug, and I suspect that many of the cases of sudden outbursts of eczema are due to the epithelial structures endeavouring to eliminate the uric acid compounds. The kidney certainly does so. The synovial membranes of the joints, which consist of a basement membrane and epithelium, would seem to be irritated by this effort, and this irritation induces a synovitis. The same line of reasoning would explain the attacks of bronchitis which gouty patients so often suffer from.

I would ask, in conclusion, to be allowed to express my belief that many more of the skin rashes will be best explained by recognising the fact that there is in them all an inherited want of stability in the epithelium. The laws of inheritance are still obscure, and after careful recording and reflecting over many notes of cases, I am still unable to postulate what eutaneous manifestations will ensue in the offspring of parents who may be the subject of some form of skin disease. I know eczematous parents with psoriatic children, and I know of psoriatic parents with eczematous children; and I see several members of the same family with different forms of skin manifestations.

The group of symptoms which I have endeavoured to picture are in many respects similar to those which Hardy designated dartrous, and which the older writers speak of as herpetic.

---

A WELL-DESERVED REWARD.—The Secretary of State for War has sanctioned the payment of a gratuity of six months' pay to Surgeon J. Magill, M.D., Coldstream Guards, in consideration of the wound he received in action at Abu Klea on January 17, when he was in charge of the Guards Division of the Camel Corps. It has been stated that this officer, after being struck, actually removed the bullet from the wound himself during the progress of the action.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### NORTH-EASTERN HOSPITAL FOR CHILDREN.

#### NEUROMATA IN CONNECTION WITH THE MEDIAN NERVE.

(Under the care of Mr. GODLEE.)

JAMES S., aged 7 years 10 months, was admitted on February 2nd with a tumour of the palm of the hand, which the child had first noticed about one year ago. It had never caused him any inconvenience, or trouble at any time. He could give no reason for its presence: it had remained quite stationary in size.

On admission he was a well-nourished boy. There was a circumscribed, semi-fluctuating tumour apparently beneath the palmar fascia of the left hand, on palpation conveying the idea of a palmar ganglion; its contents could not be emptied, nor could the tumour be diminished in size on pressure. Manipulation produced no pain; sensation was normal; there was no unnatural pigmentation over the hand, and no pulsation.

Under an anæsthetic Mr. Godlee cut down on the tumour after an Esmarch's bandage had been applied. The incision was  $1\frac{1}{2}$  inches long, in front of the annular ligament. It exposed what appeared at first sight to be, as had been expected, a fatty tumour; it bulged into the wound, and on the surface was easily isolable. But on endeavouring to separate it above it was found to have a thick pedicle, coming down from beneath the annular ligament, while below it gave origin to numerous thick white cords, the much hypertrophied branches of the median nerve to the thumb and index finger. It was thus clear that the tumour was intimately connected with the median nerve, in fact it appeared to be little more than an enormous hypertrophy of the fibrous elements of the nerve. An endeavour was made to separate the mass from the nerve, and a considerable portion was removed, but at the cost of dividing one or two of the thick cords passing to the fingers. Ultimately a considerable portion of the mass was returned into the wound.

The wound, which was treated antiseptically, healed without the slightest trouble, and the boy left the hospital ten days after the operation. He attended from time to time, and beyond some slight numbness and anæsthesia in the thumb and index finger, suffered no ill effects from the operation. The numbness was less than had been anticipated, and confirmed the idea that the nerves cut were very much hypertrophied, and thus less important branches than they appeared to be.

Remarks by Mr. GODLEE.—The case is placed on record as one of considerable rarity and of difficult diagnosis. I confidently expected to find a lipoma beneath the palmar fascia, and am unaware of any previous record of a similar condition.

---

MR. ERNEST HART has just issued his address to the electors of the Mile-end Division, and after promising to devote himself to all measures of Liberal reform, the candidate states that he intends to establish centres in the borough, so that he will be able personally to attend and answer all questions.

# Medical Times and Gazette.

SATURDAY, AUGUST 29, 1885.

THERE is little, if any, real diminution of the cholera in Spain as yet; the daily official returns do not often show fewer than 5,000 fresh cases or less than 1,500 deaths. During the first three weeks in August more than 100,000 cases were stated to have occurred, of which some 36,000 odd proved fatal. The epidemic appears to have been particularly severe in Granada, whence most pitiable details reach us. From 200 to 300 deaths are daily occurring there; in some streets as many as a hundred persons have been attacked in a single day, and sometimes everybody in a house has been carried off by the disease. At Marseilles the disease is steadily gaining ground, and in place of the twenty deaths a day which we had to chronicle a week ago there are now from sixty to seventy or more; the cases are said to be of a very malignant type, the stage of collapse supervening even before there has been any diarrhoea or vomiting. The arrangements for the admission of patients into the Pharo Hospital are exceedingly unsatisfactory, and much valuable time is wasted in complying with a lot of vexatious regulations before the unfortunate patient can be received into the hospital. The death-roll at Toulon is rapidly increasing. Dr. Ferrán, unabashed by the treatment he has received at the hands of the Paris Academy of Medicine, offered to place his services at the disposal of the Marseilles authorities a few days ago. There can be little doubt as to what the reply will be, though we have not yet heard that it has been actually given. Koch is sending a representative to Marseilles to carry on investigations.

WHEN will the French, Italians, and Spaniards learn that it is by cleanliness in their homes and streets, by better arrangements for the removal and disposal, not necessarily through sewers, of excreta and slops, and by purer water supplies, that cholera is to be kept at bay, and not by quarantines of a character to paralyse commerce, and sanitary cordons which have no other effect than to aggravate the misery of the poor? The climax of absurdity seems to have been reached when, in the height of the epidemic, while the towns of Andalusia are being decimated by cholera, a cordon is placed by the Spanish Government around Gibraltar, because a few cases have occurred there, evidently imported from the mainland, and when Italians denounce England as a standing danger to Europe for her neglect of quarantine at home.

BUT in each country a few voices have been raised on the side of common sense. In Portugal, Dr. Dacunha Bellem, who took so prominent a part in the Medical Congress in London in 1881, has spoken out

in no uncertain sound. In France, Dr. Daremberg, writing to the *Debats*, denies that the epidemic at Marseilles is the result of importation from Spain, pointing out that thousands of refugees have crossed the frontier without carrying the disease to Paris and other parts of France. Marseilles is by no means the most likely destination of such persons, though it might be of Italians, and it is beyond doubt that the present epidemic is but a resuscitation of that of last year. Imported then, cholera has found in that den of filth a congenial home. Dr. Brouardel, one of the most eminent and judicious of French sanitarians, has depicted the gross violation of every rule of health and decency in graphic language. Stagnant and pervious sewers in some parts, and open gutters doing the duty of sewers in others, polluted water, and pestilential odours. *Ex uno disce omnes*: he describes one house with 700 occupants, two staircases down the wells of which the lodgers from the fifth to the first floors throw all their refuse, even putrid fish, and the ejecta of the sick to form in the basement a seething hot-bed of putrefaction, which is only removed when it has attained the dimensions of an ordinary cart-load. The pail system, which works so well at Birmingham and others of our northern towns, would meet the evil pending the execution of proper sewerage works, if it did not render them superfluous. But it will scarcely be believed, the police regulations do already impose the use of pails and their daily removal by the scavenger on all houses unprovided with water-closets; the law exists, but householders and local authority alike are too apathetic to enforce it, so slops of all kinds, with solid as well as liquid excreta, are still poured out on the surface of the roadways under a hot autumnal sun!

IN Naples, efforts have been made to introduce a better water supply, the immunity from cholera enjoyed by Rome having been so clearly due to the purity of its waters, the only sanitary condition in which it had any advantage over other Italian cities. In all other respects Naples remains what it was last year. Improvement schemes were invited, and numerous plans sent in, but the Municipal Council were under the necessity of rejecting them one and all, since though drawn up regardless of cost, and calculated to make Naples one of the grandest cities in the world, they left out of consideration the poorest quarters, and those in which improvement was most needed.

IN Liverpool grave anxiety is being maintained by the continuance of the dry weather. At this time last year the stock of water in the reservoirs amounted to two thousand million gallons. It is now only seven hundred and thirty million gallons. The average daily consumption in the city is nearly eighteen million gallons; and in consequence of the alarming prospect before them the Authorities decided on Monday to restrict the supply to six hours per day. It is to be hoped that this may prove the only serious inconvenience which the population may have to suffer; and that the warning which such a state of things embodies—one to which we have called fre-

quent attention—will not be allowed to pass unheeded by other places which may for the time being happen to be more fortunately situated.

It is somewhat remarkable that though the opponents of vaccination are loud in their assertion that in sanitary improvements we have the best or only protection against small-pox, Leicester, the head-quarters of their party, should year after year show a death-rate which is higher than that of any town of its size and population of like character, and highest at the very time of year when insanitary conditions come most into play in determining the mortality, though it cannot plead in extenuation a vast aggregation of the very poor as Glasgow and two or three other of our largest towns can with more or less justice. A week or two ago, we noticed that the death-rate of Leicester was no less than 32·2, a figure surpassed only in the lowest and poorest quarters of Salford, Manchester, Liverpool, and a few others, while that of Wolverhampton was only 13·2. As usual, it was to the deaths from diarrhoea in infancy that much of this was due, and if reform, like charity, begins at home, it behoves the Radical party, who in Leicester form a larger majority of the electors than they do in Birmingham itself, to bestir themselves in earnest, to put an end to this annual "slaughter of the innocents."

THE return of the Registrar-General for London last week, shows that there was one more death in the metropolis than during the previous week. The deaths under the head of zymotic diseases show a

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eleven weeks.

very distinct fall, being in fact 94 below the corrected average. There were only 5 deaths from small-pox,

and the number of cases under treatment continues to decrease in a satisfactory manner. Whooping-cough caused 43 deaths and measles 38, scarlet fever and diphtheria reckoning 12 and 13 deaths respectively. The deaths from diarrhoea, which were 222 last week, fell to 163, being 50 below the average for the week. This, no doubt, may be attributed in great measure to the weather, the mean temperature for the week having been 58·2, the sun only putting in an appearance for some nineteen hours. The deaths of nine women were recorded as due to puerperal fever, and eight infants lost their lives through suffocation. Preston suffered the most severely of the 28 large towns from diarrhoea, 32 deaths being there recorded, which sent up the zymotic death-rate to 13·5; diarrhoea also proved very fatal at Liverpool, Birmingham, Sheffield, Manchester, and Salford.

THE return of the Registrar-General for England and Wales for the second quarter of this year shows a total of 132,202 deaths, giving a death-rate which is 0·9 below the average for this quarter in the preceding ten years. The highest county rate was reached in Northumberland, viz., 23·7; the lowest, viz., 14·8, was in Sussex. The death-rate in London was 19·3, whilst in Manchester it was 29·5, and in Newcastle 31·8. The mortality among infants under one year of age was 4·7 per cent. above the average. The deaths from measles reached the large total of 4,391, giving a death-rate which was 0·21 per 1,000 above the average, whilst, on the other hand, the deaths from scarlet fever only numbered 1,288, giving a rate 0·32 below the average. Of the 1,186 deaths registered from small-pox, 1,008 occurred in London or the immediate neighbourhood. The proportion of uncertified deaths was 3·4 per cent., whilst in Wales alone it was 8·6 per cent. In London this proportion was only 1·1 per cent., whilst in Hull and Halifax it was 6·3 and 6·4 per cent. respectively; in these calculations inquest cases are excluded. During the quarter under consideration the weather maintained an average level. The mean reading of the barometer was slightly below the average, whilst the mean temperature was a trifle above the average, and the rainfall was almost identical with the average amount. The total amount of sunshine recorded at Greenwich was 524 hours which exceeds the amount in any corresponding quarter on record.

FROM the return of the Registrar-General for Scotland for the second quarter of the present year we gather that the general death-rate was 19·3 per mille, a trifle below the average for the past ten years. It is worth noting as a curious coincidence that the death-rate in England and Wales during the quarter was also 19·3, whilst in Ireland, as we stated the other day, it was 20·5. The average daily number of deaths was 217 for April, 200 for May, and 203 for June. The reasons for this must probably have been accidental; at any rate, that the weather had nothing to do with it is proved by the fact that diseases of the respiratory system caused a somewhat larger number of deaths in May than in June. Moreover, May is described as having been cold, wet, windy, and afflicted with a barometric pressure only once before (in 1878) excelled

for lowness ; the mean temperature, too, was only once lower, viz., in 1869, whilst the number of rainy days has never, so it is stated, been equalled before in any month of May. June, on the other hand, was dry and windy with a high barometric pressure and very large barometric range ; the rainfall was only one-third of the average amount, and excepting last year was the smallest on record. A more careful examination indicates that the chief cause of the increased deaths lay in the zymotic diseases, including thereby diarrhoea and dysentery. Of the eight principal towns Glasgow heads the list with a general death-rate of 25·0 per 1,000, Paisley running it close with 24·8, whilst Leith has the lowest death-rate, viz., 15·5. Small-pox, we are glad to see, finds no place amongst the causes of death, whilst measles caused 204, scarlet-fever 74, and whooping-cough 290 deaths. There were 52 deaths from diphtheria and 59 from enteric fever during the quarter. We are glad to see that the plan has been adopted of furnishing some registrar's notes at the end of the report ; the only fact of interest we glean at present is that centenarians are far less common than in the sister isle, the death of only one being mentioned.

A REPORT has recently been made by Mr. R. D. R. Sweeting to the Local Government Board, in connection with the prevalence of diphtheria in the Farnham Registration District during 1884. This district, which includes the Aldershot Urban Sanitary District, has a total area of 41,215 acres, and sustained in 1881 a population of 40,395 persons. For the five years 1880 to 1884, the total deaths from the seven principal zymotic diseases numbered 447, and of these 114—or more than a fourth of the whole—were due to diphtheria : these again, almost all occurred in 1883 and 1884, the total deaths from this disease in the latter year being more than double those recorded in 1883. The drainage and other sanitary arrangements appear to be very defective throughout the whole district, and the sanitary by-laws are obsolete or inefficient. Cess-pits and privies of the worst construction, usually so placed as to make probable the contamination of the shallow surface wells on which a large proportion of the inhabitants depend for their water-supply ; drains, where such exist, often leaky, draining into open ditches and water-courses, and inadequately flushed, the use of the more imperfect form of hopper-closets—in many cases only hand-flushed ; a general absence of ventilation and traps to cess-pools, sinks, drains, and soil-pipes ; no sufficient provision for the removal of refuse and ashes, &c., and an inadequate water-supply constitute conditions which might be allowed to be favourable to the existence and spread of diphtheria, though the milk supply, and, generally speaking, school-influence are exonerated. Some of the defects mentioned are in process of being remedied. Mr. Sweeting considers that the local medical practitioners were both slow and reluctant to recognise the true nature and dangerous qualities of the throat disease with which they had to deal during the earlier period of the epidemic. In fact, 56 cases registered under such headings as "croup" and "laryngitis," should be added to the total of 115 deaths from diphtheria

recorded during the five years 1880–84. No system of notification of disease was prescribed, and no provision was made for isolating the sick when the true nature of the malady had been at length made out. A partial exception to this statement must be made for the South Camp at Aldershot, where a hut is utilized for infectious cases, but its position (surrounded by other huts) is objectionable, and a more suitable site is now said to be in course of acquisition. The disease would appear, in the first instance, to have spread from the South Camp (whither it might of course, be easily introduced from any part of England) to the contiguous town of Aldershot, whence its extension into the surrounding district "was greatly facilitated by its extremely tardy recognition ; by utter absence of attempt at isolating the sick . . . and generally, by complete neglect on the part of the sanitary authority of any serious step to deal with the epidemic."

RIPARIAN owners are proverbially bad neighbours ; the fact that the two ends of a bridge happen to belong to different states, has ere now been the starting point of an international quarrel ; and it is to be hoped that there are not many viaducts the two sides of which are in the hands of separate corporations, if the resulting complications are always so serious, and so tediously difficult of adjustment, as seems to have been the case in the matter of the now notorious Highgate Archway. The terrors of the neighbourhood were continuously exercised by the small urchins who were in the habit of choosing the ledges of its parapets for displaying their agility as precocious Blondins ; while as a resort of suicides it has rapidly attained a dismal fame second only to that of the Clifton Suspension Bridge, and from its greater accessibility has gained a much longer death-roll. For several years past, both the Hornsey Local Board and the Islington Vestry have been urged after every suicide from the Archway to take adequate measures for its protection ; and until a few months ago they had both declined to do so, on the ground, it is understood, that such measures would necessarily have the effect of "interfering with the view." The suicides all took place from the Hornsey side, and ultimately the Hornsey Board agreed, "because of the danger of pedestrians on the lower road being struck by falling suicides," to protect their side of the Archway, and the Islington Vestry was asked to co-operate by putting up an unclimbable railing on that side also. But this the Vestry, unmoved by the plea for uniformity, declined to do, reminding the Hornsey Board that the suicides had not been from their side of the arch at all. Then another suicide took place (there have been no less than five within the last eight months), and the Vestry reconsidered its decision. The Home Secretary also opportunely addressed a letter to the Clerk of the Islington Vestry asking to be informed what they proposed to do towards preventing the repetition of these catastrophes. Ultimately, a committee, after visiting the works in progress on the Hornsey side, recommended that a uniform railing should be erected upon both sides, the Hornsey authorities to carry out the work, and the Islington Vestry to pay one-third of

its cost, that being the proportion which Islington now pays, under agreement, towards keeping the Archway in repair. This will probably be accepted by the Vestry: though it seems that, in referring to this proposition, the Chairman of the Hornsey Board remarked that it would have to be seriously considered before the Board could accept it. We trust that the tender consideration already extended, on paper, to "the pedestrians on the lower road," will combine with some regard for architectural unity and the implied wishes of a paternal government to secure the neighbourhood against the perpetuation of a state of things which formed a serious reflection on the humanity of all concerned in its permission. The whole affair reads like some miserably tragic version of Tweedledum and Tweedledee. The Home Office is not without its value if it has awed the disputants into uniting for the protection of all classes of the way-faring public from the combined results of the laws of gravity and the eccentricities of suicidal mania.

A CORRESPONDENT calls attention to the large amount of harm which is often done by the exhibitions of needlework that are commonly held in connection with Church and National Girls' Schools during the earlier summer months. The stitching is often so fine, each stitch sometimes taking up but two threads of the delicate material, as to require very careful inspection for its recognition by adult eyes; and work of this kind must be prejudicial when carried on during the early years of life, when any tendency to ametropia is so easily increased and rendered permanent. As a matter of fact, girls of twelve or thirteen have been in the habit of sitting up until past midnight in order to complete their task in time; and not the least suggestive case is that of the exquisitely finished work of a youthful prize-winner of eleven, who was, however, excused from marking her exhibit "on account of bad eyes." It must be remembered that results of this kind imply long-continued labour in a more or less cramped position, and often under defective hygienic conditions, by young and growing children—in addition to the actual vision strain. Further, the children who engage most continuously in such work are the naturally delicate, quiet and industrious—those, in short, to whom more fresh air and exercise and less sedentary occupation are necessary. The responsibility of a competitive system which is cruel in its exercise and in its results out of all proportion to its usefulness or beauty, lies in the hands of the ladies who admire and require work of this kind at the hands of children, and who act as judges. Let them remember that the training which secures the highest success of this kind will not help a girl to be a better wife and mother, nor even a more useful nurse or lady's maid, if she has seriously impaired or spoilt her eyesight in the process. In the present day of sewing-machines Hood would probably not have been moved to write the "Song of the Shirt"; let us hope that it is nothing worse than want of thought which threatens to transfer an added burden from the woman to the yet weaker shoulders of the child, for we may then hope that the evil, once recognised, will not be allowed to continue.

SLEEPING draughts containing chloral hydrate are often prescribed with some alcoholic tincture or "concentrated infusion" as an adjuvant or flavouring agent. Under these circumstances it is usual for the mixture to separate into two layers after standing for some time. Mr. G. F. Markhoe, Professor of Chemistry in the Massachusetts College of Pharmacy, points out that this is due to the formation of chloral alcoholate in the place of the more soluble hydrate. Anhydrous chloral is a thin oily liquid which combines with water to form a crystalline hydrate, and which also combines with an equivalent of alcohol to form acicular crystals of chloral alcoholate which is much less soluble in water, has a more disagreeable taste, and acts more powerfully upon the system than the hydrate. The presence of the bromides of potassium or of sodium, or ammonium, while it does not appear to facilitate this decomposition, adds another element of risk; for if the solutions are at all concentrated, the separated chloral alcoholate rises to the surface of the liquid, and an overdose of the narcotic, more potent in quality as well as larger in quantity than was intended by the prescriber, may thus be administered to the patient.

MANY attempts have been made to overcome an almost fatal characteristic of iodoform—its disagreeable smell—without destroying the antiseptic virtues which it possesses. Surgeon-Major Oppler, of Strassburg, has just communicated to the *Centralblatt für Chirurgie* the results of some experiments in this sense, which seem to have solved the problem. He takes finely-ground coffee and mixes it with the iodoform in varying proportions; 30 per cent. of coffee almost neutralises the odour, while 40 to 50 per cent. completely destroys it. Mixed with iodoform ointment (1-10) in the same proportion, coffee quite deodorises it. A point of great importance is that coffee itself possesses great antiseptic power, and exerts no deleterious effect on the wounds. Thus, a smaller quantity of iodoform suffices, the disagreeable odour is abolished, and the occasional evil effects are done away with. Coffee has the power not only to arrest decomposition, but also to postpone it. Professor Lücke is of opinion that coffee-iodoform may answer well enough for outward applications, but that it is unsuited for the interior of wounds, as the coffee would be a foreign body and interfere with healing. The coffee, previously roasted, of course, must be ground into a very fine powder before the iodoform is added, and the two must then be intimately mixed. Time alone can decide whether this combination will secure a much-desired end; or whether, like peppermint oil, tonquin beans, tannin, peruvian balsam and other substances which have from time to time been tried, the iodoform will prove itself the stronger.

HOUSEHOLDERS can never afford to ignore the responsibilities which are entailed on them by the very advantages of modern sanitary methods. There are very few dwellings in which, at some point in their drainage system, the only provision against the "sewer ventilating itself into the house" consists in a water-seal two or three inches deep. The continual presence of a sufficient depth of water is entirely dependent

upon the regular use of the apparatus with which the trap is connected. If this sink, or closet, or lavatory basin, or whatever it be, remains unused for a comparatively short time during warm weather, the trap becomes unsealed by evaporation, or the seal, at all events, becomes so shallow, that it is insufficient to resist the pressure of sewer gas, which, rapidly bubbling through it into the house, soon completes its annihilation. In several instances which were observed towards the close of the two or three weeks of dry weather which prevailed in the earlier part of the year, cases of throat illness and of gastro-intestinal derangement were traced to this unsealing of lavatory and other traps thus defectively arranged, in houses which had been for a while comparatively empty; the diminished population had not been large enough, in fact, to keep all the sanitary appliances in regular and constant use. Of course, when the house drainage is arranged throughout on the best system, danger from this source is much reduced; and the weak points, which, it should be clearly understood must always exist somewhere, can be more effectually guarded. Most houses, however, fall far short of perfection in this respect; and it behoves the occupants to realise this and to act accordingly. While the family is away from home, care should be taken that all sinks, lavatories, closets, etc., and the outside traps and gullies beneath rain-water and bath-waste pipes, are periodically flushed with plenty of water at short intervals. When a house has been left shut up without a caretaker, or when about to inhabit a house which has been for some time unoccupied, it is even more necessary that similar precautions be observed for some days beforehand, while every door and window should be left open for as long as possible, in order to secure the beneficent disinfecting action of fresh air and sunlight. A good deal of the illness which is apt to prevail in the later autumn months might thus be avoided; and people would not so frequently be heard to complain that they and their families seem rather worse than better after the return from their holiday outing.

ANTI-VIVISECTION legislation in Germany has hitherto been of a mild and harmless type. Agitators have been temporarily stilled by the enforcement of regulations of a nominal character only. An edict lately issued in Austria, however, approaches the subject in a more vexatious manner, and enacts that experiments on living animals shall only be carried out in those medical institutes which have received the government license. Experiments in private laboratories are no longer to be permitted. Such a regulation does not by any means put a check upon the performance of experiments, but it does essentially interfere with the freedom of research which should be allowed to individual physiologists. Experimental research in other sciences than that of physiology is not of necessity precise and definite in the objects which it pursues, or in the methods employed by investigators. The most valuable lessons are taught by means of repeated failures, and there are probably many pioneers of scientific advancement now living, who, if compelled to carry on their researches in

public, would have shrunk before the temporary obloquy which such a series of failures might entail, and who would hence have never given to the world the results of their genius. Fortunately, it is out of the power of sensational legislation to bar the advance of knowledge altogether, and although the experimental physiologist is hampered by fanciful restrictions on every hand, the good sense of students and teachers may be safely trusted so to comply with the letter of the law that the onward progress of science shall not suffer.

WE hear that Jæger's chair of ophthalmic surgery in Vienna is likely to be given to Professor Fuchs, of Liège.

IN an age which is everywhere supplanting nature by art it is remarkable that infants are still allowed to enter the world after the old-fashioned inconvenient and painful method. It is a reproach to the profession that the remedy is to come from outside its ranks. The inventor of the "Human Parturient Machine," which is already provisionally protected, has been struck by the difficulty of child-birth amongst the women of northern countries as compared with the very trifling inconvenience which it causes to their sisters of Southern Italy and of tropical Africa. Confessedly lacking data to decide whether this difference is one of race, he finds sufficient evidence that it is largely dependent upon temperature. Also, since an unusually rapid and painless premature delivery occurred in a captive balloon one very hot afternoon during the last Paris Exposition; it is obvious that atmospheric pressure is an important, though hitherto neglected factor. Mr. John Bland therefore proposes to encase the lower part of the body of the parturient female in a strong air-tight box, filled with a hot-water cushion, two panes of glass, a thermometer, a manometer, and an air-pump. The hot water will secure a temperature "a few degrees above that of the interior of the womb." The air-pump is to effect "the reduction or entire removal of the pressure of the atmosphere" on the approach of a pain. The glass windows will afford facilities for watching the progress of events. Amidst other ingenious contrivances, too numerous to specify, provision is also made for filling the interior of the machine with gas or "with vapour of a composition similar to that used in the Ammoniaphone," or with an anæsthetic. "My machine," says the inventor, "is an attempt to surround the woman in labour with all the conditions most favourable to easy parturition. But," he adds, with a modesty not always found amongst inventors in our ranks, "as I am not a medical man, and as I have never even seen a birth, it is quite possible that I have omitted something essential." Perhaps he has. But beyond suggesting some further consideration of the principles of pneumato-dynamics before putting the machine into the market, we would only hazard the remark that the project does not appear to have been conceived quite in the same spirit in which the chemist's assistant labelled the mixture prescribed *pro re nata*—"For the thing that is born." Some consideration is due to the infant whom it is proposed to seduce into a torrid vacuum.

PROFESSOR HUMPHRY, in his oration before the Medical Society a few weeks ago, which has just appeared in a separate form, spoke very plainly upon the subject of gratuitous hospital work. "I must express the feeling," he said, "that it is not right or just that in this the wealthiest city the world has ever seen, and in this very wealthy land, so much of the time and energies—the best time and energies—of many of the younger members of our profession should be devoted to attendance upon out-patients of hospitals, and that so much of the time of a far larger number of the profession should be employed in the onerous and anxious duties of the poor law service with such an inadequate remuneration. For the sake of all concerned, reform is needed here." As regards the poor law service, there can be little doubt that these words of Professor Humphry's will meet with the emphatic approval of the profession. But the case of the hospital officers is a little different. We are met at once with an overwhelming financial difficulty. A man generally spends some ten or twelve years after entering as a medical student before he is elected on a hospital staff; his remuneration, therefore, if he is to be paid for his services, could not well be less than say 150*l.* a-year, with a possible rise to 400*l.* The full physician or surgeon must, of course, be paid in like proportion, and his salary, therefore, would range from 500*l.* a-year onwards. It is needless to say that none of the hospitals dependent upon voluntary contributions could for one moment entertain the idea of paying their honorary officers at even one-tenth of this rate. So long as our hospitals are supported solely by charity, and so long as the patients are treated free of expense, we believe that the medical officers must be willing to give their services gratuitously, and be content to accept as their reward the opportunity of being useful in their day and generation, both as regards the immediate relief they afford to their patients, and the share they may have in the great work of advancing knowledge.

THE news of the death of Dr. J. R. Wardell, F.R.C.P., at Brighton, on Friday last, after a very brief illness, will have been received by all who had the good fortune to know him with feelings of the deepest regret. Born at Pickering, in Yorkshire, Dr. Wardell was educated at a private school in Doncaster, and subsequently at the University of Edinburgh, taking his M.D. degree there in 1844. After having filled the posts of Assistant Pathologist and Resident Physician to the Royal Infirmary at his Alma Mater, he came to London and offered himself for a post at one of the leading schools. Failing, however, to obtain it, he settled down to practise as a pure physician in Tunbridge Wells. Here he rapidly gained the esteem and regard not only of his patients, but of his brother practitioners, to whom his quiet unobtrusive life and his kindly disposition naturally endeared him. Dr. Wardell was for many years on the staff of the Tunbridge Wells General Hospital, and at the time of his death was consulting physician to that institution. Of his numerous contributions to medical journals and periodicals, those on relapsing fever and the signs and treatment of pleurisy are widely and deservedly known;

he will also be remembered as the writer of the article on hypertrophy of the heart in Quain's "Dictionary of Medicine." Acting upon the advice of some of his best friends, he decided on retiring from active professional work to collect together some of his papers, and the result was a volume entitled "Contributions to Pathology and the Practice of Medicine," which was only just out of the publisher's hands when he was seized with his fatal illness. He died at the age of 65 years from acute jaundice, notwithstanding the most assiduous attention of his life-long friend, Dr. Withers Moore.

FROM the most recent American papers that have reached us, we learn that Sir James Paget and Sir William MacCormac do not fail to realise the gravity of the situation in America as regards the prospects of the Washington Congress. Private letters from them to friends across the water have been published, in which they strongly condemn the proposal to place restrictions upon those who wish to become members of the Congress. Sir James Paget goes further and adds his conviction that there will be few visitors from this country, if the arrangements as now proposed are carried into effect. Let us hope that this strong expression of opinion on the part of the President and Secretary of the great Congress of 1881, will succeed in bringing those who have assumed the management of the Congress of 1887 to their senses.

#### MEDICAL LYING.

THE Bishop of Carlisle, in his manly vindication of political veracity, has conceded to the medical profession a dispensation as regards truthfulness which it neither desires nor needs. "It is held," he says, in his letter to the *Times*, "and not unreasonably, that a medical man in certain critical cases may deceive his patient"; upon which we can only remark that cases sufficiently critical to justify any resort to deception have never fallen under our observation, and that it is a well-understood principle in the profession that a falsehood is never under any circumstances justifiable. We may go as far as to assert that a medical man, worthy of his calling, may pass a long and active life without once experiencing any difficulty in reconciling his professional duty to his sense of right, or any temptation to deviate from strict fact by a hair's breadth. That deep-rooted and instinctive principle of veracity in the human mind, planted there as some maintain by supernatural power, evolved there as others would have us believe by the observation through countless generations of the absolute and inexorable truthfulness of Nature in all her dealings, is fortified in medical men by their studies, which constantly bring before them the connection between error and misery and rectitude and well-being, and by their work also, which can only be successfully conducted on the basis of complete sincerity in the mutual communications between them and their patients. They become deeply convinced, not only of the moral dignity, but of the practical utility of truth. We recall a somewhat cynical epitaph on a man who, in the days before the invention of the ballot-box, had evidently anticipated

the advice now given by spiritual guides to our agricultural labourers, and which was to this effect :

“ Truth is indigenous in some,  
In others it will scarce take root,  
But he would never tell a lie  
Unless he fancied it would suit.”

But the verdict of the medical profession will be that even this cautious and discriminating fabricator was sadly at fault, and that a lie never does suit. It would, we imagine, be inclined to dispute Paley's famous dictum, that there can possibly be occasions when a man is not bound to speak the truth, and dispose of his constantly quoted illustration, by pointing out that if it were a universally understood rule, that a promise made by a man to a robber holding a pistol to his head is not binding, then no robber would think it worth while to exact promises under such circumstances. All robbers would then take more effectual guarantees for silence, and instead of holding a pistol to the head, put a bullet through the brains. And so with medical men, it is obvious that were it currently received that they are justified in deceiving in critical cases, as the Bishop of Carlisle opines, critical cases would have nothing to do with them, for sick men seek foresight and relief, and not dissolving views and expensive placebos. Any individual medical man who acquired a reputation for being skilfully deceptive in critical cases, would speedily lose not only his character, but his practice.

It is only, we presume, with reference to prognosis or predictions as to the issue of an illness that any question as to the justifiableness of deception by a medical man can possibly arise, and here there seems to be confusion between deception and professional reserve. A medical man, although bound to speak nothing but the truth to his patient, is not bound to speak the whole truth. To do so would often be impossible owing to the patient's ignorance, or undesirable owing to his temperament, and when a doctor sees that his forecasts would be misunderstood, or exert a prejudicial effect, he is perfectly entitled to keep them to himself. Even when directly challenged by a patient under such circumstances, he is in ninety-nine cases out of a hundred entitled to decline to answer, or to evade the question without creating any deceptive impression thereby, or to place before his challenger in guarded language the most favourable of several views that are present to his mind even although that view may not be the one which he is himself most disposed to adopt. A practitioner must allow for the personal equation in himself as well as in his patient, and recognising the restorative power of hopefulness, must not depress and perhaps injure the latter by his forebodings, which may be the offspring as much of a lugubrious and anxious disposition as of reasonable calculation. It is to be recollected that in prognosis medical men are dealing, not with accomplished facts, but with anticipations more or less uncertain, and that the real difficulty which they experience is not to deceive their patients but to convince themselves.

“ Our very fears belied our hopes,  
Our hopes our fears belied.”

Patients who seemed foredoomed to death recover miraculously, and those who were pronounced con-

valescent droop and die, so that extreme caution is necessary in medical prophecy, and culpability would attach to any medical man who gave premature or exaggerated expression to his own apprehensions. No doubt as medical science advances our power of precise prediction is increasing vastly, but with this our power of affording relief is also increasing, so that the cases in which a practitioner is confronted with the difficulty supposed by the Bishop of Carlisle are not of more frequent occurrence than they were. And when that difficulty does arise, when a case occurs in which prognosis seems certain, and in which a knowledge of that prognosis would in all likelihood be injurious, the medical man has simply to choose between two courses. He has either to decline to say anything or to tell the truth. He need never deceive by word or deed. And in a large majority of cases of this kind a candid statement of the truth is best. To that candid statement the patient, if of mature years and sound mind, is almost invariably entitled if he directly demands it, for it is what he is actually purchasing of his medical advisers. And by that candid statement he is often far less injuriously affected than it was imagined he would be. Sometimes it positively does him good. Under a knowledge of the inevitable, he becomes tranquil to a degree that was impossible while he was harassed by alternating hopes and fears, and instead of his days being shortened they are actually prolonged by the announcement which was made perhaps with so much dread and reluctance.

Honesty is the best policy in the long run in medicine as in all other branches of human affairs, and we are confident that the Bishop of Carlisle will not find in our profession anyone inculcating the sacred duty of lying either at the ballot-box or at the bedside.

---

#### THE REPORT OF THE COMMISSIONERS IN LUNACY FOR 1884.

THE thirty-ninth report of the Commissioners in Lunacy forms a bulky tome, the greater part of which is as usual composed of statistical tables and voluminous appendices. It might have been expected, in view of the recent agitation in the public press and the threatened reform in the Houses of Parliament, that some allusion would have been made to the impending changes in the constitution of their own body as well as in regard to the lunacy laws generally; changes, moreover, which were more imminent when this report was being drawn up than they are at the present moment. But there is no mention of them. This is the more extraordinary, as at the time the report was presented, the Government had expressed pretty plainly their intention of endeavouring to pass Lord Selborne's Bill, which was then before the House of Lords. Nevertheless, the fact remains that there is nowhere in the Report any expression of a feeling of “*morituri te salutant*.”

On the first of January this year, there was a grand total of 79,704 insane patients, of which 7,751 were classed as private patients, 71,215 as paupers, and 738 as criminals. The grand total represents an increase

over last year's return of 1,176, which is an increase very considerably less than in any recent year. The question might very fairly be asked, does this represent an actual increase in insanity? are we as a nation gradually presenting a larger proportion of insane persons? or is it merely that cases are now brought to light which in former years were not heard of? It would seem that the latter is the more true explanation, for we find that last year there was an actual decrease of 74 amongst the private lunatics, and of 6 amongst the criminal lunatics, and an increase of 1,256 pauper lunatics which was almost wholly due to the transfer of large numbers of this class from the workhouses in Lancashire to the Asylums. On the whole, the ratio of fresh admissions to population for 1884 is brought down to 4.95 per 10,000, which it is satisfactory to note is a lower ratio than has prevailed for the last ten years. The total proportion of lunatics to population at the end of last year was 28.98 per 10,000. In the thirty-eight statistical tables which they have embodied in their report the Commissioners endeavour to give all possible information respecting those under their care both as regards their numbers, calling, age and sex, state of life whether single or otherwise, the form of the malady, suicidal tendencies, &c. A careful analysis of the tables relating to the occupations of the patients would afford ample material for reflection for those who find time hanging heavily on their hands. Our own profession, as is well known, contributes largely to the ranks of the insane, and accordingly we find that about 1 in 700 of all the physicians and surgeons are insane, and the proportion of clergy is much the same, whilst that of barristers and solicitors is even higher still, about 1 in 500. But the most startling fact that a perusal of these statistics has revealed is the effect of the practice of the medical art on the female mind. At the census in 1881, there were 25 female practitioners, though doubtless the numbers have increased considerably since then. During the five years 1880-4, 8 were admitted as patients, and at the end of the latter year 3 remained under treatment. Should these statistics be corroborated by subsequent experience, the insanity of this class will become proverbial. The admissions during 1884 included 6,752 cases of mania, 3,587 of melancholia, 2,362 of dementia, 760 congenital cases, and 847 not classified under any of the above heads. Excluding the congenital cases, we have a total of 13,548, of which number 9,054 represented a first attack of insanity.

We hope that whenever the changes in the Lunacy Acts are made the new Board will have more power to enforce its recommendations than the present one has, for we note that it is stated that "the question of asylum accommodation for the County and Borough of Cambridge and the Isle of Ely remains in a very unsatisfactory state; the asylum is crowded, patients are boarded out, yet the Committee of Visitors do not appear to be alive to the necessity of active measures." If the Commissioners have really not more power than to make a feeble remonstrance of this kind, there is imperative need for reform. The particulars are given of the eighteen cases of suicide that have occurred during the year, all of which probably, and certainly most of them, would have been prevented by more

efficient supervision; it is but just to the medical officers in charge to add that in several instances they had given special injunctions in reference to those particular patients, but that their orders had been disregarded. The case of feigned lunacy which occurred a year ago, by which a young man was admitted into one of the metropolitan licensed houses and afterwards wrote a highly-coloured description of his experiences in an evening contemporary, was investigated by the Commissioners. They found that all his charges were more or less exaggerations, and that they were not sufficiently substantiated to justify them in taking criminal proceedings. An attendant who had been charged in the letter with "boisterous fun" was called upon to resign and left. The report concludes with a brief reference to some prosecutions for breaches of the Lunacy Acts, with the results of which the Commissioners with good reason were not wholly satisfied.

---

#### REGULAR HOURS FOR THE PRACTITIONER.

THERE are two errors which still flourish largely in the popular mind with regard to illness. One is, that medical men object to being called in to cases of trifling indisposition; and the other, that the doctor is of most use when the disease is at its worst. Add to these a flavouring of irresolution, and a little false shame and falser economy, with that pseudo-patience which prefers to "wait and see," rather than to act and know, and we have the explanation of the frequent neglect of valuable opportunities by our patients, and of much of the irregularity and uncertainty which makes our daily labours needlessly harassing. There are few practitioners who have their calling and the interests of their patients really at heart, who would not welcome a change in popular sentiment which might lead to their being summoned thrice on account of ailments quite amenable to simple domestic treatment, if, on the fourth occasion, their opportune arrival enabled them to avert a really threatened illness, or—as in the case of infectious disease—to take timely measures for the effective isolation of the sufferer. For the wise man knows, and even the unwise are made in time to feel, that its so-called trifles are the really important things of life—a truth which the apostles of preventive medicine are never weary of expounding. As to their art being of most use when the need of it *seems* greatest—when the neglected chill has developed a rheumatic carditis, or the unheeded fall has been followed by cerebral inflammation—they know that the truth is really the other way; that the greatest and most beneficent achievements of medicine and surgery are those which make least noise and attract least notice, because they consist in preventing changes rather than in undoing or in staying changes already effected. For the first mistake, medical men have themselves to blame to some extent; it is not rare for them to pooh-pooh passing ailments, and to complain that they have been called in needlessly. For the second, the public is chiefly responsible, but with much excuse, for in the height of illness, the doctor's is the only human aid available; and the consideration that he may and

often does do much to alleviate and to cure, obscures the fact that by simple precautions taken at the proper time, the danger and the suffering might have been avoided altogether. How many cases does the general practitioner know of, where slight illness complained of in the morning, has been borne throughout the day under the impression that it would pass off, or that if it got worse the doctor could be sent for, until as evening sets in, the advent of more urgent symptoms, and the prospect of a night of suffering unrelieved, terrify the patient or his friends into sending an urgent and immediate summons for the doctor, who now finds the patient past the point at which abortive treatment might have proved successful. It will be granted, then, that in the vast majority of cases it is to the patient's real and substantial benefit to consult his medical adviser on the earliest indications of even slight ill-health. With the wider dissemination of hygienic truths, and of the principles of preventive medicine, this rule is one which people would soon learn to follow in a reasonable spirit and with greatly increased advantage to both patient and practitioner. The latter—in whose interest, indeed, this is chiefly written—would find his work more in hand; he would feel that he was doing more for his patients than they would let him do before; he would find himself less driven towards the close of his day's work, would have less of the wearying night and late evening calls; and would thus be enabled to arrange for work and leisure in something like orderly sequence.

Surely such a change would be welcomed by the thousands of hard-working men, whose leisure is now practically useless to them, because it is cut up into separate quarters of an hour or so, and distributed hap-hazard throughout the day. There are plenty of men whose abilities rust and wither simply because they have not time to keep them polished and well exercised. What chance has such a man of doing continuous work with the microscope or in pathology for instance, so long as each of his patients knows that he can send for him at any time of the day or night, and that kindness, self interest, and custom will combine to secure a rapid response to the summons? All honour to the few whose dread-nought energy enables them still to keep some old hobby, some scientific pet, above the distracting currents of their daily avocation; but do not forget the many others who would have done as much if the trial had been a little less severe. Too often, as matters stand, it is only when a position and a competency have been won—and when youth's enthusiasm has paled its ineffectual fires amid grey hairs and presbyopia, when what was the special knowledge of the young man has grown antiquated or obsolete, when the hands have lost something of their cunning, and the mind something of its method—that leisure comes, or can be commanded, too late to be utilised.

If medical men would exercise something of the independence which is naturally assumed by the other professions, they would do much to lessen these evils, benefiting at the same time both their patients and themselves. Birth and death are not matters of human decree; accident and disease do not regard the clock-hands; time and season wait no man's appeal.

Yet there are numberless matters which might perfectly well be relegated to certain hours, but which are now done at any time that suits the fears, the fancy, or the convenience of their patients, merely because medical men allow themselves to be thus made use of. What we plead for is the establishment, as far as is possible, of more regular hours in the now too-extended working day of the general practitioner. Let it be clearly and generally understood that home patients can only be seen within certain fixed hours; and that a call away from home between certain hours in the evening and the early morning will entail a certain substantial increase in the fee; and we believe that the public would after a while, not only acquiesce and work with such a system, but would find that it redounded very considerably to their own comfort and material advantage. With certain special exceptions, such as those already alluded to, the patient would not only know when and where to find his doctor, but would be induced to seek his aid as early as possible, that is at the very time when it is of the greatest value; while the doctor would know when to expect his patients, and when he might reckon upon the leisure which could thus be better utilised to their benefit and to his own. That leisure he might plead for, not merely as some recognition of deserving toil ungrudgingly given and too often inadequately rewarded, not merely as one clause in a bargain for which he might fairly stipulate, nor as a bare necessity of existence, but as something essential to the best interests of all concerned. The system which our Transatlantic brethren have established in their large towns to the mutual interest of their patients and themselves, might fairly be accepted by us here. The only real obstacle lies in the promptings of a sordid self-interest and an unwillingness to work together for the common good on the part of certain members of the profession. Should this be allowed to triumph, and will their patients short-sightedly abet it?

---

## ESSAYS ON MEDICAL CLASSICS.

---

### X.—CONOLLY.

JOHN CONOLLY, whose services in connection with the rational treatment of insanity are still held in grateful remembrance, did not enter the profession till comparatively late in life. Born in 1794, at Market Rusen, he served as a militia officer for five or six years before he finally commenced the study of medicine at Edinburgh in 1818. His attention, however, had already been turned towards the subject of insanity by a visit to the Asylum at Glasgow when a boy; the impression thus made was subsequently deepened by the writings of Pinel and Tuke, and he chose insanity as the subject of his inaugural dissertation on taking his degree. Fixing on Chichester as his first field of work, he made the friendship of Sir John Forbes, who had just settled in practice there. The fact is important, as it served to introduce Conolly to literary work; for when, shortly after, Forbes founded the *British and Foreign Medico-Chirurgical Review*, Conolly became one of his most able contributors. Chichester, however, was soon left for Stratford, where Conolly passed some of the

happiest years of his life, busily engaged in private practice and in writing medical articles for Sir John Forbes' Review and for the "Cyclopædia of Practical Medicine" and articles on popular science for Lord Brougham. He seems also to have held the post of Inspecting Physician to the Lunatic Houses in the County of Warwick. In 1827 the Professorship of Medicine at the Institution now known as University College, London, was offered to him through the instrumentality of Lord Brougham; he accepted the post, but only held it for four years. He found a London life uncongenial to him, and, throwing up his appointment, returned to practice at Warwick. While in London he wished to give a course of clinical lectures on insanity, but his offer was declined, although of regular teaching on the subject there was then none. From the time of the opening of the large asylum at Hanwell, in 1831, he cherished the ambition of undertaking its management, and in 1839, on the post becoming vacant, he realized his desire. For the ten years that he held it he was most active and vigilant in performing his duties and in carrying out his plans of reform. For three years after ceasing to be Resident Physician, he held the appointment of Visiting Physician, but in 1852 his connection with the Hanwell Asylum practically ceased, and he henceforth confined himself to consulting practice. A few years later he had a slight apoplectic attack; his health and mental energy began to fail, and he died very soon after a second seizure in 1867. He helped to establish the British Medical and the Medico-Psychological Associations, and was one of the chief founders in 1847 of the Idiot Asylum, the second institution of its kind in England, now permanently established at Earlswood. His attempts to found a lunatic asylum in Middlesex for the middle classes were fruitless, but he subsequently succeeded in establishing one at Coton Hill, Stafford.

Conolly was well-known and highly honoured abroad as well as at home, and the University of Oxford bestowed on him the honorary degree of D.C.L. He had great natural talents, a calm philosophical temper, and a mind of high culture. Many distinguished men who knew him well, including his biographer, Sir James Clark, have borne witness to the charm of his personal character: he was cheerful and amiable, courteous and conciliatory in manner, and a true philanthropist, ever ready to take an active part in schemes of social improvement. He gained alike the love of his patients and the esteem of the profession. These qualities, combined with his strong convictions, fervent enthusiasm, and tenacity in carrying out his purposes, served to fit him pre-eminently for the task he set himself. His success in that work has won him a name that will last for ever in the closely linked histories of humanity and medicine, as that of the man who struck the heaviest blow against the old barbarous method of treating the insane, and who, in England, gave at once the strongest impulse to reform and the first pattern of the more enlightened treatment now theoretically, if not practically, in universal use. Though standing among the leading promoters of the reform he was not the first to bring it about. The change was very many years in progress,

and was effected but slowly and by degrees. The first steps were taken, as we have recently been reminded, by Pinel, who, at the Bicêtre in Paris, in 1793, released many patients from the chains by which they were constantly confined, an action realistically commemorated in the statue just erected to him. Pinel's action was followed up almost immediately by William Tuke in England, and the first stage in the reform may be said to close with the opening of the York Retreat in 1796. About this time, and soon after, many attempts were made, hesitatingly and on a small scale, to do away with mechanical restraints. Many large asylums were also erected in England, in a few of which there was some improvement on the old plan, but it was at Lincoln Asylum that mechanical restraints were first totally abolished. In 1821 Dr. Charlesworth, the Visiting Physician, first had his attention drawn to the injurious effect of restraint, and Mr. Gardiner Hill, the Medical Officer, suggested and carried out their abolition; so that he was able in 1838 to report that, so far as he was concerned, they had fallen into complete disuse.

Sir William Ellis, who resigned the superintendency of Hanwell in 1837, still used various appliances of confinement and coercion, though he introduced from Wakefield the practice of employing those patients who were able to work; but Dr. Millengen, who succeeded him, evinced no desire for reform. When Conolly was appointed in 1839, he had seen the milder treatment in use at Lincoln Asylum, and in after years he publicly acknowledged his obligations for what he had learnt there. Thus he came to Hanwell with the settled idea already in his mind that complete non-restraint was practicable, and he started with the firm intention of carrying it out. On his appointment he found 40 out of 800 patients under restraint; four months later the limbs of all were free. Though he encountered much opposition and misrepresentation, he was loyally supported by the magistrates who formed the Asylum Committee. Chiefly to give confidence to the attendants he often employed temporary seclusion for violent patients, but he never abused the practice. He found, as he had been led to expect, that greater supervision, together with occasional seclusion in the place of mechanical restraints, were followed by increased tranquillity and diminished danger. He states that he himself never received a blow all the time he was at Hanwell, that under the changed *régime* cases of furious mania became quite rare, and the improvements in the tranquillity and order, of the male epileptic wards in particular, since the change was almost inconceivable.

Thus, though he was not the first to dispense invariably with the means of restraint, he *was* the first to do so on a large scale. But in Conolly's mind, the phrase "non-restraint" meant a great deal more than the simple removal of chains, coercion chairs and strait-waistcoats. This was only the preface; the complete scheme went much further. To use his own words, "Non-restraint includes relief of the mind from the restraints of severity and unkindness, and the perfect protection from all neglect, and a never-failing attention to every particular that can remove mental excitement and prevent its return." To

carry out this ideal required much energy, but in the end it was accomplished. Conolly insisted that insane patients should be constantly watched by competent attendants, and treated invariably with patience, kindness, and gentleness; that asylums should be well-built, well-warmed, and well-ventilated, and kept scrupulously clean; that the inmates should be properly clothed, should have good, sufficient and regular meals, and that proper exercise (in the fullest sense of the term) and amusement should be provided for all who could be benefited by them. He was thus the first to organise a large asylum on the modern plan; his experiment was attended with convincing success, and there has been little need since of departing from the lines he laid down. In one or two small points, he perhaps carried non-interference rather too far; for instance, he was very averse to forcible feeding, and says (in 1846) that for four years he had not resorted to it at all, so that it is not improbable he may have omitted it on occasions when it was indispensable in the interests of the patients. With all his success he was not ostentatious, though with a just pride he said: "I feel grateful to God, who has entrusted me with duties that an angel might stoop to perform."

An adequate idea of what he did and of the views he held on the subject which most interested him, can be best obtained by a perusal of the writings he has left. He was equally eloquent with his tongue and his pen, and there could have been no better exponent of the doctrines he was anxious to make public. The subject is always one of the greatest interest, but it must of necessity appear to the most advantage when dealt with by the enthusiastic originator of the movement at the very time when it was being most actively and successfully carried out. The following are his works:—(1) An Enquiry into the Indications of Insanity (1830); (2) On the Construction of Lunatic Asylums (1847, reprinted from the *Lancet* of 1846); (3) The Treatment of the Insane (1853), with the annual reports of Hanwell Asylum while in his charge; (4) Croonian Lectures (1849); (5) Study of the Play and Character of Hamlet (1860); besides Clinical Lectures on Insanity (*Lancet*, 1845-6); Recollections of Insanity (*Medical Times and Gazette*, 1862); various papers in the *British and Foreign Medico-Chirurgical Review*, and *Journal of Mental Science*; some articles in the *Cyclopædia of Practical Medicine*, and a few small volumes published by the Society for the Diffusion of Useful Knowledge. His works on the construction of Lunatic Asylums and the Treatment of the Insane contain full details of his work at Hanwell Asylum; the smallest particulars that are of so much importance in the management of a large asylum are not overlooked, and all his remarks will be read with equal pleasure and profit by those who are familiar with asylum life, and by those who desire to obtain some acquaintance with it.

The "Enquiry into the Indications of Insanity," his *magnum opus*, is a charming specimen of elegant and refined English literature, and may be read more as a relaxation than as a study. Full of sound psychology, it has more in common with the classical periodical essays of the last century than with the tendencies to

excessive abstraction and analysis that have since come into vogue. The style is clear and dignified, the divisions of the mind and the terms used are exceedingly simple and practical, all pedantry and over-refinement being carefully avoided. Mental diseases more than any other department of medicine adapt themselves to literary handling. The author was anxious that insanity should be regarded as a natural phenomenon just like other diseases. He said, "Correct views of insanity are only to be obtained by a wider range of observation of the peculiarities of the mind than has commonly been thought necessary." So as the indications of insanity are chiefly shown by perversions of the intellect, he devotes most of his enquiry to an investigation of the nature of the intellect, and the way in which it operates. "Whoever aspires to anything like certainty of diagnosis, or to an enlightened treatment of insanity, and not merely as a trade, must at least make it the subject of careful study no less than disorders of any other part of the human economy." He first discusses the sound mind, defining sanity as "that condition by which an individual is enabled to judge well and to act well in all ordinary emergencies." After resolving it into its several faculties, he comes to the conclusion that insanity is due to an "impairment of one or more of these, accompanied with or inducing a defect of the comparative faculty"—a term that will be familiar to readers of Sir W. Hamilton's lectures. This definition of insanity is arrived at by analysing several cases which had deeply impressed him. Then follow chapters on "Inequalities of the Understanding which do not amount to Insanity"; "The Influence of various Stimuli"; and "The Modification of Intellectual Power and Activity by Disease." Many remarks attract attention, e.g.: "Accurate comparison, imagination and good memory are the great instruments by which greater intellects act on the mass of their fellow-creatures." "Education can give equality in the acquisition of the knowledge of other men; but the knowledge which has been said to be power, comprehends what cannot be taught, and what very few attain of themselves." In the final chapter on the "Duties of Medical Men," he lays down strict injunctions against confining patients in an asylum simply on the grounds of insanity, without considering whether they are dangerous to themselves or others.

The essay on "Hamlet" is a good piece of criticism, though it is not necessary to accept his conclusion that the subject of it was mad; for on a matter so much discussed, every one forms his own opinion. His descriptions of insanity in the Croonian Lectures and at greater length in the Clinical lectures reported in the *Lancet*, are, as pictures, most vivid and accurate. With the improved accommodation of lunatics, their habits and peculiarities could be better and more conveniently watched, and Conolly's descriptions are almost as complete and as exact as any that have appeared since. He gives his opinion of the value of the various kinds of ordinary medical treatment which he had fairly tried, but he continually demonstrates that no means are so efficacious in restoring sanity as the system of mental treatment of which he was the apostle.

## REVIEWS AND NOTICES OF BOOKS.

*Pathological Mycology: An enquiry into the Ætiology of Infective Diseases*; by SIMS WOODHEAD, M.D., and A. W. HARE, M.B. Pp. 119, with two Appendices and sixty Illustrations. Edinburgh: Young J. Pentland, 1885.—The authors of this little volume on micro-organisms have done a very great service in prefacing their work with the bold statement that the methods of research for micro-organisms are "extremely simple." Yet the impression is widely spread and deeply fixed that some very special training is required for the examination and cultivation of bacilli, micrococci, &c. We are certainly not aware that investigation of and for these differs very materially from that of any other form of research connected with pathology in requiring more manipulative skill. As a matter of fact, less manipulative skill is required than in the ordinary processes of histology. Certainly care is needful; but beyond that there is nothing very abstruse, and as care is a principal ingredient in the mixture known as success, it is not very wonderful that this universal requisite must have its usual share in a successful examination for micro-organisms. Yet if we were to believe some persons, nothing short of a few days residence in a continental town can impart the necessary afflatus, without which, to become a mycological expert, is a sheer impossibility. We have known men with the average amount of intelligence who have become suddenly infected with this microbial malady. The symptoms of this disease are, in the first place, the sudden disappearance of a person of ordinary modesty, and in the usual condition of average intelligence. After a period of one or two weeks he makes a sudden reappearance in his accustomed haunts; but now his features wear the self-conscious smile of superiority, and he becomes almost transfigured as he imparts the awe-inspiring revelation that he has been to Mycenæ, and that Agamemnon, who received him with great distinction, gave him a room to himself. Now, though we desire to express a very favourable opinion of this work, we cannot refrain from pointing out that though the authors state their endeavour has been "to place succinctly before the reader the methods employed in the examination and cultivation of micro-organisms, especially of those that are supposed to have any relation to disease, yet, their about-nothing-in-particular-and-everything-in-general introduction to the study of bacteriology occupies quite a fourth of the letter-press. It is that kind of work which nobody ever reads except, perhaps, the unfortunate reviewer, and which is usually known as padding. In this connection we may refer to the illustrations, which are on the whole very good, but in some directions are scarcely numerous enough, while in others—as, for example, division and inoculation of sterilised media—they are over-abundant. This might be termed padding by illustration. With regard to the text, we do not think it is as clear in all places as it might be, and we should like to ascertain the exact meaning of the opening sentence of paragraph 32, on page 46. This runs as follows:—"In many cases it is necessary to stain micro-organisms, as they exist in fluids which contain no albumen, and in which there is nothing that by the application of heat, alcohol, or bichloride of mercury can be rendered insoluble, and which, therefore, have to be stained and washed in such a manner that they are not removed from the slide or cover-glass during the process." This luxuriance of relatives induces us to ask which is which? We regret to see such a statement as occurs in paragraph 34, where we find that "some authorities" "even prefer Powell and Lealands  $\frac{1}{2}$  oil immersion to the Zeiss' glass." We have always understood that these English makers were unrivalled both as to quality and to price, and we should like to meet with any "authority" who thought otherwise. These few exceptions, however, do not detract from the general merits of the work, considered merely as an introduction to the study of mycology. As such we may recommend it, and we may part from it by again expressing the opinion that the authors have done a real service to the profession at large by enunciating such a common-sense dictum as that the methods of mycological research are "extremely simple."

*Our Dwellings, Healthy and Unhealthy*; by MRS. C. M. BUCKTON. London: Longmans, 1885, 8vo., pp. 153, with 39 illustrations.—A reprint of lectures originally addressed to the elder girls of the Leeds Board Schools, and illustrated by models not unlike the Sanitary and Unsanitary houses at the International Health Exhibition, except that they were portable, and represented a different class of houses, such, in fact, as are occupied by the working classes in provincial towns. The lectures, fourteen in number, treat in popular and easily intelligible language of the plan and construction, drainage, ventilation and warming, water supply and decoration, and furnishing of the house in general, and of that of the respectable artisan in particular. In place of the models which served for the demonstration of the lectures as delivered, we have in the book numerous well-executed drawings of the same, and of sanitary appliances, some useful and withal artistic articles of furniture, as well as plans of Bagshot House from Mr. Rogers Field's report, published by permission of H.R.H. the Duchess of Connaught. It would be superfluous to enter into an analysis of a book which does not profess to contain anything new or original. Suffice it to say that we have not been able to detect anything to which we could take exception, and that it would be well if not working men's wives only, but householders of all classes, would make themselves acquainted with its contents. We much doubt if, with the price of land in and near London, even a company could build such a house as Mrs. Buckton describes to let at so low a rent as appears to be possible in Leeds; but we would call the attention of the architect of this class of houses to her suggestion that there should be no fireplace other than that under the copper in the kitchen or scullery, so as to avoid the constant practice of a whole family crowding into a small kitchen for six days in the week, reserving the parlour, the best room in the house, for Sunday use and the entertainment of company. As might have been expected, especially in addressing a Leeds audience, Mrs. Buckton borrows much from Mr. Pridgin Teale. Nor does she neglect "sweetness and light" in an æsthetic sense in her hints on decoration and furniture, showing how artistic appearance may be compatible with usefulness and economy.

*The Science of Change of Air*; by DAVID S. SKINNER, M.D. Brussels, Fellow of the Royal Meteorological Society. Tinsley Brothers, 1885, pp. 62.—It is not usually difficult to define the objects kept in view by the writers of monographs with attractive titles. In the present case we must confess ourselves puzzled. No original researches are ventilated herein, whether for the author's relief or for the public's enlightenment. It is not a popular rendering of well-known facts, since it is written in a style in which technical expressions are so largely made use of, that no lay reader could make any sense out of it. As an exceedingly simple and superficial comment upon certain well-known passages quoted from old editions of students' textbooks, it is not likely to appeal to the medical reader. Probably every qualified medical practitioner has, or thinks he has, an equal right to make brilliant speculations, founded on such hypothesis as to the influence of ozone and electricity upon the human body. Although we sincerely hope that the sale of the work may compensate the author and publisher for their outlay of time and money on it, we cannot honestly recognise it as a contribution to the advancement of medical or meteorological science.

*Handbuch der Gerichtlichen Medicin (Manual of Forensic Medicine)*; by Dr. HERMANN KORNFELD, Grottkau. Stuttgart: Ferdinand Euke, 1884, pp. 610.—This work has been undertaken by its author with the view of elucidating more clearly the legal aspects of what is generally included under the term medical jurisprudence. Mindful of the significance of his title, the writer has evidently endeavoured to keep the style of his book to the level of a "handbook," but his subject would seem rather to have run away with him and expanded the completed work to proportions more suited to the desk than to the pocket. In their general arrangement the subjects follow

much the same order and division as obtain in the English works of the same class, the most noteworthy difference being in the addition to each section of a reference to the French and Austrian laws relating to them. Especially interesting on this account are the chapters relating to the administration of impure drugs, and of adulterated articles of food. The necessary limitation of the scope of the work, however, leaves too little space for a thoroughly satisfactory reference to many points like these. The section relating to the medico-legal aspects of epidemics, is for the same reason hardly comprehensive enough to render the reader independent of the larger text-books on the subject. The chapters on poisons, although inclusive of a very long catalogue of poisonous substances, do not present many additions to the present knowledge of the subject, and in some few instances would admit of considerable improvement by the introduction of some reference to recent cases. On the difficult matter of sexual offences, the author speaks with an absence of reserve quite in keeping with the mode of discussing such subjects which has of late been so strikingly introduced into England, adding at the same time a good deal of minute information on these points, the scientific value of which is not immediately apparent. Taken as a whole, however, the work discusses the subject with which it deals in a manner presenting many points of practical usefulness, and is especially to be commended to those who find interest in the study of international methods of medico-legal practice.

*Overzicht van de wisselende Chemische Samenstelling en Pharmacodynamische Waarde van eenige belangrijke Geneesmiddelen* (On the Chemical Composition and Therapeutic Value of some Important Drugs); by Prof. C. P. PLUGGE. Amsterdam: F. van Rossen, 1885.—This work, by a professor in the University of Groningen, is somewhat of the nature of Martindale's Extra Pharmacopœia, but it enters more fully into the chemistry of such drugs as it touches upon. English authorities and their researches are mentioned, but somewhat sparingly, e.g., Langley's Observations on the Action of Jaborandi on the Heart, and Tweedy's Paper on the Mydriatic Effect of Gelsemium on the Eye, are referred to, but there is no mention that we can find of Ringer's researches on Digitalis, Aconite, or Gelsemium; the action of aconite in fever is not even alluded to, and though several very rarely used, and, as far as we know, unimportant drugs, as thevetine, nigelline, dita, and cevadilline are mentioned, we look in vain for nitrite of amyl or nitroglycerine, and the researches of Lauder Brunton, Murrell, and others, upon them. At the end, a valuable comparative table of many important preparations, according to all the different pharmacopœias, except the Russian, is given. The work being in Dutch renders it unfortunately practically inaccessible to the profession in this country.

*Sixteenth Annual Report on the Health of Salford*; by JOHN TATHAM, B.A., M.B. Dubl., S.S.C. Camb. 1884.—Dr. Tatham's thorough mastery of the principles and practice of vital statistics, and clear apprehension of the many fallacies incident thereto, is a distinguishing feature of his reports, and gives them a special value. This year his introductory reflections on the constitution of the population as affecting the birth and death rates are more than usually instructive, and would well repay a careful perusal by other medical officers of health. Not that there is anything really new in them, but that few have made a study of a subject the principles of which must be gathered from the scattered writings of Rumsey, Noel Humphreys, Hampden Shoveller, Finkelnburg, &c. Thus Dr. Tatham suspects that the apparent decline in both birth and death-rate is due to an over-estimate of the population, a suspicion confirmed by the fact that with the increase of population assumed by the Registrar-General of 25,322 there was an increase of only 2,036 occupied houses. He denounces the notion that a high birth-rate necessarily involves a high death-rate, and quotes Mr. Noel Humphreys to prove that though the proportion of children is increased there must be in a few years a larger proportion of young persons of the

age when the death-rate is lowest, while the aged, who contribute a large number of deaths to the general mortality, are at the same time reduced; so that any unavoidable excess of deaths among infants is or ought to be more than compensated for at other ages. Compulsory notification of infectious diseases has been very successfully carried out in Salford, and their spread in schools thus prevented; no fewer than 1,300 letters giving such information having been addressed to teachers, and the attendance of children from infected houses prevented. There is happily a growing feeling among the poor in favour of the fever hospitals, to which 713 cases were sent in 1884 as against 366 in 1883. In view of the possible advent of cholera, Dr. Tatham, at a great expenditure of time and labour, drew up a map of the entire borough, dividing it into blocks or areas, the actual death-rates of each of which are indicated by figures, and the relative healthiness may be seen at a glance by the colours. Those having a mortality below 15 per 1,000 are left uncoloured, those with one under the general average of 25 are red, and those above it blue; a lighter or darker shade indicating a difference of 5 per 1,000. He has thus been able to call the attention of his Sanitary Committee to what he describes as the "black spots" of the borough, places where the death-rate rises to 36 or even 40 per 1,000, and where cholera if once introduced would assuredly find the most favourable conditions for its spread. The application of the Dairy, Cowshed and Milkshops Orders has had the effect of closing a large number of such as were unfitted for the purpose, as has that of the Bakehouses Act of last year, 24 out of the 83 having been in so unsatisfactory a state as to call for immediate interference, and 28 were closed during the year. The influence of illegitimacy on the infant mortality appears in Salford more marked than usual, the deaths during the first year of those born in wedlock being 167 per 1,000 for the year 1884, and 157 on an average of the preceding five years, whereas those of the illegitimate were 391 and 355 per 1,000 respectively. An analysis of the infant deaths from particular diseases or causes in the four registration districts is full of instruction, and we regret that we cannot afford space for it in full. Dr. Tatham's remarks on the duty of avoiding infection of scarlatina in early life, by isolation, notification, &c., well deserve consideration. "Admitting for the sake of argument the stock assertion of the anti-sanitarians—that scarlatina, *inter alia*, is an inevitable accompaniment of child-life—it should surely count for something, that by postponing the period of life at which a child is to have scarlet fever we are able to reduce the risk of his death . . . from the proportion of 1 death in about 3 attacks to 1 in 23 or 25." And in the same table he shows that the argument holds good for diphtheria. His table giving the distribution of enteric and scarlet fevers in each month bears out in a remarkable manner the conclusions arrived at by Dr. Longstaff. The remainder of the report consists of matters of local interest, or of such as do not differ from those contained in the reports of other medical officers of health.

## ABSTRACTS AND EXTRACTS.

WESTPHAL ON PERIODIC PARALYSIS OF LIMBS, WITH LOSS OF ELECTRIC EXCITABILITY.—A remarkable case of periodical paralysis of all the extremities is recorded in a paper by Professor Westphal, *Berliner Klinische Wochenschrift*, Nos. 31 and 32, 1885. The patient, a boy of 12 years, was under close observation for several months, during which he was subject to occasional attacks of absolute loss of power in the limbs, coming on almost always at night, lasting for a few hours and disappearing with a period of quiet sleep before the morning. His general health was good, and no signs of nervous disease could be traced in the case. During the periods of paralysis, however, the remarkable fact was observed that the nerve trunks and the individual muscles in the affected limbs had completely lost their electric excitability even under the irritation of a very strong current. At other times, the reactions were quite normal, but slight differences between the two sides persisted for some time after the complete return of volun-

tary movement. There was no sign of rigidity or contraction in any of the muscles during the attacks, nor was the general sensation disturbed. The plantar reflex was absent, but the cremaster and abdominal reflexes and the knee-jerk were normal. The latter was at times unequal upon the two sides. The fullest particulars of each seizure are given in detail in Dr. Westphal's paper. The progress of the paralysis of the limbs could be clearly described by the patient, who remained quite sensible throughout. In the early history of the case, there was reason to believe that scarlatinal nephritis had formerly been present, but the renal and all other functions remained normal throughout the period during which the patient was under observation. The onset of the attacks was attributed to exposure to a draught, the boy having complained the day before of indefinite sensations in the limbs, and pains in the feet. He became quite powerless in the following night, and suffered from great thirst, a feeling of extreme heat, and profuse sweating. At first the attacks of paralysis recurred at intervals of four to six weeks, but became more frequent, at last sometimes appearing many times in one week. In his remarks upon the case, Professor Westphal cites three other published cases as bearing some relation to this apparently unique form of paralysis. In all of them there were points of resemblance to it, although none could be said to be identical. Especially with regard to the periods of recurrence, there was a marked difference, as in two of them the attacks followed a regular quotidian or tertian course. In all the cases the paralysis began in the lower extremities. The muscles of the face and of the eye remained unaffected in all, nor was any affection of bladder or rectum observed. The loss of electric contractility and its rapid recovery are conditions apparently quite peculiar to Westphal's case. In relation to it he says: "We know of no disease either of the spinal cord or of the spinal nerves in which anything similar to it has ever before been observed; and as regards any explanation of it, physiology leaves us completely in the dark." The sensations of heat and the extreme sweating experienced by the patient suggest the possibility of some profound alteration of the vascular supply, and hence of the nutrition of peripheral nerve endings, but such an explanation is of necessity purely conjectural.

**SYPHILITIC PSEUDO-PARALYSIS.**—In the July and August numbers of the *Revue de Médecine* there are important articles on this disease by Mr. F. Dreyfous, who proposes with perfect justice to call it Parrot's disease, after the late M. Parrot, to whose labours we are indebted for all our knowledge of the disease. The symptoms are absolute loss of power with complete muscular flaccidity; the limbs only are affected, generally more than one limb; the disease is usually symmetrical, and is more common in the arms than in the legs. The muscles act naturally to the battery currents, and the cutaneous sensibility is unaffected. There is not much to be seen amiss with the affected limbs unless any of the joints or epiphyses should happen to be swollen. There is no fever, and the onset is quite insidious. Three clinical forms are described: (1) The paralysis appears as a manifestation of syphilis resembling a specific paralysis. (2) It appears as a consequence of an injury resembling a surgical affection. (3) There may be no obvious signs of syphilis, and it then resembles a case of infantile paralysis. The apparent paralysis owns two causes. It is partly due to the pain which is always present in marked degree on any attempt to use the limb, and partly to the actual changes that have taken place in the continuity of the bones, the epiphyses being invariably separated and suppuration common, but the joints themselves are never involved. To these two well-recognised causes M. Dreyfous adds a third: he suggests that there may exist a sort of reflex paresis consecutive to the injury, similar to some cases of muscular atrophy associated with joint lesions that have already been recorded. The diagnosis depends upon the age of the patient, this being a disease of early infancy, the pain, the fact that some power of movement remains in the paralysed limb, the swelling in the neighbourhood of the epiphysis, the general state of the patient and the family history, the two latter without much difficulty

supplying a history of syphilis. The prognosis is always grave, but much depends upon the surroundings of the patient and the period at which the disease is recognised. Whilst fully admitting the great value of these papers, we cannot accept all the author's conclusions. For instance, in our own experience we have found it much more common for one limb alone to be affected than for two, nor do we think that there is always or even often suppuration—that we believe must be exceptional. We should, too, be disposed to give a much more favourable prognosis than the author does, and under suitable mercurial treatment we are confident that in almost all the cases a speedy and complete cure results.

**THE INFLUENCE OF COCAINE, ATROPINE, AND CAFFEINE ON THE HEART AND BLOOD-VESSELS.**—There are few known drugs that have, within such a short space of time, risen from comparative obscurity to such practical as well as theoretical importance as cocaine. Its great value as a local anæsthetic, and its wide application in all the branches of medicine and surgery, together with our comparative ignorance in regard to many points of its action on the animal organism, are sufficient to attract attention to a valuable experimental paper on the influence of cocaine, atropine, and caffeine on the heart and blood-vessels, by Dr. H. G. Beyer, U. S. N., which appears in the July number of *The American Journal of the Medical Sciences*. Dr. Beyer finds (1) That cocaine is exceedingly prompt and uniform in its effects upon the heart; (2) in small doses it is a powerful stimulant to the heart's action; (3) in medium doses it has an inhibitory influence over the ventricular contractions; (4) in large doses it produces diastolic arrest, from which, however, the heart may be recovered under suitable conditions; (5) in small or large doses it produces contraction of the blood-vessels, independent of the central nervous system; (6) a rise in the blood pressure, consequent upon the administration of cocaine, is due to a direct action of the drug on the heart and blood-vessels, stimulating the former and constricting the latter; a fall in blood-pressure coming on after the rise must be accounted for by the action of cocaine on the heart alone, since its constricting influence on the blood-vessels outlasts the stimulating influence it exerts over the ventricle of the heart. (1) That atropine in certain doses increases the rate of beat of the heart and also the amount of work done; (2) that it exercises an inhibitory influence over the contractions of the ventricle; (3) that it first causes a contraction and afterwards a dilatation of the blood-vessels; (4) that cocaine acts on atropized vessels in the same way that it does on normal ones, e.g., it causes their contraction. That caffeine in small as well as large doses produces dilatation of the blood-vessels in the terrapin; any rise in arterial pressure due to caffeine is, consequently, to be explained only by the stimulating effect caffeine exerts on the heart itself.

**MANGANESE AS AN EMMENAGOGUE.**—Dr. F. Martin, writing in the *Chicago Medical Journal*, states that he has found from considerable experience that peroxide of manganese, given in capsules in doses of 2 or 2½ grains every four hours, is a very efficacious and prompt remedy in restoring tone when amenorrhœa is due to some previous depression of innervation. In young girls, when the irregularity of menstruation is due to the natural weakness of the partially developed organs of generation, or when from an overworked serous system the organs are robbed of their natural nerve force, this remedy seems to possess the stimulating properties required to bring them into healthy action. Dr. Martin has also found the remedy very useful in cases of menorrhagia, when this has arisen from anæmia or any depressing constitutional disease producing a perversion of the functional activity of the menstrual organs.

**HABITUAL CONSTIPATION.**—Professor Grasset, of Montpellier (*Semaine Médicale* No. 6), observes, founding his statement on the thesis of Dr. Eymeri, that the experiments of French observers have quite confirmed the value attached by the American physician, to the *cascara sagrada* (belonging to the family of *rhamnus catharticus*), which grows on the Pacific shores of North America, as a remedy

for habitual constipation. The dose is 25 centigrammes of the powder of the bark grain in a wafer; one dose sometimes suffices, but generally two, or even three, are required. Two or three solid stools are produced, but if the administration is then discontinued, the constipation will recur. To be effectual, the treatment requires to be persevered in for two or three weeks or a month. A dose of 25 centigrammes of the powder is given night and morning for a week, and then it is continued every other day, gradually diminishing the dose and increasing the intervals, until the stools are produced spontaneously. As far as yet tried, it would seem to be the most efficacious of remedies for chronic constipation.

**UNILOCULAR DIPLOPIA.**—At the recent meeting of the French Ophthalmological Society (vide *Bulletins et Mémoires de la Société Française d'Ophthalmologie*, 1885), Dr. Fontan brought forward a case of diplopia with one eye only. The patient was a lad of 14, who dated the affection, which was of some five months' standing, to a blow on the head. Viewed at a distance of one metre, an object gave two images one above the other, the lower one being the best defined and the smallest. The distance between the images increased in proportion as the object was placed further off. There was no scotoma. The diplopia persisted over an area extending for some distance beyond the macula, but in the marginal part of the field only a single image was perceived. A prism of 12°, placed with its base upwards and cutting the pupil in two, produced a third image. This fact Dr. Fontan considered very important, as if there had been any error of refraction quadriplopia would have resulted from this experiment, and not triplopia. There was no astigmatism and no ophthalmoscopic change, except a slight pallor of the disc. Besides the diplopia, there were other functional troubles, such as contraction of the field of vision, impaired colour perception and diminution of central acuity of vision, all pointing to some degree of atrophy of the optic nerve, to which cause Dr. Fontan decided to attribute the diplopia. M. Dufour, who took part in the discussion on this case, suggested that there might be a small rent in the iris near its attached margin, which would be quite capable of giving rise to the symptoms.

**PARALDEHYDE.**—Dr. Stallard, writing at San Francisco in the *Pacific Medical Journal*, states that having employed this substance 300 or 400 times, he is able to speak of its value in many cases in which opium and chloral are contra-indicated. In insomnia he has found it very useful in a 15 minim dose at bed time and repeated in an hour if required, which was usually not the case. Cases of cardiac asthma with insomnia, and of mild delirium from alcoholic excesses, are also referred to as greatly benefited by 20 minim doses. Mixed with mucilage also, and given as an enema, it acts very beneficially. It should be given in some form of alcohol, as whisky, flavoured by lemon. It produces no depression of the circulation, and never is followed by sickness, headache, constipation or anorexia. The effect which it produces is somewhat more permanent, than that of the more common ethers. In one case (in which the patient had taken half a dram for two nights), the odour in the breath was perceptible 15 hours after the paraldehyde had been taken. There is no difficulty in leaving off the remedy. Dr. Stallard has not used it for the relief of acute pain, for which it does not seem suitable, as the sleep produced is not very profound. "It seems to me," he says, "that it possesses all the advantages of moderate dose of chloral without its disadvantages, and I am satisfied that it is a very valuable addition to our list of hypnotics."

**BROMIDE OF SODIUM IN SEA SICKNESS AND THE NAUSEA OF PREGNANCY.**—Dr. Robins, writing to the *Philadelphia Medical News*, corroborates the statement made by another correspondent, that bromide of sodium is a useful preventive of sea-sickness; and, he adds, that in place of the large doses recommended, he has found that the best effect can be produced by the administration of small ones. About a week before the voyage has to be taken he gives the salt in 10 grain doses three times a day, reducing the quantity to 20 grains per

diem after the vessel has sailed. He also endorses Dr. Albert Smith's recommendation of this bromide in cases of nausea and vomiting of pregnancy, the severity of which is invariably modified, and in many cases the complication is removed. But here no smaller doses than 30 grains three times a day have succeeded. Of 21 cases in which Dr. Robins has employed the bromide, in 16 the nausea disappeared entirely, in 2 it persisted in a milder form, and in 3 was unaffected.

**DR. GALEZOWSKI'S POMMADE FOR ULCERS OF THE CORNEA** is composed of from one to two parts of porphyrised iodoform to ten parts of vaseline, which are then thoroughly mixed. It is recommended for herpetic and scrofulous ulcers of the cornea, and acts favourably in the ulcers which are developed in syphilitic subjects. It should be introduced within the eye several times daily. Besides the iodoform, it is very useful to have recourse to the instillation of a pilocarpin collyrium and douches of carbolic acid spray. Under this treatment, in fifteen or twenty days the ulcer is found to have become filled up with tissue of new formation, and cicatrization follows.—*Union Médicale*, July 9th.

**INTOLERANCE OF IODIDE OF POTASSIUM.**—In an article in the *Lyon Médical*, March 29th, M. Aubert calls attention to the utility of belladonna in enabling patients to take the iodide which without its aid proved in their cases not to be tolerable. Most persons on commencing a course of the iodide have some irritation in the throat and nose, coryza, or headache, but this is usually moderate and temporary, and does not prevent persistence in its employment. In a few cases, however, these symptoms acquire an intensity and persistence which renders the continuation of the remedy impossible. M. Aubert finds that a pill composed of 5 centigrammes of extract of belladonna given once or twice a day entirely removes this inconvenience, and enables the patient to continue the iodide, even in considerable doses. In some cases the belladonna may be suspended after a few days, but in others it has to be continued while the iodide is taken.

**BOROLYCEIDE.**—Dr. Mac Smith, of the German Town Hospital, Philadelphia, states (*Medical News*, June 6) that the boroglyceride has been employed there with great success. It is a marked hæmostatic, antiseptic, deodorant, and germicide, and prevents and arrests fermentation and putrefactive changes. When applied to wounds, mucous membranes, &c., there is usually experienced a smarting sensation, which quickly subsides; and it frequently renders a previously painful wound absolutely painless. If, after minor operations, the flaps be turned backwards, and a 25 per cent. solution applied freely, the edges of the wound being nicely coaptated, capillary hæmorrhage will be found to have been arrested and granulation promoted. Usually, union by first intention takes place. In an anaplastic operation this agent will be found invaluable. Chronic ulcers which have resisted ordinary treatment have readily yielded to applications of a 50 per cent. solution, being first washed with alcohol. Chronic suppurating buboes promptly yielded to the use of this solution. The boroglyceride, with carbolic acid, forms a useful injection in gonorrhœa and gleet; and when irritation has been produced by the passage of a bougie, sound, &c., it may be allayed by a weak solution of the boroglyceride. In gynecological practice the boroglyceride will be found of much value; and a tampon, moistened with boroglyceride, may be left for eight or ten days without being offensive. Most inflammatory affections of the skin, especially those of a burning or itching character, are greatly benefited by this agent. In cases of tonsillitis, pharyngitis, &c., a 50 per cent. solution, diluted about one-half with water, and with the addition of carbolic acid, forms a useful gargle. Tannic acid may be added with advantage. Great relief is obtained also in acute coryza by diluting a 50 per cent. solution one-half, and drawing it through the nostrils by forced inspiration. The following ointment is very convenient, and is especially adapted to the treatment of ocular diseases:—Boroglyceride (50 per cent. solution), ʒij, vaseline ʒvj, oil of roses q.s. Heat the boroglyceride, and while hot, slowly add the vaseline, stirring carefully until thoroughly mixed.

**A NEW METHOD FOR THE EXTERNAL EMPLOYMENT OF CRY SOPH ANIC ACID.**—Under the name of traumaticine, a solution of gutta-percha has been employed for some time as an excipient in certain drugs, as the solution painted on the skin by the aid of a brush leaves firm pellicles which will serve to preserve the skin from friction. Dr. Auspitz has recently employed this solution for the external application of crysophanic acid, so as to cause it to adhere to the skin and protect it from rubbing, and to prevent this drug from staining bodies which come in contact with it. This preparation has been employed with success in the treatment of psoriasis, and it is evident that it may serve for the application of a large number of drugs which are soluble or capable of suspension in chloroform, and which appear to the physician a valuable method of treatment. Auspitz (*Nouveaux Remèdes*, May 15, 1885) dissolves one part of crysophanic acid and one part of gutta-percha in eight parts of chloroform, and the preparation so prepared has been also used with success by Dr. Fournier. Dr. Besnier, however, prefers to apply first a solution of crysophanic acid in chloroform, and then to cover this with a varnish of gutta-percha in chloroform. His formula is one part of crysophanic acid dissolved in eight or nine of chloroform for the first solution, and one part of purified gutta-percha dissolved in nine of chloroform for the second.—*The Therapeutic Gazette*, July.

**LOTION OF POTASSIUM SULPHIDE.**—M. Vigier observes (*Gazette Hebdomadaire*, May 29th) that the disgusting odour of rotten eggs which permeates this valuable lotion may easily be converted into one of even an agreeable character by simply adding tincture of benzoin in the same proportion as the sulphide of potassium employed, taking care to strain the mixture through muslin in order to prevent any fragments of benzoin passing. Thus, a lotion of 1 part of the sulphide and 1 part of the tincture to 100 of distilled water disengages a perfume much resembling that of acacia flowers; while, if 50 parts of the distilled water be replaced by 50 parts of rose water, another perfume equally as agreeable as the former is produced. Dermatologists, indeed, frequently employ some such combination; but it is as well to have a simple formula which is easily recollected.

## NOTES ON FOREIGN HEALTH RESORTS.

### STOOS, A MOUNTAIN HEALTH RESORT.

THOSE who are seeking for a bracing mountain health resort of moderate elevation, and easy of access, will find such a place in the Kurhans *Stoos*, between two and three hours, by good carriage road, above Brünnen, the well-known port of canton Schwyz on the Lake of Lucerne and a station on the St. Gothard Railway. The road to *Stoos* passes by Axenfels, with its well-known hotel and pension, and then by the hamlet of Morschach, close to which a road to the left ascends to the finely situated hotel and pension Axenstein. The new carriage road continues to ascend, and soon reaches a very steep portion which zigzags through shady pine and beech woods, and commands fine views, here and there, over the Schwyz valley and a portion of the Lake of Lucerne. Soon the Kurhans *Stoos* is seen surrounded by green pastures, in a somewhat protected situation on a northern spur of the Frohn Alp, 4,242 feet above the sea. From the extremity of this spur a very fine view is obtained to the west, over a great part of the Lake of Lucerne, with the Rigi and Pilatus as prominent objects; a portion of the Lake of Zug and the little lake of Lowerz are also seen. At the foot of the mountain lies the smiling valley of Schwyz stretching into the Muottathal; the two striking conical peaks, the Great and Little

Mythen, at the foot of which the town of Schwyz lies, rise immediately facing one. The Kurhans is a commodious building capable of accommodating 120 guests, and has arrangements for hot and cold baths, for baths of *petit-lait*, and for carrying out the whey and milk cures. The food is plain, but sufficient, and the accommodation somewhat homely; at present it is frequented chiefly by Germans and Swiss.

The climate is fresh and bracing, much more so than at those resorts immediately over the Lake of Lucerne, for between *Stoos* and the East shores of this lake the Frohn Alp rises to an elevation of 6,270 feet. There are plenty of walks in the surrounding meadows and in the woods, which extend up the sides of the Frohn Alp. The summit of this can be reached from *Stoos* in an hour and a half, and from it a finer view, in some respects, is obtained than from the Rigi, as it commands the whole extent of the Lake of Lucerne from Fluelen to Lucerne itself.

With regard to the lower resorts on the steep slopes of the mountains which rise immediately from the shores of this lake, such as Axenstein, Axenfels, Seclisberg, Burgenstock, and others, it should always be borne in mind that owing to the peculiar situation of the Lake of Lucerne these resorts, in very hot weather, are not bracing, but somewhat moist and relaxing stations. For this narrow lake occupies a very deep depression amidst lofty mountains which surround it on all sides; in the hot days of mid-summer the fierce rays of the sun stream down into this depression, and cause that intense heat on the surface of the lake with which most travellers are familiar, as well as the close moist atmosphere observed in the town of Lucerne. The air over the surface of the lake becomes greatly heated and saturated with the vapour of water generated by the action of the great sun-heat on the lake's surface, and this hot moist air rises to a considerable height on the steep mountainous sides of the lake, until higher up it becomes condensed into cloud and mist, and hence also the frequency of light mist and clouds over the tops of the surrounding mountains. Occasionally a cold northerly or north-easterly wind will blow down the valleys which open on the lake on its north-easterly side, and then such places as feel the influence of these winds will be cooled by them, but it would be a mistake to believe that these resorts in the hot weather of summer escape the hot, moist, relaxing climate which so constantly prevails on the level of the lake itself.

For beauty of situation nothing perhaps can surpass that of *Axenstein*, only about three-quarters of an hour above Brünnen, at a height 2,330 feet above the sea, commanding a most exquisite view of the lake, as well as of the valley of Schwyz. The hotel is surrounded by a well-wooded park, through which there are numerous shady walks, amongst which one encounters interesting traces of glacier action in the shape of glacier beds and remarkable erratic blocks of stone. The hotel is spacious and well appointed, but unfortunately adheres to the German habit of paralysing one's energies with a heavy dinner at one o'clock, after which there is only a light and insufficient supper at seven.

A few hundred feet below Axenstein is the Pension Axenfels in a much inferior position, and with a far less extensive and attractive view.

On the opposite side of the lake, and immediately facing Axenstein, is the well-known resort of Seclisberg, somewhat higher than Axenstein, the Kurhans at Seclisberg being 2,772 feet above the sea. The Kurhans consists of three separate buildings, capable together of accommodating 300

guests; it is situated in a sunny spot, almost on the very brink of the steep precipices which here form the west shore of the lake. From its position facing east, the sun shines upon it till mid-day or later, and in the afternoon it is in the shade. Behind it there are woods which afford agreeable shady walks, and many pleasant excursions can be made from it. The view of the lake from the Kurhans, though very beautiful, is not so fine as that from Axenstein.

I. B. Y.

## SPECIAL CORRESPONDENCE.

### INDIA.

(From Our Bombay Correspondent.)

*The Recent Earthquakes—Unemployed Pay of Surgeons-Major—Report of the Public Analyst for Bombay—Cholera at the Sailors' Home—Recent Appointments.*

August 3rd.

CERTAIN parts of India, more especially the picturesque and romantic Valley of Cashmere and places in Eastern Bengal, have recently been visited by severe earthquakes, causing great loss of life and vast devastation of property. I read that in Cashmere upwards of 2,700 lives were lost on the 30th May and following days. The deaths in the City of Sringaghar are reported to be small, comparatively, to those in other places in Cashmere. Mr. Leahy, the Civil-Surgeon, and Mr. Neve, of the Mission, I understand, rendered valuable professional services.

In a previous letter I commented on the subject of the grade-pay of Indian medical officers, and observed that the assimilation of the pay of these officers to those of the Medical Staff should not be restricted to the rank of Surgeon, in the case of those not holding any sort of appointment, but employed on "general duty." And I pointed out that as soon as surgeons-major were without appointments in consequence of the change in the original order of the Government of India, they would draw only the *unemployed pay* of their rank, which is below the grade-pay of the surgeon-major of the home service, and that discontent and heart-burnings would be produced which could not but tend to render the service unpopular. I notice in the current issue of the *Indian Medical Gazette* a letter from a correspondent headed "Unemployed Pay of Surgeons-Major." He refers to the "India Army Circular" of February 6, and says that the order came as a welcome, although not unreasonable concession, removing as it did the grievance of "unemployed pay," and placing officers of the service who entered since the 7th of November, 1864, on the same footing as their brethren whose commissions bore a prior date. At the same time it abolished a ground of invidious comparison with the sister service. The dream has, however, been a short-lived one, at least as regards a large proportion of the members of the service. On the 20th May, 1885, another army circular was issued effecting a so-called "correction," and substituting the words "a surgeon" for the words "an officer" in the former document. Thus at one fell swoop all those medical officers who had served the Indian Government for upwards of twelve years were deprived of advantages which, for three-and-a-half months, they were led to believe had been secured to them. A few weeks ago the Under-Secretary of State for India informed the House of Commons that the Government of India had been referred to for a statement of future possible retrenchments. Can this be the result of the reference, and under the cloak of correction are the shears being applied to a defenceless department? There is an editorial note to this letter expressing much the same views as those to which I gave utterance, viz., "it seems to us that the order, as originally worded, ought to have been allowed to stand unmodified, as our correspondent contends." It is a thousand pities that the

authorities should have recourse to such penny wise pound foolish policy, which runs counter with all considerations as to equity and the keeping of faith. It is to be hoped that they will retrace their steps and reproduce the original order without any "correction" for the plain and simple reason that there was nothing therein which was not "correct." The Government of India have early this year issued another order which is received with disfavour, viz., for all Indian medical officers in military employ to provide themselves with "a pocket case of instruments" to fit into the pouch of the belt. This is in contravention of the terms under which they enter the service, that the Government will provide all surgical instruments required for service use, and as this is to be provided at the officers' own expense, it does not tally with the terms of the India Office Circular issued to candidates.

I have before me a reprint from a Government resolution on the annual report of Mr. Lyon, F.C.S., Chemical Analyser to the Bombay Government. From it, it appears that the total number of articles analysed in 1884 was 1,895, and the number of medico-legal cases referred to by him was 314, which was larger by 52 than the average number in the three years ending 1882-83. In 42 of these instances articles supposed to be stained with blood or other animal fluids were sent for examination; but in 26 only was any such fluid detected. The number of cases of poisoning of human beings (alleged as real) in connection wherewith substances were forwarded for analysis was 169. Poison was detected in 83 of these, or 49.1 per cent. In 2 cases no trace of poison could be found, though the accused persons confessed that they had administered poison. The number of persons who appeared to have been poisoned in the cases in which substances were analysed was 98, of whom 36 died. As in previous years, the poison most used was arsenic. It was administered to 50 persons and caused 22 deaths. There were nine cases of opium-poisoning, all of which proved fatal; 2 deaths were caused by aconite, 1 by datura; 1 by strychnia, and 1 by hydrocyanic acid. The number of cases of suspected poisoning of cattle was large, but the cases of real poisoning were small compared with previous years. During the year, 98 samples of potable waters were analysed, as compared with 61 in the previous year; 42 examples were pronounced to be good, and 52 bad. I may remark here that as water is sent generally for analysis when suspected to be contaminated or otherwise injurious to health, this result does not speak well for the health prospects of the community.

Cholera, which continues to prevail in Bombay, has made its appearance in the Sailors' Home. I understand that eight cases have occurred there, out of which five proved fatal. The sanitary condition of the home does not, it appears, account for the appearance of the disease, and I learn that it is quite satisfactory. The history of these cases, as well as of others occurring in Bombay, goes to show that the *fons et origo mali* is drinking water, and that the virus was communicated by the cheap aerated waters sold in the bazaars, manufactured by native vendors who are proverbially careless and indifferent as to where they obtain the water from. The nearest well or tank, containing any dirty or filthy water, it may be, answers their purpose. It is time that there should be some legislative power not only to proceed against such vendors, and for them to be awarded severe punishment, so as to act effectively as a deterrent, but that there should be proper sanitary supervision and control over those manufactories which disseminate broadcast the *contagium vivum* of cholera, typhoid fever, &c.

Mr. J. H. Potter, M.B., is appointed to act as Police-Surgeon and Surgeon to the Coroner of Bombay during the absence in Europe of Dr. Sydney Smith. Mr. A. Barclay, M.B., is confirmed in the appointment of Secretary to the Surgeon-General and Sanitary Commissioner with the Government of India; and Mr. G. Harris as Second Resident Surgeon of the General Hospital of Calcutta. I regret to announce the death of Mr. A. Skeen, M.B., of the Indian Medical Service, who held the appointment of physician and tutor to the Maharajah of Patiala. He died, on the 10th ultimo, at the hill-station of Kussolie. Mr. Skeen entered the service (Bengal establishment), in March, 1865, and was promoted Surgeon-

Major, 1877. I regret also to announce the death of Mr. A. E. McL. Ross, L.R.C.S., of the Indian Medical Service (Madras establishment), which took place on the 1st ultimo, at Secunderabad. The deceased held the appointment of Staff-Surgeon of the Hyderabad Subsidiary Force.

## MEDICAL NEWS.

UNIVERSITY OF LONDON.—Intermediate Examination in Medicine. — Examination for Honours. — Pass List.—Anatomy.

*First Class.*—Henry Percy Dean, B.Sc., Exhibition and Gold Medal, University College; Frederick Howard Taylor, Gold Medal, London Hospital.

*Second Class.*—Alfredo Antunes Kanthack, B.A., University College, Liverpool; Percy Ashworth, B.Sc., Owens College, Alfred Herbert Tubby, Guy's Hospital, equal; Milton Prentice Ledward, Owens College, Guy Bellingham Smith, Guy's Hospital, equal.

*Third Class.*—Cyril William Jecks, University College; John Ogle Tunstall, University College; George Edward Rennie, B.A. Sydney, University College.

Materia Medica and Pharmaceutical Chemistry :—

*First Class.*—George Edward Rennie, Exhibition and Gold Medal, University College; \*Ernest Henry Starling, Guy's Hospital; \*Alfredo Antunes Kanthack, University College, Liverpool; Percy Ashworth, Owens College; Theodore Fisher, Guy's Hospital.

*Second Class.*—Evelyn Oliver Ashe, London Hospital, Charles Percival Crouch, St. Bartholomew's Hospital, Alfred Herbert Tubby, Guy's Hospital, equal.

*Third Class.*—Milton Prentice Ledward, Owens College; Walter Stacy Colman, University of Edinburgh and University College; George Hartley O'Reilly, King's College; Isabella Macdonald Macdonald, London School of Medicine for Women; Cyril Cecil Barrow Burt, Westminster Hospital.

Organic Chemistry :—

*First Class.*—Ernest Henry Starling, Exhibition and Gold Medal, Guy's Hospital; \*Henry Percy Dean, University College.

*Second Class.*—John Wilkie, St. Bartholomew's Hospital, William Griffith Williams, St. Bartholomew's Hospital, equal; William Page May, B.Sc., University College, Arnold Scott, Guy's Hospital, equal.

*Third Class.*—John Ogle Tunstall, University College; Walter Stacy Colman, University of Edinburgh and University College; John Lloyd Roberts, B.A., B.Sc., Guy's Hospital.

Physiology and Histology :—

*First Class.*—Ernest Henry Starling, Exhibition and Gold Medal, Guy's Hospital; Percy Ashworth, Gold Medal, Owens College; Alfredo Antunes Kanthack, University College, Liverpool; Brian Melland, Owens College; John Lloyd Roberts, Guy's Hospital; John Wilkie, St. Bartholomew's Hospital.

*Second Class.*—Cyril William Jecks, University College; Frederick Howard Taylor, London Hospital; Henry Edward Leigh Canney, University College; George Edward Rennie, University College; George Black, Guy's Hospital; Walter Stacy Colman, University of Edinburgh and University College.

*Third Class.*—William Page May, University College; William Griffith Williams, St. Bartholomew's Hospital.

Those marked \* obtained the number of Marks qualifying for a Medal.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, August 20th, 1885 :—

William Robert Yeates Ines, Portswood, Southampton; William Paynter West, Turnpike Lane, Hornsey, N.

On the same day

John Frederick Bate, University College,

passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise.

ARMY MEDICAL DEPARTMENT.—List of Candidates who were successful for appointments as Surgeons in the Medical Staff of Her Majesty's Army at the Competitive Examination in London on the 10th and following days of August, 1885 :—M. T. Yarr, 2,980; B. L. Mills, L. P. Mumby, 2,880, equal; C. H. Melville, 2,870; J. B. Wilson, 2,810; H. Rayner, 2,765; C. A. Renny, 2,707; R. E. Genge, J. Kearney, 2,680, equal; H. Thiele, 2,679; F. A. Saw, 2,625; G. S. Cardew, 2,590; H. Coeks, 2,510; W. J. Lee, 2,500; F. W. Hennessy, 2,475; H. W. M. Kendall, 2,440; J. G. Black, 2,430; H. P. G. Elkington, 2,400; F.

W. G. Hall, G. S. Tate, 2,380, equal; R. H. Cox, A. Kennedy, 2,350, equal; R. C. Gordon-Dill, 2,345; F. T. Skerrett, 2,340; H. M. Ramsay, 2,300; W. B. Stokes, 2,280; J. B. Buehanan, D. Simpson, 2,270, equal; E. H. Loeker, 2,215; J. Rose, 2,182; T. G. Lovie, 2,180; H. M. Adamson, 2,160; J. H. Corkery, W. P. Squire, 2,120, equal; W. R. Crooke, C. L. Walsh, 2,110, equal; H. H. Brown, 2,100; S. J. W. Hayman, 2,080; J. P. S. Hayes, J. J. O'Donnell, 2,070, equal.

NAVAL MEDICAL DEPARTMENT.—At the competition for Commissions in the Medical Service of the Royal Navy, held on the 10th August and following days in the Hall of the University of London, Burlington Gardens, the under-mentioned gentlemen were the successful candidates :—W. E. Home, 3,200; R. A. Fitch, 2,890; H. B. Beatty, 2,710; W. Spry, 2,700; P. E. Maitland, 2,380; G. H. H. Symonds, 2,360; W. J. Winckler, 2,320; J. J. Walsh, 2,275; J. Moore, 2,260; C. J. Mansfield, 2,100; R. Hickson, 2,060; H. P. Shuttleworth, 2,005; J. Lowney, 2,000; G. D. Trevor-Roper, 1,980; O. S. Fisher, 1,960; J. S. Fogerty, 1,900.

INDIAN MEDICAL SERVICE.—The following were the successful candidates at the examination held on August 11, 1885 :—H. R. Woolbert, 3,208; G. H. Baker, 3,005; T. Grainger, 2,915; A. R. Edwards, 2,830; J. M. Cadell, 2,827; A. C. Younan, 2,825; J. R. Adie, 2,822; A. W. Aleoek, 2,760. There were 22 candidates for the eight vacancies; 21 were reported qualified.

SOCIETY OF APOTHECARIES OF LONDON.—Mr. John Walter Carr, of University College Hospital, L.S.A., has been elected to the Medical Scholarship of the Society of Apothecaries of London, of the annual value of 100l. The Examiners report that Mr. James Harry Ernest Brock, L.S.A., of University College Hospital, obtained a number of marks nearly equal to those of the successful candidate.

ROYAL PATRONAGE.—Her Majesty has accepted the position of patroness of Lady Dufferin's fund for providing medical assistance for the women of India.

THE WAR IN THE SOUDAN.—General Lord Wolseley in his despatch to the Secretary at War, just published, says that "the Medical Department was administered with ability by Deputy Surgeon-General O'Nial. I have never seen the sick and wounded better cared for. The arrangements were good, and the medical officers worked with untiring zeal and great devotion to their duties. At Suakin, Deputy Surgeons-General Barnett and Hinde directed all medical matters with great credit to themselves and to their department. Both there and on the Nile the work done by the nursing sisters was highly appreciated by doctors and patients. The Commissariat duties were well performed throughout, the department being excellently directed by Assistant Commissary-General Hughes. At Suakin, Assistant Commissary-General Robinson did good work; all his arrangements were satisfactory." And as to services deserving special mention, we subjoin the following list :—Medical Staff—Deputy Surgeon-General J. O'Nial, C.B.; Deputy Surgeon-General S. A. Lithgow, M.D.; Deputy Surgeon-General O. Barnett (since dead); Deputy Surgeon-General G. L. Hinde; Surgeon-Major E. C. Markey; Surgeon-Major G. C. Gribbon; Surgeon-Major R. Waters, M.D.; Surgeon-Major G. E. Will; Surgeon-Major C. H. Harvey, M.D.; Surgeon-Major T. F. O'Dwyer, M.D.; Surgeon-Major F. Ferguson, M.D.; Surgeon-Major B. B. Connolly; Surgeon T. J. Gallwey, M.D.; Surgeon W. H. Briggs; Surgeon J. Magill; Surgeon W. B. Allin; Surgeon H. L. Donovan, M.D.; Staff-Sergeant Arbeiter. The Queen has been graciously pleased to approve of the following promotions being conferred upon the under-mentioned officers in recognition of their services during the recent operations in the Soudan :—Medical Staff.—To be Surgeons-General—Deputy Surgeon-General John O'Nial, C.B.; Deputy Surgeon-General Oliver Barnett, C.I.E. (since deceased). To be Brigade-Surgeons—Surgeon-Major Robert Waters, M.D.; Surgeon-Major George Elmsly Will; Surgeon-Major Charles Hamilton Harvey, M.D. To be Surgeons-Major—Surgeon Thomas Joseph Gallwey, M.D.; Surgeon William Simson Pratt, M.B.; Surgeon William Hamilton Briggs; Surgeon William

Briggs Allin, M.B. The Queen has been graciously pleased to give orders for the following promotions in, and appointments to, the Most Honourable Order of the Bath:—To be an Extra Member of the Military Division of the Second Class, or Knights Commanders of the said Most Honourable Order, viz.:—Thomas Crawford, Esq., M.D., Director-General of the Army Medical Department. To be Ordinary Members of the Military Division of the Third Class, or Companions of the said Most Honourable Order:—Deputy Surgeon-General Stewart Aaron Lithgow, M.D., Medical Staff; Deputy Surgeon-General George Langford Hinde, Medical Staff; Brigade Surgeon James Howard Thornton, M.B., Bengal Medical Department.

HOSPITAL FOR INCURABLES, DUBLIN.—At the monthly meeting held on the 18th instant, the Board proceeded to the election of male patients. There were 21 applicants, and only two vacancies. Two were admitted, and a third on pension till there should be a vacancy. Two were bad cases of cancer, and one of consumption. At the next meeting, female patients will be elected.

MERCER'S HOSPITAL, DUBLIN.—This institution is the oldest of its kind in this city. It is open at all hours, both day and night, to receive accidents and urgent cases. About sixty persons of all denominations are attended to daily at the dispensary. The financial position of the hospital is unsatisfactory, and the Governors solicit contributions in aid of the pressing calls upon them.

HOUSING OF THE POOR, ISLINGTON.—This parish would appear to be in a somewhat enviable position in respect to the almost universal evil, over-crowding. A full and detailed report of the General Purposes Committee of the Vestry has been issued, which deals with the report of the Royal Commission on the Housing of the Working Classes. It expresses the belief that over-crowding does not, and has not existed, to any great extent in the parish, but it was a matter that demanded great vigilance. It appears that through Dr. Meymott Tidy, the Medical Officer of Health, 78 houses were demolished in the parish, connected with the "High Street (Courts and Alleys) Scheme," and replaced by the blocks of dwellings known as "Torrens and Myddelton Buildings," and 276 houses were demolished in carrying out the Essex Road Improvement Scheme.

CHARITABLE BEQUESTS.—The late Mrs. Masson, of Elm Park, Inverness, daughter of the late Bailie Alexander Masson, of Aberchalder, has left by her will to the Northern Infirmary 500*l.*, the Inverness Dispensary 200*l.*, and the Institute for the Blind 200*l.* Mr. James Benham, late of 50, Wigmore Street, bequeaths by his will 100*l.* each to the University College Hospital and the Hospital for Sick Children, Great Ormond Street, free of duty. Mr. T. Emsley, late of Burley-en-Wharfedale, Yorkshire, has bequeathed 1,000*l.* each to the Bradford Infirmary, Ilkley Convalescent Home, Harrogate, Bath Hospital, and the Leeds General Infirmary; 500*l.* each to Coatham Convalescent Home, the Leeds Public Dispensary, the Leeds Institution for Deaf and Dumb Mutes, the Leeds Hospital for Women and Children, and the Cookridge Convalescent Hospital. Miss Charlotte Maitland, daughter of the late Sir Alexander Charles Maitland Gibson, of Clifton Hall, who recently died at Greenhill Park, Morningside, has bequeathed 1,000*l.* each to the Royal Infirmary and to the Institution for the Relief of Incurables.

THE LATE DR. THOMAS COLAN, R.N.—The death of this gentleman, Inspector-General of Hospitals and Fleets, is announced as having taken place on August 18th, at Halliwell, near Bolton, at the age of 54 years. He entered the Royal Navy in 1853, served on board the "Royal George" during the two campaigns in the Baltic, and also on board the "Beagle" in China, being present at the capture of the Peiho Forts. He also served in the Ashantee war, being specially promoted to the rank of fleet surgeon for his services. In 1875 he went out in the "Alert," as principal medical officer in the Arctic Expedition under Sir George Nares, and from 1877 to 1880 he was employed as Deputy Inspector-General at the Royal Naval Hospital at Jamaica, during which time yellow fever broke out twice at Port Royal. Besides receiving the Baltic, China, Ashantee

and Arctic medals, he was awarded Sir G. Blane's gold medal for his "Medical Journal on the West Coast of Africa for 1872." He retired from the service in 1883.

BEQUEST BY THE LATE DR. N. CAMERON.—Dr. Nathaniel Cameron, a distinguished graduate of the University of Aberdeen, who died recently at Sierra Leone, has bequeathed, it is understood, to the Aberdeen University Museum a valuable collection of fossils, &c.; in addition, the Aberdeen University Extension Building Fund receives 50*l.* Another collection, consisting of shells, fossils, gold dust, &c., has, it is stated, been bequeathed to the British Museum.

THE LEWES LUNACY CASE.—On August 25th, a very large and enthusiastic public meeting of the inhabitants was held in the County Hall, Lewes, to express sympathy with Dr. Crosskey in connection with the lunacy trial in which he figured as a defendant. The Mayor called upon Alderman Kemp, the deputy mayor, to preside, and that gentleman read a number of letters from the leading inhabitants of the town, and others. He said Dr. Crosskey had been subjected to great annoyance and expense in consequence of the action, but they had never doubted of the result. Dr. Sutherland, of London, had written to ask permission to start a medical subscription on behalf of Dr. Crosskey, and an offer of five guineas had been received from Mr. W. L. Christie, M.P. A resolution was proposed expressive of sympathy with the doctor, which was supported by the Rev. Lord Sidney Osborne, who contributed five guineas. This was carried with great enthusiasm, as was another appointing a committee to raise subscriptions. A large sum was promised in the room.

MEDICINE AND THE DRAMA.—We understand that "Sister Grace," a new play founded on some incidents of hospital life, is the work of Mr. Scott Battams, a young member of the medical profession. Our readers will remember that the play was originally produced at the Avenue Theatre last year at a *matinée* given in aid of the East London Hospital for Children, when it scored a distinct success. Since then, "Sister Grace" has been carefully revised; and was produced for the first time in the provinces on August 8th, at the New Theatre, Devonport. We are inclined to believe that a play which appeals to so large a section of the public would have a good reception if produced in London.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE.—The following is the list of prizemen for the Session 1884-5:—Lawrence Scholarship and gold medal of 40*l.*—W. G. Spencer. Brackenbury Medical Scholarship of 30*l.*—W. J. Gow. Senior scholarship in anatomy, physiology, and chemistry of 50*l.*—J. Wilkie. Open scholarships in science of 130*l.*—B. Pierce, R. Rickard, and E. N. Reichardt. Preliminary scientific exhibition of 50*l.*—R. G. Elliot. Jeaffreson Exhibition of 50*l.*—H. G. Cook and W. A. Murray. Kirke's Gold Medal—W. J. Gow, *proxime accessit*, W. G. Spencer. Bentley Surgical Prize—A. M. Gledden. Hichen's Prize—E. H. Hankin. Harvey Prize—1, E. H. Hankin; 2, W. G. Williams; 3, G. Heaton; 4, J. G. C. Colby; 5 and 6, S. Blackman and T. J. Bokenham; 7, R. Bird. Practical Anatomy, Junior—Treasurer's Prize—1, C. H. Roberts; 2, H. G. Cook; 3, D. T. Belding; 4 and 5, T. J. P. Jenkins and W. G. Willoughby; 6, Hansby Maund; 7, J. G. Ogle; 8, H. A. Sylvester; 9, W. F. Cholmeley; 10, C. E. R. Rendle; 11 and 12, C. E. Hutt and J. J. Macgregor. Practical Anatomy, Senior—Foster Prize—1, C. S. Edwards; 2, A. Lucas; 3, J. Rust; 4 and 5, W. N. Evans and T. J. Lissaman; 6, W. B. Lane; 7 and 8 F. M. Brown and H. Symonds; 9, H. Huxley; 10 and 11, G. Heaton and J. E. Spencer. Junior scholarships of 50*l.*, 30*l.*, and 20*l.*—1, B. Pierce; 2, C. H. Roberts; 3, R. Rickard.

GUY'S HOSPITAL MEDICAL SCHOOL.—The following is the list of prizemen for the session 1884-85:—Open scholarship in arts, 125 guineas—James M'Donald Gill. Open scholarship in science, 125 guineas,—Alfred Parkin. The Treasurer's gold medal for clinical medicine—William Leonard Braddon. The Treasurer's gold medal for clinical surgery—John Wychenford Washbourn. Beaney Prize for Pathology, 30 guineas—George C. C. Anderson, William Henry Bowes, *proxime accessit*. Mackenzie Bacon

Prize for Ophthalmoscopy, 10*l.* 10*s.*—Charles Drummond Muspratt. Mackenzie Bacon Prize for Nervous Diseases, 15*l.*—George Ezra Halstead Balderton. Michael Harris Prize for Anatomy, 10*l.*—Arthur Edward Poolman. The Gurney Hoare Prize for clinical study, 25*l.*—Letterstedt Frederick Childe. The Burdett Prize for Hygiene, 10*l.*—William Leonard Braddon. Fourth year students—John Wychenford Washbourn, first prize, 25*l.*; Frederiek Lever, second prize, 10*l.*; Sidney Wachter and Edward Deane, certificates. Third year students—Frederic Francois Burghard, first prize, 25*l.*; Herbert Vaughan Rake, second prize, 10*l.*; William Bett and Edward Petronell Manby, certificates. Second year students—Ernest Henry Starling, first prize, 25*l.*; Guy Bellingham Smith, second prize, 10*l.*; George Herbert Pennell, certificate. First year students—Robert Devereux Mothersole, 37*l.* 10*s.*, and Alfred Parkin, 37*l.* 10*s.* (equal); Ramsay Allan Bremner and Cecil Price Jones, certificates.

NAPLES AND THE CHOLERA.—The *Times* correspondent writes under date August 16:—"So far, then, we are safe, and strong hopes are entertained that cholera will not approach us this year. Orders have been given to inspect all the wine and oil shops, for both wine and oil are usually much adulterated, and it is difficult to procure either article in a pure state. A great outcry is made about the water supply—in some quarters that there is none, in others that it is foul. The Vice-Syndic of that quarter replies that he is aware that it is so, but that he can do nothing until the time has terminated for which notice was given to the landlords to remedy the evil; after that he will order the wells to be closed. How is it that it has not been done before? A decree has been wisely issued by the Government prohibiting the imposition of quarantine by the local rulers of any town or village. Last year, especially in Calabria, quarantine was imposed on many places by the authorities, to the extreme inconvenience and peril of the inhabitants. The same thing, I read, has been done in Spain, where the Government has acted with energy, and has summoned the local rulers before the judicial power. There might possibly be some danger of Sicily committing the same folly. I have already reported great excitement in Palermo, and the urgent request of the municipal body to close it against all intercourse with the outer world. Since then a vessel came into port from some part of the French coast and was admitted to *libera practica*. The consequence was that there was a violent demonstration, and a renewal of the request to be shut up. Signor Mozana firmly resolved to refuse such application as being perfectly unnecessary. Should cholera, however, enter the kingdom, which he does not think likely, he will give orders for closing the larger islands. The names of all who cross the French frontier and travel by Ventimiglia are telegraphed to the Syndics of the places to which they are destined, and such persons are supplied with medical certificates stating that they have been inspected."

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The fourteenth meeting of this flourishing body has been held with great success at Grenoble, under the presidency of Professor Verneuil, the most accomplished orator which the medical profession possesses in France. There is good reason for his appointment in the fact that the section for the Medical Sciences occupies a very important position in the Association; and his discourse has been pronounced to be one of remarkable power, and has been published verbatim in the medical journals. In a part of it he took occasion, under the title of the "Confessions of a Surgeon of our Century," to animadvert upon the great tendency which the surgery of the present day has to over-encourage operations. Not that this confession is applicable to himself, since in the present state of feeling he would be regarded as rather timid in this respect, and he had often protested against the over-culture of the knife. The confession he passes on to other surgeons, and especially those of other lands, France being comparatively free from the defect he deplors. The most perilous operations, he says, are multiplied on futile pretexts, and commenced in any one country, are repeated through mere imitation until the fashion passes away. "All these operations have been singularly abused, that is to say, there has

been too much transposing, too much trephining, too much tenotomizing, too much resection, too many strictures have been incised, and excision of the iris has been too often practised. The cavity of the female pelvis has been far too frequently meddled with, while cold abscess has been too often scraped, and the thermo-cautery too often applied to the skin, and if peremptory proof of these abuses are demanded, I will simply call to mind that in a great country like ours, with its 37,000,000 of inhabitants, we can reckon at the outside half-a-dozen transfusings and a dozen trephinings, while the spinal and lingual muscles are in future to be left at rest in the deformed and the stammering; that in England, where there was so much excision going on, that operation is scarcely ever performed now; that a certain foreign surgeon who was so enthusiastic an admirer of resections that he performed them by the dozen, now declares them to be detestable; that the oculists who formerly disbelieved in the success of cataract operations without iridectomy, are now almost all agreed in respecting the iris; and that the famous *raclage* is every day so losing ground, that two years hence it will be relegated with the points of actual cautery to a museum of antiquities." And all this is nothing to the anathemas launched at all the useless or ill-justified extirpations of the larynx, pharynx, stomach, kidney, and uterus. "We may imagine," the *Gazette Hebdomadaire* observes, quoting the above passages, "what a treat this exposition must be for the general public who has to pay the costs of these epidemics of armed force." This confession is applicable to himself, since on various occasions he has protested against such procedure, but is made a vehicle for satirical allusion to a practice which he regards as far too general. The most perilous operations, he observes, are multiplied on quite futile pretexts, and inaugurated in one country they make the round of the world, separated by mere imitation until the fashion passes away. "All these operations have been singularly abused."

EDINBURGH UNIVERSITY ANATOMICAL MUSEUM.—The arrangement of specimens and certain museum details are still not quite complete, but the constructive work is practically finished, and other matters are far advanced. The measurements of the Museum are 112 feet long by 39 feet broad, and 45 feet 5 inches high to the tie beam of the roof. Besides the space thus gained for Museum purposes, there is also a smaller cabinet *en suite* with the Museum proper, and entering from its west end. Then, to make the most of the whole space thus obtained for exhibition purposes, the Museum itself has been provided with two galleries running round the walls, and the smaller room with one such gallery. Now that the mason and joiner, and their allies, have completed their share of the work, and the Museum exhibits have, roughly speaking, been got into place, the visitor cannot fail to be at once struck with the excellence of the result obtained. Few, indeed, will have the slightest difficulty in admitting the claim that few medical schools or Universities can boast its like. To give, first, a general idea of the structural and exhibition arrangements, it has to be said that the ground floor of the Museum, which is beautifully laid in Italian mosaic, has a series of side cases projecting from the walls in the intervals between the windows, and rising to the height of the first gallery. The intervals between these projecting cases corresponding to the breadth of the windows will form a series of well-lighted recesses, provided with a table and chair, in which the student can work in quiet at the special subject on which he may be engaged. Below each window a glazed case is placed against the wall for the display of specimens, and the interval between it and the floor is occupied by drawers for the storing of objects. The floor with its cases is to be devoted to the illustration of objects of comparative osteology. The first gallery is set apart for the illustration of objects of human and comparative anatomy, whilst the second gallery is given up to the illustration of pathological objects—surgical as well as pathological proper. Both these galleries have side exhibition cases covering the walls of their several portions of the Museum, and desk cases which run round the gallery, and the upper gallery is provided with a thick glass floor, so as not to intercept the light. The galleries, besides

being connected by spiral staircases let into the walls with the floor of the Museum, communicating with the several teaching departments just mentioned, are also connected by means of "lifts" with each other and with the ground floor, for the convenience of the movement of specimens. The specimens contained in the Museum are the accumulations of a century and a half; for the nucleus of the collection consisted in the gift by the second Munro in the year 1800 of his own and his father's anatomical collection to the University. During the present century it has received numerous additions, both by the late Professor Goodsir and the present Professor of Anatomy (Professor Turner), and through the benefactions of many other Professors in the Faculty and of students and graduates. Starting with the upper gallery, it is seen that the surgical specimens occupy the cases standing against the south and east walls, at the junction of which is the door of communication with Professor Grainger Stewart's and Professor Chiene's departments. The specimens more especially used in the pathology department by Professor Greenfield occupy the cases standing against the other walls of the same gallery, and the door of communication with the department stands in the south-west corner of the gallery. The desk-cases on this gallery are intended for the display, for purposes of study, of wet pathological dissections or specimens, prepared after the manner recently adopted with such excellent teaching effect in the anatomical department. Each dissection or specimen will have its descriptive manuscript or catalogue after the manner also adopted in the teaching of anatomy; and, to facilitate close study without injury to the cases, these are provided with sliding desks. It may be added, in passing, that the doors of communication between the Museum and the departments just mentioned are double and constructed of iron, so as to make them fire-proof. These desk-cases will, besides, contain exhibits of calculi of the liver, intestine, kidney, &c.; and the arrangements for displaying pathological bones, with drawers for tabulated specimens, show some ingenious and useful modifications of the arrangements usually adopted for the display of such objects. Coming now to the first gallery, there are doors of communication between it, as between the second gallery and the ground floor, both in the north-east and south-west corners of the Museum. Beginning at the north-east corner, the exhibits gradually ascend from the skeleton, which comprehends shell, cartilage, and bone, to periosteum, bone and its peculiarities, joints, muscles and muscular arrangements, tendons, fat and pigment. Thence there come in order oral apertures, horny jaws and beaks, whalebone, teeth, &c., and so on through the series of animal organs, dealing not alone with vertebrates, but with invertebrates also. In the desk-cases running round the first gallery will be found a number of specimens of variations in the skeleton. In this gallery are numerous objects in illustration of the vascularity of organs, in which the blood vessels have been filled with coloured materials. This part of the collection was started by the late Professor Goodsir, and it has been materially added to by the present Professor of Anatomy. On the same floor there is a very fine series of eye preparations, as also a valuable collection of casts of cleft palates, only recently contributed to the Museum. At the west side, enthusiasts in natural history will find delightful opportunity of studying a beautiful collection of salmonidæ, illustrating their condition both in health and disease, with preparations of their various organs, some of which are injected. On the ground floor, the side cases are given over to the undisputed possession of a very instructive and general series of skeletons. The series begins at the east side of the Museum, at the right hand of the visitor as he enters from the Museum vestibule, with human skeletons and crania, and passing through the higher apes, finishes, on the other side of the Museum, with the reptiles and fishes. Many of the skeletons, owing to the limited space in the old Museum, have not for many years been shown, and some of them are of not a little interest. For instance, there is here the skeleton of the notorious Burke. The cabinet at the west end of the Museum, to which reference has already been made, is to accommodate the anthropological collection of crania. Of these several are even more interesting than the skeletons to which attention has

been drawn. One is said to have held the brain of George Buchanan; another to have been that of Haggart; another, that of a New Hebridean who killed Williams, the missionary; another, that of Howison, the Cramond murderer—the last man, it is said, that was sentenced to be hung and handed over to the doctors for dissection; whilst yet another is said to have been owned by the notorious pirate Pepe, who is credited with having in his murderous career killed ten thousand persons.

**EXPERIMENTS ON INTRA-OCULAR PRESSURE.**—At a meeting of the Berlin Physiological Society, Dr. Hölzke, following up a communication recently made by him respecting the influence of narcotics on pressure in the eye, reported experiments he had made concerning the influence of the blood-pressure on the intra-ocular pressure. The view had hitherto been universally accepted that the pressure in the eye was dependent on the blood pressure, and a series of experiences and experiments had been collected by way of proving this dependence. The nerves had likewise shown that they exerted an influence on the pressure in the eye, so far as they influenced the vascular system. Of the sympathetic in particular it was asserted that its paralysis induced an augmentation, whereas stimulation of the nerve caused a diminution of the intraocular pressure, and this converse process was said to be connected with the expansion and contraction of the vessels. Seeing, however, that some investigators maintained that the effect of the sympathetic on the pressure of the eye was exactly the opposite to that just referred to, the speaker had instituted new measurements by means of a manometer, utilising the second eye in the way of control. The result at which he arrived by this means was that the cutting of the sympathetic always entailed an abatement of the pressure to an average of 6 mm. mercury, and that stimulation of the peripheral nerve ending caused an increase of the pressure amounting to 14 mm. mercury. Stimulation of the supreme ganglion of the sympathetic had the same effect. If the veins of the neck were bound on the under side and the carotid was compressed, then had neither the cutting nor the stimulation of the sympathetic absolutely any effect on the pressure in the eye—a proof that the influence of the sympathetic as above stated was only mediate, that the paralysis of the sympathetic induced the lowering of the ocular pressure only in consequence of the decrease of pressure in the vascular system, and that the stimulation of the nerve caused the increase of the intra-ocular pressure only because of a rise of pressure in the blood. An experiment with a view to measuring the influence of the sympathetic on an atropinised eye did not yield perfectly decisive results, a circumstance which determined the speaker to investigate once more the influence of atropine on the ocular pressure. The result was somewhat different from that recently communicated. It was now ascertained with perfect certainty that the influence of atropine by itself was a diminution of the ocular pressure, and therefore the contrary of that of eserine. Only when the pupil was powerfully expanded by the atropine, did the pressure in the eye rise in correspondence with the other experiences that each expansion of the pupil was accompanied by an augmentation of pressure, and each contraction of the pupil was followed by an abatement of the ocular pressure. On the expansion and contraction of the pupil, the rise or the reduction of the blood-pressure became, in turn, observable, and this latter again on its side generated a rise, or, as it might be, a fall or the pressure in the eye. This parallelism of the ocular and the blood-pressure the speaker had found to hold good in all his experiments. The pressure in the vitreous body invariably showed the same changes as did the pressure in the watery chamber.—*Nature*.

**CHARGES OF PECULATION BY RUSSIAN MEDICAL OFFICERS.**—"Stepniak" writes to the *Times* a long account of the peculations of the officers of the Army Medical Staff in Russia, which, though no secret, have been brought prominently into public notice by some trials that have taken place in consequence either of dishonest individuals having quarrelled, or by the attempt of some whose notions of morality were higher than those generally prevailing to kick against the existing system. According to Stepniak,

nominations to appointments are paid for; sometimes in the most unblushing way the applicant will be informed by the chief how much he must pay him; at other times the information is conveyed by means of signs, the figures being written in the air, or the attendant trusty satellite sees that applicants are possessed of the exact terms on which appointments are made. In some cases, haggling and bargaining are resorted to, and occasionally an annual tribute is demanded in addition to the nomination fee. If it be true that the food and drugs are adulterated, cream of tartar being supplied for quinine, &c., it is to be feared that the life of a Russian soldier in hospital is treated as of small value by those whose whole lives ought to be devoted to caring for his interests.

**THE FIFTY-EIGHTH MEETING OF THE GERMAN NATURALISTS AND PHYSICIANS.**—The directors of this meeting, Profs. Kussmaul and De Bary, announce that it will be held at Strassburg from the 18th to the 23rd of September, and have published a very attractive programme. After the 1st of September all communications and enquiries may be addressed to Herrn Quästor, Schmidt Universitätsgebäude, Strassburg.

**RUSSIAN MEDICAL WOMEN.**—The St. Petersburg medical women are establishing an Ambulatorium for women and children on the pay principle.

**SLOW PROMOTION OF HOSPITAL-SURGEONS IN FRANCE.**—M. Richelot, the Editor of the *Union Médicale*, while congratulating (August 13th) two successful candidates at the *concours* just over, on their admission as hospital surgeons at the Bureau Central, wonders whether they are aware of the lot which awaits them in this place of delayed expectations. The successful candidates, it seems, having gained admission within its envied precincts, must await their turns for appointments at the hospitals; and at this time there are seventeen so-called surgeons of hospitals who are thus waiting; so that after all their laborious preparation and anxieties entailed by the formidable contests they have gone through, they find themselves deprived of the recompensing advantages by reason of the bad organization of the hospitals, and the spirit of routine which characterises the administration of the Assistance Publique. It is naturally asked why two new hospital-surgeons are thus created every year, when so many are yet unplaced. Surgeons who have been kept in this quarantine will get placed in 8 or 10 years; and the new comers, averaging 35 years of age, may, in the course of 15 years, find the happy day arrive. Alike with those of the successful candidates, the interests of the patients are sacrificed, and the good renown of French surgery seriously compromised. The present services are far too large, being most insufficiently officered, and the assigning 300 patients to the control of a single surgeon has been attempted to be justified by pointing to the example of Billroth. But here a misunderstanding prevails, for neither Billroth or any other surgeon could minister to the wants of 300 patients. He supervises and directs the whole, it is true, but the service is really accomplished by his assistants, who have their well-defined authority and responsibility, and not the false position which worn-out regulations assign to French *internes*. M. Richelot contrasts the energetic activity which characterises the services of 60 beds with the overgrown services now in question, the heads of which, overloaded with work, renounce the attempt to struggle against an impossible task, and finding themselves unable to do all, finish at last by doing almost nothing, still retaining all the responsibility which the regulations refuse to those who assist them. A radical reform in the organization is evidently called for, and of whatever nature this may be, at all events the absurdity should be terminated that while certain hospital patients are suffering from want of sufficient attention, men of 40 years of age, selected by *concours* as surgeons of hospitals, find themselves unable to fulfil their functions and justify their title.

**FOOD ANALYSIS IN PARIS.**—Any person bringing a sample of food may have a so-called qualitative analysis performed without fee. Practically it is often quantitative, but in the certificate the article is merely described as

good, passable, bad but not injurious, or bad and injurious. For the convenience of the public, articles to be submitted to this examination are received at any of the police stations, whence they are conveyed daily to the laboratory in a police van. For a more complete or quantitative examination in which numerical estimates are furnished, a fee is charged, varying from 5 to 50 francs. Each purchaser must give the name and address of the vendor of the article he submits, and if found "bad," an inspector is at once sent to the shop to inspect the similar articles in stock, and to obtain samples with the usual formalities for their identification. If these are again condemned, proceedings are instituted by the Municipal Authorities. The names of the original purchasers are not made public, but though they omitted to comply with the legal precautions required for a prosecution, yet knowing that they did not tamper with the articles themselves, they naturally withdraw their custom from the shop in question. The fraudulent tradesman thus suffers in the loss of custom, a further penalty and probably a heavier one than the fine imposed by the Court, which alone is too often but a small discount on his ill-gotten profits. This is certainly one of the matters that they order better in France.

**ACTION FOR A SURGICAL FEE.**—M. Labbé, the well-known Parisian surgeon, performed ovariectomy in a lady in 1881, having fixed his fee at 1,500 francs only in consequence of the pecuniary circumstances of his patient. The operation proved fatal; and not having received payment, M. Labbé in 1883 brought an action against the husband and his nephew, who were joint heirs of the deceased. They refused payment on the ground that the operation, which was performed in a *maison de santé*, so far from taking place with the consent of the husband, did so in spite of his opposition to it. The tribunal, however, chiefly relying on a letter of the husband acknowledging the debt, condemned the defendants to the payment of the sum sued for.

**FATAL CASE OF DIPHTHERIA CAUGHT FROM A PATIENT.**—The superintendent of the municipal hospital of a Russian city has died of diphtheria after three days illness. He caught the disease from a child whose throat he was painting. The Town Council has arranged to provide for the family of the deceased medical officer.

**ESTIMATION OF UREA.**—The hypobromite process is without doubt the simplest and most rapid, but the solution being very unstable has to be always freshly prepared. Dr. Squibb suggested the substitution of the U. S. P. Liq. sodæ chlorinatæ, but for reasons not well understood, it does not give such constant or accurate indications. Dr. A. B. Lyons believes, however, that he has overcome the difficulty by an extemporaneous conversion of the hypochlorite into hypobromite. To the solution of chlorinated soda (which must answer the U. S. P. requirement of containing at least 2 per cent. of available chlorine), 25 cc. of which should be sufficient to decompose the urea in 4 cc. of urine, he adds 5 cc. of a 20 per cent. solution of potassium bromide a few minutes before the urine is introduced. With some samples of the solution of chlorinated soda, it is necessary to add a little caustic soda, 2 to 5 cc. of a 10 per cent. solution, to insure the absorption of all the CO<sub>2</sub> evolved. The results are identical with those of the hypobromite and the re-agents always easily procurable.

**DETERMINATION OF CASEIN IN COW'S MILK.**—J. Frenzel and T. Weyl (*Zeit. physiol. Chem.*) have proposed a method of precipitation by dilute sulphuric acid, after previously diluting the milk with 3 vols. water. The results obtained by this method are compared with those of Hoppe-Seyler's, which consists in acidification with acetic acid after previously diluting the milk to 20 vols., and completing the precipitation by passing a stream of CO<sub>2</sub>. The effect of varying the conditions of precipitation was also investigated. The results differ but slightly from those obtained by Hoppe-Seyler's method, over which the authors' has the advantage of being more expeditious.

**DISTRIBUTION OF AMMONIUM SALTS AND FORMATION OF UREA.**—According to W. Salomon, the blood of dogs, rabbits, and kine contains 2.2—4.9 mgrams. ammonia per

100 c.c.; 100 grams rabbit liver contain 7.0—11.8 mgrams.; 100 grams muscle of dog and rabbit 6.1—12.4 mgrams. The kidneys are not necessary for the change of the ammonium salts into carbamide, and in the herbivora the seat of change is the liver.

**MUSTARD POULTICE ON A SPONGE.**—The latest method of applying a mustard poultice is by means of a sponge. The plaster having been prepared in the usual way, a sponge is dipped into it, then wrapped in a soft handkerchief, and applied to the part. By simply warming the sponge again and moistening it afresh, it may be reapplied, the strength being perfectly preserved. — *Philadelphia Medical Reporter.*

**SHAKESPEARE'S DOCTOR.**—Under this heading, the *Allegmeine Wiener Medicinische Zeitung* (July 21) announces that a grave-stone exists in the churchyard of Fredericksburg bearing the following inscription:—"Here lies Edward Heldon, a medical and surgical practitioner, the friend and companion of William Shakespeare, of Avon. He died after a short illness in the year of our Lord 1618, in the 70th year of his age."

**HOW TO TAKE A PILL.**—For the very numerous class of persons who find the taking pills a difficulty or even an impossibility, Dr. Asthalter directs (*Philadelphia Medical Reporter*, July 25) them to place the pill or pills under the tongue, then take a mouthful of water or other liquid, and swallow this just as in ordinary drinking. The tongue turns back upon itself, and the pill is imperceptibly washed down.

**LONDON HOSPITAL MEDICAL COLLEGE.**—The following is the list of prizemen for the Session 1884-5:—Entrance science scholarships for proficiency in the subjects required for the Preliminary Scientific M.B. examination at the University of London—60*l.* scholarship, W. S. Fenwick; 40*l.* scholarship, J. H. Sequiera. Buxton Scholarships for proficiency in the subjects required for the Preliminary examinations—30*l.* scholarship, H. M. Speechly; 20*l.* scholarship, R. J. Williams. Clinical medicine—20*l.* scholarship given by the House Committee and the Medical Council—W. Rawes; certificate, F. J. Smith. Clinical surgery—20*l.* scholarship given by the House Committee and the Medical Council—W. Rawes; certificate, F. J. Smith. Clinical obstetrics—20*l.* scholarship given by the House Committee and the Medical Council—W. Rawes; certificate, A. Barrell. Duckworth Nelson Prize—W. Rawes; certificate, F. J. Smith. Letheby Prize for proficiency in chemistry, 30*l.*—C. R. Killick; certificate, J. K. Warry. Anatomy, physiology, and chemistry—25*l.* scholarship given by the Medical Council—E. O. Ashe; certificate, S. J. Cole. Anatomy and physiology—20*l.* scholarship given by the Medical Council—J. J. Coulton; certificate, O. M. Jones. Dresser's prizes for zeal, efficiency, and knowledge of minor surgery, given by the House Committee—15*l.* prizes, B. Walker, and one not awarded; 10*l.* prizes not awarded; 5*l.* prizes not awarded. Dissection prizes—1, S. J. Cole; 2, W. S. Fenwick; 3, J. J. Coulton; 4, C. R. M. Green.

**THE NEEDLE OF A HYPODERMIC SYRINGE LOST IN THE BODY.**—It has been proposed to make hypodermic syringes of metal, the needle being in one piece with the rest of the instrument. A case illustrating the danger of a needle becoming loosened has occurred in Russia. While a baby was being operated on with a Pravaz syringe the needle suddenly disappeared into the pleural cavity. The case terminated fatally.

#### APPOINTMENTS.

**BOURNE, ALFRED, L.R.C.S., L.R.C.P.**—Medical Officer to the Osmotherly District, Northallerton Union, *vice* Mr. J. M. Cumine, resigned.  
**BULLOCK, JOHN GEORGE WRIGHT, L.R.C.S. Ire., L.R.C.P. Edin.**—Medical Officer to Rugby District and to the Workhouse, Rugby Union, *vice* Mr. G. F. Sadd, deceased.  
**CHETHAM, STRODE REGINALD, M.B., C.M. Edin.**—House Surgeon to the County Hospital, Huntingdon.  
**COX, WILLIAM L., M.R.C.S. Eng., L.S.A. Lond.**—Medical Officer to the Bishop's Castle No. 1, and Lydbury North District, Clun Union, *vice* Dr. Lemon, resigned.  
**ELKINGTON, THOMAS, M.R.C.S. Eng., L.R.C.P. Edin.**—Medical Officer to the Priors, Marston District, Southam Union, *vice* Mr. F. W. Powke.

**FLEMING, W. J., M.D., C.M. Glas., F.F.P.**—Visiting Surgeon to the Glasgow Royal Infirmary, *vice* Eben Watson, whose term of office expires.  
**GORDON, W. S., B.A., M.B.**—Resident Medical Officer to the District Lunatic Asylum, Mullingar.  
**MATHEY, ARTHUR, M.R.C.S., L.R.C.P.**—House Surgeon to the Croydon General Hospital.  
**WEBB, J. EUSTACE, M.B., C.M.**—Junior House Surgeon to the Western General Dispensary, Marylebone Road.

#### VACANCIES.

**BRIDLINGTON UNION.**—Medical Officer for the First District, and to the Workhouse, in succession to Dr. C. F. Hutchinson, resigned. Area, 13,989 acres. Population, 10,607. Salary, £65 per annum. Salary for Workhouse, £15 per annum.  
**COVENTRY AND WARWICKSHIRE HOSPITAL.**—House Surgeon. (*For particulars, see Advertisement.*)  
**EASTERN DISPENSARY OF BATH.**—Resident Medical Officer. (*For particulars, see Advertisement.*)  
**GENERAL HOSPITAL FOR SICK CHILDREN, PENDELBURY, MANCHESTER.**—Junior Resident Medical Officer. Salary, £80 per annum, with board and residence. Candidates must be doubly qualified and on the Medical Register. Applications, stating age, and accompanied by not more than six recent testimonials, to be sent to the Chairman of the Medical Board on or before September 2nd.  
**MANCHESTER ROYAL INFIRMARY.**—Resident Medical Officer. (*For particulars, see Advertisement.*)  
**NORTH EASTERN HOSPITAL FOR CHILDREN, HACKNEY ROAD, E.**—Physician. Candidates must be Fellows or Members of the Royal College of Physicians, London. Applications, with qualifications and testimonials, to be addressed to the Secretary, City Office, 27, Clement's Lane, E.C. (from whom further particulars may be obtained), on or before August 31st.  
**ROMSEY UNION.**—Medical Officer for the Fourth District, in succession to Mr. H. Dayman, deceased. Area, 2,000 acres. Population, 948. Salary, £16 per annum.  
**ST. BARTHOLOMEW'S HOSPITAL, CHATHAM.**—Assistant House Surgeon. Salary £100 per annum, with board, lodging, washing, &c. Candidates must be registered Medical Practitioners. Applications, stating age, with testimonials, to be sent under cover to the Clerk to the Trustees endorsed "Application for Assistant House Surgeon," on or before September 19th.  
**THE GENERAL INFIRMARY AT LEEDS.**—Resident Obstetric Officer. Salary, £100 per annum, with board and residence in the Infirmary. Applications to be sent to Mr. Blair, General Manager, before September 10.—Also, Honorary Obstetric Physician. Candidates must have obtained a degree in Medicine at one of the Universities of the United Kingdom, or be Members or Fellows of the Royal College of Physicians of London. Applications to be sent to the Treasurer at the Infirmary, marked "private" before September 5.  
**UNIVERSITY OF ABERDEEN.**—Examiners in Medicine. (*For particulars, see Advertisement.*)  
**WESTON-SUPER-MARE HOSPITAL.**—House Surgeon. Salary, £70 per annum, with board, lodging, and washing. Candidates must possess a registered Medical and Surgical qualification and be unmarried. Applications and testimonials to be sent to the Honorary Secretary on or before September 5th.

#### DEATHS.

**CHALMERS, DAVID, M.D.,** of Slades, Bramley, Surrey, on Aug. 21st in his 75th year.  
**DAYMAN, HENRY, F.R.C.S.,** at Brooklands, Millbrook, Southampton, on August 19th, in his 77th year.  
**WARDELL, J. R., M.D., F.R.C.P.,** of Calverley Park, Tunbridge Wells, at Brighton, on August 21st, aged 65.  
**WEST, JOHN RUSSELL, M.B.,** at Royal Marine Terrace, Bray, on August 17th, aged 35.

#### NOTES, QUERIES, AND REPLIES.

##### THE CASE OF DR. BRADLEY.

TO THE EDITOR OF THE MEDICAL TIMES.

SIR,—I enclose a further list of subscriptions, which, perhaps, you will kindly publish in the next issue of your Journal.

I remain, yours faithfully,

August 26th, 1885.

RICHARD JEFFREYS.

Sir Prescott Hewett, Bart., £10 10s.; Sir James Paget, Bart. £5 5s.; Dr. Wilson Fox, £5; Mr. J. W. Hulke, Dr. Hughlings Jackson, A Friend, £3 3s.; Sir Joseph Fayrer, K.C.S.I., Dr. Lionel S. Beale, Mr. Charles Higgins, Dr. Ogle, Mr. Heury F. Butlin, Dr. Jackson, Mr. E. Nettleship, Dr. Thomas Barlow, Dr. Macnaughton Jones, Dr. T. Lauder Brunton, Dr. Felix Semon, £2 2s.; Dr. James F. Goodhart, Dr. W. Murray, Dr. J. Langdon Down, Mr. Charles J. Bracey, Mr. E. B. Whitcombe, Dr. Thomas Cargill Nesham, Dr. Elliott, Mr. J. Vose Solomon, Dr. Heywood Smith, Mr. James R. Lownds, Mr. Edward Skinner, Dr. W. J. Cleaver, Dr. Edward Jackson, Dr. W. E. Parkes, Mr. G. B. Morgan, Mr. J. W. Bramwell, Dr. W. Stewart, Mr. J. Wright Baker, Dr. H. Radcliffe Crocker, Mr. Thomas Collier, Dr. Drysdale, Mr. Francis Mason, Dr. J. Shearwood Roberts, Mr. Henry Power, Mr. Bruce Clarke, Dr. F. de Havilland Hall, £1 1s.; Dr. John Harvey, Dr. Samuel Morton, Dr. E. Gaylor, Dr. Alfred Harvey, Dr. Charles Vokes, Dr. W. J. Irvine, 10s. 6d.; Dr. Kaye, Dr. J. A.

Malcomson, Dr. Gibb, Mr. R. N. Robson, Mr. E. S. Robson, Mr. W. J. Lancaster, Mr. Thomas F. Hopgood, Dr. Philip P. Fentem, Mr. John P. Bradley, Mr. G. Everitt Norton, Mr. H. T. Woodd, 10s.; Mr. Charles Evans, 5s.; Mr. F. J. Burman, 2s. 6d.

### MEMORIAL TO SIR MOSES MONTEFIORE.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—The Memorial to be raised as a tribute to the memory of the late Sir Moses Montefiore in connection with the Chelsea Hospital for Women, has been approved by the leaders of the Jewish Community and other influential persons, and encouraged by contributions given or promised. The reasons, which have induced the Board of Management to undertake the Memorial are:—

(1) That there is no similar hospital where poor Jewish women, suffering from the distressing diseases peculiar to the sex, can secure privacy in companionship with their co-religionists, have supplied to them Kosher food prepared in Kosher utensils, and be able to observe the cherished rules of their faith. It is impossible to overestimate their appreciation of these privileges.

(2) That the late Sir Moses Montefiore was one of the first Governors of the Hospital, and that no more honoured name could be associated with a first effort to make a proper provision for poor and suffering Jewesses. This object may be attained for £1,500, £500 to name a Montefiore Ward and £1,000 to endow and name a Montefiore Bed. Jews and Christians alike are asked to subscribe to this Fund as an "In Memoriam" offering to the memory of the late patriarchal philanthropist, and those who are kind enough to do so will have the power to recommend the patients for the Montefiore Ward. The Board of Management beg you to allow them to appeal to the readers of the *Medical Times* for their generous support, for not only will it assist them to supply a deficiency in our benevolent organizations of a very humane character, but the Funds will enable the Board to reduce the large debt upon the hospital. Cheques payable to James Debae, Esq., Treasurer, and crossed London and County Bank, or postal orders or notes payable at G.P.O. and also crossed, will be promptly acknowledged by

Your Faithful Servant,  
J. S. WOOD, Secretary.

Chelsea Hospital for Women, Fulham Road, S.W.,  
26th August, 1885.

### MORTALITY IN WINDSOR.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Permit me to correct a mistake in your number of to-day. I am quoted as giving the death-rate of Windsor as 20 per thousand. That figure represents the mortality in what is perhaps our worst slum, the rate for the whole borough being only 13'4.

I am, Sir, yours, &c.,  
EDWARD CASEY.

Park Street, Windsor, August 22nd, 1885.

### COMMUNICATIONS RECEIVED—

Prof. GAIRDNER, Glasgow; Dr. GIBBONS, London; Dr. GUILLEMARD, Cambridge; Dr. CASEY, Windsor; Dr. WILLOUGHBY, London; THE DIRECTOR-GENERAL OF THE NAVY MEDICAL DEPARTMENT, London; THE SECRETARY OF THE UNIVERSITY OF LONDON; Mr. H. K. LEWIS, London; Mr. JOHN BLAND, London; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; THE DIRECTOR-GENERAL OF THE ARMY MEDICAL DEPARTMENT, London; Mr. R. JEFFREYS, Chesterfield; THE TOWN CLERK, Hastings; THE SANITARY COMMISSIONER FOR THE PUNJAB, Lahore; OUR BOMBAY CORRESPONDENT; Dr. BURNEY YEO, London; OUR ROME CORRESPONDENT; THE MILITARY SECRETARY OF THE INDIA OFFICE, London; Dr. SHELLY, Hertford; Mr. T. HOLMES, London; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; Dr. MAXWELL, Woolwich; Mr. E. NETTLESHIP, London; Dr. J. WARD COUSINS, Southsea; Dr. CRICHTON BROWNE, London; Dr. TIRARD, London; Mr. SCOTT BATTAMS, London; MEDICUS; THE BOARD OF MANAGEMENT OF THE CHELSEA HOSPITAL FOR WOMEN, London; Mr. STEVENS, London.

### BOOKS RECEIVED—

A Text-Book of Medical Physics, by John C. Draper, M.D., LL.D.—Report on the Health, Sanitary Condition, etc., of the Borough of Hastings, for the quarter ending June 30th, 1885—Report on the Health and Sanitary Condition, etc., of the City and County of Bristol, for the quarter ending July 4th—Old Age and Changes Incidental to it, by Professor Humphry—A Schoolmaster's Retrospect, by Maurice C. Hinne, M.A., LL.D.

### PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Weekblad—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—Revue Médicale—Alienist and Neurologist—The American Journal of Obstetrics—The Western Medical Reporter—Scienze Mediche—La Cronica Medica—Canada Medical and Surgical Journal—El Monitor Médico—The Ophthalmic Review.

### HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.; Chelsea Hospital for Women, 2.30 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## ACUTE ANTERIOR POLIOMYELITIS.

By R. A. GIBBONS, M.D., M.R.C.P.,

Physician to the Grosvenor Hospital for Women and Children.

A BOY, aged 9 years, was seen by me on May 15th of the present year, because he was suffering from pain on the inner side of each thigh. I heard that on the previous day, whilst attempting to jump over a string, he tripped and fell on his knees, the thighs being wide apart. He felt pain at first, which soon passed off, and he walked about; during the afternoon he worked at his lessons in school without complaint, but on returning home later in the day said that he felt tired. He went to bed before his usual hour, but did not sleep well.

On examination I found that there was considerable tenderness to touch along the whole inner aspect of each thigh, and that this was especially marked along the ramus of the pubes on either side, but there was no swelling observed. He could move his limbs freely in bed, although it caused pain in the thighs and in each groin. Temperature 99° F., pulse 100, perfectly regular. He was ordered no medicine, but rest in bed with hot fomentations to the pained parts.

In the family history it is only important to mention

that an elder sister still suffers from the effects of infantile paralysis. There are four children older and one younger than the patient, but, with the exception mentioned, there is nothing calling for observation. There is no history of nervous disease on the mother's or father's side.

*Previous History.*—He has always been a quick and intelligent child, but never robust. He has had whooping-cough, chicken-pox and mumps. After the latter he suffered from pain in the left ear, soon followed by discharge, from which he quite recovered. Occasionally he has had attacks of uric acid in the urine. He used formerly to have "night-terrors." About five years ago he had rather a severe blow on the head from a fall, and for some time afterwards is said to have constantly blinked his eyes as if he could not keep them open. During last winter, whilst in the country, he frequently complained of pain in the lower part of the back, and of being tired, but no notice was taken of this.

On the following morning I again saw him, because the pain of which he complained was no better, the fomentations only giving temporary relief. On the inner aspect of each thigh there was still tenderness to touch, but the pain seemed now to be more general over the thighs. There was also distinct loss of power in the lower extremities; he could draw them up in bed, but only slowly and with great difficulty. I ascertained from the nurse that seven days ago (the 9th) he had received a blow on the lower part of

the back with the butt end of a toy metal pistol, weighing about four ounces, which caused him great pain at the time. This was in the same region of the back of which he had frequently complained last winter. On examination of the spinal column I found that he complained of pain on pressure over the lower dorsal region—especially the lower three dorsal vertebræ which were more prominent than the rest. There was also sensitiveness to pressure in the lower cervical region, and in both of the situations mentioned the application of a hot sponge caused great pain, which could be only endured for a second, whereas in other parts of the spinal column it produced no great uneasiness.

The patella-tendon reflex was absent from each limb; the plantar reflex was not active, but was not lost. All the other superficial reflexes were present. There was no ankle-clonus. Sensation perfect; grasp of each hand good. Temperature 101°, pulse 100, regular. In the evening of the same day the loss of power was more marked, and the superficial reflexes, with the exception of the cremasteric, gone. He could not now raise or draw up either limb, and could only move the toes slowly and, apparently, with considerable effort. He could not sit up in bed properly; when asked to do so he dragged the lower limbs upwards along the bed by using his hands as a fulcrum and partially raising the trunk; he then placed his arms behind him, and endeavoured to prop himself up. But he could remain in this attitude for a few seconds only. The squeeze of each hand was not so good as it ought to have been. The bowels had acted naturally, and he had passed water freely. It had a specific gravity of 1.015, was acid in reaction, phosphatic, and loaded with urates; but contained no albumen, sugar or bile.

Swallowing was perfect, and he took nourishment well. Vision good; pupils natural and active; accommodation good. Ophthalmoscopic examination revealed nothing abnormal.

There was no tendency to the formation of sore over sacrum. Respiration was regular and natural. Hearing and taste normal. Towards night the pain in the limbs, for it had now extended to the legs also, was increased, and he said that he felt numbness in the latter. The nurse stated that she noticed occasional twitches in the legs. He was lying in the posture of a paraplegic. As the pain was so severe I ordered bromide of potassium in doses of ten grains.

On the morning of the following day he was crying with the pains in his limbs, but I heard that, on the whole, he had passed a fairly good night, and that the medicine seemed to soothe him.

I now had the advantage of Dr. Gee's opinion, who suggested, as to treatment, tincture of belladonna in doses of ten minims every four hours, in addition to a belladonna plaster along the spinal column. The prognosis was undoubtedly grave.

On the 18th he was in considerable pain, and now complained of "pain in the stomach." On asking him what kind of pain it was, he replied that it was a "peculiar pain as if something tight were tied round him"; this expression was not suggested to him. Temperature 101.2°. The other signs remained the same, the superficial and deep reflexes being abolished with the one exception of the cremasteric, which acted feebly. He also complained of "pins and needles" in his feet. It was noticed that the muscles of the thighs and legs felt flaccid and flabby, and already seemed somewhat wasted.

On the 19th his condition was precisely the same. On this day I examined his muscles with faradism. Commencing with a weak current and gradually increasing until the greatest strength was reached from the primary coil, I obtained no reaction whatever in

any of the muscles, which were tested in regular order, of either lower extremity. With a very powerful current from the secondary coil there was no reaction at all in the left leg or thigh; in the right all the muscles failed to respond with the exception of the tibialis anticus, which acted very feebly. The reaction of the flexors and extensors of the upper extremities was not so good as natural. This examination caused considerable pain. I may state that the battery was freshly charged, and had recently been put into good order.

From the day following, his condition gradually improved, the first favourable sign being that he could move the toes of each foot.

On the 21st he could move the legs slightly, and on the 22nd could draw them up and move them with ease in bed. On again testing with the faradaic battery it was found that the contractility had returned in all the muscles.

On the 24th he was able to stand for a minute unsupported, and the belladonna was omitted. The superficial reflexes were all again present, as well as the knee-jerks.

With regard to the belladonna it is noted that he was taking it, in all, for eight days, from the 17th to the 24th inclusive. After administering it for a little more than 24 hours it was omitted for 8 hours because of slight delirium, the pupils being well acted upon; but he did not complain particularly of dryness of the throat, and no rash was noticed. With the exception mentioned he bore it well until it was stopped.

On June 7th a poroplastic jacket was applied which gave him great support and comfort. He afterwards walked about gently, but not up or down stairs, and he seemed in excellent spirits. Three weeks later I examined the back. He complained of no pain on percussion over the three lower dorsal vertebræ, and the prominence in this region, although still present, was certainly not so pronounced. He was kept at rest a good deal, but was in the open air as much as possible, either driving or in a little carriage which could be drawn about. He was then taking quinine, iron and cod-liver oil with good nourishing diet.

This case presents some points of extreme interest. Although it might be contended that the fall upon the knees, followed, as it was almost immediately, by severe pain in the thigh, was the starting point of the inflammatory trouble in the cord, yet I think that, taking all into consideration, it was much more probably due to the blow upon the weakened part of the spinal column. It will be remembered that during the past few months he had been complaining of pain and aching in the lower part of the back, and although it was not then considered of sufficient importance to seek advice concerning it, one cannot now doubt that commencing Pott's disease was present, and was most likely the indirect cause of the alarming symptoms following the blow. As, however, these symptoms did not appear until seven days after the blow, and the pain immediately followed the shock caused by the fall on the knees, it might still be argued that there existed cause and effect between the latter. And in dealing with such a case it is of great importance that the etiology should be clearly understood both in reference to prognosis and to the treatment.

One cannot lightly pass over the fact that the shock to the spinal column, from the fall upon the knees, must have been considerable, especially to the already damaged part, but it can hardly be believed that such clearly indirect violence communicated through the femora would have so great an influence as a blow directly delivered over the affected region. I have been unable to find the record of any case of a similar nature, whereas it is well known that occasionally

direct violence to the spine is followed by symptoms comparable, in some respects, to the foregoing, without the existence of any previous disease of bone.

Now, as to the diagnosis of the exact lesion causing the train of symptoms present. This is of the greatest importance in such a case, on account of the possibility of giving a favourable prognosis, or otherwise, on the full development of the symptoms. As these symptoms were, without doubt, the result of a blow, the first point that must be enquired into is as to whether they were due to what is commonly called spinal concussion. But, as no signs of anything wrong appeared for so many days after the blow, and the pain consequent upon it rapidly disappeared; and as, moreover, the signs and symptoms could not be regarded as corresponding in any way to the ordinary varieties of spinal concussion, time need not be taken up with this point. It may, however, be remarked that in those cases of spinal shock where at first the patients think nothing of the injury, and where, later, symptoms develop, they point to a meningo-myelitis associated with disturbances of the cerebral functions rather than to spinal trouble alone.

It is hardly necessary to say that this case had nothing in common with the paraplegia sometimes met with in cases of Pott's disease, due to compression of the cord from purulent or inflammatory material within the canal. In such a case, although there would be well-marked paraplegia, and sensation would remain (unless, indeed, the compression had reached the grey matter), the cord would be healthy below the seat of pressure, and the excito-motory function would remain; so that the reflexes would be all present. And as the membranes would be involved, and, therefore, an irritation of the cord would exist by means of the roots of the nerves, there would probably be spasm and rigidity, faradaic contractility being present. But in the case related the reflexes and faradaic contractility were absent.

There was nothing in the onset and symptoms suggestive of hæmatorrhachis or of pachymeningitis, and the ætiology of such affections would almost certainly exclude them; but as they both occasionally happen in Pott's disease they are worthy of mention. It might be as well to add that in both these affections the pains are generally most severe, there being the usual signs of first spinal irritation and subsequent paralysis; in both, also, the chief symptoms of motor irritation are spasmodic jerking of the muscles, increased cutaneous reflexes and tendon reactions—motor and sensory paralysis next appearing.

Nor was the pathological condition one of pure spinal meningitis; for although he complained of pain in the back, it was not of the severe character usually met with in this affection during any muscular movement or bending of the spinal column. Nor was there any rigidity or spasm of a tetanic character; and sensation, as well as the action of the rectum and bladder, was unaffected. These functional disturbances appear early in the disease, probably because of spasm of the sphincters.

The next affection which would probably occur to one in thinking over the diagnosis would be myelitis. But it will at once be granted that the signs and symptoms of the case related do not agree with those which are known to be present in true myelitis. For instance, in the latter affection, although it is characterised, as in the case quoted, by rapid loss of muscular power, it must be remembered that the grey matter of the cord is primarily affected, and that, as a consequence, sensation will certainly be as greatly affected, and probably as quickly, as motion; whereas in the foregoing case sensation was perfect throughout. Again, in a typical case of acute myelitis, speaking generally, there is comparatively little pain, and it is rare for any

pain of a neuralgic character to be present as in this case; although it must always be borne in mind that symptoms in myelitis are often so variable that it is important not to lay too much stress upon the presence or absence of pains of any kind. As the disease advances the feeling of numbness which usually exists gives place to partial or complete anæsthesia. Moreover, in myelitis the sphincters are involved; indeed, paralysis of the bladder is occasionally one of the earliest symptoms, and there may be either retention or incontinence of urine, whilst the bowels also act involuntarily, none of which symptoms were present in this patient.

By a process of elimination we come to a disease to which all the symptoms and signs can be referred, namely, acute anterior poliomyelitis. When this affection occurs it is so usual for it to be purely of an idiopathic origin in children that it is apt to be forgotten in dealing with such a case as the one under consideration. The fact that the blow was received seven days before well-marked symptoms supervened will not invalidate this diagnosis, for there are many cases on record of several days elapsing between the receipt of an injury and the development of spinal symptoms. A very remarkable example of this is to be found in a case recorded by Mr. Simon in the Pathological "Transactions" for 1855. In this case a girl, aged 18, had a fall, soon recovered from its effects, and walked home a distance of three or four miles. After eleven days pain in the back with vague symptoms of pain and tenderness over the body, not altogether unlike hysteria, manifested themselves. Movements of the trunk in bed were difficult. This was soon followed by numbness and twitching in the extremities, and after a few hours by paralysis, complete in the legs, and to a marked degree in the arms. She died on the fourth day from the beginning of the symptoms.

Dr. Wilks in his work on "Diseases of the Nervous System" mentions the case of a boy aged fifteen, who was admitted into Guy's Hospital. He had been playing with another boy three days previously and had received a blow on the back, of which he thought little at the time; but he applied to the hospital on account of increasing pain, and died with spinal symptoms twenty-two days after the receipt of the injury.

It is evident that my case was not one of sub-acute anterior poliomyelitis or general spinal paralysis, because here the paralysis commences insidiously and progresses gradually, tending to invade all the voluntary muscles until the patient can neither stand nor walk. It is important to note that it is unattended by febrile disturbance, and although, in the rapid loss of faradaic contractility and bulk, in the retention of cutaneous sensibility, control over the sphincters, and tendency to ultimate recovery, it somewhat resembles the case under consideration, yet it is essentially chronic in its course, extending over a lengthened period.

No doubt the malady from which this patient suffered is identical in many respects with that of infantile paralysis; and the fact of its occurring at the age stated would, perhaps, be sufficient ground, in the opinion of many, for immediately placing it under that heading. Now, although the pathology may be similar, the case related is different in several essential particulars. Apart from the important facts that the vast majority of cases of infantile paralysis occur at a very much earlier age, especially during the first dentition, and that there is seldom any assignable cause, the onset alone of the case related would certainly place it beyond the category of infantile paralysis; for in the latter the children are usually struck down in the midst of apparent health. According to Dr. West<sup>1</sup>

<sup>1</sup> On Diseases of Infancy, p. 242.

cutaneous hyperæsthesia is often present at the commencement, although this is certainly not a constant accompaniment. "Often, however," he says, "sensation in the affected limb appears to be exalted when the paralysis is recent, the degree of hyperæsthesia in the early stage being in such cases proportionate to the completeness of the loss of power which afterwards is apparent." Again, it is very common to have only one limb or a group of muscles affected. Of sixty-two cases which have been observed by Duchenne (fils) twenty-five were of the right lower limb, ten of the right or left upper limb, seven of the lower limb, one hemiplegia, two crossed paralysis, two lateral paralysis of the upper limb, only nine of paraplegia and five of general paralysis; the remaining one being paralysed in the muscles of the trunk and abdomen. So that out of this number forty-seven cases were partial only. Of forty-four cases under the observation of Dr. West, forty were merely partial, that is involving one or two limbs only. In infantile paralysis it may be mentioned that there is always a loss of five or more degrees of temperature in the paralysed parts, and in proportion to the amount of loss of electro-muscular contractility do the muscles undergo atrophy and subsequent degeneration, and tend to increase the gravity of the prognosis. One more very important point in relation to infantile paralysis which should be noted is that there is, comparatively speaking, very rarely absolute recovery. And this is true of cases which at first might appear to be most favourable. In nearly all, some general weakness remains, or a group of muscles does not regain power, or, perhaps, even only one or two muscles are left permanently unfitted for use.

As before remarked, it is unquestionable that in some respects there is great similarity between the case under consideration and infantile paralysis, and, as I shall presently explain, my belief is that it is merely a question of degree in the amount and intensity of the hyperæmia affecting the substance of the anterior horns and the ganglionic cells contained therein. In reference to this point, I may be allowed to quote at length a passage from Reynold's System of Medicine, written by Dr. Radcliffe more than thirteen years before the exact pathology of these affections was understood. He says, "It seems to me that the peculiarities of infantile paralysis, instead of showing that it is unlike paralysis in adults, only show a close analogy to, if not an actual identity with, the paralysis which has been seen to result from spinal congestion. In infantile paralysis sensation is exaggerated rather than dulled in the paralysed parts; in paralysis from spinal congestion it is the same. In infantile paralysis the bladder and lower bowel are obedient to the will, so also in paralysis from spinal congestion. In infantile paralysis the limbs are limper, not rigid: so also in paralysis from spinal congestion. In infantile paralysis recovery more or less complete is the rule rather than the exception; so also, and very much in the same order in paralysis from spinal congestion. Neither do I know of anything to invalidate the conclusion which these resemblances would seem almost to necessitate that infantile paralysis is nothing more than paralysis from spinal congestion.

In detailing the affections which this case might suggest, it is necessary to include diphtheritic paralysis. As is now well known, the pathology of this disease is identical with the two preceding disorders, and it is, therefore, important to mention it; more especially as it is now known that severe forms of diphtheritic paralysis occasionally follow cases of apparently the mildest sore throat, indeed, in some where no complaint whatever has been made. But it is hardly possible for this case to have been one of diphtheritic paralysis. He had no sore throat nor any

history of one, or of exposure to poison, nor was there the least reason to suspect paralysis of the soft palate. Again, sensibility is nearly always diminished in the paralysis following diphtheria, and there is usually in cases so severely ill as this patient more or less impairment of the organs of sense. The eyes especially suffer, there being loss of accommodation owing to paralysis of the ciliary muscles, or squinting, or double vision, none of which were present.

In reviewing the series of phenomena presented by this case, one is forced to the conclusion that they must be of rare occurrence in patients of this age. As far as I am able to ascertain, it is the first recorded case of what may be paradoxically called "Adult Spinal Paralysis," *i.e.*, acute anterior poliomyelitis. From the receipt of the blow to the onset of symptoms was seven days; from the commencement of symptoms to the stage of absolute paralysis was forty-eight hours, and from the onset of paralysis until recovery of reflexes and return of faradism was seven days.

In adults such cases are by no means extremely rare, and have been easily recognised since Duchenne and Charcot first described them, but the interest of this record lies in the fact that hitherto cases have not been noted as occurring at so early an age.

From the cases of adult spinal paralysis or acute anterior poliomyelitis, published by Duchenne and Charcot, it would appear that adults are attacked by a disease resembling in all particulars infantile paralysis. These records show "that it comes on in adults, as in children, with febrile symptoms, lasting it may be for a few days, and attended with, or followed by, motor paralysis of a greater or lesser number of voluntary muscles, but without implication of cutaneous sensibility, loss of control over the rectum or bladder, or tendency to the formation of bed sores; that the muscles are flaccid, incapable of excito-motor action, and tend rapidly to lose their faradaic contractility and to waste, and that after the paralysis has reached its highest degree, more or less amendment takes place."<sup>2</sup> It sometimes happens in the case of the adult, as also probably in the child, "that pain in the spine with forward curvature, and some degree of pain in the limbs, attend the onset of the disease." Of course, the history of the disease in adults differ from that of the infantile disorder in the necessary absence from it of all mention of the varied deformities resulting from defective development.

The pathology of this affection is doubtless identical with that of infantile paralysis; that is to say, that the changes usually described occupy only the anterior cornua of the spinal cord, as they do also in diphtheritic paralysis, concerning the pathology of which our knowledge has much increased of late years. There can be no doubt but that in this case the parts principally affected were the anterior cornua. As occurs in diphtheritic paralysis the large motor cells were in all probability merely swollen, thus causing loss of function, and in many spinal cases it must be purely a question of degree as to how much or how little these multipolar cells suffer. If they are only slightly affected, function is but temporarily in abeyance, whereas if the swelling is considerable and persistent, permanent damage occurs and atrophy ensues, leading to lasting paralysis as in infantile palsy. It is a matter for others to decide as to how these multipolar nerve cells become swollen at all. But it is reasonable to suppose that, owing to a general or localized hyperæmia, there is a certain amount of exudation from the nearest capillaries, which by a process of osmosis finds its way into the transparent membranous capsule surrounding each ganglion cell.

In the Transactions of the International Medical

<sup>2</sup> "Theory and Practice of Medicine." Bristowe. Last Edition.

Congress for 1881, Dr. Abercrombie published an important paper on diphtheritic paralysis in children. He says "the only pathological changes I have been able to detect are in the grey matter of the anterior cornua, and they consist in a swollen condition of the large motor cells. The margins of these are very ill-defined, and the processes have in most instances entirely disappeared. The contents of the cells have a granular aspect, and the nuclei have disappeared, or where still visible are highly granular. These changes only occur in very limited areas, and I have not found them constantly in any one region of the cord; but more commonly in the upper and middle dorsal regions than elsewhere. Where one cell of a group is affected all the cells of that group show some change. In some places the cells appeared shrunken rather than swollen. Perhaps this is a later stage of the same process."

In five cases of diphtheritic paralysis examined by M. Déjerine,<sup>3</sup> similar changes, although more advanced, were found, and he also discovered on investigation that the posterior roots were all healthy whilst the anterior were affected by neuritis.

Dr. Percy Kidd, in the Transactions of the Medico-Chirurgical Society for 1883, gives the result of a careful examination of the pons, medulla, and spinal cord from a fatal case of diphtheritic paralysis. In many sections from the dorsal region of the cord there was numerical atrophy of the anterior nerve cells. In the same cornua, mingled with the ordinary multipolar nerve cells, were small indistinct cells which had lost their processes, and in some cases tended to assume a globular form; these cells were more often granular than natural. In none of these sections were the nerve cells observed to be swollen, but the changes all tended towards atrophy. This may have been due to the fact that the patient was ill for a little over two months.

In the Transactions of the Pathological Society for 1879, there is the report, by Dr. Charlewood Turner, of a case said to be acute anterior poliomyelitis in a child aged two years and a half, fatal within six weeks from the onset, which evidently originated from a fall on the back. But this case differed from mine in several respects. Sensation over the limbs was lost at the beginning, and the evacuations were passed involuntarily; the latter alone would suggest the idea of acute myelitis. The child died of measles complicated with broncho-pneumonia. In a most careful microscopical examination of the cord of this case, made by Mr. R. W. Parker, it was found that the antero-lateral column of the left side was distinctly smaller than that of the right. About the centre of the lumbar enlargement there was a patch of reddened gelatinous-looking matter corresponding with the anterior cornu of the left side. The margin was darker in colour than the centre as from a de-colorisation of hæmorrhagic extravasation. In the neighbourhood of this point of hæmorrhage the grey substance had undergone extensive changes. No other similar patches of hæmorrhage were found. Although both anterior cornua were profoundly affected in the lumbar enlargement, it is noted that the posterior cornua were also involved, the right posterior cornu being less extensively affected than the left and showing more numerous polar cells. Mr. Parker considered these latter changes to have been of a secondary character, and not sufficient to remove the case from the category of infantile paralysis. Probably, judging from the state of the cord, the child would have been permanently paralysed had she survived the measles.

Drs. Andrew and Duckworth have recorded a

case of "all but universal paralysis in a child aged two and a half years, following exposure to heat, with complete recovery."<sup>4</sup> In this there was anæsthesia of all the parts affected by motor paralysis. In the legs a strong faradaic current excited only slight reflex movements. The action of the sphincters was involuntary. The child was ordered belladonna at the suggestion of Dr. Gee. Ten days afterwards it was noted that the child could raise both hands over her head and feed herself, and that there was increasing power in the right leg, whilst sensibility had returned in both. Four days later she had control over the sphincters. The belladonna was continued for three weeks and then omitted. After an attack of nephritis she slowly recovered. In this case the signs and symptoms would suggest rather a general myelitis than an inflammation of the anterior horn, for, as the authors state, it was not an ordinary case of infantile paralysis. They attribute the onset to direct exposure to the sun and severe thermal influences. They note that the first symptoms of amendment were observed on the fourth day after commencing the belladonna, which was prescribed in the form of the extract, one-third of a grain three times daily in a sweetened mixture, and a strip of belladonna plaster along the whole length of the spine. It is worth calling special attention to the employment of this drug in such nervous cases as those quoted. The view held by therapeutists that it possesses an influence of checking spinal hyperæmia seems to be frequently justified by results. Dr. Abercrombie speaks highly of its employment in a severe case of diphtheritic paralysis which recovered,<sup>5</sup> and I have seen certain nervous cases where its employment seemed to be undoubtedly followed by much benefit.

It is well worthy of note how admirably this case illustrates the remarks of Müller, referred to by Dr. Buzzard,<sup>6</sup> that notwithstanding the complete disappearance of faradaic excitability, or even "the reaction of degeneration in the first stage, one can conclude nothing as to the curability or incurability" of any patient under examination.

In concluding these remarks, I desire to state that although I have carefully searched many records I have failed to find any case similar to the subject of this communication. The onset, symptoms, absence of paralysis of sphincters, complete loss of faradaic contractility, retention of sensation, ending in perfect recovery, make the case of sufficient importance to place on record.

---

ALEXANDER'S OPERATION FOR PROLAPSE OF THE UTERUS.—In the *Medical Chronicle* for August, Dr. Alexander gives an account in two of his earlier cases of this operation. As is well known, the operation consists in cutting down on the external ring and shortening the round ligaments until it is found that they maintain the uterus in its normal position. The first of these cases had been submitted to operation three years and two months previously; on examination he found the uterus well up, the cervix almost beyond the reach of the finger. The body of the uterus was in a slightly anteverted position. The vagina was very wide, its walls disposed in numerous folds that covered both the vesical and rectal surfaces. The patient had become much stouter, and during the interval had lived a laborious and irregular life without any thought of the weakness of her breech. In the second case, the patient was re-examined more than two years after the operation, when the uterus was found in excellent position; some slight rectocele and cystocele still existed, but there was no tendency on the part of the uterus to prolapse even when tested in various ways.

## PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,  
President of the Health Department, Social Science Association.

### DISEASES OF THE EYE.

(Continued from page 219.)

*Malignant Diseases of the Eyeball.*—Many specimens of various forms are preserved in the Calcutta Medical College Museum:—252, "Epithelioma of the ball of the eye, springing by a broad base from the sclerotic adjacent to the cornea;" 283, 293, "An encephaloid tumour between the ball of the eye and the orbit, pressing upon and causing flattening of the optic nerve prior to its penetration of the sclerotic;" 294, glioma, fungating; 295, 306, 315, 317, 320, "A very unique specimen of melanosis of the ball of the eye, causing complete disorganization of the organ. The section is now of a chocolate colour."

Dr. Robert Brown has reported the case of a Mussulman, of Sylhet, aged 20, with melanosis of the eyeball. The organ was enucleated.<sup>17</sup>

Mr. C. Macnamara says that he considers *cancer* of the orbit to be common. Fresh cases of this formidable disease were seen every year in the Calcutta Hospital, whereas the other forms of malignant disease were rarely seen. Mr. Macnamara's predecessor, Mr. Martin, had only three cases of excision of the eyeball, for malignant disease, in four years.

Considering the unusual prevalence of enervating influences in India, it is remarkable that a larger number of cases of *Amaurosis* should not be observed there among Europeans and natives.

In an old report of the Madras Eye Infirmary, it is stated that the majority of 877 cases of amaurosis (only 12 of which were Europeans), were treated for partial loss of sight, "depending chiefly upon exposure to the sun and night chills," many instances were "the result of febrile disease and inanition succeeding parturition."

I, for some years, watched with interest the condition of a well-grown and healthy English gentleman, who was rendered quite incapable of work in India, by what appeared to be mere congenital weakness of vision. There was no visible defect in the eyes, and the case was not one of amaurosis. He retired from India soon after the age of 30.

In the old report of the Madras Eye Infirmary cited above, it is mentioned that *Night Blindness* is a very prevalent disease in that country; 672 cases, of which only 4 were in European soldiers and 8 in Sepoys, having been treated in 9 years. It was found to be principally confined to the native agriculturists and artisans, and was seldom met with in the European and the Indo-Briton. The alleged causes were exposure to the strong dazzling light and ardent heat of a tropical sun by day, and to chilling dews by night, severe attacks of fever, scanty and bad food, "a disordered state of the alvine secretions" and worms. Females were frequently observed to be affected with this complaint after parturition. It was considered that many of the cases of amaurosis and cataract treated in the infirmary had their commencement in night blindness.

While I was a member of the medical committee for the Calcutta Pilot Service, I saw a great deal of *Hemeralopia* in men who attributed it to the incessant movement of the sun-lit sea when they were stationed in the small light vessel moored at the Sand Heads.

Weavers are liable to be similarly affected by the constant tremulous movements of the threads. Night blindness used to be very prevalent in native jails, probably as an expression of scorbutic cachexia.

Dr. J. W. Moore concludes some valuable remarks<sup>18</sup> on nyctalopia and hemeralopia, as they occur in India, with the following summary of treatment which represents the practice usually followed in that country. "Attention to the general health and prevention of exposure to the exciting causes. Blisters behind the ears, or on the temples have been recommended, but are rarely beneficial. A similar remark applies to leeches. Tonics are always required. But the most important means of cure is confinement during the day in a darkened room. I have found this plan perfectly successful within a week, and it is highly recommended by others. Exercise should be taken in the dark, and companionship provided for the patient to as great an extent as possible."

I always gave quinine in Bengal. An antiscorbutic course will be needed in a large proportion of cases; and, even where signs of scurvy cannot be detected, it will never be wrong to give the patient the benefit of acting on the suspicion that he may be the subject of a scorbutic taint.

*Snow Blindness.*—A friend and brother officer of mine, who was an excellent landscape painter, greatly injured his eyesight by too anxious endeavours to represent the outlines of the snowy range from Khatmandoo. The degree of his blindness fluctuated, but, although much consideration was shown to him he was never practically fit for duty. He died early in England, as I understood from brain-disease. Dr. Cayley has noted<sup>19</sup> that ophthalmia appeared, in many cases which he treated among the inhabitants of Ladak, to have arisen from the glare of the snow whilst crossing mountain-passes, as a protection from which the natives often wear snow-spectacles made of plaited-hair.

*Musca Volitantes*, generally due to functional causes, are frequently complained of in India. Twenty-three years ago, I was sitting writing in a room which was shaded, except that the sun-light entered rather more freely than I usually allowed it to do, and fell upon my left eye sideways. Suddenly there appeared a vivid play of sharp iridescent lines, as if quite outside the temple on that side, rapidly moving in zig-zags, like the lines of an old-fashioned fortification. This has occurred on one or two subsequent occasions, but never since my return to England, more than nine years ago, until, sitting with the left eye towards a moderate light, in cool rainy weather, in July, 1884, the lines appeared in front and on the outer side of that eye. The lines were at first of hair-like tenuity, but brightly coloured. In a few minutes they formed a fortification-like line of prismatic colours, in which blue prevailed, about a sixth of an inch broad. There was not any headache or other uneasiness. On closing the left eye and then both eyes, they did not disappear. The appearance passed off in about a quarter of an hour. A healthy brother officer complained to me, in India, of the same symptom, which caused no more uneasiness than the flash of a lucifer match would do. This did not appear to point to any ill-consequence in either case. This play of colours has been repeatedly noticed by observers at home.

The first observation of *Filaria Oculi* is ascribed by Mr. Curling, in his lectures on morbid anatomy, to Dr. Nordmann, of Odessa. In the sixteenth number of the "Indian Annals," Mr. Charles Macnamara gave the details of two cases of *filaria papillosa* in the

<sup>17</sup> "Indian Annals of Medical Science," No. 15, p. 272.

<sup>18</sup> "On Maladies attributed to Lunar Influence, &c.," *Indian Medical Gazette*, Vol. iv, p. 181.

<sup>19</sup> *Indian Medical Gazette*, Vol. iii, p. 4, "Notes on Ladak."

anterior chamber of the human eye, *vide* pp. 330 of his manual. In the first volume of the "Transactions of the Medical Society of Calcutta," are elaborate papers, by Messrs. P. Breton and Twining, on "Worms found in the Eye of the Horse." Mr. Brett also made some remarks on this subject.<sup>20</sup> Much more recently, my friend, Dr. W. B. Beatson, now of Bath, has published<sup>21</sup> a valuable account of filaria as infesting the eye of the horse in India.<sup>22</sup>

*Cataract.*—As is well-known, Mr. Macnamara has long practised, with great success, a modified operation for linear extraction without iridectomy. During the five years preceding the publication of his work in 1868, he had operated in India on upwards of six hundred cases, the results surpassing those which he had obtained by any other operation for the removal of an opaque lens. He considers the operation to be equally applicable to cases of either hard or cortical cataract. He points out that, after this mode of extraction, we have much less cause for anxiety as to the occurrence of that most terrible complication of flap extraction—suppurative keratitis. He adds: "Even among the poor rice-fed Hindoos, who form a considerable portion of our hospital patients in Calcutta, we seldom meet with instances of suppuration of the cornea following linear extraction. I hardly exaggerate the case when I assert that some thirty per cent. of the operations performed in Calcutta formerly failed in this way."

The native operations, by reclinatio and solution, have been described by several authors. Mr. Breton<sup>23</sup> saw Sautcouree, a Mussulman, operate in Calcutta. His narrative is fully illustrated by plates. Mr. Raleigh also described the native operation.<sup>24</sup> Dr. Percival Lord gave an account of the operation which he saw employed by a native at Dera Ismael Khan.<sup>25</sup> He considered that the operation ended far more frequently in the total destruction of the globe than in the restoration of even an imperfect vision. Mr. Macnamara stated that hardly a week passed in which he did not see several of the huckeems' and kobirages' patients in the Calcutta hospital suffering from either inflammation of the choroid or from retino-choroiditis. In 1876, Dr. Cayley successfully extracted an opaque lens in a leper.<sup>26</sup>

Recollecting how frequently *Strabismus* was met with in England before the practice of tenotomy was adopted, and having travelled a good deal in out-of-the-way parts of India, I think it certain that the natives of India are far less subject to squinting than the inhabitants of Europe are. Several of my retired brother officers of great up-country experience have made the same remark. Dr. John Murray does not quite agree with us. He tells me that, when the operation was first introduced, he, in driving through the streets, used, whenever he saw a man who squinted, to tell him to jump up upon his vehicle, and to take him to the dispensary, where he generally had an operation every day. *Strabismus* occurs in Hindoos, Mahomedans, and Eurasians; and I have noticed that European children born in India, are very liable to acquire it on coming to England.

Two ladies, born in India, have large families also born in India. Four of these children squinted. The parents and grand-parents are free from visual obliquity.

### Congenital Defects.

*Cyclops.*—Prep. 1010 in the Calcutta Medical College Museum is "a monstrous foetal calf. There is only one ocular socket containing the eyeball, which is provided with two corneæ, and protected by imperfectly developed upper and lower eyelids. The eye is in the centre of the forehead (cyclopean)."

Mr. G. C. Hall reported in the *Indian Medical Gazette* a case of *Dermoid Tumour of the Cornea and Sclerotic* in a native. It was of the same brown colour as the skin of the face, and had three long hairs growing out of it. He dissected it off and the patient got perfectly well, the cicatrix contracting to about half. Microscopical examination showed that it consisted of true skin with subcutaneous fat, sweat glands, hair bulbs, and everything complete. Assistant Surgeon R. K. Mahomed<sup>27</sup> removed a dermoid tumour from the conjunctiva. The part healed well.

A poor little native *albino* boy, suffering from malignant disease in one of our surgical wards, had the characteristic ocular defect very markedly. Although his bed was as much as possible in the shade, daylight greatly depressed and embarrassed him, but, towards nightfall, he became playful. I have happened to see the *Tapetum choroideæ* twice, once in a young lady of very light complexion, but by no means an albino, the other time in a young man with dark brown eyes and hair. In the first, the tapetum shone out in a darkened room brassy yellow; in the second, it had a deep ruby lustre.

I never saw *Exophthalmic Goitre* in India, but I heard of the case of a young lady, born in India, who probably had a strain of native blood, in whom this condition was present.

### DISEASES OF THE NOSE.

The history of *Rhinoplasty* is too well known to need recapitulation here. It was adopted by the huckeems to repair the mutilations which were long commonly practised and are not yet quite disused in India, and of which I have given an account at p. 487 of my *Medical Jurisprudence*.

For *Lupus* and *Rodent Ulcer* see General Diseases.

*Ozæna*—*Peenash*.—In various hot climates, maggots have been noticed to infest the noses of dying animals. In 1868, Dr. N. Jackson, of Deega, near Patna, sent to the editor of the *Indian Medical Gazette*<sup>28</sup> larvæ found at the summit of the nostrils of full-grown sheep. It is not mentioned under what circumstances the animals died. They were examined by the late Dr. Stolicza, and pronounced to be a species of a large æstrus-gadfly. He stated that these creatures lay their eggs in the nostrils of various ruminants, and that the young larva, when developed, walks up the nasal bones and ensconces itself in any part of the surrounding tissue. It frequently lodges itself in the brain. These larvæ are very common in the heads of sheep in the Punjab. I am told that a like condition is frequent in England.

In 1827, Mr. W. L. MacGregor reported<sup>29</sup> the case of a man suffering from venereal disease of the nasal bones, in which larvæ fully half an inch long were discharged from the nose alive and active. The pain, which was excessive, occupied the position of the antrum, and he became almost delirious. The means employed for his relief were an injection of turpentine and laudanum in olive oil, the vapours of Aq. Ammoniacæ and sulphuric ether, and an infusion of tobacco gr. x to the pint. Under this treatment, he

<sup>27</sup> *Indian Medical Gazette*, January, 1879.

<sup>28</sup> Vol. iii, p. 278

<sup>29</sup> *Calcutta Medical and Physical Transactions*, Vol. iv, p. 23.

expressed himself perfectly recovered on the fifth day. The number of living maggots discharged was upwards of a hundred. When he was at the worst, he was "*literally covered with flies.*"

In 1836 Dr. Dempster placed on record<sup>30</sup> the case of a man who suffered two attacks within thirteen months, in which upwards of 300 and 172 larvæ of the blue flesh fly came away. During both attacks, he was *much teased with numerous blue flies*, buzzing about his head and face.

Dr. Dempster's report embodies a valuable abstract of the literature of this subject, giving the observations of Morgagni and Boerhaave, and facts relative to the presence of the larvæ of the gad-fly in the nasal passages in the West Indies.

In the *Bulletin Médicale Belge*, 1839, there is notice of the case of a woman in whom the entrance of a fly to the nostril was followed by severe frontal pain, often so distressing as to cause delirium. Several full-formed grubs were discharged. Upwards of fifty came away during the next week. They were those of the common fly; several, being kept under favourable circumstances, became flies.

Bahoo Taruck Chundra Lahory has given<sup>31</sup> a very careful description of this state under its vernacular name of *Peenash*, a word of Sanscrit origin signifying disease of the nose. He relates five cases, in at least three of which it appears probable that syphilitic disease existed. He says that, in five years, there were 91 admissions at the Allyghur Dispensary for worms in the nose; of these 46 recovered, 14 were relieved, 2 died, and 29 ceased to attend. In a fatal case, he found worms in the cribriform plate of the ethmoid bone, ulceration "(?)" of the bodies of the sphenoid and ethmoid bones, and slight congestion of the vessels of the brain.

Dr. D. T. Lyons has recorded<sup>32</sup> an important contribution to the literature of this subject under the title of "An Account of a Disease of the Nose and Cranial Sinuses prevalent in the Zillah Rhotuck, in the Punjab." He says, "Invariably there is a depression or flattening of the bridge of the nose." There was not in two out of Lahory's five cases; but, doubtless, this is merely a question of degree.

This disease, or rather complication of disease, is again described by Dr. W. J. Moore in his account of Marwar.<sup>33</sup> He says, "as a rule, persons so afflicted will be found to have suffered from syphilitic ulceration. In some instances, however, the primary condition is scrofulous inflammation, or other affection of the nasal mucous membrane. This affection is frequently seen in the nose of the camel. Three valuable contributions to this subject will be found in the fifth volume of the *Indian Medical Gazette*.<sup>34</sup> Dr. Alexander Garden shows that, in four years, 303 cases of ozæna were treated at the Saharunpore Dispensary. Out of 168 cases which were sifted, *peenash* occurred in 63. Ozæna was found to be more frequent among females than among males. The persons being, as a rule, the very poor, weak, emaciated, half-starved anæmiated sufferers from fever, exposed to vicissitudes, and living a precarious life, the day's meagre meal most often depending on the day's wage. No marked connection has been traced between this and malarial and other diseases of the liver and spleen, though such might be supposed to exist from the frequency with which epistaxis is met with as the first symptom. In some 8 or 10 cases, there was an undoubted syphilitic taint. Dr. Garden shows that ozæna is rare before puberty, but is common afterwards. It

occurs chiefly in the hot months of the year. It ends, as a rule, in recovery, often leads to injuries of the soft parts, occasionally ends in death. It is essentially a disease of debility, without any marked connection with scrofula.

In a patient treated by Dr. Higginson, 56 maggots were discharged, all living, from the nose. "These were put into a bottle over the mouth of which a piece of paper was tied. They went through the necessary changes, and all developed into able-bodied blue-bottle flies."<sup>35</sup>

Dr. Whylock<sup>35</sup> treated a European soldier, aged 24, the subject of secondary syphilis, who suffered in this manner. The maggots became blue-bottle flies. Turpentine vapour was very successful in this case. Baboo Bhawani Doss<sup>36</sup> values chloroform in these cases.

Mr. Thomas Mayne relates<sup>37</sup> the fatal case of a man with old (syphilitic?) perforation of the soft palate, whose nasal passages were the resort of live specimens of *œstrus hominis*, varying in size from four to six lines.

For a notice of a similar affection of the auditory passages see the chapter on *Diseases of the Ear*.

For *Nakra*, an acute inflammatory thickening of the Schneiderian membrane, to which natives of Bengal suffering from fever are liable, see *Malarious Cachexia*. I do not think that, at least in Bengal Proper, *nakra* is liable to end in ozæna. It is, however, allowable to argue that the ozæna of Upper India is an aggravated form of *nakra*. Both occur in sufferers from malarial fever. The following is Dr. Garden's description of the symptoms and progress of ozæna—apart from the miserable complications of syphilis and *peenash*. In a few cases coryza was given as the starting point. The first stage is essentially inflammation of the Schneiderian membrane; low in type and rapidly tending to ulceration. In many, if not most, the first sign is a sense of fulness and discomfort in the nose, accompanied by more or less pain, and soon followed by a thin foetid ichorous discharge. In some the foul odour is perceived for some time before there is any discharge. At this time the mucous membrane will be found in a greater or less degree inflamed, dark red, and swollen. Very frequently the first symptom that attracts attention is epistaxis; and the case, if seen at once, may never go beyond this point, and, hence, figure in the returns as epistaxis. Dr. Garden has met with numerous cases in which, after a time, the diagnosis has had to be altered in accordance with facts. In 1869, of 75 cases, 22 commenced with bleeding from the nose; and in 8 others, entered as epistaxis, it is very questionable whether in most the true ultimate diagnosis would not have been ozæna, as the epistaxis had been going on in some cases daily for weeks. In all cases where the first symptom was epistaxis the discharge became continuous, at first apparently nearly pure blood, then sanious and foetid, then merely tinged with blood, and finally more or less yellow in colour, the foul odour remaining the same.

Whatever the first symptom, the discharge, after a time, becomes thin, purulent, or muco-purulent, sanious, ichorous, and foetid. After a longer or shorter interval, if the case is not treated, ulceration of the mucous membrane occurs. In the majority of cases, especially when proper treatment has been employed, the disease goes no further. The discharge is less purulent, sanious, and offensive. The ulcers, chiefly superficial, heal, and the mucous membrane resumes its normal condition. In some few cases the stage of ulceration is not attained. But, in a considerable proportion, no such favourable termination occurs. The ulceration is

extensive, and involves structures deeper than the mucous membrane. From the first, the skin of the nose, and even of the face, presents an erysipelatous condition, is swollen, red, hot, and painful, whilst the surrounding parts are œdematous. The skin over the bridge of the nose ulcerates or sloughs, the nasal bones become carious or necrosed, the bridge of the nose is destroyed and a permanent deformity is left. Dr. Garden has seen a sinus left by the destruction of the soft parts of the nose below the nasal bones. The inflammation may extend to the antrum of Highmore, or even originate there. One of Dr. Garden's earliest, and certainly most severe cases, commenced with epistaxis followed by the usual symptoms. The inflammation spread to the antrum and mouth, and ultimately to the contents of the orbit, through the nasal duct. Sloughing of all the implicated parts supervened, destroying them all, and the patient's intense suffering only ended with death.

The parts most commonly affected are the superior and middle meatus. In these cases the inflammation is not unfrequently found extending to the palate and gums, and even to the soft palate, giving them a dusky red erysipelatous look. He has seen sloughing of the gums and perforation of the hard palate. In one case there was marked ptyalism. In nearly all there is an erythematous condition of the skin of the upper lip, caused by the contact of the acrid discharge.

The amount of pain varies much, but pain is rarely absent. It is often referred, chiefly or entirely, to the vertex or forehead, being apparently sympathetic and affecting the frontal and other sensory nerves of the scalp. When the upper meatus and the frontal sinuses are involved, the pain is referred to the forehead, and is constant and agonising, destroying sleep night and day. In slight cases, and at first, there are no very marked constitutional symptoms. There is no fever; the tongue is, as a rule, furred, and there may be anorexia. Usually, there is a weak quick pulse, with considerable general debility. In the more severe cases, the constitution suffers to a considerable degree. Loss of rest and of appetite, diarrhœa, dysentery, hectic, are all met with, the results of an exhausting disease, and possibly of poisoned blood.

Dr. K. P. Gupta treated a Goorkah wood-cutter in whom epistaxis was found to result from the presence of two large *leeches in the nasal passages*. He used turpentine. When leeches were much employed in Indian practice, an onion, instead of salt, was always used to make the creature drop off.

The following cases are cited by Dr. Gordon<sup>38</sup>:—A naturalist, who had for some months travelled in Formosa, suffered from epistaxis and pain in the head. A leech was perceived in the nostril by a speculum, protruding its head between the blades of the instrument. Its head was seized with an artery forceps and salt and water injected. In a little time it came away, it was an inch and-a-half long. He recollected to have drunk from a pool in which he noticed some leeches about half-an-inch in length, and he afterwards picked two or three such from the roof of his mouth.

A gentleman was affected in a similar manner. Every now and then the head of the animal would be protruded from the nostril and wander about over the lip and nose. Its owner could generally cause it to protrude by dipping his face in a basin of water. At Formosa, a monkey had a leech in its nostril.

For *Epistaxis*, see Malarious Cachexia. A remarkable case in which the death of a European soldier appears to have been caused by arterial hæmorrhage from the nose is related<sup>39</sup> by Mr. F. Sievwright. Two

days previously, having been in a state of inebriety for several days, he fell down a flight of stone steps and injured the head and nose, marks of violence being evident on both. He lived two days and a night after the hæmorrhage commenced. No fracture of the base of the skull could be detected; liquid blood was effused between the skull and dura mater in the left occipital region, and blood clots were found in the frontal sinuses and in the antra. Death was not fully explained, but it was probably due to that hæmorrhagic tendency which is so frequent in systematic inebriates.

Preparations 189 to 195 in Ewart's Catalogue represent four specimens of *Gelatiniform Nasal Polypi*.

There is a very fully reported case by Dr. R. Browne<sup>40</sup> in which the death of a Northern European was caused in India by a nasal polypus, apparently non-malignant, which made its way upwards through the base of the cranium by partially destroying the ethmoid and sphenoid bones, occasioning meningitis.

*Rhinoliths*.—Assistant-Surgeon Bhowance Day<sup>41</sup> found the nostril of a Mahomedan woman, æt. 35, who was suffering from profuse epistaxis, distended by a protruding stone. When removed, the rhinolith was found to present a perfect mould of the nostril. It was one-and-a-quarter inch long and three-quarters-of-an-inch broad, and weighed 88 grains. Its nucleus appears to have been formed in the lacrimal sac, whence it descended.

Assistant-Surgeon K. K. Mitter<sup>42</sup> extracted, under chloroform, a small oval calculus, with an hour-glass contraction in the middle, which was firmly adherent to the mucous membrane of the ala of the nose of a native girl of five.

S. Gozdar treated<sup>43</sup> a native man, æt. 25, who had suffered for years from obstinate catarrh, confined to the left nostril, with severe neuralgia-like pain of that side of the face, attributed to a blow with a stone which broke into pieces. A stone, doubtless a rhinolith, one-and-a-half-inches in length and nearly three inches in girth at its thickest part, was removed.

It is probable that *foreign bodies* usually form the nuclei of these concretions when they occur in children. I had considerable difficulty in clearing the nostrils of a boy of four, who if still living is a baronet, from masses of lime from the terraced floor which he had passed the morning in cramming in.

I met with a healthy and eminent Scotsman in India who considered that, although he believed that he had full powers of taste, the sense of smell was absent from birth.<sup>44</sup>

Thirty-seven years ago, an Indian civilian informed me that, a year or two previously, he had sustained a dangerous injury to the head—probably fracture of the base—which left him without sense of smell. I believe that he is now living.

M. TERRILLON'S POWDER IN PHAGEDENIC CHANCRE.—Pyrogallie acid 20 parts, starch powder 80 parts. This is to be carefully mixed, used only when fresh, and kept dry in a well-stoppered bottle. In phagedenic chancre with anfrauctuosities and multiple prolongations, the powder is to be blown, twice daily, into the depths of the wound by means of a bellows.—*Union Médicale*, July 4th.

<sup>41</sup> *Indian Medical Gazette*, 1882, p. 311.

<sup>42</sup> Harriet Martineau did not possess the senses of taste and smell. She said, "I tasted a leg of mutton and it was delicious." The gift was withdrawn as suddenly as it came. The sense of smell was denied to Wordsworth. In his case, too, it was vouchsafed to him only on one occasion. "He once smelt a beanfield and thought it heaven."—*James Payn's Literary Recollections*.

## ON THE INOCULATION OF VENEREAL SORES.

By H. DE MÉRIC, M.R.C.S.,  
Surgeon to the French Hospital.

THE following cases are of practical interest in the study of venereal sores, inasmuch as they show the difference of the inoculation (on the same person) of the syphilitic, or what is called "hard" chancre, and of the simple or "soft" chancre. I select them from amongst many others in my note-book at the French Hospital, eight or ten years ago, which will account for a certain want of completeness in several instances; for I had not then so constantly in my mind the importance of length of incubation, state of the glands in the groin, &c., for the study and diagnosis of venereal ulcers.

CASE I.—F. J., April, 1875. One chancre, which I saw nearly six weeks after connection, the patient having remarked it a week before he came to me. The incubation therefore was evidently between four and five weeks. I inoculated the man in the thigh from the chancre with no result. The sore healed up rapidly under the influence of iodide of mercury pills. Six weeks afterwards the secondary symptoms appeared in the form of a well-marked papular eruption with "plaques muqueuses" in the mouth. I had this patient under observation and treatment for eight months in all, at the end of which time all symptoms had disappeared.

CASE II.—G. B. E., June, 1875. Five or six chancres which I saw a fortnight after connection, the patient having remarked them more than a week before he consulted me, so that the incubation could not have been more than five or six days. These I treated by the local application of nitrate of silver and black wash, and in my then inexperience I gave some iodide of mercury pills; the sequel, however, soon convinced me of the error into which I had fallen, for, a couple of weeks after commencing this treatment, seeing some new sores appearing near the first ones, which by the way seemed to heal slowly and most indolently, my suspicions seem to have been aroused, and I inoculated the patient in the thigh. To quote my own words: "Three days afterwards the inoculation had taken beautifully." Of course, I then at once ceased the pills, and merely ordered an astringent lotion, enjoining strict cleanliness. The sores on the penis were all healed in about a month, but the place of inoculation in the thigh gave some trouble. In this case there was nothing at all in the groin. In 1879, four years after, I treated the patient for primary and secondary syphilis.

CASE III.—E. K., July, 1875. Two chancres, one on the foreskin, the other on the prepuce. I inoculated in the thigh with no effect whatever. Ten days after I had first seen this patient a well-marked papular copper-coloured eruption appeared. This being evidently a case of syphilis, was ordered appropriate treatment. Unfortunately my notes on this case give me nothing concerning the length of incubation or the state of the glands in the groin.

CASE IV.—C. L., July, 1875. Four chancres, from which I inoculated in the thigh, producing another similar chancre. In this case there was a suppurating bubo in the groin, another proof added to that of the inoculation that the chancres were simple and not syphilitic. The sores healed up in about three weeks with an astringent lotion only. Two months after their first appearance no other symptoms were present.

CASE V.—F. L., July, 1875. In this case I inoculated in the thigh from a single sore, which the patient had seen for six weeks, and which had appeared fifteen days after connection. The inoculation produced no result whatever; but, in this instance, it was performed when the secondary eruption had already made its appearance.

CASE VI.—L. T., August, 1875. One sore with very slight induration between the prepuce and gland, from which I inoculated twice at an interval of seven days without any result. The reason I inoculated this patient twice was, I find, because the glands in the groin on the left side looked inflamed and like suppurating, which they subsequently did, and the bubo thus formed was largely incised by my father, who was kind enough to see this case during my absence. Unfortunately, this patient had to be turned out of the hospital for insubordination, but the note which my father added to mine is conclusive; it runs thus: "This is evidently a case of infecting chancre with exceptional suppuration of lymphatics along the dorsum penis and the groin. The failure of inoculations proves it; besides, the suppuration was not a deep one in the groin, as is usual with bubo connected with soft chancre, but superficial, and lying over a mass of hard glands."

CASE VII.—G. F., November, 1875. This case was admitted into the hospital with several simple sores and a bubo which rendered the patient unable to walk. I opened the bubo freely, and inoculated the man in the thigh from one of the chancres on the penis. The inoculation produced a chancre in the thigh which, however, was not so inflammatory and difficult to heal as these inoculated sores generally are; this was on account of the perfect rest the patient enjoyed in the hospital. Six weeks after I first saw this man, the chancres on the penis were perfectly healed, and the one on the thigh nearly so. Vin Aromatique was applied to all, and of course no specific treatment was ordered. I saw the patient six months after he had quitted the hospital, when he told me he had since been perfectly well, and that no eruption whatever had appeared.

CASE VIII.—E. M., December, 1876. One indurated chancre on foreskin which was very long. Glands in the groin indolently enlarged. The sore appeared fifteen days after connection, and he consulted me fifteen days after he had remarked it; I inoculated in the thigh without any result, and ordered specific treatment with very beneficial effects to the chancre, which healed up rapidly. Thirty-five days after the chancre had first appeared the patient was covered with secondary eruption. In the meanwhile, the glands in the groin had become more enlarged and painful; they never went as far as suppuration, but subsided with the rest of the symptoms. I had this patient three months under my care, during which time appropriate remedies were ordered.

These cases that I have selected are necessarily few in number, as it is not always easy to obtain the consent of a patient to inoculation. However, as far as they go, they prove what has been pointed out by so many eminent men, viz., that from the constitutional syphilitic sore the result of inoculation to the same person is "nil," the poison being already in the blood, whilst from the localised simple sore another similar and probably more inflammatory chancre is produced on the same person by inoculation of the virus. This, as has been demonstrated by others, can be repeated *ad infinitum*.

In perusing these eight cases I cannot help being struck by a few facts that have since been impressed on me in hundreds of other instances. In the first place, it appears to me that the incubation of the

primary lesion of syphilis is not so long as most authors seem inclined to make it. I think a fortnight or three weeks is about the general length of time the poison takes before it shows itself by the initial symptom, this being very distinct from the simple sores which appear in two or three days after connection, having no real incubation period at all; in the second place, the groin is evidently our great guide in the diagnosis of venereal sores; in the syphilitic chancre there is *always* enlargement of the glands, and if any supuration appear it is quite superficial. In the simple sores there is either nothing at all in the groin, or else a deep suppurating bubo; in the third place, syphilitic chancres heal very quickly with very little pain or discharge; simple sores are often very difficult to heal, giving rise to much pain and discharge, the local treatment in the latter being very often difficult and disappointing, whilst in the former the surgeon may almost lose sight of the lesion itself in the all-absorbing struggle with the poison of syphilis in the patient's system.

AND SURGERY.**

CUMBERLAND INFIRMARY, CARLISLE.

DISLOCATION OF THE HIP IN A CHILD OF  
FIVE YEARS—EASY REDUCTION THREE  
MONTHS AFTER.

(Under the care of Dr. LEDIARD.)

SARAH FERGUSON, aged five, was admitted on June 10, 1885. Eleven weeks previously she was pushed off the door-step; her mother found that she was unable to rise, and that her left leg was bent up.

A notorious bonesetter in the county saw her on three occasions, but did not recognise the nature of the injury, and attributed the distortion to weakness, but the child was laid up from the time of the accident, and never walked unless supported under the arms. Medical aid was sought for the first time on June 9th, when Dr. Pearson, of Maryport, advised sending the child to the Infirmary.

The usual signs of dorsal dislocation were present, the toe of the left foot resting on the dorsum of the foot of the sound side. On administering chloroform and manipulating, a few adhesions were felt to be disturbed, and soon after the bone slipped into its place audibly, almost without thought being taken of the usual steps for reduction; it was found, however, that if left to itself, the head of the femur slipped out of place, and several times by pushing and pulling in the axis of the limb, it was found possible to dislocate and reduce. A long splint was applied, and the next day a long sand bag was bandaged to the splint, as the child rolled about like a salmon on a line. Pain there was none, from first to last, complained of, and the child was discharged at the end of six weeks rest, with instructions that further rest in bed was essential.

On August 31st, she was brought up for examination, and could walk well enough, but had been allowed to do so very little.

*Remarks.*—The shallowness of the acetabulum at this age seems to account for the easy dislocation and easy reduction even at the end of three months; whilst the same cause must necessitate a prolonged rest after reduction. As far as I could gather from the mother, the child was pushed from behind and fell on the left knee down the step, and this may account for dislocation rather than fracture having resulted.

# Medical Times and Gazette.

SATURDAY, SEPTEMBER 5, 1885.

THE returns for the month of August show that there were 48,778 deaths from cholera in Spain out of a total of 142,248 cases. The grand total from the commencement of the epidemic to the beginning of the present month is 270,000 cases and 96,000 deaths. In Madrid alone, up to the end of August, there were 932 deaths. From the experience of the last few days it may reasonably be hoped that the epidemic is drawing to a close, but the mortality is still at the rate of over 1,000 a day. From Gibraltar, the report is that the cholera is spreading in the Spanish lines. In Marseilles the latest bulletins lead us to believe that the epidemic there is on the wane, but it is spreading at Toulon, and it is rumoured that it has also broken out at Nîmes. As we surmised, the Sanitary Commission declined with thanks Dr. Ferrán's offer of his services at Marseilles. Cholera has made its appearance on Italian territory, the first fatal case occurring on August 27th at Trivio in the province of Caserta. Its importation is said to have been traced to a parcel of clothes which came by post from Marseilles, and the sanitary condition of the village is reported to be exceedingly bad.

TAKING up by chance a Spanish newspaper published at Denia, and devoted to the interests of the fruit trade, our attention was called to an article on the progress of cholera in the district, and the measures to be adopted to check it. Among these were the provision of hospital accommodation, and medical attendance, the disinfection of houses by sulphurous acid, and of the *clothes of the sick and deceased* by immersion in water kept at the boiling point *in the cauldrons used for scalding the raisins!* We may as well add that they are no longer actually used for that purpose, the raisin harvest being long past, but the idea is not a nice one.

THE size and growth of London is for some people a source of solemn and unalloyed statistical pleasure. They revel in its records of a birth every three minutes, and a death in every five; in its seventy miles of taverns and gin-palaces, in the number of its churches, and in its mighty consumption of coal. They marvel, as well they may, at the order which is so well maintained amongst its four million inhabitants; at the restitution of stolen watches; at the regulation of its bewildering traffic; at the capture and death of its mad dogs—by a police force mustering, all ranks included, only a paltry twelve thousand strong. But while they congratulate themselves on the addition of sixty miles of streets and two thousand houses to the metropolis during the past year, they are apt to overlook the increasing inadequacy of its sewerage arrangements. By yearly increments, such

as this, London is already rapidly outgrowing the capacity of the main drainage system, which, since its completion more than twenty years ago, has been deservedly regarded as one of the grandest of engineering feats. The improvement in the health of [the metropolis which followed the completion of that great scheme has been maintained ever since, and the system, in fact, has worked for something near a quarter of a century with scarcely a hitch and with markedly good results. If it now fails to accomplish all that is required of it, the shortcoming is due to the rapid and continuous overgrowth of a huge city to an extent which could scarcely have been foreseen, and for which its originators were not asked to provide. The principles of the main drainage system designed by Sir Joseph Bazalgette hold good to the present day, but the disgusting and dangerous condition of the Lower Thames is a warning that the flow of London sewage is now too great and too continuous to allow of its being any longer poured into the river within such a short distance of the metropolis as the situation of the present outfalls.

By far the greater part of London lies on the north bank of the river, and it is this section of the metropolis therefore which is chiefly responsible for the present condition of affairs. The drainage of the area in question is collected by three great trunk sewers; the High Level sewer, starting from Hampstead and passing *viâ* Stoke Newington and Old Ford; the Middle Level, draining Kensal Green and the Northern District; and the Low Level Sewer, which, coming from Acton through Hammersmith and Pimlico along the Thames Embankment, and by the densely peopled regions of the Tower and the East End generally, reaches West Ham, where its contents are pumped by huge engines at the rate of some eighty thousand gallons a minute to the top of the Embankment carrying the other two sewers. From this point all three mains run alongside one another, and the sewage descends by gravity to the Northern Outfall near Beckton, where it is received in vast reservoirs before being allowed to escape into the river with the ebbing tide. The four reservoirs cover ten acres of ground, and have a total capacity of one hundred and sixteen millions of gallons. They are connected with a smaller chamber which communicates with the river by iron pipes that run some hundreds of yards into the stream. As soon as the tide begins to ebb the sluices which have hitherto closed these pipes are opened, and the sewage is thus enabled to discharge itself into the stream, there to be carried seaward by the current. At every tide one hundred and thirty million gallons of sewage are thus discharged daily; and since this quantity takes four hours and more to flow it is clear that a considerable proportion of that last discharged is carried only a comparatively short distance below the outfall, before the tide turns again and sweeps it up the river. It should be noted that the sewage does not flow into the stream in all its original depravity; as it rushes through the discharge pipes it is mixed with deodorising fluid in the proportion of six hundred gallons of the latter to thirty times that

bulk of sewage in each hour. Different materials are used for this purpose from time to time with a view to testing their relative efficiency; and the cost of the experiments thus being carried on amounts to not less than 4,000% a week.

It should be observed that "deodorisation" is the object ostensibly aimed at; and so far as can be judged at the outfall itself this appears to be attained: for the smell of sewage in that neighbourhood is a trumpery bagatelle compared with the vile emanations from the cement factories, bone, glue, gas and chemical works which cluster on the malodorous borders of the Lower Thames. Deodorisation, however, by no means necessarily implies either disinfection or the prevention of putrefaction. And it is more than possible that the chemicals which for the time being destroy the smell of the sewage, and perhaps also temporarily arrest its infectious power, cease to be effective when it is mingled with the diluting river water, and that the sewage may then resume its odoriferous changes and regain or develop morbid virulence. But there is another matter of even greater significance as pointing to the inadequacy of the present arrangements for dealing with the refuse of a rapidly increasing population. The four great reservoirs already spoken of are provided with waste pipes through which, when they become overfull, their contents overflow into the river, whatever the state of the tide—whether it be coming in or going out. Until lately this happened only very rarely and at long intervals—occurring, for example, now and then after a rain storm of unusual severity. But now it takes place at least weekly, and sometimes day after day, so that a vast bulk of fæcal refuse is discharged direct into the Thames to be carried up to London by the flood tide, and deposited more or less upon the foreshore as the stream again recedes.

DESPITE, then, of all that has been effected up to the present time in the way of drainage works, and of all that is being done—with much temporary success—in the way of "deodorisation" at the outfall, it remains that the present arrangements are inadequate even for the discharge of the London sewage. It is clear that the formation of additional reservoir space would do little to abate the evil and nothing towards curing it; for already the bulk of refuse turned into the river during one ebb-tide, is greater than that which one tide can carry away from the site of the present outfall; and this latter difficulty is one which must always continue to grow with the increasing growth of the metropolis itself. In fact, all the various schemes which have been advanced for dealing with the problem agree in removing the outfall to some point nearer the Thames estuary. There can be no question that the sooner this is done, and the farther the point chosen is from London, the better will it be for the welfare of the metropolis and for the health and comfort of those who live upon the banks and traverse the surface of its polluted stream. The cost will necessarily be heavy, but while London

continues to grow and prosper—and with cities the two processes are practically synonymous—its inhabitants must be prepared to pay the bill of health. The sooner people's eyes are opened to the plain facts of the question, the better it will be for them, and the less they will grumble. "You cannot do as you like and get well." Nor can you keep a city healthy without properly draining it; and you cannot drain a growing city properly without a proportionately increasing expenditure. The price must be paid in one way or in the other; in solid cash or in injured health. A lighter heart, and a clearer head, and a longer life, would make amends for the emptier pocket, and Londoners will pay even the heavier sewer rate less grudgingly if they have thereby gained the right to say *Non olet* of the Thames.

NOTWITHSTANDING the complaints about defective sewage arrangements and other things hurtful to the community at large, to which our attention is being constantly drawn in the daily papers, the health of London is wonderfully good. Last week there were 1,371 deaths, being 155 below the corrected average. The great saving of life which this represents is due to there having only been 408 deaths of infants under one year, a number vastly below anything recorded in the last six years. Diarrhoea caused 121 deaths instead of 192. There was a slight rise again under the head

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past twelve weeks.

of measles, which caused 55 deaths, and whooping cough kept up its high average with 45 deaths. Scarlet fever counted 12 victims, and diphtheria 14. The deaths from diseases of the respiratory system which had been steadily decreasing for several weeks

numbered 201, a figure in excess of any return since the second week in June. This coincides with a mean temperature for the week 3.3° below the average. In the chief provincial towns, diarrhoea proved largely fatal in Birmingham, Leeds, and Liverpool, where 31, 30, and 29 deaths occurred respectively from this cause; whilst Salford and Preston contributed 22 and 18 victims, and Portsmouth 15 in the same category.

A FEW days ago the Registrar-General for England and Wales issued an edict to the following effect:—Registrars are instructed, before registering any death of either of the following descriptions, to report such deaths to the coroner, viz. :—(1) All deaths occasioned directly or indirectly by violence. (2) All deaths occurring under suspicious circumstances. (3) All deaths the cause of which is stated to be unknown. (4) All deaths which are stated to be sudden, and respecting which no medical certificate is produced. (5) All deaths of infants in houses registered under the Infant Life Protection Act, 1872. We are sure that all who have considered the matter will be glad to know that the discretionary powers hitherto enjoyed, or, at any rate, used by some of the registrars are done away with. The decision as to whether an enquiry into the cause of death is or is not necessary ought always to rest with the coroner, though practically, no doubt, this has not always been the case. As we interpret them, paragraphs 3 and 4 of the above order will preclude registrars in future from registering an uncertified death, a result much to be desired.

THE Hospital Saturday Movement, as we noticed last year, was then first introduced into the North of Ireland by the friends of the Belfast Royal Hospital, who for the first time appealed to the public generosity in the way that has ceased to be a novelty with us on this side of the Channel. The first attempt was a decided success, a sum of nearly 600*l.* being raised. A good deal of interest and curiosity was excited in anticipation of the second attempt which was made last Saturday, some of the supporters of the charity being sanguine that a very substantial addition to this sum would be collected. We regret to notice, however, that a very decided diminution has been the unexpected result. The usual amount of enthusiasm and energy only succeeded in obtaining from the public rather less than 400*l.* Whether the day—Saturday—which, though suitable in England, may not be the best day for the Irish hospitals, or whether the season, which always takes so many of the wealthy and well-to-do class out of every large city to the sea-side during July and August, has to answer for this, is an open question which will be doubtless carefully debated by the Managing Board of the Charity next year. The proceeds of the Hospital Saturday collection go entirely to the Belfast Royal Hospital, and are not distributed amongst the numerous special hospitals, as is the rule in the English cities.

A GOOD deal of interest has been aroused in an inquest conducted in the Belfast Royal Hospital upon

the body of a man recently admitted suffering from a compound fracture of the leg, which was amputated; slight secondary hæmorrhage occurred, and after some days the patient died. As usual, an enquiry was held as to the cause of death, and the nature of the accident. The proceedings were of unusual importance from the assertion made by the wife of the deceased that her husband had stated to her before his death that he had been allowed to bleed for four or five hours without anything being done to stop the hæmorrhage. The medical testimony given by the house-surgeon failed to satisfy the Coroner, and the enquiry was adjourned till the next day. It appears, from the evidence given by the surgeon in charge of the case at the adjourned inquest, that there was no unusual amount of hæmorrhage, and that every care, skill and attention that could be given to the patient by all the officials in the hospital had been bestowed upon him. The Coroner, himself a medical man, and once a member of the Staff of the hospital, expressed himself in very strong language, and is reported in the local papers as having made very serious statements regarding his opinion of the genuineness of the testimony submitted. The question being one vitally influencing the prosperity of the hospital has been made the subject of an exhaustive investigation by a sub-committee of the Managing Board, who appear to have gone into the whole matter fully. Already a forecast of their finding has appeared in the local papers to the effect that there is no foundation for the statements of the widow of the deceased or the strictures of the Coroner. The hospital authorities have stated their determination to publish the evidence and the result of their enquiry in detail, allowing the public to judge of the accuracy and impartiality of the Coroner's remarks.

Not long since an inquest was held on the body of a youth, who had died of hydrophobia some weeks after having been bitten by a rabid dog. The wound was duly "cauterised" at the time and quickly healed, and serious symptoms appeared only a short time before death. Cases of this kind are, unfortunately, not infrequent; and the general public is familiar with the fact that the virus of rabies may remain latent for a considerable period before the dreaded disease undergoes its characteristically fatal development. But what far too few people do know is that cauterisation of the wound—as it is ordinarily performed, with nitrate of silver—is absolutely useless as either a protective or curative measure. When silver nitrate is brought into contact with the tissues it at once forms an insoluble compound with their albuminous constituents, which it coagulates as it does white of egg. The insoluble and superficial sheath thus instantaneously produced protects the parts beneath it from any further action of the caustic, and the remedy is thus prevented, by its own chemical action, from penetrating below the surface. In fact, it merely serves to bottle up any virus that has been absorbed by the wound. It is, indeed, conceivable that, if applied at the very moment of the injury, this mere superficial action would, in some instances, suffice to destroy the poison momentarily lying in contact with a smooth

surface of slightly abraded and but slowly absorbent skin. But it is idle to suppose that it can be of any real use as a remedy in the case of wounds of any degree of depth or laceration, or which have been inflicted even a few minutes before. Its application may be justified, in the few cases in which it is quite certain that the risk of infection is absolutely nil, as a placebo; and it may thus serve to avert the development of that hystero-mimetic form of the disease, the most marked symptom of which is "barking like a dog." In any other case its employment is worse than a delusion, since it implies the neglect of other and more potent remedies which might prove really efficacious. The distinction between its action and that of other caustics is realised when we consider that a lump of caustic potash, for instance, if placed on the palm of the hand, would go on eating through skin and flesh and tendons to the bone, so long as any of the material remained chemically uncombined; while a piece of argentic nitrate forms but a superficial eschar which involves only the outer layers of the skin, and thus protects everything beneath from injury.

For the effectual cauterisation of the bite inflicted by a rabid animal, a few drops of strong mineral acid are worth all the lunar caustic in all the chemists' shops of London. Means nearer to hand, and as effectual when thoroughly used, are found in the actual cautery—which can be extemporised out of an ordinary knitting pin or the points of a pair of scissors heated to bright redness in the fire. Another means, even more readily available in some cases, is found in gunpowder, which can be placed on the wound and fired by an ordinary match. This is a plan which has been adopted in the case of snake-bite with success. These rougher methods are of course more painful in accordance with their more efficiently destructive efficacy. But pain is a minor consideration under such circumstances, and is willingly borne by the sufferer in consideration of the far better chance of cure which accompanies it. It can be much mitigated by temporarily tightening the ligature which ought always to be bound above the affected part, wherever its application is anatomically possible; and by the subsequent application of pure carbolic acid—itsself an antiseptic caustic of no mean power. Despite the laboratory work hitherto accomplished we can scarcely yet congratulate ourselves upon being within a measurable distance of stamping out hydrophobia. Even the man who would submit to a protective inoculation of the attenuated virus with the greatest faith in its efficacy, would probably wish that the immediate treatment of his wound should be efficient so far as it goes. Such, at all events, is the desire of ordinary mortals; and to this end they must make use of a chemical agent more potent and more penetrating than nitrate of silver, one which is, at any rate, less "self-denying" in its action as a caustic upon animal tissues.

WE are constantly being reminded, that with the increased facilities for travelling, and the many measures taken to make known foreign health resorts,

our own somewhat old-fashioned, but nevertheless most admirable health resorts suffer from a totally undeserved neglect. Malvern is just one of these places, a visit to which will repay the health-seeker quite as amply as a much more costly expedition to the newest place in the Engadine. Dr. Waller Johnson, in his little pamphlet on Malvern as a health resort, especially recommends it on account of its air and its water. The Malvern Hills certainly have much to recommend them to an invalid. Their height is such that no one is debarred from going or being taken up to the top with ease, and yet they are high enough to command a delicious air and charming views for miles around. The water is peculiarly soft from containing a small proportion of earthy salts. Those who like the modern fashionable town, will stop at Great Malvern; whilst Malvern Wells will commend itself to others as a quiet old-fashioned village; and those who wish for a still more quiet and rustic spot, will do well to go to Little Malvern.

THE Medical Congress which assembled at Antwerp towards the close of last week under the leadership of Dr. Kuborn, the President of the Belgian Royal Academy of Medicine, was naturally occupied with the burning question of the day—the prevention of cholera. As a proof of the more rational views that are now becoming general it is satisfactory to note the adoption of the following resolutions by the Members of the Congress, viz. :—(1) In the present state of relations between the peoples of Central Europe, land quarantines and sanitary cordons are useless and even dangerous measures; the fumigation of letters is useless; and (2) The rendering healthy of towns and rural communes by cleanliness imposes itself before everything upon the nations as a means to oppose the invasion of infectious diseases. The Congress agreed to advise the continuance of quarantine in sea-ports and at the mouths of rivers.

DRS. LEVSHIN AND VYSSOZKI, extraordinary professors of theoretical surgery in the University of Kazan, have been appointed ordinary professors, and Dr. Chomyakov, extraordinary professor of pathology and therapeutics, has been appointed ordinary professor of the same. Dr. Fenomenov has been appointed to the chair of midwifery.

PROFESSOR GERHARDT, on taking his leave of the University of Wunzburg, was entertained by the "Docenten" at a farewell dinner; the Medical Society elected him an honorary member, and the students, in an imposing torchlight procession, presented him with a farewell address.

"How to avoid being drowned" is the title of a small book by Mr. F. W. Brewster, which, at any rate, has the not inconsiderable merit of being seasonable. We suppose most people, if asked this question,

would reply, "Learn to swim," and when told that this did not afford sufficient protection they would say that he who would avoid all risk of being drowned must not go into or on the water. With all due deference to Mr. Brewster, we should be disposed to agree with such persons that absolute immunity from drowning cannot be obtained upon any other terms. Mr. Brewster has spent a considerable amount of labour in estimating the capacity for floating of the human body under various circumstances, and we have no doubt that in the main his conclusions are correct. He has not, however, studied his subject from a scientific standpoint, as is evident from the following passage, in which, after alluding to some experiments performed on the flesh of dead animals, he says, "The fact of any animal floating without artificial flotation, therefore, shows that during life the viscera are largely charged with air and other substances of far less specific gravity than water, and the effect of this is further supplemented by the presence of considerable cavities in the neck and head." The author has here ventured out of his depth, and is certainly on the verge of being drowned in pools of his own misconceptions.

THE recent despatch of Lord Wolseley, so far as it concerns the medical officers, is satisfactory, inasmuch as it proves that he is now capable of appreciating their services, and in this respect it contrasts very favourably with his unwarrantable treatment of them two years ago. But at the same time the despatch cannot fail to create much heart-burning in one very important branch of the service. With a single exception, not one member of the Indian Medical Contingent has been decorated, promoted or even mentioned. We are quite at a loss for any explanation of this extraordinary omission, and moreover, there were several medical officers in that contingent who have done good service on previous occasions. This is especially applicable to the four senior men in that department, one of whom has served in several important previous campaigns, amongst them being the Crimean, Indian Mutiny, China, and Abyssinian wars. We trust that steps will speedily be taken to repair this neglect, and remove what we cannot but feel to be to an unintentional and certainly wholly undeserved slur upon a very highly esteemed portion of the service.

THE endeavour to promote sobriety by legalising the restraint of the habitually drunken is an experiment which has not yet sufficiently emancipated itself from its first infancy to justify us in speaking with confidence as to the ultimate result. The report of the Inspector appointed under the Habitual Drunkards Act for the year 1884 is, however, satisfactory. He appends reports from the licensees of the various houses that have hitherto been sanctioned, from which we gather that all are hopeful that the work they are engaged upon will ultimately prove beneficial, some naturally being much more sanguine than others. Amongst the blots, or, at any rate, the defects under

the present system pointed out either by the inspector or one of the licensees, we observe that the commingling of private patients who are not bound in the same retreat with those who are bound, is strongly, and in our opinion very properly, objected to. Many complaints are made of the inconvenience created by the necessity for obtaining the signatures of two justices of the peace, and it is urged that one signature would be sufficient, more especially as in towns the attestation of one stipendiary magistrate is enough. A third objection to the present scheme is, that the man who has entered voluntarily with a real desire to be cured is shut up with one who is actuated by no such motives, and who has been placed in the retreat as a last resource by his friends, of his own free will no doubt, but without any determination to lead a new life. The influence of such a person is always for evil, and it would certainly be to the advantage of the willing patient that such a man should be kept out of his way.

---

#### AN APOCRYPHA OF EVIL.

WERE cholera unhappily to invade these islands again, and carry off as many victims as it has done on previous visitations, it would be, we do not hesitate to say, a less serious public calamity than the flood of obscenity which has lately inundated the country, flowing freely through our great towns and cities, and trickling into remote hamlets and mountain valleys. The cholera would curtail many useful lives and spread consternation and sorrow around for a season, but it would evoke much heroism and devotion, would reveal the weak places in our sanitary armour, and stimulate us to redoubled efforts in the provision of wholesome homes for the masses; whereas this moral plague by which we are now afflicted can but blight while it lasts, and leave a rich crop of demoralisation behind it. So pernicious are its immediate effects, and so disastrous are its consequences likely to prove, that it is incumbent on all those who have any love for their country to do their best to stem its tide and restrain its ravages. And especially is it incumbent on the medical profession to speak out plainly respecting this new danger to the public health, for a danger to the public health undoubtedly is and must be whatever tends to debauch the mind, provoke vice, or weaken the power of self-control. It will be in vain for medical men to insist on the cleansing of sewers as long as the streets are floating with garbage. They will but waste their energy in preaching the importance of pure water, while fountains of poisoned literature are allowed to bubble up at every corner. They know better than even clergymen what the consequences are certain to be, and they are bound therefore to denounce vigorously those who have brought this new plague upon us.

And not only have medical men special opportunities of knowing what the present agitation is likely to lead to in the future, but they are in a better position than others to judge of the justification which has existed for it in the past. It will, therefore, have

a tranquilising influence when they declare as a body, as we feel confident they ultimately will do, that what Mr. Llewellyn Davies has called "an apocalypse" might be more appropriately termed an apocrypha of evil, a mere mass of more than doubtful statements, which, although solemnly confirmed by the œcumenical council of the Mansion House, on which a Cardinal, an English Archbishop, and an eminent Baptist sat side by side, is not binding on faith. It will at once strike anyone accustomed to scientific enquiry that no attempt is made in the pages of this apocrypha to compute the prevalence of the crimes which are described in them with so much unction. Adjectives and adverbs are freely used to convey the idea that they are of common occurrence. The sale and violation of children, the procurement of virgins, and other brutalities and atrocities are said to be constantly and systematically practised in London, but no indication is given whether such offences occur at the rate of a hundred a day or a hundred a year. A certain number of typical cases, typical, we are given to understand, of large classes, are described, and as one of these, the only one which it has as yet been possible to investigate, has hopelessly broken down, and proved a mere trumped-up story, it is reasonable to conclude that many others of them will dwindle into nothingness on close scrutiny, while it is of course clear that the general statements of those who have disseminated them are not particularly worthy of credence. And this conclusion will seem all the more reasonable when scores of medical men come forward, as we have no doubt they will do should occasion require, and attest that during long professional experience in London, and intercourse of the most confidential kind with all classes of the community, they have never heard of the crimes which the journalist has discovered in such abundance.

No doubt, in London, as in other great cities, shocking instances of aberration of the sexual appetite occur from time to time. In high civilisation tending to effeteness, there are sometimes reversion to the most offensive traits and degraded habits of savage life, but there is no evidence that in the Anglo-Saxon race and in our metropolis such back-slidings are anything but extremely exceptional. When they do occur, they are often connected with disease, either local or of the nervous system, and if strict justice were meted out, many of those who have lapsed into them would not be punished as criminals, but shut up in lunatic asylums as rabid animals. Medical men are sometimes consulted by patients advanced in life or of neurotic families who are horrified to find themselves visited by loathsome thoughts and desires, who are in terror lest they should in some unguarded moment give way to them, and who earnestly crave protection against themselves; and in such cases some source of pelvic irritation, or some actual disease of the brain, is almost invariably discovered. It would be indeed singular if the reproductive instincts which bulk so largely in human nature, and often bulk most largely in men of energetic intellect, were of all the propensities exempt from morbid perversion. The well-known fact is, that they are liable to temporary disorder or protracted derangement, but when such is the case, it is no more rational to be-

stow rigorous censure on their offensive manifestations than it is to condemn indignantly the chalking of an hysterical girl, or the potatoes of an insane dipsomaniac. They require medical treatment, not Hyde Park demonstrations. The symptoms of disease are often very hideous and repulsive, but they are not to be mended by graphic delineation of them in daily papers, or by eloquent public protests. Assuming that there is any truth in the revelations that have been made, we think it more than probable that some of the sinners who have been held up to execration would be found, on enquiry, to be the victims of parorexia, a disease by the nature of it very difficult to identify, and not be cured in those afflicted by it, or warded off in others, by prurient studies of its manifestations.

The sexual vices by which this age is beset, and beset in a way that may well awaken anxiety, and the dangers by which, in consequence of these vices, it is threatened, are of a kind different from those which have lately been brought so prominently and pictorially before us, and the pity is that the widespread discussion that has taken place about imaginary or comparatively insignificant evils is well calculated to promote the propagation of other evils about the prevalence of which there can be no doubt. The tone and tendency of the new apocrypha with which we have been favoured are of the most lamentable description. The story which it has to tell might have been clothed in chaste and uninflamatory language, and would then have been much more effectual in securing the end which it professes to have in view; but instead of this, every page of it is soiled with details which must have tinctured with impurity many young minds, for the young in all parts of the country, prompted by that curiosity and craving for a knowledge of good and evil in relation to the sexual functions, which are strong in youth, have devoured it greedily.

The œcumenical council of the Mansion House, as we have called it, which sat to enquire into the authenticity and inspiration of the new apocrypha of evil, was singularly ill-qualified for its self-imposed task, and the decision at which it arrived is accepted by nobody. The idea that a few clerics, and a young anti-vivisectional Q.C., were competent to investigate such a subject is too preposterous to be entertained for a moment. An experienced medical man would have speedily given a very different complexion to the deliberations of the council, and guided it perhaps to condemn with sufficient severity the documents laid before it. That the Archbishop of Canterbury should have been connected with this council is a subject for national regret. We do not now enter upon any detailed criticism of the apocrypha of evil, but we may confidently assert that many of its statements must at once awaken the suspicion of any intelligent medical man. The Secret Commissioner would have done well before beginning his investigations to have spent a little time in a hospital for women. He would then have escaped some absurdities into which he has been betrayed. That he has grossly exaggerated, or been greatly imposed on, we cannot doubt. But even if all that he says were true he must for ever stand hopelessly condemned for his manner of saying it.

### POLLUTION OF THE LEA.

THE pollution of the lower reaches of the River Lea by the sewage of Tottenham, East Ham, and some other adjoining districts has for many years been steadily on the increase. Attention was incidentally called to it during the enquiry into the pollution of the Thames by the Royal Commission of 1883-4, from the fact that the Lea discharges itself into the Thames some distance above the outfall of the Metropolitan Main Sewerage Works, but for the time the question of the lesser river was thrown into the background by that of the greater.

Not that the several authorities answerable for or injuriously affected by it have been altogether idle. The purity or impurity of the Lea has been for more than twenty years a subject of legislation and litigation, though few except the lawyers have been in any way benefited thereby.

At the date of the appointment of the Royal Sewage Commission of 1862, only three towns on its course had any regular system of sewerage: these were Luton, Enfield, and Tottenham; and when the Lea Conservancy Act was passed in 1869, empowering the Conservators to insist on the exclusion of sewage from the river, an exception was made in their favour, as well as of Hertford, provided they previously submitted the sewage to some satisfactory method of "purification." From Ware to Stratford there are two channels running more or less parallel to one another: the old and winding stream, and a new one cut for purposes of navigation. In all legislation concerning the river the interests of the navigation have to be taken into account as well as those of the Water Companies drawing their supplies wholly or in part from the river. But there is a third consideration which has recently come to the front, and that is the health of the population along the lower course of the river. The New River Company derives a large part of its water from wells at Chadwell, Ware, Amwell, St. Margarets, Hoddesdon, Broxbourne, Cheshunt, Enfield, Edmonton, Southgate, Hornsey, &c., but about a third part is drawn from the Lea by means of a branch cut connecting the New River a little below its source with the Lea. This water is therefore not absolutely free from sewage contamination, but is fairly pure, for the sewage of Luton has been subjected to a long run, and that of Hertford is "rarified" to the satisfaction of the Company. They have also pumping engines for drawing water from the Lea at Tottenham, but to their credit, be it said, they have not used these for twenty years, having continuously sought new sources in wells sunk in the chalk or tertiary sand overlying it.

The East London Water Company, on the other hand, are content to rely almost exclusively on river water, having but two wells sunk in the chalk. Their pumping station is situate between Chingford Mill and Higham, where they raise somewhere about thirty million gallons daily from the old river Lea. This water, indeed, is not inferior to that taken by the New River, since the Enfield sewage is conducted by an intercepting sewer to below Tottenham Lock, but it is not like that of the New River, largely diluted with water drawn from wells. They trust to sub-

sidence and exposure of the water to the air in reservoirs of unexampled extent, contamination of which by soakage from the Lea after it has become fouled by the sewage of Tottenham is avoided by an intercepting channel carried between the river and the reservoirs.

They have also a subsidiary source of supply in a culvert carried for a distance of nearly twenty miles to Sunbury-on-the-Thames, from which they may pump a quantity not exceeding ten million gallons a day, but they do not resort to this unless the supply from the Lea runs short of their requirements. The reason for this extraordinary means of supplementing their original sources is that they are prohibited by their Act of incorporation from sinking wells within the rich water-bearing area occupied by their rivals of the New River. A knowledge of these facts is essential to a comprehension of the issues at present before the public. The population of Tottenham is increasing at an almost unprecedented rate. In 1861 it was about 9,000; in 1871, 22,857; in 1881, 46,441; and it is now estimated at 55,000, or if we include some adjoining districts draining into the same sewers, it may be between 60,000 and 70,000.

The pollution of the river below the outfall of the Tottenham sewer has been growing worse year by year, until the river has become no better than a large open sewer, and the Hackney Board of Works and the inhabitants generally are loudly demanding that an end should be put to the danger. Already in 1875 the nuisance had become such as to attract the attention of the Conservators, who applied to the Home Secretary for redress, that functionary being by the Acts of incorporation appointed arbiter between them and the Tottenham Local Board. He, however, decided in favour of the latter. Since then they have from time to time urged the matter on the notice of the Local Board who have, it is true, expended large sums on the construction of settling and filtering tanks wherein to treat the sewage, as they say "with chemicals and other precipitants with a view to obtaining a good effluent." So long as the Home Secretary was satisfied that the Tottenham Local Board "were using their best endeavours," whether successfully or not, the Conservators could do nothing but wait; they succeeded, however, in obtaining in January, 1884, a public enquiry, the result of which was that on June 7th he gave his decision "that the Tottenham Board were not properly treating their sewage." Next month the notice was served, twelve months, now expired, being given them wherein to discontinue sending the foul effluent into the river. The Local Board, instead of taking any active steps to abate the nuisance, commenced an action in the Court of Chancery with a view to upset the decision of the Home Secretary, but lost their case.

Early in last month, the period of grace having expired, the Conservators obtained from the Edmonton Bench a summons against the Tottenham Local Board for fouling the Lea, and for the enforcement of the penalties of 100% for the first day, and for 50% for every following day on which the nuisance could be proved. But the Tottenham Board were equal to the occasion, and availing themselves of the loopholes of

the law, met the summons by taking advantage of the 145th section of the Rivers Pollution Act, which allows the case to be removed by *certiorari* to the Court of Queen's Bench. The order not having been made until the end of the month, the case cannot be heard until after the long vacation, and the Local Board have further secured themselves by accepting a contract for 20,000% for the enlargement and improvement of their sewage work, and have commenced operations. What will be the decision of the Court it is impossible to say, but judging from the experience of the past, there is little hope that any satisfactory improvement will follow the extension of the existing works. Hitherto every extension has apparently led to the aggravation of the evil. The coarser particles have indeed been removed, but the effluent has been a putrefying liquid little better than untreated sewage plus the nuisance created by the chemicals comparable to that caused by factory wastes. This year it has been further intensified by the drought, the effects of which have been visible in rivers everywhere, and have been seriously felt by all water companies drawing their supplies from drainage areas.

The East London Water Company have been compelled to resort to their supplementary supply from the Thames, but since their consumption rose a few weeks ago to 43,000,000 gallons, only 3,000,000 of which was obtained from wells, it follows that they withdrew from the sea not less than 30,000,000 gallons daily. It is true that by cutting off the water from certain districts for nine hours of the night they have reduced this by 7,000,000, but the fact remains that they take, so to speak, nearly the whole of the water (not required for the supply of the navigable channel), coming down the river, which below Tottenham contains little else than the sewage of that district and of Enfield.

Mr. O. Coope, in a letter to the papers written in defence of the East London Water Company, of which he is Chairman, complains of the scarcity of water which only continued rains can relieve, and of the wanton waste by consumers. He lays the entire blame on the shoulders of the Tottenham Board, and suggests as the only remedy that their sewers should be connected with the Metropolitan Main Sewerage system. This would doubtless have the effect of leaving the Lea comparatively pure, if nearly empty, but we fear that the Metropolitan Board of Works have already more sewage on their hands than they know well how to dispose of. We would fain believe that a sufficiency of low-lying land could be found beyond the area of suburban London, say at Wanstead Flats, whither the sewage of Tottenham, Enfield, Walthamstow, and the adjoining overgrown villages could be carried by a culvert and disposed of by irrigation, the effluent finding its way into the Roding, and by it to the Thames near Barking. An acre of the best sandy loam can purify the sewage of 1,000, and one of the worst clay when properly prepared that of 250 persons. At this calculation, 500 acres would suffice for a population of 100,000.

On the other hand, the East London Water Com-

pany should be compelled by Parliament to follow the example of the neighbouring New River Company, and sink a dozen or more wells in different parts of its extensive district. These would derive their supply from the chalk, or more often and better from the overlying tertiary sands and gravels.

They would be thus more independent of variations in the volume of the Lea, which these wells would in no wise effect, and would supply a far purer water to their customers. Hitherto, they have not shown the same regard to the quality of their water that has honourably distinguished the older Company, which has spared no expense to maintain its reputation, and to extend its subterranean resources. We cannot forget that it was only by the action of Parliament that the disuse of the open reservoir at Old Ford, and of the cut to the Lea at Tottenham, was effected after the connection of the former with the spread of cholera in 1866 was clearly proved. The actual polluters of the Lea are indeed the Tottenham Board, but the East London Water Works are responsible for intensifying and aggravating the nuisance by seriously reducing the volume of the river and the dilution of the sewage.

---

#### THE NEW PHARMACOPŒIA.

THERE is a lull before a storm, there is comparative silence before the dawn, but the indications of both are influences seen and felt universally; atmospheric conditions have given their warnings long before the first lightning flash, and judging from previous experience, we have some idea of the subsequent phenomena which will doubtless cause surprise and dismay in some quarters. The dawn is heralded by a few joyful twitterings of those anxious for light, but the final outburst of joy is delayed until the glory of new light is fully appreciated. For some time past, with one notable exception, there has been comparative repose in the publication of books on *Materia Medica*; force has been allowed to accumulate without finding expression beyond that afforded by periodicals; the need for new editions has been felt, even painfully, but authors and publishers alike have held their hands, waiting and longing for the coming of an authoritative guarantee of the truth. Rumours of a New Pharmacopœia from time to time have made their way into the medical journals; rumours at first definite, when a Pharmacopœia Committee was formed, then losing their air of verisimilitude as hope was deferred from month to month, from year to year. Every now and again a brief paragraph made its appearance, reminding us that the work of revision was progressing, but it seemed almost like the untimely crowing of a careless cock at midnight when no Pharmacopœia was issued. But from this period of unrest relief has for some months past been more definitely promised. The medical world has heard, with more or less certainty, not only that the revision Committee were nearing the termination of their labours, but it has also in a general way been allowed to know some of the special directions in which these labours have been carried on.

The coming light has touched the mountain peaks, and as their formless shapes came into being from the darkness, we have scanned the horizon anxiously waiting for others to follow. Would the light deign to shine upon each and all of those with whose names we have long been familiar? Would the Pharmacopœia embrace in its scope every drug which has been clamouring for attention since the last edition, and the last issue of additions? At length the flutter of excitement is at an end; the answer is given to all anxious questionings; and the Committee naively comfort the friends of those drugs shut out by remarking that they either have not been sufficiently recognised by the medical profession, or that there are already in the Pharmacopœia agents having like properties, and of equal if not of greater value. Although this statement seems like a tacit admission of incompleteness, it is only fair to bear in mind that in this, as in former editions, care has obviously been taken not to allow the entrance of any drugs of doubtful composition. A pharmacopœia is essentially a book containing rules for the making or composition of medicines, hence all whose origin is veiled in mystery are of necessity excluded. The book is not, and never professed to be, a complete list; we have to take it as it stands and to be thankful for its help.

Apart from all considerations of new substances, the present volume is of the greatest value in the alterations which have been made to bring it up to the present level of chemical and botanical knowledge. Every page exhibits evidence of incalculable labour, for not only have the old formulæ been swept away entirely, but the formulæ previously printed in the heavier Egyptian type have been very thoroughly revised. For example, chlorinated lime appears now as a compound of hypochlorite and chloride of calcium ( $\text{CaCl}_2\text{O}_2$ ,  $\text{CaCl}_2$ ), or as a direct compound of chlorine and lime ( $\text{CaOCl}_2$ ); two forms of alum are rendered official, the sulphate of aluminium and potassium, and the sulphate of aluminium and ammonium, while dried alum is now, in deference to the practice of the manufacturers, directed to be prepared from potassium alum. Another striking instance of care in this direction is afforded by the formula of hyposulphite (thiosulphate) of sodium, the absolute number of atoms of each element remains the same as in the last edition, but by rearrangement the formula for the salt is now recognisable, instead of looking most hopelessly entangled. Another sign of the times, a sign making us hopeful for a further change in the next Pharmacopœia, is that throughout the book, wherever a temperature is mentioned, it is given both on the Fahrenheit and Centigrade scales, the latter in brackets it is true, but when once admitted on any footing it cannot be long before we find ourselves finally in harmony with the practice of foreign scientists.

An alteration likely to cause some confusion at first, is the almost universal adoption of the terms ammonium, potassium and sodium when dealing with the compounds of the substances; although chemically correct, we venture to predict that it will be long ere these terms displace their predecessors in common

use, for *Sodii Bicarbonas* certainly does not look like our old familiar friend. The desire for chemical accuracy has also produced a disturbing influence in changing the terminology of the alkaloids; all alkaloids are now made to end in *ina*; practically it used to be immaterial whether we spoke of strychnia or strychnine, quinia or quinine, but by the fiat of the Pharmacopœia an act of uniformity has been passed, ordering the future employment of *quininae sulphas*, *morphinae hydrochloras*, *codeina*, *strychnina*, &c. Disquieting as these changes may appear for a time, there can be no doubt that they are soon likely to displace the older terms which have only the plea of custom in their favour. Another landmark has been removed in the alteration of the strength of the official liquors containing active ingredients intended for internal administration. It used to be a fixed fact (for examination purposes) that these, with one exception, contained four grains to the fluid ounce. They have now been changed to form one per cent. solutions, *i.e.*, they now contain rather more than four grains (four and a third) in one fluid ounce.

Turning now to the botanical portion of the volume we find that here also the changes are far greater than might be inferred from the lists of alterations given in the earlier pages. In the first place the value of the work has been very greatly enhanced by the addition of references to various authorities both for description and for plates. As we had hoped, the references to the classical work on medicinal plants by Bentley and Trimen are very numerous; yet, in spite of the excellence of these plates, room has been found for abundant references to authorities ranging from the year 1665 to the present time. Two classes of individuals can hardly be expected to express unmixed joy at some changes in this portion of the volume, the unfortunate student who has been referred to his studies, and the teacher who has to unlearn much that he has been planting deeply; these will most certainly not feel ready to welcome the change in the botanical sources of many of the drugs. The names of the drugs have been changed as little as possible, yet new strange-looking names of plants strike us repeatedly as weird and uncanny from their very novelty. It is sufficient to refer to *Garcinia Hanburii*, *Fœniculum Capillaceum*, and *Aloe Perryi* as illustrations. Innovations like these are immaterial to the practitioner, but deal hardly with the two classes above indicated. The occasional substitution of *Rhizoma* for *Radix*, of *Semen* for *Faba*, and the universal adoption of *Asafœtida* in place of *Assafœtida*, are sufficient evidence of the minute care which has been bestowed upon the older portions of the Pharmacopœia.

With regards to the omissions and additions, "as it seems to be essential that some victims should be found," there is a list of twenty-two of the former, and they "never would be missed," unless we give a sigh of regret for the iodide of cadmium ointment. The additions form a much more imposing array, numbering some hundred and odd new articles and preparations. In another column will be found a list of the more important of these. It is needless to say that the same desire for careful accuracy has been exhibited here as in the revision of the older portions. Three lamellæ

and three new glycerines have been added, also ten new acids and acid preparations. It is satisfactory to have the cocaine *v.* cocaine controversy authoritatively decided in favour of the former. With every sympathy for the labours of the editors and committee, with every feeling of thankfulness for their work, we yet feel that a few inconsistencies have forced their way into the Pharmacopœia. For example, *extractum cascarae sagradae* and the liquid extract are both directed to be prepared from "cascara sagrada"; on searching for this it is not to be found in its alphabetical position, but appears only as a synonym for *ramni purshiani cortex*. And, again, on p. 314, *unguentum glycerini plumbi acetatis* is mentioned in place of *subacetatis*.

Still, upon the whole, the work is admirable, and our congratulations are due to the chairman, Dr. Quain, to the committee, and to the editors, Professors Redwood, Bentley, and Attfield, upon the production of a highly satisfactory Pharmacopœia. It comes like a new religion, or a revised version to the medical world, and as such is likely to be for a time disquieting to all accustomed to working in the old grooves. Many will, of necessity, still cling closely to their old errors and superstitions, refusing to accept the new reading. In spite of the pain of uprooting our familiar faults, there can be no doubt that the scientific gain will be very great. The Pharmacopœia is practically a new creed, and, as such, we thankfully accept it, with sundry reservations and until the times do alter.

## REVIEWS AND NOTICES OF BOOKS.

---

*Die Ætiologie der Chronischen Lungenschwindsucht vom Standpunkt der Klinischen Erfahrung (The Ætiology of Chronic Consumption from the Clinical Point of View)*, von DR. HERRMANN BREHMER, sen., Gcrbersdorf. Berlin: Hirschwald, 1885, pp. 517.—Of all modern discoveries to which importance has been given by the unanimous chorus of the multitude, there have been few which have had so little effect upon practical medicine as Koch's discovery of the tubercle bacillus. For years it had been conjectured that some minute organism must be present to account for a part at least of the degenerative process in phthisis; but it was left to Koch to demonstrate the truth of the assumption. Now that we have the means of stating positively that the parasite is indeed present in the case before us, we are placed in a more complete position as far as diagnosis is concerned, but there the value of our new knowledge finds its limit. We have again to turn to the information which is to be gathered from other sources than the microscope in order to form a true judgment of the important questions of treatment and prognosis. The clinical aspect of consumption has already been made the subject of treatises in many tongues; but there still remains something to be found out and studied even upon so familiar a disease as this. In the work before us, Dr. Brehmer has apparently set himself a double task. He has endeavoured as far as possible to discount the clinical value of the bacillary nature of tubercular phthisis, and at the same time to prove the relative influence which other conditions are exercising to produce that particular habit of body which is found to favour the development and progress of the disease. With this object in view, the work is opened by a lengthy criticism of the weak points in the theories to which Koch's discovery has opened the way, and especially in the notion that phthisis may be contagious by way of desiccated sputa. The extreme rarity of any cases

which give even a plausible support to such an idea, and the absolute want of any proof of direct inoculation through recent wounds, are points in themselves which outweigh any number of assertions founded on theory. The author makes a great deal also of the failure of experimenters to demonstrate the presence of the bacilli in the air of hospitals or other places where the exhalations of infected persons are of necessity present. The results which followed the investigation of the flues of Brompton, form the only evidence at present before the public, and further observations made recently by Celli and Guarnieri have done much to discount the value of these. Referring to the attempt to settle the question of the contagion theory by means of collective investigation in England, he expresses a very decided opinion that the record of the personal impressions of a large number of irresponsible medical men is of but very little scientific value. Looking to the points in the ætiology of the disease, which may really be said to bear a part in its causation, Dr. Brehmer lays much stress on a disproportion in size between the heart and the lungs, and endeavours to trace the effect of such disproportion in the previous history of the patient. He presents a series of one hundred cases to shew the circumstances under which isolated members of families, not labouring under hereditary taint, have become the subjects of tubercular disease. Almost all of them had been very small eaters, and had suffered from palpitation and dyspnoea about the period of puberty, and it is remarkable that nearly all were later members of large families, generally the sixth in order. Several series of cases follow, in which various points find illustration, both with respect to hereditary phthisis and to phthisis without any taint. Amongst other points of interest it is clearly shewn that heredity from parents only can be regarded as really powerful in its influence, and that the tendency to inherit is greater in children born within 12 months of their elder brother or sister than those born after a longer interval. Space does not permit of a detailed mention of the many interesting questions discussed in Dr. Brehmer's work, which deserves a prominent position in the literature of the subject. It has the great merit not shared by all such treatises, that its arguments and reasoning are founded upon carefully ascertained facts.

*The Journal of Physiology*; edited by MICHAEL FOSTER, M.D., F.R.S., vol. vi, No. 3.—We are not sure that the existence of this publication is known even to many, perhaps the majority, of the readers of purely medical literature, but we should like to direct the attention of all who take an interest in the progress of physiology, and thus, in the development of scientific medicine, to the extremely valuable periodical of which the number before us is a small instalment. The *Journal of Physiology* is the only periodical publication in English dealing exclusively with this subject. It had a somewhat chequered existence at first, but has sailed along under the care of its present able editor into somewhat smoother waters. Its success deserves, however, to be much greater (from a publisher's point of view) than it has been. When we say that the vast majority of all the original work done in physiology in this country finds its record in the pages of this Journal, it is not saying too much to assert that it ought to be on the library table of every medical man in the country who endeavours to keep pace with the rapidly advancing knowledge of medicine. The subscription price is not high, and the numbers appear at somewhat irregular intervals during the year, dependent upon the amount of material at the disposal of the editor; but during the course of the year a sufficiently interesting and important amount of material is published to form a portly volume. None but original matter is here admitted, and many of the papers are detailed account of researches already read in abstract before the Royal and other Societies. The Journal has thus become the great medium for publication of their researches by English physiologists. The number before us may be taken as a sample. The first paper is one by Professor Gerald Yeo on "An Attempt to estimate the Gaseous Interchange of the Frog's Heart by means of the Spectroscope," his experiments appearing to modify much

some currently accepted doctrines concerning the respiration of muscle. We have next a paper by Professor Yeo and Mr. Herron on the "Summation of Stimuli in Striated Muscle." This is followed by a "Note on the Nature of Nerve Force," by Dr. Bowditch, of Harvard University. The author thinks that nerve force is transmitted by some sort of molecular vibration after the manner of light or electricity. A very important paper by Sheridan Lea, "On the Isolation of a Soluble Urea Ferment from the *Torula Urea*," follows. In this the author concludes that the ferment is retained by the living organism, and is not secreted into the surrounding fluid. The ferment can be dissolved out of the cells by treating them up with appropriate solvents. This addition to our knowledge of the origin of ferments in living organisms has an important bearing on the physiological conditions of bacterial and bacillary life. The last paper in the number is one by Dr. James Blake, of San Francisco, "On the Supposed Catalytic Action of Insoluble Reagents." It will thus be seen that the papers in this number are of more than average importance and of fair interest to the general medical reader. One of the features of the Journal is the important supplement published from time to time, containing a carefully prepared and tabulated list of all papers in foreign and home periodicals relating to physiology which appear from time to time. The proceedings of the Physiological Society are also incorporated with the Journal from time to time. The Journal is one well worthy of more support from the medical profession than it has hitherto received, and we trust that the reading medical public will supplement the efforts of the editor and his collaborateurs, who have fought with many difficulties, and we fear with some losses, to place English physiological literature on a worthy footing.

*Lehrbuch der Physiologie*: von OTTO FUNKE, neu Herausgegeben: von Dr. A. Gruenhagen. Parts IV and V.—We have before spoken of this excellent text-book of physiology, now re-appearing in parts. These two latter numbers are fully equal to the first and second numbers in their quality. In these parts the subjects of nerve and muscle physiology are dealt with, and these very difficult matters are laid before the reader in a clear and succinct manner. The exposition of nerve physiology particularly strikes us as worthy of all praise, and as a remarkably able exposition of a most difficult subject. With these two numbers is ended the first volume, which is occupied by the physiology of blood and circulation, digestion, absorption, respiration, secretion of the physiology of the nervous system. The second volume opens with muscle physiology. We are certain that there is not a better or more trustworthy guide to the whole subject of physiology existant in any language; and we cordially recommend the book to our readers who know German. These numbers, like the earlier ones, are well up to date in their information. The fact of the book being now in its seventh edition speaks for itself.

*Croonian Lectures on the Hygiene and Climatic Treatment of Chronic Pulmonary Phthisis*; by HERMANN WEBER, M.D. London: Smith, Elder & Co., 1885.—On the occasion of the delivery of these lectures at the College of Physicians early in the present year, we expressed our high sense of their value, and of the importance of the method of treatment which they were designated to inculcate. We welcome their appearance in a separate form, and hope they will be widely and thoughtfully read.

*A Guide to the Examination of the Urine*; by J. WICKHAM LEGG. Sixth edition; London: H. K. Lewis, 1885.—This is an old public favourite, and needs no commendation at our hands. The present edition seems in most respects to be up to date, but we observe the omission of any mention of peroxide of hydrogen as a test for pus.

## ABSTRACTS AND EXTRACTS.

### CHANGES IN THE BRITISH PHARMACOPŒIA.

THE following is a list of the principal additions to the new Pharmacopœia arranged alphabetically:—

Acidum Boricum.  
 Acidum Chromicum.  
 Acidum Hydrobromicum Dilutum.  
 Acidum Lacticum.  
 Acidum Oleicum.  
 Acidum Salicylicum.  
 Apomorphinæ Hydrochloras.  
 Argenti et Potassii Nitras.  
 Arsenii Iodidum.  
 Butyl-Chloral Hydras.  
 Caffeina.  
 Chrysarobin.  
 Coca.  
 Cocainæ Hydrochloras.  
 Codeina.  
 Elaterinum.  
 Ergotinum.  
 Extractum Cascaræ Sagradæ.  
 Extractum Cascaræ Sagradæ Liquidum.  
 Extractum Gelsemii Alcoholicum.  
 Extractum Jaborandi.  
 Gelsemium.  
 Glycerinum Aluminis.  
 Glycerinum Plumbi Subacetatis.  
 Glycerinum Tragacanthæ.  
 Injectio Apomorphinæ Hypodermica.  
 Injectio Ergotini Hypodermica.  
 Iodoformum.  
 Jaborandi.  
 Lamellæ Atropinæ.  
 Lamellæ Cocainæ.  
 Lamellæ Physostigminæ.  
 Liquor Arsenii et Hydrargyri Iodi.  
 Liquor Ferri Dialysatus.  
 Liquor Sodii Ethylatis.  
 Menthol.  
 Oleatum Hydrargyri.  
 Oleatum Zinci.  
 Oleum Eucalypti.  
 Oleum Santali.  
 Paraffinum Durum.  
 Paraffinum Molle.  
 Pilocarpinæ Nitras.  
 Salicinum.  
 Sodii Bromidum.  
 Sodii Iodidum.  
 Sodii Salicylas.  
 Sodii Sulphocarbolas.  
 Spiritus Ætheris Compositus.  
 Tabellæ Nitroglycerini.  
 Tinctura Gelsemii.  
 Trochisci Santorini.  
 Unguentum Acidi Borici.  
 Unguentum Chrysarobini.  
 Unguentum Hydrargyri Nitratis Dilutum.  
 Unguentum Staphisagriæ.  
 Unguentum Zinci Oleatis.  
 Zinci Sulphocarbolas.

The following Drugs and Preparations are omitted in the new Pharmacopœia:—

Areca.  
 Cadmii Iodidum.  
 Castoreum.  
 Decoctum Ulmi.  
 Digitalinum.  
 Dulcamara.  
 Enema Tabaci.  
 Ferri Iodidum.  
 Ferri Oxidum Magneticum.  
 Ferri Peroxidum Humidum.

Hydrargyri Iodidum Viride.  
 Infusum Dulcamaræ.  
 Liquor Atropiæ.  
 Mistura Gentianæ.  
 Pilula Quiniæ.  
 Rhamni Succus.  
 Sodæ Acetas.  
 Stramonii Folia.  
 Syrupus Rhamni.  
 Tinctura Castorei.  
 Ulmi Cortex.  
 Unguentum Cadmii Iodidi.

### NEUROLOGY.

PROGRESSIVE TABETIC CONTRACTURE OF THE ATHEROMATOUS.—M. Demange, whose paper on the arterial origin of spinal sclerosis was noticed in a former number, has made a further communication on this subject to the *Revue de Médecine* for July. This last communication is based on the case of an old woman, aged 75, who presented a progressive loss of power in the legs accompanied by spasmodic rigidity; contracture gradually set in, commencing first in the flexors. After death a diffuse sclerosis of the spinal cord was found, which closely agreed in its characters with those described in his previously recorded cases. These now number four, and M. Demange has therefore felt justified in treating them as belonging to a disease under the above head. The disease occurs in aged women (all his patients were females) who present marked general atheroma. The onset of the disease is always gradual and insidious, commencing with loss of power in the legs, which then feel stiff, become somewhat rigid, and finally contracture declares itself. This commences as a rule in the limbs and in the extensors, but it ultimately spreads to the muscles of the trunk, though never apparently to the muscles of the face; the tendon reflexes are at first increased, but in the later stages they may be altogether absent. Atrophy of groups of muscles may be observed; the electrical reactions were not ascertained. There is no fever, and the intelligence is unaffected; the course of the disease is always progressive; in the most rapid case death ensued in four months, in the longest in thirteen months. The chief points of difference between this disease and the spasmodic dorsal tabes of Erb and Charcot are that in the latter the arms are commonly affected, and the contracture is never painful, and most important of all, that the progress of the disease is exceedingly slow; moreover, spasmodic tabes is a disease of adult life, whilst this is a disease of the aged. The lesion consists in a diffuse and disseminated sclerosis of the spinal cord of vascular origin chiefly confined to the white matter, and stimulating the combined systematic scleroses, but the lesion is never really systematic—the lateral columns, it is true, are mainly affected, but never alone or in their whole extent; the lesion is never limited to the pyramidal tracts, but spreads to neighbouring territories; the sclerosis will be found in varying stages at different points, the chief thing, however, being the extreme vascularity of the part affected. In the centre of each sclerosed patch is a small diseased arteriole from which the sclerosis spreads along the neuroglia; the arterioles show a condition of endarteritis and peri-arteritis, and generalised atheroma throughout the body was found in all the cases. As regards the pathogeny of the disease, it is easy to understand when it is seen that it depends on these changes in the vessels themselves; the circulation to the spinal cord is somewhat difficult in the normal state, and when the artery is partly blocked by disease it becomes so difficult that the nutrition of the cord is soon impaired, and the myeline becomes granular—this corresponds with the first stage of weakness; later on, perivascular changes take place, and the sclerosis spreads to neighbouring systems of the cord. The diagnosis from spasmodic tabes has already been considered; that from amyotrophic lateral sclerosis, the only other disease with which it could be confounded, does not

present any real difficulty. M. Demange does not recommend any special treatment; the patients should be taken care of, electricity should be avoided; anodynes may be necessary to relieve the painful cramps in the contracted muscle.

**AN ANOMALOUS CASE OF PARALYSIS.**—Dr. John K. Mitchell, in the July number of *The American Journal of the Medical Sciences*, records a curious case, a female, aged 50, which presents a total of several unusual conditions: paralysis without any degenerative reaction, enormous hypertrophy of the skin and subcutaneous tissues, and increase of the size of the muscles due to the extraordinary overgrowth of their fibrillar elements. It has certain features in which it resembles scleroderma, and some that are like elephantiasis, and without the microscopic investigation it might have been taken for what on the first superficial examination of the patient it was thought to be, pseudo-hypertrophic paralysis. But the skin had not the tense, hard induration which scleroderma shows. Scleroderma is usually found with more or less pigmentation; it begins with pain and œdema, and is nearly always accompanied by atrophy of the underlying muscles, and though it varies in position and may be limited or diffuse, it is seldom or never so absolutely symmetrical as the lesion described. Certainly there is a slight likeness to elephantiasis in the skin condition, but the general fever and inflammatory symptoms of that disease were never present, nor has the course been like that of elephantiasis, which progresses by recurrent attacks. Nor on careful comparison does it seem much like pseudo-hypertrophic paralysis. The age of the patient—this paralysis is almost unknown in adults except where it has continued from infancy—the persistence of the knee-jerk, and the troubles being, even after lasting so long, entirely confined to the lower extremities, are some of the differences. Here, too, no loss of voluntary contractility in any other than the affected muscles, nor any atrophy of the pectoral or dorsal muscles, a condition which Gowers calls diagnostic of pseudo-hypertrophy, could be discovered. To the eye and touch, besides, the muscles in this case were much more lumpy and less homogeneous than they are in the false overgrowth. A few cases of true muscular hypertrophy have been reported. The overgrowth in all of them was limited to the muscular tissue, and the malady began after great and long-continued exertion, or after depressing disease or injury. All of them were unilateral and in one limb only. Studies of extracted fragments of muscles showed the fibres to be double the natural breadth, and demonstrated an increase in the number of nuclei. So far as Dr. Mitchell has been able to discover during the year which has passed since he first examined the case, there has been nothing like it known, and he thinks he has good grounds for saying that the complexus of symptoms is entirely a new one.

**LOCOMOTOR ATAXY AND SYPHILIS.**—Few questions have of late years exercised the professional mind so much as this, viz., to determine the relation of locomotor ataxy and syphilis. It was the subject of discussion at our own Congress in 1881, and has been hotly discussed elsewhere both before and since. As on other much-disputed points, opinions differ within the widest possible limits, and we are indebted to M. E. Ricklin (*Revue des Sciences Medicales*, July) for an admirable and impartial summary of existing views. Quinquaud finds syphilis in all his cases, Fournier and Erb each find it in 91 per cent., Althaus in 86 per cent., Gowers in 70 per cent., Buzzard in 47 per cent., Westphal in 33 per cent., Rosenthal in 18 per cent., whilst Leyden and Lancereaux altogether ignore any causal relationship, and when syphilis is present see in it nothing more than a mere coincidence. All writers are agreed that the syphilitic form does not present any points either in its symptoms or course whereby it may be distinguished from the non-syphilitic variety; and a similar accord practically exists as to the effects of treatment on the actual lesion, whether this has preceded the onset of the disease or not. Pathology does not throw any light on the question; the lesions found in advanced cases being the same in the syphilitic as in the non-syphilitic cases. The discrepancies between the

different authors above referred to may be partly explained on the hypothesis that in the practice of some of the writers a much larger proportion of the patients would be likely to have had syphilis than would be the case with other writers, and partly on the fact that there is considerable difference of opinion as to what is sufficient evidence of previous syphilis. In the great majority of cases where syphilis was admitted, a very considerable period had elapsed between the date of infection and the first appearance of the tabetic symptoms.

**EFFECTS OF NERVE-STRETCHING UPON THE SPINAL CORD.**—Nerve-stretching, though recommended in many affections, has been principally practised for the relief of pain, either in sciatica or in locomotor ataxy. The exact effect of the operation (as performed for the relief of sciatica) upon the spinal cord has been the subject of a critical paper in the *Archives de Neurologie*, Nos. 28 and 29, by Pauline Tarnowski. The author has not only examined the results given in the hitherto-recorded cases, but has investigated the results of the operation on animals, and has arrived at a very definite and decidedly adverse opinion as regards the operation. The effects are chiefly manifested in the lumbar enlargement, and consist of traumatic irritation of the cord with capillary hæmorrhages at different levels, leading to atrophy of the posterior cornua, wasting of the intra-medullary part of the posterior roots, and lastly vascularisation and atrophy of the nerve cells of the anterior cornua. The changes are, of course, in proportion to the amount of force used, and are slight when the traction has not been great. Amongst the large number of purely empirical observations on the effect of nerve-stretching in locomotor ataxy, there are, says the author, many where the symptoms of the disease grew worse after the operation, others where the disease remained incurable, some fatal cases, but not a single instance of permanent cure. The author hopes that the paper will have the effect of rendering persons more prudent in employing nerve-stretching, and concludes by stating that in locomotor ataxy the operation is always more or less prejudicial to the patient according to the amount of force used, and that the operation can never give permanent relief, still less cure.

**HEMILATERAL SYPHILITIC MYELITIS.**—In the *Birmingham Medical Review* for August, Dr. C. W. Suckling records a case of acute hemilateral myelitis, due to syphilis. The patient, æt. 61, had been under treatment for primary syphilis, in August, 1884, and had subsequently presented secondary symptoms. In May of this year, he was found to be suffering from complete motor paralysis of the left leg with flaccidity; the loss of power had come on gradually, and had been complete in a week. Sensations of touch, temperature, and pain were all exaggerated on the left side, and there was vaso-motor paralysis and impairment of muscular sense with elevation of temperature. In the right leg there was complete analgesia and thermal anæsthesia. The hyperæsthesia of the left side and analgesia of the right extended upwards over the abdomen to a line drawn round the body two inches above the umbilicus, ending abruptly; there were no zones of anæsthesia or hyper-æsthesia at this level. The plantar reflex was excessive on the left side; the patellar and cremasteric reflexes were absent on this side; the abdominal reflex was also absent on this side; on the right side these reflexes were present. He had retention of urine for a day or two, and was delirious towards night and very stupid in the day. He was energetically treated with iodide of potassium and mercury internally and mercurial inunctions, and made rapid progress towards recovery; in four weeks time he could walk without difficulty, but a fortnight later the sensory disturbances were still present, though in slight degree. The lesion was presumably seated on the left side of the cord extending from the eighth dorsal to the fourth lumbar nerves.

**BRACHIAL MONOPLÉGIA.**—In *Brain*, part 29, Drs. Hughes Bennett and C. M. Campbell narrate the case of an old Indian officer, who at the age of 80 was seized with left brachial monoplegia at first accompanied with facial paralysis. At the *post-mortem* examination a limited area of

softening was found at the upper part of the internal capsule; it was flattened, notching the outer and upper border of the caudate nucleus, reaching downwards across the internal capsule to just touch the lenticular nucleus. The fact that the lesion only caused paralysis of the arm leads the authors of the paper to surmise that the fibres coming from the cortex in the motor area run in separate ribbon-shaped bundles through the internal capsule, and that their flattened surfaces are at right angles to an antero-posterior section of the cerebrum. The authors point out that their case supports the view that some such arrangement did exist, which was recently advanced by Mr. Victor Horsley.

## SURGERY.

**A CASE OF CHOLECYSTOTOMY.**—The rather recent revival of operative procedures for the relief of obstruction of the biliary ducts, has awakened a new and lively interest in all such cases; especially as the entire number of reported operations falls within a total of fifty. To this list Dr. Charles T. Parkes, of Chicago, in the July number of *The American Journal of the Medical Sciences*, adds a very instructive case:—Of the cases submitted to operations, by far the larger portion has been of cholecystotomy, by means of which a distended gall-bladder has been positively relieved, and in most of them the cause of obstruction, retained gall-stones, removed. In a few no gall-stones were found, while in others the cause of the obstruction could not be remedied. In Dr. Parkes' case the gall-stones were not lodged in the gall-bladder, and it is highly probable that they were retained in some of the dilated hepatic ducts, and were washed into the cyst by the flow of biliary fluid which came on immediately after the formation of the fistula. He is inclined to believe that they had but little to do with preventing the flow of bile into the intestine, at least the patulency of the passage was not restored by their removal. The remarkable and profuse flow of muco-biliary fluid, coming through the sinus established, argues very strongly in favor of the operation which contemplates the formation of a fistula in the gall-bladder in distention thereof by confined secretions. Certainly no tube of the dimensions of the ductus communis choledochus could have given a free exit to the secretions; at least the accompanying back pressure on the walls of the cyst would have greatly endangered, if not certainly destroyed, the adhesions in any recent wound thereof, even when protected by the continued suture. Most of the cases of reported cholecystotomy tell of the presence of a freer flow through the fistula, so that it is a condition to be expected, and makes immediate closure of the bladder wound without drainage a dangerous proceeding to adopt, even if we can be positively sure of a clear common duct. Dr. Parkes, in conclusion, advises from his experience in this case, the general practice of sounding the common duct through the external opening. He is quite sure that such procedure can be safely carried out, and equally certain that its adoption in his case resulted in relief that did not follow the removal of the calculi alone.

**OVARIOTOMY WITH DENSE ADHESIONS.**—Dr. Ott brought before a Russian medical society, a short time ago, a case in which he had opened the abdomen for a large cyst, situated on one of the ovaries, though it was impossible to say upon which until the operation. On the opening of the peritoneal cavity, it was discovered that the tumour was about the size of the head of a child of 8 to 10 years old, and that it was adherent to all the neighbouring organs. In particular, there was a dense adhesion connecting it with a loop of the small intestine. In consequence of the impossibility of detaching the tumour from its adhesions, part of it was excised, and afterwards the cyst wall was sewn to the peritoneal wound. The resulting cavity was plugged, and the wound dressed. After the operation, there was scarcely any fever, the highest temperature being only about 38° C. The cavity of the cyst

healed almost without suppuration. Even on microscopical examination of the dressings removed from the cavity of the cyst, no pus could be found. Dr. Ott considered that here the white blood corpuscles were transformed directly into firm tissue without becoming pus. Subsequently, however, when the cavity of the cyst was closed, there was a small quantity of pus.

**COCAINE IN AVULSION OF IN-GROWING NAIL.**—Dr. Porcher relates, in the *Philadelphia Medical News*, July 11th, the case of a lady upon whom he operated for in-growing nail of the great toe. A 4 per cent. solution of the hydrochlorate of cocaine was instilled, drop by drop, from the point of a hypodermic needle upon the raw surfaces in the furrows on each side of the nail. A rag wet with the same solution was kept pressed against the upper surface of the toe, and three injections of the same strength were made in the flesh at the base of the nail, just above the matrix. The tissues being thin here, and not very cellular, probably ten or fifteen drops may have been inserted. After the lapse of fifteen minutes, avulsion was performed in the usual way, without any pain being felt.

**DIGITAL COMPRESSION OF ANEURYSM.**—Dr. D. F. M. Héctor, of Guanabacoa, relates an interesting case of aneurysm in a Cuban medical journal. The patient was a man of 31 years of age who had had syphilis. Nine months before coming under observation he had fallen on his right foot, two months after which he noticed a swelling in the right popliteal region; this gradually enlarged, and when measured it was found to have a vertical diameter of 12 centim. and a transverse diameter of 13 centim. The pulsations and fluctuation left no room for doubt that it was an aneurysm. It was treated by digital compression in Scarpa's triangle for about twelve hours every day. On the tenth day the tumour, which had decreased in size, ceased to pulsate, and became hard. The compression was now practised during alternate periods of 2 hours, a freezing mixture being applied to the tumour in the intervals. The periods were afterwards reduced to one hour, and the treatment only carried out during the daytime, and finally on the 17th day it was stopped; the patient being, however, kept in bed for 16 days longer. The tumour has continued quite hard and without pulsation, and the man has returned to his work quite cured.

**CATHETERIZATION IN SENSITIVE URETHRA.**—Dr. Stamps, writing in the *Philadelphia Medical Reporter*, July 4th, states that in some cases of a hyperæsthetic state of the urethra, he has been enabled to pass a catheter almost painlessly by inserting the nozzle of a syringe filled with water as hot as the patient can bear into a soft catheter. As the catheter is gently passed along the canal, the water is slowly injected, the water which regurgitates between the catheter and the urethra until this has reached the prostatic portion of the canal preventing too much water being injected into the bladder.

## NOTES ON FOREIGN HEALTH RESORTS.

### BLOEMFONTEIN AND THE ORANGE RIVER FREE STATE.

FROM the beginning of the present century, the southern extremity of the great continent of Africa has been regarded as possessing certain climatic advantages, which, when combined, as they used to be, in the period antecedent to the Suez Canal, with equal advantages of position, rendered our territory there of great value. It was found that the tropical invalids homeward bound from India recovered rapidly from the malarial fevers and liver disorders with which they were affected. As the colony increased in size, the small percentage of deaths from pulmonary disease became noticed, and before long patients of that class

visited it regularly for their health. It was then noticed that the higher altitudes seemed the most favourable, and, about the year 1870, the vast flats of the Orange River Free State were suggested as affording the best climate to be found in South Africa, if not in the world. Since that time considerable numbers of English have gone to Bloemfontein—the capital—for their health, and a large proportion of them have undoubtedly derived considerable benefit from their residence there.

The journey fifteen or sixteen years ago was a somewhat formidable one. It is now much more rapid and easy, but, at the same time, it is still attended with not a few discomforts. The South African Colonies certainly bear the palm for roughness, and from the very nature of the country will probably do so for many years to come. There are but few luxuries, and necessaries are decidedly dear, and, in short, the Orange Free State, like the northern parts of the Cape Colony, suffers from its distance from civilisation and the enormous difficulties of transport. Year by year, however, these are being overcome. For some time past a line connecting Cape Town with the Diamond Fields has been in course of construction. It is expected that it will be completed very shortly, and, as Bloemfontein is only one hundred miles distant from Kimberley, over a perfectly level plain, it is to be hoped that the former town may soon be in steam communication with England.

The voyage to the Cape is now an affair of from nineteen to twenty-one days, instead of five-and-thirty as it was not so very long ago. There are two lines of steamers running between England and the South African Colonies: the "Union" and "Castle" Companies, the latter being better known as Donald Currie's. These leave Plymouth and Dartmouth respectively every Friday at noon, and generally touch at Madeira, and occasionally at either Lisbon or St. Helena. The fare to Cape Town is thirty guineas. The voyage after the first three days is for the most part on a perfectly even keel, and is one of the most enjoyable in the world, though rough weather is occasionally to be met with a day or two before reaching Table Bay. The port at which the traveller disembarks will depend upon the route he has chosen. The Free State, owing to its central position, can be reached either from Cape Town or Port Elizabeth, or even from Natal. The latter is, however, not advisable owing to the lengthened sea voyage, the trouble attending transshipment into another steamer, and the difficulty in getting heavy baggage over the Drakensberg.

Formerly, travellers to the Free State almost invariably took the route *via* Port Elizabeth, Fort Beaufort, Queenstown, and Alival North; but the railway from Cape Town has lately been extended so considerably that it is by far the quicker as well as the most comfortable plan to take advantage of it. Cobb's coaches connect the temporary terminus with Bloemfontein, and, packed tightly in the clumsy looking vehicles, half choked with dust and bruised with jolting, the traveller speeds across the level plains whose monotony is emphasized by the myriads of ant-hills which dot the arid ground as far as the eye can reach. It is certainly not an attractive introduction to a new home, and the Diamond Fields, though of late years very much improved, are still less pleasing. The eastern route, to which allusion has just been made, is quite as rough. The railway has not as yet been brought over the formidable range of mountains here known as the Stormberg, and the traveller consequently has to cross them in the coach, an operation that may or may not be pleasant, according to the season. The Orange and Caledon rivers also lie before him, which, in "the rains," are occasionally so swollen as to be impassable by means of the "ponts" used to ferry the coach across, but this is a rare occurrence. The more frequent cause of delay arises from the sudden filling of *spruits*, or small tributary streams, by the heavy thunderstorms that so frequently break over the country; for bridges, it should be understood, are as yet comparatively unknown. Once over the Caledon the road, or track as it more justly should be called, leads to Bloemfontein over the same boundless stretches of prairie as those just alluded to.

From the foregoing it will be gathered that those in

search of health in Southern Africa may have to undergo a considerable amount of discomfort, not to say actual hardship, during the journey to their destination; such discomforts indeed as would prove a very severe trial to a woman of delicate constitution. It must not be inferred that these are always to be met with. It is even possible for the journey to be, comparatively speaking, pleasant; but the "disastrous chances, the moving accidents by flood and field," are nowhere more common than they are in the South African colonies, and the traveller, without previous lessons in resignation, will often find it hard to imitate the *nonchalant* way in which the old colonial will meet misfortune. Such minor discomforts as indifferent food and having to share bedrooms with two or three others, will commonly be met with, and unless the traveller is prepared to undergo them, he had better not try the climate of the Orange River Free State.

The conditions of travel have here been somewhat enlarged upon, as the writer has on several occasions met with invalids who were, up to the time of their being brought in contact with them, in absolute ignorance of the roughness of life in this part of the world. With the limited experience afforded by ordinary continental travel, they had never realised the "infinite possibilities" of a journey in South Africa, and the London physicians at whose recommendation they were to seek the health-giving breezes of the Free State, though doubtless thoroughly well posted in the climate of the country, had failed to inform themselves as to the other conditions of life there, which, after all, are of equal if not greater importance to the invalid. But few details have been given of the journey from the coast to Bloemfontein, owing to the constant changes taking place with the progress of the railways &c., but the latest information can always be obtained from the agents at the port where the traveller disembarks. It should be mentioned that the coaches running from the end of the railway to the Free State do not take heavy baggage. The amount that used to be allowed to each person was 56 lbs. The rest follows by bullock wagon, and those only who have managed for some weeks on the limited wardrobe contained in a hand bag, can realise the pleasure with which they hear of the arrival of their portmanteaus.

Of Bloemfontein itself the best that can be said is that it is less interesting than other Free State villages. The country is, it must be confessed, almost heartbreaking to a new arrival on account of its monotony. Vast expanses of slightly undulating flats, unbroken by the presence of a single tree, stretch away to the level horizon. Here and there, perhaps, is a low *kopje*, or stony hill, whose sides are clothed with a few stunted bushes, and every now and then, at intervals of some thirty or forty miles, long thin lines of willows mark the course of some stream, nearly dry in winter, but in summer often a formidable torrent. The whole country is one vast sea of grass, whose surface is broken into ripples by countless thousands of oven-like ant-hills. Such is the usual aspect of the Orange River Free State, but the capital, built beneath a rocky hill, and on the banks of a pretty, willow-fringed streamlet, has a certain claim to beauty, especially when seen under one of the magnificent sunsets that are of daily occurrence during the winter on the table land of South Africa. Its inner life is scarcely more interesting. The general language is, of course, Dutch; but owing to the number of English storekeepers and others the latter tongue is the one with which the visitor will chiefly be brought in contact. All residents speak both languages as a matter of course, but the Kafirs and other natives use Dutch only. The monetary system is purely English, and the Bloemfontein bank, with its English managers and clerks, is a flourishing and perfectly sound institution. There is an English church, with a pronounced Ritualistic service, and our colonial bishop has established a sisterhood of English ladies in the town for various ecclesiastical and educational purposes. Some time ago he was also arranging for the building of a sanatorium for consumptives, which is doubtless at the present time in working order. There is an excellent, but small, cottage hospital, and an English and one or two German doctors were, a year or two ago, resident in the town. There are a couple of passable

hotels where it is possible for a visitor to put himself *en pension*; but, from our European standard, both board and accommodation are, considering their great inferiority extremely dear. A few years ago, the writer and a friend paid thirty shillings per diem, sharing a small bedroom between them. The cooking was beneath contempt, and the price of a small bottle of Bass's ale was four shillings and sixpence, while, at night, numerous individuals of a certain hemipterous insect known to naturalists by the name of *cimex lectularius* shared his couch. Since then both accommodation and food have doubtless much improved, but the visitor must not expect anything beyond what, in Europe, might be described as tolerable. A cheaper plan for a bachelor, and one often adopted, would be to live in rooms and board at one of the hotels. For families it would be best to commence house-keeping after a certain knowledge of the Dutch language has been attained, but house rent is extremely dear. The servants are almost invariably Kafirs. If white servants are imported or hired the result is, in ninety-nine cases out of a hundred, unsatisfactory. Meat is cheap, but the prices of vegetables and other provisions are often enormous. Cabbages and cauliflowers commonly fetch from 1s. to 2s. 6d. apiece, and indifferent butter as much as 3s. or 4s. per pound. The writer has indeed known the latter article fetch as much as 18s. 6d. per pound.

It must not be supposed that the amusements of the place are such as will compensate to any great extent for the above mentioned drawbacks. Billiard tables there are, of course, for Bloemfontein is too near the Diamond Fields to be without such sources of combined amusement and profit. Riding is perhaps more worthy of mention, but even the most ardent lover of horse exercise will in time tire of riding over the monotonous prairies with no particular goal in view. It should be mentioned that horses are cheap, and that a very decent pony can be bought for ten or twelve pounds, but it is equally necessary to state that feed is extremely dear. Shooting is available to almost anyone, and within a few miles of the town a tolerable bag of *knorhaan*, or small bustard, can not unfrequently be obtained, while, on the banks of the Modder River, guinea-fowl are abundant, and there is a fair chance of an occasional springbok. Lawn tennis has penetrated, as we all know, to every part of the civilised world, and Bloemfontein is no exception to the rule. But the above list of the amusements open to visitors may be regarded as an exhaustive one, and even the naturalist, who above all others is least likely to find a place unprofitable, has here but little scope for work. Birds and insects are equally rare; the botany has been tolerably worked out, and after all is not particularly rich, and unless the observer is anxious to work at the natural history of the Termites, it would be somewhat difficult to indicate a field in which he would be repaid for his labours.

From what has been written, it will be gathered that the Free State has need of an extraordinary excellence of climate to atone for the many drawbacks that force themselves upon the notice of even the least *exigeant* of visitors. And though, like every other climate, it has certain disadvantages, it must, nevertheless, be conceded that it is in many ways an extremely good one, and that it is often of the very greatest benefit even in advanced cases of phthisis. Roughly speaking, its chief characteristic is the extreme dryness of the air. Bloemfontein is situated at an altitude of about 4,300 feet above the sea level. To the north and west lie the arid wastes of the Kalahari desert, while on the east and south the lofty ranges of the Stormberg and Drakensberg receive the contents of the moisture-laden winds that sweep over the Indian Ocean. The result is a dryness that is unequalled in any other part of the civilised world, and hardly excelled in the Atacama or Sahara deserts. Thus, the writer has on one occasion registered a difference of no less than thirty-four degrees between the wet and dry bulbs of the hygrometer, and during the day, in the winter months, twenty degrees of difference is common. The extreme thinness or the air is often very unpleasant to those in health, but it appears to be less felt by the invalids. It is of an irritating character, especially unsuitable for those of nervous temperament, and hence,

especially in spring and the beginning of summer, neuralgia and other allied disorders are not uncommon. Epistaxis, periodic headache, and rheumatism often attack the new comer, the latter, indeed, being a very common complaint, the aetiology of which it is rather hard to explain.

The invalid who has resolved on a trial of the Free State, will most probably arrive at the Cape some time in the month of November. It is then, of course, summer in the southern hemisphere, and Cape Town and its neighbourhood will be found excessively hot. He had better make his way up country without loss of time. The railway route *via* Beaufort West will probably be the most advisable, but the journey over the Stormberg from Port Elizabeth, although it should never be undertaken in winter, when the cold is often intense, is at this season very pleasant, although the travelling is, of course, much rougher. Summer in the Free State is the rainy season, the opposite being the case at the Cape, and though the rainfall is not heavy, the country is not unfrequently visited by thunderstorm of appalling violence. Nowhere in the world, perhaps, are they more severe, and the traveller is not likely ever to forget his first experience of them. The first rains begin to fall towards the end of October, though previously many months have passed with hardly a passing shower, day after day and week after week being absolutely cloudless. This drought, however, does not interfere with the advent of spring, and in the middle of August the buds appear upon the willows. This season would be pleasant enough were it not for the wind and dust, the latter of which is intolerably, forcing its way through the minutest chinks and crevices, and filling a room with closed doors and windows almost as completely as if they were open. The wind is chiefly from the north and north-west, not steady, but at one time almost calm, and at another blowing in short but furious gusts. At night, during the winter and early spring, the thermometer sinks to two or three degrees below the freezing point; the ground is white with hoar frost, and the roadside puddles have often a thin coating of ice. The exhilaration produced by these magnificent mornings is wonderful: they bring back once more that strong physical delight in mere existence that, for most of us, has departed with our early manhood. Yet the thermometer at midday will mark over 70° in the shade, and the sun heat is greater than it is in England in the summer. The daily range is thus often 45°, and generally as much as 40°; a difference that is actually greater than that between the absolute maximum and minimum in Madeira *for the whole year!* Towards the end of September, the weather has improved in being less dusty. The nights are still cold, but the maximum day temperature is as much as 80° or 85° Fabr. The winds are light and irregular, blowing from almost all quarters except the south. In October, there is a marked increase in temperature; the shade maximum will not unfrequently be as high as 105°, while at night the minimum indicates 45° or 50°. Owing to the extreme dryness this first spell of heat is not felt so much as that at a later period during the rains. On the 24th October a few years ago, the writer's instruments registered a minimum of 43°; the maximum in the shade was 95°, and the difference between the bulbs of the hygrometer at 10 a.m. *thirty-four degrees*, the wind at the time being easterly and moderate! On the afternoon of the following day the first rains fell.

The rainfall in this region is so extremely variable and so local, that it would be impossible without observations extending over many years to form an idea of its mean. There are places not more than 300 miles from Bloemfontein to the north-east where rain has been known not to fall for two years, yet within the borders of the Transvaal hardly by, the annual amount must be considerable. Roughly speaking, it may be said that November and December are less rainy than the two following months. Results of observations from one season only are apt to be so misleading that they are hardly worth publication, but it may be mentioned that from the 11th to the 28th of February, in the year already alluded to, there were only six days on which rain did not fall, and the total amount registered was 8.83 inches. As in the preceding months this rain is almost entirely from heavy thunderstorms. There are

certain cases in which a simple fact is more striking than the most vivid of descriptions. It is not within the province of this article to describe one of these storms of the South African table-land, but it may be stated that it is thought necessary to provide every tombstone in the cemetery with a lightning conductor!

The temperature of November is very pleasant. The thermometer rarely registers a minimum of less than 50° Fahr. At 9 a.m. it stands at about 70°, and between 1 and 2 p.m. the maximum day heat, which varies from 85° to 95°, occurs. Instead of the absolutely cloudless days of winter, the skies exhibit tier after tier of fleecy cirro-stratus stretching like a great roof to the horizon. December, January, and February are all hot months, not so much from the actual increase of temperature as the greater humidity of the air. It has over and over again been said that our sensations of heat do not necessarily bear any relation to the height of the thermometer, and the patient need not be alarmed at records reaching to three figures. The writer has felt a steady 85° at Singapore far more than a temperature of more than twenty degrees higher on the uplands of South Africa. The heat of the Orange River Free State during the summer months is no doubt very great thermometrically speaking, but owing to the thinness and purity of the air, and its intense dryness, it is absolutely without any ill effects, except of course in cases where the individual is insufficiently protected from the rays of the sun.

March and April, and sometimes part of May, constitute a species of autumn. The weather is at this season delightful. It is much cooler, although the night temperature in the former month at least, is not often less than 50°. The maximum during the day will range from 75° to 85°. Thunderstorms are rare, but there are occasional showers, especially with the east winds. The pluviometric record for this month (which may be taken as a fair average) in the year already alluded to, was 3.14 inches, rain falling on eight days. The weather throughout April becomes progressively colder, the difference being most noticeable at night; there are fewer showers and the mornings are often keen. In May, the winter fairly sets in and lasts, with the climatic conditions already described, until the middle of the month of August.

A few words may be added as to the general characteristics of the climate. The rains, though often very heavy, are never long continued, and the invalid will seldom, if ever, be kept to the house on their account. The cold winds at the end of winter and in spring are certainly a drawback, and are not unproductive of violent catarrhs, though they do not often affect the lungs. They should especially be guarded against, and plenty of warm clothing should be brought out for that purpose. The chill at sunset is often extreme, and the invalid should, if possible, always try to be indoors at that hour.

Although admitting the climate of the Free State to be wonderfully suitable for certain cases of phthisis in which extreme dryness of the atmosphere appears to be the one great desideratum, the writer is far from regarding it as perfect, and it is so inseparably connected with certain discomforts and roughnesses, that the cautious physician will only recommend its trial after a most careful consideration of every point of the case. In Bloemfontein and Madeira—an article on which, as a winter residence, appeared a few months ago in these columns—we have instances of two health resorts, that, in almost every single particular, are as wide as the poles asunder. In the one, we have every advantage that civilisation can afford: easy accessibility, first rate accommodation, good society, capital yet cheap living, and a climate that is chiefly remarkable from its extraordinary equability. In the other, the patient has to contend with the disadvantages of distance, poor accommodation and living, great expense, and a comparative absence of society. The very cases that would fail in the one country, would probably do well in the other. But the physician should suit the locality to the individual. The life and surroundings of a health resort are, in the writer's opinion, of even more importance than the climate. Young men with a love of sport, who would be able to hire a wagon and live an open air life antelope-hunting, or married men who could embark in some

business or profession in one of the Free State towns, these might do well. But life without some occupation in such places would be absolutely intolerable, and to the society man, or the book-worm, no greater purgatory could by any possibility be imagined.

## SPECIAL CORRESPONDENCE.

---

### A HOLIDAY IN WHARFEDALE.

(By a Wandering Contributor.)

BEN RHYDDING, *September 1st.*

A BROAD green valley edged above by purple moorland over which the air drops as fresh and cool as in Switzerland, tapering into a long wooded gorge where a clear trout stream swirls or ripples as the rocks close in or open out before it—Wharfedale deserves the name of a "health resort," much better than many a place on which that much-abused term is foisted. Within six hours of London, the healthy can gain it without the loss of precious days, and the sickly without the worry and fatigue that a journey further afield entails. Once there both well and ill will alike be loath to leave it. For the strong there are walks up and down the dale, and over the moors into neighbouring valleys each of which has its own peculiar charm. On the south side of the valley lies the wide stretch of Rombald's Moor, over which one may tramp at will, knee-deep in heather. Its twelve square miles or so of undulating moorland covered with fern and heather, and studded with druidical circles, engraved stones, barrows and other prehistoric relics, offer in themselves sufficient interest for a month of wanderings. Beyond the moor lies the valley of the Aire, a busy dale still beautiful in spite of mill chimneys and smoke; in one of its tributary valleys is Haworth, with its steep winding street, which would be squalid and uninteresting to English eyes but for the memory of the Brontës. To the north, Wharfedale is shut in by a sweep of solitary moorland, intersected by deep valleys, and rising here to heights (some 1,300 feet above the sea) whence one can look over the high plateau on which Harrogate lies, and on to miles and miles of distant hills. Following the Wharfe up dale one comes upon one of the most beautiful and most visited spots in England—Bolton Abbey and Bolton Woods, of which I need only say that one could spend weeks there and find a fresh scene of beauty or of interest every day. All the places mentioned lie within a few miles of Ilkley, the chief resort of visitors to Wharfedale, and they are surrounded on all sides by a beautiful and fascinating country, quite within the powers of an active walker.

Offering these advantages to the strong, Wharfedale is not less adapted as a health resort for those in feebler health, and it is yearly gaining in reputation as such amongst the medical profession. Forty years ago one of the best sites in the valley was fixed on with great sagacity for the erection of the hydropathic establishment, since well known as Ben Rhydding. Similar institutions have arisen in the neighbourhood, but Ben Rhydding still remains pre-eminent for its happy situation, and its reputation as a sanatorium. Erected in the first flush of the hydropathic evangel by ardent followers of "the Silesian peasant, Vincent Priessnitz," Ben Rhydding has progressed with the times, and is now by no means obstinately devoted to "the system

of cure by cold water." Indeed we should be inclined to say that the use of cold water really forms quite a subsidiary element in the treatment of most of the cases sent to Ben Rhydding. What is probably, by the way, the most important use of cold water in the treatment of disease, viz., as an antipyretic, was certainly not contemplated by the followers of Priessnitz.

It is very creditable to those who have had the management of Ben Rhydding, that they should have been able to break through the hydropathic tradition, and to call in the aid of other appliances of treatment, such as the compressed air bath, galvanism and massage. For the functional nervous diseases, however, which now form a large proportion of the ailments treated there, it is reasonable to suppose that the fresh, sleep-giving air of Wharfedale, the regular life imposed on residents in the establishment, and the constant association with vigorous and healthy people, make quite as much for cure as the rubbing or the galvanism, or even the French douche. It is difficult to assess the exact value or to define the exact mode of action of a strong stimulant such as the cold douche, in cases of nervous prostration and hysteria. A thick stream of cold water, slightly broken, but striking the skin with such force as to give almost the impression of a hot spray, must necessarily exert a powerful stimulus on the cutaneous vessels and nerves, and secondarily on the general circulation, as its successful use in the treatment of cold feet would seem to show; but, in the cases and in the manner in which it is applied under Charcot, it is difficult to imagine that its action is exclusively physical. Administered alike to men and women by a doctor, as is their use and wont in Paris, a considerable part of its success may be safely set down to the psychical effect, of which it forms a very convenient vehicle. In some respects it is simply a refinement of the old-fashioned corporal castigation, which was not without success amongst the nervously afflicted in the Middle Ages, and later. It is very important to bear in mind that in all these modern modes of treating functional nervous disease, there is danger of falling into the error of regarding the mechanism of the treatment as purely physical, and so of neglecting to bring the whole battery of treatment, physical and psychical, to bear upon the patient. At Ben Rhydding the latter element derives reinforcement from the unconscious help of the healthy visitors, and one of the pleasantest experiences that the present writer has met with there, has been the sight of strong and happy visitors devoting themselves to interest some nervous patient, and to draw his brooding thoughts away from his own sufferings. The institution would, no doubt, lose in therapeutic success in proportion as it became more of a sanatorium for invalids, and less of a hotel for healthy and vigorous holiday-makers. For may not there be a neuro-mimesis of health as well of disease?

It is claimed that the Weir-Mitchell treatment of nervous prostration can be systematically carried out at Ben Rhydding, where they thoroughly understand the principles and practice of massage, and there can be little doubt that it is very well adapted for the after-treatment. Patients who have been restored to comparative health by rest and feeding elsewhere, will find in Wharfedale a very fair imitation of the life on a P. and O. steamer, some months of which are usually deemed necessary to complete their cure. There is no doubt a valuable sphere of usefulness open to Ben Rhydding in the care of such convalescents, always assuming that too many of them are not admitted at a time.

Ben Rhydding enjoys the credit of having for years

possessed the only compressed air bath in England. The use of this bath is little understood in this country, and English physicians will do well to receive with caution the extravagant accounts which come from abroad as to its marvellous efficacy in all sorts and conditions of disease. It will, however, no doubt be found useful as a gymnastic for the muscles of expiration, and probably for the heart-muscles in cases of emphysema and bronchitis. Whether it can claim to be more than this has yet to be seen. Another specialty of Ben Rhydding is the Russian bath, said to be the only complete one in this country. It consists of a small room heated by the introduction into it of steam to a temperature of from 100° to 115° Fahr. Fifteen or twenty minutes in this atmosphere produce more or less profuse perspiration, after which the bather is put into the rain-bath, wrapped in a warm bath-sheet, and relegated to a couch to cool down. It consumes less time than the Turkish bath, and its results appear to be equally satisfactory. This form of bath is especially indicated in certain forms of chronic bronchitis, as well as in those affections for which free diaphoresis is prescribed. The electrical department at Ben Rhydding, it may be added, is supplied with the broad brass electrodes, by means of which the induced or constant current can be applied to extensive surfaces of the body. But after all, as remarked above, the pure air and hygienic surroundings of Ben Rhydding constitute its pre-eminent advantages over many rival resorts, advantages which are secure against the sway of medical fashion, or the transitory influence of medical enthusiasms.

## MEDICAL NEWS.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, August 27th, 1885:—

Robert Ashton Bostock, 73, Onslow Gardens, S.W.; Edmund Walter Emtage, 1, Endsleigh Gardens, N.W.; Oliver Richard Archer Julian, St. Bartholomew's Hospital; Hugh Brodrick Mathias, Minehead, Somersetshire; Edmund Taylor Milner, Crescent, Salford, Manchester; Archibald Thomas, Towey House, Wellingborough.

**THE LIVERPOOL WATER SUPPLY.**—The works at Vyenwy, North Wales, for the supply of water to Liverpool, are making good progress. The total length of the aqueduct, from Lake Vyenwy to the present reservoirs at Prescott, near Liverpool, will be 67½ miles. It will consist of three tunnels, through each of which the water may be passed with pipes, and of three parallel lines of pipes. The discharging power of each line of pipes will exceed 13 million gallons per day.

**THE CITY OF DUBLIN HOSPITAL.**—The appeal on behalf of this Institution, which the failure of the Munster Bank has affected financially, is receiving encouraging support. Mr. Geale Wybrants, has offered 100% on the same conditions as "A Friend," who promises a similar amount. The Honorary Secretaries urge that in order to receive these donations, the required sum, about 700%, should be paid before the 1st proximo.

**ST. THOMAS'S HOSPITAL.**—By order of the Governors of St. Thomas's Hospital, the triangular hoarding in front of the hospital has been removed, and the large vacant space of ground will shortly be formally handed over to the Guardians and Vestry of the parish of Lambeth.

**ST. JOHN'S AMBULANCE ASSOCIATION.**—A new centre (the second established in India) has been organized in Bangalore, Mysore, of which Lieutenant General Sir Frederick S. Roberts, G.C.B., is president.

**GREENWICH.**—Dr. H. Watney has definitely accepted the invitation of the borough of Greenwich Liberal Association to contest Greenwich in the Liberal interest at the next general election, and he will introduce himself to the electors of that borough on the 9th September.

**PHARMACEUTICAL CONGRESS.**—The proceedings of the Pharmaceutical Congress were opened at Brussels on Monday by the Minister of Foreign Affairs. The Minister dwelt on the importance of the questions before the Congress to the well-being of the people. M. Van Bastelaere, President of the Congress, traced the history of pharmaceutical science in Belgium, and explained the nature of the labours awaiting the Congress. The composition of the provisional bureau was then made permanent. Among the Vice-Presidents are Professor Redwood, President of the last London Congress; and Messrs. Cartwright, President of the British Pharmaceutical Society, and Brunker, President of the Irish Pharmaceutical Society. The President declared the question relating to drinking water to be the most important of all. The Sections will discuss—(1) professional questions; (2) questions of theoretical and practical pharmaceutical science; (3) questions of chemistry in relation to hygiene; and (4) questions concerning general and applied biological and juridical chemistry.

**TESTIMONIAL TO PROFESSOR KOCH.**—A testimonial has been recently presented to Geh. Med.-Rath Professor Dr. Koch by the practitioners who last winter attended his course of lectures on cholera at the Reichsgesundheitsamt, Berlin. It consisted of an ebony casket richly ornamented in silver, having a silver shield in front bearing the inscription "Dedicated to Herrn Geh. Med.-Rath Professor Dr. Robert Koch with thankfulness by his first pupils, Berlin, 1884-85." A silver plate is let into the lid on which, in raised work, is a bust of Dr. Koch, on a pedestal, against which the goddess Hygeia leans holding in the one hand the staff entwined by the serpent, the symbol of the medical art, and in the other a laurel crown. A nude child seeks to conceal itself amidst her flowing drapery in fear of a haggard woman at the foot of the pedestal, who with a scythe in her hand symbolises the devastating disease which Dr. Koch has chosen for the special object of his study. On either side of the pedestal are groups of palms. Professor Echtermeyer is the author of the design for this relief. The casket is lined inside with dark blue satin plush.

**THE Belgium Academy of Medicine** has appointed a Committee consisting of MM. Gille, Depaire and von Baslelauer, to examine the memoir on "The Experimental Determination of the Effect of Desiccation used for Preserving Purposes on Simple Vegetable Drugs," which has been sent to the Academy.

**CHARITABLE BEQUESTS.**—Sir Moses Montefiore, Bart. F.R.S., late of East Cliffe Lodge, Ramsgate, has bequeathed 500*l.* each to the Jewish Convalescent Home, and the Beth Holim Hospital, 300*l.* to the Jews' Hospital at Norwood, 250*l.* to the Ladies' Lying-in-Charity for the Relief of Jewish Women, 200*l.* each to the Samaritan Fund of St. Bartholomew's Hospital, the London Hospital, and Mrs. Palmer's Cancer Hospital, 100*l.* each to the Royal Sea Bathing Infirmary, Margate, the Seamen's Hospital, Ramsgate, and the Ramsgate and St. Lawrence Dispensary. All the legacies are given free of duty. The late Mr. James Stevenson, 24, Sandyford Place, Glasgow, has left the following bequests, which will be payable at the first term of Whitsunday or Martinmas after the death of Mrs. Stevenson, who survives her husband: The Royal Infirmary, 500*l.*; the Western Infirmary, 500*l.*; the Deaf and Dumb Institution, 300*l.*; the Asylum for the Blind, 300*l.*

**THE SANITARY STATE OF DUBLIN.**—Dr. P. C. Little writing on this subject to the *Irish Times*, after referring to the system of house scavenging introduced by Mr. John Mulligan, which had since been superseded, says: "The inevitable results of the suppression of the old ashpit system and the propagation of w.c.'s are now experienced in the increased foulness of our city air, owing to the escape of more condensed gas from the main ventilators, and in the highly offensive and more putrid waters of the Liffey.

Should an epidemic unhappily visit Dublin now, I fear its effects would be deplorable—a sad commentary on all our improvements. What now is best to be done? Are we to push on another huge main drainage scheme? Are we thus to add a half million, or say honestly one million sterling, to our civic liabilities? Are the citizens willing to bear that additional burden with possibly 2*s.* 6*d.* in the pound increase on our present heavy taxation? Has the recent propagandism of w.c.'s led up to another golden vision—a beautiful dream for sanitary engineers and contractors—a dream, rumour says, already realised—on paper? I believe the ratepayers of the metropolis will never sanction it. Why not develop the rational and simple system of the late Councillor Mulligan? Why not carry away from our homes refuse of all sorts, as is done so admirably, economically, promptly, and completely in the great cities of Birmingham and Manchester by the pan system? It is applicable with comparatively a very small outlay, without loss of time in establishing, and requires little or no experience to work it. The nuisances may be converted into valuable manure, and so the product of the earth will properly go back to fertilize it. The Paris Municipality have recognised the value of this material, and for its elaboration and utilisation they occupy and cultivate 1,200 acres of land, making, it is said, a profit over the outlay on the compost. We are not going to copy the London mode of main drainage, which has proved a failure, as may be learned from the fact that the authorities there have recently been obliged to cast into the Thames in hot weather hundreds of tons of chloride of lime with the object of neutralising the poisonous gases emanating from decomposing sewage in the river. Such conditions could not arise with the pan system. The Liffey would by this means cease to be corrupted, our river fishery would be revived, our magnificent bay would escape the consequences of a weekly deposit in its bosom of 1,500 tons of fœtid matter, most injurious to our fishing industry, and to the preservation of deep water of our coast. The latter danger is not imaginary."

**HEALTH OF NAPLES.**—The *Times* correspondent writes: "The public health continues to be good, and all apprehension of a visit from cholera has ceased. Great numbers of Italians of the poorer classes are flying from Marseilles, and the lines from Modane and Ventimiglia are crowded. Yet not one suspicious case has been met with in Genoa, to which fugitives tend, and the whole of Liguria is said to be healthy. No doubt this may be attributed to the wise and extraordinary precautions of the Government. All the dirty packages of the poor travellers are examined, and when necessary burnt, but a large supply of clothing has been provided gratuitously for those in want." On August 27th, the same correspondent wrote:—"Yesterday there were no reports, but on the day before they were said to be 'good' for the whole kingdom. A descent has been made, therefore, from the superlative to the positive degree demanded by the two or three sporadic cases in the north, and proving that the truth will be spoken. The members of the Provincial Council expressed themselves fully satisfied with the explanations given as regards Nisida, and popular anxiety is calmed. Private letters from Nice, which is on the borders of Italy, and hence always awaken the sympathies as well as the apprehensions of Italians, state that cholera had appeared there. In some spots on the heights above Nice there are several desirable places, which are much frequented by the Nizzards and foreigners who have protracted their visit till the dog-days. Cholera had visited these places. Nine cases were reported, and there was a general flight. I am not much disposed to attach credence to private letters, but the Naples journals also confirm the fact. The council of a Neapolitan society have already decided on forming on the quarter of Monte Calvario a complete sanitary service for the relief of the poor who are sick. Ten eminent medical men have offered their gratuitous advice, and five druggists have offered to give a supply of medicines."

**A CHOLERA STRICKEN CITY.**—The following appeared in a Valencia paper:—"In the province of Valencia the place which has comparatively suffered most is Torres, situate about 10 kilometres from Saquinto, and containing about

800 inhabitants. In the place itself there are neither doctors nor dispensary, but medical assistance and medicines were supplied from Agimi, where the cholera was also raging. Very soon the former failed them, for of the two doctors one died of the disease, and the other, after losing his wife, was also attacked by the terrible epidemic. As these towns and that of Alfará de Algimia were thus deprived of medical aid, the mayor went to Valencia to lay the state of the case before the governor and pray for help. On his return he also fell a victim to the scourge. The panic was increasing. The butcher and his family died, and the town was without a supply of meat; but this was not all, the baker and his family suffered the same fate as the butcher's, which made things still worse, as the families still in existence were with few exceptions unable to make bread. There was still more to come. The gravedigger was struck down, and on the Tuesday there were 18 dead bodies with nobody to bury them. The force of the civil guard in barracks consisted of four men and a sergeant; one man and the wives of three of the guards had died, and the remaining guards were all ill. When assistance arrived, which infused a little animation into the people, the greater part of the houses were found shut up, either in consequence of the death or flight of the owners, only about 40 were inhabited, and these all occupied by stricken patients."

**CHOLERA IN THE PENAL ESTABLISHMENT, CARTAGENA.**—The following is the system of treatment employed by the medical officers of the penal settlement of Cartagena, Drs. Lopez Perez and Montaldo Y. Botella. *Primary intestinal symptoms.*—Infusion of Manzanilla with cream or powder of sub-nitrate or sub-carbonate of bismuth and 15 or 20 drops of laudanum every two hours. Hot soup with good wine every two hours alternately with the bismuth mixture, barley water, application of warmth. *Grave symptoms.*—Hypodermic injection of 3-4 grammes of bromohydrate or other salt of quinine (25 per cent.). Cramps disappear when injections of two centigrammes of chloride of morphia are given in conjunction with massage. *Vomiting and intense thirst.*—Bits of ice and wine and soup and ice cream alternately. Provocation of diaphoresis. Repetition if necessary of the injections.

**ST. MARY'S HOSPITAL MEDICAL SCHOOL.**—The following are the prizemen for the session 1884-85:—Scholarship in natural science, 75*l.*, Mr. Holloway and Mr. Lewitt. Scholarship in Natural Science, 50*l.*, Messrs. Graves, Hieckley and Maek. Scholarships in Pathology, Mr. R. S. Anderson; Prosectors, Messrs. Bays and Graham. Scholarship in Natural Science of 105*l.* (for students of Epsom College), Mr. Graveley and Mr. Lewis (equal). Summer Session, 1884—First Year—Materia Medica—Prize, Mr. H. C. Barr; Certificates, Messrs. Bays and Collier. Botany—Prize, Mr. Bottomley; Certificates, Messrs. J. C. and H. C. Barr. Practical Chemistry—Prize, Mr. J. C. Barr; Certificates, Messrs. Kidd and Bottomley. Second Year—Midwifery—Prize, Mr. A. R. S. Anderson; Certificate, Mr. M. M. Bird. Medical Jurisprudence—Prize, Mr. A. R. S. Anderson. Winter Session, 1884-85—First Year—Anatomy and Histology—Prize, Mr. A. Lewers; Certificates, Messrs. Davis, Lewitt, Henvey and Kingston. Chemistry—Prize, Mr. Hieckley and Mr. Hewitt (equal); Certificate, Mr. Severs. Second Year—Anatomy—Prize, Mr. H. C. Barr; Certificates, Messrs. Graham, Collier, Bays, Ridley and M. M. Bird. Physiology—Prize, Mr. Symes; Certificates, Messrs. Bays, Ridley, M. M. Bird, Graham, Collier, and H. C. Barr. Third Year—Medicine—Prize, Mr. Holloway. Surgery—Prize, Mr. Holloway; Certificate, Mr. H. H. Norton. Practical Surgery—First Prize, Mr. J. J. Clark. Second Prize, Mr. Holloway. Pathology—First Prize, Mr. J. J. Clark. Second Prize, Mr. Holloway. Third and Fourth Years—Clinical Medicine—First Prize, Mr. Caley; Second Prize, Mr. Spear; Certificates, Messrs. Tanner, Maudsley and Facey. Clinical Surgery—Prize, Mr. Sleman; Certificates, Messrs. Batchelor, G. Murray, Norton and Williams. Prizes in Ophthalmology, 10*l.* 10*s.*—Mr. Tanner. Scholarships—First Year—20*l.*, Anatomy, Histology, Materia Medica and Chemistry, Mr. Bays. Second Year, 25*l.* Anatomy, Physiology, Midwifery and Medical Jurispru-

dence, Mr. W. Williams. Third Year, 30*l.*—Medicine, Surgery, Pathology and Operative Surgery, Mr. H. Tanner.

**THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.**—The following are the prizemen for the Session 1884-5: Scholarships and Prizes.—Broderip scholarships for the best examination at the bedside and in the *post-mortem* room—First, B. Lawson; second, T. H. Williams. Governors' prize, F. W. Clark and J. R. Gaylard (equal). Hetley prize, F. W. Clark. Exhibition in anatomy—First year—J. Gordon. Lyell medal, W. B. Cockill; medicine, T. H. Williams; surgery, C. J. Deyns; pathological anatomy, C. J. Tabor; practical surgery, W. G. Nash; anatomy, W. H. Charles; physiology, J. Gordon; chemistry, J. K. Couch; dissections, R. H. Gilpin and E. E. Lewis; midwifery, F. W. Clark; forensic medicine, F. W. Clark; materia medica, J. K. Couch; practical chemistry, J. W. Gill; botany, Alfred Clark; practical physiology, J. K. Couch; psychological medicine, F. C. Brodie and W. K. Sibley (equal). Entrance scholarships—First, E. A. Falkner; second, H. B. Shepherd. Exhibition—Alfred Clark. Entrance science scholarship—J. Gordon. Certificates in order of merit—Medicine—F. C. Brodie, E. W. Clark; pathology, F. W. Clark, H. Bartlett, and W. J. Spoor (equal); practical surgery, W. B. Cockill, W. K. Sibley, W. H. Vickery; anatomy, F. R. Buswell, E. E. Lewis, G. C. B. Atkinson, R. F. Thomas, G. Seymour and W. G. Nash (equal); physiology, T. H. Clarke, W. H. Vickery, Alfred Clark, W. G. Nash, W. H. Charles, C. F. Rilot; chemistry, Alfred Clark, J. A. Hutton, H. C. Fox, F. C. Spurgin, T. W. Gann; midwifery, W. H. Vickery, W. B. Cockill, W. K. Sibley; forensic medicine, H. Bartlett, W. K. Sibley; materia medica, J. A. Hutton, T. R. Hamlen; practical chemistry, J. Ring, W. E. Jones, E. A. Falkner and J. A. Hutton (equal), T. W. Gann and H. G. Morris (equal), A. Clark, T. R. Hamlen, and A. E. Watson (equal); practical physiology, E. A. Falkner; psychological medicine, F. W. Clark.

**MEDICAL EDUCATION IN NEW SOUTH WALES.**—In the Medical School at Sydney University there are now 23 students for graduation in medicine and surgery—a number which may be considered very fair after only two years' existence of the school; seeing also that every medical student must have passed one year in arts before entering the school. Great progress has been made in the way of organising the different teaching agencies connected with this school, and considerable additions have been made to its special library and to the museums and scientific apparatus in the different departments. In the Prince Alfred Hospital, which is by statute and by its position on land surrendered by the Senate for the purpose, specially connected with the University, arrangements have been made for the teaching of medical students in accordance with the university curriculum and time-table. The direct authority given by statute to the university with a view to clinical instruction in this hospital is considered of essential importance to the efficiency of the Medical School. It is hoped that future regulations may make all hospitals enjoying State aid available as places for instruction, under suitable regulations. In response to applications made by the Senate, the General Council of Medical Education and Registration in the United Kingdom has recognised the Sydney matriculation examinations as qualifying for registration. It has also been arranged that the Royal College of Surgeons of England will exempt from examination in the medical subjects such of the Sydney graduates as may go up for the M.R.C.S.; while the University of London has placed the Medical School of the University on the list of institutions which it recognises. The University of Edinburgh in like manner has agreed to accept three years spent in the Sydney School as equivalent to three spent in its own school. In each case the maximum of privileges has been conceded.

**THE SPREAD OF HYDATID DISEASE IN AUSTRALIA.**—The Melbourne Central Board of Health, we learn from the *Australasian Medical Gazette*, have issued a useful circular for the information of the public, in relation to this matter, pointing out the dangers to be avoided and the best methods

of preventing this terrible evil. It shows that next to Iceland, where one-sixth of the deaths occur from hydatid disease, Victoria is more subject to it than any other country. It recommends the urgent necessity of proper care being taken by the authorities for the efficient carrying out of the registration of dogs, a matter which, though perhaps not carried out as it might be in Victoria, is, by the police authorities in New South Wales, culpably and almost absolutely neglected. It is regrettable that the power given under the New South Wales Dog Registration Act to prosecute the police officer who neglects his duty in this respect is not oftener put into force, and it might very justifiably commence with the Inspector-General, as the police officer in charge of the Metropolitan district where unregistered and ownerless dogs are almost innumerable.

**DEATH FROM IMPACTION OF A SHRIMP'S HEAD IN THE TRACHEA.**—Mr. Carttar recently held an inquest at Greenwich on the body of a child named William Geldie, aged 15 months. Mrs. Jane Hills, of 49, Blissett Street, Greenwich, identified the body, and said the child had been placed in her charge by its father, a marine engineer. On Tuesday evening she was sitting at tea, when the child picked up something and placed it in its mouth. Witness tried to see what it was, and found that it was a shrimp's head, which she tried to take from the child's mouth, but could not. The child choked a little, and witness called in a neighbour, Mrs. Colley, and afterwards the child was seen by Dr. Purvis, of Royal Hill, Greenwich, who advised his removal to the Seamen's Hospital, where he was taken, and died the same night. When witness saw the child choking she did all she could to remove the obstruction. Mrs. Colley, the neighbour, corroborated a portion of this evidence. Mr. E. Booth, Medical Officer at the Seamen's Hospital, said that when the child was admitted to that institution he showed signs of suffering. Witness opened the windpipe, but did not find anything to obstruct breathing. Witness had made a *post-mortem* examination, and found the shrimp's head at the bottom of the trachea, at the junction of the passage to the lungs, which was the cause of death. The Jury returned a verdict of Accidental Death.

**A FATAL MISTAKE.**—The *Times* published the following telegram on Wednesday last from Philadelphia:—A chemist, carrying on business at Jersey City, New Jersey, on Sunday last, having received a physician's prescription of quinine, by mistake supplied morphia. The dose was given to two ladies. On the same night one of them died, and the other is dying. When the chemist heard of his fatal mistake yesterday he took atropine, but did not succeed in killing himself. The physician who had written the prescription, and who was betrothed to one of the ladies, is completely prostrated, and his life is despaired of.

**POISONING FROM INTERNAL USE OF CHLOROFORM.**—In the *New York Medical Record* for July 11, Dr. Eliot, of Washington, relates the case of a gentleman, 60 years of age, to whom he was called ten minutes after he had swallowed two ounces of Squibb's chloroform, his wife having already given him some mustard and ammonia. He found the patient lying on the bed in an apparently exhausted condition, with dilated pupils, cold extremities, a weak pulse (70), intense burning in throat and abdomen, sighing respiration, and great inclination to sleep. Ipecac. and sulphate of zinc soon brought on vomiting, emptying the stomach of a yellowish fluid, smelling strongly of chloroform. Strong coffee was given to overcome the great drowsiness, and plenty of sweet oil to relieve the burning sensation. These remedies were continued for some hours, and every effort made to keep him awake. In the evening, four or five hours after taking the chloroform, only the burning sensation remained, and this was eventually relieved by the oil. Next morning he appeared very well, and in a week had recovered from all ill-effects. To this narration, Dr. Eliot appends a useful analysis of the particulars of 56 cases which have been recorded, 16 of the number (26·78 per cent.) proving fatal.

**FATAL CASE OF MUMPS.**—Dr. Michalski, relating a case of fatal mumps (*Union Médicale*, Aug. 25), refers to Dr. Longuet's paper on the disease in recent numbers of

the same journal, in which he calls attention to the fact that in spite of its reputation for benignity, mumps sometimes proves fatal, and that this usually arises from meningitis. Such cases, however, are rare. The present one occurred in a boy 7 years of age, who when seen by Dr. Michalski was suffering from well-marked parotiditis on the left side, accompanied by an unusual amount of fever, which seemed to be explained by a concomitant tonsillitis. The fever, however, persisted until the 5th day, when it as well as the parotiditis suddenly disappeared, the child recovering its liveliness and asking for food. He slept well during the ensuing night, and no anxiety was felt about him; but in the early morning he was seized with convulsions, which were followed by coma. Strong restoratives aroused him, so that for a time he recognised those who were about him; but the convulsions recurring, in a few hours he expired. There was no orchitis.

**DELIRIUM IN BRIGHT'S DISEASE.**—On the occasion of a case of delirium in Bright's disease being read at the Paris Hospital Medical Society, Dr. Quinquaud observed (*Gazette Hebdomadaire*, August 28), that in clinical practice great difficulty often exists in determining whether this symptom arises from primary cerebral disease or is an uræmic manifestation. But there is a very simple means of determining the point; for if analysis of blood obtained by cupping reveals an excess of urea, we have to do with uræmic accidents. This is almost a constant rule whatever may be the pathogeny of the uræmia. There is no proof that excess of urea in the blood is the proximate cause of the morbid manifestation, but when uræmia exists, this excess is almost always met with.

**FALL IN THE PRICE OF COCAINE.**—Dr. Squibb states in his *Ephemeris*, for July, that, owing to the large shipments of coca leaves, the hydrochlorate of cocaine can now be furnished at 10 cents. per grain. The leaves cost 50 cents. per lb., and 33 grains of the alkaloid are obtainable from the pound of leaves. The cost of the extraction is 1 dollar 20 cents., thus making the actual cost of the salt about 5 cents. and a fraction per grain.

**THE ACTUAL DEATH-RATE OF WAR.**—Some tables have recently been published, based upon a report of the Adjutant-General of the United States Army, showing the actual percentage of deaths from sickness and by battle during the War of the Rebellion. It is a truism that in war disease kills more than the bullet. The detailed facts, however, showing this, in the case of our own war, are of special interest. The States and Territories contributed to the Army of the Union 3,500,000 men. Of these, during the four years of war, there were killed in action 67,030, or 2·88 per cent.; there died of wounds 43,000, or 1·8 per cent., making a total of deaths from violence of 110,030, or 4·73 per cent. On the other hand, there died from disease 224,586, or 9·68 per cent.—disease being thus twice as fatal as the bullet. The total mortality among Union soldiers during the war would be 334,616, or 14·41 per cent. of those engaged. This is an enormous death-rate, but the figures are often wrongly used, and they do not accurately indicate the mortality attributable to the war. The ordinary death-rate among male adults is about 9 per 1,000 annually in this country. During the four years of the war there would have occurred under any circumstances, among the 3,500,000 of soldiers, about 126,000 deaths, leaving, therefore, only somewhat over 200,000 deaths attributable to the war. To put it in a general way, instead of four men who would have died in the natural course of events, 15 men out of every 100 died in the course of the war. The death-rate from bullets is only a little greater than the death-rate of civil life, but the soldier has added the enormous risks from disease.—*New York Medical Record*.

**THE CRIME OF ATTEMPTED SUICIDE.**—The Metropolitan Police have hitherto, with respect to persons who have attempted to commit suicide, taken them into custody and charged them before a magistrate with the offence of attempted suicide. This process is to be abolished in future, and, by an order issued by the Commissioners, all officers are in future, when called to a case where a person has attempted to commit suicide, to render all assistance necessary, and, when the person is removed

to a hospital, workhouse, or infirmary, and the surgeons deem it advisable for the person to be watched so as to prevent the act being repeated or the person harming any one else, then a police constable shall be stationed by the bedside to watch the person till all fears are removed, and instead of the person being taken into custody an application shall be made to a magistrate for a warrant for the apprehension of the person on the charge of misdemeanour.

**THE ART OF EMBALMING.**—Several Genevan physicians, writes the correspondent of a daily paper, make embalming a part of their business, with great advantage to themselves, the fee being necessarily a heavy one. But the most successful embalmer in Geneva, probably in Europe, is Professor Laskowski, of the University, and his process, of which he makes no secret, is being generally adopted. He has been equally successful in the preservation of anatomical specimens, to which, besides making them absolutely inodorous, he imparts all the appearance and suppleness of fresh pieces. An English physician, with whom our correspondent once visited the museum of the Medical Faculty, assured him that the specimens were far superior to anything of the sort in any other European collection which he had seen. A short time ago, Professor Laskowski, at a meeting of the Geneva Medical Society, read a paper on the art of embalming, in which he gave a full explanation of his method. Yet he was careful to point out that the mere process was no more than half the battle, and that only a special talent, improved by long and persevering effort, could insure complete success. The method of embalming practised by the ancient Egyptians was rudimentary in the extreme. It consisted merely in disembowelling the body, replacing the viscera with aromatic herbs and melted pitch, and, after drying it by means of a salt which extracted the humidity, enveloping the corpse in a mass of bandages. In modern times the more rational method has been adopted of injecting into the body to be preserved antiseptic fluids through the veins and arteries. This process has been largely practised by Signor Franchina, of Naples, and M. Ganal and Dr. Dupré, of Paris, but owing to the defects of the solutions employed and mistakes in manipulation, with only partial success. The liquid used by Professor Laskowski consists of a mixture of carbolic acid, chloride of zinc, and corrosive sublimate, with the addition of an odoriferous essence. This solution is as clear as crystal and pleasant to smell. To obtain certain results the operation (the method of which the professor explained in great detail) must be conducted with the utmost care and attention. But success, when once achieved, is as complete as could be desired. A body skilfully treated by Professor Laskowski's method assumes "the natural and agreeable expression" it bore immediately after death, and the skin becomes firm and as white as Carrara marble. Exhumations of bodies thus preserved, and the condition of the specimens in the anatomical museum, which after the lapse of years are as perfect as on the day they were prepared, prove that they will remain intact almost indefinitely, always provided that the specimens are kept in air-tight cabinets and the bodies placed in hermetically-closed coffins or other receptacles.

**SANITARY LEGISLATION.**—Mr. Mark H. Judge, writing to the *Times* on Wednesday last on this subject, says:—Without unduly interfering with individual action, and without adding one penny to the burden of the ratepayers, a Sanitary Act enforcing some such simple rules as the following would insure that every inhabited house was reasonably fit for human habitation: (1) All public sewers or common drains (where combined drainage is permitted) to be public property, and to be in charge of the sanitary authority of the district. (2) Every house drain to have between the house and the public sewer or common drain an air chamber and disconnecting siphon trap, or an air inlet disconnecting siphon trap, in a position where it can be readily inspected by the officer of the sanitary authority. (3) The drain between the disconnecting trap and the public sewer or common drain to be public property, and to be in charge of the sanitary authority. (4) The flushing and ventilation of all public sewers and common drains to be the duty of the sanitary authority.

(5) No house drain to be connected to any public sewer or common drain until after a duly-signed certificate as to the sanitary condition of the house has been deposited with the sanitary authority. (6) The owner of every house to obtain a certificate from some qualified person as to the sanitary condition of the house, such certificate to be deposited with the sanitary authority before it shall be lawful for the house to be inhabited (the Act to specify the persons qualified to give certificates, such, for instance, as properly qualified architects, surveyors, and civil engineers). (7) The owner or occupier of any house with drains to be responsible for the disconnecting siphon trap, for the flushing and ventilation of the drains on the house side of this trap, and for keeping the sanitary arrangements of the house in such a condition that no nuisance shall result therefrom. (8) Any person certifying the sanitary condition of any house to be deemed to have examined the arrangements certified, and for the issue of a false certificate to be liable to fine and forfeiture of right to certify.

**MILITARY PIGEONS IN FRANCE.**—In an article in the *Revue Scientifique*, August 8th, it is stated that although France has now the most complete organisation of military pigeons; the Government long refused to entertain the question, but at last it consented to accept as a gift from M. la Perré de Roo a gift of 420 pigeons procured from the most celebrated dovecots. The Minister of War then directed the construction of a dovecot of the most spacious and convenient description, which was completed in 1878 and accommodated 200 pair of pigeons. There are now 8 dovecots well peopled and managed at Paris, Vincennes, Marseilles, Perpignan, Verdun, Lille, Toul, and Belfort. A sum of 100,000 francs is inserted every year in the budget for the pigeons and optical telegraphy; and, imitating the Austrian Government, the Government does all in its power to encourage the rearing of pigeons by private persons. Couples are given gratuitously to the soldiers of the reserve and to persons of well-known character. During the manœuvres private persons are encouraged to compete for prizes, and an officer has been detailed to organise a system of intercommunication among the various pigeon societies and amateurs so as to facilitate the formation of a reserve of pigeons to draw upon in the day of need. This mission has proved quite successful, so that in the event of a new war breaking out, the carrier pigeon service will not have to be suddenly got up as in 1870, there being now a complete interchange of correspondence between the central authority and the intrenched places. General Boulanger has found the carrier-pigeons of great service for intercommunication in Tunis.

**ASPIRATION IN TRAUMATIC CATARACT.**—Dr. A. Trousseau relates in the *Union Médicale*, Aug. 27, a successful operation for cataract which he performed on a boy 12 years of age. The accident occurred from a fragment of iron which had entered the eye. When seen by Dr. Trousseau a week afterwards, a completely formed soft cataract was found to exist, which quite prevented all luminous perception. There was a good deal of pain and tension of the eye, which were relieved by a discharge of the aqueous humour. In about a month's time this was discharged again, and twelve days later the cataract was removed by aspiration, complete insensibility of the eye having first been secured by cocaine. The boy having rested three hours at the clinic, left by the railway for his home in the environs of Paris. All went on perfectly well, so that he was considered as cured in less than a week after the operation. This operation for cataract Dr. Trousseau regards as well suited for traumatic cataract. He performed it slowly by means of a buccal aspirator, which he considers very preferable to any syringe. By it the force of the aspirator can be much better graduated. For a good account of the operation Dr. Trousseau refers to a paper by Dr. Coppez, of Brussels, read at the French Ophthalmological Society in 1885; and the instrument which he prefers is that of Desmoris modified by Redard.

**HOT WATER IN HÆMORRHOIDS.**—Dr. Bryaut, of Savannah, writing to the *New York Medical Record*, July 18th, states that he has employed with great success for the treatment of both internal and external piles the application of water as hot as it can be borne. The

patient sits over a bowl containing the water, with a soft cloth dipped alternately in the water and applied firmly to the anus. This should be continued for ten minutes and repeated every four hours. The first application gives prompt relief to the smarting and burning pain; and from 24 to 36 hours are sufficient to complete the cure.

**SOLUBILITY OF BI-IODIDE OF MERCURY.**—At the meeting of the Académie de Médecine, August 25th, M. Mehu read a note drawing attention to the solubility of the bi-iodide of mercury in oils, lard, vaseline and some other excipients. Of these castor-oil is one of the best solvents. It dissolves one-fiftieth part of its weight, so that 20 grammes are dissolved in 1,000 of the oil. In this matter castor-oil therefore meets all the exigencies of therapeutics.

**ERRATA.**—In the article on the French Association, p. 302, col. 2, line 1, for "transposing" read "transfusion." The portion of the article commencing with "This confession," line 29, was inserted inadvertently.

### APPOINTMENTS.

- BEDDOES, T. P., M.R.C.S. (extension).—Clinical Assistant to the Skin Department, St. Thomas's Hospital.
- CLARKE, J. M., B.A., M.B. Cantab., M.R.C.S.—Resident House Physician to St. Thomas's Hospital.
- CROWDY, F. D., M.B. Oxon., M.R.C.S., L.S.A.—Assistant House Surgeon to St. Thomas's Hospital.
- Dow, W. O., M.B., C.M. Ed.—House Surgeon to the County Hospital, Ayr, N.B.
- GRUGGEN, WILLIAM, L.K. and Q.C.P. Irel., L.F.P. and S. Glas.—Medical Officer to the Hatfield District, Dunmow Union, *vice* Mr. C. Wade, deceased.
- KERSHAW, J. E., M.A., M.B. Oxon., L.R.C.P., M.R.C.S.—Resident Accoucher to St. Thomas's Hospital.
- KIDD, H. C., M.R.C.S., L.R.C.P. (extension).—Clinical Assistant to the Ear Department, St. Thomas's Hospital.
- LAWSON, R., M.R.C.S., L.S.A.—House Surgeon to St. Thomas's Hospital.
- LYON, T. GLOVER, M.A., M.D. Cantab., L.R.C.P., M.R.C.S. (extension).—Non-Resident House Physician to St. Thomas's Hospital.
- MAJOR, H. C., M.D., C.M.—Honorary Medical Officer to the Bradford Fever Hospital.
- OWEN, D. O. LLOYD, F.R.C.S.—Consulting Ophthalmic Surgeon to the Children's Hospital, Birmingham.
- PALMER, FRANCIS C., M.R.C.S. Eng., L.K. and Q.C.P. Irel.—Medical Officer to Bisley District, Stroud Union, *vice* Mr. B. W. Cawthorne, resigned.
- PLOWMAN, S., L.R.C.P., M.R.C.S., L.S.A. (extension).—Clinical Assistant to the Throat Department, St. Thomas's Hospital.
- RELTON, B., M.R.C.S., L.S.A.—House Surgeon to St. Thomas's Hospital.
- RITCHIE, E. D., M.R.C.S., L.S.A.—Assistant House Physician to St. Thomas's Hospital.
- ROBERTS, D. LLOYD, M.D., F.R.S.E., F.R.C.P. Lond.—Obstetric Physician to the Manchester Royal Infirmary, *vice* Dr. John Thorburn, deceased.
- RUTTER, JOSEPH, M.B., C.M. Edin.—Medical Officer to the Heworth District, Gateshead Union, *vice* Dr. Hugh Hopper, resigned.
- WEBB, J. EUSTACE, M.B., C.M.—Junior House Surgeon to the Western General Dispensary.
- WILLIAMS, R. M., L.R.C.P., M.R.C.S., L.S.A. (extension).—Resident House Physician to St. Thomas's Hospital.

### VACANCIES.

- ABINGDON UNION.—Medical Officer for the Third District, in succession to Mr. M. S. Todd, resigned. Area, 13,334 acres. Population, 2,916. Salary, £130 per annum.
- BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £150 per annum (with £30 per annum for cab hire), furnished rooms and attendance. Candidates must be registered and possess both a Medical and Surgical qualification. Applications, together with original testimonials and certificates of registration, to be sent to the Secretary on or before September 22nd.
- COVENTRY AND WARWICKSHIRE HOSPITAL.—House Surgeon. (*For particulars, see Advertisement.*)
- DROITWICH UNION.—Medical Officer for the Stock and Bradley District, in succession to Mr. J. W. Leacroft, resigned. Area, 2,976 acres. Population, 363. Salary, £15 per annum.
- ECCLESALL BIERLOW UNION.—Medical Officer for the Sixth District, in succession to Dr. G. H. De Wolfe, resigned. Area, 5,083 acres. Population, 1,545. Salary, £15 per annum.
- MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Candidates must be registered and hold a Medical and Surgical qualification, and not be less than 25 years of age. The appointment will be for 12 months from October 1st. Applications, with testimonials, stating age, to be sent to the Chairman of the Board, on or before September 12th.

NEWPORT INFIRMARY AND DISPENSARY.—House Surgeon. Salary, £100 per annum, with board and furnished apartments. Candidates must possess both a Medical and Surgical qualification, and be registered. Applications, with copies of testimonials, to be sent to the Secretary not later than September 12th.

Applications to be sent to the Treasurer at the Infirmary, marked "private" before September 5.

WEARDALE UNION.—Medical Officer for the Stanhope District and to the Workhouse, in succession to Dr. C. Arnison, resigned. Area, 22,830 acres. Population, 4,833. Salary, £20 per annum. Salary for Workhouse, £10 per annum.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon. Salary, £70 per annum, with board, lodging, and washing. Candidates must possess a registered Medical and Surgical qualification and be unmarried. Applications and testimonials to be sent to the Honorary Secretary on or before September 5th.

### DEATHS.

JONES, WILLIAM, F.R.C.S., at Lichfield House, Weston-super-Mare, on August 25th, aged 73.

TREVOR, ROBERT, Surgeon, A.M.S., at Malta, on August 15th.

### NOTES, QUERIES, AND REPLIES.

#### THE LATE DR. A. F. GRAHAM, OF LIVERPOOL.

WE have been requested to give prominence to the accompanying circular, which has lately been issued by an influential local committee, of whom Mr. Clarke Aspinall, the Coroner for the district, is Chairman. The circular runs as follows:—"The sad and untimely death of Dr. A. F. Graham, of 59, Everton Road, has left his young family of four children without any provision for their maintenance and advancement in life. A Committee has been formed with a view of raising a fund to place them, as far as possible, in a position to maintain themselves. Dr. Graham was so much respected and so highly esteemed by all who knew him, that the Committee hope to receive a very generous response to their appeal. A considerable sum of money is still required to enable the Committee to carry out the objects which they have in view." We may add that the Rev. Robert Irving, M.A., 21, Ivanhoe Road, Sefton Park, Liverpool, is the Hon. Treasurer, and Dr. James Barr, 1, St. Domingo Grove, Liverpool, the Hon. Secretary.

The following sums have been already promised:—The Liverpool Reversionary Company, £100; James Barr, M.D., £21; D. M. Drysdale, Esq., G. Graham Kirklington, Esq., A Friend, yearly (for four years), each, £10; W. Mitchell Banks, F.R.C.S., J. Cameron, M.D., E. H. Dickinson, M.D., Dr. McCulloch Higgins, Arthur Wrigley, Esq., each, £5 5s.; Gray Hill, Esq., President Liverpool Law Society, Malcolm Guthrie, Esq., T. P. Minton, Esq., Dr. James Johnson, each, £5; Mark Wright, Esq., £4; T. R. Glynn, M.D., Reginald Harrison, F.R.C.S., Messrs. Whitehead & Sou, each, £3 3s.; Robert Gee, M.D., President Liverpool Medical Institution, R. Blezard, Esq., Rev. J. Burbidge, J. Tarbuck, Esq. (per Mr. Clarke Aspinall), W. Carter, M.D., Dr. Clampitt, A. Dunbar, M.D., J. H. Finegan, M.D., J. A. Harris, M.D., Dr. A. C. E. Harris, Thomas Haughton, Esq., John Houlding, Esq., C.C., Rev. R. Irving, Dr. McCann, J. Birkbeck Nevins, M.D., Dr. Oliver, Roger Parker, Esq., W. Perkins, Esq., Sir J. A. Picton, W. Preston, Esq., Dr. Richardson, Thos. H. Sheen, Esq., C.C., F. Vacher, F.R.C.S., George Walker, M.D., Birkenhead, J. Wallace, M.D., each, £2 2s.; Clarke Aspinall, Esq., W. Alexander, M.D., James Armstrong, M.D., W. Macfie Campbell, M.D., Dr. Edis, D. Forbes, M.D., J. Muir Howie, M.D., Dr. Jones, Everton Road, Thomas Lee, Esq., J. W. Lloyd, Esq., Rushton Parker, F.R.C.S., Dr. Pierce, Rev. R. Postance, A. Cresswell Rich, M.B., G. Shearer, M.D., G. W. Steeves, M.D., George E. Walker, F.R.C.S., Dr. Ewing Whittle, each, £1 1s.; Mrs. Hugh Shimmin, Mr. Hobbins, Miss Torick, each, £1; Glynn Whittle, M.D., J. C. Langley, Esq., each, 10s. 6d.

## THE ATMOSPHERE IN THE UNDERGROUND RAILWAY.

TO THE EDITOR OF THE MEDICAL TIMES.

SIR,—With reference to your remarks regarding the pestilential condition of the Underground Railway, I would state that I have again written to the Board of Directors and offered to guarantee a successful result, if they will afford me an opportunity of purifying their tunnels by means of the "Chemical Lung," the expense of which will not exceed the single fare of one additional first class passenger per train.

I am, Sir, yours, &c.,  
RICHARD NEALE, M.D. Lond.

August 31st, 1885.

## THE CASE OF DR. BRADLEY.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—I enclose a further list of subscriptions, which, perhaps, you will kindly publish in the next issue of your Journal.

I remain, yours faithfully,  
RICHARD JEFFREYS.

Eastwood House, Chesterfield, September 2nd, 1885.

Sir George Burrows, Bart., Mr. Arthur E. Durham, Dr. J. Russell Reynolds, Dr. Richard Neale, Dr. G. H. Kidd, each, £5 5s.; Mr. John Langton, £3 3s.; Mr. George Lawson, Dr. J. Matthews Duncan, Dr. Sydney Ringer, Dr. Arthur V. Macan, Mr. Reginald Harrison, Mr. Thodore Davis, Dr. Brixton Hicks, Dr. John W. Ogle, Mr. N. Davies Colley, each, £2 2s.; Dr. Seymour Sharkey, Dr. C. Y. Biss, Dr. J. C. F. Fenwick, Mr. C. A. Ballance, Dr. Robert Liveing, Mr. A. E. Boulton, Dr. Fincham, Professor Gairdner, Mr. Frauk T. Paul, Dr. A. C. F. Rabagliati, Mr. John Waterson, Mr. J. Corrie, Dr. William Cayley, Mr. Walter H. Brown, Mr. George Weller, Mr. Pridgin Teale, Dr. Eddison, Dr. W. Stirling Anderson, each, £1 1s.; Mr. G. Browning, Mr. W. T. Alkey, M. M. M., Dr. W. A. Alchin, Mr. R. H. Meade, Dr. James C. Herbertson, each, £1; Dr. A. R. Macdougall, Mr. Jno. E. Kenyon, Dr. Knox, Dr. A. Swann, Dr. George Knapton, Mr. Chauncey Puzey, each, 10s. 6d.; Mr. J. B. Lee, Dr. A. H. Guest, each, 10s.

## COMMUNICATIONS RECEIVED—

Professor GAIRDNER, Glasgow; Dr. GUILLEMARD, Eltham; Dr. SHELLY, Hertford; Dr. WILLOUGHBY, London; Dr. J. K. FOWLER, London; Mr. R. ROBINSON, London; Mr. ACKERMAN-LAURANCE, London; Dr. J. BARR, Liverpool; Dr. HITCHMAN, Liverpool; Mr. H. DE STYRAP, Saltburn by the Sea; THE SANITARY COMMISSIONER FOR THE PUNJAB, Lahore; THE SECRETARY TO THE GOVERNMENT GENERAL DEPARTMENT, Bombay; THE EDITOR OF *Hibernia*, London; Dr. MAXWELL, Woolwich; Mr. E. COTTERELL, Bicester; Mr. W. J. BLACK, London; Dr. TIRARD, London; Dr. CLIFFORD BEALE, London; Dr. R. NEALE, London; Dr. B. ANNINGSON, Cambridge; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; THE MANAGER OF THE ROYAL AQUARIUM, London; Dr. D. L. ROBERTS, Manchester; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; Mr. MARK H. JUDGE, London; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE SECRETARY OF ST. THOMAS'S HOSPITAL, London; Mr. R. JEFFREYS, Chesterfield; Dr. ANGUS FRASER, Aberdeen; THE REGISTRAR-GENERAL, Brisbane.

## BOOKS RECEIVED—

Bad Drains, and How to Test Them, by R. Harris Reeves—Notes of Medical Experiences in India, &c., by S. E. Maunsell, L.R.C.S.I.—Veterinary Pharmacology and Therapeutics, by J. B. Gresswell, M.R.C.V.S.—Rickets, by T. C. Railton, M.D.—The Encyclopædic Dictionary, Part 20.—Cantor Lectures on Climate in its Relation to Health, by V. G. Poore, M.D.—Report of the State Lunatic Asylum, St. Joseph, Missouri—Notes on Rooks, by Messrs. Longmans & Co.—British Pharmacopœia.

## PERIODICALS AND NEWSPAPERS RECEIVED—

## STUDENTS' NUMBER.

THE present number of the *Medical Times* is intended to provide the student with concise and intelligible information as to the numerous medical schools in the United Kingdom, and to serve him as a guide through the chaos of regulations known as the requirements of the examining bodies. The former function is the more important of the two, as the student, his school once chosen and joined, will soon be put in the way of mastering the regulations of the examining body to whose tender mercies he may design to submit himself. We therefore devote the bulk of this number to a series of original articles on the various English schools, and abstracts of the prospectuses of the Scottish and Irish schools. The former series, written for our last year's Student's number, have just been revised and in some cases entirely rewritten by their respective authors, to whom we again owe our most cordial thanks. But besides his choice of a school, there is another matter which must engage the early attention of the intending student, and that is his choice of a preliminary arts examination, which must be passed somewhere or other before the status of medical student can be assumed. We trust that most of our young readers have already satisfactorily complied with the demand of the General Medical Council on this point, as otherwise they will be belated, and may find it necessary to make a hurried resort to the Victoria University, the Glasgow Faculty of Physicians and Surgeons, or other bodies which hold an arts examination in October. Those who are not intending to enter a medical school next month, we would strongly advise to enter for the January matriculation examination of the London University, an examination which serves as a preliminary pass-key to almost any medical qualification, except the degrees of the older Universities. Another duty incumbent on the commencing medical student is to register himself, or to see that he is registered by the Dean of his school, at the office of the General Medical Council 299, Oxford Street, as soon as possible after the commencement of the session, and in any case not later than October 15th, as any time spent in medical study does not count until this formality has been gone through. After these preliminaries, the one of which may be regarded as a farewell to his school life, and the other as a formal introduction to his medical work, the student will do well to settle down, with what earnestness and enthusiasm he can command, to his professional studies, in and through which we wish him all prosperity and success

## MEDICAL EDUCATION AND EXAMINATIONS IN ENGLAND.

### INTRODUCTORY ARTICLE.

THERE are eight different bodies in England which can grant Licences to Practise Medicine, viz., the Universities of Oxford, Cambridge, London, Durham, and Manchester (Victoria University), the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries. Within the last year, however, the two Royal Colleges have decided only to give their ordinary diplomas in conjunction.

(1) THE UNIVERSITY OF OXFORD grants degrees in Medicine to those of its students who have resided the requisite number of terms, who have taken the B.A. degree, and have fulfilled certain conditions and passed certain examinations under the following conditions:—

There are two degrees in Medicine—B.M. and M.D. Every candidate must take the degree of B.A. Hence he must matriculate at some College or Hall, or as a non-Collegiate Student, keep twelve terms or three years of residence, and pass the following examinations: Responsions, or the examination in lieu of Responsions, held annually shortly before Michaelmas Term; Moderations, Rudiments of Faith or the Substituted matter, and the Final Pass School or one of the Final Honour Schools. Of the latter the School of Natural Science offers many advantages. There are in it two examinations, the Preliminary and the Final Honour Examinations. The former includes (1) Chemistry; (2) Mechanics with Physics; (3) Elementary Morphology, Physiology, and Botany. The certificates for (1) and (2) exempt the holder from further examination in these subjects at the First B.M. Examination, and in case he is unable to proceed to Honours reckon as two out of the three certificates necessary for the Pass Degree. The Final Honour Examination includes Chemistry, Physics, Botany, Animal Morphology, Animal Physiology, and Geology. Honours are granted in every one of these subjects separately. Whoever obtains a First or Second Class in the five first named, may present himself as soon as he chooses for First B.M. Examination. A First or Second Class in Botany frees the student from further examination in that subject.

The degree of B.M. may be taken by a B.A. in the twenty-seventh term from matriculation. There are two examinations held annually in Trinity Term (usually in June) after due notice given by the Regius Professor of Medicine, to whom names are (by statute) to be sent at least fourteen days before the week of examination. The examinations are conducted partly by papers, partly by practical work, and partly *vivâ voce*. Conditions and subjects are as follows:—

(I) *First Examination*.—Candidates other than those privileged as above stated may not enter earlier than two years, or eight terms from the date of the first certificate in a Final School, Pass, or Honour. The subjects are—(1) Human Anatomy and Physiology to a certain extent, (2) Comparative Anatomy and Physiology to a certain extent, (3) Botany (exemption see above), (4) Chemistry, and (5) Mechanics with Physics (exemption see above). Subjects (4) and (5) may be taken together on an occasion other than that at which the remainder are offered. A candidate who has passed this examination is exempt from the First M.R.C.S. Examination.

(II) *Second Examination*.—A candidate may present himself four years or sixteen terms after the date of the first certificate in a Final School, Pass, or Honour, provided two years or eight terms have elapsed from the date of his certificate in the First Medical Examination. Certificates of attendance at some hospital of good repute must be sent to the Regius Professor of Medicine, and be approved by the major part of the examiners. The subjects are—(1) Theory and Practice of Medicine, including Diseases of Women and Children, (2) Materia Medica, (3) Thera-

peutics, (4) Pathology, (5) Principles of Surgery, and (6) of Obstetrics, (7) Forensic Medicine, and (8) General Hygiene. A paper is also set containing passages from two out of four ancient medical authors (Hippocrates, Aretæus, Galen, Celsus), and from more modern writers in Latin, French, and German; e.g., Sydenham, Pasteur, Koch, approved by the Regius Professor. Candidates are usually required to select two passages, one from an ancient, and one from a modern author.

A B.M. may proceed to the degree of D.M., provided he has passed three years from the degree of B.M. in the study or practice of Medicine. He has to write a thesis on a subject previously approved by the Regius Professor, to read it publicly before him, and then to deliver to him a copy. Incorporation, under certain conditions, is possible to a Cambridge or Dublin graduate.

(2) THE UNIVERSITY OF CAMBRIDGE grants degrees in Medicine and Surgery under the following conditions:—

*The Degree of Bachelor of Medicine (M.B.)*.—A Student proceeding to this degree must (1) reside in the University the required portion of each of nine terms; (2) pass (or obtain exemption from) the previous examination; (3) pursue medical study for five years, unless he has obtained honours in one of the triposes, in which case four years only are required.

There are three examinations for the M.B. Degree. The subjects of the *First Examination* are—(1) Chemistry and other branches of Physics. (2) Elementary Biology. These two parts may be taken together or separately. Before presenting himself for the First Examination, the Student must produce certificates of attendance on a course of Lectures in Chemistry and a course of Practical Instruction in Chemical Manipulations.

The subjects of the *Second Examination* are—(1) Human Anatomy and Physiology, (2) Pharmacy and Pharmaceutical Chemistry. These two parts may be taken together or separately. Before presenting himself for the Second Examination, the Student must have attended Hospital Practice during six months, must have practised Dissection during six months, and produce certificates of attendance on Lectures in (1) Human Anatomy, (2) Physiology, (3) Pharmacy and Pharmaceutical Chemistry.

The *Third Examination* is divided into two parts. The subjects of the first part are—(1) Principles of Surgery, (2) Midwifery and Diseases peculiar to women. Before presenting himself for this part the Student must have attended the Surgical Practice of a recognised hospital during one year, have attended ten cases of midwifery, produce certificates of proficiency in vaccination, and of attendance on Lectures in (1) Pathological Anatomy, (2) Principles of Surgery, and (3) Midwifery. The subjects of the second part are—(1) Pathology, (2) Principles and Practice of Physic, (3) Elements of Hygiene, (4) Medical Jurisprudence. Before presenting himself for the second part, the Student must have attended Hospital Practice during three years, have acted as clinical clerk for six months, and produce certificates of attendance on Lectures on (1) Principles and Practice of Physic, (2) Physiological actions and Therapeutic uses of Remedies, and (3) Medical Jurisprudence. After the Third Examination, an Act has to be kept, which consists in reading an original thesis, followed by a *vivâ voce* examination on the subject of the thesis, as well as questions of a more general nature connected with medicine.

*The Degree of Bachelor of Surgery (B.C.)*.—A Student is admissible to the Examination for this degree at any time after he has passed the first part of the Third Examination for the M.B. The subjects of the Examination are—(1) Surgical Operations and the application of Surgical Apparatus; (2) The examination of Surgical patients. Before admission to the Examination, certificates are required (1) Of attendance on Surgical Practice for two years, and of having acted as Dresser or House-Surgeon for six months; (2) A course of instruction in Practical Surgery. Before admission to the Degree of B.C., the candidate must also have passed the second part of the Third Examination for the Degree of M.B.

*The Degree of Doctor of Medicine (M.D.)* may be taken three years after the M.B. An Act has to be kept, by reading a Thesis on some subject chosen by the candidate, but approved by the Regius Professor of Medicine. In addition an extempore essay has to be written on some subject relating to Pathology, Physiology, the Practice of Medicine, or State Medicine. A Master of Arts of four years' standing can proceed direct to M.D., provided he produces the same certificates and passes the same examinations as for M.B.

*The Degree of Master of Surgery (M.C.)*.—A candidate for this degree must have passed all the Examinations for B.C. two years previously. The subjects of the Examination are:—(1) Pathology, (2) Principles and Practice of Surgery, (3) Surgical Anatomy and Surgical Operations, (4) Clinical Surgery and a short extempore essay on a Surgical case or topic relating to Surgery.

Certificates in Sanitary Science are granted by examination, without residence, to Registered Medical Men, of 24 years of age at least. For details, apply to Prof. Living, Cambridge.

(3) THE UNIVERSITY OF LONDON, which has its headquarters in Burlington Gardens, W., grants degrees in Medicine and Surgery (M.B., B.S., M.D. and M.S.) after a very complete and arduous series of examinations. These degrees have achieved a high reputation throughout the country, and the student who has received a good preliminary education, and is confident of being able to devote the requisite time to the curriculum, and has not had the advantage of residing at one of the older universities, cannot consult his future prospects better than by competing for the London degrees. He must first pass the Matriculation Examination which is held in London and in certain provincial centres twice a year, in January and June, no other preliminary examination being accepted by the University in lieu of it. The candidate must have completed his sixteenth year, and the fee for the examination is 2*l.* The subjects of the examination are: (1) Latin. (2) Any two of the following languages:—Greek, French, German and either Sanskrit or Arabic. (3) The English Language, English History and Modern Geography. (4) Mathematics. (5) Natural Philosophy. (6) Chemistry. It is scarcely advisable for the student who has already entered on his medical studies to think of passing this and the succeeding Preliminary Scientific Examination, as his medical studies must necessarily be suspended for that purpose, no medical studies being counted by the University until the student has matriculated. Both examinations ought to be passed before entering as a medical student, though many of the London Medical Schools now give facilities for the study of the subjects included in the Preliminary Science Examination. These subjects are: (1) Inorganic Chemistry; (2) Experimental Physics; (3) General Biology. The candidate must have completed his seventeenth year, and the fee is 5*l.* The examination is held twice a year toward the end of January and July, and candidates who do not intend to compete for honours may take two of the subjects at one examination and the third at a subsequent examination, or *vice versa*, one subject at the first examination and two at the second. Honours are given only at the July Examination. The examination is also held in a few provincial centres, except in respect to the practical examination in Biology, which must be carried on at the University. The passing of this examination involves a very complete and practical knowledge of the preliminary sciences which cannot be acquired without special instruction. Further particulars, both of this and of the matriculation examination, may be obtained from the Registrar of the University, and information as to the arrangements made at various institutions for pre-

paring students for them, will be found in our advertisement columns.

The requirements of the University in respect to the later examinations—the intermediate examination in Medicine, and the M.B., B.S., M.D. and M.S. Examinations will be found concisely put in the synoptical tables at page 373 of this Journal, and more fully in the calendar of the University, as well as in the extracts from it, specially printed for the use of students, to be obtained from the Registrar.

(4) THE UNIVERSITY OF DURHAM grants degrees and licences in Medicine and Surgery, particulars of which may be gathered from our synoptical tables. In respect to residence required of its students, it stands midway between the older universities and the University of London, one year's study at the University College of Medicine, Newcastle-on-Tyne, being required of candidates for all its degrees, except the M.D. degree for practitioners of 15 year's standing. There are three examinations for the degree of M.B. which are very similar in scope to those of the so-called Examining Board in England, and the two first of which free the corresponding examinations of that Board; while students who have passed the first examination of the "Examining Board" are exempt from the first Durham examination, except in the subjects of Chemistry and Physics. Candidates for the Durham Degrees have to pass a special Arts examination, which is held twice yearly, in April and September, but which may be taken at any time previous to entering for the Third degree examination. Certain examinations by other Universities, as well as the preliminary examination now qualifying for the Membership of the London College of Physicians free this examination. The first and second professional examinations may be passed prior to the commencement of attendance at Newcastle.

(5) THE VICTORIA UNIVERSITY, which has affiliated to it the Owens College, Manchester, and University College, Liverpool, and will soon probably affiliate the Yorkshire College at Leeds, grants the degrees of M.B., M.D., and Ch.M. Candidates for its medical degrees must pass the Entrance Examination in Arts, or a cognate Examination of some other University, the Preliminary Examination in Science, and two professional examinations, the Intermediate and Final M.B. examinations. The Matriculation fee of 2*l.* includes the fee for the Entrance Examination in Arts; the fee for the Preliminary Science Examination is 1*l.* The subjects of this examination, which is held in July and October, are Chemistry, Elementary Biology, and Physics, and its scope is very similar to that of the corresponding examination of the London University. Candidates must have attended during at least one year courses both of lectures and laboratory work in each of the above-named subjects. The more important particulars relating to the professional examinations will be found in our Synopsis. The next Entrance Examination in Arts will be held early in October. The calendar of the University may be obtained of Mr. J. E. Cornish, Manchester, or of Messrs. Macmillan, London, price 1*s.*

(6) THE ROYAL COLLEGE OF PHYSICIANS OF LONDON and (7) THE ROYAL COLLEGE OF SURGEONS OF ENGLAND have recently arrived at an agreement to give a conjoint diploma (L.R.C.P.L. and M.R.C.S.E.), and for this purpose they have appointed a common board of examiners, known as the "Examining Board in England," and are about to build a commodious examination hall on the Thames Embankment. They are also contemplating the advisability of applying to the Crown for the power to confer a degree on those

who take the double diploma. Whether the Colleges decide to apply for this power or not, and whether having applied for it they succeed in obtaining it or not, there can be no doubt that the large majority of English students will strain every nerve to take the double diploma, which will become by far the most important British qualification. For the small minority who are unable to pass the examinations or to pay the large fee (35 guineas) required of candidates for the diplomas of the Colleges, there will still remain open the cheap and kindly portals of the Apothecaries' Society and the Scottish Corporations. The regulations of the Colleges, and the curriculum required by them of students have been drawn up with wisdom, and leave both to the medical schools and to the student considerable liberty of action. The details of the requirements and examinations of the Colleges will be found in our synopsis (p. 374). The new regulations apply to all students who commenced their professional studies on or after October 1st, 1884. Those who became students previous to that date are allowed to take the separate diplomas of the Colleges on the old terms, and each College still retains its right to confer its diploma on practitioners already possessing a registrable qualification. With regard also to the higher diplomas, viz., the Membership of the College of Physicians and the Fellowship of the College of Surgeons, each College retains entire independence. The former diploma is taken almost exclusively by those who intend to practise as consulting physicians. The Fellowship of the College of Surgeons, on the other hand, though taken as a matter of course as a preliminary to the practice of pure surgery, differs from the higher diploma of the Physicians, in that it does not practically disqualify from general practice; indeed, it is possessed by many hundred practitioners throughout the country, and the student who cannot spare the time required for a University degree, but is ambitious to raise himself above the generality of practitioners, should lay himself out for taking the Fellowship of the College of Surgeons. It is not necessary here to particularize the requirements of the College for this diploma, but it may be stated that the candidate must have passed a preliminary Arts examination, which includes Greek as one of its subjects, and he must be prepared to spend a third winter at his anatomical studies, and to devote considerable attention to the study of Comparative Anatomy. The examinations, especially the first, are sufficiently severe.

(8) THE APOTHECARIES' SOCIETY OF LONDON, which occupies an interesting old building in Blackfriars, has during the past year freed itself from the reproach of being the only English licensing body giving an incomplete diploma. Special examiners in surgery have been recently elected, and candidates for the Licence of the Society are now examined in every branch of the medical art. The Examinations required for the License are two, each divided into written, practical and oral. The first examination, which is held on every Wednesday and Thursday, includes the subjects taught during the first eighteen months at the medical schools, and may be taken as soon as the student has completed his second winter session. The final examination is divided into two parts, and may be taken at the end of 45 months from registration as a medical student, provided the candidate has attained the age of 21, has passed three Winter and two Summer Sessions at a recognised medical school, and has fulfilled various other requirements. This examination is divided into two parts, which may be taken separately. The first part is held on the second and fourth Wednesday and Thursday in each month, and includes Surgery, Surgical Anatomy and Pathology, and a written examination in Midwifery. The

second part, held every Wednesday and Thursday, takes in Medicine, Pathology, Forensic Medicine, Mental Diseases and Hygiene, together with an oral examination in Midwifery and the Diseases of Women and Children. At all the examinations the student is examined on the living body, healthy or diseased. Candidates who have obtained qualifications from any British Licensing Body but the three Colleges of Surgeons are exempt from the primary examination and from the written part of the final, and various exemptions from the primary examination are allowed. The License of the Society is a cheap one, costing only 6*l*. Candidates must have passed an Arts examination, a special one, recognised by the Medical Council, being held by the Society three times a year, fee one guinea. Particulars may be obtained of Dr. Peregrine, Apothecaries Hall, E.C.

---

## METROPOLITAN SCHOOLS OF MEDICINE.

---

### ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

---

ST. BARTHOLOMEW'S HOSPITAL was founded in 1123, and the first medical treatise due to its opportunities of observation is the "Breviarium Bartholomæi," written about 1380. From scattered remarks of the author, John Mirfeld, it appears that some medical instruction was even then given by the Hospital Staff. In the sixteenth century a few members of the Universities studied under the Physicians, while the Surgeons had apprentices, but it was not till the reign of Charles II. that any regulations were made with regard to the Hospital as a School of Medicine. Two years after the Great Plague a library was formed for the use of the students. One of these was Edward Browne, of Trinity College, Cambridge, son of Sir Thomas Browne, and a manuscript note-book of his studies is still extant. Dr. Caius, though never on the staff, lived within the Hospital walls and took interest in its work, and six members of his College have since been elected physicians to the hospital, one being the immortal Harvey, who held the office for 34 years. Since 1660 the history of the Medical School has been one of continued improvement. In 1724 there was added a museum, and in 1734 a regular dissecting-room. The Physicians had before this lectured on Anatomy outside the hospital in Monkwell Street, where Dr. Terne's lectures, delivered early in Charles II.'s reign, were remarkable for their fulness and lucidity; but from the time of Edward Nourse, who was elected Surgeon in 1745, the teaching of Anatomy passed into the hands of the surgeons. In 1765 Percival Pott, whose name every medical student associates with two well-known surgical affections, gave the first full course of lectures on Surgery. John Hunter was one of his pupils. Dr. William Pitcairn and Dr. David Pitcairn gave lectures on Medicine. In 1787 lectures on Physiology were first given, and these were soon followed by lectures on Chemistry. Abernethy next appeared upon the scene, and his genius for teaching trebled the number of students, so that during his time the anatomical theatre was twice rebuilt.

The Governors of the Hospital have always shown a wise liberality towards the School, and they had already seven times added to its accommodation and conveniences during the nineteenth century, till, in 1876, the regular increase for several years in the

number of students made it desirable to re-model all the school buildings. The question was discussed as to whether this re-building should provide for a moderate further increase, or whether provision should be made for as many students as it was ever likely the practice of the hospital could instruct. The more extensive scheme was wisely adopted, with the result that, while the School is the largest in London, it has abundant accommodation for an annual entry of 200, a number which is not likely to be reached for many years to come.

The out-patient practice of the Hospital is the largest in the United Kingdom, and the enormous advantage of this to the students is shown by the fact that they have opportunities of receiving instruction on examples selected from more than 160,000 cases of medical and surgical affections in the course of the year. The total number of beds under the control of the staff is 750, and the 75 beds just added in the new Convalescent Hospital will materially increase the clinical advantages of the students by making it possible to admit a larger number of urgent cases.

It would be impossible to conduct so large a practice without the aid of a great body of competent students. After passing their Anatomical and Physiological Examination, and receiving a systematic course of instruction in the rudiments of practical Medicine, Surgery and Midwifery, students are eligible for hospital appointments: clinical clerkships, dresserships, out-patient clerkships and dresserships, ophthalmic, gynecological, and *post-mortem* clerkships, about 140 such appointments being made every three months. Four House-Physicians, ten House-Surgeons, an Assistant Chloroformist, two Ophthalmic House-Surgeons, two Assistants in the Electrical Department, and a Midwifery Assistant are chosen annually from the most diligent students when duly qualified. The holders of these appointments receive rooms and an honorarium. They also receive all the fees for *post-mortems* and inquests upon persons brought dead to the Hospital. Every two years three Casualty Physicians are appointed, and though the appointment is open, former members of the Junior Staff have usually been selected. Each Casualty Physician receives 100*l.* a year. The House-Physicians and House-Surgeons are under the direct control of the Physicians and Surgeons, and during the absence of their Seniors have the advantage of being the sole medical authorities of the Hospital.

Besides these clinical opportunities, an industrious student at St. Bartholomew's has a succession of Scholarships and other prizes to stimulate his application to his work. At entrance there are two science Scholarships of 130*l.* each, and one Scholarship in Arts of 50*l.* In the first year two Scholarships of 50*l.*, one of 30*l.*, and one of 20*l.*, with a prize in Anatomy, are offered for competition. A further anatomical prize of 15*l.* has been founded this year. In the second year, three prizes and a Scholarship of 50*l.* In the third year, two Scholarships of 30*l.*, a Gold Medal, and three prizes; and in the fourth year a Scholarship and Gold Medal of the value of forty guineas. A student of distinction, when qualified, may obtain one of the junior teaching posts. Three Assistant Demonstrators of Anatomy, two of Physiology, and an Assistant Medical Tutor are appointed every two years. All these are paid offices, and, with the private tuition to which they lead, enable a man of ability to support himself in London while he is considering his future course of practice, or while preparing himself to compete for higher posts at St. Bartholomew's or elsewhere.

The College of St. Bartholomew's Hospital, in which students can reside with many of the advantages of residence at a University, occupies the side of the

Hospital looking into Duke Street, Little Britain. Each student has two rooms, and there is a common hall. The College is presided over by the Warden, who has usually also discharged the duties in the School at large, which are elsewhere associated with the title of Dean. The earliest use of the word "Warden" at St. Bartholomew's is in 1182, when one Alan is so described, and the title was happily revived in 1843, when Sir James Paget was elected head of the College. The general discipline of the School is in charge of a special Committee which sends every month for all students who have been irregular in their attendance. The Committee is always ready to receive every explanation and to make full allowance for slowness of apprehension or occasional thoughtlessness, but persistent idleness is not permitted, and *aut disce aut discede* is the alternative offered to every student who persists in neglecting his studies.

Lastly, as to fees. The principle rigidly adhered to at St. Bartholomew's is that the fee for a perpetual ticket shall cover everything required for qualification. The library and the chemical laboratory and chemicals are free to every student. The only extra payment of any description is the small fee for a ward-dressership. Forty such dresserships are given away as prizes by open competition every year, so that an exemption from this payment is within the reach of every one who chooses to work for it. The prize dresserships thus afford a widely diffused and very useful stimulus to the exertions of the students of the first year.

These are the main features of St. Bartholomew's. The graces of its antiquity, its vast modern opportunities for observation in Medicine, Surgery and Pathology make it a place to which both its teachers and its students are devotedly attached, and all are actuated by a desire to be worthy of its past reputation and to extend its fame in the future.

## CHARING CROSS HOSPITAL AND MEDICAL SCHOOL.

(By a Member of the Staff.)

THE Charing Cross Hospital and School of Medicine occupy a prominent position in the very heart of London, in close proximity to the spot from which they take their name. The Hospital proper compactly occupies a mass of buildings which lie between King William Street, Chandos Street, and Agar Street; and the apex of the triangle is aptly completed by the Westminster Ophthalmic Hospital, which is also open to Charing Cross students. Across Chandos Street, and connected with the Hospital by means of a sub-way, stands the Medical School, an entirely new building within the last few years. To students who may be anxious to avail themselves fully of the many and unique advantages presented by the Metropolis over other cities as a place of medical education, the central situation of Charing Cross Hospital will at once commend itself. Not only is it easily reached from all parts of London and the suburbs—no small matter when lectures commence at nine in the morning—but the neighbourhood in which it stands might be taken as the very type of all that is Metropolitan, for every character of patient and all classes of disease and injury come daily under observation. Some of the greatest arteries of traffic pass its very doors. The river is within a hundred yards of it. A walk of two minutes brings the student to Trafalgar Square, Pall Mall, St. James's Park, and all the imposing grandeur of Royal palaces, Parliament, and the Clubs. Behind the Hospital stretches a very different region—the

great districts of St. Martin's and St. Giles's, with Leicester Square, Drury Lane, and Seven Dials. From each of these fields of life and of disease comes a constant supply of material for medical relief and medical study.

The character of the instruction given at the School reflects very accurately these advantages of situation. It has come to be essentially a school for training the general practitioner, a place where the student who enters the profession with a love for Medicine as the healing art, can enjoy to the full the pleasures and benefits of practical training and experience. Whilst sending up to the Universities a number of distinguished pupils who worthily maintain the reputation of their hospital amongst other schools, Charing Cross especially rejoices in preparing men for an honourable and useful career in family practice and in the public services. The hospital which can claim a Huxley amongst its former pupils, is not less proud to point to a Livingstone, a Fayrer, a Gnyer Hunter, and to the many younger men who have taken and who now hold the highest places in the Medical Department of the Army and Navy, or the highest professional positions in London and the provinces.

The Committee and Staff of Charing Cross Hospital thoroughly appreciate the character and the traditions of their School, and strive earnestly to maintain them. They avail themselves of the obvious advantage that attends the moderate size of the institution, to make themselves intimately acquainted with the character and abilities of every pupil, and to give him both the amount and the kind of individual attention which he specially requires. In a school of 150 students this is quite practicable. This care is especially practised at the commencement of the student's career. The first importance is attached to the soundness of his training in the great natural sciences of Anatomy, Chemistry, and Physiology, which are taught practically and tutorially as well as by systematic lectures. The chemical laboratory is thoroughly complete. The dissecting room is probably unique of its kind in London, situated in the roof of the building, large, light, elegant, and sweet. Dissecting goes on here in summer as well as in winter. The physiological laboratory is intended to be a second dissecting room, open all day, and fully provided with material and the means for studying it. During his first year the student is allowed to whet his appetite for Medicine and Surgery by occasionally visiting the hospital and holding minor appointments; his second winter is entirely devoted to the completion of his scientific knowledge, and to preparation for his first examinations, which will enable him to proceed untrammelled to professional work proper.

Having passed his primary examination or examinations, the student has his attention directed to Surgery, Medicine and Midwifery, as well as the related subjects of Pathology, Therapeutics, and Forensic Medicine. Here an important change in the right direction has been made within the last four years, by the establishment of regular Chairs of Practical Medicine and Practical Surgery. By this means a vast amount of instruction which was given casually by the different officers of the hospital, and of which the students could not always take advantage, has been systematized—indeed, rendered compulsory. Physical Examination, Clinical Chemistry and Microscopy, Minor Surgery and Bandaging, and Practical Pathology are now studied in regular courses, in which the demonstrative and tutorial system is closely followed. A proper groundwork being thus laid down, the student undertakes his work in the wards and out-patient rooms with intelligence and profit. Another advantage of the moderate size of the school is now seen. Every student obtains (and that in proper order) a clinical

post, without more than that amount of difficulty which enhances its value in his eyes, the appointments to clerkships and dresserships being made in order of merit, as tested by the previous performances of the men in the school and at the public examinations. Every pupil is required to hold an out- and in- door clerkship, and an out- and in- patient dressership, each extending over a period of three months; besides which he is encouraged to fill similar posts in one or all of the special departments, and to serve as pathological assistant. An interesting feature in this connection is the arrangement by which the students virtually keep the professional records of the hospital. The "cases" of the out- as well as of the in- patients are carefully preserved, and they are entirely taken by the clerks under the close direction of their superiors. Instruction and work thus go hand in hand. The greatest importance is attached at Charing Cross to the training in the out-patient department. The officers believe that this is an unrivalled field for the students to observe just that kind of general practice which every man has to meet when he enters the profession for himself.

At the same time all the important specialties are represented. The students attend the gynæcological practice in rotation. The lying-in institution is efficiently organised. There are departments for diseases of the skin, of children, of the ear, and of the teeth, where instruction is not only freely but systematically given. The students have the invaluable privilege of attending the practice of the Westminster Ophthalmic Hospital. The Dental Hospital of London is within three minutes' walk, in Leicester Square, and the lecture hours have been specially arranged to enable dental pupils to take full advantage of the instruction at both institutions.

The students of Charing Cross Hospital have abundant opportunities of occupying with advantage the time not actually devoted to classes or hospital work. The large library and reading room is always open. They may study in the museum, which is rapidly increasing in the number, variety and value of its contents. And when work is over they are encouraged in every way to enjoy their hours of relaxation after a wholesome fashion. The Students' Club is a social bond which confers upon the members the right of belonging to all the sub-institutions of the hospital—the Foot-ball and Cricket Clubs, the Medical or Debating Society, and the society for organising entertainments to the patients in winter. Charing Cross Hospital has the honour of having been the first to establish a Volunteer Army Hospital Company, and the majority of the students are now fully equipped with uniform, accoutrements, and stretchers. By these and similar means the life of the student at this School is made as bright and happy as possible.

---

## ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

"LONDON is the capital of England, and the capital of London is Leicester Square," so a popular French guide-book for tourists used to inform its readers. To the inhabitants of modern residential London, the metropolis may be said to centre in Hyde Park Corner; and the most conspicuous object at Hyde Park Corner, since the happy removal of the Iron Duke and his charger, is the façade of St. George's Hospital. It is singular to reflect, so magic has been the growth of the great city, that the noble charity which now occupies the very focus of the western residential districts was founded, not more than 150 years ago,

to give poor patients from London the advantage of treatment in the clear country air. As it stands at present, enlarged, rebuilt and added to, with the populous industrial quarters of Westminster, Pimlico, and Chelsea but a short distance away, the hospital is fully employed in meeting the wants of its own neighbourhood, and furnishes ample material for instruction in all branches of medicine and surgery. Private munificence has enabled it to establish a branch in the country beyond Wimbledon, to which convalescent patients are drafted as soon as their state permits, leaving the wards of the central hospital free for such cases as require a serious exercise of medical or surgical skill. Of the 351 beds of the establishment at Hyde Park Corner, all of which are available for the purposes of the teaching staff, 205 are given to surgical cases, 146 to medical ones; and special wards are set apart for diseases of the eye and diseases of women. In addition, the whole of the out-patient department has been organised for the purpose of clinical instruction, to an extent hardly possible except under the peculiar circumstances of a West End hospital, so that students have full opportunities of becoming familiar with the minor as well as the major ailments they will be called on to treat. Special out-patient departments have been arranged for diseases of the eye, of the skin, of the throat, for diseases peculiar to women, for orthopædic and for dental surgery, and in all of these instruction is systematically carried on.

The school buildings, containing the lecture theatres, dissecting room, laboratories, library and museum, are compactly and ingeniously arranged, and immediately adjoin the hospital, so that the student loses no time in going to and fro. Busts of John Hunter, of Brodie, and of other past celebrities of the School, adorn the main corridor. The well-known pathological collection, which was commenced by Sir Benjamin Brodie and the late Mr. Cæsar Hawkins, is housed in a lofty hall in the school precincts. It has recently been entirely rearranged and recatalogued on a new system with the view of affording students every facility in consulting it. Among the historic relics shown in connection with the museum are the skin of the cow from which the first vaccine lymph was taken by Edward Jenner, the anatomical table and chair of John Hunter, and the famous coin that nearly proved fatal to Brunel the engineer. Commodious reading and writing and refreshment rooms, where luncheon and dinner are served at a fixed tariff, complete the arrangements of the school buildings.

As is well known, the school of St. George's has long borne an especial *cachet*, as one particularly affected by the "bene nati, bene vestiti," among aspirants for a diploma. In rougher days, when a pilot coat and an absence of collar were the outward marks of the typical medical student, strange tales went the round of the city schools, how the St. George's men dissected in white kid gloves, and wore evening dress when they attended the Surgeons in the wards. A process of levelling up has long since taken place; the student of Albert Smith's day is as extinct as the dodo, and the prowess of St. George's men at Lillie Bridge and Kennington Oval has finally extinguished the legend of the white kid gloves; but the school, owing perhaps to its peculiar position, still retains a good deal of its ancient characteristic, and draws a large proportion of its students from the universities and public schools. The existence of an important school of medicine in so favoured and so accessible a spot does not fail to be appreciated by London residents, especially those of the western districts, whose sons are enabled to prosecute their studies while living at home, without

the loss of time and health involved in long daily journeys by omnibus or underground rail. A pleasant walk through park and gardens brings the student from Kensington, or Bayswater, or Notting Hill to the scene of his morning's work, and the proximity of the Victoria stations places the hospital in direct connection with all the southern and western suburbs.

Five entrance scholarships are offered to competition each year in September—two of the value of 50*l.*, one of 75*l.*, one of 90*l.*, and one of 125*l.* The most important prizes open to students after commencing study at the Hospital are:—The William Brown Exhibitions, of 100*l.* per annum, tenable for two years, and of 40*l.* per annum, tenable for two years, and the Brackenbury prizes in Medicine and Surgery, value 32*l.* 6*s.* each. In addition, the Treasurer's prize, the Thompson medal, the Brodie and Acland Clinical prizes, the Henry Charles Johnson prize in Anatomy, the Pollock prize in Physiology, Sir Charles Clarke's prize, and three general proficiency prizes, of smaller value, are annually competed for.

An exceptional value attaches to the hospital offices which are open to students of St. George's, both on account of the length of the term of office and of the magnitude of the charge which is placed upon the officers. No extra fee is asked for any office whatever, and all are awarded as the result of open competition. After passing through the usual dresserships and clinical clerkships, which are an obligatory part of the curriculum, the intending house-surgeon or house-physician is called on to compete with his fellows for the post of Assistant to the Registrar. The successful competitor then passes six months in systematically observing and recording the cases in the wards under the Registrar's supervision; alternating his work, on the surgical side, with a period of assistantship in the ophthalmic department. Having completed this first six months' work he obtains by another competition the office of Assistant House-Surgeon or House-Physician, and spends a second period of six months in attending on the out-patient department under the instruction of the Assistant Physicians and Surgeons. From the subordinate position he passes at the expiration of six months into the full House-Surgeoncy or House-Physiciancy. These offices are held for twelve months, and the officers are provided with board and residence in the hospital.

The hospital appoints at one time two House-Surgeons and two House-Physicians, who share the heavier duties of their office week and week about. Each House-Surgeon will therefore have on an average about 90 cases, and each House-Physician about 70 cases under his charge, the entire responsibility of which rests upon him in the absence of the visiting Physicians and Surgeons. He is called on further to deal with such urgent cases as arrive, and to attend the visiting officers to whom he is attached upon their rounds of the wards. By a tacit custom, moreover, he is expected to aid in instructing the clinical clerks, dressers, and other students who accompany him on his morning rounds. The value of two years of such training and work as this, before entrance into ordinary practice, it would be difficult to over-estimate, and it is not surprising that the competition for these posts is keen. A further office of great value is open to the house-officer on completing his term, that of Obstetric Assistant. The Obstetric Assistant, who attends to the out-door midwifery department as well as to the gynæcological ward, and holds his office on an annual tenure, is given a salary of 100*l.* a year, with board and residence.

For those who wish to devote themselves to hospital work for a further period, there are available the Medical and Surgical Registrarships, and the Curatorship of the Museum, each with an honorarium of 50*l.*

<sup>1</sup> The remainder of the All Souls' formula is scarcely applicable to the School of Chambers and Young, of Hunter and Brodie.

a year; and the Demonstratorships of Anatomy, Physiology, Physiological Chemistry, Histology, and Practical Pathology in the School, to all of which a salary is attached. From the men who have served in these last-mentioned posts the staff of the hospital is almost uniformly recruited. The old practice of canvassing a large Board of Governors for hospital appointments, with all its discreditable incidents, is happily a thing of the past, as far as St. George's is concerned. Appointment to staff offices is made by a select standing committee, sedulously guarded from communication with the candidates; that to junior offices is determined by the recommendation of the Medical School Committee, who are intimately acquainted with the merits of the applicants. A student entering at St. George's with the view of eventually becoming attached to the staff and joining the higher ranks of London consulting practice, thus knows that his course is clear before him, and that his prospects depend entirely on his own exertions.

### GUY'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

THE medical school of Guy's Hospital is provided with every requirement for giving the students a thorough and complete education. There are two large theatres, the Anatomical and the Chemical Theatre. In the former are delivered the lectures on Anatomy, Physiology, Medicine, Surgery, Midwifery, Mental Diseases. Adjacent to this are class-rooms, one of which is fitted with all the appliances in splints, bandages, models of dislocations, &c., for the classes in Practical Surgery. Another is a large room suited for the practical classes in Histology, Zoology, and Botany, and in this also are held the various written examinations for testing the student's knowledge, and for the award of prizes. Two other rooms are used as histological laboratories. The dissecting room has been enlarged from time to time, and is now a spacious and lofty room, lighted entirely from the top and well-ventilated; and connected with it is a smaller room with every arrangement for special demonstrations on the dissected subject. Dissection is now carried on both summer and winter, as for several years the subjects have been perfectly preserved for long periods by the injection of glycerine and arsenic. The student's work in the dissecting room is supervised by three demonstrators, and two assistant-demonstrators. Special demonstrations are given regularly during the winter session, and students who are candidates for the various anatomical examinations are divided into classes, systematically taught and tested from time to time by written examinations.

In the Chemical Theatre are delivered lectures on Chemistry, Physics, Medical Jurisprudence, and Materia Medica, as well as clinical lectures in Medicine and Surgery. It is fitted with appliances for lecture experiments, and close by are the lecturers' private laboratory, and a laboratory arranged for large classes of Practical Chemistry. In all these various departments, besides the lectures and classes prescribed by the examining bodies, special classes are held for the examinations of the Conjoint Examining Board and for the examinations of the University of London. Students find further opportunities of study in the Library, containing upwards of 5,000 volumes, which is open to all students, and from which books may be taken out for a limited period by special arrangement, and in the Museums which are situated in different parts of the Hospital. On either side of the Anatomical Theatre are two large rooms forming the Pathological Museum. This contains not only the various

morbid specimens arranged according to the physiological systems of the body, but also a unique collection of 800 wax models, the work of the late Mr. Joseph Towne. These comprise a complete series of models of diseases of the skin, illustrative of typical forms, and several models of rare or anomalous forms of skin disease; a large number illustrative of other conditions, such as gout, tumours, &c., and finally some accurate representations of typical visceral lesions, such as cerebral hæmorrhage, pneumonia, phthisis, which are of service in the lectures on Medicine and Pathology. The Anatomical Museum also contains a collection of wax models by Mr. Towne, numbering over 200. They include perfect representations of dissections of every part of the body, and a number illustrating the anatomy of the lower animals, and the development of the ovum. This Museum also contains a complete zoological collection of typical specimens of the several divisions of the animal kingdom. The Materia Medica Museum contains specimens of all the drugs in the Pharmacopœia, with their several preparations; as well as others commonly used, though not official. All the Museums are open to the constant inspection and use of the students.

Having passed through his earlier studies, the student at Guy's Hospital gains a thoroughly practical acquaintance with his profession by study in the wards, the out-patient's rooms, and the *post-mortem* room. The Hospital contains, besides general medical and surgical beds, special wards for diseases of women, and for diseases of the eye, a large operating theatre, an electrifying room, and spacious out-patient rooms in which arrangements are made for the study of diseases of the skin and of the ear, as well as those mentioned above. The *post-mortem* room has been quite recently built, and offers every advantage for the demonstration of morbid anatomy.

Every part of the Hospital is systematically utilized for clinical study, by the appointment of students for periods of two, three, or six months as reporters, clerks, or dressers. One of the earliest appointments is that of surgical clinical clerk, in which the student, having a certain number of beds allotted to him, keeps an accurate record of the cases therein, being guided and assisted by the Surgical Registrar. He then learns to observe the more obvious facts of ordinary surgical cases. Subsequently he takes the junior dresserships, dresser in the surgery, and assistant-surgeon's dresser, for three months each, and then becomes qualified for the office of medical clinical clerk, whose duties are of a similar kind to those of the surgical clinical clerk, and are superintended by the Medical Registrar. All the students in turn undertake the above appointments; but there are several other offices, *post-mortem* clerks, extern obstetric attendants, assistant-surgeons' clerks, and others in special departments, such as clerks to the obstetric physician, and dressers in the aural and dental departments. These appointments are distributed by a special committee of the staff, according to the merits of the candidates, as judged of by their previous work in the dissecting room, at lectures, in the earlier appointments and at examinations. In a similar way a selection is made for the more responsible appointments, surgeon's dresser, clinical assistant, dresser in the eye wards, resident obstetric assistant, house surgeon and house physician. These are appointed entirely according to merit, and without additional payment; the last three reside in the Hospital, free of expense, and the surgeon's dressers also for a short time during their period of office.

As an incentive to careful study, the medical school offers several prizes and scholarships. There are two open scholarships of 125 guineas each, the Arts Scholarship for classics, mathematics, and languages; and the Science Scholarship for chemistry, physics,

botany, and zoology. Prizes are offered at the end of each year in the subjects of the year's work. In the first year 50*l.* and 25*l.* In the second year 25*l.* and 10*l.* (Joseph Hoare Prizes). In the third year 25*l.* and 10*l.* In the fourth year 25*l.* and 10*l.*; and certificates to candidates who have done creditable examinations. In addition there are the following special prizes:—Two gold medals given by the Treasurer for clinical medicine and clinical surgery respectively; the Gurney Hoare prize of 25*l.* for clinical medicine: the Mackenzie Bacon prize of 10*l.* for medical ophthalmoscopy; the Beaney prize of 30 guineas for pathology; the Burdett prize of 10*l.* for hygiene; the Sands Cox Scholarship of 15*l.* per annum for three years for physiology; the Michael Harris prize of 10*l.* for anatomy. The Pupils' Physical Society, which meets once every fortnight during the winter session for the discussion of medical subjects, also awards five prizes of 5*l.* each, and one of 10*l.* for papers and essays presented to it, and for excellence in debating.

### KING'S COLLEGE AND KING'S COLLEGE HOSPITAL.

(By a Professor of the Medical Faculty.)

KING'S COLLEGE was founded by Royal Charter in the year 1829, and opened in 1831. Its foundation was due to the creation in 1826 of what was then called the "University of London," in Gower Street, and the fear that the new institution, while widening the bases of a purely secular education, would, by definitely displacing theology from the curriculum, refuse to religious training any recognition in education. The leaders of the Church of England at that time naturally became alarmed, and at once took action to form a teaching institution in which definite religious training on the principles of the Church of England should be combined with a full and thorough theoretical and practical scientific education. The Duke of Wellington placed himself at the head of the movement, and the first meeting of its supporters was held in June, 1828. The constitution of the College as it now exists was then determined on, viz., a principal to superintend the general discipline, professors and tutors for the various branches of literature and science, a Council to conduct the general affairs of the institution, composed of a number of life governors and official governors and some elected members, with the Archbishop of Canterbury as visitor, and His Majesty the King as patron. At all times the College has been resolutely kept aloof from all special parties in the Church, and a virtual "Conscience Clause" has always been in operation, students of all creeds, some not Christians, being freely admitted. The foundation was intended to be on a large scale, and probably 150,000*l.* has been spent on the building and establishment of the College. There is no professorial endowment, so that the incomes of the teachers have always been, and still are, dependent on the fees paid by the students only. In the year 1831, on the opening of the College, it consisted of a department of general literature and science, a medical department, and the school. Rooms for a certain number of resident students, then a new feature in London colleges and medical schools, formed part of the original plan, and this feature was more fully developed as the College grew older. At present rooms are provided for about thirty students. The first lecture on the separate opening of the medical session was delivered by Professor J. Henry Green, F.R.S., in October, 1832. For the lectures, being all then required by the College of

Surgeons and the Apothecaries' Hall, the total fees were 54*l.* 12*s.*

In 1833, the second year after the opening of the Medical Department, the number of matriculated students was 77, and of occasional students, 233. Frequent class examinations were instituted, and all students, occasional as well as matriculated, were expected to attend them. A regular register of attendance on lectures and examinations was also kept. Students were earnestly recommended to devote themselves for some time to the general studies of the College, before they entered on a more exclusively professional course of instruction, and it is worthy of notice that a course of instruction in medical Latin is specially mentioned in the first medical prospectus. It was not for many years after this that passing a preliminary examination in arts was made compulsory on every medical student by the Examining bodies, and this great reform was always strenuously urged by the medical authorities of King's College. In 1836 the Institution in Gower Street had been incorporated by charter as "University College," and in 1837, mainly owing to the rivalry between the two bodies, the present University of London was founded as an Examining body, granting degrees, and power was given to it to affiliate the two Colleges and other colleges of higher education.

The chief drawback to the thorough and efficient medical education contemplated by the founders of the College, and anxiously desired by the teachers, was the want of a hospital for the purposes of clinical teaching. The students were obliged to obtain practical instruction and ward work at the then existing hospitals under other authorities, who looked with some jealousy and distrust on such of their surgeons and physicians as were attached to the new institution. For the due development of the Medical School it had therefore become a matter of urgency that a hospital should be obtained, and that the eminent teachers at its head should have proper scope for their practical skill as well as their acknowledged theoretical efficiency. In the year 1839, King's College Hospital was opened on the site of the old St. Clement Danes' Workhouse, in Portugal Street; 120 beds were at once made available for teaching purposes, and its position, in one of the poorest and most densely populated parts of the Metropolis, was especially favourable for the reception of the worst and most varied forms of disease. In consequence of the creation of the hospital, several changes took place in the teaching staff; both Dr. (afterwards Sir Thomas) Watson and Mr. Moncrieff Arnott resigning their professorships, and retaining their appointments at the Middlesex Hospital. Dr. George Budd now undertook the lectures on medicine, and Mr. William Fergusson was elected professor of surgery. The first members of the hospital staff were—Surgeons, Richard Partridge, William Fergusson; Physicians, Robert Bentley Todd, M.D., and George Budd, M.D.; Robert Ferguson for diseases of women and children; Physician Accoucheur, Arthur Farre, M.D.; Assistant Surgeons, William Bowman, John Simon; Assistant Physician, William A. Guy, M.B., and Arthur Farre, M.D., for diseases of women and children; Surgeon-Dentist, John Tomes. A more distinguished staff of officers could not possibly have been brought together. Farre, Simon, Bowman, Guy, and Tomes are still living, and we need only point out how fully their subsequent career testified to the wisdom of the Council's selection. The sparkling originality and successful teaching of Partridge, the thorough kindness and extensive erudition of George Budd, who has so recently passed away, are household words among all old King's men. But undoubtedly among the first teachers Todd and Fergusson are the names that will be the longest kept in memory, and will be first recalled when the old

hospital is spoken of, for in 1861, the present building, with its 220 beds, took the place of the former makeshift.

Robert Bentley Todd gave the whole of his life-work to King's College and King's College Hospital, for in 1836, at the early age of 27, he began to lecture on Physiology, and he only resigned his office of clinical physician at the close of 1859, just six weeks before his death. His name will always be identified with the "alcoholic" treatment of disease, in favour of which perhaps even now the last word has not been spoken. We prefer to remember him as the accurate clinical observer, the correct diagnostician, the fearless exponent of unpopular views, and the earnest and convincing teacher. Probably no man was ever more truly loved and admired by his pupils than Robert Bentley Todd. William Fergusson was well known as a successful demonstrator of anatomy, and a bold operator in Edinburgh when he was appointed the surgical head of King's College Hospital. He was less successful as a teacher, perhaps, than as an operator, yet those who daily attended to Fergusson's maxim, "Learn with your eyes as well as your ears," will place him on a higher level in this respect than those who only casually heard him. Imbued with the teaching and example of Liston and Syme, he was at his best in the operating theatre. Conspicuous for the brilliancy and ease with which he performed the most difficult and unusual operations, he at the same time simplified his art by always leaning to what he called "conservative" surgery. His self-command and temper, unperturbed by any unforeseen circumstances, were peculiarly striking. As a result of the teaching of the exceptional staff then at the head of King's College, it may be mentioned that alumni of this school have been elected to appointments in every medical school in the Metropolis, with one exception only.

Since 1861, new chemical and physiological laboratories, and an enlarged dissecting-room have made King's College a well appointed and even an almost ideally complete medical school. With the new developments in medical education, King's College has kept pace. Special teachers and professors have taken charge of the teaching of biology and physics, whilst tutorial and practical instruction has been largely increased for the requirements of the examinations at the University of London and the Royal Colleges of Physicians and Surgeons. On the death of Sir William Fergusson, in 1877, it was thought desirable to strengthen the surgical staff, and Mr., now Sir Joseph, Lister was induced to resign his appointment at Edinburgh, and to accept a clinical professorship and the post of surgeon at King's College Hospital. By thus becoming the head-quarters of antiseptic surgery, King's College Hospital has increased its attractiveness, not only for its own students, but also for the practitioner, from whatever country he may come. The medical students at the College, probably from being under more direct discipline, and drawn to a large extent from the relatives of the clergy of the Church of England, have been in a very large proportion public-school men. Athletics have always been assiduously cultivated. In the foundation of the Inter-Hospital Athletic Sports King's College men took a great share, and for many years produced winners in all the principal races, whilst the Inter-Hospital Cricket Matches were mainly due to their initiative, and for the first two years they held the champion cup. An athletic club has recently been formed, and a large piece of land taken by the Council close to Wormwood Scrubbs Station for lawn tennis, cricket, and football. Entrance exhibitions in science and literature, to the amount of 270*l.* per annum, have been placed at the disposal of the Council by the munificence of the late Dr. Warneford, Mr. T. G. Sambrooke, Mr. Rabbeth

and the Clothworkers' Company, and besides many endowed and class prizes, medical scholarships to the value of 130*l.* are awarded annually. The residents at the Hospital are elected by competition, and have rooms and commons free, and the registrars are endowed officers. A marked point in the tenure of the resident appointments is the absence of a resident superintendent, so that in the absence of the visiting officers the house-surgeons and house-physicians are in sole charge, and the names of the eminent men who have held these offices show how good a training is secured by giving them such responsibility and scope for learning medicine and surgery. Selected students are made Associates of King's College each year, and Honorary Fellows have been elected since 1847, as a special mark of distinction.

## THE LONDON HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

EVERY hospital and medical college has some advantages and peculiarities that offer attractions to those about to begin their medical education, and the variety of choice tends to embarrass rather than help one who has to select an *alma mater*. The especial attraction of the London Hospital is that, owing to its great size and position, it offers, in excess of every other medical school, an enormous amount of clinical material available for study and teaching purposes. In order to appreciate the importance of this fact we must point out that to gain a thoroughly competent knowledge of our profession two things are essential, namely: good systematic teaching, and abundant opportunities at the bedside and in the dead-house, of acquiring a large practical experience and insight into disease in all its many and varying forms. No didactic teaching of medicine and surgery, however good, can make a fully equipped practitioner of medicine. Such teaching may lay the foundation for acquiring knowledge, which will up to a certain point be of the greatest value and assistance to the student, but the structure will be dwarfed and incomplete unless accompanied by large clinical opportunities. Such teaching may make a scholar, but it will not make a successful doctor; for medicine is an art as well as a science, and must be learned by studying nature, diseased and distorted though it be, and not from books and lectures. Books and lectures can never develop and ripen the habits of observation which are essential to a true knowledge of disease. These can only be gained by long and patient study at the bedside and in the *post-mortem* room. It is not sufficient to *walk* the hospital, that is, to accompany the teacher in his visits to the wards, but the student must have the training and responsibility of individually watching patients day by day, and of recording their conditions, and of personally adapting the appliances of surgery under supervision before he is qualified to treat the diseases and injuries he will afterwards be called upon to deal with. Hence the failure of some teaching establishments, with hospital opportunities insufficient for the number of students. Such establishments turn out students who may be successful at examinations such as test only book knowledge, but when the education of these students is supposed to be complete they find it has really to commence. This is evidenced by the fact that a number of legally qualified men come each year to the London Hospital from British and other Universities to supply the deficiencies of their medical education, and eagerly fill the subordinate appointments open to junior students.

The London Hospital stands in the midst of the large manufacturing region of East London, quite close to the Docks, and in the centre of a densely populated, but poor neighbourhood. It is the largest general hospital and contains nearly 800 beds. The beds are fully occupied, and last year 8,015 patients passed under treatment in its wards. The great size of the hospital and the number of patients necessitate a proportionately large number of offices, which afford the greatest educational opportunities to the student. He can, as a rule, hold all the appointments in turn, without waste of time in waiting for them. And though the number of students has undergone a remarkable increase during the last few years, there is no likelihood, owing to the great size of the hospital, of this special feature being lost. There are the following resident appointments:—five House Physicians, five House Surgeons, a Resident Accoucheur, a Receiving Room Officer, and two Resident Maternity Pupils. All the resident officers are provided with rooms and board entirely free of expense, and all these offices are open to the full students of the hospital without additional fee.

Every student is *required* to act as in-patient clinical clerk dresser, and *post-mortem* clerk, for a certain period, though usually this period is voluntarily exceeded. As already stated, there are no extra fees for dresserships. The physicians and surgeons take every opportunity of making use of the large number of patients in the wards for the instruction and training of the students. The out-patient departments are on a scale proportionate to the size of the hospital, and last year there were 64,958 out-patients. In the out-patient departments the students are instructed in elementary medicine and surgery, by the physicians and assistant physicians, and the assistant surgeons, so that when their ward work commences, they have the requisite training to enable them to perform their duties. There are special departments for diseases of the Eye, the Ear, the Teeth, and the Skin, and the number of patients attending in these departments is so large that the student who avails himself of his opportunities cannot fail to obtain a competent knowledge of the more or less specialised branches of medicine. There is also a completely equipped Obstetric department, with wards and an out-patient department, for the study and treatment of gynæcological cases, and a maternity department, for the attendance of parturient women at their own homes. The opportunities of obtaining practical experience in midwifery are simply unlimited.

The great and steady increase in the number of students for several years past, has rendered necessary increased accommodation in the College buildings. The authorities have, therefore, decided to spend 15,000*l.* on the enlargement and reconstruction of the school. An entirely new dissecting room, new physiological theatre and physiologists' room, a practical histology room, a room for the teaching of pathological histology, new library and reading rooms, new class rooms, and curators' rooms, will be erected. Building operations will be commenced during the vacation, and are arranged not to interfere with the work of the school. It is expected that these additions and alterations of the College buildings will render them entirely complete.

The arrangements of systematical lectures and teaching are as complete as possible. In the winter session there are lectures on Anatomy (Mr. Frederick Treves), Physiology (Mr. McCarthy), Chemistry (Dr. Meymott Tidy), Experimental Physics (Mr. Page), Medicine (Dr. Stephen Mackenzie), Surgery (Mr. Rivington). In the summer session the following courses are given:—Midwifery and Diseases of Women (Dr. Herman), Morbid Anatomy and Pathology (Dr.

Sutton), Toxicology (Dr. Meymott Tidy), Medical Jurisprudence and Public Health (Dr. Sansom), Materia Medica (Dr. Prosser James), Practical Chemistry (Mr. Page), Botany (Dr. Francis Warner), Comparative Anatomy (Mr. C. W. Mansell-Moullin). Practical Histology (Mr. McCarthy), Practical Surgery (Mr. Reeves), Operative Surgery (Mr. Rivington). Besides these lectures, there are courses of lectures on Ophthalmic Diseases (Mr. Waren Tay), Aural Diseases (Dr. Woakes), Diseases of the Throat (Dr. Morell Mackenzie), Anatomy and Pathology of the Teeth and Dental Surgery (Mr. Ashley Barrett). In the winter and summer session Mr. Jonathan Hutchinson, Emeritus Professor of Surgery, gives two short courses of lectures on Clinical Surgery.

The Standards of the Examining Boards have of late years advanced, and, in order to meet an evident need, special Tutorial Classes have been instituted for all the examinations, and especially for the Preliminary Scientific and Intermediate M.B. London Examinations, and for the Primary and Pass Examinations for the Fellowship of the Royal College of Surgeons. Great care is taken with the teaching in the department of practical anatomy, and the supply of subjects is always so large that the new student can count on getting a "part" at once instead of wasting several weeks at the commencement of the winter session before settling down to dissection. The advantages of a large supply of subjects cannot be overrated. A sound knowledge of anatomy can be obtained in the dissecting room, and in the dissecting room only. When work commences in the department of practical anatomy at the beginning of the coming session, some twenty bodies will be available for use on the first day of the session. At the London Hospital every student can dissect the entire body twice during his first two winter sessions, and facilities are offered to gentlemen preparing for the higher qualifications for undertaking special anatomical work. Dissecting is also carried on during the first two months of the summer session. The ample supply of bodies is taken advantage of during that session for the teaching of operative surgery in an exhaustive manner.

Though the hospital is situated in a neighbourhood that has a somewhat evil reputation (not by any means, from a sanitary point, deserved), the writer knows by experience, having lived there when himself a student, that residence there is healthy and cheerful, if not *élite*. Good lodgings, at reasonable charges, are easily obtainable. At the present time, however, a student may live at any part of London he prefers, or in the suburbs, the numerous railways, with conveniently situated stations, bringing him quickly to the hospital. The Metropolitan and Metropolitan District Railways have stations exactly opposite the Hospital.

The material wants of the students are not neglected. There is a Students' Club, where refreshments of all kinds can be had, and better rooms for its accommodation and convenience will be provided in the new buildings.

---

BROMPTON CONSUMPTION HOSPITAL.—The clinical practice of this Hospital, which has over 300 beds, is open to students of medicine and practitioners. Fee for three months, 3*l.* 3*s.*; six months, 5*l.* 5*s.*; perpetual, 10*l.* 10*s.* A course of clinical instruction in Auscultation will be given by the medical officers. Certificates of attendance on the medical practice of this Hospital are recognised by the University of London, the Apothecaries' Society, and by the Army, Navy, and Indian Boards.

## ST. MARY'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

THE first stone of this Hospital was laid in the year 1845, by the late Prince Consort, and the Institution was enlarged in 1865, when the Prince of Wales opened a new wing. Last year the Princess Louise conferred a similar distinction on a second wing, containing 70 additional beds, which was built through the liberality of the late Mr. J. F. Stanford, who left 25,000*l.* for structural improvements. The Hospital is managed by an open Board of Governors (President, Lord Carlingford), who meet every Friday at 4 p.m. It contains 270 beds, 130 of which are devoted to medical, and 140 to surgical cases. Two wards are appropriated to the diseases of children, and one to those of women; beds are also provided for ophthalmic, aural, and cutaneous cases. During the past year relief was afforded to 2,322 in-patients, and 25,000 out-patients and casualties. Among some of the teachers on the medical and surgical staff who have now passed away, may be mentioned Sir James Alderson, late President of the College of Physicians, Dr Francis Sibson, Dr. Tyler Smith, Mr. Coulson, Mr. Ure, Mr. Toynbee, Mr. Gascoyen, Dr. Murchison, Dr. A. B. Shepherd, and among those who have retired from active work in the Hospital and School—Messrs. Samuel and James Lane, Mr. White Cooper, Dr. Graily Hewitt, Dr. T. K. Chambers, Dr. Markham, Dr. Burdon Sanderson, Mr. Ernest Hart, Mr. Spencer Smith, Dr. Farquharson, M.P., Mr. St. George Mivart, and Dr. Handfield Jones.

The Hospital is situated in one of the most pleasant and open districts of London, and by its nearness to the Great Western Terminus, and to the Praed Street, Bishop's Road, and Edgware Road Stations of the Metropolitan Railway, students are enabled to live conveniently at short distances from it. A Students' Club has lately been founded; the club rooms are situated in the basement of the Mary Stanford Wing, and comprise a library, reading-room, and dining rooms. About one hundred students dine daily at a moderate cost. There is a College in connection with the Hospital for the residence of students under the superintendence of the Warden, Dr. Robert Maguire.

The Medical School has been constructed with careful attention to ventilation, and in the additions recently made to the school buildings, every sanitary requirement has been amply supplied. In 1883 the School was considerably enlarged, at a cost of 6,000*l.*, and many additions were made in the Physiological and Chemical Laboratories. The past and present students of the Hospital have subscribed largely towards a fund for thoroughly fitting up the physiological laboratories for the double purpose of advancing the interests of the School and of commemorating the services of three of their late teachers, Dr. Sibson, Mr. Lane, and Mr. Gascoyen. Since last year Dr. Waller has been elected to the Chair of Physiology, and Mr. E. Poulton, Tutor of Keble and Lecturer at Jesus College, Oxford, has been appointed Lecturer on Comparative Anatomy. Dr. Sidney Phillips and Dr. Robert Maguire, physicians to out-patients, are the latest additions to the staff. Three tutors have been appointed this year to assist in preparation for the Final Examinations. One in Medicine (Dr. Phillips), one in Surgery (Mr. Pye), and one in Obstetrics (Dr. Montagu Handfield Jones).

One open scholarship in natural science, of the value of 100*l.*, and four of the value of 50*l.*, tenable for one

year, will be competed for on Tuesday, September 22nd, 1885, and following days. Subjects:—Inorganic chemistry and experimental physics, with either botany and vegetable physiology or zoology. There will be a practical examination in addition to the paper in all the subjects. Candidates must not have completed a full year of study at a London Medical School. No candidate will be allowed to hold a scholarship or exhibition at another Medical School in London. The successful candidate in each case will be required to enter at the Hospital as a perpetual pupil immediately after the examination. In addition to the above, at the same examination, a scholarship of a hundred guineas is offered for competition to such students of Epsom College as are sons of medical men. Names of intending candidates should be forwarded on or before Saturday, September 19th, to the Dean. Also, in addition to the above, scholarships of 30*l.*, 25*l.*, and 20*l.*, are offered annually for first, second, and third years' students respectively.

Besides the clinical instruction and lectures given in the wards daily, distinct clinical lectures will be given on Fridays throughout the Academical year, at 3.30 p.m., in the Anatomical Theatre. All the Medical Appointments in the Hospital, including the five House Surgeoncies, are open to its pupils without further fee, an advantage of the highest importance to the student, and a valuable addition to the scholarships and prizes. Preference is given to the qualified perpetual pupils of the Hospital. *Post-mortem* examinations are made by Mr. Silcock, the Pathologist, at 2.30 p.m., as opportunities occur. About 300 inspections are made annually. Surgical operations are performed on Wednesdays, at 1.30 p.m. The Medical Society meets on alternate Wednesday evenings, during the winter session, at 8 p.m., for the exhibition of pathological specimens, the discussion of clinical cases, and the reading of papers on medical, surgical, and collateral subjects by the students. The museum is open to students; it contains about 3,000 specimens, illustrating healthy and morbid anatomy.

Special classes are held for the preliminary scientific and intermediate M.B. of the University of London, and for the F.R.C.S. examination.

## MIDDLESEX HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

ALTHOUGH unable to boast of great antiquity, the Middlesex Hospital has during the major part of the 140 years of its existence taken a prominent share in the work of medical education. During most of this time its sphere was confined to clinical instruction, and in the interval that elapsed between the foundation of University College and the building of University College Hospital, it was for this purpose resorted to by the students of the Medical Faculty of that College, amongst whose professors were some of the leading members of the Middlesex Hospital Staff. Then came the decision to found a medical school in direct connection with the hospital, which was carried into effect in 1835, so that the session now to be opened will be the fifty-first of the independent existence of this medical school. The buildings, erected in a corner of the hospital garden, originally comprised a laboratory and class room, library, lecture theatre, dissecting room and museum. The dissecting room was narrow and encircled the theatre, but more than 30 years elapsed before any material alterations were made. At length,

owing to the increasing number of students and the needs of education, these became imperative. New class rooms were added, the old theatre removed, and the present dissecting room constructed on its site, and a new spacious theatre was built. At the present time the accommodation is sufficient for its purpose; but there is every prospect of the buildings being further extended at no distant date.

Systematic lectures are delivered regularly throughout the winter and summer sessions, the longest courses being Chemistry and Anatomy, each four times a week, Physiology, Medicine and Surgery, each three times; the other winter courses include Practical Surgery, two and three times, Practical Medicine, thrice a week, and Practical Midwifery. In the summer session the lectures comprise Practical Chemistry, Botany, Practical Physiology and Histology, *Materia Medica*, Midwifery, Forensic Medicine and Pathological Anatomy, each three times a week; and shorter courses of Therapeutics, Comparative Anatomy, Psychological Medicine and Public Health. To meet the requirements of the Examining Board for England, arrangements have been made for instruction in Botany and *Materia Medica* during the winter as well as the summer session. Many of the hospital staff hold lectureships, but the subjects of Chemistry, Physiology, *Materia Medica* and Psychological Medicine, are taught by lecturers not upon the staff. It will be seen that the school is essentially a *medical* one; and that the fact is recognised that instruction in preliminary scientific subjects is not a duty that should be imposed on a medical school. Although this may prevent the enrolment of students intending to graduate at the University of London, unless they have previously passed the preliminary scientific examination, it is, in the present writer's opinion, a limitation founded on a right principle. The stress laid by the University on a preliminary scientific training implies that this should be full and thorough; and it is needless to multiply centres of scientific study, which require for their equipment not only a large amount of material, but a staff of specially trained teachers. The endeavour to teach science in every medical school tends to defeat the object of the University, and hampers the medical curriculum by encouraging the student, to his own detriment, to combine these two distinct phases of his career. In declining to institute special lectureships in Science, the Middlesex Hospital School declares that its primary object is the medical curriculum, and this it endeavours to make efficient and complete.

The opportunities for gaining practical knowledge in the various subjects have been considerably extended of late years. In addition to the anatomical demonstrations, and the practical classes in Physiology, Chemistry and Surgery, there have been instituted classes on Practical Medicine and Midwifery. In Morbid Anatomy, besides the daily work in the *post-mortem* room, the pathologist gives demonstrations every week, and the microscopical examination of diseased tissues has been included in the course of Pathological Anatomy. The continued advance in this direction is one of the most notable features of the present educational system, and one of which the value might be more fully recognised by examining boards. Mention should also be made of the fact that this school has for very many years recognised the importance of tutorial teaching; and although the duties of the tutor's office have been materially modified, in accordance with its special needs, it is still retained, and ably directed with much profit to the students. Respecting the museum, which is particularly rich in morbid specimens, and to which of late a series of dissected anatomical preparations has been added, it may be said that it is put to good service as a means of education. This valuable collection has hitherto lacked a

printed catalogue, but this want no longer exists, as the work, upon which much labour had been expended, was published last year.

But the work of the class room and laboratory is subsidiary to that of the hospital, and this school is fortunate in being attached to a hospital that possesses advantages, both natural and acquired, if we may so phrase it. Occupying a central position, it is a building without pretension, but remarkably free from the straggling irregularities that often disfigure such edifices, and bewilder the visitor. Nothing could well be devised on a more simple plan than this building, with its two wings and uppermost floor devoted to wards, and the central block to the rooms and offices of the resident staff; whilst annexed to the eastern wing are the special wards and out-patient department, now made continuous with the block devoted to the Nursing Home. The wards, which contain mostly from twelve to twenty beds, are thus assigned: six to medical cases, nine to surgical (exclusive of three special female cancer wards), and one to gynaecological cases; and besides these there are several small special wards. The hospital is always well supplied with patients. It cannot be said that there is not here ample scope and opportunity for clinical work; nor is there any lack of encouragement in its pursuit. The visits are made by each member of the staff three or more times a week; and in addition to this instruction, surgical and medical clinical lectures are delivered by each in turn throughout the session. The number of Dresserships and Clinical Clerkships is sufficient to enable every student to hold these necessary offices each for a period of six months; and there are (at present) twelve resident appointments open for competition annually.

During last year very extensive structural alterations were carried out in the out-patient department, from the acquisition of property at the south-eastern angle. The block of new buildings is also intended to increase the accommodation of the resident staff, to supply additional wards, and extend the Nursing Home. The new out-patient department and casualty rooms, and the special departments in connection with the hospital, have been thoroughly reorganised, and the facilities for instruction proportionately improved.

As to the various class-prizes and scholarships obtainable by students, reference must be made to the *prospectus*. It may merely be mentioned that here, as elsewhere, there are entrance scholarships, two in general subjects and one in science, open for competition at the end of September. An entrance scholarship has also been founded for competition at the opening of the summer session.

Nor would a sketch cursory as this is be complete that did not include mention of the Students' Medical Society, a society that has the distinction of being the oldest of its kind in London. The meetings are held once a fortnight during the winter session, and encouragement in the preparation of papers, exhibition of specimens, &c., is given by a system of prize-awards. The president is a member of the hospital or lecturing staff, but all the other officers are elected by the students from amongst themselves. The meetings are well attended, and have considerable educational value. Lastly, it may be added that the school adheres to the time-honoured custom of prefacing its winter session with an introductory lecture on the 1st of October, a ceremony which is followed in the evening by the less formal gathering of past and present students at dinner. The same social feeling amongst those who in past times have been connected with the school is promoted by the Middlesex Hospital Club, established many years ago, the members meeting annually at dinner in the spring.

## ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

ST. THOMAS'S HOSPITAL appears to have been first founded early in the 13th century, but to have remained little more than an infirmary until the year 1553, when it was endowed with lands as one of the Royal Hospitals by Edward VI., and placed under the Lord Mayor and commonalty of the city of London as perpetual Governors. The endowment was from time to time enlarged by bequests and donations, and in 1693 the fabric of the hospital, then situated in Southwark, was rebuilt. The building was considerably enlarged at different times, but the whole was at length sold, in 1862, to the Brighton Railway Company, and after a temporary sojourn in the Surrey Gardens, the well-known extensive buildings on the Albert Embankment were opened in 1871.

Apprentices appear to have been received at the hospital as early as 1561, but it was not till 1718 that the first lectures, those of William Cheselden, were given. In 1768 St. Thomas's Hospital was united with Guy's, so far as the attendance of students on the surgical practice of the two hospitals was concerned. About the same time the anatomical and surgical school, in connection with St. Thomas's Hospital, was founded, and was subsequently carried to the height of its reputation by the labours of the two Clines, Astley Cooper, and Joseph Henry Green. Meanwhile, the lectures on Medicine, Materia Medica, Midwifery, and Physiology were delivered at Guy's Hospital, and no physician of St. Thomas's was allowed to share in them. But in 1825 the "United Hospitals" were severed, and a complete school set up in both. The majority of the students clung to Guy's, and St. Thomas's school began to sink. The establishment of the Aldersgate Street private school, under Tyrrell and Lawrence, materially aided in this declension, as did also the secession of Dr. Elliotson to the newly-established University College, and the foundation of a fresh school at King's College, where for a time the surgical lectures were given by Mr. Joseph Henry Green, although a surgeon of St. Thomas's. Owing to the unprosperous state of affairs, in 1842 the Governors came forward to reorganise the school, and the aid of Mr. R. D. Grainger, whose popularity had been established in the Webb Street private school, was obtained. Mr. Green also rejoined the school; and Dr. Marshall Hall, Dr. Hodgkin, Dr. Martin Barry, Dr. Gregory, and Mr. Benjamin Travers contributed to its efficiency. This state of affairs continued until 1858, when the Governors gave back the management, and its attendant risks, into the hands of the lecturers. For some years it was maintained with difficulty, and at much self-sacrifice on the part of the staff, during what may be termed a transitional period, in the hope, now realised, of its once more developing into an institution worthy of its old traditional glories.

The present hospital contains in all 572 beds, and consists of six blocks appropriated to the reception of patients; with one for the administrative and other offices, and one for the Medical School. The ward blocks, though connected by corridors, stand apart, so as to afford free exposure in all directions. Generally, each ward affords accommodation for 28 beds, which are placed against the piers between the windows, so as to secure thorough ventilation. Of the whole accommodation of the hospital, about 180 beds are appropriated to ordinary medical cases, and 230 to ordinary surgical cases. There are also special wards for the reception of diseases peculiar to women; for diseases of the eye; for venereal affections; for children, and for infectious diseases. The out-patients' department is extensive and well arranged to meet the large de-

mands upon it of the poor and crowded districts in its vicinity, and every facility is afforded for the treatment of different forms of medical and surgical casualties and diseases. Clinical instruction is given to the students both in the wards and out-patient rooms in all branches of medicine and surgery, including the diseases of the eye, ear, skin, throat and teeth, and in vaccination. Clinical lectures are delivered weekly during the session. During the twelve months ending December 31st, 1884, the number of patients admitted into the hospital amounted to 4,593. In the same period, 20,429 out-patients have been treated, and in the maternity department 2,385 women have been attended at their own homes. Casualties to the number of 57,859 attendances were treated during the same period.

The school buildings stand at the southern extremity of the hospital, from which they are quite isolated. They contain ample accommodation for large classes of students. The museum is one of the most important in the metropolis. There is a large reading room and library for the use of the pupils. In addition to these are the various lecture rooms, the dissecting rooms, the laboratories for Practical Physiology and for Practical Chemistry, and the *post-mortem* rooms.

Two Scholarships in Natural Science, of the value of 100*l.* and 60*l.* respectively, are awarded annually, while over 300*l.* in scholarships and prizes, besides several medals, are yearly offered for competition to students who are undergoing their curriculum at the hospital.

Three House Physicians, two Resident and one Non-Resident, and an Assistant House Physician, two House Surgeons, an Assistant House Surgeon, and a Resident Accoucheur are selected every three months from gentlemen who have obtained their professional diplomas; they hold office for three or six months. One House Physician, the Assistant House Physician, and the Assistant House Surgeon, are non-resident, but the other Officers, together with the Dressers and Obstetric Clerks, are provided with rooms and commons during their period of attendance in the hospital, free of expense. An Ophthalmic Clinical Assistant is appointed for six months with a salary at the rate of 50*l.* per annum, with board but not residence; the appointment is renewable for a limited period. Clinical Assistants in the special departments for diseases of the skin, throat, and ear are appointed every three months. Clinical Clerks and Dressers to in-patients are selected to the number of at least 100 in each year. Two Hospital Registrars, at an annual salary of 100*l.* each, are appointed in each year, and there are several other appointments.

There are special classes for students preparing for the Preliminary Scientific and Intermediate M.B. Examinations of the London University.

## UNIVERSITY COLLEGE AND HOSPITAL.

(By a Professor of the Medical Faculty.)

THE Institution now known as "University College" was opened as the "University of London" in 1828 on the most unsectarian principles, with the object not only of affording a liberal education of a high class order, but also of conferring degrees. The Medical Faculty commenced work on October 1st, and is a month older than any of the other Faculties. Having thus a history of little more than half a century, this College has during that period exerted a remarkable influence upon the progress of education in this country, as well as upon many social and other questions of importance. Such an influence has been particularly evident in the improvement of medical education, to

which it has so largely contributed, as well as in the advantages which it has afforded for the acquisition of scientific knowledge and training. Before University College was founded, medical education in England was in a very low state; but the medical school set a pattern of teaching that raised this branch of education throughout the whole country, and it has continued ever since to occupy a leading position. In 1836 the name was changed to "University College," the power to confer degrees having been transferred to a separate merely examining institution, since known as the "University of London."

At first there was no hospital connected with the College, and arrangements were made with Middlesex Hospital for clinical study. The first portion of the present hospital was opened on November 1st, 1834, and it was subsequently enlarged, but it cannot be denied that until a comparatively recent period, the number of cases in the hospital was inadequate to supply the large number of students with sufficient practical work. Nevertheless, it must be noted that the cases were systematically used for clinical instruction, and also that the out-patient departments have always been thoroughly utilized for this purpose. At present the hospital contains 208 beds, which, with the out-patient practice, afford a large field for clinical instruction and study. All the important "special" branches connected with medicine or surgery are now recognised as separate departments, and are systematically taught by members of the staff. Although University Hospital is thus very thoroughly worked for clinical purposes, yet, not only for the sake of the students, but also taking into consideration the vast number of the artizan, labouring, and poorer classes for whom this hospital is most convenient, and its proximity to important thoroughfares, to numerous manufactories of various kinds, and to some of the most extensive and busy railway stations in London, it might be considerably enlarged with great advantage to all concerned. It may be mentioned that the hospital contains a very efficient system of baths, which are of great service in the treatment of patients, and which were established through the efforts of the late Dr. Tilbury Fox, for many years physician to the skin department. The new north wing of University College, opened on October 1st, 1880, affords most important facilities for the study of physiology, zoology and comparative anatomy, and chemistry, and the present arrangements for teaching these subjects are probably unsurpassed, even if equalled, elsewhere.

The history of the progress of University College is intimately associated with the names of the eminent men who laboured within its walls as professors, or who did no less service as members of the medical or surgical staff of the hospital. Many acted in both capacities. The Chair of Physiology has been successively occupied by Dr. Sharpey, Dr. Michael Foster, Dr. Burdon-Sanderson, and Professor Schäfer, its present holder. The Chair of Anatomy has been held by Dr. Jones Quain, Mr. Richard Quain and Mr. George Viner Ellis, and the department is now worked with great energy and efficiency, under the superintendence of Professor Thane and his staff of demonstrators. The Professorship of Medicine has been held in succession by Drs. Elliotson, C. J. B. Williams, Walshe, Sir W. Jenner, Russell Reynolds, and Sydney Ringer. Associated with the Chair of Surgery are the names of Mr. Moncrieff Arnott, Mr. Erichsen and Mr. Marshall, who has recently resigned, and been succeeded by Mr. Marcus Beck. Dr. Garrod followed Dr. Thomson as Professor of *Materia Medica*, and occupied the Chair for some years. His successors have been Drs. Sydney Ringer and Frederick Roberts. Associated with Pathological Anatomy are the names of Drs. Walshe, Sir W. Jenner, Wilson

Fox, and Charlton Bastian. A Professorship of Medical Jurisprudence and Toxicology was instituted in 1849, and was held until 1860 by Dr. Carpenter, followed by Drs. G. Harley, Maudsley, and Poore. The Chair of Ophthalmic Medicine and Surgery, established in 1852, was occupied by Mr. Wharton Jones until 1881, when Mr. John Tweedy was appointed. There is a lectureship in Dental Anatomy and Surgery, held for many by Mr. Ibbetson, who was succeeded by Mr. Hutchinson.

A branch of medical education which has of late years undergone special development at University College, is that of Hygiene and Public Health. Professor Corfield was appointed to the newly instituted Chair in 1869, and since that time the subject has progressively increased in interest and importance. The arrangements for imparting instruction in its various departments are now, through Professor Corfield's efforts, of the most complete character. Successful classes for the teaching of Operative Surgery and Practical Surgery have been in operation at University College for several years. At present Mr. Godlee is Teacher of Operative Surgery, the Practical Surgery being under the direction of Messrs. Berkeley Hill and Barker, with the assistance of Demonstrators.

The names of many who have stood out prominently as leaders of the profession have been associated with University College Hospital as members of its Staff, and some of the most eminent are still on its Consulting Staff, although not actively engaged in its work. The name of Liston cannot be passed over without reference, and the death of this great surgeon, in 1847, was a loss to the Hospital that was deeply felt. It may also be noted that several of the members of the staff have contributed to medical literature publications which have gained a firm standing in the profession, and are recognised as standard works.

In connection with University Hospital it is only right that special allusion should be made to clinical instruction, which has always been a prominent feature in this Hospital, and has been carried out systematically. It may truly be said that every member of the Staff takes an active interest in this work. Every physician and surgeon receives the title of "Clinical Professor," and there are special Holme Professors of Clinical Medicine and Clinical Surgery. The Professorship of Clinical Medicine has been held successively by Drs. Walshe, Parkes, Jenner, Russell Reynolds, and Wilson Fox; that of Clinical Surgery by Messrs. Liston, R. Quain, Erichsen, and Christopher Heath. Several years ago classes were commenced for the more elementary instruction in Clinical Medicine and Surgery, and these have now become so developed and systematised that a most complete practical training may be obtained by any student who chooses to avail himself of the privileges which are within his reach. Those who conduct these classes are called "Assistant Professors," or "Assistant Teachers," and they work along with and under the superintendence of the Holme Professors, Clinical Medicine being taught by Drs. Gowers and Barlow, and Clinical Surgery by Messrs. Barker and Godlee.

Owing to the constitution of University College the students attending the medical faculty, as in the other faculties, have come from various parts of the world, and have belonged to different races and creeds. Some of its most distinguished students have hailed from distant colonies, and from India. Their number has varied considerably at different times, and in this respect the College has experienced some checks in its progress. In the first session the number was 165, a remarkable number to start with, but it rapidly rose until in the session 1838-39 it amounted to 494, the highest which has ever been reached. With occasional rises there

was on the whole a gradual decrease until the years 1865 and 1866, when the numbers fell to 161 and 163 respectively. After this there was a rapid growth of the medical school in point of numbers, and this has been maintained until the present time, University College in this respect holding its position as one of the leading schools of medicine. Moreover, a large number besides, who are not strictly medical students, attend the scientific classes, in order to prepare for the Science Examinations of the London University.

Although not in any way officially connected, there has always been some sort of traditional association between University College and the London University. A large proportion of students enter with the view of preparing for the degrees granted by this University. Of those who take these degrees, a considerable number come from University College; the names of its students are usually conspicuous in the Honours lists, and they have also taken a large number of the exhibitions, scholarships, and medals granted in different subjects. Of late years students preparing for medical degrees at the older Universities—Oxford and Cambridge—seem to have recognised the educational advantages to be obtained at University College and Hospital, and are entering for part of their curriculum in increasing numbers. Many students from this college have taken high positions in the public services. It may also be noted that it has trained numerous eminent men who now hold prominent positions on the Staffs of other medical schools and hospitals, both in London and in the provinces.

University College offers to its students considerable advantages in the way of scholarships and prizes. These amount to about 630*l.* annually, exclusive of twelve gold medals and thirty silver medals awarded in the different classes. The appointments at the Hospital are also free, and are awarded according to merit, there being competitive examinations for the higher resident posts, which are usually keenly contested.

A most successful Students' Medical Society has flourished at University College for a great many years, and it has done very good work. There is also a well-established Christian Association. Of late years more attention than formerly has been paid to physical exercise, and now athletics, cricket, boating, football, &c., have their several clubs. There is at present a disposition to promote the development of the social element among the students at University College, and to increase their *esprit de corps*, which has not always been what it ought to be. A general "University College Society" has been recently established for this purpose, which promises to be of much service. A most successful dinner of past and present students was held last October, Sir William Jenner occupying the Chair. The dinner next October is to be presided over by Mr. John Marshall, and a large gathering is anticipated.

## WESTMINSTER HOSPITAL AND MEDICAL SCHOOL.

(By a Member of the Staff.)

WESTMINSTER HOSPITAL owes its origin to a meeting which was held at St. Dunstan's Coffee House on the 14th of January, 1715, nearly 171 years ago, and was first established in a small house in Birdcage Walk, under the name of the "Publick Infirmery for the Sick and Needy." At this time the only hospitals which existed for the medical and surgical relief of the sick poor were St. Bartholomew's and St. Thomas's, both having been established and carried on by the

religious houses of their respective neighbourhoods, and created royal hospitals soon after the suppression of the monasteries in 1537. Westminster is remarkable as being the first hospital in London which trusted for its support to the voluntary contributions of the public. Guy's Hospital, founded by the munificence of one individual, was not established until a few years later.

After four years' work, as an institution for the administration of medical relief, the hospital was opened for the reception of in-patients, with 30 beds, and with an entrance from Petty France. So rapidly did its usefulness develop, that in 1724, having been in existence little more than nine years, it opened its wards in Chapel Street, with 60 beds. At this time Cheselden, the teacher of John Hunter, was appointed its lithotomist, a post which he held for fifteen years. His portrait hangs in the Board-room of the hospital. A few years later the celebrated and courtly Mead, Queen Anne's Physician, whose monument is in Westminster Abbey, was consulting physician to the hospital. In 1733, the removal of the hospital to a larger building again became necessary, and a warm discussion arose among the governors as to the comparative eligibility of a house in James Street, and of Lanesborough House at Hyde Park Corner. The majority considered the latter site too far from the poor of Westminster, and determined to purchase the building in James Street, which was opened early in 1734. The minority, with a portion of the medical staff, were dissatisfied with this decision, and determined to purchase the lease of Lanesborough House, which in their opinion "on account of the strength of the building and the airiness of the situation was much more convenient to answer the ends of charity." This was the origin of St. George's Hospital.

In James Street, the Westminster Hospital did its work for nearly 101 years; but the building having become dilapidated and the accommodation insufficient, the requisite money was collected, and a very eligible site was obtained in the Broad Sanctuary, under the very shadow of the grand old Abbey. The new building was well and solidly constructed upon a block of concrete, and was remarkable for its thoroughly efficient drainage and ventilation. The removal of the patients from the old hospital to the new was effected on November 14th, 1834, under the superintendence of Dr. Basham and Mr. Henry Hancock, the resident medical officers. Westminster had for some years enjoyed a great reputation for its clinical teaching, and at this time its surgeons were Mr. Lynn, Sir Anthony Carlisle, Mr. Anthony White, and Mr. Guthrie, successively Presidents and all members of the Court of Examiners of the College of Surgeons; and its Physicians Sir G. L. Tuthill, Dr. Bright, and Dr. Hamilton Roe.

The removal of the hospital to a new building stimulated a portion of the staff to establish a medical school in the same year, but it was not until 1849 that this school became intimately connected with the hospital. Its buildings were then constructed on a site leased for a period of 40 years from the Commissioners of Her Majesty's Woods and Forests. It unfortunately happened that after only three years' occupation, twelve months' notice was given to terminate the lease, the ground being required for the Stationery Office. In the following year, therefore, the school buildings were transferred to the ground at the rear of the hospital. They have been added to from time to time by the erection of light and commodious laboratories, &c., but at the end of 30 years the requirements of the school had outgrown the space at its disposal. A larger site was obtained next to the Westminster Town Hall, five minutes' walk from the hospital, and upon it, school buildings

affording the most complete accommodation have been erected from the plans of Mr. Salter.

The new school, which is completed and will be opened on October 1st with an introductory lecture by the senior surgeon of the hospital, Mr. Cowell, contains three lecture theatres, a large and well-lighted museum, the large theatre and museum occupying two floors in height; a large dissecting-room, 35 feet by 22 feet, on a level with the gallery of the museum, with an asphalt floor, and walls lined with white tiles; large histology, physiology, and chemistry laboratories; a fine council-room, available for examinations; a dean's room, a class room, a curator's room, a large library, and last, but not least, a set of rooms for a Students' Club. The accommodation is most complete, and every part of the building is thoroughly light and well arranged, with ample accommodation for 150 students. The school will be open to inspection after the introductory lecture.

To return to the hospital. About seven years ago a sum of nearly 18,000*l.* was expended in repairing and improving the building. Sanitary science was, in 1834, little understood, but in forty years a great advance has been made in this respect, and changes of an expensive kind became urgently necessary if the hospital was to offer to its patients and to its students the full benefit of the new knowledge. Towers were built to provide sculleries and water closets outside the wards with cross ventilation, separate cisterns, &c. Bath rooms and lavatories were built. The floors of the wards were relaid and covered with oak parquetry and polished. Chloroform and consultation rooms were added to the operation theatre. The greater part of the hospital was raised another story, affording dormitories for the nurses in front, day wards for the convalescent patients at the ends of the building, and separate wards at the back quite outside the hospital, but approached by a covered way, to which infectious cases can at once be removed from the wards. Healthy and airy as the hospital was before these alterations were made, the condition and appearance of the wards are now much improved, and in the surgical wards, the improved sanitary arrangements and the polished floors together have reduced the cases of erysipelas by more than one half.

Westminster Hospital, with its 200 beds and extensive out-patient department, affords in a complete form all the material that is required for a practical medical education. Its size is a very convenient one, and it combines the advantages of a general and a special hospital, as it has separate departments for all the specialties which may be legitimately so considered, or which require special instruction. These departments are devoted to *obstetric, dental, ophthalmic,<sup>1</sup> aural, orthopædic, skin, and throat* diseases, in all of which it is important that the student should have opportunities of study.

The medical school is proportioned to the size of the hospital, so as to maintain all the advantages of a small school, and especially that personal supervision and guidance which every student requires, but which is very difficult, if not impossible, in a large school, and at the same time to secure for every student in rotation clerkships and dresserships both to out and in-patients. In the more strictly school subjects also it is hardly necessary to point out the great advantage of personal supervision, aided as it is at Westminster by regular tutorial instruction, and by taking great pains with the students individually in all manipulative work. The removal of the Medical School permits of the re-arrangement of the out-patient rooms, on the ground

hitherto occupied by the school buildings, and the result cannot fail to be of great advantage to patients, students, and staff. The return of Westminster men who have passed their examinations, and taken degrees at the Universities, the prize list, and the importance of the appointments that have been gained, all show a high average of success, and it may not be out of place to mention that the first places and some of the prizes at the examinations for the Indian and Army Medical Services have been taken by Westminster men for several years in succession.

## PROVINCIAL SCHOOLS OF MEDICINE.

### UNIVERSITY OF OXFORD MEDICAL SCHOOL.

(By Two of the Science Teachers.)

THERE is not a complete Medical School at Oxford, but there are excellent arrangements for the study of the so-called Preliminary Sciences—Biology, Chemistry, Botany, and Mechanical Philosophy, and for Human Anatomy and Physiology, the former under a special Reader and the latter under Professor Sanderson, F.R.S., the Waynflete Professor of Physiology. Many of the Colleges (Balliol, Merton, Exeter, New College, Magdalen, Christ Church, Trinity, St. John's, and Keble) encourage the study of Natural Science, under the guidance of special tutors; by a few it is admitted as one of the subjects for matriculation. Scholarships to the annual value of 80*l.* for from four to five years, and Exhibitions of less annual value are given every year by some, from time to time by other, Colleges. Balliol, Magdalen, and Christ Church have private laboratories. At the University Museum the teaching in the laboratories, under the direction of the Science Professors, is most complete. In the Radcliffe Library there is accessible to students a place of unrivalled facilities for the consultation of current and periodical literature, Continental and English, in Mathematics, Science, and Medicine. Regular courses of lectures are given by the professors and tutors, of which a list is issued terminally by the Board of Faculty of Natural Science. In February there is competed for annually, by those who have obtained a First Class in any School or a Scholarship, or Prize, open to general competition in the University, one Radcliffe Travelling Fellowship. It is tenable for three years, and is of the annual value of 200*l.* The examination is partly Scientific, partly Medical. The holder must travel abroad, and take the degree of B.M., Oxon.

The *Radcliffe Infirmary* contains 138 beds, and the annual average of in-patients for the last ten years has been 1,265; of out-patients and casualties, 4,686. Surgical accidents and urgent cases are admitted without "turns." There is a special block for children. The members of the staff (three Medical and three Surgical) take pupils for six months' attendance at six guineas, for twelve at ten guineas, and perpetual at fifteen guineas. Advanced students are allowed to act as Clinical Clerks and Surgical Dressers. Practical Pharmacy is taught in the Dispensary. One Medical and one Surgical member of the staff are Clinical Litchfield Lecturers. Attendance at the lectures, given twice a week in Term, and under the authority of the Board of Faculty of Natural Science, is free to members of the University, but does not confer the right of attendance on the general Hospital Practice. Dissection is carried on at the University Museum, under the direction of the newly appointed Reader in

<sup>1</sup> Westminster students have also the advantage of being allowed to attend the practice of the Royal Westminster Ophthalmic Hospital.

Human Anatomy, Dr. A. Thomson, who will deliver regular courses of lectures in Term time, and students will in future be certificated for the Examination in Anatomy of the Examining Board in England.

### UNIVERSITY OF CAMBRIDGE MEDICAL SCHOOL.

(By a Member of the Staff.)

THE course of medical study in the University, and the requirements necessary for the Degree in Medicine, have now been arranged in a manner highly advantageous to students entering the profession. Of the increasing popularity of the Cambridge Medical School and the many advantages offered to medical students no stronger testimony can be adduced than that of the yearly list of entries at the different colleges of those intending to pursue medical studies. A glance at the number of entries this year shows that Cambridge is now one of the largest medical schools in England. The arrangements are such that the student can go through the whole course at a very moderate expenditure of time and money. He must enter at one of the colleges, or as a non-collegiate student and keep terms for three years. He can live quite as cheaply as in London, the expenses of residence, lectures, &c., at a college being not necessarily more than 150*l.* per annum, or as a non-collegiate about 100*l.* At most of the colleges scholarships are open for competition in science as well as classics and mathematics. As regards the length of time necessary, it is required of a candidate for the Degree of Bachelor of Medicine that he shall have completed five years of medical study, except he have obtained Honours in any tripos, in which case four years shall be deemed sufficient. It is advisable to take a Degree in Arts, and of great advantage to the student to do this through the Natural Sciences Tripos, as he is enabled to devote his work and energies to the same subjects that will be required of him in the several examinations for the Degree of Medicine, while at the same time he is laying a good foundation of scientific knowledge which will be of the greatest value to him in professional life. The shorter term of four years' necessary study is of no material advantage, as it would be unadvisable to attempt to conclude the whole course in so limited a time.

A brief summary of the course of study recommended is as follows:—A student will do well to enter early, at the age of 16 or 17, prepared to pass his "previous" examination and additional subjects at the beginning of the October term, if he have not already obtained exemption through the "Local Examinations" in the "Oxford and Cambridge School Board Examinations." It is important to do this, as he can then register as a student of Medicine, and at once join the Natural Science and Medical Classes at the commencement of the several courses in the October term. The subjects of the first M.B., namely, Chemistry, Physics, and Elementary Biology, will first occupy his attention, in all of which he will be examined for the first part of the Natural Sciences Tripos. The first M.B. may be passed at the end of his first year, or the following December, and he can then devote himself to the subjects in which he selects to be examined for the Natural Sciences Tripos. In the first part of this examination the student can present himself at the end of his second year. In preparing for the second part he will save time if he selects Human Anatomy and Physiology as two of the subjects in which he desires to be examined, as these are also included in the second M.B. He may enter

for the second part of the Natural Sciences Tripos in his ninth term, after which he may take his B.A. degree. During the following long vacation and October term he can continue dissection, preparing to pass the second M.B. in December. A certificate of attendance at a recognised hospital for six months is required of students, previously to entering for the second M.B. This can be obtained at Addenbrooke's Hospital, where regular instruction is given in term time and during the long vacation. Students who pass the second M.B. in December, may with advantage remain on until the end of the following long vacation, studying at the hospital, learning the elements of surgery and medicine and bandaging, and attending the courses of lectures required of them before the final M.B. They are then ready to enter at some London Hospital at the commencement of the October Session, having already acquired some knowledge of the more important details of practice. All the lectures for which certificates of attendance are required before the several examinations may be attended at the University.

The study of Natural Science is carried on at the Museum, where lectures are given on Chemistry, Physiology, Anatomy, and other subjects, and practical instruction is carried on at the numerous laboratories in Biology, Physiology, &c., and dissection at the Anatomical School. Classes are also held in Histology and Pathological Anatomy. At Addenbrooke's Hospital, instruction is given in the practice of Medicine and Surgery, and bandaging. The Museum contains a good series of Pathological preparations.

### UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

(By a Member of the Staff.)

THE University of Durham College of Medicine at Newcastle-upon-Tyne has, during the last few years, attracted to itself a very largely increased number of students. The advantages it offers are numerous, and appear to be every year more highly appreciated. Perhaps its greatest attraction, as compared with other Schools of Medicine, is the fact that only one of the four years of medical study need be spent at Newcastle, while the other three may be passed either at the same place or at one or more of the recognised Schools. The required year's attendance may be taken at any time before the candidate presents himself for the final examination for the M.B. Degree. This regulation has attracted many who were already qualified for practice. For "full" students there are many valuable prizes. Four scholarships of 100*l.* each have been presented by the University of Durham, and are awarded, one every year, to the student who passes the best examination in arts at the time of entry or during his first year. Five other valuable scholarships are given for proficiency in various branches of medical study, and silver medals and certificates are awarded in each class. There are eight useful student appointments at the College, and 27 at the Infirmary. At the latter institution the practice is very large and of varied interest, the patients (about 25,000 annually) being drawn from the whole of Tyneside and the densely populated districts in the neighbourhood. Every opportunity is given to students at the College for learning their work. In the chemical laboratories a separate bench is provided for each student, and the department is under the charge of Professor Bedson, D.Sc., Lond. The anatomy is taught as much as possible by individual instruction, under the able personal guidance of Dr. Mears, who until recently

occupied the position of Medical Tutor. There are special departments for practical instruction in pathology, dermatology, ophthalmology, gynæcology, diseases of the throat and ear, and minor surgery, and in operations on the dead body. It is expected that very shortly the College will be moved to more commodious and convenient quarters, and it is hoped that a residential hall may also be provided for the better accommodation of students.

### THE BIRMINGHAM SCHOOL OF MEDICINE.

(By a Member of the Staff.)

By the association of Queen's and Mason's Science Colleges for purposes of medical education, and by the amalgamation of the General and Queen's Hospitals for purposes of clinical instruction, students of the Birmingham Medical School are enabled to avail themselves of the whole teaching resources, and nearly the whole hospital practice, of the town. The advantages thus offered to the young man about to commence the study of medicine, compare most favourably with those of any other centre of medical education. Students may qualify themselves for admission to the examinations of any licence-granting body, except those of such Universities as require attendance on their own lectures. All the examinations of the University of London may be passed from here. Students can also make two *anni medici* out of the four required for degrees by the University of Edinburgh. Neither College provides accommodation for residence, but lists are kept of gentlemen prepared to receive medical students. Queen's College—the parent institution—is a well arranged building, situated in the centre of the town, close to the various hospitals and railway stations. Here are taught from the usual professorial chairs all the subjects included in the medical curriculum, except Physiology, Chemistry, and Botany; these courses are given at Mason's College. There are complete and well appointed museums of Anatomy, Pathology and Materia Medica, specially arranged for purposes of instruction, also a well stocked library and reading-room for the use of students. The dissecting rooms are extensive, commodious, well warmed and ventilated, and they have been recently remodelled and enlarged. They are under the immediate superintendence of the Professor of Anatomy, who devotes his whole time to Anatomical teaching within the College. The supply of bodies for dissection is always plentiful. Mason's Science College undertakes the teaching of Physiology, Chemistry and Botany to medical students of the town. Its special professors, its rich museums, and its magnificently appointed modern laboratories, offer advantages to the students of medicine which are equalled at few medical schools in the kingdom. Special classes are held for the matriculation and preliminary scientific examinations of London University.

The practices of the General and Queen's Hospitals are amalgamated for purposes of clinical instruction, under the direction of the Birmingham Clinical Board, a body elected from the honorary staffs. The hospitals have a total of 400 beds, and 5,500 in-patients and 70,000 out-patients are treated annually. Clinical practice and lectures commence at 9.30 a.m. daily throughout the session, the operating days being Tuesday, Wednesday, and Saturday. Attendance upon two-thirds of clinical lectures is insisted upon. There are special Ophthalmic, Obstetric, Gynæcological and Dental departments, each under the care of a specialist. Practical instruction is given in the use of the micro-

scope, laryngoscope, ophthalmoscope, surgical appliances, &c. Practical Pharmacy is taught in the dispensaries of the Hospitals. There is a special Dental department in the College, associated with the Birmingham Dental Hospital and the Clinical Board. By this arrangement students may qualify for the Dental diploma of any of the examining bodies. The Midland metropolis is particularly well off in the matter of special hospitals. There are in the town the Children's (72 beds), Eye (70 beds), Women's (30 beds), Ear and Throat, Orthopædic and Spinal; Small-pox and Fever, Skin and Lock, and Homœopathic Hospitals; the honorary officers of any of which are willing at all times to show their practice to senior students of the School.

Besides the ordinary class prizes—medals and certificates—the following are open for competition to students of Queen's College:—One or more annual Queen's Scholarships, value 30 guineas, given to first year's students on entrance; one or more Sydenham Scholarships, value 30 guineas, tenable for three years by the orphan sons of medical men; two Ingleby Scholarships, value about 10*l.*, for proficiency in Obstetric Medicine and Surgery, and Diseases of Women and Children; Sands Cox Prize, value 20*l.*, for proficiency at the end of curriculum in Medicine, Surgery, and Midwifery. The Clinical Board also offer prizes of five guineas each in Medicine and Surgery for Senior students; prizes of three guineas each in Medicine and Surgery for junior students; and a prize of four guineas in Midwifery. They also fill up, after competition, the following resident appointments twice annually, viz., medical and surgical assistants and two surgical dressers at the General; obstetric house surgeon and surgical dressers at the Queen's Hospital.

### THE BRISTOL MEDICAL SCHOOL.

(By a Member of the Staff.)

THE Medical School was founded in 1828, but long before that time lectures on Chemistry and Medicine were given, and regular courses of lectures on Anatomy by two of the surgeons to the Infirmary. A dissecting room was soon opened, under the direction of Dr. Riley, in Lower College Green, and another at the rear of 25, King Street, the then residence of H. Clark. Those were times when difficulties were experienced by everyone who wished to pursue medical and surgical studies, as obstacles were thrown in the way of the most necessary branch of training—namely, dissection. Much interest was taken in the lectures given by Dr. Riley, and so greatly did they become appreciated and their value recognised, that he and Hy. Clark were induced to prepare and issue a prospectus of a Medical School, to be opened at premises in Old Park. During the first twenty years of its existence no support or encouragement was accorded the School by the public or the profession; but gradually the claims of the School came to be recognised, and for many years now it has been in a prosperous condition, especially since its affiliation with the University College. Of the pupils who have passed through the School, many have attained high distinction. With its fame the number of its pupils has grown, and with the extension of researches in Medicine and Surgery more perfect appliances for teaching have been secured. The work of the School is carried on partly in University College and partly in adjoining buildings. As soon as funds permit, a new wing will be added to the College, especially designed for the work of the Medical School, and furnished with all modern appliances for teaching.

There is a Medical Tutor who devotes the whole of his time to the students, teaching them individually and in classes, as well as Demonstrators in Anatomy and Physiology. The teaching of Anatomy and Physiology, and the training of each student individually, are special features at Bristol, and the School justly prides itself upon having earned a very high place amongst London and Provincial Medical Schools by its work in these respects. Indeed, it is a tradition in this school, that its function is to lay a firm groundwork of thorough practical knowledge in all the departments it undertakes to teach.

Students at the School pursue their practical studies in Medicine and Surgery at the Royal Infirmary or at the General Hospital, in connection with which Institutions are valuable scholarships and prizes. The Medical School, together with the Infirmary and Hospital, provide for every detail of the professional curriculum required by the University of London, and students can complete at these Institutions the entire course of study required for the diplomas of the Royal College of Physicians of London, the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The Scholarships and Prizes connected with the Infirmary are:—Two Entrance Scholarships of 35 and 10 guineas, awarded in October, after examination in subjects of general education; Suple's Medical Prize, consisting of a gold medal, value five guineas, and about seven guineas in money; Suple's Surgical Prize, similar in character; Clarke's Prize, consisting of the interest of 500*l.*, given to the most successful student on the completion of his third year study; Tibbits' Memorial Prize, being the interest of 315*l.*, awarded the student who shows the greatest proficiency in practical surgery; Crosby Leonard's Prize, being the interest of 300*l.*, a surgical prize; three Pathological Prizes, value three guineas each. The Scholarships and Prizes connected with the Hospital are:—The Martyn Memorial Entrance Scholarship, value 20*l.*, awarded to the most successful candidate in the competitive examination in subjects of general education; Clarke Scholarship, a surgical prize of 15*l.*; Sanders' Scholarship, being the interest of 500*l.*, offered for proficiency in Medicine, Surgery, and Diseases of Women; Lady Haberfield Prize, the interest of 1,000*l.*, also awarded for proficiency in Medicine, Surgery, and Diseases of Women. All the Scholarships and Prizes at both Institutions are given annually. The Medical School has a governing body of fifteen members, five of whom are elected by the Council of University College, one member by the Committee of the Infirmary, one by the Committee of the Hospital, three members by the Staff of the Infirmary, three by the Staff of the Hospital, and two by the Faculty of the Medical School. Prospectuses and detailed information may be obtained, as to the Medical School from Dr. Markham Skerritt, Dean of the School, University College, Tyndall's Park, Bristol; as to the Infirmary, from Dr. Spencer, Dean of the Faculty, Royal Infirmary, Bristol; as to the Hospital, from Dr. Markham Skerritt, Dean of the Faculty, General Hospital, Bristol.

#### UNIVERSITY COLLEGE, LIVERPOOL.

(By a Member of the Staff.)

In the old days, when almost every medical man had one or two pupils, it was no uncommon thing in the larger provincial towns for a few of the leading practitioners to collect these young gentlemen and give them short courses of lectures, preparatory to the time

when they should proceed to "walk the hospitals" in London or Edinburgh. Even dissecting was carried on in a furtive and incomplete way. In 1834, just over half a century ago, a few of these private lecturers in Liverpool agreed to combine their efforts, and thus was founded the Liverpool Medical School. For eleven years its work was carried on in rooms belonging to one of the larger public institutions of the town; but in 1845 the Trustees of the Royal Infirmary erected a building upon the Infirmary grounds, and the school thenceforth became the "Royal Infirmary School of Medicine." Its progress for a long time was very slow, and once, indeed, the attendance was so small that the lecturers entertained serious thoughts of entirely abandoning the enterprise. By degrees, however, it drew slowly ahead, and about fifteen years ago participated in that sort of general revival which visited nearly all the provincial schools. Doubtless this was greatly due to the change which has come over the style of medical practice in the great northern towns, the increasing size and wealth of which has enabled them to support men working at specialties. Pure physicians and surgeons, oculists, aurists, gynaecologists, and dermatologists can now make good livings, and give time for teaching also, where formerly there were none but general practitioners, so immersed in practice that teaching, as we now understand it, was an impossibility with them.

In 1871 the lecturers of the school felt the necessity of improving the building in which they laboured, and by a vigorous appeal to the public succeeded in raising a sum of between five and six thousand pounds, which was expended upon additional class-rooms and upon a museum and physiological laboratory. Within the last few years the generosity of the Liverpool public founded the University College, and the medical school became allied to it as its medical faculty. Its Council wisely determined that the first thing to do was to get a staff of able teachers, who should have an assured income, in addition to their fees, so as to be placed in a position of security. Eleven chairs have therefore been endowed each with the interest of 10,000*l.* The funds immediately in hand having been thus employed, it has been found necessary to accommodate the science and arts professors (except chemistry) in a temporary building which has been altered and arranged so as fairly to meet present wants. But there is not the least doubt that before many years have passed one which shall be worthy of the College and of the city will be erected. Even now there is rapidly approaching completion a portion of a new chemical department, which when finished in its entirety will probably cost about 15,000*l.* The present chemical rooms will then be added to the physiological department. In the subjects of physics, zoology and chemistry the students of the medical faculty have the best possible opportunities of study provided in the college for which the names of Professors Oliver Lodge, Herdman and Campbell Brown are a fair guarantee.

To University College, and notably to its medical faculty, the past year has been one of the greatest interest, inasmuch as it has marked the affiliation of the College to the Victoria University, as the second of the various colleges of which that body is to be the head. Ere long it is hoped that the Yorkshire College at Leeds will make a third, and in due time probably others will come in also, thus completing the great scheme of popular university education for the north of England. The students of the Liverpool School, therefore, take rank now as university students. Touching the medical degree of the Victoria University, its general principles were laid down by a Board of Studies after much deliberation, in which

they were aided by the counsels and suggestions of such men as Lister, Gairdner, Lauder Brunton and sundry other teachers of repute, who constituted the first body of external examiners. In general outline the plan of the degree follows that of the London University as regards the number of its examinations, and the subjects thereof, but in some points the example of the University of Edinburgh has been imitated. Thus for the degree of M.B. there are an Entrance Examination in Arts, a Preliminary Examination in Science, an Intermediate in Anatomy, Physiology and Materia Medica, and a Final in the practical departments of professional study. When the Bachelor of Medicine wishes to proceed to the doctorate he is not worried with further examinations, provided he produces a thesis (after the fashion of the Edinburgh School) which shall be satisfactory to the University. So far, the examiners have shown a strong tendency to set sound practical questions, which every student ought to know, and to demand good answers to them. The examinations are conducted by the University professors, each aided in his own department by an external examiner, who is a teacher of acknowledged repute in some other school of medicine. Seeing that the Victoria University is a teaching university and not a mere examining board, it can hardly be considered unfair that it demands from its graduates two years of study out of their whole curriculum at one of its colleges. All the rest of the time may be spent at any recognised medical school.

The Liverpool Royal Infirmary, founded in 1749, has through its Committee extended a warm support to the school which so long took its name from it. Constructed at a period when sanitary knowledge, and indeed architecture in general was at its lowest ebb, the present building has been felt to be quite behind the times, and the public have recently subscribed 100,000*l.* to build a new one, which, it is hoped, will be soon commenced. The present building contains 300 beds, with 40 special beds for the treatment of the diseases of women. Among the list of those who have acted as surgeons to the institution appears the distinguished name of Park, who, next after the Moreaus, introduced the excision of joints. His celebrated case of the sailor, whose elbow-joint he excised, and who was afterwards able to follow his occupation and even to go aloft, was long quoted in surgical text-books. Alanson also was one of its surgeons, who was probably the first to practise amputation by flaps, in contra-distinction to the old circular method. Among its physicians was Currie, the friend of Roscoe, and the author of an admirable "Life of Burns," and other literary productions. In the beginning of this century he advocated the use of cold affusion in fever, and drew attention to the clinical value of thermometry. Fifty years after his death his suggestions began to be put in practice.

While it is admitted that a small school possesses certain disadvantages in its inability to afford systematic training in special subjects, it has, on the other hand, certain advantages. It may be claimed for Liverpool that it affords great opportunities in the abundant material for Practical Anatomy at the school, and in the extensive surgical work done in the wards of the Royal Infirmary. Abundance of dissection and an unlimited field for dressing, counterbalance the loss of much special work, which the student gains at the great crowded schools, at the expense of having to wait weeks for a part (even then sharing it with another man), and of having often to act as dresser to a very few patients only. Moreover, the College and the Infirmary being in the same grounds, the student does his arts' work and pursues his scientific, his strictly medical and his practical courses almost under the same roof.

## THE OWENS COLLEGE (VICTORIA UNIVERSITY) MEDICAL DEPARTMENT.

(By a Professor of the Medical Faculty.)

IN the year 1872, the Manchester School of Medicine, which had then existed for upwards of 50 years as the largest provincial school, was incorporated into the Owens College, and since then has formed the Medical Department of the College. New school-buildings were then erected, new professorships founded and endowed, and the medical school began to flourish to such an extent, that a further extension was necessary, and additional accommodation was provided ten years ago, chiefly in the form of laboratories and workrooms which are now in full working order. The permission to give medical degrees having been granted to the Victoria University four years ago, and the Owens College being then the only incorporated College of the Victoria University, a further development, especially in the clinical teaching, which is carried on in the Manchester Royal Infirmary and the special hospitals, was found requisite to meet the requirements of the University, and a number of clinical lectureships were established. The department of biology has also been considerably extended, and a special building containing the museum of Zoology, Botany, Geology, and Palæontology, with the necessary laboratories and lecture rooms, is being erected at a cost of 80,000*l.*, and will be finished in the course of the next six months. During the last session, the college had to deplore some very severe losses, which will be felt for some time. Death has unfortunately removed two of the ablest professors of the Medical Department, Professors M. Watson and J. Thorburn; Mr. A. H. Young has been appointed Professor of Anatomy, and Dr. J. C. Cullingworth replaces the late Professor Thorburn. The appointments thus made have caused further vacancies, namely, the lectureships in surgical pathology and medical jurisprudence, which have not yet been filled up. The College has also to deplore the loss of the great services of Professor A. Gamgee, who has resigned the Professorship in Physiology, which he had held since 1872 with such singular success and benefit to the College. Professor Gamgee's successor will be appointed next October. Amongst the recent additions to the Medical Department must also be mentioned the establishment of a complete Dental Department, with lectureships in Dental Pathology, Mechanical Dentistry, Dental Metallurgy, and Dental Anatomy, the clinical teaching in Dentistry being conducted in the newly established Victoria Dental Hospital. To assist the lecturers and to give students assistance in their work in the medical school two tutorships have been recently founded. Dr. A. Wilkinson has been appointed medical, and Dr. J. Thorburn, son of the late Professor Thorburn, has been appointed surgical tutor. Similar teachers in the form of registrars have been appointed in the Manchester Infirmary to supervise the clinical work of the students and to provide additional teaching power. Dr. J. Bury takes charge of the Medical Registrarship; a Surgical Registrar will be appointed next October.

The arrangements for systematic teaching in all branches of medicine and the collateral sciences are very complete. The laboratory arrangements for the teaching of chemistry are as good as any in the kingdom, and a new laboratory for qualitative analysis is about to be erected. In the anatomical department, the dissecting room has been enlarged, with additional rooms containing dissections, and always accessible to the students. The physiological laboratory consists of a large lecture room, private laboratories, laboratory for practical phy-

siology, rooms for observations on physiological optics, photographic room, and laboratories for physiological chemistry and histology. The pathological laboratories, under Professor Dreschfeld, consist of a private laboratory, a laboratory fitted up with all the necessary apparatus for bacteriological research, a large laboratory for practical pathology and morbid histology, and a room containing a teaching set of morbid specimens from the museum. The pathological museum is being re-arranged and extended, and for this purpose an additional curator has been appointed. The work done in this department consists of a complete course of lectures on pathology, extending over the session, a practical class on morbid histology, and a systematic course on bacteriology. The materia medica department possesses a very extensive museum, a laboratory for pharmacological research, and a laboratory for pharmacy. Facilities for original work in pharmacology are given. A course of demonstrations on mental diseases is held in the Cheadle Asylum during the summer session. The clinical teaching in connection with the school has been much extended, and for this purpose the large material in the different special hospitals is drawn upon, and members of the staff from these hospitals have been placed upon the teaching staff of the College, to ensure systematic teaching. The clinical teaching in medicine and surgery is done by the staff of the Royal Infirmary. Systematic courses are given on auscultation and percussion and on bandaging and minor surgery. In addition to the clinical lectures, there are also held ward classes for elementary, and special classes for advanced clinical teaching. Clinical classes in gynaecology are held in the Infirmary and St. Mary's Hospital. Clinical classes in Ophthalmology are held in the Infirmary and Royal Eye Hospital. A new and very large eye hospital with accommodation for 100 beds has just been erected in the neighbourhood of the College. Clinical instruction in the diseases of children is given in the Dispensary and Hospital for Children at Pendelbury. A maternity department exists in connection with St. Mary's Hospital, and is accessible to students. The College offers some valuable scholarships to students. The Berkeley fellowships (value 100*l.* per annum) given for original research, which have hitherto been confined to the Arts and Science department of the College, will in future also be open to the Medical Department, and an important impetus to original research in medicine is thus given.

#### SHEFFIELD SCHOOL OF MEDICINE.

(By a Member of the Staff.)

For more than half a century a good school for the teaching of practical medicine and surgery has existed in Sheffield. The large population of the town and district, consisting as it does mainly of a working class ready to avail itself of public charity, and engaged in pursuits provocative of disease, coupled with the unavoidable accidents necessarily arising in connection with the large ironworks, collieries, and factories, render the material for the study of medicine and surgery exceptionally large and varied. In the town there are the following medical charities, viz. :—The General Infirmary (200 beds), the Public Hospital and Dispensary (101 beds); and at these institutions the clinical teaching is mainly carried on, the practice of both being open to all the students of the School, and clinical instruction by the physicians and surgeons given daily. In addition to the above-named there are :—The Jessop Hospital for Women (with 45 beds and a Midwifery Department), the Fever Hospital, and the Hospital for Sick

Children. At the Infirmary there is a large ophthalmic department, and special facilities are afforded for studying this branch of practice. In connection with the Medical Charities there are five house surgeoncies (salaries varying from 130*l.* to 50*l.* a year), and one clinical assistantship. Five of these posts are held by former pupils of the School. The incorporation of the Medical School with the Firth College, which has recently taken place, will without doubt mark a new era in the medical education of Sheffield, for the students here are now offered not only the best opportunities for the practical study of the profession, but also the greatest facilities for obtaining a thorough scientific training. The teaching now is so arranged as to include not only all the subjects required by the Royal College of Physicians and Surgeons, but also those of the University of London and other Examining Boards.

#### YORKSHIRE COLLEGE MEDICAL DEPARTMENT.

(By a Member of the Staff.)

THROUGH the amalgamation which took place a year ago, the Leeds School of Medicine has become the Medical Department of the Yorkshire College. The buildings specially appropriated to the purposes of the Medical Department occupy a central position in the town, close to the General Infirmary, and a few minutes' walk from the new buildings of the Science and Art Departments situated in College Road, which were formally opened in July last by His Royal Highness the Prince of Wales. The present premises were built specially for the purposes of a Medical School, and the teaching in purely medical subjects is there given. The teaching in Chemistry and Physics, Practical Chemistry, Practical Toxicology, Biology and Botany is given in the College Road Buildings, the lecture-rooms and laboratories of which are amongst the most commodious in the kingdom. It is expected that the Yorkshire College will almost immediately be affiliated to the Victoria University, when the Leeds' students will be able to obtain a degree at the end of their ordinary curriculum. The subject of Physiology is taught by a professor, who devotes the whole of his time to the work of his chair. In the Anatomy course there are—a professor, a paid demonstrator, whose whole time is given up to the students, and four honorary demonstrators. In addition to the ordinary courses, lectures on Ophthalmic Surgery and Hygiene, and a practical course of Operative Surgery are given. The accommodation for teaching comprises all the conveniences necessary for the various branches of study. The Anatomical and Pathological Museum contains carefully prepared Anatomical Sections and other specimens of Human Anatomy, and a large number of Pathological preparations, some of them very rare and valuable. Specimens illustrative of the Pathology of the Eye, and of Dental Anatomy and Pathology are also being added. The valuable collection of Comparative Anatomy specimens, when studied along with the Zoological specimens in the Museum of the Philosophical Society, also open to students, gives every opportunity for the study of this branch of biology. The Dissecting Rooms and Physiological Laboratories include every convenience for the practical study of Anatomy and Physiology. They consist of a large Dissecting-room for the general work of students, Private Dissecting and Injecting-rooms, a spacious Students' Laboratory for Practical Physiology, and a Private Laboratory. The teaching is conducted with the aid of the most recent physiological instru-

ments and appliances, of which there is an important collection. The Materia Medica Museum contains a complete and valuable series of the official and chief non-official drugs. The Library, which contains about 10,000 volumes, is well supplied with standard works on medicine and surgery and allied subjects, and with the leading medical periodicals; it is open to all students of the school, who have the advantage also of using the books belonging to the Leeds and West-Riding Medico-Chirurgical Society. Special attention is given to the preparation of students for the higher examinations, the professors of physiology, biology and chemistry holding classes appropriate to that end. Several valuable prizes are given annually.

The Institutions to which the students of the College have access, for purposes of Hospital and Clinical Instruction, comprise the Leeds General Infirmary, the Leeds Public Dispensary, the Hospital for Women and Children, the Leeds Fever Hospital, and the West-Riding Lunatic Asylum, at Wakefield. The General Infirmary, which is close to the school, and in its teaching intimately associated with it, has accommodation for 330 beds, which are allotted as follows:— Medical cases, 71; Surgical cases, 217; Ophthalmic cases, 30; Gynæcological cases, 12. During 1884, 4,040 in-patients and 23,806 out-patients were treated. Clinical teaching is given daily by the Honorary Physicians and Surgeons, who also regularly deliver Clinical Lectures. Major operations are performed every Thursday, minor operations being done daily after the ward visits of the surgeons. Every Wednesday morning consultations are held in the operating theatre on interesting and important surgical cases, students being permitted to attend. Teaching is conducted in the Out-patient Department by the Honorary Assistant Physicians and Surgeons. Due facilities are given for the study of Diseases of the Eye and Ear, and special departments are about to be formed for Diseases of the Skin and Throat. Gynæcological and Extern Obstetric Departments have just been added, supplying a want which has long been felt. Resident Medical, Surgical and Obstetric Officers are appointed from time to time, and annually two House Physicians and four House Surgeons are elected, the appointments being open to the Leeds students. There are also three Resident Medical Officers appointed from time to time at the Public Dispensary, a stipend with residence being given; for these appointments Leeds students are frequently chosen.

## MEDICAL EDUCATION IN SCOTLAND.

### INTRODUCTORY ARTICLE.

(By our Edinburgh Correspondent.)

No one can deny that in proportion to its population Scotland is abundantly supplied with medical *examining bodies*; for while England only possesses one to about every three million of its inhabitants, the Scottish bodies are in the proportion of one to about every half million. It must, however, in justice be added that the three Scottish Licensing Corporations have recently admitted the disadvantages of their co-existence by rolling themselves into one, so far as the function of giving an ordinary diploma is concerned; while of the four Universities, one is employed very largely, and the other three to a considerable extent, in examining and giving degrees to students from other countries, especially England. The same is also true of the Scottish Corporations, the diplomas of which have been held in great favour by a certain class of English medical students. The regulations and requirements of both the

Scottish Universities and Corporations will be found concisely given in our synoptical tables (pp. 375, 376). It will be seen that the course of education required, the examinations imposed, and the fees for graduation are almost identical in the case of all the Universities, having been framed in conformity with an Ordinance of the Universities (Scotland) Commissioners, dated March 16th, 1861. By all the student is required to spend two years at a recognised University, and the Universities which have a school attached to them, require the student to reside one of these years at that school. The Licensing Corporations now only give their individual licences to candidates who have already a degree or qualification; unqualified students must take the conjoint licence. Each of the bodies, however, retains full liberty with regard to the conferment of its higher diplomas. It will be noted that the requirements of these bodies for their licence are considerably inferior to those of the Universities, and their curriculum is arranged with a view to the convenience of the many poor Scottish students, who continue their studies only in the winter, and employ themselves otherwise during the summer months. All the Scottish Corporations require the student to pass a Preliminary Arts Examination, and hitherto they have conducted one themselves; but henceforth the Arts Examination of the Edinburgh Colleges will be conducted by the Educational Institute of Scotland. The Glasgow Faculty will still hold preliminary examinations in general education, the dates of which during the next twelvemonth are fixed for October 8, 1885, and April 1 and July 1, 1886; fee 10s.

The centres of *medical education* in Scotland are the Universities of Edinburgh, Glasgow and Aberdeen. Each of these institutions possesses a complete Medical Faculty, attendance on the classes of which, besides qualifying for their respective degrees, qualifies for the examining boards in any of the kingdoms. Each city, moreover, possesses a hospital or hospitals where the necessary clinical and practical instruction can be obtained. Besides these University Schools, there exist, moreover, in Edinburgh and Glasgow what are known as Extra-mural or Extra-academical Schools of Medicine. In Edinburgh, this school comprises a body of over forty lecturers, whose courses qualify for the examining boards and to a certain extent are recognised by the University as qualifying for their degrees. In Glasgow, the Extra-academical School embraces the Medical Faculty of Anderson's College, and the more recently formed School of Medicine attached to the Royal Infirmary. In Aberdeen no such school exists, all the medical teaching being done under the auspices of the University.

The existence side by side with the University Faculty of an Extra-academical School of Medicine is a matter of the highest importance in relation to the general question of medical education in Scotland. It does not admit of doubt that this co-existence accounts in great measure for the attraction which Edinburgh, during recent years, has offered to students from all parts of the world. Here, the Extra-mural School has been in a state of high efficiency for many years, and a form of rivalry has existed between it and the University which has been fraught with the greatest benefit to the teaching of Medicine. The possible extent and effect of this competition will be seen when it is stated that a student, besides obtaining at the Extra-mural School all the classes necessary for the Boards of Edinburgh, London and Dublin, may also take out a maximum of four classes, attendance on which will count in the same way as the corresponding classes in the University would do for the University degree. How this tells on efficiency can be readily understood. It is within the nature of things that the occupant of a university chair should now and then prove either unable or unwilling to fulfil its duties in a satisfactory manner. Without the assistance of the Extra-mural School, the teaching of the subject represented by the chair would suffer seriously. No sooner, however, does such a contingency arise, than the student turns to the lecturers outside the academic walls, and among them he never fails to find one at least able and willing to supply all reasonable demands. And not only does the healthy competition of this school provide efficient substitutes for inefficient university professors, and so

maintain the standard of medical education, but the mere fact that the number of his students depends in some degree, at any rate, on his efficiency, serves as a healthy stimulus to the lagging professor, too intent on his *otium cum dignitate*. At no period has the Edinburgh Extra-mural School been in a more healthy and vigorous state than it is at present. On each of the chief branches of medical study there are several lecturers, so that there is abundance of opportunity for selection, while all the special departments, such as the eye, ear, skin, &c., are more or less fully represented. No one can doubt that the high standard of efficiency which the Edinburgh School as a whole has attained, has proved the main attraction to students during the past decade.

In Glasgow, the competitive influence of the extra-mural system is of more recent origin than in Edinburgh. It is beginning to have its effect, and its development ought to obtain every encouragement from the University. No policy could be more short-sighted and suicidal than any endeavour on the part of the University authorities to curb the growth of its less favoured rival. In addition to the healthy stimulus which such legitimate competition brings to bear on the holders of chairs, it cannot fail to develop a many-sidedness in the teaching of Medicine which is apt to be missed under the narrower auspices of a University acting alone. In such a city as Glasgow, with its wealth of material in its hospital and dispensary practice, the rapid development of its medical school is a matter of certainty provided its growth is not stunted by narrowness and jealousy.

In Aberdeen, the absence of the competitive influence is not as yet seriously felt. This is due to the fact that its numbers are comparatively small, and the field for extra-mural teaching is limited. Moreover, provided as the Medical Faculty is with a body of professors, whose efficiency and energy as teachers and workers will challenge comparison with any school in the United Kingdom, this University is producing work of the highest order. That this is due in great measure to the fact that the limited number of students permits an amount of individual teaching which is impossible elsewhere is undoubtedly true, and this consideration should not fail to point a moral.

A movement has been recently set on foot to found a medical school at Dundee in connection with the oldest of the Scottish Universities, that of St. Andrews. It has received the warm support of Professor Gairdner, of Glasgow, in an address published a few weeks ago in these columns, and we hope that another year may see the new school successfully launched.

## UNIVERSITY OF EDINBURGH—FACULTY OF MEDICINE.

Session 1885-6.

### LECTURES AND CLASSES.

- \**Practice of Physic*—Professor G. Stewart.
- \**Chemistry: Practical Chemistry: †Organic Chemistry (advanced)*—Professor Crum Brown.
- \**Surgery: †Operative Surgery, &c.*—Professor Chiene.
- \**Institutes of Medicine: Practical Physiology*—Professor Rutherford.
- \**Midwifery and Diseases of Women and Children: †Obstetrical and Gynecological Operations*—Professor Simpson.
- \**Anatomy: Practical Anatomy: Demonstrations*—Professor Turner.
- \**Materia Medica: Practical Materia Medica*—Professor Fraser.
- \**General Pathology: Practical Pathology: †Practical Morbid Anatomy*—Professor Greenfield.
- Natural History: Practical Natural History*—Professor Ewart.
- \**Medical Jurisprudence*—Professor MacLagan.
- \**Botany: Vegetable Histology*—Professor Dickson.
- Clinical Medicine*—Professors G. Stewart, T. R. Fraser, Greenfield.
- "    "    (Diseases of Women)—Professor Simpson.
- "    "    (Diseases of Children)—Dr. Andrews and Dr. Carmichael.
- Clinical Surgery*—Professor Annandale.
- \**Diseases of the Eye*—Dr. Argyll Robertson.
- \**Mental Diseases with Clinical Instruction*—Dr. Clouston.

\* Winter Session only.

† Summer Session only.

The subjects to which no reference is attached, are taken in both Sessions.

THE following means are afforded for Practical Instruction:—

The *Royal Infirmary* is open at noon daily—Perpetual ticket in one payment, 12*l.*; Annual ticket, 6*l.* 6*s.*; Six months, 4*l.* 4*s.*; Three months, 2*l.* 2*s.* *Dissecting Rooms* open daily under the superintendence of Professor Turner, assisted by David Hepburn, M.B., C.M., J. S. McLaren, M.B., C.M., and other assistants. *Anatomical Museum* under the superintendence of Professor Turner. *Chemical Laboratories* open daily, under the superintendence of the Professor, assisted by Drs. Gibson and Waddell. *Physiological Laboratories* open daily, under the superintendence of Professor Rutherford, assisted by G. F. Alexander, M.B., C.M., and H. H. Ashdown, M.B., C.M. *Tutorial Class of Clinical Medicine*, in the wards of the Royal Infirmary, by J. Murdoch Brown, M.B., C.M., under the superintendence of the Clinical Professors. *Tutorial Class of Clinical Surgery*, in the Infirmary, by James Bennet, M.B., C.M., under the superintendence of the Clinical Professor. *Materia Medica Museum and Laboratory*, open daily, under the superintendence of Professor Thomas R. Fraser, assisted by George Armstrong Atkinson, M.B., C.M., and Ralph Stockman, M.B., C.M. *Practical Pathology and Morbid Anatomy*, under the superintendence of Professor Greenfield, assisted by G. S. Woodhead, M.D., C.M., and W. H. Barrett, M.B., C.M. *Physical Laboratory*, open daily from 10 to 3, under the superintendence of Professor Tait. *Medical Jurisprudence Laboratory*, open daily from 10 to 3, under the superintendence of Professor MacLagan, assisted by Charles Hunter Stewart, M.B., C.M., B.Sc. *Natural History Laboratory*, open daily, under the superintendence of Professor Ewart, assisted by J. Ducean Matthews and E. E. Prince. *Practical Surgery*, under the superintendence of Professor Chiene, assisted by A. W. Hare, M.B., C.M. *Obstetric Operations*, under the superintendence of Professor Simpson, assisted by Alex. H. Barbour, M.A., M.D. *Royal Botanic Garden, Herbarium, and Museum*, open daily during summer, under the superintendence of Professor Dickson, assisted by Patrick Geddes and J. M. Macfarlane, D.Sc. *Practical Botany and Vegetable Histology*, by Professor Dickson, assisted by Mr. Patrick Geddes. *Natural History Museum*, in the Museum of Science and Art, Chambers Street, open to the Students attending the Natural History Class.

There are numerous fellowships, scholarships, bursaries and prizes open to graduates and undergraduates of the University, and others, particulars of which will be found in the University Calendar.

*Minimum Cost of attending the Medical Classes, with the Order of Study.*—Whilst there is no authorised order of study, the usual course is given below:—Preliminary Examination in Arts to be taken in the month of March or October, before entering medical classes. By order of the General Medical Council, all medical students require to be registered as such within fifteen days after the commencement of the session. Students are recommended to commence their studies in the summer session. *First Summer Session.*—Preliminary examination, fee, 10*s.*; matriculation fee, 10*s.*; Botany (garden fee, 5*s.*), 4*l.* 4*l.*; Natural History, 4*l.* 4*s.*; total, 9*l.* 8*s.* *First Winter Session.*—Matriculation (for whole year), 1*l.*; Anatomy, 4*l.* 4*s.*; Practical Anatomy, 3*l.* 3*s.*; Chemistry, 4*l.* 4*s.*; hospital perpetual ticket, 12*l.*; total, 24*l.* 11*s.* *Second Summer Session.*—Botany or Natural History, if not attended previously; Practical Chemistry, 3*l.* 3*s.*; examination in Botany, Natural History, and Chemistry, in October following, 5*l.* 5*s.*; total 8*l.* 8*s.* *Second Winter Session.*—Matriculation 1*l.*; Institutes of Medicine, 4*l.* 4*s.*; Surgery, 4*l.* 4*s.*; hospital examination in Botany, Natural History, and Chemistry, in April, if not previously passed; total, 9*l.* 8*s.* *Third Summer Session.*—Practical Pharmacy, 3*l.* 3*s.*; hospital; total, 3*l.* 3*s.* *Third Winter Session.*—Matriculation, 1*l.*; Materia Medica, 4*l.* 4*s.*; Pathology, 4*l.* 4*s.*; Clinical Surgery, 4*l.* 4*s.*; hospital; examination in Anatomy, Physiology, Materia Medica, Pathology, in April or July, 5*l.* 5*s.*; total 18*l.* 17*s.* *Fourth Summer Session.*—Medical Jurisprudence, 4*l.* 4*s.*; outdoor dispensary, 2*l.* 2*s.*; hospital and clinical lectures; total, 6*l.* 6*s.* *Fourth Winter Session.*—Matriculation 1*l.*; Practice of Medicine, 4*l.* 4*s.*; Midwifery, 4*l.* 4*s.*; Practical Midwifery,

1l. 1s.; Clinical Medicine, 4l. 4s.; Vaccination, 1l. 1s.; outdoor dispensary, 1l. 1s.; hospital; total, 16l. 15s. *Fifth Summer Session*.—Hospital; final examination for M.B. and C.M., 10l. 10s.; total minimum expenses for M.B. and C.M., 107l. 6s. (This total is irrespective of any additional classes which may voluntarily be attended.) Only one course of instruction on each subject is here stated, that being the minimum.

Further information as to the classes, courses of lectures, &c., may be obtained on application to Thomas R. Fraser, M.D., Dean of the Faculty of Medicine; or from the University Calendar, published by James Thin, Edinburgh.

### SCHOOL OF MEDICINE, EDINBURGH.

THE Practise Anatomy Rooms and Chemical Laboratories will be opened on October 1st. The courses of lectures will be commenced—Winter Session, October 27th; Summer Session, May 3rd.

#### WINTER SESSION.

*Anatomy: Practical Anatomy and Demonstrations*—Mr. J. Symington and Mr. Macdonald Brown.  
*Chemistry: Practical and Analytical Chemistry*—Dr. Stevenson Macadam, Mr. J. Falconer King, Mr. Ivison Macadam, and Dr. Drinkwater.  
*Practice of Physic*—Dr. John Wyllie, Dr. J. O. Affleck, and Dr. Byrom Bramwell.  
*Surgery*—Mr. Duncan, Mr. A. G. Miller, Dr. C. W. MacGillivray, and Mr. C. W. Cathcart.  
*Midwifery and Diseases of Women and Children*—Dr. Charles Bell and Dr. Peter Young.  
*Institutes of Medicine and Practical Physiology*—Dr. James and Mr. James Hunter.  
*General Pathology*—Dr. Alexander Bruce.  
*Clinical Medicine (Royal Infirmary)*—Drs. Claud Muirhead, Brakenridge, and Wyllie, Dr. Angus Macdonald (*Diseases of Women*).  
*Clinical Surgery (Royal Infirmary)*—Mr. Joseph Bell.  
*Medical Jurisprudence and Public Health*—Dr. Littlejohn.  
*Materia Medica and Therapeutics, and Practical Materia Medica, (including Practical Pharmacy)*—Dr. William Craig, and Dr. G. A. Gibson.  
*Diseases of the Ear*—Dr. Kirk Duncanson.  
*Diseases of the Eye*—Dr. John Robertson.  
*Diseases of the Skin*—Dr. Allan Jamieson.  
*Vaccination (Royal Dispensary)*—Dr. Husband.  
*Practical Midwifery*—Dr. Angus Macdonald.  
*Practical Gynaecology*—Dr. Halliday Croom, and Dr. David Berry Hart.  
*Practical Midwifery and Clinical Gynaecology*—Dr. Charles Bell and Dr. Peter Young.

#### SUMMER SESSION.

*Practical Anatomy and Demonstrations*—Mr. J. Symington and Mr. Macdonald Brown.  
*Practical and Analytical Chemistry*—Dr. Stevenson Macadam, Mr. J. Falconer King, Mr. Ivison Macadam, and Dr. Drinkwater.  
*Materia Medica and Therapeutics (Practical Materia Medica, including Practical Pharmacy)*—Dr. William Craig, and Dr. G. A. Gibson.  
*Midwifery and Diseases of Women and Children*—Dr. Angus Macdonald, Dr. Halliday Croom, Dr. Charles Bell, and Dr. David Berry Hart.  
*Medical Jurisprudence and Public Health*—Dr. Littlejohn.  
*Clinical Medicine (Royal Infirmary)*—Drs. Claud Muirhead, Brakenridge, and Wyllie, Dr. Angus Macdonald (*Diseases of Women*).  
*Clinical Surgery (Royal Infirmary)*—Mr. Joseph Bell.  
*Practical Physiology*—Dr. James and Mr. James Hunter.  
*Practical Pathology*—Dr. Alex. Bruce.  
*Pathology and Morbid Anatomy*—Dr. William Russell.  
*Laryngology and Medical Ophthalmology*—Dr. John Wyllie.  
*Botany and Practical Botany*—Mr. A. N. McAlpine.  
*Natural History, Zoology, and Comparative Anatomy*—Dr. Andrew Wilson.  
*Diseases of the Eye*—Dr. J. Robertson and Mr. George Berry.  
*Diseases of the Ear*—Dr. Kirk Duncanson.  
*Practical Medicine and Diagnosis*—Dr. Byrom Bramwell.  
*Diseases of the Ear and Throat*—Dr. P. McBride.  
*Diseases of the Skin*—Dr. Allan Jamieson.  
*Vaccination*—Dr. Husband.  
*Insanity*—Dr. J. Batty Tuke.  
*Practical Surgery*—Mr. Duncan.  
*Operative Surgery and Surgical Anatomy*—Mr. A. G. Miller, Dr. C. W. MacGillivray, and Mr. C. W. Cathcart.  
*Clinical Midwifery*—Dr. Halliday Croom.  
*Practical Midwifery and Clinical Gynaecology*—Dr. Charles Bell and Dr. Peter Young.

The lectures qualify for the University of Edinburgh and the other Universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin; and the other medical and public Boards.

*Fees*.—For a first course of lectures, 3l. 5s.; for a second, 2l. 5s.; perpetual 5l. 5s. To those who have already

attended a first course in Edinburgh the perpetual fee is 2l. 4s. *Practical Anatomy* (six months' course), 3l. 3s.; course of demonstrations, 2l. 2s.; perpetual, 4l. 4s. *Practical Anatomy, with course of demonstrations*, 4l. 4s. *Practical Chemistry*, 3l. 3s.; *Analytical Chemistry*, 2l. a month, 5l. for three months, or 10l. for six months. *Practical Materia Medica* (including *Practical Pharmacy*), *Diseases of the Ear and Diseases of the Skin*, each, 2l. 2s. *Vaccination*, 1l. 1s. For summer courses of *Clinical Surgery and Clinical Medicine*, each, 2l. 4s.; *Practical Anatomy* (including anatomical demonstrations), *Operative Surgery*, and *Practical Medicine and Medical Diagnosis*, each 2l. 2s.; *Insanity*, 1l. 1s.

The minimum cost of the education in this School of Medicine for the triple qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations is 100l., which is payable by yearly instalments during the period of study.

### UNIVERSITY OF GLASGOW—FACULTY OF MEDICINE.

#### LECTURES AND CLASSES.—WINTER SESSION.

*Anatomy, Junior; Anatomy, Senior; Practical Anatomy*—Professor Cleland and Demonstrators.  
*Chemistry, Chemical Laboratory*—Professor Ferguson.  
*Clinical Medicine*—Professor McCall Anderson, and Professor Gairdner.  
*Clinical Surgery*—Professor George Buchanan, and Professor Macleod.  
*Materia Medica*—Professor Charteris.  
*Midwifery*—Professor Leishman.  
*Pathology*—The Pathologists of the Infirmary.  
*Physiology*—Physiological Laboratory: Professor McKendrick.  
*Practice of Physic*—Professor Gairdner.  
*Surgery*—Professor Macleod.  
*Zoology*—Professor Young.

#### SUMMER SESSION.

*Botany, Botanical Demonstrations*—Professor Bayley Balfour.  
*Clinical Medicine*—Professor McCall Anderson, and Professor Gairdner.  
*Clinical Surgery*—Professor Buchanan, and Professor Macleod.  
*Embryology, and Demonstrations on Anatomy, Elementary Anatomy, Practical Anatomy*—Professor Cleland and Demonstrators.  
*Forensic Medicine*—Professor Simpson.  
*Lectures on the Eye*—Dr. T. Reid.  
*Operative Surgery*—Professor Macleod.  
*Practice of Medicine*—Professor Gairdner.  
*Practical Chemistry, Organic Chemistry, Chemical Laboratory*—Professor Ferguson.  
*Practical Materia Medica*—Professor Charteris.  
*Practical Physiology*—Professor McKendrick.  
*Zoology and Zoological Laboratory*—Professor Young.  
*Diseases of Women*—Professor Leishman.  
*Insanity*—Dr. Yellowlees.

*Class Fees*.—Fee for each course, 3l. 3s., except lectures on the Eye, 1l. 1s.; lectures on Insanity, 2l. 2s.

In addition to the University courses, the Hospitals and Dispensaries afford ample means for practical instruction in the various departments of Medicine and Surgery.

*Glasgow Western Infirmary*.—This Hospital contains 400 beds for medical and surgical patients, with wards for skin diseases and for diseases of women. The fees for admission to the practice of the Infirmary are:—First year, 10l. 10s.; second year, 10l. 10s.; afterwards free. The fees for clinical lectures are included in the foregoing.

### GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.

Lectures are delivered on the subjects necessary for qualifying, and extra courses are given on practical and special subjects now required by examining boards. During the summer, lectures on Insanity will be given by Dr. A. Robertson, Physician-Superintendent of the City Parochial Asylum.

#### LECTURES.

*Anatomy*—Mr. H. F. Clark and Dr. Macintyre, Demonstrator.  
*Chemistry*—Mr. James M. Milne, Ph.D.  
*Clinical Medicine and Clinical Surgery*—The Physicians and Surgeons of the Hospital.  
*Dental Surgery*—Dr. J. C. Woodburn.  
*Diseases of the Ear*—Dr. Macfie.

*Diseases of the Eye*—Mr. H. E. Clark.  
*Diseases of the Skin*—Dr. Provan.  
*Diseases of the Throat*—Dr. Newman.  
*Forensic Medicine*—Dr. Glaister.  
*Materia Medica*—Dr. John Dougall.  
*Medicine*—Dr. J. W. Anderson.  
*Mental Diseases*—Dr. A. Robertson.  
*Midwifery*—Dr. J. Stirton.  
*Pathology*—Dr. D. Newman.  
*Physiology*—Dr. Barlow.  
*Practical Physiology and Op. Surgery*—Dr. Barlow and Dr. Macewen.  
*Surgery*—Dr. W. Macewen.

**Class Fees.**—For each course of lectures, first session, 2*l.* 2*s.*; second ditto, and perpetual, 1*l.* 1*s.* The Anatomy Class fees are—first session, 4*l.* 4*s.*; second ditto, 4*l.* 4*s.*; afterwards 1*l.* 11*s.* 6*d.* per annum for Practical Anatomy; Practical and Systematic Pathology, 3*l.* 3*s.*

The *Royal Infirmary* contains 532 beds. Of these 214 are for medical, and 318 for surgical cases, with special wards for the treatment of venereal disease in males and diseases of women. Diseases of the ear, throat and skin are specially treated at the out-door department. The fee for perpetual attendance on the practice of the Infirmary and on the courses of clinical instruction and lectures is 21*l.*; six months, 6*l.* 6*s.*; three months, 4*l.* 4*s.* Prospectus can be obtained from Dr. Thomas, the Superintendent of the Hospital.

**Appointments.**—There are four physicians' and six surgeons' assistants, who are boarded and lodged in the Hospital free of charge, and who perform all the duties of house-physicians and house-surgeons. These appointments are held for twelve months—six in the medical, and six in the surgical wards—and are open to those students of the Infirmary who have completed their curriculum and passed all their examinations except the last, or who have a qualification in Medicine or Surgery, the latter being preferred. Clinical clerks, dressers, and dispensary clerks are selected from the students without any additional fee; and from the large number of accident cases, and cases of acute disease received into the wards, these appointments are numerous and invaluable to the student.

#### ANDERSON'S COLLEGE, GLASGOW.— FACULTY OF MEDICINE.

The Winter Session begins on Tuesday, October 27th, 1885, and closes on Friday, 2nd April, 1886, and the Summer Session begins on the first Tuesday of May, and closes about the middle of July.

##### WINTER SESSION.

*Chemistry*—Professor Dittmar.  
*Surgery*—Professor Dunlop.  
*Junior Anatomy, Senior Anatomy, Practical Anatomy*—Professor A. M. Buchanan and Demonstrator.  
*Institutes of Medicine (Physiology) and Practical Physiology*—Professor Christie.  
*Materia Medica*—Professor Morton.  
*Practice of Medicine*—Professor Gemmell.  
*Ophthalmic Medicine and Surgery and Clinical Instruction at Ophthalmic Institution*—Dr. J. R. Wolfe.

##### SUMMER SESSION.

*Operative Surgery*—Professor Dunlop.  
*Surgical Anatomy, Dissection, Osteology*—Professor A. M. Buchanan and Demonstrator.  
*Midwifery*—Professor A. Wallace.  
*Ophthalmic Medicine and Surgery and Clinical Instruction at Ophthalmic Institution*—Dr. J. R. Wolfe.  
*Aural Surgery*—Dr. Thomas Barr.  
*Medical Jurisprudence*—Professor Alex. Lindsay.  
*Public Health*—Dr. James Christie.  
*Practical Medical Chemistry*—Professor Dittmar.  
*Botany*—Professor Wilson.

**Class Fees.**—For each of the above courses of lectures (Anatomy excepted), first session, 2*l.* 2*s.*; second session, 1*l.* 1*s.*; afterwards free. **Anatomy Class Fees.**—First session (including Practical Anatomy), 4*l.* 4*s.*; second session (including Practical Anatomy), 4*l.* 4*s.*; third session, and perpetual, 1*l.* 1*s.*; summer fee (including Practical Anatomy), 1*l.* 11*s.* 6*d.*; Practical Anatomy only, 1*l.* 1*s.*; Osteology, 1*l.* 1*s.* Students who have attended classes at other schools, but who desire to pursue their studies at Anderson's College, will be admitted to such classes as they may have attended elsewhere at the reduced fees.

Vaccination fee, 1*l.* 1*s.* *Clinical Instruction* may be obtained at the Royal Infirmary (v. above); also at the Ophthalmic Institution, students of Anderson's College being admitted to the practice of this Institution on paying a matriculation fee of 5*s.*

The fees for all the lectures and hospital practice required of candidates for the Diplomas of Physician and Surgeon amount to 48*l.* This is not payable in one sum, but students simply pay the fees for their classes as they take them out.

#### UNIVERSITY OF ST. ANDREWS.

There is no proper Faculty of Medicine in this University, but it is possible for the student to make an *annus medicus* by attendance on certain of the courses—as *Natural History*, Professor McIntosh, M.D.; *Chemistry*, Professor Heddle, M.D.; and *Anatomy and Medicine*, Professor Pettigrew, M.D.

#### UNIVERSITY OF ABERDEEN.—FACULTY OF MEDICINE.

##### LECTURES.—WINTER SESSION.

The Winter Session commences on Wednesday, October 21st, and the Summer Session on Monday, April 26th.

*Anatomy*—Professor Struthers.  
*Practical Anatomy and Demonstrations*—Professor Struthers and Assistant.  
*Chemistry*—Professor Brazier.  
*Institutes of Medicine*—Professor Stirling.  
*Surgery*—Professor Alex. Ogston.  
*Practice of Medicine*—Professor Smith-Shand.  
*Midwifery and Diseases of Women and Children*—Professor Stephenson.  
*Materia Medica*—Professor A. D. Davidson.  
*Pathological Anatomy*—Professor D. J. Hamilton.  
*Practical Pathological Anatomy*—Professor D. J. Hamilton.  
*Natural History*—Professor Alleyne Nicholson.

##### LECTURES.—SUMMER SESSION.

*Botany*—Professor Jas. W. H. Trail.  
*Practical Botany*—Professor Trail.  
*Practical Anatomy and Demonstrations*—Professor Struthers and Assistant.  
*Practical Chemistry*—Professor Brazier and Assistant.  
*Natural History*—Professor Alleyne Nicholson.  
*Practical Natural History*—Professor Alleyne Nicholson.  
*Practical Physiology*—Professor Stirling.  
*Practical Pathological Anatomy*—Professor D. J. Hamilton.  
*Operative Surgery*—Professor Alex. Ogston.  
*Practical Pharmacy*—Professor A. D. Davidson and Assistant.  
*Practical Midwifery and Gynaecology and Clinical Diseases of Children*—Professor Stephenson.  
*Medical Logic and Medical Jurisprudence*—Professor Matthew Hay.  
*Practical Medical Jurisprudence and Hygiene*—Prof. Matthew Hay.

The Anatomical Course in Summer includes instruction in Histology and in the use of the Microscope; and instruction in Osteology for beginners.

The following additional Courses of Practical Instruction are delivered in the University, or at the Institutions mentioned: *Practical Ophthalmology*—Prof. A. D. Davidson. *Dental Surgery*—Dr. Williamson. *Insanity*—Dr. Reid, Royal Lunatic Asylum. *Public Health*—Dr. Simpson. *Diseases of the Ear and Larynx*—Dr. McKenzie Booth, Dispensary. *Diseases of the Skin*—Dr. Garden, Royal Infirmary and Sick Children's Hospital.

The *Aberdeen Royal Infirmary* contains about 200 beds, and is visited by the members of the staff daily, at noon. Perpetual Fee to Hospital Practice, 6*l.*; or, first year, 3*l.* 10*s.*; second year, 3*l.* *Clinical Medicine*—Drs. Smith-Shand, Beveridge, and A. Fraser, 3*l.* 3*s.* *Clinical Surgery*—Drs. A. Ogston, Will, and Garden, 3*l.* 3*s.* *Pathological Demonstrations*—Dr. Rodger.

*Sick Children's Hospital.* Daily at 11 a.m.

*General Dispensary, and Lying-in and Vaccine Institution.* Daily, 10 a.m.

*Eye Institution.* Daily, 2.30 p.m.

*Royal Lunatic Asylum.* Physicians—Drs. Jamieson and Reid.

The Regulations relative to the Registration of Students of Medicine, and the Granting of Degrees in Medicine and Surgery, may be had of Professor Brazier, Dean of the Faculty of Medicine.

## MEDICAL EDUCATION AND EXAMINATIONS IN IRELAND.

### INTRODUCTORY ARTICLE.

(By our Dublin Correspondent.)

In Ireland there are five Licensing Bodies, namely:—(1) The University of Dublin. (2) The King and Queen's College of Physicians. (3) The Royal College of Surgeons. (4) The Royal University. (5) The Apothecaries' Hall of Ireland.

I.—THE UNIVERSITY OF DUBLIN, founded by Queen Elizabeth in the year 1591, is the most ancient of the educational institutions in Ireland. On the 3rd of March in the year named, a College was incorporated by Charter, or Letters Patent, as "the mother of an university," under the style and title of "the College of the Holy and Undivided Trinity, near Dublin, founded by Queen Elizabeth." Since that date, several Royal Charters have been granted by succeeding Sovereigns, extending the privileges of the University, and making such alterations in the statutes and constitution of Trinity College as were from time to time deemed necessary. The degrees in Medicine, Surgery, and Midwifery granted by the University are as follows:—(1) Bachelor of Medicine; (2) Doctor of Medicine; (3) Bachelor in Surgery; (4) Master in Surgery; (5) Master in Obstetric Science. The last-named degree (M.A.O., or "Magister Artis Obstetriciæ") was instituted in June 1876, when also a Licence in Obstetric Science was established. A candidate for the Degree of Bachelor of Medicine must be a Graduate in Arts, but may obtain the Degree of Bachelor of Medicine at the same Commencements as those at which he receives his Degree of B.A., provided the requisite medical curriculum shall have been completed, and the requisite Examinations passed. A Bachelor in Surgery must also be a Bachelor in Arts, and have spent four years in the study of Surgery and Anatomy. He must further have passed the M.B. Examination before presenting himself at that for the B.Ch. Degree, having previously completed the prescribed curriculum of study. A Master in Obstetric Science must have passed the M.B. and B.Ch. Examinations and produce certificates of having attended—(1) One winter course in Midwifery; (2) six months' practice in a recognised Lying-in Hospital, or Maternity; (3) a summer course in Obstetric Medicine and Surgery; and (4) two months' practice in the Cow-pock Institution of the Local Government Board for Ireland. The higher degrees in Medicine (M.D.) and Surgery (M.Ch.) are conferred on graduates in Medicine and Surgery of three years' standing on complying with certain regulations, such as the reading of a thesis publicly before the Regius Professors of Physic and Surgery respectively. The University also grants Licences to Practise Medicine, Surgery, and Midwifery—or Obstetric Science—to candidates who have matriculated in Medicine, and who have completed two years in Arts, and four years in Medical Studies. The curriculum and examination required for these Licences are identical with those for the Degrees in Medicine, Surgery, and Obstetric Science respectively. From the antiquity and fame of the University of Dublin, and from the fact that their possession implies a full curriculum in Arts, the degrees in the Medical Faculty of the University are in great repute, and deservedly so. A qualification in State Medicine is also granted, after a searching and practical Examination, to candidates who are Graduates in Medicine of the University.

II.—THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND was incorporated by Charter in 1667, and was re-incorporated by Charter of William and Mary in 1692, since which year it has been known under its present name. The College of Physicians grants the following qualifications:—(1) Licence to Practise Medicine; (2) Licence to Practise Midwifery; (3) Licence to Practise as a Midwife

and Nurse-tender. Of these the first two are registrable qualifications, and are in much request. In the year 1884 as many as 143 candidates presented themselves for the Licence in Medicine, of whom 99 were successful; and 106 for the Licence in Midwifery, of whom 100 passed. Stated Examinations for the Licences in Medicine and Midwifery are held in the week following the first Friday in each month, except August and September. Among other requirements for the Licence in Medicine is an attendance during twenty-seven months at a recognised Medico-Chirurgical Hospital, six winter and three summer months in each of three years being the period allotted for clinical instruction. A three months' clinical study of fever, with notes of five fever cases, is also required of candidates. The word "fever" in the By-law as to fever cases includes the following diseases only, viz.:—Typhus, Typhoid, or Enteric, Scarlet Fever, Small-Pox, Measles. The Professional Examination is divided into two parts, namely,—First: Anatomy, Physiology, Practical Physiology including Histology, Chemistry, and Materia Medica. Second: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics. The Licence in Midwifery is open to qualified candidates, who are not Licentiates in Medicine of the College, on certain specified conditions, a privilege which is largely availed of. The College also grants a Certificate in Sanitary Science to Licentiates in Medicine, as well as to Registered Medical Practitioners of the United Kingdom generally. In the case of the latter class of candidates the fee is raised from five to ten guineas. The examination for this certificate is held quarterly, in January, April, July, and October, and embraces the following subjects:—(1) Engineering; (2) Law; (3) Ætiology and Prevention of Disease; (4) Chemistry; (5) Meteorology, Climatology, and Vital Statistics. The Candidates are further examined in the analytical chemistry of air, water, and food. The higher qualifications are the Membership and the Fellowship. Only Licentiates in Medicine of the College are eligible for the Membership, and Members alone are eligible for Fellowship. An examination for the Membership is held quarterly in January, April, July, and October, except in the case of candidates who were already Licentiates in Medicine on December 12th, 1878, the date upon which the Supplemental Charter of the College, constituting the order of Members, was granted. The Fellows are elected by ballot on fixed days in April and October. It is necessary to observe that the College of Physicians admits women to its Licences and the Membership. They are, however, debarred from the Fellowship under the terms of Russell Gurney's Act of 1876 (39 & 40 Viet. cap. 41.).

III.—THE ROYAL COLLEGE OF SURGEONS IN IRELAND was founded just over one hundred years ago, in 1784. In 1882 the Regulations relating to the Education and Examination of Candidates for the Licence to Practise Surgery were completely re-modelled. Every candidate for the diploma, or "Letters Testimonial," is required to pass a Preliminary Examination, and Four Professional Examinations in successive years. The Letters Testimonial will not be granted to any candidate at an earlier period than forty-five months subsequent to his registration as a medical student, or to any one who has not attained the age of 21 years. The First, Second, and Third Professional Examinations are held in the July and October of each year. Should a student fail to pass in July, he may present himself at the Examination held in October. As a rule, the Examination of each year must be passed before a new session can be entered on. The Fourth and Final Professional Examination is also held in July and October, and in the following April. The College grants, in addition to the Letters Testimonial, a Diploma in Midwifery. Every candidate must be a Fellow or Licentiate of the College. Candidates for the Fellowship are admitted to Examination under five grades:—(1) As candidates possessing no qualification; (2) as Licentiates of the College of less than ten years' standing; (3) as candidates of less than ten years' standing, possessing qualifications in Surgery of other bodies; (4) as Licentiates of the College of more than ten years' standing; and (5) as candidates of more than ten years' standing, possessing qualifications in Surgery of other bodies. The College has recently been granted a new Charter,

which provides among other things for the admission of women to the examination for the Letters Testimonial.

IV.—THE ROYAL UNIVERSITY OF IRELAND. On the 15th of August, 1879, an Act "to promote the advancement of learning, and to extend the benefits connected with University Education in Ireland" received the Royal Assent, and on April 27th, 1880, Letters Patent were issued founding an University in accordance with the provisions of the University Education (Ireland) Act, 1879, just referred to, under the style and title of "The Royal University of Ireland." This, the youngest but one of the Universities of the United Kingdom, may be said literally to have been built upon the ruins of the Queen's University in Ireland. In the Medical Faculty four degrees, those of Bachelor of Medicine, Doctor of Medicine, and Master in Surgery, and Master of Obstetrics and a Special Diploma in Sanitary Science, are conferred. The degrees of M.Ch. and M.A.O. and the diploma in Sanitary Science are granted only to graduates in Medicine of the University. The course for the degree of M.B. is of at least four years' duration. Besides fulfilling the specified curriculum all candidates are required to pass the following examinations:—The Matriculation Examination; the First University Examination; the First and Second Examinations in Medicine; and the Degree Examination. The last three are to be passed at intervals of one year from each other. The Matriculation and First University Examinations, which must be passed by candidates for Medical Degrees, embrace the following subjects:—(1) Latin; (2) Any one of these languages, viz., Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic; (3) English Language and Literature; (4) Mathematics; (5) Experimental Physics. One Academical year must intervene between these two Examinations. It will thus be observed that one year in Arts only is required of candidates for medical degrees in this University. Furthermore, the fees are low, namely:—Matriculation Examination, 10s.; First University Examination, 1*l.*; First and Second Examinations in Medicine, 1*l.* each; M.B. Degree Examination, 3*l.*; M.D. Degree Examination, 5*l.*; M.Ch. Examination, 5*l.*; Diploma in Obstetrics Examination, 2*l.*—18*l.* 10s. in all, compared with 43*l.* 1s. payable by a candidate for the Licences of the Colleges of Physicians and Surgeons. All the degrees, honours, prizes, &c., of the University are open to students of either sex.

V.—THE APOTHECARIES' HALL OF IRELAND was incorporated in 1791 (31 Geo. III., cap. 34, "An Act for the more effectually preserving the Health of His Majesty's Subjects, for erecting an Apothecaries' Hall in the City of Dublin, and regulating the Profession of an Apothecary throughout the Kingdom of Ireland"). The Hall grants one Licence which entitles its possessor to practise Medicine and Pharmacy, and is recognised as a full qualification in Medicine for appointments in the Army Medical Department, the Naval Medical Department, and the Poor Law Medical Service in both England and Ireland. Candidates for the Licence must undergo a preliminary examination and a professional examination, of which the latter is divided into two parts. The fee for the Preliminary is 10s., and that for the Professional, 16s.; so that the total cost of this qualification is only 1*l.* 6s. The Hospital attendance required of candidates is apparently only eighteen months, namely, Practice of Medicine and Clinical Lectures on Medicine, during two Winter and two Summer Sessions, and Practice of Surgery and Clinical Lectures on Surgery, during one Winter and one Summer Session; there being no proviso that the surgical attendance shall not be synchronous with the Medical.

For the Examinations of the above Licensing Bodies, students are prepared in five Metropolitan and three Provincial Medical Schools, in all of which the Course of Study is adapted, with more or less variations, to the requirements of the Licensing Bodies.

THE METROPOLITAN SCHOOLS are:—(1) The School of Physic in Ireland; (2) The School of Surgery of the Royal College of Surgeons; (3) The Carmichael College of Medicine; (4) The Ledwich (Original) School of

Anatomy, Medicine, and Surgery; (5) The School of Medicine of the Catholic University. The Provincial Schools are those connected with the Queen's Colleges at Belfast, Cork, and Galway. A few explanatory remarks touching each of these institutions may prove of interest:—

1. *The School of Physic in Ireland* is a Medical School formed by an amalgamation of the Schools of the College of Physicians, and of Trinity College, Dublin, in conformity with the "School of Physic Act" (40 Geo. III., cap. 84), and subsequent Acts of Parliament, particularly the Statute of 30 Vict., cap. 9. The School is governed jointly by the Provost and Senior Fellows of Trinity College, and by the President and Fellows of the College of Physicians. The Teaching Staff of the School consists of five Professors appointed by the College, and four Professors and one Lecturer appointed by Trinity College. Of the five Professors appointed by the College of Physicians, four King's Professors are, by virtue of their office, Clinical Teachers in Sir Patrick Dun's Hospital, Dublin, of which the President and the four Censors of the College are *ex-officio* Governors, and have a voice in all matters connected therewith. And in this connection it is necessary to observe that this is the only instance now in Ireland of a School of Medicine being intimately bound up with, or attached to, a hospital. A few years ago the Medical School attached to Dr. Steevens' Hospital became extinct, although clinical work is still effectively carried on in that Hospital. In this respect the Irish Hospitals and Schools present a remarkable contrast to those in London and in the larger provincial towns of England. The Irish arrangement no doubt arises from the comparatively short distances between the hospitals and schools in Dublin, and it possesses the advantage of securing for both hospitals and schools a variety of talent from different quarters. The School of Physic stands at the east end of the park of Trinity College, and includes a splendid chemical laboratory, a physiological laboratory, extensive dissecting rooms, and lecture theatres and museums. In addition to many recent enlargements and improvements the Board of Trinity College are about to spend a further sum of 11,000*l.* upon the buildings of this Medical School.

2. *The School of Surgery of the Royal College of Surgeons* is attached by charter and has existed as a department of the College for nearly a century. It is carried on within the College buildings and is specially subject to the supervision and control of the Collegiate Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued in the School. Within the past few years the School has been considerably enlarged, indeed reconstructed, and fitted with the most modern and improved appliances. The Anatomical Department has been entirely remodelled, and a new laboratory has been constructed for the special accommodation of students in practical physiology.

3. *The Carmichael School of Medicine* was founded in the year 1826, by Ephraim MacDowel, Richard Carmichael, and Robert Adams, Surgeons to the Richmond Hospital, under the title of the Richmond Hospital School of Medicine. Subsequently, Mr. Carmichael endowed it with a valuable Prize Fund amounting to about 100*l.* a year, and bequeathed a large sum of money to the School for building purposes. In consideration of this munificent bequest the school has since been called the Carmichael School. In 1878 it was determined to transfer the School to the south side of the city. Accordingly a site was obtained at the corner of Aungier Street and Whitefriar Place, facing York Street, in immediate proximity to the Meath; Adelaide, and Mercer's Hospitals, and but a moderate distance from the City of Dublin Hospital. On this ground the present buildings, entirely new from the foundation, were erected; and in their construction and arrangements the directors have rendered every department fully adequate to the requirements of the most advanced modern teaching of Medicine and Surgery. In consequence of these changes the title was altered to that of the Carmichael College of Medicine. The buildings include a Dissecting Room of large size, a "Bone Room," a Chemical Lecture Theatre and Laboratory, a Histology Room, capable of accommodating 250 pupils, and separate

rooms for Physiological Chemistry and Physiological Instruments. Prizes to the value of over 100*l.* are awarded annually.

4. *The Ledwich School of Medicine* was founded in 1810, by Dr. Kirby, and since then has been successively under the management of the Messrs. Ledwich and Mason, after the former of whom it is named. It is situated in Peter Street, Dublin, close to the Adelaide Hospital, with which institution, however, it has no direct connection. Its governing body have gone with the spirit of the times, and have introduced many modern improvements, including the lighting of the Dissecting Room at night with electricity.

5. *The School of Medicine of the Catholic University* is situated in Ceilia Street, Dublin. It is conducted under the authority and supervision of the Catholic University of Ireland, of which institution it practically forms the Medical Faculty. Its students are sent up for Degrees in Medicine to the Royal University, of which several of its Professors and Lecturers are Fellows.

THE PROVINCIAL SCHOOLS OF MEDICINE are the Medical Faculties of the Queen's Colleges, which were established by Charter in 1849. These Colleges are three in number, and are called Queen's College, Belfast; Queen's College, Cork; Queen's College, Galway. Before the dissolution of the Queen's University in Ireland, these Colleges were its feeders; and in order to graduate in the University not only was it necessary to undergo the two University Examinations, but three sessions at one of the Colleges had also to be kept. Now, the place of the Queen's University has been taken by the Royal University, but no such intimate connection exists between the Colleges and the new University, to which the Colleges are in no way affiliated.

THE CLINICAL HOSPITALS OF DUBLIN are ten in number, exclusive of the Rotunda Lying-in Hospital, the Coombe Lying-in Hospital, Cork Street Fever Hospital and House of Recovery, the Children's Hospital, Eye and Ear Infirmaries, Orthopædic Hospitals, Westminster Lock Hospital, &c.

We name them here in chronological order.

1720.—Dr. Steeven's Hospital.

1721.—The Charitable Infirmiry, Inn's Quay (afterwards Jervis Street Hospital).

1734.—Mercer's Hospital.

1770.—Meath Hospital (constituted the County Dublin Infirmiry in 1773).

1791.—House of Industry Hospitals (Richmond, Surgical, Whitworth, Medical, and Hardwicke, Fever).

1798.—Sir Patriek Dun's Hospital (opened in 1808).

1832.—City of Dublin Hospital.

1834.—St. Vincent's Hospital.

1861.—Mater Misericordiæ Hospital.

1861.—Adelaide Hospital.

Among the principal PROVINCIAL HOSPITALS are the Belfast Royal Hospital; the North Charitable Infirmiry, Cork; the South Charitable Infirmiry and County Hospital, Cork; the County Infirmiry, Galway; and Barringtons' Hospital and City of Limerick Infirmiry.

THE HOSPITAL FOR WOMEN, SOHO SQUARE, W.—In connection with this Institution there is now an organised School of Gynæcology, open to qualified Medical Men and Students after their third year. A strictly limited number of Clinical Assistants to the Physicians and Surgeons in the in-patient and out-patient departments are appointed every three months. A course of Lectures on the Anatomy and Physiology of the Female Pelvic Organs is given during each Quarter by Dr. J. A. Mansell Moullin, Senior Assistant Physician to the Hospital. Clinical Lectures are given in the Operating Theatre on alternate Thursday afternoons at 3.30 p.m. throughout the winter Session. Prizes are given annually after examination, and are open to past and present Clinical Assistants. For the three months course, five guineas. Any further information can be obtained by letter addressed to the Dean at the Hospital.

## THE CLINICAL HOSPITALS OF DUBLIN.

### DR. STEEVENS' HOSPITAL.

MEDICAL AND SURGICAL STAFF.—*Physicians*: Dr. H. J. Tweedy; Dr. R. A. Hayes. *Surgeons*: Mr. W. Colles; Mr. E. Hamilton; Mr. R. M'Donnell. *Ophthalmic Surgeon*: Mr. P. W. Maxwell. *Resident Surgeon*: Mr. Percy Drought.

FEES.—Hospital Practice, nine months, 12*l.* 12*s.*; ditto, six months, 8*l.* 8*s.* Further particulars may be learned from the Resident Surgeon at the Hospital; or from Dr. R. A. Hayes, Hon. Sec., 32, Merrion Square South.

### JERVIS STREET HOSPITAL.

MEDICAL STAFF.—*Physicians*: Drs. MacSwiney and Martin. *Surgeons*: Messrs. Austin Meldon, Wm. Stoker, J. J. Cranny, Robt. McDonnell, J. V. Lentaigne, Christopher Gunn and Arthur Chance.

This Hospital is now rebuilt on an extensive scale, and will be opened on 29th September. From its proximity to the quays, principal factories and large railway depôts it presents unrivalled opportunities of studying every form of surgical injury. Resident Pupils and Dressers are appointed without the payment of any additional fee. Twelve Interns are appointed yearly, and are provided with apartments, &c., free of expense. Special certificates are given to the Resident Pupils and Dressers who have performed their respective duties to the satisfaction of the Physicians and Surgeons. Gold and silver medals will be given after examinations held at the close of the Summer Session. Certificates of attendance are recognised by all the Licensing Bodies and Examining Boards in the kingdom.

Clinical Instruction is given every morning from 8 till 11. Operation days, Tuesday and Friday at 10 a.m.

The prospectus of the Hospital can be obtained from the Hon. Secretary, A. G. Chance, Esq., 15, Westland Row, Dublin.

### MERCER'S HOSPITAL.<sup>1</sup>

MEDICAL AND SURGICAL STAFF.—*Physicians*: Dr. T. P. Mason; Dr. Charles Frederick Knight. *Surgeons*: Mr. E. S. O'Grady; Mr. F. Alcock Nixon; Mr. M. A. Ward.

This Hospital is situated in a central position, and is in close proximity to the School of the Royal College of Surgeons, to the Carmichael College of Medicine and Surgery, to the Catholic University, and the Ledwich School of Medicine.

Fees for the winter and summer session (nine months), 12*l.* 12*s.*; for the six winter months, 8*l.* 8*s.*; for the three summer months, 5*l.* 5*s.* Further information can be obtained from any of the medical officers of the Hospital, or from Dr. James Shaw, Registrar to the Medical Staff.

### MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.<sup>1</sup>

MEDICAL AND SURGICAL STAFF.—*Physicians*: Dr. Arthur Wynne Foot and Dr. John William Moore. *Surgeons*: Sir George H. Porter, Mr. James H. Wharton, Mr. Philip Crampton Smyly, Mr. Rawdon Maenamara, Mr. Lambert H. Ormsby, Mr. William J. Hepburn.

The session will commence on October 1st, and the course of clinical lectures on the first Monday in November. Clinical lectures, of which four will be delivered weekly, and instructions in Medicine and Surgery will be given on

<sup>1</sup> No return.

alternate days. The physicians and surgeons on duty will visit the Hospital at 9 a.m., so as to allow the members of the class to be in attendance at their respective Schools of Medicine at 11 a.m. The Hospital, which contains 120 beds for the reception of medical and surgical cases, and to which an extensive dispensary (open daily), lending library, and physical laboratory are attached, is within a few minutes' walk of the University, the Royal College of Surgeons, the Carmichael College of Medicine and Surgery, and the Ledwich School of Medicine. An additional ward has been erected for the reception of children, in which the pupils will have an opportunity of studying that highly important subject—infantile disease. Certificates of attendance at this Hospital are recognised by all the universities, colleges, and licensing bodies in the United Kingdom. Prizes will be given at the termination of the winter course to the best students in their respective classes. The office of Resident Pupil is open to pupils as well as apprentices. Further information may be obtained on application to Mr. W. J. Hepburn, Hon. Sec., 31, Upper Merrion Street, Dublin; or at the Hospital.

#### RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

**MEDICAL AND SURGICAL STAFF.**—*Physicians*: Dr. J. T. Banks; Dr. B. G. McDowel; Dr. S. Gordon; Dr. R. D. Lyons. *Surgeons*: Mr. William Stokes; Mr. William Thomson; Mr. W. Thornley Stoker; Mr. A. H. Corley. *Consulting Obstetric Surgeon*: Dr. Kidd. *Assistant Physician and Pathologist*: Dr. G. P. L'Estrange Nugent. *Assistant Surgeon*: Mr. J. J. Burgess. *Resident Surgeon*: Mr. J. P. Kennedy. *Curator of the Museum*: Mr. Blake Knox. *Ophthalmic Surgeon*: Dr. A. Jacob.

Clinical instruction will commence on October 1. These Hospitals contain 312 beds—110 for surgical cases, 82 for medical cases, and 120 for fever and other epidemic diseases. Premiums will be awarded in Clinical Medicine and Surgery. The Richmond Institution for the Insane, containing over 1,200 patients, adjoins these Hospitals. Eight resident clinical clerks are appointed each half year.

**FEES.**—For the winter and summer session (nine months), 12*l.* 12*s.*; for the six winter months, 8*l.* 8*s.*; for the three summer months, 5*l.* 5*s.* Resident clinical clerks, 21*l.* for the winter session, 15*l.* 15*s.* for the summer session, including certificate of attendance.

#### SIR PATRICK DUN'S HOSPITAL.<sup>1</sup>

**MEDICAL AND SURGICAL STAFF.**—*Physicians*: Dr. John Malet Purser; Dr. W. G. Smith; Dr. J. Magee Finny. *Midwifery Physician*: Dr. J. R. Kirkpatrick. *Surgeons*: Dr. Thomas E. Little; Dr. Edward H. Bennett; Dr. Charles B. Ball.

**FEES.**—*Clinical Lectures and Hospital Attendance.*—The payment of 12*l.* 12*s.* entitles a student to the benefits of hospital attendance and clinical teaching for the winter and summer sessions, commencing October 1. Fee for winter session only, 8*l.* 8*s.*; fee for summer session only, 5*l.* 5*s.* *Practical Midwifery.*—Students desirous of entering for twelve months' instruction in Practical Midwifery are required to pay a maternity fee of 3*l.* 3*s.* each. Students of Trinity College are not liable to any other payment for instruction in Practical Midwifery. Other students are required to pay 3*l.* 3*s.* each to the King's Professor for twelve months' practical instruction, in addition to the hospital maternity fee. Students who have paid the hospital maternity fee are entitled to attend the demonstrations in Obstetric Surgery given by the King's Professor.

**PRIZES.**—The governors of the Hospital award a silver clinical medal in Medicine to the student who shall pass the best examination on the medical cases treated in the Hospital during the year; and a silver clinical medal in Surgery to the student who shall pass the best examination on the surgical cases treated in the Hospital during the year.

<sup>1</sup> No Return.

#### CITY OF DUBLIN HOSPITAL.

*Physicians*: Dr. Hawtrey Benson and Dr. George F. Duffey. *Surgeons*: Mr. Henry Gray Croly, Mr. William I. Wheeler, and Dr. Henry Fitzgibbon. *Ophthalmic and Aural Surgeon*: Mr. Arthur H. Benson. *Gynaecologist*: Dr. William J. Smyly.

**FEES.**—Nine months' hospital attendance, 12*l.* 12*s.*; six months, 8*l.* 8*s.*; three months, 5*l.* 5*s.* For further particulars apply to Mr. Wheeler, 27, Lower Fitzwilliam Street.

#### ST. VINCENT'S HOSPITAL.

**MEDICAL AND SURGICAL STAFF.**—*Physicians*: Dr. Francis J. B. Quinlan, Dr. M. F. Cox. *Assistant Physician*: Dr. M. McHugh. *Surgeons*: Mr. Edward D. Mapother, Mr. J. S. McArdle. *Assistant Surgeon*: Mr. R. F. Tobin. *Gynaecologist*: Dr. J. A. Byrne. *Ophthalmic Surgeon*: Mr. Redmond.

**FEES.**—Winter and summer session, 12*l.* 12*s.*; separately, 8*l.* 8*s.* and 5*l.* 5*s.* Further particulars may be learned on application to the Secretary of the Medical Board, Dr. Quinlan, 29, Fitzwilliam Street, Dublin, or at the Hospital during the hours of attendance.

#### MATER MISERICORDIÆ HOSPITAL.

**MEDICAL AND SURGICAL STAFF.**—*Physicians*: Dr. Christopher J. Nixon, Dr. Joseph Redmond, Dr. Michael Boyd. *Assistant-Physician*: Dr. John Murphy. *Surgeons*: Mr. Patrick J. Hayes, Mr. Charles Coppinger, Mr. Malachy Kilgarraff. *Assistant-Surgeon*: Mr. Kennedy. *Obstetric Physician*: Dr. T. M. Madden. *Dental Surgeon*: Mr. D. Corbett. *House Surgeon*: Dr. Conway Dwyer.

Certificates of attendance upon this Hospital, which contains 250 beds, including 50 beds for fever and other contagious diseases, are recognised by all the licensing bodies in the United Kingdom.

**PRIZES.**—Two clinical prizes (the "Leonard Prizes") of 15*l.* each, one medical and one surgical, will be given at the end of the winter session.

**FEES.**—For nine months, 12*l.* 12*s.*; six winter months, 8*l.* 8*s.*; three summer months, 5*l.* 5*s.*

#### ADELAIDE MEDICAL AND SURGICAL HOSPITALS.<sup>1</sup>

*Physicians*: Dr. Henry H. Head and Dr. James Little; *Obstetric Physician*: Dr. R. D. Purefoy; *Assistant Physician*: Dr. Wallace Beatty; *Surgeons*: Mr. J. K. Barton and Mr. Kendal Franks; *Ophthalmic Surgeon*: Dr. Rosborough Swanzy.

Further particulars can be obtained from any member of the staff.

#### ROTUNDA HOSPITAL.

*Master*: Arthur V. Macan, M.B., F.K.Q.C.P.; *Consulting Physician*: James Little, M.D., F.K.Q.C.P.; *Consulting Surgeon*: William Colles, M.D., F.R.C.S.I.; *Assistant Physicians*: John Lilly Lane, B.A., L.K.Q.C.P., L.R.C.S.I., R. H. Fleming, M.B., B.Ch. This Institution consists of two distinct Hospitals, namely, the Lying-in Hospital, into which 1,200 labour cases are on an average admitted annually, and the Auxiliary Hospital, set apart for the reception and treatment of patients suffering from the various forms of uterine and ovarian disease; about 500 patients are received into this Hospital during each year. There is also in connection with the Hospital a large Extern Maternity (1,700 patients were in the past year attended at their own homes), and a dispensary for Diseases Peculiar to Women, which is open daily. Pupils are admitted to the practice of all these departments.

<sup>1</sup> No Return.

Clinical Instruction in Midwifery and the Diseases of Women is given daily, and Lectures are delivered regularly during the Session on these subjects. The diploma from this Hospital is granted to pupils on their passing an examination before the Master and Assistants after a period of six months' attendance on the Practice of the Hospital. It is recognised by the Local Government Board as a qualification in Midwifery for all hospitals and dispensaries under their control. Accommodation is provided for a limited number of intern pupils. Pupils can enter at any time.

TERMS OF ATTENDANCE.—Intern pupils, for six months, 2*l.*; three months, 12*l.* 12*s.*; two months, 9*l.* 9*s.*; one month, 6*l.* 6*s.* Extern pupils, for six months, 10*l.* 10*s.*; three months, 6*l.* 6*s.* Application to be made to the Master or Assistant Physicians at the Hospital, Britain Street.

## PROVINCIAL MEDICAL SCHOOLS IN IRELAND.

### QUEEN'S COLLEGE, BELFAST.—FACULTY OF MEDICINE.

#### PROFESSORS AND LECTURERS.

*Anatomy and Physiology*—Dr. P. Redfern.  
*Chemistry*—Dr. E. A. Letts.  
*Materia Medica*—Dr. J. S. Reid.  
*Medical Jurisprudence*—Dr. J. F. Hodges.  
*Midwifery*—Dr. R. F. Dill.  
*Natural Philosophy*—Dr. J. D. Everett.  
*Practice of Medicine*—Dr. James Cuming.  
*Practice of Surgery*—(vacant).  
*Zoology and Botany*—Dr. R. O. Cunningham.

The demonstrations in Anatomy are delivered by Dr. Sinclair. The lectures in Medical Jurisprudence and the courses of Botany and Practical Chemistry will commence in May.

FEES.—Anatomy and Physiology—First course, 3*l.*; each subsequent course, 2*l.* Anatomical Demonstrations and Practical Anatomy—each course, 3*l.* Practical Physiology and Histology, 3*l.* 3*s.* Practical Chemistry, 3*l.* Other medical lectures—first course, 2*l.*; each subsequent course, 1*l.*

Two Medical Scholarships are awarded to the students of each year of the medical course. The examinations commence on October 27.

*Clinical Instruction is given at the following Hospitals:—*

BELFAST GENERAL HOSPITAL.—A winter session, 5*l.* 5*s.* A summer session, 2*l.* 2*s.* Perpetual fee, payable in two instalments, 10*l.* 10*s.* Hospital fee, 10*l.* 6*d.* each winter or summer session.

THE ULSTER HOSPITAL FOR DISEASES OF WOMEN AND CHILDREN AND MIDWIFERY DISPENSARY, 11, FISHERWICK PLACE.—Fee for winter or summer six months, 3*l.* 3*s.*

THE BELFAST LYING-IN HOSPITAL.—Fee for six months, 2*l.* 2*s.*

THE BELFAST DISTRICT LUNATIC ASYLUM.—Fee for summer session, 3*l.* 3*s.*

### QUEEN'S COLLEGE, CORK.—FACULTY OF MEDICINE.

#### PROFESSORS.

*Anatomy and Physiology*—Dr. J. J. Charles,  
*Chemistry and Practical Chemistry*—Dr. Maxwell Simpson.  
*Materia Medica*—Dr. C. Yelverton Pearson.  
*Midwifery*—Henry Corby, B.A., M.D., M.Ch.  
*Natural Philosophy*—Prof. John England.  
*Practical Anatomy*—The Professor, assisted by Demonstrators.  
*Practice of Medicine*—Dr. D. C. O'Connor.  
*Practice of Surgery*—Dr. Stephen O'Sullivan.  
*Zoology and Botany*—Professor M. Hartog.

All the lectures are recognized by the Royal University of Ireland, by the Universities of London, Glasgow, Aber-

deen, and St. Andrew's; the Colleges of Surgeons of Dublin, Edinburgh, and London; by the Apothecaries' Companies; by the Army, Navy, and East Indian Medical Board, &c.

HOSPITAL ATTENDANCE.—Clinical lectures on Medicine and Surgery are delivered at the North and South Infirmaries, by the Physicians and Surgeons of those Institutions—Fee for twelve months, 8*l.* 8*s.*; fee for six months, 5*l.* 5*s.* Practical Pharmacy at the same Infirmaries—Fee for three months, 3*l.* 3*s.* Clinical Midwifery at the Lying-in Hospital, with Practical Attendance upon thirty Midwifery cases—Fee for six months, 3*l.* 3*s.*

Clinical instruction is also given at the Mercy Hospital, the District Lunatic Asylum (Fee, 3*l.* 3*s.*), the Children's Hospital, the Fever Hospital, and the Ophthalmic and Aural Hospital.

SCHOLARSHIPS.—Eight Scholarships are awarded to students in Medicine, if qualified, viz., two Scholarships of 25*l.* each to students commencing their first, second, third, and fourth years. Clinical Medicine and Surgery at the North and South Infirmaries, and Clinical Midwifery at the Lying-in Hospital.

### QUEEN'S COLLEGE, GALWAY.—FACULTY OF MEDICINE.

#### PROFESSORS AND LECTURERS.

*Anatomy and Physiology, and Practical Anatomy*—Dr. J. P. Pye.  
*Botany and Zoology*—Dr. R. J. Anderson.  
*Chemistry*—Dr. T. H. Rowney.  
*Logic and Mental Philosophy*—Dr. T. W. Moffatt.  
*Materia Medica*—Dr. N. W. Colahan.  
*Medical Jurisprudence*—Dr. R. J. Kinkead.  
*Midwifery and Diseases of Women and Children*—Dr. R. J. Kinkead.  
*Natural Philosophy*—Dr. Joseph Larmor.  
*Practice of Medicine*—Dr. John I. Lynham.  
*Practice of Surgery*—Dr. J. V. Browne.

Clinical instruction is given at the County Galway Infirmary, Town, and Fever Hospitals which are in the immediate vicinity of the Queen's College.

Eight Scholarships of the value of 25*l.* each, and Exhibitions varying in value from 12*l.* to 16*l.*, are appropriated to students pursuing the course for the degree of M.D.

FEES.—Anatomy and Physiology, 3*l.* first session; afterwards 2*l.* Practical Anatomy, 3*l.*; Practical Chemistry, 3*l.*; Operative Surgery, 3*l.*; other classes, 1*l.* for each course extending over one term only, 2*l.* for each course extending over more than one term, and 1*l.* for each re-attendance on the same. Hospitals, 4*l.* 4*s.*

For further information, application may be made to Professor Townsend, M.A., D.Sc., Registrar.

MR. THOMAS COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, SURGERY, &c.—This school is intended to meet the requirements of three classes of students—(1) Qualified practitioners and advanced students, *i.e.*, gentlemen wishing either to obtain some of the higher qualifications, or to compete for appointments in Her Majesty's Army, Navy, and Indian Medical Services. (2) Students preparing for the usual Primary and Pass Examinations of any of the Licensing Bodies. (3) Beginners entering upon their Medical Studies, either by a short term of apprenticeship, or under the new Regulations of the Examining Board in England. Rapid advance classes, complete in three months or less but still thoroughly practical, are provided: and also, as required, more elementary classes of six months' duration. The instruction is given on the dissected and undissected body, with normal and pathological specimens, microscopical preparations, chemical, physiological, and surgical apparatus, splints, &c. The operations of surgery are performed on the dead body. Arrangements can be made for attendance on midwifery cases, and for practical work in the dispensary. The dissecting room is open daily. The physiological and chemical laboratories are fitted with the requisites for practical work, and every effort is made to render the teaching thoroughly practical and demonstrative. For prospectus of particulars and terms, apply to Mr. Thomas Cooke's private address, 40, Brunswick Square.

SYNOPSIS OF THE REGULATIONS OF THE EXAMINING BODIES.

EXPLANATION OF LETTERS USED IN TABLES.

- (a) A first or second class gained in the Natural Science School, enables the student to dispense with these two years of study.
- (b) In each examination, subjects (1) and (2) may be taken separately.
- (c) Four years, if B.A. has been passed with honours.
- (d) The examination in Physiology and Histology may be postponed to a subsequent year.
- (e) Graduates who have passed the B.S. or M.B. respectively in the First Division are excused one year of hospital, or two years of private practice.
- (f) The University of Durham also grants Licences in Medicine and Surgery. The subjects of examination and other conditions are the same as those for the corresponding degrees, but no extra examination in Arts is required.
- (g) The October examination is intended only for students who have failed in the previous July, or who have received special permission to present themselves.
- (h) The first part may be passed at any time subsequent to completion of third year from registration as a medical student.
- (i) The different parts may be taken separately.
- (j) Graduates in Arts of a recognised university are exempt from this examination; and candidates who have passed a recognised Arts examination are not re-examined in the subjects in which they have passed.
- (k) The first two parts may be taken together at the end of the third year, or all four parts together at the end of the fourth year.
- (l) Graduates in Arts of a recognised university are exempt from examination in Logic, Moral Philosophy, &c.
- (m) The curriculum and fees for the degrees of the University of Glasgow are the same as in the case of the University of Edinburgh.
- (n) Candidates who have passed the previous professional examination of a recognised corporation are excused from passing this examination.
- (o) The University also grants Licences in Medicine, Surgery, and Obstetrics respectively to candidates who have completed two years in Arts but have not taken the B.A. degree; also a degree in Obstetrics.
- (p) Unless attended in first year.

## MEDICAL EDUCATION IN VIENNA.

(By Our Vienna Correspondent.)

I HOPE that a short account of the educational arrangements at the Medical Faculty of Vienna, which has long been a favourite place of resort for foreign medical students and practitioners, may prove of some use to your English readers. Those who cherish the intention of some day visiting the school at which Hyrtl, Rokitansky, and Skoda received their education and carried on their important work, and which is now represented by such distinguished men as Brücke, Billroth, Bamberger, Nothnagel, Braun, Stellwag, Kaposi, and others, will find perhaps in these lines a special interest.

Before giving you a view of the educational facilities at the Vienna Medical Faculty in general, I must devote a few words to the arrangements which especially concern the students who wish to pass their examinations here. Every student of an Austrian Medical Faculty has to attend lectures during a period of five years, and he cannot be admitted to the final examinations for the degree of Doctor of Medicine until he has fulfilled the so-called "quinquennium." Foreigners who possess the right of attending the Universities of their own country are also received at the Universities in question, and are subjected to the same laws as native students. If they have already taken the degree of doctor at a foreign faculty, they are received as "extraordinary students," and are not obliged to complete the five years if they wish to take the degree at one of the Medical Faculties of Austria, but may pass their examinations when they please.

All public lectures, most of which are delivered by ordinary professors, are open to foreigners for the same fee as is required of the ordinary student. The fee for each course of lectures is in proportion to the number of hours which they occupy during one week, each hour a week being charged at the rate of 1fl. 5kr. (about 1s. 10d.) for the whole semester. Thus for the course of lectures on Internal Medicine, which occupies ten hours a week, the fee is 10fl. 50kr. per semester. Payment is made each semester at the commencement of the course.

The lectures in the different departments of Medicine are so arranged that the student has an opportunity of attending all his subjects in the course of five years. To elucidate this point it will be necessary to give the hours of the different lectures. The lectures on Anatomy are delivered every day, except Sunday, from 9 to 10 a.m. The dissecting rooms are open on the same days from 8.30 a.m. till dusk, the respective professors giving demonstrations from 3 to 5 p.m. The fee for dissections and demonstrations for the whole semester is the same as that for a course of six hours a week, namely, 6fl. 30kr. The lectures on Anatomy and the demonstrations in the dissecting rooms are in the hands of two professors, Prof. Charles v. Langer and Prof. Charles Tolddt. Their hours of lecturing coincide, as in all cases where there are two professors for the same subject, so that the student may follow whichever of the teachers he please. The lectures on Physiology and Histology, by Professor v. Brücke, take place from 11 to 12 o'clock five times a week. The physiological laboratory, also under the direction of Professor Brücke, is open on every week-day, and the fee for the whole semester is the same as that for a course of six hours (6fl. 30kr.). Besides these lectures there are many others in the same departments which serve as "repetitoria," and in which students have the opportunity of perfecting their knowledge, as for instance, two so-called "private courses," by Professor Schenck, on Histology and Embryology, and courses on some selected subject in Physiology by the Extraordinary Professors Exner and v. Fleischl, assistants to Professor Brücke. The fees for these lectures, however, differ from those I have mentioned above, the extraordinary professors, privat-docents, &c., being allowed to fix whatever fees they please; hence the name "privat-Curse," or briefly "Curse," the name of the official lectures being "Vorlesungen," or "Collegia." The students of the Vienna Medical Faculty

are occupied during their first two years with the various branches of Natural History (Zoology, Botany, Mineralogy,) and with the above-mentioned subjects, and in the second year with Pharmacology five times a week, from 10 to 11 a.m. (delivered only in winter), by Professor Vogl.

At the beginning of the third year they commence their clinical studies and the subjects connected with them, as Pathological Anatomy and so on. The hours for Internal Medicine are from 8 to 10 a.m. in winter (in summer from 7 to 9 a.m.), those for Surgery from 10 to 12 in winter (from 9 to 11 in summer). In each case the lectures are delivered by the respective professors at the same hour five times a week, Bamberger, Nothnagel and Schrötter having charge of Internal Medicine, Billroth and Albert of Surgery. Pathological Anatomy is taught from 12 to 1 in winter (from 11 to 12 in summer), by Professor Kundrat. The class of Practical Pathology is held three times a week from 3 to 4 p.m., also under the direction of Professor Kundrat. Besides this there are also, as in other subjects, private courses by the assistants of the professors and others, by extraordinary professors and privat-docents, as for instance by the Extraordinary Professors Benedikt, Stern, Drasche, Rosenthal, Stoffella, and by the Privat-docents Bettelheim, Breuer, Heitler, Drozda, Jakseh, Biach, Langer, Abeles, Oser, Kretsch and Hein, in Internal Medicine; in Surgery by the Extraordinary Professors Mosetig-Moorhof, Dittel, Salzer, Böhm, Wölfler, Hofmohl and Ultzmann, and the Privat-docents Englisch, Fieber, Jurié, Frisch, and Maydl. The lectures on General and Experimental Pathology, by Professor Stricker, are delivered from 1 to 2 p.m. on five days a week in winter, in summer from 9 to 10 a.m. Forensic Medicine from 2 to 3 p.m. (five times a week), by Prof. Edward Hofmann; lectures on Mental Diseases from 5 to 6 p.m., by Professor Mcynert, five times a week, and by Professor Leidesdorf, from 5 to 6½, three times a week. A student has therefore the opportunity of attending the lectures on Internal Medicine, Surgery, Pathological Anatomy, General and Experimental Pathology, Forensic Medicine and Psychiatry, or some of them in the same semester. The lectures on Dermatology, by Professor Kaposi, are delivered from 8 to 10 a.m. in winter (7 to 9 in summer); Ophthalmology from 10 to 12 in winter (in summer 9 to 11), by Professor v. Stellwag and Dr. v. Reuss (the Second Chair of Ophthalmology being vacant); Gynæcology and Obstetrics from 12 to 2 in winter and summer, by Professors Charles v. Braun and Spaeth. All these lectures are delivered five times a week, and they are fixed at such hours that they can all be attended in the same semester. The lectures on Syphilis, by Professor Neumann, are delivered from 3 to 4 in winter, (in summer from 9 to 10) and the lectures on the same subject, by Professor Auspitz, are given from 9 to 10 a.m. in winter, and 10 to 11 a.m. in summer, in both cases five times a week. The student who desires to study dermatology has the best possible opportunity in Vienna. In winter he may attend Kaposi from 8 till 10; Auspitz from 10 till 11; and Neumann from 3 to 4. In summer Kaposi lectures from 7 till 9; Neumann from 9 till 10; Auspitz from 10 till 11. There are also several courses by privat-docents and assistants. Lectures on Children's Diseases are delivered four times a week by Professor Widerhofer, and on Surgical Pædiatrics once a week by Professor Weinlechner, both in the St. Anna Children's Hospital, from 11 to 12 in winter and summer.

Besides these official lectures, the fees for which are fixed on the scale already mentioned, there are some important courses which deserve to be noticed. The lectures on Laryngoscopy and Rhinoscopy, by Professor Schrötter, take place five times a week from 10 to 11 a.m. The course lasts six weeks, and the fee for each course is 20 florins. Professor Stoerk holds a course on the same subjects from 11 to 12 a.m. also five times a week, the length of the course and the fee being the same. Professor Schnitzler's course on the same subjects occupies from 8 to 10 five times a week, the course lasting four weeks; the fee for this too is 20 florins. There is also a course on the same subjects by Privat-docent Dr. Chiari, occupying five hours a week (the time of meeting is fixed according to the wishes of the class); the fee for each course of six weeks is 20 florins. Courses on Diseases of the Ear are delivered

by the Extraordinary Professors Dr. Adam Politzer, five times a week from 12 to 1, and Dr. Gruber, five times a week from 11 to 12; each of these courses lasts six weeks, and the fee is, for practitioners 15 florins, for students 10 florins. A further class on Diseases of the Ear meets six times a week, from 4 to 5 p.m., under the direction of Privat-docent Dr. Urbantschitsch, the duration of the course being six weeks, and the fee being for practitioners 15 florins, for students 10 florins. Privat-docent Dr. Albertus Bing also holds a class on Ear-Diseases twice a week, Saturday and Sunday, 10 to 11.30 a.m.; duration of course three months; fee both for practitioners and students 10 florins. It would take too much space to enumerate all the other "courses" in the different departments of medical science, and I will content myself with remarking that in each semester lectures are delivered by about 18 ordinary professors, 36 extraordinary professors, 61 privat-docents, and 31 assistants; the number of the courses being 201.

The study of Medicine at Vienna is greatly facilitated by the fact that almost all the lectures are delivered in the General Hospital, and in adjoining establishments, as the Institution for Anatomy and Physiology, the St. Anna Children's Hospital and the polyclinics. The new building of the University (a master-piece of architecture) is also in the neighbourhood of the General Hospital, so that medical students and practitioners have a good opportunity of attending the lectures delivered in the other faculties if they care to. English students and practitioners who are not acquainted with the German language, will find that almost all the teachers in Vienna are more or less acquainted with English, and can give the necessary explanations; the only difficulty is in understanding the official lectures delivered by the ordinary professors, but they may be looked upon as providing a good opportunity of learning German.

## MISCELLANEOUS INFORMATION.

### CHANGES IN THE STAFFS OF THE LONDON HOSPITALS AND SCHOOLS.

*St. Bartholomew's Hospital.*—Dr. Francis Harris, one of the Consulting Physicians, has died since the issue of our last student's number. Dr. Davies and Dr. Nias have succeeded Dr. Steavenson and Dr. Herringham as Casualty Physicians.

*Charing Cross Hospital.*—Dr. H. Montague Murray has been appointed Assistant Physician. Drs. Willcocks and Murray have been appointed to be Joint Teachers of Practical Medicine. Mr. Stanley Boyd has been appointed Demonstrator of Morbid Anatomy.

*St. George's Hospital.*—There have been no changes of importance.

*Guy's Hospital.*—Dr. R. E. Carrington and Dr. W. Hale White have been elected Assistant Physicians. The School and Hospital have lost the services of Dr. Mahomed since last year.

*King's College Hospital.*—Dr. N. I. C. Tirard has been appointed Assistant Physician in place of the late Dr. Buchanan Baxter; he has also succeeded Dr. Baxter as Professor of Materia Medica and Therapeutics. Dr. Burney Yeo has been appointed Professor of Clinical Therapeutics. Dr. Norman Dalton has been elected Pathological Registrar.

*The London Hospital.*—Dr. Herbert Davies, Consulting Physician to the Hospital, has died since last year. The vacancy on the Surgical Staff caused by the resignation of Mr. James Adams has been filled by Mr. Treves; Mr. F. S.

Eve has been elected Assistant Surgeon. Dr. A. H. Lewers has been appointed Assistant Obstetric Physician.

*St. Mary's Hospital.*—In consequence of the resignations of Drs. Handfield Jones and Shepherd, Dr. Sydney Phillips and Dr. Robert Maguire have been appointed Physicians to out-patients. Dr. Waller has been appointed Lecturer on Physiology.

*Middlesex Hospital.*—Dr. D. W. Finlay has been appointed Physician, and Dr. J. J. Pringle Assistant Physician.

*St. Thomas's Hospital.*—Mr. Battle has succeeded Mr. Makins as Resident Assistant Surgeon. Mr. Shattock has been appointed Curator of the Museum in succession to Mr. Stewart.

*University College Hospital.*—Mr. John Marshall has been appointed Consulting Surgeon. Mr. Marcus Beck succeeds him as Surgeon and Professor of Surgery. Mr. Victor Horsley has been elected Assistant Surgeon. Mr. Bilton Pollard has been appointed Surgical Registrar.

*Westminster Hospital.*—There have been no changes of importance.

EDUCATIONAL VACCINATION STATIONS.—In order to provide for the granting of those special certificates of proficiency in vaccination which are required as part of the medical qualification for entering into contracts for the performance of public vaccination, or for acting as deputy to a contractor, the following arrangements are made:—

1. The Vaccination Stations enumerated in the subjoined list are open, under certain specified conditions, for the purpose of teaching and examination.

2. The Public Vaccinators officiating at these stations are authorised to give the required certificates of proficiency in vaccination, to persons whom they have sufficiently instructed therein; and

3. The Public Vaccinators whose names in the subjoined list are printed in italic letters, are also authorised to give such certificates, after satisfactory examination, to persons whom they have not themselves instructed:—

LONDON.—Principal Station—Surrey Chapel, Blackfriars Road. *Dr. Robert Cory*, who attends on Tuesday and Thursday, at 2 p.m. North-west Stations—Marylebone General Dispensary, 77, Welbeck Street: Mr. William A. Sumner, on Tuesday, at 2 p.m.; Hall of the Working Men's Christian Association, Omega Place, Alpha Road: Mr. William A. Sumner, on Wednesday, at 10 a.m. West Station—9, St. George's Road, Pimlico, S.W.: Mr. Edward Lowe Webb, on Thursday, at 10 a.m. East Station—Eastern Dispensary, Leman Street: Mr. Charles T. Blackman, on Wednesday, at 11 a.m. North Station—Tottenham Court Chapel, Tottenham Court Road: Mr. William Edwin Grindley Pearse, on Monday and Wednesday, at 1 p.m. South-west Station—Western Dispensary, Rochester Row: Mr. William Edwin Grindley Pearse, on Tuesday, at 10 p.m. Strand Station—14, Russell Street, Covent Garden: Mr. Robert William Dunn, on Thursday, at 11 a.m. South-east Station—Vestry Hall, St. John's, Horselydown: Mr. John Gittins, on Monday, at 2 p.m. St. Thomas's Hospital: Dr. Robert Cory, on Wednesday, at 11.30 a.m.

BIRMINGHAM.—St. Jude's School-room, Hill Street, near Small-bank Street, on Monday, at 11 a.m.; the Assembly Rooms, 103, Constitution Hill, opposite Bond Street, on Monday, at 11 a.m.; the Wesleyan Methodist Infant School-room, Monument Road, on Wednesday, at 11 a.m.; the Wesleyan School-room, Peel Street, Winson Green Road, on Wednesday, at 2 p.m.; and "The British Workman" Reading Rooms, Sherborne Street, near Grosvenor Street, on Thursday, at 11 a.m.: *Dr. Edmund Robinson*.

BRISTOL.—The Public Vaccination Station, Peter Street; *Mr. Henry Lawrence*, on Wednesday, at 10 a.m.

EXETER.—The Odd Fellows' Hall: *Mr. William A. Budd*, on Thursday, at 3 p.m.

LEEDS.—Heed Street: *Mr. Frederick Holmes*, on Tuesday, at 2.30 p.m.

LIVERPOOL.—The Welsh Chapel, Holt Road, Edge Lane, West Derby: *Mr. Roger Parker*, on Thursday, at 2.30 p.m.

MANCHESTER.—72, Rochdale Road: *Mr. Ellis Southern Guest*, on Monday, at 2 p.m.

NEWCASTLE-UPON-TYNE.—The Central Vaccination Station, 21, Nuu Street: *Mr. John Hawthorn*, on Wednesday, at 3 p.m.

SHEFFIELD.—The Public Vaccination Station, Townhead Street: *Mr. William Skinner*, on Tuesday, at 3 p.m.

EDINBURGH.—Royal Dispensary: *Dr. William Husband*, on Wed-

nesday and Saturday, at 12. The New Town Dispensary: Dr. James O. Affleck, on Wednesday and Saturday, at 1.

GLASGOW.—The Hall of the Faculty of Physicians and Surgeons: Dr. Hugh Thomson, on Monday, at 12. The Royal Infirmary: Dr. Robert Duulop Tannahill, on Monday and Thursday, at 12. The Western Infirmary; Dr. David Caldwell McVail, on Monday, at 1 p.m.

Candidates for the certificate by examination are recommended to communicate some days beforehand with the Examiner at whose station they propose to attend.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN: SCHOOL OF PHARMACY.—The session will commence on October 1st, 1885, and extend to July 31st, 1886. Lectures on Chemistry will be delivered by Professor Dunstan, on Monday, Tuesday, and Wednesday mornings, at 9 o'clock, commencing on Monday, October 5th. There will be two courses of sixty lectures during the session—the course which commences in October and ends in February being repeated, with additions, in the following five months. Each course will be complete in itself. Demonstrations in Practical Pharmacy will be given by Joseph Ince, F.L.S., under the direction of Emeritus Professor Redwood. Lectures on Botany and Materia Medica, by Professor Bentley, on Thursday, Friday, and Saturday mornings, at 9 o'clock, commencing Thursday, October 1st. During the session, two courses of lectures will be delivered, each consisting of 60 lectures. The first course, extending from October to the end of February, will comprise Botany and Materia Medica with especial reference to Structural Botany, and the use of the microscope in distinguishing the various drugs; and the second course, which commences in March and extends to the end of July, will also comprise Botany and Materia Medica, with especial reference to Systematic and Practical Botany. Each course will be complete in itself, although each will have a definite object in view. The portion of the second course on Systematic and Practical Botany, consisting of 20 lectures, commences in May and ends in July. Separate entries may be made for this portion. The laboratories for the study of Practical Chemistry will be opened on Thursday, October 1st, at 10 a.m., under the direction of Professor Atfield, assisted by the Demonstrator of Practical Chemistry, Mr. F. W. Short, and the Assistant-Demonstrator, Mr. E. J. Eastes. Pupils can enter for any period at any date. A complete course of instruction, including the higher branches of Quantitative Analysis, occupies ten full months, and dates from the day of entry to that day twelvemonth. The laboratories are open daily. Vacation months, August and September. Prospectuses and further particulars may be had of the professors or their assistants, 17, Bloomsbury Square, W.C.

WEST LONDON PREPARATORY SCHOOL OF MEDICINE.—At the school recently organised in connection with the West London Hospital lessons are given in the subjects of the first part of the first examination for the conjoined diplomas of L.R.C.P. and M.R.C.S., namely, chemistry, physics, materia medica, and botany. Osteology is also taught, and the students are admitted to the practice of the hospital, which contains over 100 beds and has a large out-patient department. The time counts for a part of the four years' curriculum; and the fees are—18 guineas for one winter session, 25 guineas for one year. The school has an excellent laboratory—chemical and physical—and a complete collection of materia medica. One of the main purposes of the school is to give intending medical students an early insight into medical work so that they may, without needless loss of time or money, be able to judge whether or not they have chosen the right profession.

DEVON AND EXETER HOSPITAL, EXETER.—Medical and Surgical Staff: *Consulting Physician*, Dr. Drake; *Physicians*, Dr. Lewis Shapter, Dr. H. Davy; *Consulting Surgeons*, Mr. A. J. Cumming, Mr. T. U. Caird; *Surgeons*, Mr. Bankart, Mr. Budd, Mr. Harris, Mr. Domville; *House Surgeon*, Dr. Blomfield. The Hospital contains 214 beds (including special children's ward). There is a good library, museum, dissecting and *post-mortem* rooms. Attendance on the practice of this Hospital qualifies for all the examining boards. Arrangements may be made by which students can attend Midwifery. For further particulars as to fees, &c., apply to the House Surgeon. WEST OF ENGLAND EYE INFIRMARY, EXETER.—*Surgical Staff*, Mr. Bankart, Mr. Tosswill; *Registrar*, Mr. Roper. The Infirmary contains 50 beds. Arrangements could be made for students of the Exeter Hospital to attend the practice of the Eye Infirmary.

THE LONDON SCHOOL OF MEDICINE FOR WOMEN.—Three of the licensing bodies now admit women for their diplomas and degrees, viz., the University of London, the Royal University of Ireland, and the King and Queen's College of Physicians in Ireland. All the courses of lectures required by these bodies are given at 30, Henrietta Street, Brunswick Square, W.C., the sessions corresponding with those of other medical schools. Clinical instruction and lectures are given at the Royal Free Hospital, which contains 150 beds; attendance on confinements is obtained in connection with one of the lying-in hospitals, and practical experience of fever cases, a certificate of which is required by the Irish College of Physicians, may be acquired at the London Fever Hospital. The composition fee for the ordinary curriculum and clinical instruction at the Royal Free Hospital amounts to 125*l.* An entrance scholarship of 30*l.* is offered for competition at the end of September in each year.

BATH ROYAL UNITED HOSPITAL (120 beds).—Honorary Consulting Physician, Dr. Coates; Honorary Physicians, Drs. Goodridge, Cole, and Fox. Honorary Surgeons, Messrs. Stockwell, Fowler and Frecman; Honorary Medical Officers for out-patients, Dr. Field, Messrs. Cowan and Craddock; Honorary Assistant Surgeons, Messrs. Green, Scott, and Ransford; Dental Surgeon, Mr. Gainc; Pathological Registrar and Curator, Mr. H. Culliford Hopkins. The Hospital is recognised by the Royal Colleges of Physicians and Surgeons, &c., and licensed for dissections. It contains a library and an excellent museum, in which are a large number of interesting specimens, both in pathology and comparative anatomy. Fees for attendance—twelve months, 10*l.* 10*s.*; six months, 5*l.* 5*s.*; instruction in Practical Pharmacy, 5*l.* 5*s.* Number of patients admitted during the past year, 1,159; out-patients, 8,383. Operations performed, 189. Anæsthetics recorded, 199. For further particulars apply to Registrar and Curator.

LONDON FEVER HOSPITAL, ISLINGTON.—This Hospital is recognised by the Royal University of Ireland, and certificates of attendance on fever cases given by the Resident Medical Officer are accepted both by the University and by the King and Queen's College of Physicians in Ireland.

SPECIAL HOSPITALS IN LONDON.—Besides those special hospitals already mentioned, the practice of the following may also be attended:—The Hospital for Sick Children, Great Ormond Street, W.C. (9 a.m. every day). The Evelina and East London Hospitals for Children. The Hospital for Diseases of the Throat, Golden Square, W. The Central Throat and Ear Hospital, Gray's Inn Lane, W.C. The Hospital for Women (clinical lectures during the Session). St. Peter's Hospital for Stone. St. Luke's Hospital for the Insane (two Clinical Assistants appointed half-yearly). The National Hospital for the Paralysed and Epileptic, &c.

UNIVERSITY OF CAMBRIDGE, CERTIFICATE IN SANITARY SCIENCE.—The next examination for this Certificate, open to all whose names are on the Medical Register of the United Kingdom, will begin on Tuesday, October 6th. The names of Candidates must be sent, on or before September 23th, to Professor Liveing, Cambridge.

# Medical Times and Gazette.

SATURDAY, SEPTEMBER 12, 1885.

## THE PROSPECTS AND THE PROMISES OF MEDICINE.

EVERYONE who makes choice of a profession, is at some time exercised by a consideration of the prospects it presents to him for the attainment of "success." Few words convey at different times and to different men more varied meanings. Comfort, independence, wealth, the satisfied ambition of rank, or fame, or power have their share in that eagerly sought compound of material welfare which the world for convenience' sake groups under a single name. But all these are differently valued by each separate individual, who also imports into his estimate of their relative and collective importance the personal element of his own peculiar idiosyncrasies; so that for him success in life—whether he ultimately succeeds in attaining it or not, whether Fortune seems to withhold it to the last or to yield it almost unsought, or whether he carves it for himself from out a formless chaos of adversity—has a meaning differing by something subtle yet distinct from that assigned to it by his fellows. Not long since a would-be philanthropist took occasion to point out that of all the professions open to aspiring youth, medicine presented the least enticing prospects of material success. Already overcrowded, it promised to become still more so. Compared with other callings it was poor in prizes. Amongst its members competition was keen, and not always over-scrupulous in method. It is not possible to deny the general truth of these statements. For the modern Æsculapius, though he reach the utmost pinnacle of success in his profession, there is nothing like the Woolsack or an Archbishopric in store; the man whose personal skill has saved a hundred lives, and who has enriched humanity with knowledge that will save millions throughout years to come, receives from the State less honour and reward than awaits the successful soldier and the complaisant politician. But the whole truth is something more. There can be no doubt that one great secret of the attraction which calls so many to the ranks of our profession, and which enables them to find therein if not success its next best substitute, lies in the scope which it affords for the exercise and cultivation of a man's individuality. While human beings come into the world and pass out of it, there will be need of the doctor. But while ignorance and vice and folly breed sorrow and disease, there will be no lack of work for him to do; and in doing it he will succeed best who knows and appreciates not merely the bodily ailments, but also the several personalities of his patients. It is a trite saying that no man knows all minds. But the delicate shadings of character which one will miss are recognised by another, and *vice versa*. So it comes

to pass that, just as each practitioner comes in time to reckon amongst his patients mainly those whose mental leanings he is specially able to appreciate—there being as it were a link of unconscious congeniality between their natures and his own—amongst the diverse peculiarities of individual character, there are always to be found those whom the complemental individuality of some medical man will suit. In some sense this is a doctrine of affinities, but such affinities hold an important place in human nature, and their due appreciation is an important factor in real professional success. The practice of medicine, in short, is concerned with human nature no less than with the structure and the ailments of the human body. Herein lie at once its difficulties and its charm, and some would say, its dangers. The charm has been already alluded to as one of the great attractions of the profession. The difficulties are not greater than those which attend any work that is worthy of man's best efforts, and for which this life is all too short. Its so-called dangers will not deter him who enters on his calling with a reverent appreciation of its nobility, determined to fulfil its duties in the spirit of an upright honourable man. It is but a cynical doctrine, degrading alike to patient and practitioner, which teaches that the human nature which enters so largely into those problems of disease that we are asked to solve, shall be studied only in the abstract—as if anatomy were to be learned only in the dissecting room and not applied practically for the alleviation of the living sufferer; which would have the doctor comport himself like some physiological combination of spanner and cil-can, prepared to screw up the slackened bolts and to lubricate the creaking joints of the human machine with a cold metallic accuracy: but which would sternly repress any interchange of human sympathy and friendship. By friendship is here meant, of course, something infinitely different from the familiarity which sometimes masquerades under that name, and whose very essence is the contempt which is sooner or later proverbially developed on one or both sides. No practitioner was ever yet the worse for having honestly gained the honest friendship of a patient, and it would be hard to say how often and how greatly such friendships have proved of benefit to both. What would the world at large gain by the practice of a social asceticism which would seriously limit our usefulness by setting up a bar to mutual confidence, and rendering barely possible the exercise of mutual respect?

On the whole, then, there is encouragement as well as welcome to those whose names will appear in the Students' Roll of 1885. They may be assured that there is still room in the profession for all those who adopt it with unselfish earnestness, and that honest labour for lofty aims will not fail of due reward. We might go further still, and say that there is probably no other calling in which a man, who really knows his work, and who performs it in the courteous spirit of a conscientious gentleman, will find so much satisfaction, and the world so pleasant a place to live in. Whatever be the line of practice that he may have adopted, the educated physician is surrounded by opportunities of keeping touch with those who are making the history

of other branches of knowledge. His daily work is on the borderland of all the sciences ; he can gather information from the nooks and corners of existence ; and it is his province to teach some of the truths most important to the welfare of mankind. And all this can be done, can be best done, without any sacrifice of humanity to science. His words of warning, of advice, or of encouragement will not be the less regarded because they fall from the lips of a man who—while he cannot afford to be merely sentimental—feels real sympathy and exhibits true kindness. Surely this is not a despicable prospect, but one which any man might gladly strive to realize. Towards it there runs no certain road but that of honest work—work which is good in plan, in inception, and in execution. Genius will raise one man in a million above his fellows ; but even genius, in so far as it is more than an infinite capacity for taking pains, acts by making a man work exceptionally well in an exceptional manner. Whatever the superstructure, and whether that be completed or not, the foundation of success in the medical profession, as in any other, is painstaking application. Work done at its proper time and in the proper way, steadily and conscientiously, is one of the best safeguards against the worries and disappointments which injure the health and the *morale*, and sour the temper of the half-hearted dreamer. Work so done in such spirit enables the doer to face his examinations as the well-mounted horseman takes the easy fences in the hunting field, almost in his stride. His professional life is the great examination of the medical man, who can never cease to be a student, and his achievements there must be largely dependent upon the thoroughness of his earlier training. For such a man the rewards of material prosperity are reasonably assured ; but they will not be found sweeter than the consciousness of good work well done to the best of his ability. And, although public honours and distinction have their value, it is also true that in this world, in which it is not always the best man who wins, it is sometimes better to deserve than to have attained “success.”

---

#### PHTHISIS AND THE HIGHER EDUCATION OF WOMEN.

IN Dr. Crichton Browne's introduction to the translation of Dr. Hertel's work on “Overpressure in High Schools in Denmark,” some statistics are given as to the relative liability of the sexes to phthisis, which are, we believe, entirely new, and which are certainly deserving of close attention. “At all ages above thirty-five,” Dr. Crichton Browne says, “men die of consumption in much larger proportion than women ; the rate for England and Wales, calculated on a period of twenty years (1861–80), was 3,535 per million living for the one, and 2,613 for the other. From twenty to twenty-five years of age the death-rate from this disease is almost equal for the two sexes ; thus in the twenty years 1861–80 it was per million living 3,688 for men and 3,748 for women. But from five

to twenty years of age a very different state of things is met with, for then the death-rate of females from consumption is vastly in excess of that of males. In the twenty years 1861–80 the death-rate from consumption of males between fifteen and twenty years of age was 954 per million living, while that of females between the same ages was 2,740. In males again from five to fifteen years of age the death-rate from consumption was 459 per million living, while in females it was 669.”

Various interpretations may be put upon these remarkable figures, but there seems to be no escaping Dr. Crichton Browne's deduction from them that they supply a clear indication of the importance of avoiding in the education of girls every condition and habit of life that can possibly contribute to the establishment of lung disease. That studious pursuits unduly prolonged may, by the imperfect expansion of the lungs which they involve, conduce to consumption, cannot be doubted, and that the nervous excitement which necessarily accompanies rivalry and competitive trials in beings of sensitive organisation, has the same tendency is more than probable. Were there no other answer to the unphysiological demand that boys and girls should be educated on the same plan, along the same lines, and at the same rate, it would be sufficient to point out that girls from fifteen to twenty years of age are three times more liable to consumption than boys.

Consumption has, of course, been greatly restricted in its ravages by social and sanitary reforms, and the death-rate from it has been falling steadily at all ages during the last twenty years. But curiously enough girls from five to fifteen years of age, who ought, we should have thought, considering their indoor life, to have benefited by these reforms more than boys, have really benefited by them less. The death-rate has in their case fallen considerably less than that of boys, and during the last five years it has actually ceased to fall and has indeed risen slightly. Here we have, at any rate, the suggestion that the pressure which has indisputably been brought to bear upon girls of all classes of late years has led to the extension of phthisis and counterbalanced some of the gains to health which the sanitary work has accumulated. The case of Ellen Watson—a brilliantly distinguished graduate of London University, who succumbed to consumption in her twenty-fourth year—is referred to by Dr. Crichton Browne, as a typical one of pulmonary mischief set up by education when pursued not wisely but too well, while that of Professor Clifford, Ellen Watson's teacher, is pointed to as a corresponding instance in the opposite sex. It is unfortunately too true that young men and women of the highest promise often fall victims to phthisis, and that in many of them there are good grounds for believing that they have squandered their living in riotous study, and a prodigal expenditure of strength. The whole subject of the connection of phthisis with educational excesses is eminently deserving of investigation.

---

## EDITORIAL NOTES.

THE following are the arrangements by which the opening of the ensuing session will be celebrated at the various medical schools. At St. Bartholomew's Hospital there is, as usual, to be no introductory address on October 1st, but in the evening there will be the ordinary old students' dinner; on October 8th Mr. Marrant Baker will open the session of the Abernethian Society with an address. There will also be no address at Charing Cross, Guy's, and the London Hospitals. At the last-named there will be no public ceremony at all, as the College is in the builder's hands, but at Guy's there will be the usual *soirée* on the evening of the 1st. At St. George's Hospital the address will be delivered at 4 p.m. by Mr. Timothy Holmes. At King's College the prizes will be distributed and an address delivered by the Bishop of London at 4 p.m. At St. Mary's the Session will open with an Introductory Address by Mr. Pepper, after which the prizes will be distributed by Dr. Handfield Jones. The Annual Dinner of past and present students will take place the same evening, Dr. Cheadle in the chair. On Friday, October 2nd, a *Conversazione* will be held in the New School Buildings, at 8.30 p.m. At the Middlesex Hospital Medical School, which is now entering on its second half century, Dr. J. K. Fowler will occupy the position of Orator, and there will be the usual dinner in the evening. At St. Thomas's the address will be delivered by Mr. Mackellar, and the annual dinner will be held in the Governor's Hall at 6.30. At University College Professor Schäfer will give the address at 4 p.m., and the annual dinner will be presided over by Mr. John Marshall. At the Westminster, as already announced, an entirely new medical school will be opened on the 1st. Mr. George Cowell will give the address at 3 p.m., and there will afterwards be a *conversazione*. In the provinces, the Yorkshire College, at Leeds, has secured Mr. Jonathan Hutchinson to officiate at the opening on October 1st of its second session, which corresponds to the fifty-fifth session of the Leeds School of Medicine. At University College, Liverpool, the opening meeting of the Session will be held at St. George's Hall, on Saturday, October 3rd, at 3 p.m., when the prizes will be distributed by Lord Derby, and the address delivered by Professor Bradley. At Sheffield, the address will be given on the 1st, at 5 p.m., by Mr. Rutherford Pye-Smith. At the other provincial schools, the session will open, we believe, without an address on the 1st, though at Newcastle there will be a distribution of prizes at 2 p.m. by Mr. Gainsford Bruce, Q.C.

THE cholera is still raging in Spain, though with diminished severity, as shown by the smaller proportion of deaths to cases. On Wednesday last, 1,569 cases and 572 deaths were recorded. In France, the epidemic has not increased to any notable extent; but there has been an outbreak in Sicily, at Palermo, in the house, it is said, of a laundress who had washed the linen of a sailor disembarked from a French steamer. Cholera

is also stated to have broken out in Belgium at Mons; and during the week the death of a man at Cardiff, who had been engaged to unload a ship from Spain, and had drunk some foul water shipped in that country, has caused a certain amount of consternation in this country. Active measures were, however, at once taken, and the disease has not spread.

THE accounts that reach us of the state of things in Spain grow more and more terrible. The articles of the special correspondent sent out by the *Times*, and still more the letters from a medical correspondent published in the *Scotsman*, bring before us a tale of horror which needs a Defoe to do it justice. And still in England not a finger is raised to send out help, our city merchants being apparently indisposed to be charitable to a nation which taxes our manufactures. This neglect is not unnoticed in Spain, as the following extract from one of the letters of the *Scotsman's* medical correspondent will show: "Last night I was sitting with my good friend the cura, smoking our cigarettes. There is, I think, a certain Freemasonry between us which rises above creeds, as we have stood together often in the same scenes of woe and sorrow. 'Amigo,' he asked drily, 'how many do you think have already died in this epidemic?' 'Well, padre,' I replied after what I considered a decent interval of silence, 'I should say about seventy thousand.' 'Yes, my friend, that is my calculation, too; and do me the favour to answer another question—Which, in your opinion, was the bloodiest war of modern times?' 'The Civil War in the United States; and in that war, padre, as I read the other day, from the opening shot at Fort Sumter, including seven days' terrible fighting in what are called the battles of the Wilderness, down to the day when the rebel leader gave his sword up to his victorious junior before the lines at Richmond, there fell in the Northern armies in battle 66,000 men.' 'Yes, my friend, and to every quarrel where blood is to be shed, neutral nations send money, doctors and nurses; but here, with a nation in its agony, all Europe stands aside with folded arms gazing upon us, and criticising our statistics as we die.'"

THE fifty-fifth annual meeting of the British Association was opened on Wednesday, at Aberdeen, under the presidency of Sir Lyon Playfair. The President delivered a long and most interesting address on the relations of science to the public weal, comment on which we must defer through want of space until our next number.

OUR Pharmaceutical friends would seem to have lofty ideas as to their own functions, for we observe that at the recent Congress at Brussels a discussion on cooking and drinking water took place, but such a debate was perhaps not inappropriate, seeing that a few days before they had resolved that the title of Doctor of Pharmacy ought to be substituted for the now generally used terms of apothecary, chemist, &c. We can readily believe that they were in earnest when they decided that "this assembly desires to see pharmaceutical patent medicines absolutely prohibited."

THE death-rate of London last week touched a lower point, viz., 15·8 per 1,000, than it has reached for exactly four years. The month of September is generally almost the healthiest of the year; the diarrhoea curve which usually attains its highest in the hot weather of July and August has then almost fallen to its normal level, while the cold weather mortality from bronchitis, whooping-cough, &c., has not yet begun to rise. If only enteric fever, the autumnal disease *par excellence*, is not more than endemically present, a temperate September is almost always distinguished by a low death-rate. Last week London was fortunate in its mortality compared with other large centres of population; only two of the 27 large English towns taken

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past thirteen weeks.

account of by the Registrar-General scored a lower death-rate, viz., Huddersfield and Hull. The London death-rate, in fact, was nearly 4·0 per 1,000 lower than the average death-rate of the other large towns. The total deaths in London were 252, and the zymotic deaths 134 below the average. The deaths of London residents from small-pox numbered only 6, but there was a slight rise in the week's admissions. The deaths from scarlet and enteric fever, whooping-cough, and diarrhoea were also below the average, the mortality from the last-named disease being less than half the average; but the deaths from measles and diphtheria were above the average. Diarrhoea was very fatal in Birmingham, Portsmouth, Salford, and Preston. The temperature of the week was 2·7° below the average and there was aggregate rainfall of 0·40 of an inch.

LAST Saturday, in the unavoidable absence of the Home Secretary, a numerous and influential deputation

representing the Local Board and inhabitants of Hackney, waited on Mr. Godfrey Lushington, to whom they presented a memorial drawing attention to the "dangerous and pestilential condition of the river Lea," and suggesting "a large scheme of drainage as a necessary work for the future" as well as the urgent need for temporary relief not only by frequent flushing, but by dredging the river bed. Mr. Gane, Chairman of the Local Board, Mr. Runtz, the representative of the parish on the Metropolitan Board of Works, Sir Guyer Hunter, and Sir Lewis Pelly were among the speakers. Mr. Gane suggested the turning of the Tottenham Sewage into the Metropolitan system, but Mr. Runtz urging, as we did in our article of last week, that those sewers were already over-taxed, advised the construction of a Lea Valley sewer to convey the sewage of the entire district to Barking, and that the Tottenham Board be meanwhile compelled to use the same means for deodorisation as have been employed with very fair success by the Metropolitan Board. The cost of the sewer spread over 50 years, would not, he thought, necessitate a rate of more than 5*d.* or 6*d.* in the pound. Sir W. G. Hunter thought that if the unanimous concurrence of all the local authorities could be secured, the burden would be even less, but meanwhile urged the adoption of temporary measures, and the reconstitution of the Lea Conservancy Board with increased powers. Sir Lewis Pelly would have the Imperial Government interfere, and take the matter in hand, relying on the subsequent sanction of Parliament.

MR G. LUSHINGTON'S reply was even more unsatisfactory than those which are usually vouchsafed to deputations; though it must be conceded that he could not speak with the authority of an actual minister. The Home Secretary, he said, sympathised with them, but could not rectify the evil by a stroke of the pen. He could not order the Water Company to take less water than they were entitled to and the people of London required, nor the Conservancy to do more in the way of cleansing the river than they had done, nor the Metropolitan Board of Works to undertake the disposal of more sewage than they considered their sewers could accommodate. Legislation alone could effect a remedy, but it was not in his power to anticipate the form it should take, nor the public department or private individuals by whom it should be promoted. Of the duties and shortcomings of the Tottenham Board he said nothing.

THE inhabitants of north-east London, however, are in real earnest, in fact in a state bordering on open insurrection, so much so, that one of the speakers at the demonstration that took place later in the day deemed it necessary to deprecate resort to violence. This demonstration was, as befitted the occasion, grim and funereal, albeit almost grotesque in its hideous paraphernalia. Black boats, draped with crape, were carried on carts, while black and white banners were plentifully displayed, bearing such mottoes as "Death," "Sewage and Starvation," "Tottenham Sewer, once our River Lea," "Cholera invited," &c., and profusely

adorned with skulls and crossbones, most of the devices having been designed and executed by a boat proprietor, who felt a painful pleasure in conducting to the effectiveness of the scene, his takings having fallen from 35*l.* to 2*l.* weekly, in consequence of the state of the river. A steady downpour of rain added to the gloom as the processions numbering some thousands in all wended their way, enlivened only by the bands of the Conservative and Radical Clubs.

THE meeting was even more representative than the previous deputation. On the improvised platform were the members for the present borough, the Liberal and Conservative candidates, the leading members of the Local Board, the several political clubs, the clergy, medical men, and inhabitants generally. The matter of the speeches was the "old, old story," but the Conservative candidates were loudest in their demand for radical reform, Mr. Darling urging continued agitation until the authorities, and especially the Lea Conservancy, were roused to action, and Sir Louis Pelly stating it as his opinion that the nuisance had attained to such proportions as to be beyond the reach of parochial authority, and that as the subject was one of deep interest to the whole of the metropolis, he thought the meeting was quite justified in appealing to the Local Government Board. Dr. East moved that the future members of Parliament for the Borough (of whom we sincerely trust Sir Guyer Hunter will be one) should seek to obtain a Select Committee of the House of Commons on the whole subject, and that the existing Local Committee be made permanent.

THE anomaly of the exemption of the metropolis from the provision of the Public Health Act adds to the difficulties by which the question of the Lea pollution is surrounded. The sufferers therefrom being within the metropolitan area cannot, in the present state of the law, appeal to the Local Government Board, though the originators of the nuisance are within its jurisdiction, and any sewerage scheme for the relief of the population of the East London Boroughs would come under the cognisance of that Board, and be entirely out of the jurisdiction of the Home Secretary, who is the supreme arbiter for the metropolis in such matters. It is not generally known that the process by which the Tottenham Board pretend to purify their sewage is that of Hillé, one which has long been proved utterly useless for the purpose. It is simply the old lime process with the addition of carbolic acid. Could not the Local Government Board compel them to make some temporary arrangement with the A.B.C. Company pending the construction of sewerage works for the whole valley of Lea? Whatever opinion may be held as to the value of the artificial guano as a manure, or the commercial success of such undertakings, we can assert from personal knowledge that the A.B.C. effluent is odourless and colourless, which cannot be said of Hillé's.

THE late public excitement about the pollution of the River Lea and the sanitary state of Tottenham, has stimulated the Local Government Board to make public a report which has been pigeon-holed since the latter end of May. About that time, in consequence of the prevalence of diphtheria and enteric fever in the Tottenham Urban Sanitary District, Mr. R. D. R. Sweeting made a report upon it. From diphtheria during 1884 there were 48 deaths, and besides these 33 deaths referred to various throat troubles, such as cynanche, laryngitis, ulcerated throat, &c., may with great probability be also attributed to diphtheria. Up to the end of April this year there were 17 deaths from diphtheria. With the exception of 7 cases all these deaths were of children under ten years of age. From enteric fever during 1884 there were 29 deaths, and up to April 9th of this year there were 7 more; in all cases the victims were above 15 years of age. The fatal cases of both these diseases appear to have been evenly distributed over the whole district. As a result of his enquiry M. Sweeting reported that ventilation of the sewers is irregularly provided throughout the district, and is in many places inadequate. Systematic flushing of the sewers is not provided. He found that there was a strong public belief that these diseases were due to faulty sewer conditions. The water supply of Tottenham is intermittent, and as a consequence water is stored in cisterns many of which were so situated as to render the water stored in them unfit for drinking. Defects in the house drainage of the usual kind were found in 65 per cent. of the houses where enteric fever had broken out, and in 20 per cent. of those where there had been cases of diphtheria. The want of regular systematic scavenging is pointed out as a serious cause of complaint, and many of the houses are unprovided with ashpits. Since the last inspection eleven years ago by Mr. Netten Radcliffe, the Moselle Brook has been culverted in a great part of its length, and where still open its bed and sides have been cemented, but notwithstanding he found it in places foul-smelling, and silted up with sewage deposit, the result of the emptying into it of the overflow from an 18-inch sewer. There are no adequate means of isolation, but the Sanitary Committee of the Local Board are said to be on the look-out for one. The report concludes with recommendations for amending the various defects to which attention has been called.

PEASANT proprietorship, which is proclaimed in some quarters as the surest means of elevating the masses and relieving national want, does not seem entirely satisfactory when the results for which it is responsible in other lands are examined with the unprejudiced eye of the sanitarian and tested by the principles of political economy. The French peasantry, for instance, are quoted all the world over as examples of thrift, and in France peasant proprietorship has now been for long a part of the national order of things. But the patch of landed property to which each peasant is so rigorously *adscriptus*, is so small, or so broken up into scattered morsels, that "thrift" becomes for the most part only another name for the struggle

of keeping body and soul together, which allows no time and no means for the softening or embellishment of life and its surroundings. The pictures which Lady Verney gives of peasant existence—it scarcely accords with our ideas of life—in France are corroborated by other observers, and they afford the clearest explanation of the stationary condition of the population of the country. Every additional mouth to feed is a serious burden to people who buy their land, when they can afford to buy at all, by the *toise* (six feet square) or so at a time. Amidst the hardy French Canadians, who have trebled their numbers within the last hundred years, the average number of children in a family is six. In rural France there are seldom more than two or three, not rarely none; and the reply to questioners on the subject is “*Je n'en ai pas; á quoi bon avoir des enfants? Il faut vivre.*” This “voluntary limitation of families” is forced upon the people as one of the conditions of their life. In the words of a Frenchman remarking on this fact, “*Ils n'ont pas le Malthus, mais ils pratiquent instinctivement ses principes.*” A Swiss writer—and some of the Swiss cantons furnish examples quite as striking—says, “It is only because the French have such small families and the population is absolutely stationary, that the peasant proprietors can live.”

IN some alarm, apparently, at the numerical stasis of the population, the French Chamber of Deputies has recently revived a law of the Revolution which provided board and education at the expense of the State for the seventh child of French families, and have agreed to a vote of 400,000 francs for the purpose. By the law of 1805 the privilege was limited to boys only; but both sexes are now to be placed on an equality, the only restriction being that the children shall be in necessitous circumstances. The State will not adopt the child before the age of six, and will again disown it on the completion of its education. The paradox appears complete. The liberty which enforces the ownership of small holdings by compelling the subdivision of a man's landed property amongst his children, leads to the abuse of individual freedom. The equality which gives a share of the land to every one is no friend to fraternity, for these small owners are admittedly bad and jealous neighbours. And the bounty which was offered eighty years ago with a view to recruit the military strength of the country, exhausted by wars and pestilence, is resuscitated in 1885 by a Government startled into offering a premium for the growth of the population which its own laws keep in check. England is not a sparsely populated country; but we should be sorry to see the growth of its people stunted by such a cause as this. Providence may not be the most striking virtue of the English labourer; and his lot is too often hard, monotonous and unhealthy. But we would not willingly see it transformed into a sordid and unlovely struggle for a bare existence, with no room for beauty and no leisure for enlightenment.

## CORRESPONDENCE.

### THE DISSENSIONS IN AMERICA.

[To the Editor of the Medical Times.]

DEAR SIR,—I notice in the *New York Medical Record*, of August 1, a quoted editorial article from your Gazette (date not given). Instead of replying directly to your editorial, it may be just as well to send you a copy of a letter sent to Sir William MacCormac a few days ago, in reply to a letter from him, published in the *Boston Medical and Surgical Journal*, of August 13th. The numbers of the Journal of the American Medical Association which I send with this letter, will substantially answer your editorial, and all other similar editorial articles that have appeared in various journals in Europe.

I am, Sir, yours, &c.

N. S. DAVIS.

*Journal of the American Medical Association*,  
65, Randolph St., Chicago, Aug. 20, 1885.

To SIR WILLIAM MACCORMAC, 13, Harley Street,  
London.

MY DEAR SIR,—Having just read in the *Boston Medical and Surgical Journal*, of August 13th, your letter to Dr. J. Collins Warren regarding the International Medical Congress, I feel that it is incumbent upon me to reply to it personally, not only on the part of the medical profession of the United States, but also on the part of the American Medical Association; and also on account of your manifest misapprehension of the “serious disagreement” of which you speak in your letter. *Imprimis*, I will say that everything that has as yet been said by the European press generally, and by the letters of individual men in Europe, bears the evidence of misapprehension and misinformation. Our foreign *confrères*, have accepted, unreservedly, the statements of certain medical journals and private parties in Philadelphia and New York, who from the very first of this little misunderstanding (which should be a private affair until it is definitely settled in one way or the other) have endeavoured to obstruct the Committee of Arrangements for the Ninth International Medical Congress. I have said that it should be a private affair until it is definitely settled. It is unfortunate that some Americans have a morbid tendency to hang their laundry on the front street, where each passer-by may tell at a glance the character and extent of his neighbour's wardrobe. But still, it ill becomes his neighbour to tell it the world; still less does it become the outside world to animadvert on it before hearing both sides of the question. The profession in Europe seems to have heard of this matter from one side only, and, without being conversant with the facts, have hastily jumped to very illogical conclusions. As there is only one body in England representative of the whole English or British profession, the British Medical Association, so there is only one in the United States which could, under any possible circumstances, represent the profession in the United States; and that is the American Medical Association. From Maine to California, and from the British possessions on the North to Mexico on the South, every State and Territory is represented in that body. Now, you say in your letter that you are “sure that it was present to the mind of every one there (Copenhagen) that the invitation (to have the Congress meet in Washington in 1887) was one from the profession of America and not from any section of it, or any particular medical society in it.” To which it may be replied: The invitation was extended by Dr. Billings, and Dr. Billings had been appointed to extend the invitation. Who appointed him? Whence came his authority for assuring the Congress that it would receive a warm welcome in this country in 1887? He was one of a committee appointed at a meeting of the American Medical Association.

tion, by the President of the Association, who acted for the Association, and by the authority of the Association. And the necessary funds for enabling this Committee to perform their work were voted to it by the Association; and they drew upon the Treasurer of the Association for the money. Further than this, the Committee was known and recognised as the Committee of the American Medical Association on the Organisation of the Ninth International Medical Congress. They themselves recognised the fact that they were the Committee of the American Medical Association; else why should they have reported to the Association at its last meeting, in April, 1885? Can any one imagine a body of sane men reporting to another body to which they owe nothing, and to which they are in no way amenable? Yet, when the creator of that Committee, the body to which it owed its very existence, saw fit, on just grounds, to revise a part of their work, and to appoint additional members to the Committee to aid in such revision, they boldly say that the Association has nothing to do with it. The merest tiro in Parliamentary law knows that the power which appoints a committee may refuse to accept any of the work, and appoint a new committee if it see fit. That right is unquestionable, and unquestioned save by those who know not whereof they speak. The American Medical Association has invited the Congress to meet in Washington in 1887, and the invitation has been accepted. The American Medical Association is fully competent to make all necessary arrangements for that meeting, on as liberal a basis as has characterised any of the preceding Congresses. We only ask that our brethren in Europe will reserve their comments until the programme is completed and before them.

I am, Sir, yours, &c.,  
N. S. DAVIS.

[We have not space in the present number to deal fully with Dr. Davis's letter or with the other documents stating the case of the American Medical Association which have reached us. We may, however, point out here that the British Medical Association has never claimed to represent the whole English profession, though we believe its claim to do so, if it should ever be so ill-advised as to make it, would be much more valid than the claim put forward on behalf of the American Medical Association. Whatever Dr. Davis may say, the fact remains, as the officers of the London Congress have stated, that on no previous occasion has any medical body attempted to capture and run the International Congress as the American Association is now attempting to do.—EDITOR *Medical Times*.]

**NOTES, QUERIES, AND REPLIES.**

**THE CASE OF DR. BRADLEY.**

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Will you kindly publish the following additional list of subscriptions received for the Bradley Fund?

I remain, yours faithfully,  
RICHARD JEFFREYS.

Eastwood House, Chesterfield.

P.S.—The following is a copy of a letter received:—

Cromwell House, Chapel-en-le-Frith,  
near Stockport.

DEAR SIR,—I enclose cheque for one guinea towards the subscription you are getting up for Dr. Bradley. I was in the Court

during the hearing of the case, and thought the verdict a most shameful and illegal construction of the evidence. With sincere sympathy for your cause and trusting it may prosper,

I remain, Sir, yours, &c.,  
R. Jeffreys, Esq. W. STIRLING ANDERSON.

- Mr. Frederick William Jowers, Mr. Edward Lund, each, £5 5s.;
- Mr. C. A. Aitkin, £3 3s.;
- Dr. T. Grainger Stewart, Dr. Arthur W. Edis, Mr. Septimus W. Sibley, Dr. Anthony H. Corley, Dr. Marriott, Dr. J. T. Banks, Dr. Dyce Duckworth, each, £2 2s.;
- Mr. G. O. Siddall, Dr. M. Griffith Evans, Dr. Robert Laurie, Mr. Charles J. Pinching, Dr. Thomas William Kyle, Mr. M. George Biggs, Dr. C. J. Cullingworth, Dr. George Ernest Herman, Dr. Arthur W. Orwin, Dr. J. Halliday Croom, Dr. G. H. Rickards, Dr. Joseph Coats, Dr. Withers Moore, Dr. S. J. Ramsbotham, Dr. W. J. Sinclair, each, £1 1s.;
- Dr. J. Caldwell Unthoff, Dr. Henry S. Ferguson, Mr. Joseph Bell, each, £1;
- Mr. Ethelbert Hosking, Mr. Langsford Clay, Dr. G. Dickson, Dr. C. K. Hitchcock, each, 10s. 6d.;

## CLINICAL REMARKS ON PERITONITIS.

CHRONIC, OR SUB-ACUTE, PERITONITIS IN THE YOUNG—TUBERCULAR PERITONITIS AND “TABES MESENTERICA”—TYPICAL CASE—INCIDENTAL REMARKS ON SUPERFICIAL AND DEEP PERCUSSION—PHYSICAL DIAGNOSIS OF THICKENING OF THE GREAT OMENTUM.

By W. T. GAIRDNER, M.D., LL.D.,  
Professor of Medicine in the University of Glasgow.

(Continued from page 275.)

THE case which I mentioned to you as comparable in some respects with that of Jane M., is that of Mary Jane S., aged 10, who was admitted to the Western Infirmary on the 13th March, 1885. There is this marked difference, however, between the two cases, that while I was never at any time very uneasy as regards the one already narrated, I felt on the other hand, from the first, that Mary Jane S. was in great, even immediate, danger of collapse; and it was only from the observation of the good effects within a few days of the remedies employed, that I

began to hope that she might so far recover as to be a chronic invalid, and that with very great care she might possibly escape for a more or less considerable time. Yet she, not less than Jane M., had passed for a healthy child up to three weeks before admission; her previous history is, indeed, not so well known to us, but we know that she was at school up to a week before the day of her admission, although she is described as listless and drowsy and unable to learn; also as physically very weak during her reported illness, *i.e.*, from the latter end of February. I am tolerably certain, but still without positive evidence, that she may have been failing in health even before this; her first symptoms were in every particular those of what is commonly called “*tabes mesenterica*” (or, popularly, “consumption of the bowels,” as in the elder sister of Jane M.), *i.e.*, flatulence with pain, tumid abdomen, diarrhoea, some cough, emaciation, and probably more or less fever. It was the diarrhoea, gradually increasing in severity, that finally drove her away from school, and led to her being brought to us. Vomiting had been an early, but by no means a persistent, symptom, being brought on apparently by some powders prescribed for her. There was nothing to lead us to infer that she had been the subject of any serious illness preceding the present.

When she first came under our observation I was afraid to handle or disturb her too much. There was great tenderness of the whole abdomen, which was much distended, and the superficial veins very much

enlarged. Had it been a case of typhoid fever (and there was no absolute security that it might not prove to be so) I should have been apprehensive of perforation, either actually present or impending. The face was flushed and bedewed with perspiration. The temperature, however, did not exceed  $101.6^{\circ}$ , and I noticed that she had not the peculiar aspect of acute peritonitis from perforation; nor had she the disposition to draw up the knees, nor to lie in a constrained position on account of pain. There were no rose-spots, and I concluded, on the whole, that it was probably not a case of typhoid fever. The statement of the physical signs in the abdomen is very much a repetition, with variations in detail, of what we observed together so carefully in the case of Jane M., and accordingly I shall abstain from giving you all the facts over again. But in the chest there were both symptoms and physical signs not present at any time in Jane M.'s case; in the main those of a mild general bronchitis, but without any expectoration; and we learned that cough, though not much complained of, had even preceded the abdominal symptoms. Both mucous and sonorous râles were heard on both sides, predominating towards the bases. The percussion of the chest was normal.

These facts were not fully ascertained till three days after admission, as I was unwilling to disturb her by too much examination. Opium was at once begun in doses of  $\frac{1}{3}$  gr. with gr. ij of quinine three times a day. Fomentations were applied to the abdomen evidently with much relief. On the 16th of March she was already so much better that I was able to present her to the clinical class, but still with extreme precautions as to handling the abdomen overmuch. We were able at that time to make out that, as compared with a purely tympanitic abdomen (e.g., from flatus), or a purely ascitic abdomen from serous effusion in the peritonæum, there were slight variations in the elastic resistance of particular parts of the abdomen. These differences further corroborated and reduced to order, by a very delicate and careful use of percussion, gave us as a final result the diagram you see here, which I

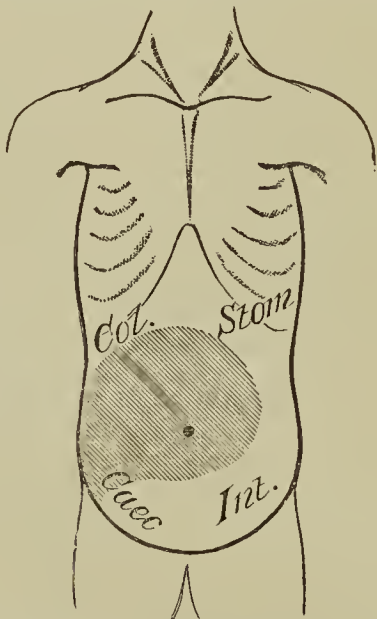

Diagram of percussion of abdomen in case of Mary Jane S., æt. 10.

do not, however, mean to do more than indicate generally as emerging from several examinations by myself and Dr. Middleton, sketched out and perhaps a little idealised, on the blackboard in lecturing on the case within the next week. In other words, the observations had to be made with such reserve, and the facts themselves were so difficult to demonstrate, that I cannot suppose them to have been made quite clearly apparent to the whole class, or perhaps in all

points even to the very few who were allowed to participate in the observations. Still, the report of the 16th March bears that I had no doubt at all, myself, even at that date, as to the essential facts, and you may therefore compare this diagram of them, constructed on the basis of data then obtained, with the much more detailed report, at a much later date (July 10th), of Jane M.'s case, which almost every one of you could verify for himself. The facts are essentially the same in both cases—there is a relatively dull area corresponding, I suppose, with the great omentum, which you can shew to be *relatively* dull (but only to the most extremely delicate and superficial percussion-stroke) by comparing it with the gastric area or with that of the colon, cæcum, or intestine anywhere except at the anatomical seat of the great omentum. In other words, the great omentum is thickened in front of the small intestines; but not so much thickened as to prevent your being able easily to elicit everywhere the tympanitic note proper to the abdomen generally, *which only fails to be elicited in this particular area when the force of the percussion-stroke is very carefully reduced to a minimum*. And it is further to be observed (though I will not now trouble you with the details) that both Dr. Middleton and I succeeded in convincing ourselves, and I think also some members, if not all, of the class at this period, that there was no considerable amount of freely gravitating fluid (or perhaps of fluid at all) in the abdominal cavity to interfere with the observations in other respects. We concluded, therefore, that there was thickening of the peritonæum generally, and especially of the great omentum, from fibrinous deposits, including, perhaps, some fluid, but not such an amount as to give rise to physical signs as such.

Upon this subject of the *minimised percussion-stroke*, I should like to take this opportunity of making a few remarks incidentally, because it is one, in my opinion, erroneously, or at least ambiguously, stated in some of your text-books; and practical errors and confusions arising from this source are not uncommon in my experience.

Most persons, and almost all beginners, in employing percussion for the delimitation of organs, *err by percussing too hard*. The desire is, naturally enough, to get a definite and recognisable *quantity* of sound; and, by percussing hard, more sound is got, of course, than when, as in the observations just referred to (case of Mary Jane S.), a carefully minimised stroke is employed. But in increasing the quantity of sound so as to make it apparently or really more easily audible, you are, in most cases, *exactly in a corresponding degree reducing the value of your results*. In other words, the carefully minimised stroke gives you approximately exact definitions: while the stronger stroke necessarily gives you less exact, or wholly inexact, limits of dull and clear areas under like circumstances; the degree of inexactness or vagueness of the results increasing immensely with every degree of added force employed, so that, according to the quite ordinary mode of percussion used by many persons, and by almost all young or inexperienced persons, nothing like exact results can ever be obtained at all. Both in the case of Mary Jane S., for example, and in that of Jane M., all the best results of our percussion would have wholly escaped us, had we employed such a force of percussion-stroke as I observe many of you employ through an instinct and habit that it seems to take much teaching to get over.

Piorry, the great master of *mediate* percussion (as he first called it), and unquestionably a very great man in this art, appears in his numerous writings to proceed throughout on the assumption that percussion operates directly downwards, or in the direction only of the impact, in the way of educing the characteristic sound; and accordingly he speaks always of *superficial* and of

deep percussion (*pereussion profonde*) as if they were facts of the same order and of equal exactness in the delimitation of organs. No doubt Piorry had ways of his own of attaining valuable results both from superficial and from deep percussion, and of thus obviating practically some of the faults of his method, or, at all events, of his doctrine. But he left a legacy of fatal confusion to his successors by teaching that for every organ or structure in the body there was a process of delimitation of its deeper relations, which he implicitly regarded as equally available for exact definition with the superficial; the means for deep percussion being simply a stronger percussion-stroke, which, as I have already said, can never under any circumstances give an exact, or even approximately exact, result in delimitation at all. For it is a physical law which no amount of experience can evade or set at nought, that percussion does *not* operate directly downwards or in the direction of the impact *only*; but, in proportion to the strength of the stroke, laterally, diagonally, and in every possible direction in educing sound. And, therefore, as I said before, deep percussion (so-called) is *necessarily* inexact percussion; and what you gain in volume of sound, by strengthening your stroke, you lose, and far more than lose, in definition,<sup>1</sup> according to a physical law which no amount of skill can overcome. To trace this principle out into a refutation of all the nonsense that has been written in books about the deep and superficial, absolute and relative, limits of certain organs according to percussion, would occupy too much time. I will, therefore, pass to one consideration only, which is very directly related to the subject of this clinical lesson.

What I mean by a *carefully minimised* percussion-stroke is this: You are to percuss so as to elicit the distinctions of sound depending on air-filled or not air-filled viscera when superficially placed in reference to the abdominal wall; but you are not, as a rule, to strengthen your stroke beyond what is absolutely necessary for this purpose, at least when you are in search of objects, such as the thin edge of the liver, which closely underly the surface, or rather the wall of the abdomen.<sup>2</sup>

When your object is (as it may very well be) to determine not *limits*, but the qualities of large masses of sound as elicited by strong percussion, remember always that what is gained in volume is more than lost in exactness of delimitation; and that by no sort of management is it physically possible to determine accurately an edge, or limit, or any kind of definite form of an object, even half-an-inch below the wall of the thoracic or abdominal cavity under ordinary circumstances. Hence, you can determine with tolerable accuracy the fact, and the extent, of a thickened omentum; but you cannot determine with like accuracy, by percussion alone, the enlargement of a mass of mesenteric glands: unless, indeed, they are thrusting aside the intestines, and (what is quite unusual in fact) thus becoming superficial. By using palpation along with percussion, you can sometimes, but not always, distinguish the two conditions. About this diagnosis I have something to say further on.

Meanwhile, observe the precautions which, in this case and in the other, we actually employed, and have

<sup>1</sup> The introduction of Wintrich's hammer in percussion was, from this point of view, a great misfortune; and after using it for some years, more or less, from my earliest initiation into physical diagnosis, I abandoned it entirely on this account, except in eliciting the cracked-pot sound; because I found that the result of using it habitually was to cultivate a habit of too strong, and therefore inexact, percussion. Yet I found the hammer, in the hands of Traube and others, almost universal in Berlin in 1872.

<sup>2</sup> I have again and again been obliged to demonstrate to young and even to some skilful operators, that the lower edge of the liver has been shewn by them as half-an-inch, or even an inch, too high, in consequence of the percussion-stroke not being carefully minimised.

reason to urge upon you as necessary in exploring the abdomen by percussion in search of thickening of the great omentum or any similar lesion. The first point is to determine the existence, or the absence, of gravitating fluid in such quantity as to affect separately the percussion. In this case, our diagnosis on this point, by the quite ordinary tests, was in the negative. Then, we had to consider that under normal circumstances the intestinal canal, in one or other of its divisions, occupies the whole anterior wall of the abdomen, giving rise to a well-defined, though not identical, tympanitic note, which is reached by a nearly equal force of percussion-stroke all over the anterior surface. If, therefore, we can find even a few points at which a very gentle tap elicits this normal quality of sound, we know that under like physical conditions the same gentle percussion-stroke, and no more, ought to elicit a more or less similar tympanitic note all over; and if it is otherwise, we ought to study the facts carefully in detail, and to know, if possible, the reason why. These points or areas of quasi-normal percussion afford us the necessary data, then, for what I call *minimising the stroke*. Now if we find that over a particular area corresponding anatomically with the area of the great omentum, or of some portion of it, there exists a dull percussion which contrasts notably with the quasi-normal areas just referred to, being absolutely without sound to a *minimised* stroke, while to a very slightly stronger stroke it gives a tympanitic percussion quite like the quasi-normal areas, to what conclusion can we possibly come but that within this area of abnormal percussion there is something interposed between the abdominal wall and the air-filled intestines; something which is thick enough to differentiate the percussion, but not so thick as to give dull percussion to a stronger stroke; which is therefore, as I expressed it in the report, "easily penetrated" by percussion? And if this "something" is in the anatomical position of the omentum, why should it not actually be the omentum, involved in a possibly more general peritoneal morbid process, but presenting (owing to its double fold) the changes due to this in a more marked form? And, although this diagnosis may be confirmed and strengthened indefinitely by palpation, showing a diminution of elastic resistance over a like area as compared with other parts of the abdomen, it may, and often does, emerge with a fair amount of accuracy and security from the percussion alone, employed in the manner now described.

Such were the physical data, the processes and the results, by which, and to which we were guided in our examination on 16th March last (three days after her admission), in the case of Mary Jane S. I will now enquire shortly how far the progress of the case, which has been most anxiously watched and carefully reported in great detail through many changes occurring over four months, corresponds with, or modifies the views thus adopted. The opium and quinine employed from the first along with local applications in a few days very greatly relieved the pain, and also controlled the diarrhoea, which had been the leading and most urgent symptom on admission, so completely, that on March 20th we were able to report constipation (evidently from the opium), as substituted for the former condition, no alvine evacuation at all having taken place for several days. The temperatures, too, had been normal since the 17th, and the abdominal tension was much reduced; pulse 96, tongue nearly clean and natural, so that in four days this girl seemed to have passed from a prospect of immediate death into a state of almost complete convalescence as regards the acute symptoms. Even the physical details of the percussion and palpation of the abdomen appeared, on March 22nd, to be undergoing a satisfactory modi-

fication, especially on the left side; and a very critical examination of the chest next day, showed there also a considerable improvement, though leaving a mere *suspicion* of some disease (apart from the general bronchial râles) in the left apex.

Under these circumstances, the opium and quinine were intermitted, and cocoa-nut oil, very gently rubbed over the whole abdomen with the hand, was substituted as a local remedy for the fomentations. A complete and very detailed survey of all the facts, on March 30th, left no doubt of still further progress, although pain in the abdomen had never been entirely absent, and was easily excited by anything like too much or too careless manipulation.

During the whole month of April, being the academical recess, I was absent from home and from hospital duty, and I found on my return that no notes had been made during this period, and that, while improvement had continued during the earlier part of the month, there was reason to doubt if it had been continued during the later. On May 6th, I found that she was losing rather than gaining in weight; that the temperatures, which had been normal up to 16th April, were again more or less disturbed, and that ten days in succession showed a mean morning temperature of 98.5°, while the evening mean was 100.4°, and on 28th April a maximum of 102° was recorded. But a still more patent fact in the direction of an unfavourable change was the existence of manifest signs of a considerable amount of gravitating fluid in the abdomen, and although we have seen in the case of Jane M., that in a child this fact does not necessarily carry a very grave prognosis, or even interfere greatly with comfort, yet in the case of Mary Jane S. it was distinctly, and almost alarmingly, associated with the other ominous facts just alluded to. Accordingly, during the entire months of May, June, and July, we find that there has been a progressive loss of body-weight, which, although not extending to more than six lbs., has been steadily progressive, and a certain amount, not great, but still appreciable, of febricula has usually been present; the abdomen, on the whole, rather diminishing in size, from the absorption of a part, at least, of the fluid effusion. But pain has never been long entirely absent, and has sometimes been severe; the child looks ill, and is weak and dispirited: very unlike the physiognomy, habit, and manner of Jane M., on which I remarked to you already, directing your attention to it as an important element in the prognosis. I greatly fear that in this poor girl we must give up the hope of a "cure," in the popular, or in any practical sense of the word. But we are still working in that direction, well knowing that in young subjects, although too many cases disappoint our expectations, still there are now and then recoveries apparently complete, and of a marvellous order, even under the most unfavourable circumstances. I do not absolutely despair of Mary Jane S., grave as the aspect of her case was on admission, and in a certain sense still is after four months of treatment.

[Up to the date of printing this communication, the progress in this case is still, though very slowly, downwards. There is no diarrhoea, and the appetite is well, perhaps too well, maintained. There is absolutely no pain, but feverishness continues, although upon the scale only of an exceedingly mild febricula, and this not constant (max. temp. during July and August 101.2°, the majority under 100°). Nor is there any chest symptom of importance, but she is still slowly losing weight, and is even increasingly dispirited and languid. I have very little doubt that there is now extensive tuberculation, not only of the peritonæum, but of the mesenteric glands, and also, more or less, of the mucous membrane of the intestinal canal, as well as of the lungs and bronchial

glands. The treatment of late has been limited to careful nourishment, and the use of belladonna externally in order to restrain sweating, if possible, the weather having been unusually warm.]

(To be continued.)

## CLINICAL REPORT ON THE EFFECTS OF SMALL CONTINUOUS DOSES OF A NATURAL MINERAL SALINE WATER IN RICKETS, GLANDULAR SWELLINGS, AND OTHER DISORDERS OF CHILDHOOD.

By WALTER PYE, F.R.C.S.,

Surgeon to St. Mary's Hospital, and to the Victoria Hospital for Children.

For the past four months I have been observing and noting the action of Friedrichshall water upon children of all ages up to eleven years. The cases in which I have ordered it fall naturally into two groups: those where it was given as a simple aperient in some transitory ailment, and those where it was desired to produce some definite alterative effect upon a disorder of growth, nutrition, or the like.

It is not necessary to give details of the cases in the first of these groups. As a simple aperient I have given it in seventeen cases in all, in doses of from one ounce and a half to four ounces, and have found it generally efficient to procure one or two actions of the bowels without griping. On the whole, I am inclined to believe that this water has a somewhat less purgative effect in children than in adults, other things being equal.

On two occasions an undue amount of griping with watery evacuations resulted, but on the other hand in two or three others it was said to be more comfortably borne than any other purgative medicine which had been tried. For young children, as a purgative, Friedrichshall water will probably be found to be preferable only in exceptional cases to the common vegetable laxative preparations of rhubarb and senna.

But the case stands differently with regard to the second group, and for this reason I append short notes of the following fifteen cases in which the water has been given in small doses for weeks or months together. The general outcome of these cases seems to show that in the saline ingredients of Friedrichshall water we have an efficient means of quickening tissue changes throughout the body, and especially of improving the condition and work of the lymphatic glands and of the liver. Its effect also in regulating the action of the intestines in the colicky attacks which are so common in diseases of nutrition, such as rickets and congenital syphilis, is very marked.

In almost every case it was found to be desirable to lessen the dose after the first week or ten days in order to avoid purging, but this increased susceptibility never amounted to intolerance, Cases VI and XV being ones in which the water was unsuitable from the first.

Friedrichshall water should be given warm, and the first thing in the morning. In children, at any rate, it is best to warm it by the addition of a little very hot water. Any attempt at flavouring or disguising the saline taste only makes matters worse, but children, as a rule, take the plain water quite readily. A cup of tea or warm milk and water a quarter to half an hour after it has been taken, aids its purgative action,

but it is not required when small doses are being regularly given.

*Abstract of Notes of Fifteen Cases where small continuous doses of Friedrichshall Water were given.*

CASE I.—(*f.*) 3 years. Born in India in a malarious district; stated to have had intermittent fever; is but slightly better in health since leaving; suffers from attacks every ten days or so of colicky pains with loose clayey stools; in the interval is generally constipated, but the stools always pale. Is wasted looking, with dirty complexion, but no real jaundice. The whole abdomen is tumid, and the liver is easily felt to be enlarged; spleen apparently normal. Has slight rickety curvature of tibiae. Has been taking cod-liver oil and Parrish's food, small doses of quinine and grey powder occasionally. The oil was continued, and Friedrichshall water, in tablespoonful doses, ordered to be taken every morning. This was increased to an ounce in a few days, which was shortly able to be gradually reduced. The stools improved in colour quickly, and in ten days the abdomen felt almost natural, the liver edge hardly lower than it should be. She steadily gained flesh, and her complexion became fresher. She had no colicky attacks whilst she was under direct observation, and is now, four months later, stated to be "very well, for her," and to be still taking the Friedrichshall water frequently, but not regularly.

CASE II.—C. B. (*m.*), 1 year and 4 months, suckled 3 months only. Brother to Case I; also born in India; suffering with much the same symptoms, but in a much less degree, and having, in addition, cervical glandular enlargements, threatening to break down, and head and wrists having the appearance of commencing rickets. Ordered Friedrichshall water, a small tablespoonful every morning, and an almost exclusively milk diet. He improved very rapidly, but it should be noted that the symptoms were at no time severe, and that at his age the effects of the change of climate would naturally be more quickly apparent.

CASES III (*f.*), IV (*m.*), and V (*m.*) were all cases of rickets developing between the years of 3 and 5, with marked glandular enlargement and large abdomen. In all, the usual intestinal troubles which are associated with rickets were present, and in all, doses of Friedrichshall water of from one to four tablespoonfuls were very distinctly beneficial. In these three cases the need for a gradual diminution of the dose after the first week, or even after five days, was very apparent.

CASE VI.—(*f.*) 3 years, 9 months; was to all appearance similar to III, IV, and V, namely, one of rickets with constipation, alternating with diarrhoea, colicky pains, and lumpy stools, but the water was not at all well borne. On two occasions two and one and a-half tablespoonfuls respectively, given in the morning, produced no action of the bowels until the evening of the same day, and then caused a rather copious and griping purge with some mucus. Grey powder and rhubarb was afterwards borne well.

CASE VII.—S. T. (*m.*), 11 years; has suffered from hip disease, with abscesses, &c., for years. Two years ago his hip joint was excised by myself. The acetabulum and pelvis were extensively diseased, but he made a fair recovery, and for the past 18 months has been and now is getting about with a stick. The wound, however, has never closed, and during the past six months he has had albuminuria, occasional attacks of jaundice, and latterly some ascites. He is also troubled much with constipation and commencing piles. He finds that nothing that I have previously ordered for him has acted so well in procuring soft painless motions as half a large wineglassful of

Friedrichshall water. He has taken this for the last month. The ascites is somewhat less, the urine is increased in quantity, and *pro tanto* the albumen is diminished. This improvement is no doubt partly due to the favourable weather at this time of the year, and is at best only temporary, still it may be taken as a proof that the water is borne well in cases of advanced amyloid disease.

CASE VIII.<sup>1</sup>—C. F. (*f.*), 7 months; was brought to me as "suffering from the effects of vaccination." However that might be, the infant had an attack of patchy cutaneous erysipelas, which attacked various parts of the body successively. The bowels were obstinately confined, and by the eighth day of the attack the child's condition was somewhat critical. The action of half ounce doses of the Friedrichshall water in relieving the constipation and regulating the bowels without any purging, was quite distinctly beneficial.

CASES IX and X, aged 7 and 5 years (brother and sister), were cases of strumous glandular enlargement in the arm pit and groin respectively. They had been taking preparations of iron and cod-liver oil for some months, and were hardly improving. They were often constipated, and had taken for this, grey powder, with or without rhubarb. The iron was left off, and the cod-liver oil continued, with small doses of Friedrichshall water every morning, and occasional larger ones. Both children improved rapidly.

CASE XI.—G. H. (*m.*), 4 years. A case of congenital syphilis, with wasting; puckered, fissured mouth, dirty sallow complexion, and a distinctly enlarged liver, with clayey stools. Had been treated by mercurial inunction, and was fast recovering from an attack of stomatitis, probably mercurial. Three grains of iodide of potash were given thrice a day, and two tablespoonfuls of Friedrichshall water every morning, with cod-liver oil and a nearly exclusive milk diet. The child's nutrition improved, the motions became natural in colour, and the liver has receded.

CASE XII.—(*m.*) aged 9. One of multiple strumous periostitis of the fingers and toes, five digits being affected. The lymphatic glands to be felt over the body generally were enlarged. The patient was poorly nourished, and frequently suffered from "bilious attacks" with light coloured motions. Three to four tablespoonfuls of water were taken every morning at first, and after a week the dose was reduced to two. The cod-liver oil and Parrish's food which had been previously taken were continued. The abdominal symptoms quickly disappeared, and the patient is steadily improving.

CASE XIII.—H. C. (*m.*), 9 months. Born in India, and never suckled; said to have nearly died on the voyage home of sickness and diarrhoea. The infant was brought to me in consequence of a congenital hydrocele, which has not returned after tapping. Since he has been home he had alternating diarrhoea and constipation; small doses of Friedrichshall water have done more to relieve this than anything else which has been tried.

CASE XIV.—(*f.*) 3 years. A case of rickets with enlargement of the liver, similar in all respects to III, IV, and V. The water has only recently been ordered, but is apparently having a beneficial effect.

CASE XV.—(*f.*) 7 years. This child suffers from habitual constipation, probably due to mismanagement and ill-feeding. Small doses of the water have no effect, and larger ones produce griping and general discomfort. It does not seem to be suitable to this case.

<sup>1</sup> This case hardly belongs properly to this series, but is given as an example of useful action of the water.

PRACTICAL NOTES ON THE ORDINARY  
DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,  
President of the Health Department, Social Science Association.

(Continued from page 315.)

DISEASES OF THE EAR.

THE Bengal Census return of 1881<sup>45</sup> gives 12.32 per 10,000 of *Deaf Mutism* against 5.07 in England.

A poor woman, of the Koonjur class, applied to Dr. R. F. Hutchinson saying that she was outcasted because the largely perforated lobe of her right ear had been accidentally torn through. Two snips with scissors, removing the cicatrised ends, and one suture did the needful for her and restored her to her tribe.

*Pendulous Tumour.*—Dr. A. Campbell and Mr. M. J. Bramley have described<sup>46</sup> a "Pendulous Tumour of the External Ear." Both ears are usually affected. The tumours arise from any portion of the external ear. The growth is so rapid that a tumour two months old can seldom pass unobserved. These are liable, when growing from the helices, to draw down and double over the ears so as greatly to obstruct hearing. They may be so large as to reach the shoulder. A pair removed from a woman weighed two pounds. Men, women and children are alike subject.

Dr. Campbell describes this as a very frequent disease in the Valley of Nipal, often occurring in the subjects of goitre. His enquiries, as far as he was able to carry them, led Mr. Bramley to believe that it only occurred in Neel Kheut, a small village which, with its environs, may occupy a square mile. In the first volume of the "Calcutta Medical and Physical Transactions," Dr. John Adam described and figured a pendulous tumour of the integument, surrounding the outer ear, which rode upon the shoulder, and descended behind and before, reaching, at last, the plane of the nipple. It was clearly *molluscum*. I have alluded, in the chapter on *Leprosy*, to the tuberculated hypertrophy of the lobe of the ear which is so almost invariably a characteristic of that disease.

*Ear-Ache*, from diffused or circumscribed inflammation of the external meatus, is not infrequent in India.

A case published in April, 1884, makes me aware that laudanum with oil has not yet gone out of use as a soothing application. In cases of ear-ache, &c., this "venomous distilment" acts like liquid fire upon the sensitive mucous membrane. I always used pure opium rubbed up with olive oil. The application of two or three leeches precisely in the cleft between the mastoid process and the ear, and the free use of steaming by means of a jug of hot water and a towel, will, I believe, nearly always render incision needless.

When I was civil surgeon of Howrah, opposite to Calcutta, in 1853, *Inflammation of the External Meatus* giving rise to *Chronic Otorrhœa*, was a widely spread endemic, among natives, thousands of cases occurring along the right bank of the river. I did not see any case in a European, nor could I learn that the disease was prevalent on the Calcutta bank. In the Mutiny, a young brother officer contracted the disease when sleeping on the ground at Barrackpore (on that side of the river) and lost hearing in that ear.

Dr. W. J. Moore<sup>47</sup> speaks of diseases of the ear as being remarkably common in Joudpore. Children especially suffer from these complaints, and deafness of one or both ears is very frequent. The affection generally commences by inflammation of the external auditory canal, which, being neglected, leads to extension of the disease inwards, perforation of the membrana tympani and destruction of the internal apparatus. It appears to originate from irritation produced by the fine particles of sand which, during the hot weather, load the atmosphere and are deposited in the aural passages. Instead of frequently washing and cleansing the parts, inserting wool is a common practice. This tends to extend rather than allay irritation. In the early stages of the affection frequent washing and gentle syringing will effect a cure.

Mr. G. C. Hall speaks<sup>48</sup> of *Bather's Ear-ache* as a very common affection in India wherever there is a swimming bath. He attributes it to diving, the pressure of the water causing small foreign bodies to be carried into the meatus, causing inflammation. It occurs especially in those who dive much. The symptoms given are those of catarrh of the meatus, sometimes going on to abscess. Mr. Hall uses opium and glycerine and 15 grains of alum to an ounce of glycerine warmed and poured into the ear.

The water of a bathing-place near Athens is said to cause ear-ache.

*Maggots in the Ear.*—At Chittagong I attended an officer's daughter, aged 18, who was a paralysed and bed-ridden idiot. The meatus of one ear was suppurating and filled with large maggots. I used various lotions [I learnt at Guy's not to syringe the ear, but to place the head flat on a low pillow and to fill the meatus and concha with warm water or medicated fluid, which was allowed to remain there as long as might be needful] which did not appear to trouble the parasites at all. I, therefore, removed them with dissecting forceps, all of them clinging on and resisting with great tenacity. In doing this, I found that the bony canal was quite bare. The meatus was lightly plugged and dressed regularly. The surfaces granulated, and healing went on to such an extent that the cicatrised meatus remained as a round hole two-thirds smaller than was natural. At the same time in the following year I was called to her again and found her moribund, the other meatus was filled with maggots.

In the article cited above, Dr. Moore, in describing *Peenash*, as it occurs in Marwar, says, "Similarly I have occasionally met with maggots in the ear, after otitis and perforation of the tympanum."

*Foreign Bodies.*—At Howrah an East Indian boy, of 4, was brought to me with a custard apple seed far back in the meatus, which was a good deal inflamed and swollen. This spindle-shaped seed is as hard, polished and slippery as a piece of smooth carnelian of the same form would be. It took me nearly an hour to hook it out.

Assistant-Apothecary Adie reported<sup>49</sup> the case of a native male child which had a pea in the meatus for eighty hours, the passage being much swollen. He broke it in two with a sharp probe and so removed it. The handiest instrument for this purpose is a lady's black wire hair-pin bent into the form of a scoop.

The fact that I only observed *disease of the mastoid cells* once, in a Mahomedan woman, is probably due to the immunity from struma of the natives of Lower Bengal.

REPORTS OF  
HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY.

EAST LONDON HOSPITAL FOR CHILDREN.

AURAL DISEASE—ABSCESS ABOVE RIGHT  
AURICLE—NECROSIS OF TEMPORAL BONE  
— COMA — DEATH FROM CEREBELLAR  
ABSCESS—AUTOPSY.

(Under the care of Mr. R. W. PARKER.)

(For these notes we are indebted to Mr. GELL.)

ROBERT H., aged 6 years, was admitted to the Princess Mary ward on September 1, 1885, suffering from an abscess about the size of a five-shilling piece, situated above the right auricle.

The record of his previous history was, that when 8 months old he had had scarlet fever, since which time he had always had a discharge from the right ear with considerable tenderness of that side of the head, and occasional attacks of ear-ache. Ten days previous to admission the pain in the ear had become more acute, and to relieve it poultices had been applied. Four days previous the swelling showed itself above the right ear. From the age of 18 months to 4 years he had been subject to fits of an epileptoid character, the account of which, however, was too indefinite to associate them with any localized cerebral affection; for the last 2 years he had been entirely free from them. Eight months before admission he had had an attack of pneumonia. He had never been at all a robust boy, though he had been in better health for the last few months.

The family history showed no especial taint, with the exception of the death from "consumption" of the maternal grandfather. The mother herself was not strong, and had lost 3 children: 1 from scarlet fever, 1 was stillborn, 1 had died of pneumonia.

*Present condition.*—The patient, who walked into the ward, looking decidedly ill, was a pale complexioned, fair-haired, delicate-looking boy, somewhat deaf and mentally dull. When put to bed he lay very quiet, showing great unwillingness to be roused, or to take his food, or to answer questions, but complaining of no pain except when the affected side of the head was touched. The abscess situated over the right auricle also extended about half-way down behind it, while from the right ear there was a copious purulent discharge. The fauces were slightly congested and the right tonsil was enlarged. There was no paralysis, ocular or otherwise. Pupils reacted to light. The temperature was 102·4° F.

The abscess was opened under chloroform, and about two ounces of foetid pus were evacuated; a small patch of necrosed bone was felt at the base of the squamous portion of the temporal bone at its junction with the mastoid.

September 2.—Patient has slept well, is very quiet and drowsy, and continues in the same condition of mental dulness. The discharge from the abscess cavity is small in amount and less fetid. There is considerable tenderness of this side of the head. Temperature 101° F.

September 3.—There is scarcely any discharge from the abscess cavity, and, what there is, is inodorous. Temperature 99° F. In the course of the day the boy became much duller and more difficult to rouse. He could not at first be made to take his dinner; but after two or three spoonfuls had been put into his mouth, he began to feed himself in a mechanical way, continuing the action after he had eaten all the food on his plate.

He is quite conscious and somewhat irritable. There are no signs of paralysis or rigidity. He passes his water under him.

September 4.—Patient lies either asleep or in a semi-conscious state with eyes staring; by gesture he resents any interference. Does not speak, but cries out a little when the abscess is dressed. Passes his water under him. No paralysis or rigidity. Has to be fed, but swallows well. Temperature 100° F. Pulse and respiration regular. Tache cerebrale well marked. Fundus oculi on either side normal, and the margin of the discs and the vessels quite distinct.

September 5.—Patient is becoming increasingly comatose. Has to be fed through the nose. In the afternoon some slight convulsive movements of right arm and leg were noticed. Throughout the day the temperature rose rapidly, from 97·4° F. at 6 a.m., to 106·6° F. at 10 p.m.

September 6.—Patient died at 6 a.m. The temperature which at 2 a.m. was 106°, was taken in the rectum a few minutes after death and found to be 108°.

*Post-mortem* examination of the cranium and its contents was made 8 hours after death, and showed the mischief to be localized to the temporal bone of the right side, to the dura mater covering it, and to the corresponding lobe of the cerebellum. The meninges and the encephalon otherwise showed nothing abnormal. Externally there was necrosis of the temporal bone over an area the size of a shilling at the base of the squamous portion at its junction with the mastoid. Corresponding to this interiorly there was necrosis of the roof and posterior part of the petrous portion from the internal auditory meatus up to its junction with the squamous. It was at this point that on removal of the brain an adhesion presented itself between the cerebellum, the dura mater and the bone. There was here an ulcerated hole in the dura mater about the size of a three-penny piece, while at the corresponding point in the cerebellum there was a perforation, which communicated with an abscess cavity occupying almost the whole of the right lobe of the cerebellum, and filled with thick greenish foetid pus. In the adjacent part of the lateral sinus there lay a small, partially decolourised adherent clot. The membrana tympani was obliterated, the ossicles were destroyed, and the tympanum was filled with pus while the adjacent mastoid cells were eroded, excavated and filled with thick caseous material. In the internal ear the semi-circular canals showed commencing disorganization: the cochlea was intact.

*Remarks by Mr. PARKER.*—During life, it seemed pretty evident that the boy's condition was connected with his ear disease. There had been an access of rather severe ear-ache shortly before his admission; to such attacks, however, he had been liable for many years, and no serious consequences were at first anticipated; there was tenderness over the whole side of the head, but this did not appear of much importance seeing that there was a large external abscess which had to be opened. Of the deep mischief, the only symptom was the advancing coma; at first he was noted as being intellectually dull; this dulness increased, and then he began to be drowsy; finally coma supervened, and then death. There was no paralysis, nor any localising lesion whatever, so that I was quite unable to diagnose the nature or site of the brain disease which I felt sure was present. The absence of all symptoms associated with meningitis—a so frequent cause of death in such cases—was seen at the autopsy to be due to the manner in which the brain was adherent to the dura mater around the perforation through which the tympanum and the corresponding lobe of the cerebellum had become directly continuous. It is not improbable that the firmness of these adhesions depended on chronicity of the lesion, which fact may possibly also explain the absence of symptoms.

## BECKETT HOSPITAL, BARNESLEY.

## EMPHYEMA — PARACENTESIS — FREE OPENING—DEATH FROM PERITONITIS.

(Reported by Mr. ARTHUR MAUDE, Resident Medical Officer.)

HENRY N., æt. 7, was well till July 6th, when he began to ail, vomited occasionally, had slight cough, and slight distress of breathing; was apparently feverish and delirious at night. His family history was good; he had had no acute diseases. A medical man stated that at the beginning of his illness he had broncho-pneumonia, and soon developed pleurisy on the left side.

He was admitted on July 27th, with slight dyspnoea, and a short cough, and constant left-sided decubitus. There was marked bulging of the left chest in front, especially in the upper part, and also absolute dullness to half an inch from the right side of the sternum. The heart was pushed over and felt under right nipple. The spleen was three inches below ribs; there was absolute dullness over the left back. Complete absence of breath sounds all over left chest with good breathing, and resonance over right side. There was a soft systolic bruit over the præcordium. Temperature 101.2° F. He was at once aspirated, and two pints of healthy pus withdrawn.

July 28th.—Faint breathing over root of left lung behind. Heart's impulse indistinctly felt in normal position, sounds clear. He was evidently much relieved.

August 4th.—Distinct breath sounds were now audible over both backs.

August 6th.—Breathing sounds over the two left upper interspaces in front; increasing in force over back. Temperature below 99° F. at night.

August 7th.—Temperature rose to 103° F.; aspirated again and 8 ozs. of sweet pus removed.

August 8th.—Heart again felt on right side. Temperature continued high; no change in auscultatory signs.

August 12th.—Free opening made in fourth left space, and a double drainage tube arranged on Mr. Battams' plan was inserted; 22 ozs. of healthy pus were removed. Dressings of McGill's salicylated silk were subsequently applied.

August 17th.—There was not much discharge from the cavity. The temperature continued lower till last night, when it reached 101.4° F.; the discharge is slightly offensive to-day. The cavity was washed with weak sanitas solution.

August 21st.—The discharge has continued more or less offensive. The heart continued on the right side, and there was no appreciable change in physical signs. To-day he developed pain and tenderness in the abdomen, frequent vomiting and slight distension of abdomen.

August 23rd.—The symptoms of peritonitis have increased; he gradually sank.

*Autopsy* (by Dr. G. Parker) showed the left lung to be completely compressed against its root, the pleural cavity quite empty. The right pleura contained a small quantity of thick pus in its posterior part. The pericardium was healthy. The peritonæum was covered with lymph and thin pus. There was no communication between the pleural and the peritonæal cavities.

*Remarks by Mr. MAUDE.*—In two admirably recorded cases of peritonitis secondary to emphyema (*Medical Times*, June 22nd, 1883, and Dr. Eustace Smith's "Disease in Children," p. 684), this complication occurred after free incision and drainage. I

raise the question, therefore, whether a low counter incision, on the old plan, would not tend to clear the diaphragmatic pleura of pus, and avert this danger, incomplete through the drainage afforded by an opening into such a narrow space as the lower pleura may be. Secondary peritonitis in such cases "which is usually fatal, arises from the pus making its way into the abdominal cavity through the small lymphatics of the diaphragm" (Fraentzel; Ziemssen's *Cyclopedia*); and obviously to keep the diaphragm free from pus will prevent this reflux. If then this great danger is of sufficiently frequent occurrence, it would seem to demand, especially in tuberculous subjects, any means tending to prevent it. The collection of such cases is consequently of value, and I should be glad to see other similar ones recorded.

## Medical Times and Gazette.

SATURDAY, SEPTEMBER 19, 1885.

THE British Association opened its annual Congress at Aberdeen on Wednesday week with Sir Lyon Playfair's Presidential Address, which was admirable and beyond criticism as a plea for the due recognition of science by the State, and which, we may hope, will not be without converting and convincing effect on our more enlightened M.P.'s, schoolmasters and millionaires. On Thursday, the chairmen in most of the sections delivered their opening addresses. Professor Armstrong, in the section of Chemistry, at first travelled over some of the ground previously traversed by Sir Lyon Playfair, and strongly advocated the teaching of Chemistry in schools in such a way as to develop the intellectual faculties and to teach the pupil to appreciate "the sacredness of accuracy." Subsequently, he dealt with the special subject of chemical action, not before, however, he had had a fling at a favourite topic of his, the teaching of chemistry to medical students. The following is worth quotation: "Seeing that the practice of medical men largely consists in pouring chemicals into that delicately organised vessel, the human body, and that the chemical changes which thereupon take place, or which normally and abnormally occur in it, are certainly not more simple than those which take place in ordinary inert vessels in our laboratories, the necessity for the medical man to have a knowledge of chemistry—and that no slight one—would appear to ordinary minds to stand to reason; that such is not generally acknowledged to be the case can only be accounted for by the fact that they never yet have been taught *chemistry*, and that the apology for chemistry which has been forced upon them has been found to be of next to no value. No proof is required that the student has ever performed a single quantitative exercise; and I have no hesitation in saying that the examinations in so-called practical chemistry, even at the London University, are beneath contempt: after more than a dozen years' experience as a teacher under the system, I can affirm that the knowledge gained is of no permanent value, and the educational discipline *nil!*" The remaining addresses, with the exception perhaps of Mr. Galton's in the Anthropological Section on

Types and their Inheritance, contained nothing of medical interest.

In the subsequent work of the sections, one or two matters came up which deserve brief notice. Professor Turner advocated the adoption of the axis of the pelvic brim as a basis for the classification of man. He found that the pelvis of the lower races of mankind approximated to that of the lower animals. Professor McKendrick described some experiments on the action of cold on microphytes, which proved that organic fluids might be exposed to  $-120^{\circ}$  Fahr. for at least 100 hours, and yet after being kept in a higher temperature fermentation and putrefaction went on in the ordinary way. These experiments destroyed all hope of any practical result being obtained by sterilization from cold. An analogous result was stated by Mr. Coleman to have been obtained from his experiments with ozonized air, which was found to kill putrefactive germs, but only to inhibit the action of their spores.

At the concluding meeting of the Chemical Section an important discussion on the action of water upon lead was introduced by Mr. A. H. Allen. He stated that it had been found at Huddersfield, where they had an epidemic of lead-poisoning some years ago, that chalybeate water had a more marked action on lead than water which contained no iron, but that this action could be obviated by filtering through a bed of limestone. Mr. Allen thought it was a fallacy that hard water acted upon lead more freely than soft water; but he had himself verified the statement that snow dissolved lead more quickly than ordinary water. The latter fact, Professor Frankland explained, showed that the presence of dissolved oxygen was essential to the dissolving action of water on lead. Professor Dewar described a method used in many towns in America for neutralising this action: it consisted in pumping into the water atmospheric air at a pressure of fifteen atmospheres, the effect of which was presumably to oxidise a great deal of its organic matter. Both Dr. Frankland and Mr. Dewar uttered a warning against the use of the so-called "tin-lined" pipes. Several other papers of medical interest were read in the subsection of physiology. The whole meeting is described as being a very great success. Next year the Association will meet at Birmingham, and at Manchester in 1887.

Two chief facts, both of agreeable import, have to be recorded this week in connection with the cholera in Spain. The first is that the epidemic is steadily, if not rapidly, diminishing; the second that the Lord Mayor has at length opened a Mansion House Fund, to which nearly 2,000*l.* has already been contributed. The fund is under the control of a strong Committee, and will act in concert with the Distributing Committee formed in Madrid by the Queen of Spain. Though the prevalence of cholera in that country has greatly diminished, there are still about a thousand cases and some three hundred deaths reported daily, and there is consequently much present suffering to relieve,

as well as much distress left by the previous ravages of the disease. It is estimated that since May there have been over 250,000 cases, and 100,000 deaths; and even in the first ten days of the present month there were 6,379 deaths. But an unbroken decline in the mortality may now be counted upon with fair security. Elsewhere than in Spain the cholera smoulders only. In France it is exacting scattered victims in the southern departments and is reported to have made its way to Paris, but it is dying out at Marseilles and Toulon. There has been no excessive mortality at Palermo or in other parts of the Italian Kingdom. In the whole of that Kingdom, from August 6th to September 13th there were 146 cases and 86 deaths.

LAST week is likely to be long memorable from the fact that a lower death-rate, viz., 15.6 per 1,000, than any on record was attained in London, the 1,221 deaths registered being 227 below the average. The deaths from measles fell from 46 last week to 25, but this was partly counterbalanced by a rise in the deaths from whooping cough and diphtheria, to which disorders 39 and 22 deaths were accredited, and this latter figure it may be noted is exclusive of the 10 deaths of children under the age of 5 years, which we find attributed to croup. Of the 62 deaths from diarrhoea,

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past seven weeks.

43 were of infants under the age of one year; 12 deaths were referred to enteric fever. Respiratory diseases showed a slight excess of deaths over the average of the last few weeks, attributable, no doubt, to the rough weather we experienced, for the temperature was  $2.3^{\circ}$  below the average, there was considerably more wind than usual, and a rainfall of 1.93 inches. In the provinces, diarrhoea was very prevalent and

fatal in Liverpool, Manchester, Birmingham, Nottingham, Salford, and Huddersfield. In Glasgow and Dublin, too, its effects were severely felt.

DR. HERBERT WATNEY, whose candidature in the liberal interest for Greenwich we recently announced, has followed in the steps of Mr. Ernest Hart, and expressed himself in favour of the unconditional repeal of the Contagious Diseases Act.

WE are glad to hear that some useful practical results are likely to follow the establishment of the extensive electrical department recently added to St. Bartholomew's Hospital. During the present vacation, Mr. Bruce Clarke and Dr. Steavenson have been trying the efficacy of the American plan of treatment of stricture of the urethra by electrolysis, and have obtained some most satisfactory results. Several cases have to all appearances been cured with the smallest amount of pain to the patients and without the use of an anæsthetic. Some time, of course, is necessary before it can be determined what amount of contraction is likely to follow, but we believe the gentlemen named intend bringing the subject before one of the medical societies when they have satisfied themselves on this important point. An attempt has also been made to dissolve the middle lobe of the prostate by electrolysis in a case of prostatic enlargement. Should this mode of treatment also result in success, one of the most difficult problems in surgery will have been solved. No plan of treatment at present devised for enlargement of the prostate is in any way satisfactory. When catheterism fails in relieving a patient, his condition is at the best one of most serious import. We look forward to the report of the results of this mode of treatment by electricity with considerable interest.

THE future prospects of members of the medical profession in the country parts of Ireland are not likely to be very satisfactory under the benign sway of the "Uncrowned King." Mr. Henry Donovan, the Medical Officer of the Kilfinane Dispensary District, Co. Limerick, has been peremptorily called upon to resign his appointment by the Dispensary Committee on the alleged ground that he made use of some disparaging remarks respecting certain "Redemptorial Fathers" who were holding a Roman Catholic Mission at Kilfinane. Mr. Donovan studied at Queen's College, Cork, of which he is an Ex-Senior Scholar and First Prizeman, and he holds the diplomas of the Royal Colleges of Physicians and Surgeons of Edinburgh. We can scarcely think that he should be guilty of such "outrageous conduct" (these are the words of the resolution adopted by the Dispensary Committee) as to merit the severe penalty of compulsory resignation. Surely an ample apology should atone for the offence.

THE Harveian lectures will be delivered by Dr. Buzzard at the Harveian Society, on November 19th and 26th, and December 3rd, the subject being: "Some

Forms of Paralysis Dependent upon Peripheral Neuritis."

A CORRESPONDENT tells us that some remarks which appeared in our issue of last week, anent the almost stationary condition of the population obtaining amongst the peasant proprietors of France, constitute "an eloquent pleading in favour of the prudential restriction of the birth-rate." They were not so intended, and we regret to find that they have been misconstrued in such a sense. We are told that it was not fair to compare the rapid increase of the French Canadian population with the unprogressive state of "an old country like France, where for years, practically, the whole of the available soil has been in use." The comparison was, however, a perfectly fair one, since its very object was to show how the same race, when in possession of a relatively large extent of territory, increases at a rate and has families of a size which are impossible, or not permitted, amongst an overcrowded and under-landed peasantry. England and France, however, are both old countries, and of practically the same age, in relation to Canada at all events, and a comparison between the birth-rates of the labouring classes of these two nations is not favourable to the laws by which, in one of them, a large part of the available soil is used after a particular fashion by subdividing it into minute properties. "Seeing," says our Correspondent, "that the French peasant's small holding just suffices to keep body and soul together in at most four persons, how would he and his family be benefited by this holding having to support eight or twelve individuals?" This is not, save perhaps in an unintended sense, the "simple question" which it is pleasantly termed. It is clear that what will just suffice to support at most four persons cannot by any known means support eight or twelve. And it is just this hard logic of facts which drives the small peasant proprietor to practise that system of the "voluntary limitation of families" which has so marked an effect upon the population of his country at large—a result for which we stated the system of peasant proprietorship appeared in France to be ultimately and to a large extent responsible. A thousand of these tiny estates, if worked with equal industry as a whole, might, we are told, be made to support more than the thousand several families which now all but starve upon them. It was a consideration of matters such as these that induced us to enter a warning protest against the too ready adoption of a political remedy, which appears to be at least capable of abuse, which, in its results, cannot merely plead only too persuasively for the prudential restriction of the birth-rate, but which is apt to make life, even for those whom it permits to live, a dreary hand-to-mouth existence in dwellings as bare of comfort as of ornament; which can, in short, expunge from the vocabulary of the poor the comprehensive epithet "homely"—a word as expressive and as dear to the sanitarian and to the moralist as to the poet.

WE hear from our Vienna correspondent that Dr. Fuchs, of Liège, who recently favoured our columns with an original article, has been appointed

by the Emperor Francis Joseph to the second chair of ophthalmology at the Vienna University, with the title of ordinary Professor. Prof. Fuchs will probably enter upon his duties at the beginning of the winter session. Prof. Spaeth, who was prevented from lecturing last session on account of ill health, is now able to return to work. The number of students at the University of Vienna in the summer session was 5,122, of whom 2,145 belonged to the Medical Faculty. There were also 103 occasional students studying medicine. Dr. Rosanes, late operator in Billroth's clinic in the General Hospital in Vienna, has been appointed Superintendent with charge of the surgical department of the new Crown Princess Stephanie Hospital, Neulerchenfeld. Dr. Ehrendorfer has been approved as privat-docent in midwifery and gynecology in the University of Vienna.

PROFESSOR STARKE, directing physician of the Charité Hospital, Berlin, and lecturer in the Military Academy, one of the most gifted military surgeons in Germany, died in Berlin on the 17th ultimo.

PRIVAT-DOCENT M. KAPUSTIN, has been appointed professor of hygiene in the University of Kharkov, and Dr. Penzoldt to the chair of medicine and charge of the clinic in Erlangen, rendered vacant by the removal of Prof. Leube to Würzburg.

WE wish to call the attention of the managers of convalescent homes to the exacting reports and certificates which are now often required from medical men before a patient can be admitted into their institutions. The medical officers of hospitals and infirmaries have always been anxious for the establishment of convalescent homes to which they might be able to send patients who, not being able to return to work, would more rapidly progress towards recovery if they could be removed from their insanitary surroundings, and have the benefit of a change of air. But side by side with the greater accommodation for convalescents there proceeds an increased demand upon the time, the forbearance and the charity of medical men. When some years ago the Charity Organisation Society first offered to assist out-patients of the Metropolitan Hospitals who required for their recovery change of air and other assistance, a very simple form of certificate was required from the medical officer recommending their cases. Now, in addition, a much fuller report and certificate is often required from the home into which the patient is to be admitted, involving a thorough examination of the case for that especial purpose. Many a medical man now hesitates to suggest a convalescent home to a patient, for fear of adding considerably to the excessive demand already made upon his time by gratuitous medical work. In addition to the thorough medical report required, the doctor knows that if it is not in every way satisfactory to, or full enough for the secretary of the home to which the patient has been recommended, he may be involved in a correspondence which would take up a considerable amount of time and cause him great inconvenience. By this means, the help formerly offered by convalescent homes, and so thankfully accepted by the medical profession, has

been robbed of much of its value. Some of the certificates medical men are asked to fill up almost equal, if they do not exceed, in exacting details the reports required by insurance companies on the health of those proposing to take out a policy on their lives. A full report is required of the state of the heart, lungs, and brain; the origin, history, and treatment of the attack of illness from which the patient is recovering; the present symptoms and parts chiefly affected; the present condition and state of health; condition of the uterine functions; whether paralysed or suffering from loss of memory or speech; powers of progression; whether the temperature is raised; whether there are abscesses, suppuration, or ulcers of any kind; and so on. In addition, with regard to prognosis, the medical man is often asked to state whether it is probable that the patient will be able to resume work in a certain number of weeks; whether the malady is chronic; whether the patient can support himself on his return to his own home; and an assurance that he would not require any medical attendance or special treatment at the home. Some of the answers given may not be intelligible to the non-medical mind of the secretary, and then follows a series of letters, asking for and giving explanations. No doubt it is necessary for some of the homes to have explicit information of the nature of the cases they are asked to admit, and great inconvenience is sometimes experienced by unsuitable cases being sent to them, often necessitating the immediate return of a patient to his home. But when this is the case, some of the funds of the institution ought to be devoted to the payment of suitable medical referees. Such appointments have been made in London, by some of the best managed convalescent homes. The Charity Organisation Society is now increasing its staff of paid secretaries. Would it not be an advantage, also, if they appointed some medical men to examine cases referred to them for assistance?

WE are glad to observe that the charges of mismanagement at the Aberdeen Royal Infirmary, recently made by Dr. Angus Fraser, are not likely to be hushed up. That gentleman has followed up his former communication with a more lengthy document in reply to the request of the committee of management, that the staff would specify any defects that have come under their observation, and offer suggestions for their removal. Dr. Fraser commences by citing the statement communicated to the Board more than a year ago by Dr. Garden and himself, after their visit to the Dundee Infirmary. That statement dealt almost exclusively with financial questions. In the present letter, he points out that the discipline and management are most inefficient, giving in illustration the way in which certain defects which have been pointed out to the Committee, and acknowledged by them, are nevertheless allowed to exist. But his chief complaint is in regard to the nursing. The staff, he says, have strongly represented to the Committee that it was greatly deficient, that the nurses were of a different and an inferior class to those in other large Scotch Infirmarys, and that the nurses were called upon to perform a variety of duties entirely outside their province. He enumerates

a list of the duties of the nurses supplied to him by the head nurse, and after reading it, we can readily believe that lady's statement, that a nurse is as much out of her ward as in it. The lavatory, bath-room, and water-closet accommodation he characterises as simply disgraceful. In conclusion, he strongly urges that the managers should obtain a report on the state of the Infirmary from some one who is recognised as an efficient hospital superintendent.

THE complete text of the report of the House Committee in reply to Dr. Fraser's original letter has lately been published. In it an attempt is made to show that the managers have done all that could be expected of reasonable human beings to obviate any defects as soon as they were brought to light; any that have not been remedied are only waiting until the necessary arrangements in regard to enlarging the hospital buildings have been completed, for fear of incurring considerable expense in some premature scheme which would not lead to permanent good. The only satisfactory thing about this portion of the report is the definite official recognition that the defects do exist which are here recorded. This is a great step, and now that it has been gained, the time will not be far distant before the means of applying a remedy will be discovered. The greater part of the report is occupied with an apparently plausible account of the death from secondary hæmorrhage to which we alluded in a former issue. After a careful perusal of all the documents in reference to this unfortunate case, we are satisfied that Dr. Garden is fully justified in his remarks upon it in his official statement, and agree with him that "there is no thorough method or system in the internal management and arrangements, while anything like proper discipline is at a complete discount."

Two outbreaks of enteric fever having lately occurred in the rural sanitary district of Lincoln, Dr. Gresswell was sent to investigate the matter on behalf of the Local Government Board, and his report<sup>1</sup> is now before us. The outbreaks were isolated, one occurring in the Parish of Faldingworth and the other in the parish of Barlings. The outbreak in the former village was clearly traced to a girl who had been in service in Newark, where typhoid fever was then prevalent, and who came home from there suffering from typhoid; other members of her family were subsequently taken ill, and several members of the families of the near neighbours likewise suffered. Though in some of these cases the disease might have been contracted by direct communication with infected families, it was more probable that they all caught the disease from using the water from a well in the garden of the family first infected; for no fresh cases occurred after the well was condemned, and it was subsequently ascertained when it was cleaned out that a sink cesspool close by had leaked into it. The other outbreak at Barlings was traced to impure water supply. This is derived from the village beck which

passes through the villages of Nettleham and Sudbrook, receiving the sewage from the former direct. The water is allowed to filter through the gravel bed of the beck into ordinary land drain-pipes; by these it is conducted to a well, and thence to a second well, from which it is pumped by hand for general use. It was found that the water in the beck had become contaminated by sewage, and on enquiry the way in which this had happened was very evident. When one of the wells was being cleaned some months previously some of the pipes leading to it were removed, and when they were replaced they were laid in rubble instead of in puddled clay. For some time after this there was a great scarcity of water, so that the sewage had plenty of opportunity to percolate into the pipes. As soon as these facts were discovered, fresh water pipes properly cemented were laid down, and the sewage was conveyed in an iron pipe; and no more cases of enteric fever have occurred since these changes were made.

#### THE ENDOWMENT OF MEDICAL EDUCATION.

IN his address to the British Association at Aberdeen last week, Sir Lyon Playfair stated the case for the endowment of the higher education with undeniable force. It was not his fault if his arguments were mostly of an *a priori* nature. Generations of experience are still needed before we can solve the question whether the endowment of education is likely in practice to secure the ends promised for it in theory. The magnificent scientific endowments in our manufacturing cities are all too modern to furnish an answer to this question, and certainly the history of ancient educational endowments is not one to provide us with much encouragement. In few countries has university and indeed secondary education been more liberally endowed than in England, and yet it would be difficult to find a country where ancestral dower has been so glaringly abused. Is there any guarantee that the colleges which are springing up in our great cities at the command of modern munificence, will not as years roll on sink into the same hidebound uselessness as that which so long characterized the schools and colleges endowed by the munificence of the renaissance? Is any one bold enough to predict for the foundations of our modern merchant princes a happier fate than that which has befallen the foundation of one, Thomas Gresham? It may be answered that what Sir Lyon Playfair demands is endowment and the supervision of endowment by the State, and that the State may be safely counted upon to secure a due return for the moneys expended by it or placed under its charge. That opens a very large question indeed, into which our readers would hardly thank us for entering. But we may remind them that we have frequently had reason to criticize one state-endowed institution, the University of Edinburgh, and that only last week our Edinburgh correspondent gave expression to a view held by many in that city that the medical faculty of the University is kept up to its work very largely through the competition of the

<sup>1</sup> These reports can be obtained from Knight and Co., 90, Fleet Street; Shaw and Sons, Fetter Lane; Hadden, Best and Co., West Harding Street, Fetter Lane; and P. S. King and Son, Canada Buildings, King Street, S.W.

extra-academical school. Surely an endowed institution that owes much of its efficiency to the rivalry of an institution without endowment is not far from being a concrete example of the *reductio ad absurdum*.

The cry for educational endowment is not one that is confined to older countries. We publish this week in another column an extract from one of the leading medical journals of the United States, in which the admitted deficiencies of medical education in that country are traced to the absence of endowment, and it is proposed that no school shall be allowed to be established without a sufficient permanent revenue. For our part we should have said that what is wanted to raise the standard of medical education throughout the United States is not so much the extinction of inefficient schools by the endowment of their more efficient rivals, as the restriction of degree-giving powers and an agreement on the part of the different States to grant qualifications to practise only to those who have gone through a satisfactory curriculum and passed a satisfactory examination. Such a course would do more to extinguish bogus medical schools, than any endowment. The advisability of endowing medical schools involves an entirely different question from the advisability of endowing scientific education in general. The fees at present willingly paid by medical students would be quite sufficient to handsomely remunerate medical teachers, if the work of the latter were but properly economized. If we had only four instead of eleven completely organized medical schools in London there would be no semblance of a just claim for State or individual endowments. It must be borne in mind, moreover, that, as it is, the appliances of medical education are more handsomely endowed than those of any other form of education whatever. The main difficulty in the way of procuring efficient teaching in other sciences is the expense of providing laboratories for practical work. But in the teaching of the practical side of medicine we have laboratories—in other words hospitals—splendidly endowed and freely open as a rule to the medical student without his being called upon to contribute a farthing to their maintenance. All that he has to pay for is the instruction given by his clinical teachers, and though the latter are at present very inadequately remunerated, the fees now paid by medical students would be sufficient to make clinical teaching a fairly well-paid occupation if the expenditure on the teaching of the primary medical subjects were but duly economized. It might not be unfair to claim that Anatomy and Physiology should share in the endowments now being devoted to the teaching of the wealth-producing sciences, Chemistry and Physics, but at present there seems to be no sufficient reason for asking for endowment on behalf of the ordinary teaching of the more advanced medical subjects.

There are, however, two directions in which medical education might with advantage receive some share of the liberality of enlightened beneficence. So far as it is conducted with a view to the requirements of the licensing corporations medical education can support itself. But beyond the standard of the strictest examining body, there is a field where teaching becomes unremunerative in the pecuniary sense. This, if any,

is the form of medical instruction which deserves external support. At present, setting apart the endowed lectures at the College of Physicians and College of Surgeons, and the Brown lectures at the London University, there is no recognized public teaching of advanced medicine. We are glad to know that this want in medical education, which makes of it all a sort of truncated pyramid, is thoroughly recognised by the supporters of university reform in London, and we hope that the supplying of the want will be made an integral part of their programme. The other direction in which medical education might with advantage be more liberally endowed than it is at present, is in the provision of scholarships for poor students and fellowships for poor but able physicians and surgeons. While we do not put forward any claim that the State should make medical education cheaper for the majority of students by throwing a portion of the expense on the tax-payer; while we are quite content that most practitioners should recoup themselves for the capital spent on their education out of the fees of their patients; and further, while we do not wish to see any large number of pauper students entering the profession of medicine; we cannot but confess that medicine must suffer when exceptionally able men are unable to gratify their bent to it, because handicapped by want of funds. If at every medical school a free education were given to one or two students, selected, not as the winners of medical scholarships are now, for their knowledge of Greek and Latin, &c., acquired perhaps at an expensive school, but carefully chosen for their promise and their poverty, we might draw to us many intellects which are at present sacrificed at the shrine of commerce, because they have not the fees necessary to secure them a place in the temple of medicine.

---

#### THE CANVEY ISLAND SCHEME.

THE question, what to do with the sewage of London, seems at length likely to receive a practical solution. The problem has increased in magnitude and in difficulty with the growth of the great city, but quite recently it has been further complicated by that of the disposal of the sewage of a congeries of large and populous villages in the lower valley of the Lea. As they are to all intents and purposes parts of the metropolis, legal technicalities apart, it would seem most natural that they should share in any scheme for the disposal of the metropolitan sewage. But urgent as the case of the Lea valley towns may be, the Metropolitan Board of Works feel themselves quite unable to undertake the task, their own sewers being already overtaxed. We have always maintained that there are only two satisfactory methods of dealing with the excreta and sewage of towns, viz., the midden system for poorer communities and small towns where a market can be readily found for the materials among the neighbouring farmers, and treatment of the sewage by downward intermittent filtration for large towns where it is only by water-carriage that the excreta can be speedily removed from the centres of population. We have repeatedly insisted on the fact that this mode

of treatment can by no means be viewed as utilisation, being rather of the nature of destruction in which the crops, whatever they may be, merely assist in the process. But it is owing to this destruction by oxidation and nitrification that the effluent attains such a degree of purity as to permit of its being passed into rivers without offence. Where local circumstances absolutely preclude such treatment, the A B C alone of chemical processes produces an effluent of like purity, which may be safely allowed to pass into running streams.

Were we now engaged, like the German engineer, Hobrecht, in sewerage for the first time, we should certainly follow the plan so successfully carried out by him in Berlin of conducting the sewage of separate areas by a number of radiating main sewers to as many points in the lowest lands on either side of the river, both above and below the city; but, unfortunately, it is now too late to retrieve the huge mistake of the past, and we must take the metropolitan main sewerage as we find it. One thing, however, is certain, the outfalls at Barking and Crossness must be discontinued, not only on account of their proximity to the metropolis, but because in a tidal river the sewage oscillates perpetually up and down. The Royal Commissioners in their final report declared "that it is neither necessary nor justifiable to discharge the sewage of the metropolis in its crude state into any part of the Thames"; and stated their opinion "that, however dealt with, the effluent should be taken at least as low as Hole Haven." Of the justice of these views there can be no doubt; but the question now arises whether the sewage shall be poured into the estuary as such, or be previously subjected to some process of purification, and if so whether this shall be a chemical one or simple filtration through the soil.

Sir Joseph Bazalgette, in his capacity of official adviser to the Metropolitan Board of Works, proposes to carry the sewage from the southern outfall under the Thames by means of a huge siphon to a point near Rainham, and thence to convey the sewage of both north and south London in a culvert nearly twenty miles in length to Thames Haven, where, after some sort of depuration, it would be pumped into the river, which here has become an arm of the sea. But to this project there is, in our opinion, one serious objection. By no known chemical process, the A B C excepted, can sewage be deprived of its characters, and this one is out of the question on account of its cost and the impossibility of disposing of the enormous quantity of so-called native guano that would be produced. The action of sea water on sewage, coagulating the albuminoid matters and transforming the sulphates into sulphides, would lead to consequences scarcely, if at all, less grave than exist at present, and the Local Board of Southend would justly resent the pollution of the waters in their immediate proximity.

Mr. Bailey Denton and Colonel A. S. Jones have proposed a scheme which, bold as it may appear, is perfectly feasible. It is to convert the Island of Canvey into a vast sewage farm. This island has an area of 5,000 acres of low alluvial land reclaimed from the sea. Its surface is ten feet below high water mark, but it is protected by a sea wall fourteen feet

high. Leaving a zone of a mile in width on the northern side of the island, or that adjoining the Essex coast, on which the necessary buildings would be erected, they would divide the rest of the area, about 4,000 acres, into a series of irrigation fields and filter beds, in which the sewage, brought by the culvert proposed by Sir Joseph, would be pumped, and there treated by precipitation and downward intermittent filtration. As Canvey Island is only a mile further eastwards than Thames Haven a very slight extension of the culvert would be required. The effluent resulting from the proposed method of treatment would not have the slightest deteriorating effect on the sea-water, being in fact far purer than the water of the Medway and other rivers flowing into the Thames. At Merthyr Tydvil it has been shown to contain but '012 of organic nitrogen and '025 parts of ammonia in 100,000 parts, a composition little removed from that of potable waters. Even now a slimy mud lines the sea-shore at Leigh and Southend, and it is in the highest degree probable that Sir J. Bazalgette's scheme would ruin these towns as health-resorts, and be most detrimental to the fisheries. From these objections Mr. Denton's scheme is free, and the additional cost would be insignificant. The island could be acquired by a rate on the metropolis of three farthings in the pound, and the work of buying out the 300 inhabitants who are now saddled with a rate of 13s. 4d. in the pound for the repair of their sea-wall could not be very expensive. It is calculated that the island would suffice for the treatment of the entire sewage of the metropolis for a hundred years, by which time the accumulated sludge would have raised the level of its surface to that of the sea-wall. And then—if there is need to speculate as to so remote a future—it might revert to agriculture, and perhaps a new Canvey be reclaimed from the sea, or the scene of operations be removed to the boundless flats of Foulness.

---

#### THE DISSENSIONS IN AMERICA.

A FEW days after the earliest news of the danger threatening the next International Medical Congress had been published in Europe (*Medical Times*, July 11th and 18th, 1885), the two most prominent officers of the London Congress, Sir James Paget and Sir William MacCormac, each wrote to an American friend to express their view of the situation, a view which coincided in all particulars with that previously given vent to in our columns. These letters were not merely an expression of individual opinion, but were the result of consultation with several of the most influential members of the London Congress. Sir James Paget, in giving his recollection of what took place at Copenhagen when the American invitation was accepted, writes: "Certainly it was not supposed that the Congress would be regulated with any degree of exclusiveness, by the members of one medical association, however numerous, and I think it quite as certain that, if this had been thought possible, the proposal that the next meeting should be held in the United States would not have been adopted." "I am sorry, also," he adds, "to feel sure that if the Congress be not

supported by the eminent men who have now declared that they will take no part in it, the members of the profession in this country who attend it will be very few." Sir William MacCormac, in his account of what happened at Copenhagen, says: "I am sure it was present to the mind of everyone there that the invitation was one from the profession of America, and not from any section of it, or any particular medical society in it. Otherwise, I feel pretty certain Professor Virchow's invitation to meet on the next occasion in Berlin would have been accepted." In our last issue we published what may, we suppose, be called the official reply to Sir W. MacCormac's letter. In it, Dr. Davis, the editor of the *Journal of the American Medical Association*, censures with some bitterness those Americans who have "a morbid tendency to hang their laundry on the front street," and complains that so much attention should have been given to "this little misunderstanding" by European medical journals. Possibly some of the readers of those journals may sympathise with that complaint, but as the welfare of the next International Medical Congress is not a matter solely of American interest, it seems to us to have been the bounden duty of individual men in Europe, and of the European medical press generally, to point out to what extent the organisers of the Washington Congress were departing from the established precedent, which, at any rate, has the argument of unbroken success in its favour. Dr. Davis complains that "the outside world" animadverted on the conduct of the American Medical Association before hearing both sides of the question. It may be replied to that complaint, first, that the action of the Association in disregarding the precedent of previous Congresses, and monopolising the conduct of the Washington Meeting, was in itself a sufficiently accomplished fact to warrant any amount of European animadversion; secondly, that the subsequent action and arguments of the supporters of the Association have served rather to weaken than to strengthen their case; and thirdly, that it may be fairly assumed that the publication of European criticisms has had a measurable share in determining the new Committee of Organisation to reconsider the whole question at issue during the present month, instead of deferring it, as originally intended, until next spring.

We may remind our readers that two main objections have been raised to the action of the American Association—first, that contrary to precedent the Association put itself forward as the sole and exclusive organizer of the Congress; and, secondly, that equally contrary to precedent, it determined that only its own members or delegates from the societies in affiliation with it should be allowed to take part in the Congress. We are glad to hear that the latter objection has been founded on a misconception, and that the conditions of membership were still under consideration and were not to be finally settled until the third of this month. We hoped to have been able to give our readers information as to the result of the meeting at which this point was to come on for consideration, but up to the time of going to press we have received no report of the proceedings. We trust, however, that the more liberal views which have governed the

admission of members at previous congresses will have prevailed, and if so, it may, we think, be safely claimed that the opportune advice of Sir James Paget, Sir William MacCormac, and the European journals has had some share in the result.

But the objection still remains that the American Association, in taking charge of the Washington Congress, has introduced an innovation in the conduct of International Medical Congresses, which is distinctly a matter for international criticism, and, in our deliberate opinion, for international condemnation. One of the most representative medical men in the United States, who had been looked to by the new Committee of Organization as a possible successor to Dr. Billings in the office of Secretary-General of the Congress, Dr. Packard, of Philadelphia, has stated it as his conviction "that it is contrary to all precedent for the American Medical Association to assume any control of the management of the Congress which is a body by itself, and the members of which will be in no sense the guests of the Association, or subject to it." "Were I Secretary-General of the Congress," he adds, "I should not consider myself the appointee of the American Medical Association, nor responsible to it in any degree." We believe that all the officers of past congresses will fully sympathise with Dr. Packard in this candid expression of opinion, even though it implies the condemnation of the action of the original Organizing Committee which first raised the whole question and gave itself over, bound hand and foot, to the American Medical Association, by admitting its responsibility to it. That the original Committee acted with great lack of judgment, first, by a too lavish distribution of offices amongst themselves, and secondly by reporting to the Association, is now, we believe, generally admitted. On this technical point no doubt the advocates of the Association have the best of the argument. But they have as yet proved no vestige of a right on the part of the Association to break through the rule of previous congresses, and to assume the sole management of the Congress of 1887. Dr. Davis's argument that "as there is only one body in England representative of the whole English or British profession, the British Medical Association, so there is only one in the United States which could under any possible circumstances represent the profession in the United States, viz., the American Medical Association"—is ludicrous rather than convincing to the English or British reader, especially when the wise self-effacement of our own Association at the time of the London Congress is borne in mind.

But the further action of the American Association proves better than anything how wise has been the precedent of previous congresses and how ill-advised the attempt to break through it. One of the first acts of the American Medical Association when it got hold of the Congress was to insist that only those in accord with the National Code of Ethics should become officers of the Washington meeting, and as a result of this, many practitioners whose names are household words to us, and who are described by Dr. Noyes in a published letter as "the brightest lights and best workers in the profession," have been expelled from all official connection with the Congress.

By that action, the Association at once broke the pledge deliberately given at Copenhagen, relit the old Code dispute, and attempted to score a point against the "new-coders," by enlisting against them the European visitors to the Congress. The full and final results of this policy have yet to be seen, but its first fruits, in the form of an electioneering manifesto published by the Association and sent to us by its representative, Dr. Shoemaker, are not particularly reassuring. This manifesto is headed, *more Americano*, "PENNSYLVANIA SUSTAINS THE CODE OF ETHICS," and then follows a long list of practitioners in that State, all of whom profess to heartily endorse the action of the Association in raising the Code question. We need hardly add that this single official leaflet will do more to deter respectable English practitioners from taking part in the Washington Congress than all "the statements of certain medical journals and private parties in Philadelphia and New York," of which Dr. Davis so bitterly complains in his letter to Sir W. MacCormac. In our opinion, the time has now come for the officers of past International Medical Congresses to meet together, and decide that, unless the pledge given at Copenhagen is kept, and all attempts to embroil the Congress in ethical disputes are unconditionally given up, the acceptance of the invitation to meet at Washington should be rescinded, and arrangements made to hold the Congress of 1887 in a country where the medical profession possesses greater solidarity.

---

### CLINICAL PAPERS.

---

#### XXIV.—INFANTILE CEREBRAL HEMIPLEGIA.

FOR many years the pathology of paralysis in children was wrapped in obscurity, and essential paralysis was the name given to a condition now universally admitted to be due to lesion of the spinal cord. The very name suggests that the atrophic form is *par excellence* the paralysis of childhood, and it was not without some surprise that the present writer lately met with the statement that paralysis in children is more often of cerebral than spinal origin. A careful review of his own experience since meeting with the above remark has convinced him that the statement is not far short of the truth. Paralysis in children is indeed much more commonly of cerebral origin than the amount of attention paid to it in the text-books would lead the student to suppose.

There is little need here to dwell on the symptoms. In a lecture on the diseases of children, recently published in these pages, it was stated that in regard to most diseases children are but little old men and women. The remark is certainly true in the case of infantile hemiplegia. There are, however, certain characteristics which may be briefly pointed out. First, then, in regard to the mode of onset, and here the writer purposely excludes all cases coming on after any of the acute infectious disorders: measles, whooping-cough, scarlet fever, and diphtheria in his experience are about equally liable to be complicated with hemiplegia

towards the termination of the acute stage. But there are a large number of cases of hemiplegia coming on in infants from six to eighteen months old in which no such exciting cause can be found. The onset is sudden, the child is taken with convulsions (his previous state of health having been perfectly good), which last for several hours, a whole day, or even three or four days. The convulsions are general, but are usually more marked on one side than the other. When the child comes out of the convulsions the parents find that he no longer uses the arm and leg on one side, and perhaps notice that his face is drawn. The side which was most convulsed is the one afterwards found to be paralysed. Hemiplegia coming on in this way is generally more or less permanent; a certain amount of improvement is the rule, but complete recovery is not common. The paralysis of the face usually disappears. Where the child was old enough to speak at the time of the attack some measure of aphasia is common. In a considerable proportion of cases impairment of the mental faculties comes on with the hemiplegia, sometimes amounting even to complete idiocy. In not a few cases a liability to epileptic convulsions remains. In some cases a tendency to purposeless movements, often amounting to athetosis, of the affected side is left behind. There is rarely any loss of sensation in the paralysed limbs. Some degree of rigidity in the paralysed limbs supervenes, and the deep reflexes are often, though by no means always, exaggerated. A prominent feature is that the paralysed limbs do not grow so rapidly as those on the sound side, so that by the time the child is four or five years old, the difference between the two sides may be considerable. There is no true muscular wasting beyond what would be due to mere disuse. As a rule, the optic discs are healthy. One other feature alone remains to be mentioned. If a cyrtometric tracing of the skull be taken it will sometimes be seen that there is very marked asymmetry, the side opposite to the paralysed limbs being distinctly smaller than the other side.

But little is known as to the ætiology of this complaint. The cases in which any infectious disease preceded the onset have already been excluded. In a few cases hereditary syphilis may have played a part, but in many instances there has been no reason to suspect syphilis. Sometimes there is a clear history of a blow or fall on the head, but in a considerable number no cause can be assigned, the infant up to the moment of the convulsive seizure having appeared to be in perfect health. So that in this respect much yet remains to be worked out. Nor is the pathology of the affection much better understood.

The ultimate result—for many cases have been examined after the lapse of some time—is a condition of atrophy and sclerosis of the cortex in the motor area of the opposite side of the brain, spreading into the frontal region when mental symptoms have been prominent, and accompanied by thickening and adhesion of the pia mater over the affected area. But what the changes are which lead to this final result is still a matter of speculation, inasmuch as the chance of making a *post-mortem* examination in the earliest stages is never obtained, or if it be obtained it is

before the symptoms are sufficiently pronounced for the disease to be recognised.

Tumour, which is perhaps the most common form of brain disease in children, may be set aside as negatived by the course of the symptoms. Hæmorrhage may likewise be excluded as extremely improbable apart from any hæmorrhagic or scorbutic tendency. Embolism is more difficult to exclude, and it no doubt is frequently the cause in those cases coming on after one of the exanthemata; but there must always be a cause for embolism, and in the majority of cases this cause would be discoverable if it existed. Thrombosis is still more difficult to exclude, and has the sanction of a very recent and very great authority on nervous disorders; but then, again, thrombosis is hardly a primary condition. A very recent German writer has put forward the suggestion that the lesion primarily affects the large multipolar cells in the motor area, corresponding to the lesion in infantile spinal paralysis, and proposes the name of poli-encephalitis; this view has received the approval of a well-known French neurologist, but the theory hardly accords with what is known as to the ultimate changes in the central nervous system in this disease. On the whole, it seems probable that a local simple meningitis may be the starting point, and that it may be followed either as just stated by thrombosis, or as has lately been suggested by capillary hæmorrhage into the meninges and brain substance owing to the violence of the convulsions.

## II.

### ESSAYS ON MEDICAL CLASSICS.

#### XI.—BILLING.

ARCHIBALD BILLING was born in Ireland in 1791. He studied medicine at Trinity College, Dublin, and afterwards at Oxford, taking the Degree of M.D. at the latter University. He became a member of the Royal College of Physicians in 1818, and a Fellow in 1819. He settled in practice in London, and in 1821 was elected Assistant Physician to the London Hospital. As a student he had been active and enthusiastic, and he now devoted himself with similar energy to the task of teaching; the first regular class of clinical lectures ever given at any hospital in London was instituted by him. In a few years he was appointed Physician and Lecturer on Medicine to the London Hospital, and he continued to attend and teach there regularly until 1836, when he resigned on being appointed a Member of the Senate of the newly-formed University of London. He was elected a Fellow of the Royal Society, and was a member of various continental medical societies. He wrote frequently in the medical journals, but his contributions have never been collected. His chief works are (1) the "Principles of Medicine"—his *magnum opus*. It was favourably noticed from the first, and passed through six editions, the first of only 132 pages, the sixth, including some republished clinical lectures, of more than 700 pages. (2) A treatise on Diseases of the Heart

and Lungs. (3) On "Cholera," which he studied in the London epidemic of 1832. He gave much of his leisure time to the hobby of studying and collecting gems, and published a work on that subject. After a distinguished career, he died as recently as September, 1881, at the age of 90.

Though living in quite modern times, Billing represents the past still more, by his deep appreciation and loyal preservation of what is valuable and lasting in medical tradition. Not that he was blindly or obstinately attached to ancient doctrine, for he was decidedly eclectic, and while after careful trial adopting the old methods by preference, was just as ready to seize and take advantage of any modern discoveries and improvements. He was one of the first to appreciate Laennec's method of auscultation, and to adopt the stethoscope, but on the whole he maintained a cautious attitude in regard to all novelties.

The "Principles of Medicine" is the book which most deserves attention, as it embodies the author's general views, plainly brings out his originality, and is marked throughout by great force and clearness of exposition and reasoning. He writes with evident sincerity and pleasure in communicating his thoughts, as if confident of making darkness light and rough ways smooth. The only objection that might be taken to assigning it a high place in literature is that it is intended as a text book for students and practitioners, and its style is therefore somewhat cramped. His apology for writing, after 20 years' experience as student, assistant and professor, is the recollection of the difficulties which he had met with in the study of his profession, and the hope of removing these from the path of others. As a student, he was "appalled to find medicine and surgery a complete chaos"; but he found that among opposite systems, provided the physician of each school was a man of talent and experience, the results were fairly balanced, and he therefore concluded that general principles would reconcile them. "Men who consider themselves opposed in theory, coincide nevertheless in essential points of practice." He also remarks, in the same spirit, that "every medical man has his hobby to carry him to the same point, which, though he thinks it very different from his neighbour's, is as like it as one four-legged jade is to another." And so he looks for fundamental identity beneath superficial differences. He takes care to make it thoroughly understood that nothing but clinical experience can give sound knowledge; but still it is easy and right to attain principles which shall enable us to act rationally, and not as mere empirics. Far from scepticism, he insists that remedies are by no means valueless and inoperative, but to produce the desired beneficial effect they must be of the right sort, and must be given in the right quantity and at the right moment. His rules are intended to inspire confidence and to help the practitioner to employ heroic remedies with courage and effect, and by avoiding them on improper occasions, to avoid doing injury and bringing them into undeserved discredit. On the whole his principles coincide with the ancient and traditional doctrines: as might be expected, he is an advocate of the antiphlogistic system; not, however, resorting

to it universally, but having a fresh front and method for every principal variety of disease.

Above all, he insists on the importance of always determining the actual condition of the patient at the time, and not being satisfied with recognising that he is suffering from a certain disease; for diseases of the same kind, according to the most approved classifications of the day, require very opposite kinds of treatment; and cases between which our ordinary text-books suggest no connection at all are in reality precisely alike—at any rate so far as the indications for treatment are concerned. Therefore he continually protests against the nosologists, who base everything on nomenclature, and think they have done everything in giving a disease a name. The cure of skin diseases in particular, he maintains, has been much retarded by the well-intended labours of nosologists, with their never-ending distinctions and refinements, which, after all, are only waste of time, the genera being really remarkably few, and requiring only various degrees of the same treatment; drugs must be given according to the state of the constitution. One of his first proceedings in teaching is to lay down clearly the distinction between “inflammation” and “irritation,” the two main classes into one or other of which all diseased states fall, though they often co-exist. These terms had hitherto been used equivocally and interchangeably, and for the sake of preventing such confusion for the future Billing substitutes the term “morbid sensibility” for “irritation.” It is of the greatest importance to apprehend rightly the nature of inflammation, which, after all, is a simple process, and always essentially the same wherever it exists, varying only in intensity and according to the constitutional state; and this essential condition is a loss of power (*i.e.*, of contractility) in the capillaries, so that they become relaxed and dilated; and, though the heart acts more rapidly, the current of blood through the ultimate vessels is slower. Just as a steel spring, heated in a flame, first loses its tonicity, then bends and finally melts, so do the inflamed capillaries lose their contractility, become dilated, and at last may be destroyed, leading to ulceration and gangrene. This loss of power in the capillaries may be produced by some direct local injury, or through debility of the nervous system; thus idiopathic fever, which does not essentially differ from an inflammation, is due primarily to debility of the central nervous system, brought about by some poison or other disturbance.

The therapeutic part of the work is the most suggestive and useful; the wide, general, and, on the whole, accurate notions that are given of the action of remedies, and made the grounds for their classification, are extremely striking, and are none the less thoroughly practical, being founded on the soundest principles of pathology, in correspondence with the surest indications, and it is perhaps superfluous to say that there is but little resort to the laws of pure physics and chemistry. All remedies are divided into four great groups—stimulants, sedatives, narcotics, and tonics: any one may often be substituted with indifference for another of the same group, and by properly combining two or more the effect of another may be exactly

reproduced. The action of each class is thus described. Stimulants increase the action of the heart and other organs through the medium of the nervous system, by causing an immediate liberation of nervous influence; they are either diffusible and general or local; in the latter case usually acting by sympathy through the stomach upon the distant organs with which it is related. A sedative is the exact contrary; instead of liberating it represses nervous influence; thus it diminishes the action of the heart, and in a large dose depresses the spirits and makes the muscles unsteady. But it is of the utmost importance to remember that this depressing effect is produced only in a state of health or real exhaustion; if there is *apparent* debility from oppression or plethora, sedatives will produce a healthy and pleasurable state, by removing the “morbid sensibility.” And, of course, it must be borne in mind that opposite states will produce similar appearances, and skill in diagnosis is requisite in each case to decide correctly whether the debility is real or apparent—due to exhaustion or plethora. Thus “sedative” does not imply “putting to sleep”; that is the function of hypnotics, and is much more special and brought about in various ways, according to the particular conditions of the case; but “a sedative” produces an effect on the nervous system “as if it had been refreshed by sleep,” by preventing the undue extrication of nervous influence. It is sometimes the reverse of hypnotic, causing increase of perception and wakefulness—*e.g.*, digitalis and green tea. On this account sedatives are of great use in fevers, whereas stimulants, on the other hand (until the last stage), are just as prejudicial, by increasing the excitement. The best sedatives for fevers are known as antiphlogistics, a name which, unfortunately perhaps, has now become almost a dead letter. The principal agents for the purpose are bleeding, rest, and low diet, to keep the pulse down, and sedative drugs to steady (and thereby refresh) the nervous system.<sup>1</sup> Sedatives only act either on the heart and arteries, and of these bleeding is the chief, or locally on the capillaries (chiefly of the *primæ viæ*), for which salines, antimony, mercury, colchicum, or digitalis may be employed. The heart in typhus, he says, is like a tired horse trying to pull a cart up a hill; stimulants, like a whip, force it to an effort under which it sinks; sedatives remove part of the load behind and enable it to accomplish the task, and thus they, in fact, give strength by facilitating recovery of power. The error of the Brunonians lay in confining themselves to stimulants, expecting the effect to be the same as in the healthy body. External cold is a powerful sedative. Salines constrict the capillaries and arterialise the blood. Slightly nauseating doses of antimony will prevent the formation of an abscess. The use of sedatives will often dispense with the need for venesection, but they only lessen the violence of a fever, they do not cut it short. Fever is gone when the nervous system begins to generate nervous influence—especially manifested by the *movements of the eye*.

Narcotics diminish the sensibility of the nervous system, allay pain, check volition, and promote sleep;

<sup>1</sup> Billing considers it impossible to dispense with bleeding, and absurd to try to do so, and he remarks with astonishment that there are even persons who have been thirty or forty years in extensive practice who have not made use of a lancet so many times.

they impede the communication of nervous influence, but do not alter its quantity. Some have such a strong and disagreeable local influence that they cannot be used in sufficient amount to act on the brain and produce sleep. The true mode of giving hypnotics successfully is to know what treatment, whether sedative, stimulant, or tonic, to join with them. Thus, opium, being a stimulant as well as a narcotic, requires the addition of a sedative in fever. Hyoscyamus is a sedative narcotic, and, if given when a stimulant is indicated, would produce delirium instead of sleep. Aconite, belladonna, and tobacco are likewise sedative narcotics, and in excess or wrongly applied, will produce delirium tremens and sickness. In the later stages of fever there is often much morbid sensibility and undue susceptibility to impressions on the nerves and central organs, shown by the effects on the sensory, organic and motor nerves; for this condition opium does most good, and if some fever still remains it should be associated with antimony, digitalis, or salines. Or if at an earlier period the patient be constitutionally weak, morphia may be used to lower the pulse instead of bleeding.

Tonics do not call forth action, but give power to the nervous system to generate influence. They are of most use during the reparative process after inflammation, though bleeding, purging, &c., may be needful at the same time to prevent recurrence of disease. In small doses, as an alterative, mercury may be a tonic, by causing the capillaries to contract in chronic inflammation, but in large doses it stops nutrition. Iron is of value in anæmia, not by supplying material for the formation of blood, but by restoring the tone of the system, thus encouraging the production of new blood and strength. When anæmia depends on special causes, iron fails, while bark succeeds in ague, mercury in hepatic diseases.

A good deal of attention is also paid in this work to special diseases, with a view to elucidating their nature, and giving directions for properly combating them. The disease which will most of all attract attention is cholera, the proposed treatment being novel, almost startling, and without thorough confidence in the *rationale*, requiring much courage in adoption. Billing rightly calls it a febrile disease: the characteristic collapse is not dependent on the diarrhœa, &c., but is really the usual first stage of a fever only in a very intense degree. It follows, therefore, that the same treatment that serves for ordinary fevers, will answer best in this instance. In accordance with these principles, the best prescription will be tartar emetic gr.  $\frac{1}{10}$ th with sulphate of magnesia gr. xij every half hour, and a few doses will probably speedily cause the vomiting and purging to abate, and improve the patient's condition; sometimes it will quite remove all dangerous symptoms, but of course will not save every case. But the administration of brandy and external warmth should be strenuously avoided, as these only aggravate the malady. After a good effect has been produced, five grains of calomel may be given. Sometimes a patient may be roused in the algid stage by bleeding; the blood is too thick and tarry to flow freely at first, but as soon as it does, it

gives relief. Common salt and mustard may be given if antimony, &c., are not at hand. Similarly, ague may be treated by bleeding or emetics in the cold stage, with calomel and bark in the intervals. Influenza also requires antimony at first, then salines and tonics. Billing holds that there is but one kind of fever, with several varieties—exanthematic, petechial or continued, and may-be typhous.

Neuroses, like inflammations, are diseases of the nervous system; but in the latter there is want of motive power, in the former the machinery is out of order. Ague is a connecting link between the two. Neuroses are marked by morbid sensibility in one form or another. As a rule they do not bear depletion well. The exposition of this class of diseases is very good, and considerably developed in the later editions of the work; we would especially call attention to the account and explanation given of hysteria and insanity.

As before remarked, Billing has some original and suggestive observations on the kinship and resemblance of drugs; thus cubeb is identical with a mixture of turpentine and pepper, which may be used instead with almost equal effect; arsenic is equivalent to mercury and bark, and will sometimes cause salivation. The subjects of gout and rheumatism are also touched upon, their grounds of resemblance and difference pointed out, and the error of mistaking the local phenomena for the general disease; also the entirely different methods of cure demanded by gout in a strong and a weak constitution. He protests against sending the victims of phthisis indiscriminately to a warm climate, for more good is to be done by tonics and generous living at home; and in the same way he protests against extreme restriction of the diet in dyspepsia, his aim being rather to restore the tone of the stomach, to enable it to digest ordinary food. Throughout the work there is not much room for anatomical details, and perhaps this is no great pity. Billing was equal, however, to such matters, and when occasion arose, discussed some questions warmly, taking great pains, for instance, to prove the valvular origin of the sounds of the heart. But his chief merit lies in insisting on the importance of constitutional states and their chief variations; and in showing how, by attending rightly to these, local conditions, which may be the best indices, may be best overcome. For his encouragement of the habit of taking broad and sensible views, instead of falling into the confusing ways of minute philosophers, as well as for his clearness, simplicity and sincerity, this work of his is likely for long to take a high rank among authorities to be consulted with profit.

---

UNIVERSITY COLLEGE.—The annual dinner of the old and present students of the Faculty of Medicine, will be held on October 1st, at 6.30 p.m., at the Freemasons Tavern. Professor John Marshall, F.R.S., will preside, and many distinguished former students (including Sir William Jenner) have expressed their intention of being present. Tickets, 12s. each, may be obtained from the Honorary Secretaries, Dr. Poore and Mr. Stonham.

## REVIEWS AND NOTICES OF BOOKS.

*A System of Practical Medicine by American Authors.* Edited by WILLIAM PEPPER, M.D., assisted by LOUIS STARR, M.D., Vol. II. London: Sampson Low, Marston, Searle and Rivington, 1885.—The second instalment of this great undertaking has appeared with a punctuality which is most praiseworthy. In it the general diseases commenced in the former volume are continued and concluded, and the diseases of the digestive system are subjected to exhaustive treatment. The major part of the volume is devoted to diseases of the alimentary tract, which are dealt with in twenty-six separate chapters; this has necessitated an amount of sub-division of the subject that is not altogether advantageous—for instance, in regard to the stomach alone, we have one chapter on the functional and inflammatory diseases to which it is liable, one on simple ulcer, one on cancer, one on hæmorrhage from the stomach, another on dilatation of that viscus, and lastly one on its minor affections. If the editors had “run on” some of these articles, we should not have been disposed to quarrel with them. The article on diseases of the liver, which subject has been allotted to Dr. Bartholow, is excellent, constituting, as it does, a complete account of our present state of knowledge on the subject. We notice, however, that he does not deem hypertrophic cirrhosis as a distinct variety or worthy of a separate description. Although the first to sound the gall-bladder for gall-stones, he does not consider it so safe an undertaking as a recent distinguished writer in this country would have us believe. Abscess of the liver he attributes in a majority of instances to dysentery or to a special form of inflammation of the rectum. Diseases of the pancreas have fallen to the lot of the assistant editor, Dr. Louis Starr, who has given an excellent summary of what is known on this somewhat obscure subject. Dr. Alonzo Clark contributes the section on diseases of the peritonæum, which is rendered of additional value by the interesting account he gives of the introduction of the treatment of acute peritonitis by opium, in bringing about which he had no small share. The early part of the volume is occupied with the continuation of the account of general diseases commenced in the former volume, the first article being upon rheumatism, and written by Dr. R. P. Howard. Of this and of the succeeding article on gout, by Dr. W. H. Draper, we may say that both are models of what such articles ought to be, concise and lucid descriptions of the diseases of which they respectively treat. The article on rachitis is by Dr. Jacobi, whose long experience of children's diseases entitles him to write with authority on this subject. He agrees with most writers on this side of the Atlantic in regarding the main cause as “bad, insufficient, improper food, with its immediate result, viz., intestinal catarrh”; bad air alone, even when damp, is in his opinion insufficient to cause it. The question of the part played by syphilis in the ætiology, so strenuously supported in the affirmative by the late M. Parrot, he discusses at some length, accepting the generally received view of the present day that though syphilis may be a cause of rickets, it certainly is not the cause of it. We are not so sure, however, that his views on congenital rickets will be regarded on this side of the water as quite sound; we have been learning to regard foetal rickets as a totally distinct affection, resembling ordinary rickets only in name, but for Dr. Jacobi they are one and the same disease. No statistics are given as to the relative frequency of rickets in the United States, an omission much to be deplored considering that the alleged rarity of the disease in that country as compared with England might, if duly attested, serve as a basis for a better understanding of its causation. Dr. Jacobi claims cranio-tabes and sub-periosteal vascular thickening of the cranial bones as rachitic, without a hint as to the possibility of their being syphilitic, which will probably surprise many readers here; and he does not separately recognise that large class of cases where the disease seems to have fallen mainly on the muscles and ligaments which are remarkable for their flabby and lax condition, the long bones remaining

straight and their extremities not thickened. The remarks on treatment are very good. Then follow short articles of scurvy, by Dr. Philip Wales, and on purpura, by Dr. J. E. Atkinson. The next article is on diabetes mellitus, and is written by Dr. James Tyson, who commences with a clear summary of the most recent views as to the pathogenesis of the disease. As regards the morbid anatomy, he has been quite unable to recognise any changes in the central nervous system, and he seems inclined to regard disease of the pancreas as playing an important part, at any rate in a considerable proportion of the cases. Diabetic coma is in his experience always due to acetonaemia; he does not regard coma as an absolutely fatal symptom, as it occurred in a little girl aged 12 under his observation who made a good recovery. He speaks very highly of the skim-milk treatment, which he finds suitable for all but the most advanced and complicated cases. The treatment of diabetic coma is dismissed with the single remark that transfusion of blood has been recommended for acetonaemia. Scrofula is the subject of a careful article by Dr. J. S. Lynch. Probably most of our readers will agree with his opening statement to the effect that there is no disease of which it is more difficult to give an exact and satisfactory definition. His views on the relationship of scrofula, tubercle and pulmonary consumption are a little confusing, and hardly in accord with the most modern teaching. He denies anything more than a purely incidental relationship between the two former, but between scrofula and pulmonary consumption he believes there is the very strongest possible connection, as he holds that fully 95 per cent. of all cases of pulmonary consumption are of inflammatory origin, and that every stage in the process is attended with that abundant cell production, and the process itself is marked by that inveteracy and intractability which always characterise scrofulous inflammations. The last article under the head of general diseases is on hereditary syphilis, by Dr. J. William White. The author commences with a discussion of the means by which the foetus may become infected, showing himself to be thoroughly acquainted with the views that have been at various times expressed on this subject. The symptoms of hereditary syphilis are considered in detail, but we should have been glad to see a fuller description of retino-choroiditis, and we regret to find the author attributing the prominence of the forehead to a past arachnitis and hydrocephalus, an opinion that we thought had been exploded for some time, instead of to its undoubtedly right cause, viz., massiveness of the frontal bones. A copious index concludes the volume, which, as a whole, fully justifies and maintains the high opinion we formed of the undertaking from a perusal of its predecessor.

*Les Microbes Pathogènes; Leçons professées à la Faculté de Médecine de Bordeaux;* par Le Dr. C. ARTIGALAS, Professeur Agrégé, Médecin des Hôpitaux. Bordeaux: H. Duthu, pp. 258, with six plates.—In this volume, which consists of lectures delivered by the author during the past six months, M. Artigalas has aimed at placing before his class the present state of our knowledge on micro-organisms. The first lecture plunges headlong into the subject by giving an account of actinomycosis. Next come five lectures on Methods, Cultures, &c.; then six on Tuberculosis, while the remaining six are devoted to Pneumonia. The author is an ardent supporter of the germ theory, and we gather from a perusal of the whole work that he holds the belief that tubercular and pneumonic diseases are due to micro-organisms whether present or absent. Micro-organisms having been found in tubercles, therefore, even when no bacilli are to be discovered by any known method, it is because they are in some condition insusceptible of coloration. Naturally, therefore, Professor Artigalas states that the tubercular microbe exists under more than one form. These forms, three in number, are (1) The micrococci of Aufrecht, Toussaint and Klebs; (2) The zooglæa described by Malassez, sometimes composed exclusively of spheroidal elements, sometimes being a mixture of cocci and rodlets; (3) The bacillus of Koch. The history of the tubercular zooglæa is too curious to be withheld. Two hours after the death

of a person a tubercle was taken from the skin of the external surface of the forearm. (As to tubercle in any other part of the body, no reference is made.) Examination of this tubercle showed no sign of tubercle bacillus. Guinea pigs and rabbits were inoculated with matter taken from the cutaneous tubercle, and although in all cases pulmonary and serous tubercles were found in these animals after death, no bacilli were discovered till the sixth generation, when they suddenly appeared. This account is highly suggestive of some error; but in favour of the statement we will admit that we have more than once been unable to find bacilli in cases of acute tuberculosis, but have found colonies of micrococci. The author bewails the tendency of too warm sympathisers with the germ theory to push their views to an extreme, but in more than one place he himself advocates ultramontane doctrines, such as that of panspermism; *e.g.*, on p. 15 occurs the statement that this case (actinomycosis from wall mould) would tend to prove the theory of panspermism, and to quote the actual words: "ce changement en micro-organisme pathogène, dans certaines conditions, d'une mucédinée ou d'un schizomycète indifférent de sa nature." Thus, the author, like the schizomycete, is "indifférent de sa nature" as to consistency, for at one time we find him telling us that a special microbe is required to produce tubercle or pneumonia, and at another, as in the passage above quoted, that a mere ordinary fungus, if the conditions of its life be changed, is quite sufficient to do the business. Another specimen of advanced doctrines is, "la cellule géante seul vestige du vaisseau." Now, if anything is as yet unproved histologically, it is that the giant cell is a direct derivative of a blood vessel. We have never seen anything which might be taken for a logical proof of the connection, but if assertion is to be considered demonstration, we shall then be prepared to admit the vascular origin of a giant cell. And having made the statement that giant cells are derived from blood vessels, the author proceeds from these premisses to prove why the bacilli of tubercle are found at the centre and periphery of giant cells. It would take too long to transcribe the whole cycle of tubercular inflammation as given by our author, but we feel bound to indicate his notion of the formation of a grey tubercle. Bacilli pass from the peri-alveolar blood-vessels into the endothelial cells, and owing to the swelling of these cells, find themselves in the centre of the alveoli. Then the infundibula, blocked by cells containing bacilli and by a little fibrillary fibrin, form what is called a grey tubercle. We cannot refrain from alluding to what is called cardiac tuberculosis, or perhaps, more correctly, the presence of a few microbes in the vicinity of the heart. According to M. Artigalás, when the heart is invaded by micro-organisms, these make their first appearance in what is denominated the subvalvular triangle, an anatomical area at the junction of the aorta with the aortic valves and cardiac muscle. Now, it would appear that M. Artigalás has examined the heart ten times for bacilli, and in this subvalvular space has found in one single case four bacilli. We consider the inference which is drawn from this fact to be a very fair specimen of what might be termed scientific Chauvinism. Scattered through the work are some references to certain "Fortes ante Agamemnona." It is almost needless to state that the Fortes are Gallic, and that Koch may perhaps be considered the Agamemnon. Nor is perfidious Albion spared, for in the chapter which discusses pneumonia as an infectious disease, it is stated that emanations from drains play an important part in English pathology. "C'est là une théorie chère aux Anglais." This, we think, will be quite enough to show what the author's views are like in matters associated with tubercle; and now let us turn to the last third of the work, which deals with pneumonia. Here the author shows himself even more enthusiastic, and devotes three lectures to demonstrate that pneumonia simplex, or acute lobar pneumonia, is a malady at once infectious, contagious, epidemic and inoculable. Furthermore, its invariable cause is a specific microbe distinguished by one end being larger than the other, and by the possession of a definite capsule, and these micrococci form colonies which are found in more or less abundance in the blood according to the intensity of the pneumonia. It is also as well to know that there are a con-

siderable number of bacteria free in the exudation or in the endothelium, which they occupy after the manner of the bacillus tuberculosis. With regard to the mode of ingress to the body of the specific microbe of pneumonia, the author expresses his inability to decide. It is in the blood, but how it gets there M. Artigalás does not know. These may be facts, and if so with some special meaning, but when the writer goes on to say (p. 217) that the presence of the microbe determines an intense congestion of that part of the lung affected, and that this congestion always terminates at a more or less distant time in hæmorrhage, we feel bound to regard all the facts which seem novel to us by the light of Nature and experience. Of course, it is rare to meet on the *post-mortem* table with pneumonia in its earlier stage. Yet we have more than once had this opportunity, and the microscopical appearances gave no indication of hæmorrhagic extravasation into the alveoli. Moreover, such a condition of things would presuppose a general and extensive injury of the smaller blood-vessels, and when the rapid and numerous recoveries from severe croupous pneumonia are taken into consideration such a hypothesis, for it is nothing more, is quite groundless. We, of course, do not mean to assert that red blood corpuscles are never to be found in the alveoli; but to say that the first stage of pneumonia is a hæmorrhagic congestion, and consists of a very intense diapycnosis of red corpuscles into the alveoli, seems to us an unwarrantable assertion, and we feel inclined to back up Klebs, whom M. Artigalás takes to task for mixing up the three so-called stages of pneumonia. The author brings out one important point in the pathology of pneumonia with which we can agree, and this is the prominent and efficient part played by the endothelium of the alveoli, and we are glad to see that little part is ascribed to the action of the white blood corpuscles. We will quote one more instance of the style of argument adopted by the perfervid school of mycologists. In chapter 13, it is stated, in reply to the ideas of Traube and of Bernheim, that "nothing is less rare than to find pneumonic foci round about confluent granulations in tuberculous persons. The co-existence of the two microbes in the same subject is thus demonstrated." Almost everybody who keeps an aniline dye and a test-tube half full of gelatine seems unable to resist this feminine form of logic. We have picked out from the volume a few things which seemed to call for notice: in other respects these lectures do not appear to differ much from other books of the same size on the same subject. We have not noticed anything particularly new except the point which is made of the subvalvular triangle as a receptacle for micro-organisms, and this we sincerely deplore because other mycologists less capable than M. Artigalás may now feel prompted to investigate other parts of the human frame for analagous microbial depôts.

---

## ABSTRACTS AND EXTRACTS.

---

MEDICAL EDUCATION IN THE UNITED STATES.—The *Boston Medical and Surgical Journal* in the course of a leading article on this subject remarks: "It is disgraceful, and yet it happens constantly, that men are graduated by prominent medical schools or colleges in this country without ever having listened to an abnormal heart-sound, seen a case of measles, or been present at a confinement. So long as a medical college is dependent entirely upon the fees of its students for support, the highest educational good cannot be attained. The question concerns endowment, and the statement of a few facts will demonstrate this need. With our present population of fifty millions we have eighty-seven medical schools (the irregular schools are not included in this enumeration). Of these schools thirty-nine have been opened within fifteen years, and twenty-one within five years. With them are associated 1,300 instructors and over 10,000 students, and about 3,600 new doctors are annually 'turned loose on the community.' Forty-six per cent of these schools offer only a two years' course, and practical work is for the most part optional. A little

dissection, a thesis and examinations upon the lectures are all that is required in many colleges, before receiving a diploma. There are fortunately a few colleges where a much higher standing is required. The reason why so many of our students annually go abroad to Paris, Berlin and Vienna is that they can join small classes where they can practically demonstrate every fact for themselves under the guidance of an instructor. But practical work means increased expense. There need to be laboratories for chemical, physiological, anatomical and pathological research, rooms for photography and for the reception and treatment of patients at clinics. Increased expenses mean higher charges with the risk of seeing students leave for cheaper and easier colleges. This lack of endowment is a check upon all growth. General Eaton, the Commissioner of Education, strongly advises that every medical school or college be required by law to procure forthwith an endowment of not less than \$300,000. A certain amount of endowment required by law would prevent the formation of new medical colleges without proper laboratories, apparatus, or facilities of any kind. To-day the value of income-bearing funds of eighty-seven medical colleges does not exceed \$350,000, with an annual income of about \$20,000. The precarious footing on which these institutions stand is to be inferred from the fact that fifty-one medical schools and colleges have ceased to exist within a century. It is a grave misfortune that so many medical colleges now exist, for it is a farce to attempt to educate medical students away from the hospitals and dispensaries which only the largest cities furnish in abundance. The tendency to-day in all branches of education is more and more toward placing practical work and personal observation before tradition and theoretical instruction. Medical education should not be left behind in facilities."

## PHARMACOLOGY AND THERAPEUTICS.

**ANTIPYRIN IN SUNSTROKE.**—Dr. B. F. Westbrook records two interesting cases (*New York Medical Journal*, July 25th) in which this remedy was used successfully. The first was that of an Englishman, aged 22, who, after working out of doors all the forenoon with the thermometer at 99° Fahr. in the shade, became comatose and convulsed on reaching home at mid-day. When first seen, the head was congested, eyes suffused, pulse rapid and strong, skin dry, and the coma profound. The bowels had moved spontaneously and he had vomited freely. The rectal temperature was 109° Fahr. One drachm of a fifty per cent. solution of antipyrin was administered hypodermically and ice applied to the head. About three-quarters of an hour later the rectal temperature was 107.5°. Towels wrung out of ice-cold water were applied to the head and body, and another drachm of the solution was given *sub-cute*. In thirty minutes the rectal temperature was found to be 99°. The cold applications were at once discontinued, and dry heat applied to the surface, while whiskey was injected subcutaneously. The body surface was now cool, the pulse 120, the coma profound, and all the limbs twitching convulsively. The conjunctivæ were still injected, the pupils contracted but responding feebly to light, and the respirations irregular and groaning. Two ounces of whiskey and forty grains of chloral hydrate given by enema were not retained. Half an ounce of whiskey was then given subcutaneously, and in half an hour the surface temperature began gradually to rise. Then followed a series of violent tetanic convulsions. Venesection occasioned the withdrawal of thirteen ounces of blood from the arm, but was interrupted by a most violent convulsion, in the course of which the limb was forcibly flexed, and the opening in the vein thus occluded. But after this the patient became quiet, and the rectum retained forty grains of chloral hydrate. The axillary temperature was found to be 103.75°. One drachm of Lente's solution (of quinine) was given hypodermically every two hours until four doses were administered. At 8.15 p.m., as slight convulsions were recurring, six leeches were applied to the temporal region, twenty grains of antipyrin given *sub-cute*, and forty grains

of chloral hydrate by the rectum. From this time sleep was quiet, and the temperature slowly declined until it was 99° on the morning of the next day. The patient was then put on full doses of sodic bromide and sulphate of quinine, gradually decreased as convalescence proceeded. The second case, which occurred on the same day, was less severe, although the rectal temperature on admission was found to be 110°. Thirty-five minutes after the injection of half a drachm of antipyrin beneath the skin it had fallen to 101° Fahr. No cold applications were used in this case, with the exception of ice to the head. Enemata of whiskey and chloral were used. The man, an Italian, made a good recovery. Dr. Westbrook, who had never before seen so bad a case as the first recover, remarks that where antipyrin is used the external application of cold would appear unnecessary; and that although the temperature declines under the use of the drug, the cerebral symptoms still continue—several hours being required by the vaso-motor apparatus for recuperation after such intense hyperpyrexia and vascular excitement. Half a drachm of antipyrin seems a sufficient dose. A fifty per cent. solution is easily made, and produces very little irritation when injected under the skin.

**SOLUTION OF COCAINE IN PETROBASELINE.**—M. Pierre Vigier, in one of his pharmaceutical articles in the *Gazette Hebdomadaire*, July 17, calls attention to the great value of a new vehicle for the administration of cocaine. It is a liquid hydro-carbon formed from vaseline by depriving it of the 25 per cent. of paraffine which it contains, and which gives it its consistence. It is a new prodigy of industry to which a manufacturer has given the name of *péetrobaseline*, and is now obtainable at all druggists at two or three francs the kilogramme. It is an inodorous and colourless liquid, resembling clear water in appearance; it is volatile at a high temperature, insoluble in water, and yet does not grease. It possesses the power of dissolving the carburetted hydrogens, while it is less inflammable than they are. It lubricates all bodies, and preserves them from oxidation; and, in fact, is a marvellous agent, endowed, as it is, with the principal properties of water, alcohol, glycerine, and the fixed oils. It is destined to have many applications, and already perfumery has made great use of it, and it cannot be too soon introduced into medicine and pharmacy. A solution of cocaine may be made by adding 1 gramme of this to 40 grammes of petrobaseline. This is to be dissolved by aid of a very gentle heat, and then filtered or allowed to deposit. This solution is unalterable and is convenient in application. When the price of cocaine has diminished, it will be able to be employed in the proportion of 1 gramme to 25, which is the point of saturation.

**BORATED PETROBASELINE.**—M. Pierre Vigier observes in the *Gazette Hebdomadaire*, August 28th, that if he has become so ardent an advocate of petrobaseline it is because he thinks that this beautiful preparation of vaseline is called to perform great services, while it is so cheap that it costs only 3 francs 75 cents. the kilogramme. His former observations, he says, upon the proper employment of the hydro-carburets have been so little attended to that he feels called upon to repeat them. At present practitioners seem to think all they have to do is to substitute in their prescriptions vaseline for lard; so that on the occasion of the introduction of the new hydrocarburet, termed petrobaseline, he wishes to repeat the principles which should guide the employment of topical applications: (1) Lard and oils by softening the skin form the best vehicles for medicinal substances; (2) the solid and liquid hydrocarburets, while possessing the great advantage of not undergoing any change, oppose to a certain point, or, at all events, retard absorption considerably; (3) glycerine and its compounds, not moistening the skin, entirely oppose absorption, and should be employed as topics only *sui generis*, and not as excipients. But glycerine is most useful as a vehicle when we wish to prevent absorption, as *e.g.*, with corrosive sublimate, or when irritating effects have to be attenuated, as with regard to carbolic acid or arnica. As to petrobaseline it seems destined to play an important part in therapeutics; but its properties require further study, as these are sometimes very singular. Thus, while it will not dissolve

boracic acid it will dissolve borax itself, and the following is a useful combination of this sort—liquid petrobaseline 25 and powdered borax 1 part, dissolve at a gentle heat and filter.

**PYRIDINE IN ASTHMA.**—Prof. Germain Sée, in a paper inserted in the *Bulletin de Thérapeutique*, June 30th, observes that in the treatment of nervo-pulmonary and cardiac asthma, the only curative agent is iodine, and that of 370 cases so treated by him during the last five years, most of them were cured by its agency. Still, the occurrence of intolerance of the remedy in the shape of iodism in some of them rendered it necessary to have recourse to various empirical and often secret remedies. By chemical analysis it has, however, been found that all this effect is due to a substance named *pyridine*. This is obtained by the dry distillation of organic matters of various kinds, forming a colourless and easily vaporisable liquid of penetrating odour, which is readily mixable with water, and forms very soluble salt with mineral acids, which, however, are easily separable. The conclusions to which the author arrives on this substance are as follows: 1. Whatever be the form of the asthma, whether it be nervous, emphysematous, or catarrhal, whether it be primordial or of a gouty or dartrous origin, iodisation constitutes the true curative method. When iodism supervenes, the employment of pyridine is indicated, being the most certain agent for the relief of the paroxysm, the best palliative just as iodine is the most efficacious remedy. 2. It is superior in power to the injection of morphia, its action being also more durable and far more inoffensive. 3. In simple nervo-pulmonary asthma, the paroxysms can be completely put an end to. In severe asthma complicated with permanent pulmonary lesions, the treatment has to be continued for more than eight or ten days, in order to consolidate the amelioration obtained. And when we have to do with cardiac asthma, with or without renal or dropsical complications, pyridine may still be of the greatest service in combating the most persistent and the most painful of the phenomena—that is, oppression of breathing whether continuous or paroxysmal. The pyridine is administered by inhalation.

**THE ANTIDOTE TO DATURINE.**—A Hungarian physician being called to a child of four who was in a comatose condition from having eaten, as her playfellows said, two handfuls of the ripe berries of the thorn apple (*Datura Stramonium*), and in whose vomit the berries could be plainly detected, gave pilocarpine hypodermically, thinking that as that had proved successful in atropine poisoning it ought to be useful in datura poisoning also. He began with the fourteenth of a grain, and as no effect was produced he increased the dose to a seventh. As improvement was now evident this was repeated. Altogether in five hours he gave six-sevenths of a grain, and by that time the child was convalescent. No physiological symptoms of pilocarpine were produced until the last dose was given, which was followed by profuse secretion of saliva and perspiration. The author therefore concludes that five-sevenths of a grain of pilocarpine had been required to neutralize the daturine, its own physiological action not coming into play until that was completely effected. He thinks that this case sufficiently demonstrates that pilocarpine is antidotal to daturine.

**THE CONSTITUENTS OF THE URINE.**—Dr. Dresser has investigated the relationships of the acid and alkaline constituents of urine. Solutions of acid magenta were injected into the dorsal lymph sac. After this the urine was of a deep red, and the addition of an acid did not change the tint. This shows that an acid substance is secreted equivalent to the quantity of alkali which would bleach the colour. After fifteen to twenty hours the colour was fainter, but was changed by acid but not by hydrogen peroxide or other oxidizing agents, so that it is not reduction but combination with an alkali that takes away the colour. The author found that it is possible to have an alkaline reacting solution and at the same time acid reacting substances present. He considers the urine to consist of two components—the acid and the alkaline, the former originating from the

tubuli contorti, the latter being the filtrate from the glomeruli. During unusual activity the alkaline secretion preponderates.

**IMPROVED SOLUTION OF OSMIC ACID FOR INJECTION.**—Osmic acid is very expensive, and if dissolved in water alone, the solution changes colour after three or four days, and shortly afterwards becomes unfit for use. A Russian physician, Dr. Schapiro, finds that if glycerine—which, by the way, must be chemically pure—is added to the solution, it will keep for some weeks. He advises the proportions osmic acid 1, distilled water 60, glycerine 40. He has injected this under the skin of the face without any untoward result. His treatment of neuralgia of the fifth nerve by means of injections of osmic acid has been very successful, five out of eight cases of long standing, which had resisted other modes of treatment, having been completely cured, while two were relieved. Only one case was unrelieved, and here some central disease of the nervous system was believed to exist.—*St. Petersburg Medicinische Wochenschrift*.

**AN ANTISEPTIC OINTMENT.**—Dr. Thayer has found the following ointment very useful at the hospital department of the Mexican Central Railway: Iodoform ʒj, sub-nitrate of bismuth ʒiv, boracic acid ʒij, vaseline ʒij. It is spread on a sheet of absorbent cotton sufficiently large to cover the wound and a considerable extent of surface around it. It is well suited for the after-treatment of amputation-wounds, as it can be easily removed when necessary without adhering to the wounded surface. The first dressing is usually left undisturbed for from four to six days. Even in the warm climate of Mexico, there was not present the least disagreeable odour. It was employed in more than 400 cases, comprising some very important wounds, and with great success.—*New York Medical Record*, July 18.

**ANTIDOTE IN CASE OF POISONING BY RESORCINE.**—Dr. Andreev, having remarked that in poisoning by resorcine the arteries are almost empty while the venous system is engorged, made use of hot baths as restoratives; their effect, however, was contrary to what he had expected. He then had recourse to red wines, especially the good vintages of Bordeaux and Burgundy, and under the influence of these general stimulants the toxic symptoms rapidly disappeared.—*Le Scalpel*.

## DERMATOLOGY.

**HYPODERMIC INJECTION OF LIQUOR ARSENICALIS IN MULTIPLE SARCOMA OF THE SKIN.**—At the end of 1882 K. B., aged 31, began to suffer from pain and swelling behind the angles of the lower jaw. Two months later nodules appeared in the skin over the right shoulder, then on both arms, then in the abdominal wall. The appearance of the nodules was preceded by local tenderness and followed by discolouration. In July, 1883, the patient was noticed to be pale, with œdema of the face and eyelids, most marked on the right side; the bodily functions were fairly well performed; pulse 120, regular, weak. Scattered throughout the skin of the upper extremities and of the body as far as the umbilicus were hundreds of nodules mostly of the size of a pea. On the inner aspect of the arms the nodules were discrete, not prominent, slightly tender, and the skin was movable over them and not discoloured. Elsewhere the nodules were so thickly sown as to form large plates and masses, very hard and only slightly tender; the skin covering them could not be pinched up or wrinkled, and was markedly erythematous with slight scaly desquamation of the epidermis. On the legs a very few nodules were observed, and there was no erythema. The glands at the angles of the jaw were enlarged, but those in the groins and axillæ were apparently normal. Careful examination failed to reveal any material modification of the great viscera. The diagnosis of multiple sarcoma of the skin was made by Dr. Shattuck, and confirmed by Drs. White, Wigglesworth, and Tilden. General tonic treatment was

prescribed in the first instance; but at the end of August an injection of  $\mathfrak{m}\text{iv}$  of Fowler's solution, diluted with an equal bulk of water, was given once daily, deep in the thigh. Towards the end of September the injection was increased to  $\mathfrak{m}\text{vi}$ . The patient's general health improved, and though a few fresh nodules showed themselves, the old ones disappeared in much larger numbers. On November 3rd she was discharged in order that she might resume her occupation of dressmaking, but the treatment was steadily persisted in till the middle of March, 1884, when an abscess in the thigh—the only one which formed during the whole time—was opened. A few discrete nodules were then the only ones remaining. She has since been working steadily at her trade without any treatment whatever, and now (March, 1885) remains to all appearance perfectly well. Multiple sarcoma of the skin is rare, its course is usually rapid, and the prognosis bad. Köbner's case—treated with hypodermic injections of *Liq. Arsenicalis*—is the only recovery recorded up to date. In Köbner's case the diagnosis was confirmed by the microscopical examination of one of the excised nodules; in the present instance the patient strongly objected to such a proceeding, which was therefore not carried out.—*Boston Medical Journal*.

**MEDICATED SOAP.**—Dr. Shoemaker, in an article of which an abstract is given in the *New York Medical Journal*, June 6th, expresses a high opinion of the utility of medicated soaps when judiciously used, that is to say in moderation, and as adjuvants rather than as the principal modes of cure. Among many others employed with advantage at the Philadelphia Hospital for Diseases of the Skin, he mentions the following:—*Arnica Soap* of 10 per cent. is very useful in sore nipples, and in affections around the mucous outlets, as also in clearing boils, carbuncles and many pustular eruptions: it is also an excellent remedy in abrasions, wounds and bruises of the integument; *Boro-glyceride Soap*, 10 per cent., possesses antiseptic and deodorant properties, and is valuable for cleaning ulcerative and sloughing surfaces: pruritic affections, especially of the genitals, are benefited and often relieved, and it is very useful in acne and seborrhœa; *Eucalyptol Soap*, 5 per cent., is a useful disinfectant for all foul-smelling sores, and is very efficacious in foetid perspiration; *Naphthol Soap*, 5 per cent., is one of the most efficacious of all the soaps, being useful in many skin diseases and devoid of odour: it is effectual against lice and other parasites, especially in the pubic and axillary regions, superseding the filthy mercurial ointment: possessed of antiseptic properties, it is highly useful in offensive discharges from the skin; *Salicylic Acid Soap*, 4 per cent., is far superior to carbolic acid in its antiseptic action, and is devoid of its irritant property and smell: it is admirably suited for the toilet, and is serviceable in thickened conditions of the epidermis of the palmar, plantar and extensor surfaces: it is also serviceable in foetid perspiration, and all foul-smelling wounds or sores, as it is in syecosis and pustular eczema, especially when the hair is matted, accompanied by a foetid odour; *Sublimate Soap*, 1 per cent., is a valuable antiseptic: freckles and pigmentary deposits, especially chloasma, are greatly relieved by it: it is one of the best agents in all kinds of itching, and in the various syphilitic eruptions; *Tar Soap*, 10 per cent., eczema and psoriasis, especially the chronic varieties, are greatly relieved and sometimes cured by this, and it is useful in removing the scales in pityriasis and ichthyosis: it would prove useful in the same affections as naphthol, but for its smell and irritating qualities.

**LEUCOPLAKIA (ICHTHYOSIS) BUCCALIS ET LINGUÆ, AND ITS CURE BY THE GALVANO-CAUTERY.**—Dr. Ingals states (*Boston Surgical Journal*, July 16th) that several different affections, e.g., "smokers' patches," the condition found in old glass-blowers and called "professional patches," and various manifestations of syphilis have been described as true leucoplakia or as one of its phases. It is a chronic affection of the buccal mucous membrane characterized by thickening of the epithelium and the formation of white, opaline, elevated patches, which usually become fissured and painful and are likely to terminate eventually in epithelioma. It is largely confined to men past middle life, but occurs occasionally in women. It is so commonly found in in-

terate smokers that the abuse of tobacco may be fairly claimed as an exciting cause. The affection is chronic, and most cases terminate in true epithelioma; the chief indication of this development consisting in non-inflammatory enlargement of the lymphatic glands, with exfoliation of the thicker portion of the patch and the formation of an ulcer; the supervention of sharp local pains, salivation, and, at length, induration of the subjacent tissue; finally, great swelling in the region of the jaw is apt to occur, and death takes place from exhaustion. As regards treatment, all sources of irritation—especially those resulting from the use of alcohol—should be avoided; and derangement of digestion should receive attention. Internal medication is of no avail in checking the disease, and local applications are either useless or merely serve to increase the irritation. The galvano-cautery rapidly relieves pain, and ultimately effects a cure; it should be applied to only one small spot at a sitting, and that carefully, so as not to destroy the healthy tissue beneath the changed epithelium. The actual cautery would probably act equally well, if its application can be regulated with the same nicety.

**TRAUMATIC LINEAR ATROPHY OF THE SKIN.**—Dr. V. J. Bowditch reports in the *Boston Medical Journal*, June 25, the case of a sensitive and nervous widow, aged 60, who, after suffering for some time with an annoying paroxysmal cough, began to complain of extreme sensitiveness of the lower abdomen; this region presently became notably hyperæmic, and presented numerous whitish oedematous-looking elevations, from one-eighth to one-fourth of an inch in width, most closely aggregated near the pubes, and towards the median line, and disappearing within the extreme limits of the hyperæmia. The general arrangement was dendritic, and the elevations gave to the touch the sensation of very soft crumpled rice-paper. By another week the hyperæmia had extended, and the elevations increased in size and number, in some cases having coalesced so as to produce lumps half the size of a pullet's egg. There was no marked tenderness, but a feeling of heat and puckering with distension. Two weeks later, the hyperæmia and swelling had entirely disappeared, leaving only numerous cicatrices similar to those noticed on the thighs and abdomen of a multipara. The case is regarded as one of linear atrophy of the cutis of traumatic origin, traceable to the long-continued paroxysmal cough, causing frequent and violent distension of the abdomen in a debilitated patient, the resulting acute hyperæmia and swelling finally subsiding, and leaving only the small cicatrices of the ruptured corium. The treatment adopted in this case was practically *nil*.

## SPECIAL CORRESPONDENCE.

### PROFESSOR STRICKER'S ELECTRIC MICROSCOPE.<sup>1</sup>

(By our Vienna Correspondent.)

VIENNA, *Sept. 8th*.

I HAVE no doubt that your readers will peruse with interest the following description of the electric microscope which has been invented by Professor Stricker, and his assistant, Dr. Gärtner, both of the Medical Faculty of Vienna, and constructed by S. Plössl and Co., of this city. Of the advantages of the electric microscope in the teaching of histology I will speak when I have described its construction and mode of employment.

The whole apparatus may be divided (1) into the source of illumination and the case containing it, and (2) the microscope proper. The necessary illumination is furnished by the electric arc-light, which is worked by a dynamo in the cellars of the Pathological Institution of the General Hospital here, the dynamo being driven by a gas-engine of six-horse power. The positive carbon has

<sup>1</sup> For the details of this article I am indebted to Professor Stricker and Dr. Gärtner.

a diameter of 13 mm., the negative a diameter of 12 mm. The light thus produced, disregarding resistance, is equal to an illumination of 2,500 candles. The light is regulated, not by an automatic apparatus, but by the hand, a man being specially detailed for this purpose; even the most perfect automatic regulator will not prevent that flickering which is so adverse to histological demonstrations. The regulator essentially consists of a metal rod, the upper part of which is a screw with its thread turning from left to right, while the lower half is a screw with the thread turning in the reverse direction. The inclination of the thread of the upper screw is in proportion to that of the lower as two to one. The rod, which is fixed, carries the two carbon-holders, which are provided with a female screw, and connected with a guiding rod, so that when the regulating rod is turned by means of the wheel attached to its lower end, the carbon-holders approach or retreat from each other according to the direction in which the wheel is turned. But on account of the above mentioned difference in the inclination of the threads of the screw, the upper holder always moves exactly twice the distance travelled by the lower.

Each holder carries a carbon pencil, the upper being the positive, the lower the negative one, and as the positive carbon is consumed twice as quickly as the negative, it was necessary to vary the thread of the screws as above mentioned, in order to keep the point of illumination constant. The light, in fact, always remains in exactly the

same position, for when regulated it is neither raised nor lowered, as the carbon pencils are advanced exactly in proportion to their rate of consumption. The case containing the light is provided with a glass window, through which the carbons can be observed. One great advantage of the apparatus is that one can easily move the source of light in three different directions at right angles to each other. This is done by means of three screws. The first screw (B) (*v. Fig.*) raises and lowers the lamp *in toto* without changing the mutual positions of the carbons or their distance from each other, and thus serves to regulate the height of the light, and to bring it into the same horizontal plane with the optic axis of the apparatus. The second screw (D) moves the lamp forwards and backwards, while the third (C) moves it to the right or the left. By the action of the second screw the light can be moved towards or away from the lens (F), without its position in relation to the axis of the lens being in any way altered. By this arrangement the best light for the various powers of the microscope can be obtained. Rays from the arc fall on the large condensing lens of the apparatus (F) and are thus rendered convergent, so that the luminous pencil has the shape of a cone. The height of this cone, *i.e.*, the distance of its apex from the centre of its base, depends, as we all know, on the distance of the source of light from the lens. The nearer the light is brought to the lens the further does the apex of the cone travel from it, and in a certain position, *i.e.*, when the light reaches the focus of the lens,

SIDE-VIEW OF PROFESSOR STRICKER'S ELECTRIC MICROSCOPE.

(Reproduced from Dr. Gärtner's work on the Electric Microscope.)

A, Regulating Screw; B, Screw for raising or lowering the light; C, Screw for moving the light laterally; D, Screw for moving the light forwards or backwards; E, Button for moving the inner screen; F, Lens; G, Water reservoir; H, Power holder; I, Specimen stage.

the apex of the cone is projected into infinite distance; in other words, the cone is now a cylinder, the rays of light emerging from the lens parallel to each other. Now, if a screen is placed in front of the lens at right angles to its axis, a transverse section of the luminous cone will appear on the screen as an illuminated disc. If the source of light is brought nearer the lens the illuminated disc formed at a certain distance on the other side of the lens reaches its minimum, and then, as the lamp is moved still nearer to the lens, the disc grows larger and larger until it is of the same size as the lens. Under this condition the rays of light are parallel. If the source of light is brought nearer the disc grows still larger and larger, the rays diverging as they issue from the lens.

The illuminating apparatus just described is contained in an oak case about 30 inches by 18, and 3 feet high. Two of its sides are provided with large doors, and the back of the box is also movable, so that one can easily get at the apparatus. The bottom and the top of the case are formed of strong tinned iron-plate, and the latter contains several large openings for ventilation, provided with coverings in order to prevent any escape of the intense light produced in the case. The parts of the case which are made of wood are protected from the effect of the heat by asbestos. The doors of the case are provided with large, round windows, filled with dark glass, through which one can watch the carbons. The case is made large intentionally, first, in order to allow of the light being removed sufficiently far from the lens; and secondly, to prevent its sides from getting too hot. The latter are, for the same reason, made of wood, and not, as in the case of Duboseq's apparatus, of metal, for when one uses such strong electric currents as are necessary for purposes of demonstration, the small case of Duboseq soon gets so hot that one cannot approach it, and the heat being conducted by means of the metal tube surrounding the lens to the specimen stage, most specimens are thereby irremediably damaged and rendered useless. This disadvantage is avoided by the use of a large wooden case.

The microscope-case is fixed on a firm table 3 feet high and running on wheels so that it is readily transportable, while the distance of the microscope from the screen can be regulated even during use, and the necessary corrections made. At the upper and posterior edge of the apparatus are the connections for the insertion of the wires from the dynamo. The positive pole is to be connected with the upper carbon pencil.

The second important constituent of the projection-microscope is the arrangement for the collection of the light. Various experiments have shown that mirrors are not adapted for this purpose, and that condensing lenses must be used. The lens or system of lenses by which the most distinct image could be obtained was determined empirically; it was found that lens No. IV. of Hartnack was most suitable. The distance of the specimen from its side of the lens is 31 centimetres, while the distance of the carbons from their side of the lens is 27 centimetres, when the specimen is greatly magnified. The part of the microscope (G) between the lens and the specimen stage is a reservoir of the form of a truncated cone, and is filled with distilled water, so that the rays of light must pass through a column of water 30 centimetres in length before they reach the specimen. This reservoir is bounded by two plane glass discs, and is fitted with two tubulars (not shown in the figure), one above and one below. The latter is provided with a throttle-valve and caoutchouc tube, by means of which the reservoir is filled with water, while the air escapes by the upper tube. The object of this arrangement is to cool the heat-rays and prevent the specimen from being injured. The screen for the reception of the image, which is formed of a plate of pure gypsum about five feet in diameter, fixed in a strong iron frame, is now placed at a distance of about eighteen feet from the microscope. The second auxiliary apparatus, the "Skiophtikon," which serves to give feebly magnified images of very large objects, as, for instance, brain-sections, is also inserted if necessary.

*Remarks as to the Method of Working the Apparatus.*—When the apparatus has been placed in proper relation to the screen, and the two battery-wires have been inserted,

the wheel (A) is turned to the left until the carbon-holders are at a proper distance from each other. This distance must depend on the proposed duration of the demonstration. With the electric currents usually employed in Professor Stricker's laboratory, about 9 centimetres of the carbons are consumed in an hour, viz., 6 centimetres of the positive and 3 centimetres of the negative. If, for instance, it is desired to prepare the apparatus for a two hours' demonstration, the carbon-holders are so far removed from each other that from 18 to 20 centimetres of carbon are available. The wires which proceed from the cellar of the Pathological Institution into Professor Stricker's lecture-room, are provided with a permutator which is fixed to one of the walls of the room, and which serves to turn the electric current either into 29 incandescent lamps, by which the room can be brightly illuminated, or into the arc-light of the microscope. As soon as this is done, the room is quite dark, the windows being so covered that not a ray of daylight can enter.

When the whole apparatus has been arranged for the demonstration, the reservoir filled with distilled water and the windows of the room covered, the doors of the case are shut, and the permutator is arranged for the arc-light. The electric current now passes through the carbons, which are in contact, and a slight glow is seen. The ends of the carbons are then separated to the extent of a few millimetres, by quietly turning the regulator, and soon the arc-light appears in all its brilliance. All that now remains to be done in order to have a quiet and steady light is to turn the screw every ten or fifteen seconds a little to the left, and thus bring the carbons towards each other, in exactly the proportion that they have burnt away. The experience of electricians, which is confirmed by that of Professor Stricker and Dr. Gärtner, tells us that the proper distance between the carbon points, is the shortest interval at which burning takes place without noise, and this interval, in the arrangement of Professor Stricker's electric microscope, is about 8 mm. When the light has once been correctly centred, the power and the specimen which one wishes to demonstrate are inserted, and the screw D is turned until the best distance of the lamp from the condensing lens is determined.

As to the practical employment of the electric microscope, it may be remarked that inanimate objects such as sections and specimens which have been teased out with needles should be somewhat deeply stained, and that those colouring methods should be chosen which show the histological elements in strongly contrasted colours. Carmine, gold, or silver staining is to be preferred for different tissues.

In order to give your readers some idea of the utility of the electric microscope for histological demonstration, I will take as an example, a transverse section of an inflamed tendon stained with gold chloride. The specimen, which has a diameter of 2 mm. when observed with lens No. 3, gives an image on the screen of about 30 inches in diameter. When observed near, the image clearly shows the tendon-cells stained a dark violet colour together with their processes, also stained the same colour, which form a reticulum, and enclose bright islets representing the fibrous matrix. At a greater distance, however, one only sees that a part of the specimen, that, viz., which is inflamed, is darker than the rest. The specimen is now moved until the image falls on the centre of the screen, and a stronger power, Hartnack No. VIII, is introduced. The image is now of the same size as the screen itself, and shows a quarter only of the specimen; the whole auditory, 300 persons, can now see quite distinctly the details above-mentioned, viz., the tendon cells with their processes and the bright matrix. At the inflamed part of the tendon, the cells are greatly enlarged, while their processes are thickened and more numerous than in the normal portion. When a very strong immersion lens, for instance, Seibert No. VIII, is used, one sees only a small part of the specimen in the visual field, viz., about five tendon-cells in a diameter, but the cells are now as large as the palm of the hand, and at the same time one notices a much richer reticulum of processes; secondary and tertiary ramifications which could not be distinguished in the image produced by the lower power, are now distinctly seen.

Another example: a human red-blood corpuscle, when seen with Seibert No. X, appears as a disc with a diameter of 6 centimetres, with Reichert 1.25 or Seibert No. VIII, its image still has a diameter of nearly 3 centimetres. A white blood-corpuscle, the diameter of which, as is well known, is two to three times greater than that of a red one, showed the amœboid movements (which are very favourably influenced by the high temperature), very distinctly to an assembly of 300 persons, the more distant of whom were provided with opera-glasses. In order to make the white-blood corpuscles quite distinct a procedure which Professor Stricker employs in his lectures is to be recommended, viz., he passes through the fresh blood a solution of fuchsin in water, containing 0.6 per cent. of common salt. The living cells absorb the pigment very slowly, whereas the fluid in which they are contained takes a distinct red colouration. The white blood-corpuscles, therefore, appear as bright, white spots on a coloured ground, and do not lose by this procedure anything of their mobility. The red blood-corpuscles also remain distinct with the appearance of yellow spots.

Nearly every histological specimen may be demonstrated with the electric microscope. A few objects, however, such as certain microbes, the image of which cannot be distinctly seen at a distance even with the strongest power, cannot be shown to advantage. On the other hand, there are some specimens which cannot be observed with the electric microscope in its usual form, as they do not admit of a perpendicular position of the specimen stage, but these can be shown by the aid of an auxiliary apparatus consisting of an arrangement of prisms.

The great advantages which the objective microscope presents, not only for instruction, but also for investigation, were, not long ago, brought under the notice of the Society of Physicians of Vienna by Professor Stricker, Professor Kundrat and Dr. Gärtner, Professor Stricker's Assistant. The last-named projected the picture of the mesentery of a living frog on the screen, and showed an experiment on the contraction of the blood-vessels. He demonstrated that exposure to a high temperature caused considerable contraction of the vessels, their lumen being nearly obliterated. Dr. Gärtner first protected the specimen from the influence of the heat rays, and the blood-vessels were seen on the gypsum-screen in a state of dilatation; he then arranged the apparatus so that the specimen should be exposed to the heat rays, and the blood-vessels were at once seen to undergo marked contraction. In order to meet the objection which might possibly be made in regard to this experiment—in fact, in order to prove that the contraction is indeed a vital process, and that it is not simply a shrivelling of the tissues as a result of excessive heat—Dr. Gärtner showed that when the specimen was only exposed to a high temperature for a short time the vessels dilated again after some minutes, and he claimed this fact as an argument sufficient to meet the objection. The fact that the circulation continued in the narrowed blood-vessels is also a proof that the temperature which thus irritated the muscular coat of the blood-vessels was not excessive, for if it had been only a fraction above 60° C., the albuminoid bodies of the blood would have been coagulated, and the circulation would have ceased instantaneously. Dr. Gärtner remarked that the hæmostatic influence of heat, which was especially employed in gynecological practice, has thus obtained experimental confirmation.

Before the same assembly, which consisted of 200 persons, Professor Stricker delivered a lecture on the structure of tendon with demonstration of specimens with the electric microscope, and Professor Kundrat subsequently showed some morbid histological specimens. He demonstrated on the screen a transverse section of the eye, showing an epithelial carcinoma on the margin of the cornea, a specimen of carcinomatous degeneration of the sternum, of secondary medullary carcinoma of the lung with infiltration of the bronchial mucous membrane and pulmonary lymphatics, of "carcinoma psammosum" of the ovary, a section of enchondroma of the thigh with formation of physalides on the cartilage-cells, an intracanalicular adeno-sarcoma of the mamma, interstitial orchitis, the head of a *Tænia solium*, a male *Trichocephalus dispar*, and lastly, a specimen of

phlegmonous subcutaneous cellular tissue with colonies of micrococci.

I may add that the invention of the electric microscope is mainly due to the zealous desire of Professor Stricker to perfect his lectures. He has always been most anxious to give his pupils the clearest possible explanations, convincing them of the truth of what he states, maintaining the principle of every zealous scientific investigator, to exclude the "jurare in verba magistri," and to give his pupils palpable demonstration of what he affirms to be true. No one who attends the lectures of Professor Stricker will hesitate to admit the great advantages offered by the electric microscope for instruction, and to applaud the zeal with which its inventor attempts to give a real vital force to his teaching.

During the coming session Professor Kundrat will give a demonstration of pathological specimens with the electric microscope every Saturday at 11 a.m.

(From Our Bombay Correspondent.)

### *Cholera—The Sanitary Condition of Quettah—Health of Bombay—Indian Medical Officers: Another Hardship.*

THE general health of the garrison at Quettah and neighbouring districts continues to be bad. The cholera, though it has abated somewhat, has not ceased its ravages altogether, the mortality among the troops, both British and native, being still high. Few people in England can have any conception of the terrible mortality which has occurred at Rindli, in Scinde, in the Bolan Pass, and in Quettah during the past three months. Cholera, and not only cholera, but fever and dysentery also, have worked sad havoc among all whose misfortune compelled them to stay in Lower Bolan and Rindli. It is a fact that at Quettah alone Her Majesty's 43rd Regiment lost nearly 50 men and 1 officer, whilst the 47th lost 20 men and 1 officer. An officer of the Royal Engineers and another of the Staff Corps died of cholera. The Railway Transport and Commissariat Departments have all borne their share of the dire malady. A detachment of the 17th Native Infantry lost nearly half its number at Rindli. A large number of officers have had to be sent home to England on sick leave. The medical officers at Rindli, Messrs. Wade, Pratt, and Cooper, deserve great praise, the last-named having himself taken cholera and died of it. The state of things of which I have given but a bird's-eye view is so bad from sickness, as well as other causes, that the troops loathe the very idea of serving in these parts, and domestic servants cannot be got to go there or to stop there for any time, even for exorbitant wages. It gives me, therefore, some satisfaction to announce, on the authority of a Simla telegram to a Bombay contemporary, that the Government of India have deputed General C. Macgregor, Quarter-Master General, to proceed to Quetta and select a site on a higher level in the vicinity of that place for a new cantonment, in view, it is said, of abandoning Quettah. In noticing the unsatisfactory sanitary condition of Quettah I wrote (*Medical Times*, June 6th) "it is problematical that Quettah could ever be rendered salubrious; the abandoning of the place for hygienic reasons will, ere long, have to be faced in some practical form or other." In the interests of our troops and the Government alike it is to be hoped that this will be carried out in its entirety, and not too much weight be attached to the representations of political and other officials who have personal interests at stake, or who have already pledged their opinion to the healthiness of Quettah; some one or two have even gone the length of vaunting it as a perfect "Salutland," the ideal land of health, *par excellence*, of Dr. Richardson, whereas, as a matter of fact, it is a mere barren waste, surrounded by equally barren towering hills. When the troops first went there the sanitation of the place was de-

plorably neglected, large latrines on the trench-system were put up everywhere in close proximity to sources of water-supply, and the ground then used for latrines by the troops and numberless camp-followers and others has since been built upon. Nothing short, as I have urged, of evacuating the place can now prove of any avail, and this should be effected with celerity and in no half-hearted manner if the health of the troops be looked upon as a matter of prime concern.

Mr. D. C. Davidson, Health Officer of Bombay, has recently submitted his report for the first quarter of 1885. The total mortality reached to 177 more than in the corresponding period of last year. This increased mortality is attributed by Mr. Davidson chiefly to cholera, phthisis, diseases of the respiratory system, dysentery and measles. The mortality from "fever" is less, however, than in the first quarter of 1884. There were altogether 5,730 deaths registered (exclusive of still-born), being 15 more than in the last quarter, and, as already noted, 177 more than in the corresponding months of the past year. The death-rate was equal to 27.15, taking into account the annual increment of the population. The "fever" mortality was 136 less than in the last quarter, and 84 less than in the corresponding portion of last year; 1,641 deaths are referred to "fevers," of this total 1,278 are referred to remittent fever, against 1,371 in the fourth quarter of the past year; to ague 84 are ascribed; to simple continued fever 274, and to enteric fever 5. Twenty deaths were registered from small-pox during the quarter; from measles 135, being 85 more than in the past quarter, and 28 more than in the corresponding quarter of 1884. The mortality from cholera is 141 more than in the preceding quarter, and 110 more than in the corresponding months of the past year. There were altogether 351 cases, of which 278 proved fatal. It is noteworthy that at the commencement of the outbreak which occurred towards the end of the second quarter under review, a considerable number of deaths from cholera occurred amongst pilgrims who had contracted it at Nassick. They arrived in Bombay actually suffering from cholera, or developed symptoms of a few hours or days subsequent to their arrival, showing, says Mr. Davidson, that the disease had been contracted at Nassick and not in Bombay. And in order to protect the statistics from being swelled by this death-rate from cholera from Nassick, the health department at Bombay made arrangements for the removal from trains of persons suffering from cholera, and their subsequent treatment in hospital, and for this purpose two native medical practitioners were appointed, Messrs. R. N. Spenceer and M. Bottliwalla. Another, Mr. J. C. Voz, was appointed to attend those sick of cholera at their homes, and Dr. Macdonald was appointed to the charge of a special cholera hospital. Mr. Davidson says that the stopping of the trains near to Bombay, and examining and removing those sick of cholera, was attended with such good results, that he recommends a similar course for the future. There are other details of vital statistics reported which I need not notice: 3,910 bodies were buried, 1,885 were cremated, and 262 were consigned to the Towers of Silence of the Parsees. Mr. Weir, the Health Officer of Bombay, has obtained a further extension of his leave, and Mr. Davidson continues to act for him.

Owing to the prospect of a war with Russia which had prevailed, a number of Indian medical officers, holding military appointments on furlough in England, were ordered out at once, the Government paying the passage out; but now should some of these officers desire to return and complete the remaining portions of their leave, which they can do by existing regulations, they will have to pay their own expenses back. This certainly is both unfair and a hardship. While those in military employ were thus inconvenienced, and put in many cases to great expense and pecuniary loss, apart from the passage-money, their brethren of the same service in civil employ were unaffected, and were neither troubled to return to duty or put to any pecuniary loss. This matter deserves attention, and it is to be trusted that the India Office may be moved to grant some sort of compensation, at least, to those who may wish to resume their furlough.

## OBITUARY.

WILLIAM AUGUSTUS GUY, M.B. Cantab, F.R.C.P.,  
F.R.S.

WE regret to record the death of Dr. Guy, at his residence, 12, Gordon Street, Gordon Square, on the 10th instant, in his 76th year. Dr. Guy was born of a line of medical ancestors at Chichester in 1810. He received his early education at Christ's Hospital, passed through his medical curriculum at Guy's Hospital, and took his M.B. degree at Cambridge, in 1837. In 1831 the Medical Society awarded him the Fothergillian Medal for an essay on asthma. Appointed in 1838, he filled the Chair of Forensic Medicine in King's College for many years; in 1842 he was attached to the Hospital in charge of out-patients; from 1846 to 1858 he was Dean of the Medical Department, and in 1869 became Professor of Hygiene. He was admitted a Fellow of the College of Physicians at the age of 34, and repeatedly held the offices of Lecturer, Examiner, and Censor in that institution. He was an active worker in the Statistical Society, and, in addition to numerous contributions to its Journal, filled the offices of Honorary Secretary, of Vice-President, and of President. In 1869 the Swiney Prize was awarded him for his researches in Forensic Medicine. In 1876 he was a Vice-President of the Royal Society.

Dr. Guy's writings place him in the first rank amongst statisticians and philanthropists. As often as a question arose as to the comparative mortality in Hospitals and Prisons, the influence of Vaccination on Small-pox, and the like, Dr. Guy was ready to undertake its solution, and the result has been a rich mine of medical statistics for succeeding workers, deposited in the Journal of the Statistical Society. Those of us who have but a dim perception of the value of statistics, will find assistance in the following lines:—"I do not think," Dr. Guy says, "that I attach undue importance to tabular analysis when I anticipate from its intelligent and more extended use not only greater accuracy of statement and completeness of description, but discoveries of the utmost interest and importance. Men, and the things they do and suffer, are equally the products of many factors . . . and experience justifies us in expecting that, little by little, these factors will be isolated from the tangled thread of causes, leaving the remnant more amenable to scientific treatment."

As a philanthropist, Dr. Guy has done much good in exposing the injurious effects attendant upon certain occupations. But it was against the imperfections of the Poor Laws, the abuse of Charity, and the vice of indiscriminate almsgiving that his eloquence and logic were most forcibly excited and directed. He was an intense admirer of John Howard, and he has done much to place his character in its true light, and to remove the obloquy which Carlyle and some other writers have inconsiderately thrown upon his name. By the assistance of Miss Clehorow Butler, the well-known sculptor, Dr. Guy has given to the world—in the form of a bronze vase, destined for a niche in King's College—an admirable and very pleasing likeness of the great philanthropist.

In both public and private life Dr. Guy was the perfect type of a gentleman, and his virtues are well summed up in the word "Honestas," as the ancient Romans understood it. Under cover of a somewhat impassive exterior, Dr. Guy possessed a heart glowing with generosity and chastened

by the most complete unselfishness. We cannot close this notice without expressing a hope that the time is not far distant when those who, like Dr. Guy, devote their services to the State, shall receive that recognition which their approved efforts have deserved.

---

BENJAMIN GEORGE McDOWEL, M.D., F.R.C.S.I.,  
PHYSICIAN TO THE QUEEN IN IRELAND.

WE deeply regret to announce the death, after a short illness, of one of the most popular as he was one of the ablest of Irish physicians, Dr. Benjamin George McDowel, one of the Physicians in Ordinary to Her Majesty the Queen in Ireland, and Physician to the House of Industry Hospitals, Dublin. The sad event occurred on Tuesday afternoon, the 15th instant, at Dr. McDowel's suburban residence, 5, Haddington Terrace, Kingstown. So recently as that day week Dr. McDowel was actively engaged in his professional pursuits, although feeling far from well. In the afternoon a shivering fit warned him of the onset of a serious illness—next day there was a recurrence of this ominous symptom, followed by feverishness. Soon a dangerous bronchial catarrh supervened, which ultimately proved fatal.

Born some five-and-sixty years ago, Benjamin McDowel may be said to have been cradled in the profession of medicine. His father was Dr. Ephraim McDowel, a physician of deservedly high reputation, some of whose valuable contributions to the literature of his profession may be found in the old *Dublin Hospital Reports*, edited by Dr. John Cheyne early in the present century. While still very young, McDowel had the misfortune to lose his father. Nevertheless, he worked on, until in 1841 he became a Licentiate of the Royal College of Surgeons in Ireland. Some time afterwards a connection of his family, the late Chief Justice Doherty, was the means of obtaining for him the important and much prized appointment of Physician to the House of Industry Hospitals, an appointment which he held up to the time of his death. A curious anecdote is told of the Chief Justice *à propos* of this. It seems that a wealthy gentleman, named Mr. Carroll, intended to make Dr. Ephraim McDowel his heir, but was prostrated by paralysis while in the very act of signing a will to this effect. The property, worth several thousands a year, in consequence reverted to Chief Justice Doherty. After the death of Dr. McDowel, the Chief Justice generously used his influence with the Lord Lieutenant of the day to obtain an appointment for Dr. McDowel's son, the subject of the present memoir. The Lord Lieutenant, without enquiring into the young man's profession, conferred upon him a valuable ecclesiastical appointment, but on discovering his mistake made him physician to the House of Industry Hospitals, a vacancy on the staff happening to occur at the time. The choice of his Excellency was fully justified by the conspicuous ability of the young hospital physician. McDowel threw himself with characteristic ardour into the practice of his profession, and soon made a name for himself as a well-read, intelligent and able physician. In 1845 he became a Fellow of the Royal College of Surgeons in Ireland, and in the following year he joined the Royal College of Physicians in London. It was not until the year 1880, however, that he became connected with the King and Queen's College of Physicians in Ireland; to the membership of this body he proceeded in the following year.

In 1858, upon his appointment as Professor of Anatomy and Surgery in the School of Physic in Ireland in succession to Dr. Robert Harrison, McDowel took the degree of M.D. in the University of Dublin, and in 1859 he became a Master in Surgery of the same university. For many years previous to obtaining the professorship, he had been making frequent and valuable communications to the Pathological Society of Dublin, of which he became the president in the year 1865. He also enjoyed a large and increasing practice as a physician. It was therefore all

the more to be regretted that, by virtue of his office as professor of anatomy and surgery, he was obliged to act as Surgeon to Sir Patrick Dun's Hospital—the clinical hospital of the University of Dublin. This multiplicity of duties would have proved too much for a less able man, but McDowel discharged them sufficiently well to retain the confidence of the Board of Trinity College at three septennial elections to his professorial chair. In 1879, however, he finally retired from the professorship, being succeeded by Dr. Alexander Macalister. But he did not sever his connection with his *alma mater*, for he was afterwards elected a member of the Academic Council of the University of Dublin. When the Royal University of Ireland was created, Dr. McDowel was appointed an Examiner in Medicine, and subsequently was elected to be a Medical Fellow of that University. In 1881, shortly after the death of Dr. Alfred Hudson, he was appointed a Physician in Ordinary to Her Majesty the Queen in Ireland, joining in this honour his friend and colleague, Dr. Banks.

Dr. McDowel contributed several articles to Dr. Todd's "Cyclopædia of Anatomy and Physiology," as well as numerous pathological essays and papers to the *Dublin Journal of Medical Science* and the late *Dublin Hospital Gazette*. But it was as a clinical teacher, and above all as a school lecturer that he especially shone. He had the art of investing even a dry and difficult subject with the glamour derived from a living enthusiasm translated into eloquent yet simple language. His lectures in Trinity College were always attractive, and drew large audiences of silent and attentive students. To his pre-eminent ability as a physician also a tribute must be paid. Ever kind, gentle, and sympathising, he won the hearts of countless patients, whom his keen diagnostic powers, his calm judgment, and his ripe experience enabled him often to rescue from death and always to relieve.

---

## MEDICAL NEWS.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, September 3rd, 1885:—

Charles Albert Adams, 53, Devonshire Street, N; Richard Andrews, M.R.C.S., Chestnut Grove, New Malden; William Henry Brown, Oxburgh Rectory, Brandon; Julius Labey, 34, Palace Road, Upper Norwood; Arthur Nicholas Little, M.R.C.S., 1, Highbury Place, Cotham, Bristol; Frank Postlethwaite, M.R.C.S., 41, Oxford Road.

On the same day

Charles Jno Holtom, Stoke Hall, Stoke-upon-Trent; Lewis Walter Pockett, Belgravia, Goole, Yorkshire.

passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise.

The following gentlemen also, on the same day, passed their Primary Professional examination:—

Arthur George Mellefont Creagh, University College; Ernest Morgan Hearnden, Guy's Hospital; William Hook, Westminster Hospital.

At the recent examination for the Prizes in Botany given annually to Medical Students, by the Society of Apothecaries, the successful Candidates were—

First—Edward Deanesly, University College, The Gold Medal.  
Second—Frederick William Lewitt, St. Mary's Hospital, The Silver Medal and Books.

UNIVERSITY OF HEIDELBERG.—The grand *Jubilæum* to celebrate the 500th anniversary of the foundation of Heidelberg University will be held in the second week of August, next year.

THE ELECTORAL FRANCHISE AND MEDICAL RELIEF.—Mr. L. Shadwell, the Revising Barrister of the Marylebone Revision Court, on the question whether a person would be disqualified for voting by his having been sent to an infirmary, has decided that all persons who went to an infirmary were disqualified, because they received more than

medical relief—they got lodging and maintenance. He, however, has reserved his decision with respect to small-pox hospitals.

**MEDICAL WOMEN FOR INDIA.**—The Calcutta correspondent of the *Times* telegraphs that Lady Dufferin's fund for providing medical aid for the women of India is making rapid progress. In the Central Provinces a prospectus has been circulated in the vernacular, and meetings have been held at various places. Classes for the teaching of midwifery have been started at Jubbulpore, and a native gentleman has offered to defray the cost of similar classes at Nagpore. Strong committees are being formed in Hyderabad and Mysore. The native princes have shown much interest in the movement and a desire to co-operate liberally. The Maharajah of Ulwar is not only selecting students to be sent to the female training schools, but also proposes to open a dispensary, under a native lady doctor, solely for the use of women. The Maharajah of Benares has presented a handsome subscription to the fund.

**SANITARY ASSOCIATION OF SCOTLAND.**—The annual congress of the Sanitary Association of Scotland was held in the Town Hall, Aberdeen, on the 8th inst., under the presidency of Dr. Christie, editor of the *Sanitary Journal*. There was a good attendance of sanitarians and others. Dr. Christie introduced the president-elect, Dr. Simpson, the medical officer of health for Aberdeen, who then took the chair, and read a long paper on the subject of sanitation, in which he touched specially on over-crowding. Dr. Beveridge, Aberdeen, followed with a paper on the subject of the ventilation of schools, and some discussion followed. Mr. Mackay, Dundee, afterwards read a paper on some of the causes of unhealthy dwellings in towns, and the subject of the condition of our defences against cholera was introduced by Dr. Christie. An interesting discussion followed on this paper, and the proceedings of the congress were brought to a close with the usual votes of thanks.

**NORTH LONDON NURSING ASSOCIATION.**—This institution provides trained nurses for the sick poor at their own houses, and 26,380 visits were paid during last year. The nurses are supplied solely for the benefit of those who are too poor to pay for skilled nursing aid during sickness.

**ROYAL UNIVERSITY OF IRELAND.**—The Duke of Abercorn's report on the Royal University of Ireland, presented to Earl Spencer on March 27, has just been published. This is the third year of the existence of the University, and the Duke states that the rate of progress is maintained, and that there is every ground for hoping that the success of the University is assured, and that it will take rank among the permanent institutions of the country. The figures given enable us to judge of this success. For the various examinations (not including those for women), 2,364 candidates entered their names, and of these 1,555 passed, while 478 were rejected; the rest were either absent or retired; 20 per cent., therefore, of the men who offered themselves for the various examinations were rejected. It will be remembered that in the last report the Duke spoke with particular satisfaction of the number of women. He now continues his satisfactory record. In all 127 women presented themselves for examination, of whom 112 passed and 13 were rejected. The percentage of rejected, therefore, is only half that of the men. Moreover, 47 of the women obtained honours.

**SUICIDE OF A MEDICAL PRACTITIONER.**—Dr. Diplock held an inquest on Monday, at 48, The Grove, Hammer-smith, relative to the death of Adam John Whiteford, a surgeon, who committed suicide. It appeared from the evidence that the deceased had been suffering from severe mental depression for some time past. On Friday last a medical consultation took place at the residence of the deceased, and it was decided to send him to an institution where he would receive careful attention. After the medical men had left, the deceased was seen to smash the windows of his surgery, the door of which was locked. On succeeding in obtaining admittance, it was found that the deceased had cut his throat in a terrible manner, severing the windpipe. Dr. Alderton was called in, but death took place in a few minutes. Mr. Whiteford was in his shirt

sleeves, and a surgical knife, covered with blood, was found near him. The jury returned a verdict that the deceased committed suicide while in an unsound state of mind.

**COTTAGE HOSPITAL FOR WOMEN AND CHILDREN, EDINBURGH.**—The premises of the Edinburgh Provident Dispensary for Women and Children in Grove Street, Fountain Bridge, are partially being adapted into a Cottage Hospital, in connection with the Institution. A great many cases, during the seven years the dispensary has been opened, have required careful nursing, and these have been sent to one or other of the public hospitals in the city. To obviate this necessity steps were taken to add a few beds to the dispensary with the view of completing the treatment in connection with the Institution of such patients as required surgical operations or continuous daily care. The hospital will contain six beds.

**CHARITABLE BEQUESTS.**—The Hon. Mrs. Caroline Cavendish, widow of Admiral the Hon. George John Cavendish, has bequeathed 19 guineas to the British Home for Incurables, Clapham-rise. Mr. Henry Simmonds, late of Aylesford House, Herne Hill, leaves by his will 50*l.* to the Royal Hospital for Incurables, Putney. Mrs. Julia Greene de Freville, late of Hinton Hall, Cambridgeshire, and Upper Brook Street, bequeaths 100*l.* to Addenbrooke's Hospital, Cambridge, and 50*l.* each to the Saffron Walden Hospital and Essex Hall Idiotic Institution, Colchester. The late Mr. Mackie, M.P. for Wakefield, has left 1,000*l.* to the Clayton Hospital in that town. Miss Jane Catherine Gamble, late of 67, Portland Place, London, has given 100*l.* to the Middlesex Hospital; 500*l.* to the Establishment for Invalid Ladies, 90, Harley Street; and 4,000*l.* after the death of a lady, to the Royal Hospital for Incurables, West Hill, Putney Heath; these legacies to be paid free of duty.

**DEATH OF DR. LUNIER.**—Dr. Joseph Ludger Lunier, one of the most distinguished of the French alienist physicians, has recently died, having reached the highest honours attainable in his branch of the profession, and in the full enjoyment of the honourable appreciation of his colleagues. Born near Blois, in 1822, he received his doctor's degree in 1849, and his thesis on general paralysis may still be consulted with advantage. Appointed only two years afterwards as chief physician to the asylum of Niort, in 1854 he was promoted to the same office at Blois; and ten years later had attained the high position of Inspector-General of lunatic asylums and of the sanitary condition of prisons in France. He was also an Officer of the Legion of Honour, and Member of the Academy of Medicine. He was one of the most active members of the Société Médico-Psychologique, and the author of numerous important contributions to psychological literature. After the war, he became the founder of the French Temperance Society, of which he continued to be general secretary until his death.

**VIVISECTION IN AUSTRIA.**—The Austrian Ministers of the Interior and of Education have issued a conjoint circular to the medical faculties of the empire, with a view to the prevention of abuses in the performance of experiments on living animals. In this decree it is ordered:—(1) Vivisection, or experiments on living animals, can only be undertaken for the purpose of serious researches, and exceptionally, when indispensably necessary, for the purposes of education. (2) Such experiments can only be performed in the medical institutes authorised by the State. (3) Only the directors of these institutes or their assistants are allowed to perform vivisections; or these must be performed under their inspection and responsibility, and only by those who have undergone scientific education (as practitioners and medical candidates). (4) The subjects of experiment must always, when it is possible without frustrating the object of the experiment, be kept in a state of deep insensibility. (5) Wherever it is possible, animals of the lower grades must be selected, and no animal of a higher species employed. The *Wiener Medicinische Wochenschrift* protests against the prohibition of *savants* performing experiments in their own private laboratories, seeing that the character of an experiment is entirely independent of the locality in which it is executed.

**THE HISTORY OF CHOLERA IN ENGLAND.**—The *City Press*, in an article giving particulars regarding the history of cholera in this country, says:—In 1831 cholera appeared in Sunderland, having been brought from Hamburg at the end of October. It then spread to Newcastle and Gateshead. In December it reached Addington (Scotland); in January, Tranent; in February, London and Edinburgh; in March, Glasgow, thence to Belfast and Dublin; and in April to Cork. This is an instance not only of its reaching a country late in autumn, but also of active spread during the winter months. In 1848 cholera attacked Hull (brought from Hamburg) in the beginning of October. Thence it spread to Edinburgh, London, Gravesend, Plymouth, Sunderland, Glasgow, Dumfries, &c. It lasted through the winter, breaking out with increased intensity in the spring of 1849, and ended in the late autumn of that year. In 1853 cholera reached Great Britain in the summer. It remained through the winter, breaking out afresh in the following year. In 1865 it appeared at Southampton at the end of August. In 1866 the first case in London was in Bromley, on June 26. No more cases were recorded till July 11, when there were five deaths. On the 12th and following days, 11, 20, and 15 persons died. From that time life was fiercely assailed by cholera in its most virulent form. The deaths ran up from 14 to 105 in the course of a few days. The mortality from cholera in London for the four weeks ending August 4 was 63, 481, 1,097, and 1,178. The most extraordinary character of the outbreak was its relation to the water supply. Taking that section supplied by the East London Water Company exclusively, the deaths from cholera in the four weeks above noticed were 38, 420, 955, 982, and in the portion supplied by the other water companies, 26, 61, 142, 196. Thus in those parts supplied by the East London Water Company the death-rate from cholera was 72 per 10,000, while throughout the other parts it in no instance exceeded eight per 10,000, and was in some cases less than half this amount. "The explosion of the disease was in fact confined to an area supplied with water from one particular company and from one particular source." (Netten Radcliffe.) It was shown that the excreta from the first cases entered the river Lea some 600 yards below certain open reservoirs of the company, and that these reservoirs had been drawn upon for supply. It was amongst the consumers of the contaminated water that epidemic cholera broke out on July 11 and carried off so large a number, and it is scarcely possible to assign any other cause for their being, as it were, specially selected for the ravages of the disease.

**SANITATION AT KINGSTOWN.**—The Kingstown Commissioners are somewhat exercised by a reference to the insanitary condition of the township in the report of "the Royal Commissioners on the Housing of the Working Classes." Unusual interest seems to have been felt in the meeting of the Commissioners, held on the 7th instant, Colonel Bidwell (a recently elected member of the Board) having given notice that he would bring forward the question of the sanitary condition of the township. Moreover, it appears that Dr. Power, Medical Sanitary Officer, had caused considerable perturbation by a paper read by him at a meeting held in Dublin, in which he prominently remarked upon the insanitary condition of numerous houses of the poor in Kingstown, and said that many dwellings, for which, comparatively exorbitant rents were paid by their poor inmates, were unfit for human habitation. The accuracy of these statements, made from personal observation, was tested by a house-to-house inspection, and verified by the inspectors, but from some unexplained cause the question was not considered, and left in abeyance until the reference already alluded to in the report of the Royal Commission, which apparently produced great surprise. In compliance with the desire of a member, the Town Clerk read a statement of the amount of sanitary work done in the township within a specified time, by which it appeared that within the previous month the Sanitary Officer had inspected one thousand dwellings, that eighteen summonses had been issued against offenders of sanitary laws, and that all had been convicted. Hereupon Colonel Bidwell brought forward the resolution of which he had given notice, determined to ignore local prejudice and personal

interests. He called attention to the fact that in the third report of the Royal Commissioners on the housing of the working classes in Kingstown, it is stated that—"The tenement house system prevails to a considerable extent, and the condition of these dwellings calls for some comment, overcrowding is common, the houses are badly roofed, and the floors are frequently of earth, with the filth of years accumulated upon them, and there is often no proper separation of the sexes. In the cottages the same state of things is allowed to continue—sanitary and ash-pit accommodation exists only in name, and it is not remarkable that fever frequently prevails in the town." On the strength of that report he moved "That these allegations be enquired into by the Sanitary Committee, and that the property referred to be personally inspected by them, in order that they may be able to make a full and reliable report thereon to the Board." A member seconded the resolution, but although he courted enquiry, he, with some prolixity, sought to prove that the township was in a very sanitary condition, and that the statements to the contrary were erroneous. After a prolonged discussion the following amendment was adopted—"That Colonel Bidwell's notice of motion on the sanitary condition of Kingstown be referred to the Sanitary Committee, when he will have full opportunity of instructing himself on the working of sanitation in the township, and of correcting statements which had been made without proper evidence or foundation." When the resolution was adopted Colonel Bidwell remarked that it was all that he required.

**LUNACY IN SCOTLAND.**—The twenty-seventh annual report of the Lunacy Commissioners for Scotland which has just been published, states that the whole increase of registered lunatics during 1884 was 169, consisting of an increase of 23 private and an increase of 146 pauper patients, leaving 10,918 insane persons under official cognizance on the 1st of January, 1885. There were 213 private patients discharged recovered during 1884, which is 29 above the average for the five years 1880-84. The number of pauper patients discharged recovered was 990, which is 8 above the average for the five years 1880-84. The number of private patients discharged unrecovered, excluding transfers, during 1884, was 140, or 5 above the average for the five years 1880-84. The number of pauper patients discharged unrecovered was 440, or 46 above the average for the five years 1880-84. One hundred and two private patients died in establishments during 1884; and of the 2,759 patients discharged on probation since 1862, 493 were replaced, before the expiry of the period of probation, in the asylums from which they had been removed. The whole number of changes among attendants during 1884 was 519, which is 84 less than the number for the previous year. "We continue to regard it as unfavourable to the interests of the patients that these changes should be so numerous; and we think it deserving of careful consideration by the administrators of these institutions where changes occur frequently, whether some addition to the wages or some increase of the comforts of the attendants is not desirable." The whole number of escapes during 1884 was 272. Of these, 156 were brought back within twenty-four hours, 73 within a week, and 18 after a week; 25 were not brought back during the currency of the Sheriff's order, or the certificate of emergency on the authority of which they had been detained. Two of these last were removed from the asylum registers as recovered, 3 as improved, 10 as relieved, and 8 as not improved. One was killed by being run over by a railway train, and 1 died from exposure. The whole number of accidents reported to us as having taken place during the year 1884 was 129. Of these 10 ended fatally. In two of these cases the death was suicidal. The cases tabulated as fatal accidents include two deaths from impaction of food in the pharynx—one in the case of a male paralytic, and one in the case of a feeble old woman. One death resulted from a patient falling backwards from his seat, two from injuries the result of the maniacal violence of the patients themselves, and two were the cases already mentioned under the head of escapes. One case which led to a criminal trial was that of a patient who received injuries inflicted while he was being brought back to the

asylum after having escaped. One of the attendants who were engaged in bringing him back committed suicide, and the other was tried for homicide, but acquitted. Eight cases of injury which did not terminate fatally, were the result of attempts at suicide. In 37 cases the accidents involved fracture of bones or dislocation of joints. These were occasioned in 17 cases by falls, in 8 cases by assaults made by fellow patients, in 6 by struggling with fellow patients or attendants, in 4 cases the accidents were unintentionally self-inflicted, and in 2 cases the causes were not ascertained. Of the remaining accidents there were 15 injuries to the head occasioned by falls and assaults by patients, and 1 was occasioned by the intentional act of the patient himself. In 1 case an injury affecting one of the internal organs was inflicted by another patient and in 1 case a similar injury was inflicted by the patient himself. There were 18 cases of flesh wound, abrasion, bruise, burn, or scald, and there were 39 injuries of unimportant character. It appears that, for the maintenance of 10,959 pauper lunatics, who were under care in asylums, lunatic wards of poorhouses, and private dwellings, and for other expenses connected with them, a total sum of 214,264*l.* 13*s.* 6*d.* was paid. During the whole period from 1858 to 1884, the total expenditure for maintenance alone has increased 175 per cent., the expenditure for the maintenance of patients in establishments having increased 195 per cent., and that of boarding in private dwellings 86 per cent. The average cost per annum for each patient has increased in asylums and lunatic wards of poorhouses from about 20*l.* to about 25*l.*; in private dwellings it has increased from about 8*l.* to about 14*l.*; the average expenditure for establishments and private dwellings taken together, with all other costs, having increased from about 16*l.* to about 24*l.*

**THE POSITION OF THE PHARMACIST.**—At the twenty-second annual meeting of the British Pharmaceutical Conference, which was opened at Aberdeen on the 8th instant, the President, Mr. J. B. Stephenson, of Edinburgh, devoted his opening address to this subject. He said he thought the true character and position of pharmacy might be defined in something like the following way: There was a certain well-defined and an increasingly important portion of the medical field which could not only be cultivated better, but could not be adequately cultivated at all except by a class of workers devoted to it. That he took to be the standing ground of pharmacy, and the function belonging to it consisted in the preparation of remedies for administration to the sick. The word "dispensing," whether correct or not, represented to their minds the exercise of that function, but the dispenser ought to be competent to verify the purity and the potency of every article he dealt with. That position of pharmacy as an integral part of the medical profession was one which would be admitted by all hearing him, and he was not sure but that by the medical profession and the public at large it would be conceded *in theory*, however much it might be disregarded in practice. But more than that, it was a *statutory* position. If pharmacy were so differentiated from the general medical field as to constitute a distinct department of it, there appeared to be several corollaries inevitably proceeding from that proposition. First, wherever pharmaceutical work was to be done it should be assigned to the pharmacist. As between the medical practitioner and the pharmacist, he was rather proud to believe that in Scotland, and in Edinburgh especially, that differentiation had been more general and more thorough than in the south. From his personal experience of more than forty years in Edinburgh, he could affirm that during all that time the dispensing had been exclusively in the hands of the pharmacist. He would apply the principle also to the dispensing in public hospitals, dispensaries, &c., and in the public services. There was another corollary naturally and inevitably deducible from his proposition. If pharmacy was the art of preparing drugs, and if it were a statutory entity, and the Pharmaceutical Society were its statutory exponent, surely that Society should have a considerable share, and a share not as by favour, but of right, in compiling the book the very name of which meant the preparation of drugs, and which was the statutory authority on the subject. The

last Edinburgh Pharmacopœia dated back further than the forty or fifty years to which his experience was limited, although he well remembered the time when Scotland was under its authority, even as England was under that of London, and Ireland under that of Dublin—for was not the British Pharmacopœia first published in 1864, only twenty-one years ago?—but he happened to know that in those days Sir Robert Christison constantly consulted practical pharmacists in Edinburgh, and acknowledged in his "Dispensary" his obligations to them. There was a third corollary which he wished to draw from his proposition. It was this—if pharmacy were a professional pursuit it should be remunerated on the basis of a professional fee. This was a somewhat intricate problem, but it was only to be solved by openly and honourably making a fair estimation of the imponderable elements in their transactions, intelligence, skill, responsibility, applicable in all cases, and independent of the value of the materials they had to work with. It was also a legitimate inference to be drawn from his premisses that the qualification of the pharmacist should cover all his intromissions which so-called poisons, independent of all other restrictive regulations. Poisoning by inadvertence could never be prevented by Act of Parliament. Nurses might give the wrong medicine, and pharmacists might mistake the right bottle, but there was no means, legislative or otherwise, to prevent it, and for intentional poisoning, they might as well restrict the sale of razors to prevent throat-cutting or of ropes to prevent hanging, as the sale of poisons to prevent that. Let the present restrictions remain. The qualification of the pharmacist was the only security against preventable poisoning which the Legislature was entitled to take, and it had already charged itself with the care of that, and any legislation on other lines was "grandmotherly" legislation. There was still another inference which he wanted to draw from the proposition with which he started. He had claimed a high position for pharmacy, not higher, however, than he believed it deserved. If that position involved the exercise of professional functions, let them not discredit it, let them act up to it, and that would be effected by cultivating and cherishing the true ideal of it; that mainly would keep them right, *Noblesse oblige*. If he were asked to define the proper attitude of pharmacy in that connection in one word, he would say, discountenance quackery in every shape and form. It was not necessary to tell them what quackery, the thing or the practice, was. It was the outcome of ignorance, perhaps, but still more of cupidity on the one hand, and unbounded credulity on the other; and it found a congenial soil in the field of medicine, and especially that part of it occupied by pharmacy. The President, in conclusion, made some remarks on the new Pharmacopœia just issued from the press.

**MEDICAL STUDY IN GERMANY.**—An intelligent writer in the *Boston Medical Journal*, August 15, advising American students who wish to complete their studies in Germany, and have but an imperfect knowledge of the language, strongly recommends them not, as is commonly done, to repair at once to Berlin or Vienna, where the multiplicity of subjects taught and the number of cases seen are quite bewildering to the new comer, especially if he have only an imperfect knowledge of German. In place of rushing at once into the *Sturm und Drang* of either capital, he advises the student to occupy half the time he has to spend in Germany at one of the smaller, but most efficient schools, among which he indicates Bonn as preeminently excellent. There he will be able in a much more deliberate and quiet manner to avail himself of the valuable opportunities that are offered, having attained first a sufficient knowledge of the language to make these of real service. Say that he comes abroad in June, with the intention of commencing his medical studies in one of the provincial schools, where, however, all the teachers are able men. He should settle during the vacation in some quiet town, *e.g.* Weimar, Eisenach, or Cassell, or still better in the vicinity of his intended school, and devote at least six hours a day to severe study of the language, talking wherever and whenever he can, without regard to slips and blunders, listening to a sermon on a Sunday, and going to the theatre nightly,

if possible. By October he is prepared to listen to, say, two medical lectures daily, of a practical sort, such as clinical medicine and surgery, in which the eye aids the ear. Meanwhile he reads German medicine, especially in reference to the cases which he sees, and by this means quickly familiarizes himself with German medical terms. He increases the number of daily lectures, according as he progresses in the language, and in six weeks is probably able to attend the entire course. He should remain at, say, Bonn, until August 15th of the next year, when the summer terminates. After a vacation, during which he should steadily pursue the study of the language, the student is ready for Berlin or Vienna. Now the fulness of material found there will not embarrass him, for he is familiar with the language, with German methods of teaching, and with medical expressions in that tongue. Moreover, he has far more money at his command than if he had been living in a large city, expenses of every kind being much less at Bonn.

### APPOINTMENTS.

AITKEN, CHARLES, M.B. and C.M. Edin.—Medical Officer to the St. Just District, Truro Union, *vice* Mr. G. W. Hill, resigned.  
 BRAITHWAITE, JAMES, M.D. Lond.—Obstetric Physician to the General Infirmary, Leeds.  
 BURGESS, EDWARD ARTHUR, M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Fransham District, Mitford and Launditch Union, *vice* Mr. R. W. G. Taylor, resigned.  
 FOULERTON, G. R., M.R.C.S., L.R.C.P.—House Surgeon to the Royal Isle of Wight Infirmary, Ryde, *vice* J. Walter Hopkins, M.R.C.S., L.S.A., resigned.  
 GOOD, WILLIAM ERNEST, M.R.C.S. Eng., L.S.A. Lond., L.R.C.P. and L.M. Edin.—Medical Officer to the Charminster District, Dorchester Union, *vice* Mr. John Good, resigned.  
 HENDERSON, G. C., M.R.C.S.—Assistant House Surgeon to the Cumberland Infirmary, Carlisle, *vice* F. M. Blumer, resigned.  
 HOOKER, CHARLES PAGET, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Workhouse and the South District, Cirencester Union, *vice* Mr. C. W. Wilson, resigned.  
 JACK, JOHN SEMPLE, M.B., C.M. Glas.—Medical Officer to the Workhouse, Rothbury Union, *vice* Mr. F. Barrow, resigned.  
 JONES, JOHN ELLIS, M.B., C.M. Edin.—Medical Officer to the First District, Chorley Union, *vice* Dr. W. Paterson.  
 JOHNSTON, M., L.R.C.P., M.R.C.S.—House Surgeon to the Lincoln County Hospital, *vice* E. C. Sharpin, resigned.  
 MATHEY, ARTHUR, L.R.C.P., M.R.C.S.—House Surgeon to the Croydon General Hospital, *vice* Odling, resigned.  
 MENZIES, WILLIAM F., M.B., C.M. Edin.—Junior Resident Medical Officer to the Kent County Asylum, Maidstone.  
 MILLER, HUGH, M.R.C.S., L.R.C.P.—House Surgeon to the Royal Berkshire Hospital.  
 MILLINGTON, WILLIAM, M.D. Edin., M.R.C.P.—Honorary Consulting Physician to the Wolverhampton and Staffordshire General Hospital.  
 PALTON, A. S., M.B., B.Ch. Univ. Dublin.—House Surgeon to St. Mark's Ophthalmic Hospital, Dublin.  
 PEDLEY, NEWLAND, F.R.C.S., L.D.S.—Dental Surgeon to Guy's Hospital.  
 PRESTON, GEORGE, L.R.C.P. Edin., M.R.C.S. Eng.—Medical Officer to the Sixth District, Liskeard Union, *vice* Mr. J. H. Jenkins, resigned.  
 ROBERTS, SIDNEY, M.P., M.A., M.B. Cantab., M.R.C.S.—Honorary Physician to the Sheffield Public Hospital and Dispensary, *vice* William Dyson, B.A., M.D. Lond., M.R.C.S., resigned.  
 SHADWELL, ARTHUR, M.B. Oxon.—Assistant Physician to the Sussex County Hospital, Brighton.  
 SMITH, G. FRANCIS, L.R.C.P., M.R.C.S.—House Surgeon to the Cumberland Infirmary, Carlisle, *vice* C. A. Morton, resigned.  
 TURNER, ELLERY, M.R.C.S. Eng.—Medical Officer to the Brandes Burton District, Skirlaugh Union, *vice* Mr. J. E. Edington, resigned.  
 VOIGHT, J. C., M.D. Edin.—Resident Medical Officer and Visiting Surgeon to the Southport Infirmary and Dispensary.  
 WILSON, ARTHUR H., M.R.C.S., L.R.C.P.—Honorary Assistant Surgeon to the Stanley Hospital, Liverpool.

### VACANCIES.

BEDFORD GENERAL INFIRMARY.—Surgeon-in-Ordinary. Candidates must be legally qualified to practise both in surgery and medicine, and be duly registered. Applications and testimonials to be forwarded to the Secretary on or before October 8th.  
 BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary £150 per annum (with £30 per annum for cab hire), furnished rooms and attendance. Candidates must be registered and possess both a Medical and Surgical qualification. Applications, together with original testimonials and certificates of registration, to be sent to the Secretary on or before September 22nd.  
 CHESTERFIELD UNION.—Medical Officer to the Bolsover District, in succession to Mr. Wallace, resigned. Area, 9,211 acres. Population, 2,758. Salary, £21 per annum.  
 HELSTON UNION.—Medical Officer to the No. 2A, St. Keverne District, in succession to Mr. Appleton, resigned. Area, 6,025 acres. Population, 1,264. Salary, £14 10s. per annum.  
 PETERBOROUGH UNION.—Medical Officer to the Stilton District, in succession to Mr. L. Thelwall, resigned. Area, 18,420 acres. Population, 3,765. Salary, 5s. a case and 2s. 6d. per week per annum for permanent paupers.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—Resident Medical Officer. (*For particulars see Advertisement.*)  
 ROYAL UNITED HOSPITAL, BATH.—House Surgeon.  
 ST. BARTHOLOMEW'S HOSPITAL, CHATHAM.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, washing, &c. Candidates must be registered Medical Practitioners. Applications, stating age, with testimonials, to be sent under cover to the Clerk to the Trustees endorsed "Application for Assistant House Surgeon," on or before September 19th.  
 STURMINSTER UNION.—Medical Officer for the Hinton District, in succession to Mr. James Twigewell, resigned. Area, 9,640 acres. Population, 1,807. Salary, £10 per annum.  
 TAUNTON AND SOMERSET HOSPITAL.—Honorary Physician. Candidates must have taken the degree of Doctor of Medicine, or be Fellows or Members of one of the Royal Colleges of Physicians of London or Edinburgh, or of the King and Queen's College of Physicians in Ireland, and be duly registered under the Medical Acts. Applications, accompanied by qualifications and testimonials to be sent to the Secretary, on or before October 14th.  
 TONBRIDGE UNION.—Medical Officer to the Eighth District, in succession to Mr. Hutchings, resigned. Area, 6,379 acres. Population, 5,892. Salary, £70 per annum.

### DEATHS.

ALDERSEY, W. H., F.R.C.S., at Surbiton, Surrey, on Sept. 7.  
 GUY, WILLIAM AUGUSTUS, M.B., F.R.C.P., F.R.S., at 12, Gordon Street, Gordon Square, W.C., on Sept. 10, in his 76th year.  
 RENDALL, CHARLES, F.R.C.S., at Effie Terrace, Munster Park, S.W., on Sept. 6, aged 73.  
 SNOW, JOHN ELLIOT, M.R.C.S., L.S.A., at Tottenham, on Sept. 11, in his 62nd year.  
 THOMSON, WILLIAM, M.D., M.R.C.S., at 16, Elgin Road, Addiscombe, on Sept. 14.  
 VICAR, JOHN, M.D., late of Melbourne, Canada, at Columbia, S.E., on Aug. 22.  
 WHITEFOORD, ADAM JOHN, M.R.C.S., L.R.C.P., at 48, The Grove, Hammersmith, on Sept. 11, in his 40th year.

### NOTES, QUERIES, AND REPLIES.

#### GELSEMINUM IN NEURALGIA.

TO THE EDITOR OF THE MEDICAL TIMES.

SIR,—I had some months ago under treatment a patient who suffered frequently from severe attacks of facial neuralgia. I prescribed in turn croton chloral, chloride of ammonium, so strongly recommended by the late Sir Thomas Watson, tincture of aconite, also tonga and other such remedies, but without any permanent effect. I remembered, however, having read an interesting and very instructive article in the *Lancet*, by Dr. Spencer Thomson, of Torquay, on the Use of Gelseminum in Neuralgia, and I immediately ordered my patient  $\mathbb{N}xx$  of the tincture every two hours. A few doses gave complete relief. The patient was subsequently placed under a course of quinine and iron, and seems now permanently cured. The gelseminum may be combined with bromide of ammonium. I have since treated several others on the same plan and with equal satisfactory results.

Dr. Thomson says of gelseminum, "Directly or indirectly it had been used by me or by my authority in at least forty cases to which it was applicable, and with almost constant success . . . indeed I can scarcely recall an instance of the above in which relief was not speedily given. The usual expression of the patient has been, 'It acted like a charm.'" Dr. Wickham Legg, of St. Bartholomew's Hospital, recorded sixteen cases, and added, "Nearly all of these patients said they found relief on the same day; the rest were better after a longer use of the medicine." Dr. Yurasz, of Heidelberg, has used this tincture in five cases of neuralgia. In the first case, five drops three times a day (facial neuralgia); cured in three days. Second case of the same kind as the first, four drops three times a day; cured in six days. Third case, supra orbital neuralgia, ten drops three times a day; cured in four days. Fourth case, neuralgia of the fifth pair on both sides, five drops every day, cured in two days. Fifth case, severe sciatica, eight drops three times a day; almost cured in fifteen days, and complete cure was then obtained by the continuous current and warm baths.

I am, Sir, yours, &c.,

ROBERT REILLY, L.R.C.S.I.

Boyle, Ireland, September, 1885.

#### ACID DRINKING WATER.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Mr. Byram Littlewood, of Huddersfield, was over in Keighley the other day, and informed me that fish would not live in the water supplied to Keighley for drinking purposes. His theory is, that there is an acid in the water, in which the fish cannot live. This, he says, is why the water dissolves the lead out of the service pipes. He has patented a process for neutralising this acidity, and thus preventing the water dissolving lead, and also enabling fish to live in it. He maintains that this acidity makes the water unfit for drinking purposes apart altogether from the fact that it dissolves lead. I should be much obliged if any of your readers could throw any light on this subject. It affects not only Keighley, but most of the Northern water supplies.

I am, Sir, yours, &c.,

ARTHUR ROBERTS, Medical Officer of Health.

P.S.—I should state that Mr. Littlewood is a great fish culturist, and had had some specimens of Keighley water sent to him to find out whether fish would live in them.

Keighley, September 12th, 1885.

## THE CASE OF DR. BRADLEY.

[TO THE EDITOR OF THE MEDICAL TIMES.]

DEAR SIR,—Will you kindly insert the following additional subscriptions received for the Bradley Fund.

I remain, yours faithfully,

ROBERT JEFFREYS.

Eastwood House, Chesterfield, September 14th, 1885.

Mr. Thomas Smith, £5; Dr. W. H. Ransom, F.R.S., £2 2s.; Dr. William Carter, Mr. Charles R. Crossley, Dr. A. Bostock Hill, Dr. Thomas Stevenson, Dr. Walter G. Smith, Dr. Robert Hogarth Clay, Dr. George W. Balfour, Mr. W. C. E. Taylor, Dr. Charles T. Aveling, Dr. T. Kilner Clarke, Dr. James Hardie, each, £1 1s.; Dr. James Dunscombe, £1; Mr. George C. Franklin, Mr. James Taylor, each, 10s. 6d.; Mr. Alfred Kerslaw, Mr. John Halliday, Dr. Richard Petch, Dr. Thomas H. Watson, J. M., each, 10s.

## COMMUNICATIONS RECEIVED—

Professor GAIRDNER, Glasgow; Dr. JOHN L. SPEIRS, Glasgow; Dr. POORE, London; Dr. T. MAXWELL, Woolwich; Dr. CLIFFORD BEALE, Llangollen; Dr. W. J. STEAVENSON, London; Dr. NORMAN CHEVERS, C.I.E., London; Dr. WILLOUGHBY, London; Dr. JOHN HARLEY, London; Mr. G. COWELL, London; Dr. BUZZARD, London; OUR BOMBAY CORRESPONDENT; Mr. T. W. BARRON, Durham; Mr. R. W. PARKER, London; Mr. A. ROBERTS, Keighley; THE SANITARY COMMISSIONER OF THE PUNJAB, Lahore; Messrs. W. WESLEY & SON, London; Mr. J. HUTCHINSON, Jun., London; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE PRESIDENT AND COUNCIL OF THE SOCIETY FOR THE STUDY AND CURE OF INEBRIETY, London; THE EXECUTIVE COUNCIL OF THE NATIONAL SOCIETY TO SECURE EFFECTIVE LEGISLATION AGAINST RIVER POLLUTION, London; Mr. R. JEFFREYS, Chesterfield; Mr. H. W. PHILLIPS, Bolton; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London.

## BOOKS RECEIVED—

## CLINICAL REMARKS ON PERITONITIS.

### CHRONIC OR SUB-ACUTE PERITONITIS IN THE YOUNG.

By W. T. GAIRDNER, M.D., LL.D.,

Professor of Medicine in the University of Glasgow.

(Continued from page 392.)

*A Case with several Incidents suggestive of Tubercle, and apparently taking Origin from a Caseating Femoral Gland, the result of a blow—Great Improvement under Simple Treatment, but Evidence of Omental Thickening, and Disease of one Pulmonary Apex, still present after three months.*

I HAVE now to bring before you the notes of two cases, much more remarkable in some of their details than either of those already cited; but as they occurred, and were observed as regards all their essential facts before the present clinical class assembled, or even before any individual member of it was in our wards, you will require to take most of what is to be stated about these cases for granted, and I will only say in general

terms that the facts were not less carefully watched and recorded than in the cases of Jane M. and of Mary Jane S.; and that, along with those cases, the two which I have now to relate will serve to complete so far a clinical study such as you will rarely find within the compass of a single series of observations. One of these cases is that of a boy, John P., æt. 8, who was under my care for three months in the early part of 1884, and was dismissed "much improved"; the other was, in some respects, an almost unique case in my experience, but the particulars of it have to be gathered from the journals of several years, inasmuch as the girl has been admitted to hospital on more than one occasion, and at other times sent for out of curiosity on our part. I will first dispose of the case of John P., which is more easily dealt with, being within a more moderate compass both as regards the time and the complexity of the facts.

John P., an emaciated boy, eight years of age, was admitted to the Western Infirmary on the 18th of January, 1884, and dismissed on the 20th of April in the same year, so much improved in all respects that, whether as regards the general condition or the local phenomena, it might very truly have been said at the time of his leaving us, that "you would hardly have known him." Like the other cases detailed, he had for his chief or most obtrusive symptom on admission a swollen abdomen, which measured 29½ inches in its extreme circumference on the 20th of January (two days after admission), and afterwards declined so rapidly,

that exactly three weeks afterwards (9th February) it was 4 inches less ; the other changes noted in great detail in the journal (but of which I will spare you the particulars) showing that in the interval a considerable quantity of fluid, shown to be present on admission both by the percussion-signs and by a very manifest fluctuation, had been nearly or completely absorbed, exactly as in the case of the little girl of like age, Jane M. Moreover, there were some further points of resemblance between these two cases, the statement of which here will save me, to a great extent, from the necessity of going over the same ground again in this brief narrative. As long as fluid was present in appreciable quantity, it was impossible to be quite sure of the changes in the wall which became apparent afterwards ; only it could be remarked very easily and certainly that the physical changes were not those of simple ascites to a like amount, the dulness on percussion over the whole right side of the abdomen, and even on the left side in the umbilical region, being inconsistent with the perfectly free movement or floating up of the intestines, as we have already said. Only when the fluid effusion was nearly or altogether gone did it become evident that there was an area of relatively dull superficial percussion extending across the abdomen, in the umbilical region, and with this (at date 9th February, twenty-three days after admission) "a feeling of decidedly increased resistance on the right side of the abdomen especially, and even a certain amount of irregularity as of a transverse induration just about the level of the umbilicus and for an inch and a-half above it, corresponding exactly with the type of a thickened and retracted omentum; and it is noteworthy (the report proceeds) that the dull percussion, though perhaps everywhere more apparent on the right side (it had been according to a previous report dull all over on the right side) is at this level decidedly greater, *i.e.* less easily penetrated." (You will remember the significance that I attached in the other cases to this fact.) "The left hypochondrium and epigastrium are now more approximately normal than formerly (*i.e.*, than eight days before, when it was doubtful if the percussion even over the stomach was quite normal), and it is only from about 1½ inches below the hypochondrium downwards, that delicate manipulation makes out abnormal percussion superficially, which continues from this point to the lower abdomen; being, however, very easily penetrated a little to the left of, and below, the umbilicus. On this side also, there is a feeling of undue and unequal resistance, which may very well be conceived to correspond with a thickened great omentum, but by no means so definite or so limited in area as on the other side." What gave these facts a quite peculiar interest for the clinical class at the time was that if they were not declared in advance, they were at least sought for as the probable and (as it were) normal results of the antecedent conditions, and accordingly every care was taken, by repeated comparison with healthy subjects and with the previous reports, to guard against every possible fallacy in observation.

Thus far, then, the case of John P. corresponds so much in its details with that of Jane M., that we may consider the local details of the physical facts in the abdomen as sufficiently clearly indicated. There were two other points of resemblance between these cases. This little boy, like Jane M., suffered as we were told almost no pain in his abdomen, throughout; indeed, he suffered less pain, if possible, than Jane M., though he was much more of an invalid, and, as we shall see, much more severely *ill*, altogether. Then, in the family history there was one other fact common to the two cases; this boy had, among six brothers and sisters, one who was said to have been ill of, and in fact to have died of, "a wasting of the bowels." I

give the popular expression for what it is worth, in both cases: we know, and are likely to know, nothing more of the facts, or of the family history, in either case.

But with these facts resembling, or common to the two cases, there were also very considerable differences. One was as regards the temperatures, which in the former case were scarcely ever more than just appreciably abnormal, and this only for a very brief period, while in John P.'s case they once reached 102·6° F., and were on repeated occasions at upwards of 101° within the first three weeks after admission; the temperatures so elevated being almost always the evening temperatures, while the morning temperatures were approximately normal, and the daily oscillation therefore amounted to two or three degrees of Fahrenheit's scale (one and a half to two or more C.), there being in one instance a fall of 5·4° F. during a single afternoon and night, *i.e.*, from 102·6° to 97·2° F., or from a very decidedly feverish to a very decidedly sub-normal temperature. These are typical facts for a large proportion of cases of this kind, and accordingly you might almost take the temperatures of five or six weeks in this case, here recorded on a chart or diagram, as being a clinical working model for what is to be expected in a well-defined case of chronic or sub-acute peritonitis in a child, when it is only moderately severe; so severe as to justify apprehension, but not so severe as to exclude hope of great and marked benefit through care and treatment. In this case, the abnormal temperatures gave way after six weeks' residence, and all the other symptoms underwent a corresponding improvement; so much so that but for the very decisive local lesions, you would almost have been justified in doubting the serious or dangerous character of the case. But although, as we have said, a typical case so far, it is also true that in many other diseases of the infantile period, you may have temperatures not essentially differing from those of chronic peritonitis; and it is also probable that you may have (though rarely, I believe) a chronic peritonitis in which the temperatures are never appreciably disturbed at all.

There were, however, other circumstances in the case now reported to you, which gave to it a much graver aspect in my eyes at the time than the case of Jane M., and thus enabled me to feel a corresponding sense of relief, as from something happily occurring and yet unexpected, when the course of the symptoms showed so decidedly, after six weeks, that we were on the line of a proximate, if not an absolute *cure* (popularly so-called) of this disease. One ominous-looking fact was that the serous or sero-fibrinous effusion was not limited to the peritoneal cavity, a very considerable amount of dropsical swelling of the penis and scrotum having taken place about a week after admission; this being, too, altogether without swelling of the feet, or any of the other concomitants of general dropsy, but still, on this very account, an exceptional fact, and one suggestive of lesions in the venous and lymphatic systems of the pelvis. Another fact was the presence of diarrhoea (as in the case of Mary Jane S., but not so severe) during the second week of the abdominal swelling. A third fact was the presence of a lesion, very distinct in its physical signs, and not without significantly ominous symptoms — "cough, unattended by expectoration, and sweating about the head, especially in the night-time, which had accompanied the progress of the more obvious abdominal signs from the first, *i.e.*, for about three weeks before admission." The physical signs in question were: "slight dulness on percussion at the left apex, over the two uppermost ribs in front"; respiratory murmur in this situation "loud, harsh, and with a slightly tubular quality" (as compared even with the normally puerile-

R. M. all over); this abnormal quality extending slightly to the apex behind, but without dull percussion, or any r le either behind or in front. All the other organs, so far as they could be observed accurately, were normal to physical diagnosis; but a difference like this in the respiratory murmur of the two apices is so significant of constitutional infirmity, that even if we had no other sign of disease, and no appreciable symptoms at all, we should be justified in looking upon it as a ground for suspicion of more or less chronically impaired health, especially in a child or young person.

But perhaps the most exceptional of all the points of difference between the case of John P. and that of the girl of the same age Jane M. who made such a good recovery, was one fact in the previous history which I have reserved to the last, because it involves a doubtful question of  tiology, and also one of pathology. In Jane M.'s case, beyond a vague statement that she had always had rather a large abdomen, there was nothing at all to indicate any local lesion, or any well-established cause of possible injury to the constitutional health, up to the invasion of the disease for which she was admitted. In the case of John P., on the other hand, his mother distinctly attested (as she believed) the origin of the child's ill-health from a local injury quite outside the abdomen, and only connected with it indirectly through the vascular and lymphatic systems. He was a very healthy boy, she declared at our first interview with her, till four months ago, and had no illnesses beyond what are common to most children. "At this time he received a blow on the upper part of his right thigh, which was very soon followed by a round and painful swelling, the size of a walnut, among the soft parts in the femoral region; but after a few days the pain became less, and the swelling also diminished. It has since remained quite stationary and free from pain. After this injury, the boy never seemed to recover perfect health. He lost appetite, became paler, weak, and emaciated. These symptoms went on till about three weeks before admission, when a general swelling of the abdomen was observed, which has gone on increasing until the present date (20th January, two days after admission). This swelling was not accompanied by any abdominal pain, but there has since been increasing weakness and emaciation, &c., the cough and the hectic fever being presumably of the same date, and probably of identical origin with the abdominal disease." Taking these facts in connection with the rather unusual fact above referred to, of dropsy of the scrotum and penis, suggestive of local venous obstruction in the pelvis or lower abdomen, it is difficult to avoid the conclusion that an inflamed and cascating gland at the seat of the blow had been in some way or other the starting-point of all the subsequent lesions; a theory, as you know, which has been in great favour in Germany for many years past as bearing on the causation of tuberculosis; and which, although I do not adopt it in the extreme sense of Niemeyer, for example, as regards phthisis pulmonalis, is certainly well fitted to explain, so far, the order of events in this case. Here is the actual description of the facts, as they were observed, in connection with the preceding history, a few days after admission.

January 20th.—"The swelling described as the first incident of his illness is rather less than a walnut in size, situate in Scarpa's space on the right side, about two inches below Poupart's ligament. On handling, it gives at first the impression of being soft and elastic, but deeper palpation leads rather to the belief that it consists of a solid base, the more superficial part being so highly elastic as almost to suggest fluctuation. The skin over it does not differ in appearance from the neighbouring skin. In the right inguinal region

several of the glands, chiefly belonging to the chain running in the direction of Poupart's ligament, are distinctly enlarged." And, again, on February 1st, "An examination of the usual sites of glandular en-

JOHN P.,  t. 8. TUBERCULAR PERITONITIS; CHART OF TEMPERATURE.

largements shows an entire absence of these in the neck, axill e, and left groin. In the right upper femoral region there is a soft, elastic, not decidedly fluctuant swelling, between the size of a hazel-nut and that of a walnut, fairly mobile as regards the superficial textures, and presenting no pointing or other sign of an abscess, but seeming to be attached to the deep fascia with considerable firmness. It is painless on handling, but the history quite definitely leads to the

belief that in the first instance it was caused by a blow, was painful, and considerably larger than it is at present. Dr. Gairdner finds a difficulty in determining how far this swelling is glandular, but several of the glands over Poupart's ligament are slightly enlarged, without any inflammatory thickening of the surrounding textures or pain on pressure." As this swelling, whatever it was originally, did not frankly suppurate during the whole time this patient was under observation (three months), it is certainly most probable that a caseating process had taken the place of active supuration, if indeed the latter at any time existed.

The latest information I have to give you as to the progress of this case under observation, and, I may say, under a very simple treatment much resembling that of Jane M., is contained in the following report of 8th April, which I think it worth while to present to you exactly as it appears in the journal, and which I think you will agree with me in considering, under the circumstances stated, very satisfactory.

"Since the 1st February, at which date a general survey of the temperatures was recorded, there have been on eight evenings temperatures noted extending up to, or over, 100°, the maxima being on February 4th 101·5°; on 14th, 101°; and since this barely exceeding 100° in any instance; while the great majority of the temperatures, especially since the first week of February, have been subnormal. A very distinct, though gradual, gain in weight, and a very marked filling up of the features as compared with his state on admission, has been observed throughout this period. The urine, moreover, has undergone very decided and apparently permanent increase as compared with the state on admission and during the period of febrile temperatures. The last ten daily collections recorded from 21st to 31st March give 28 ozs. as a mean. This mean quantity was even exceeded about the middle of February for some days together, 31 ozs. mean being recorded in six days from 21st to 26th February, but on the whole the above may be considered to present a fair average for the last six weeks. The last weight recorded (April 7th) was 4 st. 4 lbs. The boy seems to suffer no discomfort at all either from the abdominal symptoms or from the swollen gland in the right groin, which seems to be slowly maturing towards abscess, and presents a very distinct red blush at the most elevated point of the skin.

"The conditions in the abdomen as last described are not very essentially altered, except that the distinct feeling of transverse, almost solid impaction to the right of the umbilicus, has given way to a more diffused and less definite sense of increased resistance, with superficial dull percussion, however, almost equally characteristic of a thickening extending over a transverse zone about three inches in vertical diameter, half of this being above and half below the umbilicus. A nearly corresponding dulness on the left side is also much less in degree and in limits. Tongue, perfectly clean. There has been no diarrhoea at any time. There is still distinctly impaired percussion in the left pulmonary apex, and the R. M. is relatively less full than in the opposite; but the alteration in quality is so slight that but for the other facts it would certainly be disregarded."

On the 20th of April, 1884, as above stated, John P. was dismissed from the Western Infirmary, very much improved in health and in general condition.

(To be continued.)

TRICHINÆ IN GERMANY.—The expense of examining swines' flesh for trichinæ in Berlin amounts to 11,850l. per annum. In the whole of Prussia four million swine were examined, 2,000 being found to be trichinous.—*St. Petersburg Medicinische Wochenschrift.*

## PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.

President of the Health Department, Social Science Association.

(Continued from page 312.)

### DISEASES OF THE CIRCULATORY SYSTEM.

As I have described elsewhere<sup>1</sup> most of the principal diseases of the heart and blood vessels, I shall confine myself here to giving a few notes of cases occurring in India.

*Congenital Malformations of the Heart* are not frequently seen in India, perhaps because native children thus affected are not brought to us, and usually die early. I was more than once consulted in the case of a Jewish girl in whom signs and symptoms of stenosis of the pulmonary ostium were marked. She died, after menstruation had been established, from arterial gangrene of both feet. I also found evidences of the same defect in two officers' sons who did not survive puberty. These boys were not at all cyanosed. I found only two properly formed aortic sigmoids in an European infant which died of atelectasis pulmonum. Dr. William Mortimer published<sup>2</sup> the case of an Indo-Briton, aged 23, an ordnance artificer of healthy appearance, in whom the orifice of a two-valved aorta had, by thickening of the abnormal structures, become obstructive. I long ago adduced evidence of the law that the structures of congenitally malformed valves, &c., are especially prone to suffer further deterioration by endocarditis.

Prep. 709 in the College Museum displays a similar want of one of the pulmonary cusps.

In Prep. 710, there are four pulmonary cusps. The supernumerary valve is scarcely half as large as the others.

There are only two other valuable examples of cardiac malformation described in this catalogue; 706 is the heart of a new-born infant in which there is remarkable stenosis of the pulmonary orifice, with patency of the ventricular septum, ductus arteriosus, and foramen ovale; 508 is the heart of an infant five months old, with patent arterial duct and foramen ovale. I had preserved in the museum a very fine dry specimen of transposition of the heart and other thoracic contents from a young native woman who died in my ward. The abnormal position of the heart was clearly visible during life.

Mr. Heming reported<sup>3</sup> the case of a native male child, aged 2 years and 8 months, which was markedly cyanotic.

<sup>2</sup> *Madras Quarterly Medical Journal*, Vol. ii, p. 65.

<sup>3</sup> *Indian Journal of Medical Science*, Vol. vii, N.S., p. 345.

It is evident that the report of the condition of the heart is imperfect, but the ventricular septum was patent, the foramen ovale closed and the arterial duct open.

Dr. A. Garden has described<sup>4</sup> the appearances found in a well-formed, plump, and healthy-looking native female infant stated to have been still-born. The left half of the diaphragm was deficient. The small intestines occupied the upper two-thirds of the thorax, a portion of the colon reached almost up to the clavicle. The stomach lay across the lower part of the thorax, behind it was the spleen, part of the liver also lay in the thorax. The heart lay on the right side; the aorta arched backwards from right to left. The right lung was moderately developed. The undeveloped left lung, although seemingly normal in structure, was about the size of half a walnut. No. xv of the "Indian Annals of Medical Science" contains a valuable paper on "Malposition or Displacement of the Heart," by Dr. W. Curran.

When at Howrah, about the year 1853, happening to mention to Mr. Burgess that, although I had seen nearly every form of congenital defect, I had never met with a case of *Branchial Fistula*, he told me that there was then a large Christian family in Calcutta, most of whom displayed this peculiarity. Many years afterwards I saw a European with branchial fistula. There was a small opening half way down the neck, in front of the sterno-mastoid muscle, into which a probe passed deeply about two inches. At first sight, it looked very like a sinus, but it had a distinct mucous lining.

Dr. T. A. Wise has related and figured<sup>5</sup> the case of a strong middle-aged native who died suddenly while walking. Below the origin of the left subclavian artery and the completely impervious arterial duct, the aorta was absolutely closed as if a ligature had been placed tightly round it. Immediately below this point, the aorta appeared of its natural size, and into it "several large arteries poured in their blood." A dissecting aneurysm had been caused by a rupture of the walls of the aorta a little above the semilunar valves. This had given way, causing fatal hæmorrhage into the pleural cavity.

A very remarkable abnormality in a female infant one of twins—still-born at about the eighth month—is noticed<sup>6</sup> by Mr. G. McReddie. It appears that the pulmonary artery did not give off any branches to the lungs, but was continuous with the aorta by a widely open arterial duct. The aorta gave off a trunk which, doubtless dividing into two, proceeded to the lungs and acted as a substitute for the normal branches of the pulmonary artery.

I have always looked upon the typical "button-hole" mitral as a congenital malformation. I met with a case in which, with this condition, the tricuspid orifice, viewed from the right auricle, was also nearly in the button-hole condition.

#### *Cardiac Debility.*

There exist in India all those conditions—with the exception of senility in Europeans—which lead in other countries to weakening of cardiac muscular tone—fevers and other exhausting diseases, inordinate tobacco smoking, scorbutus, anæmia, &c., &c. I have spoken<sup>7</sup> of *Cardiac Asthenia* as a result of paludal poisoning. As, happily, most of those who suffer from this affection in Lower Bengal recover on taking change to Europe, I have not been able to judge precisely whether they are the subjects of weakness of cardiac

muscle or of a neurosis; our knowledge of another Indian neurosis, malarial asthma, leads me to incline to the latter view.

Mr. Charles Macnamara has recorded, in Part V of the "Indian Annals of Medical Science," a series of important observations upon the tendency which inactivity and over-feeding have to produce fatty changes in the heart and other organs of young soldiers in India. His remarks are equally applicable to all classes of men employed in that country. Many deaths of Anglo-Indians, in and out of India, are indirectly due to cardiac debility, predisposing to rapid asphyxia, in various states of disease. The cases of several persons, whose constitutional states were known to me, recur to me as I write. A, an anæmiated man, died at Rome of pneumonia; B, an immoderate smoker, at Paris, of enteric fever; C, a "liver-grown" individual, as soon as he reached Europe, of bronchitis; D, a subject of malarial asthma, on return to London, of what would, probably in a sounder constitution, have been merely catarrh; E, a man known to have a weak heart, soon after entering the rarified and cold atmosphere of a hill-sanitarium. Had the muscular tone of their hearts been duly conserved these individuals would probably have been living now.

*Rheumatic Fever with Cardiac Complication* occurs distinctly but very rarely in Lower Bengal. I believe that it is more frequent northward. On an average, I did not treat more than one case annually in my sixty beds. I can only recall one fatal case in my own practice, and another, an European officer, which I saw in consultation. My patient, a native lad, got pericarditis and then pleurisy, and so died. The officer had pericarditis, but I think that there was no *post-mortem* examination.

In 1839, Dr. Shanks, of H.M. 55th Regiment, observed that disease of the heart does not appear to be so usual a concomitant of articular rheumatism in India as in Europe. Commenting upon this, the editor of the *Indian Journal of Medical and Physical Science*<sup>8</sup> remarked that he could call to recollection some well-marked cases in India.

Writing in 1835 from Bangalore, Mr. Hamilton, of H.M. 39th Regiment, noticed that, although rheumatism had been rather frequent and severe, requiring active treatment, there was no distinct pericardial or heart complication.<sup>9</sup>

Reporting from Bellary (Madras Presidency) in 1840, Dr. Davis of H.M. 39th Regiment wrote, "Rheumatism, in an uncomplicated form, seldom proves fatal in India, and is unaccompanied by the cardiac affections so frequently met with in Europe."<sup>10</sup> It is stated in a report from Arcot<sup>11</sup> that, in one instance only of 241 cases of acute rheumatism, "metastasis" took place. It is added, "this character of rheumatism, so frequent in Europe, is rarely observed in India, and amongst natives it may be said never to occur; in Europeans, likewise, it is seldom seen except in young men recently arrived, who have generally contracted the disease on board ship. In the case above alluded to the "metastasis" did not affect any of the internal organs, but the disease shifted from one joint to another." Commenting upon the death of a European artilleryman of Hyderabad, Deccan, Dr. George Smith<sup>12</sup> wrote that the connection between acute rheumatic disease and pericardial inflammation is too often overlooked in India, from the idea, correct in the main, that rheumatism in the European soldier is less frequently complicated with heart disease there than in England. The very great frequency of this serious

complication in Britain, and the experience of some medical men in India, should, he urged, put us upon our guard in all cases of acute fibrous rheumatism occurring, especially for the first time, in young and healthy men, and should stimulate us to watch carefully the earliest symptoms of the approach of the disease. Morehead remarked that "*acute articular rheumatism is not so common in India as in colder climates, yet it is by no means rare*"; and a complicating pericarditis or endocarditis is, he believed, as frequent an occurrence in the one country as in the other. He added, "Of no rule of practice am I more thoroughly convinced, that it is as incumbent on the practitioner in India as in Europe carefully to watch and search for the physical signs of pericarditis and endocarditis in every case of acute rheumatism. If this rule be neglected, the co-existence of these diseases in India will necessarily continue to be considered an unusual event." Dr. C. Alexander Gordon, then of the 10th Regiment, commented upon the above observations,<sup>13</sup> and Dr. Morehead replied,<sup>14</sup> Dr. Gordon being of opinion that the endocarditis and pericarditis very rarely, if ever, occur in India during the attack of acute rheumatism; that Queen's medical officers were most careful to watch for the physical signs of these affections, and that the proportion of soldiers invalided in consequence of disease of the heart in India is not a tithe so large as in the United Kingdom. Dr. Morehead held that this last observation seems to prove the comparative rarity of acute rheumatism in India, rather than the infrequency of pericarditis as a complication. His opportunities of judging of the frequency of cardiac disease in European regimental hospitals were not few, and many cases of the complication of cardiac disease with acute rheumatism had come under his observation. In his xxvth chapter Morehead records the clinical history of 28 cases of structural disease of the heart and 3 of aneurysm of the aorta *in natives of India*. In 12 of the 28 cases it appeared that "rheumatism" had been stated to exist.

The experience of a working life-time has taught me that acute rheumatism is rare in Lower Bengal; in the majority of the very few cases which came under my notice there was cardiac complication.

No one can object more strongly than I do to mere guess-work in diagnosis. Still it may, I think, be very generally predicted that heart-symptoms—placing aside aortic aneurysm—in one long resident in India, are probably not due to serious organic mischief. The history of acute rheumatism with cardiac complication is usually wanting in these cases.

Acute rheumatism with its cardiac complications appears to be rather frequent among old Indians retired in England. During the last nine years I have heard of six cases, in three of which the heart appears to have been affected, in my own circle of acquaintance.

The thirteen preparations marked Nos. 569 to 581 in the Medical College Museum illustrate *Pericarditis* and its effects. Five of these were sent from distant stations. In No. 569 the pericarditis was attributed to violence. It is probable that some of these specimens were from European sailors.<sup>15</sup>

<sup>13</sup> "Indian Annals of Medical Science," No. xi, p. 7.

<sup>14</sup> *Op. cit.*, p. 562.

<sup>15</sup> I have always valued the Museum Catalogue of the Calcutta Medical College exceedingly. It is the work of two of India's ablest pathologists. In producing it in 1865, Dr. Joseph Ewart, now of Brighton, may be said to have re-edited that portion of Allan Webb's noble *Pathologia Indica* which describes the preparations still in existence. All more recent preparations are described by Dr. Ewart. Since I have worked at the Catalogue, I have noticed a defect for which its authors are in no way to blame. In many cases it does not appear (1) whether the specimens are from Europeans or natives, and (2) whether the lesion represented certainly or probably originated in or (as in the case of European soldiers, sailors, &c.) out of India. This being a great fault in the description

Preparations 608, 609 and 610 well represent displacement of the heart to the right by left empyema. The first and second are from natives, the third is from an European.

Before I went to India, I entered into a rather painful discussion in maintenance of a claim to the observation that, although hypertrophy and dilatation of the heart are seen in the majority of cases of old pericardial adhesion, the natural tendency of this state of the pericardium is to produce atrophy of the heart where the exit of blood from that organ is not impeded by concurrent valvular stenosis or obstruction to the pulmonary or systemic circulation. Preparation 13 markedly illustrates this pathological law, it represents atrophy of the heart consequent upon old standing adhesion of the pericardial surfaces. The agglutinating material "consists of three alternating layers of white and brown structure. It is cartilaginous in consistency, and inclusive of the thickened pericardium, measures *about half-an-inch* in thickness, whilst the subjacent wall of the left ventricle varies only from the *sixteenth to the eighth-of-an-inch* in thickness. The *carneæ columnæ, chordæ tendinæ, and curtains of the mitral valve* were also much attenuated. The aortic valves were healthy." The wall of the right auricle is only the *sixteenth-of-an-inch* thick, whilst "the altered and thickened pericardium is fully thrice as thick."

The only good that came out of this unpleasant affair was a nobly candid expression by Dr. Thomas Addison. While the contest was still recollected, a paper on pericarditis was read at a meeting of the Physical Society of Guy's Hospital. The dangerous point was avoided in the discussion until my opponent stated his case just as we were about to separate. Dr. Addison rose and proposed that the discussion should be continued. He said that he had, of course, often noticed, with others, that cardiac hypertrophy and dilatation were attendant upon old pericardial adhesion, but he had seen cases in which the heart was small and atrophied. He had never been able to reconcile these observations until Dr. Chevers gave the explanation.

I frequently met with extensive traces of old *Carditis* and *Endocarditis*, not obstructive, in examining the bodies of native hospital patients.

Cases of *Liver Abscess opening into the Pericardium* will be found in the section on Hepatic Disease.

A very remarkable case of *Rupture of the Pericardium* has been reported<sup>16</sup> by Dr. Lewtas. A Calcutta cooly fell into the hold of a ship and died in two hours after admission. There was a rent two inches long on the right side of the pericardium, its edges were blood-infiltrated. There was another similar but smaller rent nearly corresponding with the apex of the heart. There were six ounces of blood in the right pleura, doubtless from the rent pericardium.

This case is very important as showing that an extremely severe blow to the heart does not necessarily cause immediate death by nervous shock. The following case appears to indicate that the rents in the pericardium were caused by squeezing the heart.

In a cooly whose chest was crushed between the buffers of two railway carriages, Mr. John O'Neill found that the heart had been squeezed off through a hole at the apex of the pericardium, and lay quite detached, resting on the diaphragm at the extreme left of the thoracic cavity, beneath the left lung.<sup>17</sup>

At page 409 *et seq.* of my *Medical Jurisprudence* for

of an invaluable collection which must now number more than two thousand typical specimens, I trust that, as new preparations are added, my successors will provide that these points shall be made as clear as possible.

<sup>16</sup> *Indian Medical Gazette* for Nov., 1876.

<sup>17</sup> *Indian Medical Gazette* for 1878, p. 41.

India, I have cited several Indian cases of *Spontaneous and Traumatic Rupture of the Heart*. There are two, by Drs. Hutchinson and Simpson, in which a blow with a club or *lattee* (long male bamboo) ruptured the heart. A similar case has since been reported.

In the Calcutta Medical College Museum, Preparation 604 is one of spontaneous rupture of the *right ventricle* in a native, a very curious, but, to me, obscure case.

Preparation 605 represents rupture of the *right ventricle* of a native's fatty heart, presented by Dr. Mountjoy. My friend, Dr. Theodore Duka, has described<sup>18</sup> the case of a Mahometan, æt. about 65, who was reported to have had a fall during a scuffle, after which he suddenly expired. There was a *rupture of the pericardium* over the apex of the heart, about three lines long and running horizontally. Its edges were ecchymosed to the extent of about two lines. There was a considerable quantity of uncoagulated blood in the left pleural cavity; the pericardium was also distended with blood. There were two rents in the *right ventricle*, near the septum; one of these opened the coronary vein. The whole organ presented extensive fatty degeneration.

Preparation No. 606 in the College Museum is one of fracture of sternum and ribs, with *laceration of the pericardium* and rupture of the *left ventricle* from a native who died within a quarter of an hour after having been run over by the wheel of a buggy.<sup>19</sup>

Mr. McReddie examined the body of an apparently able-bodied healthy native man who was found dead on his threshing floor. There were a deep ecchymosis over the third and fourth left costal cartilages, rupture of the spleen (apparently) and a rent in the *left ventricle*, probably incurred in a struggle with thieves.<sup>20</sup>

Mr. Galt reported the case of a sepoy who died suddenly while under treatment for fever in hospital. His age is not mentioned, but he could not have been old. The description is not clear, but I think that there must have been an *Aneurysm*, which ruptured at the *apex of the left ventricle*.

Sir W. O'Shaughnessy Brooke brought before the Medical and Physical Society of Calcutta, in 1836, an *aneurysm* about the size of a walnut projecting from the *apex of the left ventricle*. The coats of the sac were thin, and it was evidently formed by the endocardium protruding through the muscular walls. The subject of this lesion, a native, died suddenly in the street, the sac having burst and caused hæmorrhage into the pericardium.<sup>21</sup>

The specimen numbered 599 in the Calcutta Medical College collection is a "heart showing two *aneurysms* in the walls of the left ventricle near the apex." Each of these is about the size of a walnut, and communicates by a comparatively narrow opening with the cavity of the ventricle. The margins of these orifices are smooth, and lined by an opaque-looking membranous structure which is continuous throughout the interior of the aneurysms, both of which have led to the entire absorption of the muscular structure, being bounded on their external aspect, which projects half an inch above the level of the cardiac surface, by thickened and adherent pericardium. In some parts this shield or barrier is a quarter of an inch in thickness; whilst, in others, it does not exceed the tenth of an inch. Each of the sacs was filled with fibrine in process of softening and degeneration, and a portion of coagulum is now seen in one of them. The patient was admitted into the Calcutta Native Hospital in a dying state.

Mention is made in my Medical Jurisprudence of the case of Israel Hinton, in whose heart a musket bullet occupies the apical part of the cavity of the left ventricle. This case has been narrated by Sir Joseph Fayrer.<sup>22</sup> At the storming of the Great Pagoda at Rangoon on the 14th of April, 1852, this poor fellow was struck a little above the anterior fold of the left axilla. He died, worn out by pulmonary disease, on the 24th of June. The preparation, numbered 607, is one of the most valuable in our Medical College Museum. The ball is described in the catalogue as being "almost completely embedded in the muscular structure of the left ventricle at its apex." It appeared to me rather that the bullet, having dropped into the cavity of the ventricle, had, by its weight, formed a sac for itself. There was a canal in the middle of the consolidated left lung in which was a small portion of the jacket cloth. "This canal, passing forwards and inwards, stopped short close to the union of the pulmonary veins." Unfortunately, the pulmonary veins, through which, in all probability, the ball found entrance to the heart, are not preserved. Dr. Burton Browne and I most carefully examined the preparation, and could not discover the slightest trace of a route by which the bullet could have entered.

Dr. Curran related to me the case of a native man at Peshawur who, while sleeping, was approached by a fanatic and shot in the heart with seven slugs. He lived long enough to identify his murderer.

Mr. John Adam published<sup>23</sup> the case of an intemperate military invalid, æt. 52, a native of Switzerland, who died suddenly in India. It was found that a large quantity of fluid blood had been effused into the right pleura. The pulmonary valves "were in a state of ossification. The *pulmonary artery* was extremely thin and enlarged to nearly four times its natural size." It contained "an organised polypus extending from the semilunar valves about four inches along the artery, of which the circumference was not less than seven inches." "The *rupture* had taken place in the middle" (doubtless half way up the pulmonary trunk). The aorta and its branches "were completely ossified."

A case of *Gummatose Tumour* of the heart occurred to my friend, Dr. Francis, while officiating for me at the Medical College Hospital in 1872.

There is a very slight and imperfect notice of an *Abscess of the Heart* reported by Mr. Knight to the Medical and Physical Society of Calcutta. During life, the patient showed no sign of cardiac affection or severe disease of any kind.<sup>24</sup> No. 602 in the Medical College Museum is described as "*an abscess of the septum ventriculorum of the heart*." It was presented by Professor Wilson.

After a life-long search for varieties of heart disease, I know little or nothing of abscess occurring in the cardiac walls except as a pyæmic deposit. I suspect that, in some cases, those putty-coloured fibrinous concretions, described by Dr. Henry Marshall Hughes in vol. iv, p. 146, of Guy's Reports, have been mistaken for abscesses. They are hollowed, and are filled with a thick pasty fluid which is mainly broken-down fibrine, but which has, to the naked eye, a puriform appearance. They evidently have a degree of organisation, as I showed in the *Medical Gazette* for August, 1845, p. 774. In a case of sea scurvy which proved fatal in my ward, I found several of these concretions;—one of rather large size occupied the right auricular appendix.

Not to speak of cases of mitral and aortic stenosis arising from ordinary endocarditis, I saw, in India,

<sup>18</sup> "Indian Annals of Medical Science," No. xv, p. 257.

<sup>20</sup> *Indian Medical Gazette*, Vol. iv, p. 141.

<sup>21</sup> *Indian Journal of Medical Science*, Vol. vi, N.S., p. 814.

<sup>22</sup> *Lancet*, May 10th, 1879, p. 658.

<sup>23</sup> *Calcutta Medical and Physical Transactions*, Vol. ii, p. 114.

<sup>24</sup> *Indian Journal of Medical Science*, Vol. iii, N.S., p. 767.

more than one example of *Congenital Narrowing of the Mitral Orifice*. I presented to the collection Preparation 623: "button-hole constriction of the mitral orifice." The opening is a mere slit, from (congenital?) thickening, puckering and contraction of the curtains of the mitral valve. From a native female, 25 years of age, who died suddenly, Preparation 621, is one of mitral stenosis from "calcareous degeneration." The slit is so narrow as to render the introduction of the little finger difficult. It was from a native of Bengal who died with general anasarca; presented by Professor Mouat. Professor E. Goodeve presented Preparation 622: "button-hole mitral constriction. The orifice will scarcely admit more than a common pencil."

I met with several cases in Calcutta in which there was clear evidence during life of *Regurgitant Disease of the Aortic Valves*, in a native merchant, in a stoutly-built middle-aged European woman, in a very powerful European. The last-named was employed in supervising the construction of the great drainage culvert which runs down Dhurruntolla. In this work, bricks were not laid down singly, but several were placed with mortar in a wooden frame and allowed to consolidate—thus masses weighing nearly a hundred-weight were formed. My poor patient was in the habit of taking these ponderous bricks in his hands and building them in. On one occasion, he felt something give way in the præcordial region and came to hospital, where he died. The European woman's case was one of rather unusual complexity. I sent the diseased structures to our museum (Prep. 631). The aortic valves are somewhat thickened, rigid, shallow and contracted, and one curtain is quite incompetent to prevent the reflex of blood during the diastole. The upper margin of another shows a tendency to retroversion. There is, consequently, a dilated and hypertrophied left ventricle. The curtains and muscular columns of the mitral are also thickened, but efficient. The ascending aorta is slightly dilated, and this, as well as the arch and descending portion, are partly atheromatous. About an inch above the faultiest cusps there is a small aneurysmal pouch, about the size of a hazel nut, which is advancing towards the descending cava at its termination in the auricle. The internal and middle coats at the apex of the tumour have given way, and there is only the attenuated cellular coat preventing the extravasation of blood. The congestion of the cellular coat of the cava, just where rupture was impending, indicates the commencement of the process of exudation of organizable material wherewith nature might have delayed the rupture of the aneurysmal sac. There was a double bruit above the aortic valves. It would have been doubtful whether this depended upon aneurysm of the ascending arch, or upon not excessive regurgitant disease of the aortic valves. The moderate water-hammer character of the pulse decided this point. While in India, I more than once found a double murmur in the ascending aorta without regurgitant diastole. Here there was probably either aneurysm of the ascending aorta or great roughening of its walls, the valves being efficient.

*Diseases of the Coronary Arteries*.—Prep. 632 displays calcareous degeneration of the coronary arteries in an old enfeebled Bengalee. There was also general atheromatous disease of the arteries. The coronary arteries are "quite ossified like quills." The heart is atrophied.

Unfortunately the race to which the subject of Prep. 633 belonged is not stated. It is a very remarkable specimen of *Aneurysm of one of the Coronary Arteries*. There is atheromatous deposit in and thickening of the semilunar valves, and in the lining membrane of the sinuses of Valsalva. The orifice of the coronary artery leading to the aneurysm is large enough to admit a goose-quill. About half an inch down is the

sac of the aneurysm, which is about as large as a small walnut. Its walls consist of the thickened visceral pericardium, the altered cellular tunic of the artery, and a more or less interrupted lamina of organized lymph. There is a good deal of thickening and opacity of the pericardium for about half an inch around the circumference of the aneurysmal sac.

Mr. Charles Macnamara<sup>25</sup> saw two cases of European soldiers, the subjects of general fatty degeneration, in whom *the aorta had ruptured*, in one case *within*, and in the other just *outside* the pericardium. "There was no dilatation of any part of the vessel, but, owing to an excessive deposit of fat from the vasa vasorum, the walls of the vessels had become infiltrated with fat, interfering with their due nourishment and rendering them incapable of resisting the force of the blood, and they had burst at the point where they had become much degenerated."

I saw one similar case in the dissecting-room at Guy's in the extremely diseased and much dilated, but not aneurysmal, aorta of an elderly man. The vessel was rent within the pericardium.

(To be continued.)

#### NOTE ON THE EFFECTS OF THE NATURAL MINERAL WATERS OF LEAMINGTON, IN SCROFULOUS AND OTHER DISEASES OF CHILDHOOD.

By R. EARDLEY-WILMOT, M.B. (Lond.).

I HAVE read with interest the able and practical report by Mr. Walter Pye, in the *Medical Times* of Sept. 19th, on the use of small continuous doses of a natural mineral saline water in rickets, glandular swellings, and other diseases of childhood. Whilst most fully endorsing Mr. Walter Pye's conclusions as to the value of such a course of treatment in this class of disease, I should wish to call the attention of the author of the report referred to, and also of the many under whose notice it must have fallen, to the fact that in the natural mineral waters of Leamington, we have a saline even more nearly adapted to the treatment of such conditions than the Friedrichshall water which was so successfully employed in the cases recorded.

The curative effect of such a mineral course is, to us at least, no new discovery, but one confirmed by the practical experience of many years and many authors. I would refer those interested in the subject, to the treatise by Londoun, 1831; to the recent work by Dr. F. W. Smith ("The Saline Waters of Leamington"); and to a paper of my own in the *Medical Times*, April 12th, 1884. In all these it is unanimously contended that, in a large proportion of the wasting, scrofulous, lymphatic, and tubercular diseases of childhood, the Leamington waters, combined with other rational and therapeutical treatment, may be exhibited with a fairly confident anticipation of a satisfactory result. This dictum is one which to residents and practitioners here, and to a large class of invalid visitors who add their testimony to ours, lies beyond the region of probation, in the calm atmosphere of fact.

The value of our mineral waters in chronic gouty and rheumatic affections, in sciatica, and in diseased conditions resulting from hepatic, portal or uterine congestions, is probably too well-known to need present reference. Their efficacy in those disorders of nutri-

<sup>25</sup> "Indian Annals of Medical Science," No. viii, p. 182.

tion in childhood in which Mr. Walter Pye has obtained such good results by the Friedrichshall course is (by those of us who have had practical experience of the Leamington waters as a remedial agent) most fully admitted. I believe, indeed, that in these waters we have a natural medicine peculiarly adapted, from its chemical constitution and degree of dilution, for the scrofulous and glandular diseases of childhood. Our springs, while presenting a general similarity to those of Friedrichshall, differ from them in the greater relative proportion of *chlorides* contained in the Leamington waters. It is upon the presence of these chlorides of sodium, magnesium, and calcium in large quantity in each of our several springs, that we chiefly rely for those increased tissue changes which are essential for the improvement of the diseased glandular and lymphatic systems in childhood. In the soundness of this view we are well supported by physiological and pathological observers, and by the results which are obtained. The lower proportion of sulphates, as shown by comparative analysis of our waters with those of Friedrichshall and other foreign spas is, we believe, an actual advantage, as rendering more gentle and equable the purgative action of the waters. The increased excretory action of the kidneys is well marked and useful during the exhibition of the saline.

I do not wish this communication to grow beyond the proportions of a "note," but would refer all interested in the subject to the papers adduced above. A word in favour of our English, as opposed to Continental spas, should never be out of place. I may say, in addition, for those who desire practical proof, that the Leamington spa waters, though best imbibed on the spot, may be obtained also carefully and reliably bottled, under direction of the Corporation, from the Leamington Spa Mineral Water Company.

ACUTE SEPTIC PERITONITIS—OPERATION—  
RECOVERY.

(Under the care of Mr. VICTOR HORSLEY.)

For these notes, we are indebted to Mr. B. POLLARD,  
Surgical Registrar.

---

A. L., aged 43, by occupation a servant, was admitted into University College Hospital at midnight, July 28th, 1885, suffering from acute septic peritonitis.

*History.*—*Personal:* previous health good. *Family:* good. *Present Illness:* It appeared that patient had been suffering for some days from a femoral hernia (?) on the right side. A surgeon was called in who was said to have reduced the rupture, but the patient's symptoms becoming very urgent, she was brought to University College Hospital.

*Present state.*—On admission, patient was found to be a small spare woman, lying on her back with the knees drawn up, complaining of intense pain in the abdomen. Face brown and pinched, eyes deeply sunken, with dark rings round each, countenance expressive of great pain and exhaustion. Temperature 100.2°, pulse fairly strong and regular. On examin-

ing the belly, it was found to be hard, the walls very rigid and excessively tender. There was a small rounded hard swelling at the saphenous opening in the right groin. It felt like an exceedingly tense hernial sac, but it was so tender that firm pressure was impossible.

*Operation.*—Considering the urgent condition of the patient and the advisability of endeavouring to relieve the peritonitis by drainage, after of course the groin had been examined, Mr. Horsley cut down on the tumour with strict Listerian precautions, the patient being under ether. He found the swelling in the groin was composed of the customary crural lymph gland, acutely inflamed, and lying in front of a very small and shrunken hernial sac, to which it was firmly adherent. Mr. Horsley then opened the sac by cutting through the lymph gland. The cavity of the sac about one-third inch in diameter was found to be greyish, almost sloughy in appearance. The neck of the sac was then freely divided on a hernia director so as to liberate any peritonæal fluid which might have accumulated as a result of the peritonitis; on this being done, about two ounces of horribly foetid pus gushed out. The smell, though excessively foul, was not at all faecal, neither was there any matter in the pus that resembled fæces in the least. The finger passed freely into the abdominal cavity, but the neighbouring coils of intestine which could be felt covered with exudation lymph, were so matted together as to give the notion that they formed an inner wall to a more or less localised abscess in the peritonæal cavity. This cavity, at any rate, was then thoroughly syringed out with warm carbolic acid solution 1 in 80, a large drainage tube passed into the abdominal cavity, the gland and hernial sac removed and the wound sewn up with catgut, a Listerian dressing being applied.

After the operation the temperature quickly fell to normal, and the patient was evidently benefited.

July 28th.—Six leeches applied to epigastrium where pain was intense somewhat relieved it. Patient was very sick during the whole day; vomit was ordinary greenish sour fluid. Ordered ice, milk, and brandy  $\zeta$ ij.

July 29th.—Still very frequently sick; wound dressed under the spray; found to be healing above the drainage tube by the first intention, quantity of foul thick discharge. The carbolic gauze dressing was changed for iodoform wool. The bowels acted to-day, the motion being very relaxed.

July 30th.—Patient not so sick this morning. Wound syringed out, not so foul. Temperature 98.4. Pulse 86. Full respirations 30.

July 31st.—Patient only sick once to-day. Legs now stretched out, but belly very tender. Hot fomentations since 29th. Nutrient enemata which were tried to relieve the vomiting produced irritability of the rectum after the 3rd, so that they had to be given up. Koumiss by the mouth was well retained.

August 1st.—Patient not sick. Bowels open now regularly by enemata. This relieved the distension, and the patient now able to take considerable quantities of iced milk. From this date the patient made a steady recovery, the wound, excepting the drainage tube track, healed by the first intention. The tube was shortened gradually, and was left out on August 13th. The tenderness in the abdomen gradually lessened, but still some remained at epigastrium and right iliac fossa even when patient left the hospital. When convalescent and walking about, patient said she felt "as if her internals were tied together."

*Remarks by* MR. VICTOR HORSLEY.

The above case is interesting as belonging to a class which have not attracted much attention up to the

present, except as instances of very fortunate recoveries, but it is clear that, in view of the revolution in surgery of the peritonæum during the last 20 years, the regular treatment in cases of acute peritonitis which are suspected on good evidence to be of septic origin, should be free incision and drainage. In this particular case, the question whether perforation had not already occurred of course came up, but though the fœtor of the discharge was most horrible, the absence of a regular fœcal odour seemed sufficient to negative the idea of perforation. It is important in connection with this point, however, to note that the severest pain appeared to be at the epigastrium, as well as the iliac fossa, and that the peritonitis involved the whole cavity, although the fœtid abscess probably was more or less localised. If at the time of opening the cavity of the abdomen the flow of discharge is intermittent rather than continuous, it would perhaps be an indication that the suppuration was not at all localised, and that the matter was pent up between the coils of intestine, under which circumstance a much freer incision and a more thorough washing out would appear to be indicated; the sequel of such a case one would expect to be general adhesion, and from the statement of this patient (who for some days walked with the spine bent) this would seem to be the case.

## Medical Times and Gazette.

SATURDAY, SEPTEMBER 26, 1885.

---

ON Tuesday the Sanitary Institute opened its Annual Congress at Leicester, the stronghold of sanitary schism, with a most able address from its President, Dr. de Chaumont, the substance of which we publish elsewhere. The address was on somewhat the same lines as those of Sir James Paget's speech at the Health Exhibition last year, and dealt mainly with the influence of sanitary science in lowering the death-rate, and so of saving some of the enormous fine which the nation yearly pays for its sanitary shortcomings. There is no doubt that hygiene has yet much work to do. At present it has attacked little more than that variable fringe to the death-rate caused by zymotic disease. But, as Dr. Longstaff has pointed out, even the entire abolition, if that were possible, of all zymotic disease would not lower the death-rate to the figure

dreamt of by sanguine sanitarians. In London, for instance, the last three weeks have been healthier than any like period on record, and yet the death-rate, leaving out the small zymotic mortality, would still be 14 per 1,000. It is evident that to reduce it to the 12 or 11 per 1,000 aimed at by even cool-headed sanitarians, hygiene must do something more than look after gulleys and water-closets. Alcohol, one of the two great breeders of preventable non-zymotic disease, has scarcely yet been touched by the sanitarians as such; while syphilis, the other, has been let drop, like a hot cinder, at the bidding of a shrieking brother-and-sisterhood. Again, infantile diarrhœa, the disease which sends up our city death-rates with such a bound in the dog-days, and which, though classed as zymotic, is in many cases no more truly zymotic than its winter analogue, infantile bronchitis, has scarcely been touched by sanitary reforms. Perhaps in many cases it is not possible or desirable for it to be touched, many of its victims being doomed from birth, and unable, however coddled, to live to maturity. But for the rest, knowledge amongst the parents is needed more than expensive sanitary appliances, and we are glad to see this extension of knowledge put forward by Dr. de Chaumont as one of the main objects of the Institute over which he presides. How far the poor are from that saving knowledge, may be realized when we still find many a practitioner among them ordering flour and biscuits and all sorts of farinaceous rubbish to tiny infants with the diarrhœa upon them. The obvious rule, then, for the sanitary expert in relation to this disease might well be "first teach your doctor." The remarks, wisely left to the last, in which Dr. Chaumont dealt with the special heresy of his host-town, were in excellent style—conciliatory, without abating a jot from the authority of the creed which he went to Leicester to uphold.

---

ON Tuesday, the section of Sanitary Science and Preventive Medicine was opened by an address from the President, Dr. Arthur Ransome, who called attention to the two shortcomings of Leicester, its high death-rate from infantile diarrhœa, and its rejection of vaccination. The former, he said, showed that there must be something wrong in the place itself, and it behoved the inhabitants to remove such a reproach to their humanity with all speed. In a subsequent paper, which was well debated, Dr. W. E. Buck, of Leicester, traced the cause to water-logged subsoil impregnated with decomposing organic matter, which gave vitality to a specific organism, the direct cause of the disease. In the afternoon, there was a lively but unsatisfactory discussion on vaccination, in which the apologists for the Leicester system met some of our most distinguished sanitarians. Dr. Ransome, in his opening address, had vividly described the horrible and destructive character of small-pox, and quoted statistics from Germany to prove the efficiency of vaccination as a prophylactic. The debate itself was opened by Surgeon-Major Pringle, who again related his remarkable experiences in India. He was followed by Alderman Windley, who described the isolation system in vogue at Leicester, and urged its application

in other towns. Professor Corfield, who spoke next, was conciliatory, and apologised for the neglect of the believers in vaccination to take proper precautions against the spread of small-pox. For the other side Mr. E. T. Mott contended that small-pox, like some other diseases, had practically disappeared from Europe, not because of vaccination, but as a result of improved sanitation; to which Sir Charles Cameron replied that in Ireland typhus still prevailed in spite of sanitation, though small-pox was practically unknown, the Irish being one of the best vaccinated nations. Dr. Alfred Carpenter compared vaccination to an asbestos coat, and isolation as practised in Leicester to a powerful sanitary fire engine, and said he preferred to have both. Mr. J. T. Stephen, on behalf of the town, reiterated some well-known anti-vaccination arguments, and Dr. de Chaumont closed the debate by admitting the importance of isolation, and congratulating the Leicester Corporation on what they had done. The debate does not appear to have been altogether a very serious one, the advocates of vaccination being handicapped by their sense of the proprieties and refraining from bringing forward with sufficient insistence conclusive facts such as those contained in the report of the recent German Commission. The Congress ought not to have gone to Leicester, unless they were prepared to fight the subject without buttons on their foils.

DURING the past week, cholera has been raging at Palermo, over a hundred deaths having been recorded each day. The proportion of deaths to cases is much greater than has been usual at other places in the present epidemic, a result attributed partly to the concealment of cases, and partly to the bigoted refusal of the sick to accept medical aid. The Palermitans have behaved almost worse under their visitation even than Spanish villagers, and for a few days all authority was set at naught, and the doctors were exposed, not merely to neglect, but to insult and injury. Within the last two days affairs have improved; the cholera has not increased, and the people are beginning to regain their senses and to seek for medical help.

IN Spain, the epidemic slowly subsides, though some three hundred deaths are daily reported. We are beginning now to realise a little better the state of misery and madness to which the outbreak reduced the Peninsula, the special correspondent of the *Times* having sent home some most able letters on the subject. In one of these he tells us of the almost forgotten English commission. Professor Roy and his colleagues, Dr. Graham Brown and Dr. Sherrington, arrived, it appears, at Aranjuez at the height of the epidemic. "In spite of the danger and confusion, they calmly established a laboratory, unpacked their microscopes, and systematically prepared culture broths. In all, they have made 24 *post-mortem* examinations of cholera cases, and have also secured many specimens of micro-organisms from living patients." "I am glad to add," the correspondent continues, "that these researches, so gallantly undertaken, are likely to prove of con-

siderable use to the cause of science. I must not forestall the results of the report, which, indeed, is not yet concluded. In a few weeks' time the British public will read with pride and satisfaction that the lives of the English scientific commissioners have not been exposed in vain, and that a distinct step forward has been made in the knowledge of the special micro-organism associated with cholera." In France, there has been a slight spread of cholera, but the cases reported to have occurred at Paris were only sporadic, and not imported from the South. Some excitement was occasioned at Liverpool last week, by the arrival of a cholera-stricken ship from Marseilles, but stringent precautions were taken, and the event is already forgotten.

OUR Paris Correspondent writes: The cholera epidemic in the south of France seems to be gradually gaining in geographical extent, while evidently diminishing in intensity. Cases, few in number, are reported at Arles, at Solon, and in the vicinity of Montpellier; while at Marseilles and Toulon the mortality from cholera ranges very low. The characteristics of the present incursion are somewhat different from those which have been noticed in previous epidemics. The character of the disease is more insidious. Slight symptoms often usher in an attack which shortly proves fatal. The worst and most infectious parts of Toulon and Marseilles are not the most severely visited. It would seem that the cholera germ (if one really exists) resembles those plants and molluscs which, like the *Limnæa impura*, love fo waters, but cannot stand too advanced a degree of putridity, however favourable that may be to lower and different organisms. The upper classes have paid a full tribute to the prevailing scourge. An inspector-general, several naval officers of high rank, and at least a dozen medical men have been swept away. A still more illustrious victim has fallen in the person of Monseigneur Forcade, Archbishop of Aix, who was seized with a sudden and fatal attack after a pastoral visit in which he personally interviewed several cholera patients. The fact that such persons as officers, medical men, &c., would be more likely than the lower classes to observe sanitary precautions, is at first sight unfavourable to the germ theory. At all events, the doctrine of "premonitory diarrhœa" is quite knocked on the head by the clinical observation of facts. It must now be allowed that an attack of cholera may be as sudden as a flash of lightning, however unpalatable the plain truth may be.

THE germ theory is at present going out of fashion; and while, in Italy, scientific men seem inclined to consider cholera as a disease of the nervous system, in France some approach is being made to the views upheld for more than half a century by M. Jules Guérin. It is clear that in the present age, a man who stands still is likely to find himself in the non-tide of fashion, provided he lives long enough. Professor Peter, whose determined opposition to the views of M. Pasteur is well known, delivered a set speech at the Academy last week, to prove that cholera is not an

isolated specimen of disease in the pathological series, but rather the last step in an ascending scale, of which diarrhoea, cholera, and cholera nostras are the earlier stages. Whatever may be thought of these views, it is certain that the premature celebration of Koch's discovery, and the gross caricature of Pasteur's doctrines trumpeted forth by Dr. Ferrán, have done much to promote a movement of retreat on all these subjects in the minds of men of science. The elaborate paper read by Professor Marey on the Statistics of Cholera leads to the same conclusion.

IN the course of his remarks relative to the treatment of cholera, Professor Peter asserted that the first indication was to combat the irritation of the digestive apparatus and solar plexus, for which purpose he applies a large blister to the epigastrium; in plethoric individuals he would not hesitate, he says, to put half a dozen leeches on the pit of the stomach. The pain and the cramps he endeavours to subdue by the hypodermic administration of morphia. He also advises the use of the constant current, one pole being placed on the vertebral column and the other on the epigastrium. Owing to the difficulty that is often experienced in employing electricity, he recommends the use of Chapman's spinal ice-bags as likely to fulfil the same indication, as he mentioned last year at the Ecole de Médecine; he has tried this treatment in twelve cases, of which only two proved fatal. Indeed, he seems then to have been even more enthusiastic in its favour than now, though he has had no fresh experience to cause him to modify his opinion. Here is what he then said on the subject—"From the first application there was a notable diminution of the vomiting, of the epigastric pain, and of the cramps. The patients became warm and the pulse perceptible. This modification of the epigastric pain is interesting, for the ice-bag is far from the epigastrium, but it exerts its influence by modifying the innervation of the great splanchnic nerves. In respect to the cramps the same thing occurs. To say that ice applied to the bodies of the sufferers, already algid (almost icy cold) warms them, is a paradox, and nevertheless is not less than the truth. In fact, by putting an end to the spasm of the blood-vessels the blood is allowed to circulate, and consequently the animal heat is generated afresh. In short, ice applied along the spine and the continuous current produce similar results; but the effects of the ice are more durable than those of electricity. This superiority is due to the prolonged application of the ice, whereas the continuous current was only applied during two or three hours each day."

DR. FERRÁN having submitted a portion of his vaccine fluid to MM. Chantemesse and Rummo, they have lost no time in investigating its properties and reporting thereon to the Académie de Médecine of Paris. They state that the sample they received, which Dr. Ferrán declared to be a typical specimen of his vaccine, was an odourless fluid of a clear yellow colour and slightly alkaline reaction. After experimenting with it and testing its behaviour in Agar-

Agar and peptonised gelatine, they are led to conclude that the vaccine is not a cultivation fluid of invariable composition: sometimes it is an impure cultivation of comma bacilli, sometimes it is a liquid containing masses of micrococci, whilst the comma bacilli are almost wholly absent. In either case the subcutaneous absorption of the so-called vaccine does not protect against the injection into the stomach of a pure cultivation of comma bacilli made according to the recognised methods. Its vaccinal power is *nil* according to their experiments. Injected under the skin of guinea-pigs, even in doses of several cubic centimetres, it does not give rise to any choleraform manifestation, though in large doses it may cause sloughing.

It is stated in a French journal that M. Pasteur, having produced a safe attenuated rabic virus, will organise a system for the protection of animals on his return to Paris. It is asserted that one child who had been severely bitten was inoculated in the summer, and is as yet in good health; but it is to be hoped that by the application of M. Pasteur's inoculations to animals, the necessity of employing it in the human subject may soon cease to exist. It is, at any rate, high time that something was done for the prevention of rabies, which is said to have been much more common in London this year than last. One veterinary surgeon states that he has seen as many as 48 cases in dogs and cats this year, or three times as many as he saw in 1884; while at the Dogs' Home there had already been 35 cases received this year up to the end of last month, as compared with 13 in 1883, and 15 in 1884. During the week, a death attributed to hydrophobia occurred in Guy's Hospital, but the house-surgeon who gave evidence at the inquest said that the apprehensions of the patient had a great share in causing his death. A correspondent, writing to us with regard to this case, asks: "Was it true hydrophobia or tetanus, a possibly shock or blood-poisoning, in a nervous, broken-down constitution? No evidence was given of the dog having been rabid. The case is surely worth sifting with a view to allaying, if possible, some of the unreasonable apprehension which often follows bites from dogs."

By invitation of Dr. Norman Kerr and the Council of the Society for the Study and Cure of Inebriety, over one hundred guests visited the Dalrymple Home for Inebriates on Saturday last. The occasion was to welcome Dr. Joseph Parrish, President of the American Association for the Cure of Inebriates, who had been staying and studying the system of the Dalrymple establishment. A meeting was held in the lecture hall, under the presidency of Dr. Norman Kerr, who accorded a cordial welcome to Dr. Parrish. Addresses were delivered by several medical men and others, and Dr. Parrish, in appropriate terms, acknowledged a resolution which had been passed in his honour. It was stated that while all patients derive benefit from three months' compulsory abstinence from alcohol, more than one-fourth are permanently reclaimed. It was urged that inebriety should be regarded and treated as a physical disease requiring hospital

supervision; that the compulsory requirement of appearing before two magistrates in order to gain admission to a home should be abolished, and that not less than six months should be the period of detention.

THE lecturers at St. Thomas's Hospital have been unusually reticent as to the improvements which have been in progress at their Medical School, but as they are now complete and ready to receive the new students it is perhaps allowable to say that during the recess a sum of 2,000*l.* has been spent on enlarging the anatomical theatre and dissecting-room, and in providing underground space for the storage and injection of bodies for dissection. Both the theatre and dissecting-room have been greatly added to by throwing into them the small rooms formerly occupied by the lecturers, and in the theatre the seats of the auditorium have been so arranged that the lecturer is able to keep an eye upon all his students, a by no means unimportant consideration. The ground beneath the dissecting-room has been excavated, and a vaulted chamber built for the tanks containing the subjects for dissection. Two lifts have been provided, the one for lowering the bodies from the mortuary and the other bringing them up, when needed, to the dissecting-room; so that the outside public of undertaker's men, &c., are not allowed to come within sight of the dissecting-tables, an arrangement which might be imitated with advantage at other medical schools.

THE health of London continues to be eminently satisfactory, as is evidenced by the low curve both of the general and the zymotic death-rate. In respect of the latter group it is not often that the expectations begotten of experience are so far falsified as they were

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eight weeks.

last week. For instance, there were 40 deaths instead of 114 from diarrhoea, 20 instead of 47 from scarlet fever, 25 instead of 34 from whooping-cough, and 9 instead of 22 from enteric fever; and, on the other hand, there were 25 instead of 14 from diphtheria. For the first time for very many weeks past the deaths from measles were below the average, only 14 having occurred, whilst there was a slight rise in the deaths from small-pox, which numbered 8, but the total number of cases under treatment at the end of the week showed a decided fall. The milder weather which prevailed would seem to have been unsuitable for those affected with diseases of the circulatory system, as a considerable increase in the number of deaths under this head was recorded. Of the chief towns in England, Preston alone presents an unsatisfactory bill of mortality, the general death-rate having been 28.6, and the zymotic death-rate 8.3; this was entirely due to the large number of fatal cases of diarrhoea.

IN Dr. Guy, of whose life and work we published a brief account in our last issue, the profession has lost one of those minds of which it stands unmistakably in need. Patient and painstaking in the collection of evidence, rigorous and unsparing in testing it, inflexible in his determination to allow his deductions from it no more weight than they could justly bear, admirably precise and clear in statement, and utterly unable at any time to sacrifice truth to rhetoric, Dr. Guy was an ideal professor of the science, or rather the medley of sciences, known as Forensic Medicine, in which he was for so long one of the leading authorities. His lectures at King's College and his handbook on Forensic Medicine constituted a remarkable example of the "dry light of science" applied to a subject whose legal relationships would seem rather antagonistic to that form of illumination. To the student his remarkable exposition of the tests of respiration in cases of infanticide may have seemed rather a useless expenditure of words, especially when one came away from the lecture-room with the fixed notion that all the tests were equally fallacious and therefore useless; but as an example of scientific criticism, that exposition was admirable, and worthy in these days of a little more frequent imitation than it gets. Of Dr. Guy's labours as a statistician and philanthropist we spoke last week.

THE following are the arrangements of our scientific societies for the commencement of the coming session, so far as we have been able to learn them. The Royal Medical and Chirurgical Society will meet on October 27th; the Pathological Society on Oct. 20th; the Clinical Society on October 9th; the Obstetrical Society on October 7th; the Ophthalmological Society on October 15th; the Medical Society on October 19th; the Society of Medical Officers of Health on Oct. 16th; and the Epidemiological Society on November 11th.

WE have been asked again to call attention to the fact that, following the example of certain of the older Schools of Medicine, St. Mary's Hospital has recently

established a Residential Collegiate Establishment. For this purpose a corner block of houses has been secured in Westbourne Terrace, Hyde Park, and Dr. Maguire has been appointed Warden.

OUR Liverpool Correspondent writes:—An effort is again being made to establish Provident Dispensaries here. Some years ago a similar attempt failed because the promoters could not induce the executive of the free dispensaries to co-operate with them, and without this it was felt that the evils resulting from too liberal a system of gratuitous medical advice would not be remedied, and that were another institution established it would, by treating the more respectable of the working classes at a merely nominal fee, still further encroach upon the sphere of private practice amongst the humbler ranks of society. Most medical men in Liverpool, as indeed in all large towns in England, admit that there is an abuse of medical charity; but here, as elsewhere, the difficulty lies in obtaining the co-operation of the existing charities in amending that abuse. If this could be done, then a scheme could be easily contrived by which the public as well as the profession would be benefited. The paupers have ample provision made for them. The majority of those above the pauper class could pay a provident dispensary fee, and where it was found that respectable poor people were unable to pay such a fee, it could well be paid out of the munificence of the rich. Young medical men would then have an honourable field wherein to exercise their talents whilst waiting for practice, and by the remuneration thereby obtained would not be so sorely tempted to resort to unprofessional methods of making a livelihood, as they are sometimes when starvation stares them in the face. Besides, by their zeal and success in attending on the poor they would have the most legitimate opportunities of creeping into the confidence of the rich. By affiliation with the hospitals, the provident dispensaries would enable the former to obtain the most suitable patients and the sick to obtain more prompt hospital treatment. Previous and after histories of patients could then be readily made up, and medical science might reap a rich harvest.

AT present, nearly all the Liverpool hospitals are in financial difficulties, and in consequence, might be induced to favour such a comprehensive scheme as would relieve their overcrowded wards, and make the cases admitted more select and suitable, both medically and socially. If influential men can be persuaded by Dr. Renton to combine and bring about such a reform as that alluded to above, then the Provident Medical Association advocated by him will be worthy of every success. If, however, he only succeeds in establishing another medical charity, the patients at which pay only a little more than the pennies paid at the already established institutions, then he has only diminished the already too narrow area from which private medical men derive their income, without any great benefit thereby resulting either to the profession or to the public. We await with interest the issue of the movement.

AT a public meeting held at Birmingham on the 3rd July, it was resolved:—"That it is desirable to commemorate the services rendered to Birmingham, and especially to its charitable and educational institutions, by the late Dr. T. P. Heslop, F.R.C.P.," and a subscription list was opened. It was also resolved that the subscriptions to the amount of 1,000*l.* should be applied to the formation of a Scholarship at the Mason College, tenable by pupils from the schools on the foundation of King Edward VI., and that any surplus beyond 1,000*l.* should be appropriated to the purposes of the Mason College Library. Subscriptions have already been received to the amount of nearly 800*l.*, and it is greatly to be hoped that some sum above 1,000*l.* may be collected, in order that so indispensable a department of the College as its library may participate in the fund. To the profession generally it will be a source of much gratification that one so widely respected as Dr. Heslop should be so gratefully remembered.

IN Dublin the air is once more thick with rumours of coming honours to the profession. It is said that a medical baronetcy and a surgical baronetcy are forthwith to be conferred. Names are freely mentioned in connection with the presumed honours. Dr. Banks, Physician to the Queen in Ireland, and Regius Professor of Physic in the University of Dublin, is universally spoken of as the medical baronet; while as to the surgical hereditary title the medical world is divided in opinion as to the respective claims of Sir George H. Porter, Surgeon to the Queen in Ireland, and of Mr. William Colles, Surgeon to the Queen and Regius Professor of Surgery in the University of Dublin. Rumour is also busy with the names of distinguished physicians, who may be said to be "in the running" for the honour of the physiciancy to the Queen in Ireland, vacant through the lamented death of Dr. Benjamin G. McDowel. The names of Dr. Samuel Gordon, Dr. William Moore, Dr. Henry H. Head, all Ex-Presidents of the King and Queen's College of Physicians, and Dr. James Little are mentioned in connection with this much-prized distinction.

IT would no doubt have been expecting too much to suppose that the managers of the Royal Aberdeen Infirmary would go so far as to censure their house committee in reference to the recent disclosures as to internal arrangements, &c., even by implication, and we are not surprised therefore that the report of the last named body should have been accepted, not however by any means unanimously. By one or other of the speakers in defence of the existing state of affairs, all the defects which have been complained of by Dr. Fraser were admitted to exist, and if the spokesmen of the house committee are to be literally believed they are and always have been far more zealous in the cause of reform than the medical staff. Mr. Esslemont, the Chairman of the committee in question, informed his hearers that although there were undoubtedly deficiencies, still great things had already been done, a statement which it is not easy to reconcile with the description of affairs as given by Sir Charles Cameron or Mr. Dunnnett

Spanton, who have within the last few days independently visited the Infirmary. They agree in condemning the utter want of proper ventilation in the wards, and the entire absence of proper baths for the patients, and the drainage and water-closet arrangements would appear to be models of what they ought not to be. On the proposition of Dr. Struthers, a committee was appointed with power to call in the aid of an expert to consider the whole question of the management of the Infirmary, and thus virtually one of the chief things for which Dr. Fraser has been contending has been granted.

THE body which calls itself the Organising Committee of the International Medical Congress of 1887, has, we are sorry to see, refused to adopt the conciliatory policy which alone can make the Washington Congress a success. It met at New York on the 3rd instant, and though all reporters were sedulously excluded, enough has leaked out to assure us that the letters of the President and Secretary of the London Congress, and the articles of the large majority of medical journals, might just as well have not been written. The *Medical News* gives the following brief account of the business done at the meeting:—"The rule of membership was amended so as to give representation to the general societies representing special departments of medicine. The Executive Committee appointed at Chicago was abolished and a new committee appointed, consisting of the President, the Secretary-General, the Treasurer, and the Chairmen of the Sections. The Committee then proceeded to fill the large number of vacancies occasioned by the declinations to co-operate with them. Dr. Henry I. Bowditch, of Boston, was elected a Vice-President of the Congress; Dr. N. S. Davis, of Chicago, was elected Secretary-General; Dr. William H. Pancoast, of Philadelphia, was elected President of the Section of Anatomy; Dr. E. O. Shakespeare, of Philadelphia, President of the Section of Pathology; and Dr. A. B. Arnold, of Baltimore, President of the Section of Medicine. The Executive Committee was given power to fill all vacancies. Dr. Austin Flint, Jun., was instructed to prepare the report of the Committee to be presented to the American Medical Association, and the Committee adjourned to meet in St. Louis on the Monday evening preceding the next meeting of the American Medical Association." No attempt, it will be seen, was made to heal the differences that have been aroused in the profession by the revival of the Code question, and the American Medical Association still clings to its usurped position.

THE more one considers the question, the more fatal do the objections appear to the principle of allowing a pre-existing medical association to play the sole part in organising an International Congress. No medical organisation whose aims are not purely and exclusively scientific can ever be truly representative of medical science. The men who are the real workers in the field of medical research, and who are therefore the only proper representatives of the profession in a scientific meeting like the International Congress, are

hardly ever found playing a leading part in associations of a medico-political nature. Quite properly they leave such functions to those of their brethren who have business proclivities and time upon their hands. The latter class may be admirably fitted for the work of conducting a large medical association, but they are not qualified to greet on even terms the medical investigators of the world, and we doubt even if they are competent to decide who are best qualified to give that greeting. Thus there is always the risk, exemplified in the United States just now, of their dragging the political and ethical questions that are nearest to their hearts into competition with purely scientific questions. The only safe way of organising a successful International Congress in any country is to leave it in the hands of the leading scientific men, who are known and acceptable not only to the hosts of the Congress but also to its guests. We hope that on some future occasion this principle, which has until now invariably been acted upon, will be formally converted into a standing rule.

THE *London Gazette* announces that the Queen has appointed Douglas Argyll Robertson, M.D., Fellow of the Royal College of Surgeons, Edinburgh, to be Surgeon-Oculist in Ordinary to Her Majesty for Scotland, in the room of William Walker, Esq., deceased.

A GENTLEMAN well known to the scientific world, M. Bertrand, Director of the Professional School of Versailles, was burnt to death in a vapour bath a few weeks ago. The accident seems to have been due to the addition of some essence of turpentine, the vapours of which caught fire from the flame of a spirit-lamp employed in the apparatus.

THE Préfêt de la Seine has officially decided that lady students shall be entitled to enter the lists in the approaching competition for the places of internes, or house-surgeons, to the Paris hospitals. As this degree is the stepping-stone to all further promotion in the medical profession, the change is a more radical one than might at first sight be anticipated. Shall we have lady surgeons and physicians to the Paris hospitals, and also lady professors? That is now the question.

IN the last series of Medical Reports published by the China Customs Board, Dr. W. W. Myers, of Takow, Formosa, gives an interesting account of his endeavours to teach Western medicine to native pupils. Recognizing the difficulty of teaching Chinese students in European Medical Schools, he has done his best to start a small medical school in connection with The David Manson Memorial Hospital, which has 24 beds and to which he is surgeon. It being impossible to get bodies for dissection, he is compelled to teach anatomy from models, the liberality of friends at home having provided him with one of the best French specimens. At first Dr. Myers tried to get native youths and teach them English, but the experiment was unsuccessful, and he now draws students already proficient in English from the Hong-Kong Central School. His

first two pupils arrived at Takow in November, 1883, for a two years' medical course, during which they were to be lodged and boarded free by the hospital. The first year was devoted to the primary medical subjects, in which the students were to undergo a searching examination before an international medical board at Hong-Kong or Shanghai, before they could begin their advanced subjects. At the end of the second year they were to undergo a final examination, on passing which they would receive a certificate containing all particulars necessary to ensure the identification of the individual holder of it. Subsequent experience has necessitated some modifications in this scheme, as it has been found impossible to teach the primary subjects in less than two years, and the full term will probably be fixed at four years. Dr. Myers certainly manages to get a great deal of work out of his pupils. They come to his house at 7 a.m. every morning and work till 7 p.m. with but one hour's interval for dinner. Out of this time Dr. Myers devotes an hour to each of four subjects, giving tutorial instruction rather than lectures. The papers set these pupils at the quarterly examinations are given in the report, together with the opinion of an independent authority to whom the answers were submitted. This opinion is extremely favourable. Dr. Myers makes a point of rigidly separating the primary from the advanced subjects, and of not allowing his pupils to study the practical applications of the former until they have passed their intermediate examination. We should be inclined, however, to think that he, if anyone, could adopt with advantage the plan recently advocated in our columns by Professor Gairdner, of teaching the applications of the primary subjects synchronously with their principles. Dr. Myers writes on his "feeble and initiatory efforts" with great enthusiasm, and we cordially re-echo his hope that they may be found worthy of emulation and expansion. "Some such plan," he writes, "may be the thin end of a wedge, which, if driven home, may serve in its proper sphere to assist in dispelling that mental and physical exclusiveness which has hitherto acted as a barrier between Chinese and Western intercourse. There can be no doubt that if persons were thus educated in matters the practical benefit of which is immediately palpable, a powerful class of intermediaries would be established, whose influence in bringing their countrymen to closer acquaintanceship with the advantages which foreigners and foreign ways are able to confer would possibly be very effective. They would prove powerful levers in bringing about that intimate relation with the natives which has so long been desired by those who aim at securing the mutual benefits of unrestricted intercourse."

DR. SEATON, the Medical Officer of Health for Chelsea, has just published his first annual report. After making the necessary corrections for the deaths occurring in the parish of persons not belonging to it, and for the deaths of parishioners which have taken place in other parts of the metropolis, the death-rate is 20.8 per 1,000. Of the zymotic diseases measles proved very fatal, 112 deaths being attributed to this cause, whilst there were only 7 from scarlet fever. Whooping-

cough caused 37 deaths and diphtheria 31, an unduly high mortality. From enteric fever there were 21 deaths, and 20 from small-pox. As regards nuisances injurious to health, two are especially pointed out as calling for the serious attention of the vestry, viz., overflowing dust-bins and closets without water supply, and a systematic house-to-house inspection is about to be undertaken in order that this latter deficiency may be in all cases recognised and dealt with promptly. Other nuisances, which are being gradually discovered and removed, relate to defective drainage, untrapped sinkstones and other drains, and dilapidation of houses. In the matter of registered lodging houses Chelsea is in advance of all the other Metropolitan districts, Hackney alone excepted, in great measure owing to the exertions of the late Medical Officer of Health, Dr. Barclay, and this fact was fully recognised by the Royal Commission in its report on the Housing of the Poor. The old method of indiscriminately distributing disinfectants is to give place to a rigorous disinfection carried out under the personal supervision of the sanitary inspectors. Dr. Seaton concludes his report with an able plea in favour of unity in the government of this great city. If we are to avoid what he calls the present aimless method of procedure in dealing with contagious disease, we must have one central authority in place of the thirty-nine nominal sanitary authorities now existing, bearing in mind that the *prevention* of infectious diseases is of more vital importance than their treatment. So long as the hospital and sanitary authorities are separate bodies, compulsory notification, of which we hear so much from time to time, and which has answered so well in some of the large provincial towns, cannot be introduced here with the full benefits that it has entailed elsewhere.

SOME very successful trials have been recently made by a Russian physician with cocaine in sea-sickness. He finds it acts both as a prophylactic and as a cure. The solution he used was composed of muriate of cocaine dissolved in a little spirit, to which water was added so that the solution contained a thousandth of its weight of the cocaine salt. Of this drachm doses were given every three hours from the beginning of the voyage as a prophylactic, and every half hour until improvement was produced in cases where the sickness had already commenced.

WE have received a circular from the National Society to secure Effective Legislation against River Pollution (Hon. Sec., H. A. Kinloch, 6, The Sanctuary, Westminster, S.W.), in which, after giving a short recital of past efforts, and insisting on the failure of the existing Act, more optional and permissive even than such Acts too generally are, to prevent or indeed to check the progress of the nuisance complained of, they state that that Act having proved a dead letter, and their Bill of last year having failed to pass the second reading, they have drafted another and, as they trust, an improved Bill, which will be introduced next session. We wish them all success, but we must express our regret that they should have adopted

the standards of purity of the Rivers Pollution Commissioners, *i.e.*, of Dr. Frankland. Not only do they depend so far as regards organic pollution on the particular procedure employed by that chemist, though disapproved by others of equal authority, but as we maintained when discussing this question on a former occasion, the application of tests or standards of purity to the effluent or wastes is worse than futile. Fix what standard one may, the manufacturer can dilute his waste down to it by pumping water from the river in question and thus defeat the purpose of the law! The pollution of the river is the same whether the waste be discharged as it is, or mixed with water drawn from the same stream. The only satisfactory, the only rational plan would be to compare the pollution or purity of the stream at a point some distance, say, 100 yards, below that at which the waste is discharged, with that of the water of the river at another point some little distance above the same, and to fix *proportional* limits which must not be exceeded. These limits would have to be determined by the result of numerous observations and experiments, but being *proportional*, not *absolute*, would be equally applicable to streams of all sizes and of every degree of original purity.

THE Clinical Society of the New York Post-Graduate Medical School and Hospital founded in 1882, has determined upon the publication of a quarterly bulletin, to contain a report of the discussions which have been held at its meetings, as well as original communications addressed to the Society which have not appeared in print elsewhere. The first number is now before us, and contains several papers possessing much interest and a high degree of merit. The first paper, on phthisis and pneumonia in relation to syphilis, is by Dr. W. U. Porter, and consists of a brief study and analysis of 100 cases in which these diseases co-existed. The diagnosis of syphilitic phthisis also forms the subject of a paper by Dr. Louis Heitzmann, and in each instance the author is satisfied that the disease is neither rare nor difficult of diagnosis. Dr. August F. Buechler writes on the bacilli of syphilis, which he has recognised in the so-called syphilitic products both of the hereditary and acquired disease. Amongst the other papers, we notice one on the physiological and therapeutical effects of the coca leaf and its alkaloids. The chief discussions reported in this number relate to erysipelas, diphtheria, and intracranial hæmorrhage in children, opened by Dr. S. J. McNutt, in a paper which is given in full. It was tacitly assumed by all the speakers that infantile hemiplegia was the consequence of intracranial hæmorrhage, but there was very little proof brought forward in support of this doctrine.

DIPHTHERIA having been very prevalent in the parish of Kempston, in the Bedford Rural Sanitary District, an enquiry was instituted by the Local Government Board, and the result is now before us in the report of Mr. R. D. R. Sweeting. During 1884, it appears probable that there were 61 cases of diphtheria, 18 of

which proved fatal. The last quarter of the year produced the greatest number of cases and the highest death-rate. The deaths were all of children under ten years of age. Some fatal cases had also occurred in 1883. It seemed most likely that the disease was introduced from Bedford where it had undoubtedly been present for some time. The influence of school attendance in propagating the disease appeared to have been very marked: out of the whole number attacked, 49 were children of the school age. The children of school age who were attacked had usually attended school up to the date of their attack, and the children not attending school were mostly attacked during periods of school closure; escapes in families invaded were usually either in persons not of school age, or if school attendants, they had ceased attending immediately the first case appeared in their family. Of the three schools, in one only two cases occurred; these were in the same family, and were probably the result of direct communication with an infected family in Bedford. At the other schools, mixed and infant, there were 18 and 29 cases respectively, and at both these schools the ventilation was deficient and there had been decided overcrowding during 1884. The prevalence of the disease during the last quarter of the year was due to the fact that after the harvest holidays several imperfectly recovered cases returned to the school. As regards the general sanitary circumstances of the parish, Mr. Sweeting found that in many streets the basements of the houses were damp from the sub-soil water rising into them. Drinking-water is mostly obtained from wells, and these were too few in number and too near privies to be free from risk of pollution. No provision of any kind exists for drainage, though it is urgently needed. The refuse is disposed of in cesspools which are seldom cleared out; and their contents in many cases leak out or overflow, and so are a source of danger. The recommendations at the foot of the report contain suggestions for meeting and amending these various defects.

WE would remind our readers that the Harveian Oration will be delivered before the Royal College of Physicians, by Dr. Quain, on October 18th. The oration has, until this year, been delivered in June.

#### A NEW INDUSTRY FOR LONDON.

A WEEK or two ago we were surprised to read an article in the *Times* lamenting the decadence of Vienna. We had not the felicity of visiting the Austrian capital when it was a walled city, before the splendid boulevard that now surrounds it like a girdle had let in air and light upon its narrow winding streets. But we should not have said that within the last fifteen years or so it had fallen off any more in popularity than Paris. Some people are apt to see a falling off everywhere except in their own powers of criticism; but there is no doubt that both Paris and

Vienna are suffering from the competition of a certain rival which every day grows more beautiful and more popular with foreigners, our own dear London. In spite of its fogs, from which no month is now secure, in spite of its sewage-laden river, its indifferent water-supply, its rookeries that lie cheek-by-jowl with its palaces, its open dust-carts, and the thousand and one sanitary defects that testify to its want of an intelligent and able government, London is by far the healthiest of great capitals, and that is a point which in these days of sanitary sensitiveness counts for a good deal in determining the choice of holiday visitors. Of its other attractions it is out of our province to boast, though we may share the satisfaction, not perhaps unmixed with sorrow, of all true Londoners that their city is fast becoming the metropolis of the world. But there is one point, as the writer of a most sensible letter in the *Times* points out, in which London cannot hold a candle even to decadent Vienna, viz., as a centre of higher clinical education. Of the excellence of Vienna in this respect it is unnecessary to speak. One by one Vienna has lost the great teachers who restored its fame as a medical school, but even in its palmiest days the teaching of Medicine was not carried on more actively than it is now. It is true that the great influx of ill-educated American physicians, fresh from their two years' curriculum, has of late years tended to lower the character of the clinical instruction given at Vienna. It is true that some of the teachers there have been corrupted by the almighty dollar until their work has lost its inherent nobleness and degenerated into a trade. It is true that in consequence of all this the well-educated English physician finds fewer facilities for following out his higher studies at Vienna than he did some ten or fifteen years ago, and often ends by leaving it for Berlin, or Leipzig, or some of the smaller German universities. Yet when all is said the fact remains, as stated in the *Times*, that Vienna still holds a supreme place in Medicine as the metropolis of clinical in contradistinction to scientific medicine. Its teachers, though fond of class-fees, are still active in independent research, as the letters sent us from time to time by our Vienna correspondent amply testify. We need hardly remind our readers that the most important therapeutic gain since the discovery of chloroform, viz., the anæsthetic use of cocaine, was achieved in a Vienna laboratory.

Vienna, then, if falling off as a caterer for the world's pleasure, is still active, more active than ever, as a manufacturer of sound medical practitioners. But why, as the writer to the *Times* most pertinently asks, cannot London rival her as well in this? Why should not London with its enormous population, its numbers of gigantic hospitals and its renowned teachers, take its rightful place as the centre of the highest clinical education? The writer might have gone further and asked, why cannot London keep even its own medical students? We have often before discussed this question, because we regard it as one of the most important of those with which we have to deal. A well-organized clinical school in London would imply a higher standard of culture and a closer brotherhood amongst the mass of the profession in

England, which, in their turn, as everyone admits, would facilitate the solution of all questions which depend on medical opinion and medical action. And if London could succeed in attracting to it the foreign students who now complete their studies at Paris, Vienna, or Berlin, we should have the satisfaction of knowing that the teaching of what after all is the soundest and sanest school of medical doctrine—the school of fewest extravagances—was exerting its due influence on the medical practice of the world.

The difficulties, however, in the way of the realisation of this dream seem almost insuperable. In the first place, as in the case of every reform in England, vested interests stop the way. The men who have been at pains and expense to build new medical schools and special hospitals, would declare to a man against any scheme which threatened their extinction. The present system of medical education in London is one that favours incompetent teachers, whose motto might well be "divide et impera." The introduction of the Vienna system would at once relegate to deserved obscurity every teacher who could not face competition in the open market. Then the hospitals are too numerous and too scattered to be combined for any effective system of clinical teaching, and the control of the medical officers over them is too limited for a perfect utilization of their clinical material. We doubt, too, whether the English patient would submit to the free and frequent manipulations which the inmate of the State-supported hospital of Vienna has to bear without a murmur. Lastly, it is very questionable whether there are a sufficient number of first-rate clinical teachers in London to meet the needs of a large school like that of Vienna. Clinical teachers are born and not made, and though there is no saying what would be the result of increased demand and higher remuneration, we are inclined to think that the English mind, admirably fitted as it is for the practice of medicine, has but rarely the requisite qualities for bedside teaching. At all the London hospitals combined there are probably not a dozen clinical teachers who are up to the standard which would be demanded in a cosmopolitan school.

So that, after all, we very much fear that this suggested new industry for London must be left to the cities where it already flourishes. But if the idea of competing with Vienna for the fees of foreign students must be given up, there is no reason why our clinical teaching should not be improved. If we cannot attract students from abroad, there is no reason why we should repel our own students and practitioners. At present London would be almost the last place to which any English doctor would think of going, who wished to perfect himself in the practice of his profession. Dublin, Edinburgh, and many of the provincial medical schools would suit his purpose much better. Here is a want which ought to be made good. We would gladly see the staff of one of our London hospitals giving up the vain attempt to teach a handful of students the whole range of the medical sciences, and devoting themselves to the clinical instruction of advanced students and practitioners. It is impossible to carry on the ordinary student's instruction at the same time with what the Americans term "post-graduate"

courses, and we are sure that if the teachers at one of our hospitals would lay themselves out for teaching practitioners only, giving them real sound clinical instruction in every branch of medical practice, they would soon have no cause to regret their decision, and their scheme might in the end become the germ of that great clinical school which we should all like, but which few of us dare hope, to see.

#### THE GERMAN VACCINATION COMMISSION.

PRIOR to the epidemic of small-pox which in the years 1871-3 raged throughout the whole of Europe, with a severity unexampled since 1838, the vaccination laws in the different German States presented every degree of laxity. In Frankfort, Nassau, and a few of the minor States, they were very stringent, and as a consequence in the first-named city a death from small-pox was extremely rare and, indeed, for many years such an event has been unknown. The German armies, too, were the best vaccinated in Europe, and the results were well seen during the Franco-German war. But in Prussia, Hamburg, and elsewhere, vaccination was very irregularly performed, and everywhere it was delayed to too late an age. In few States was it compulsory before the end of the first year, in Bavaria not until two years, and in Hamburg it was rarely practised until school age, when the Education Act required a certificate previous to the admission of a child. The consequences of this laxity were apparent in the high mortality from small-pox in early life, and in 1872 the epidemic almost decimated the populations of Berlin, Hamburg, and other large towns. In that year a new Vaccination Act was passed by the Imperial Parliament with the best results. In Hamburg, the deaths from small-pox have never since exceeded five or six in a year, and these have occurred in infants or in immigrants. In Berlin they have averaged six or eight, except in one year when they amounted to fifty among a population of a million and a quarter. More recently, re-vaccination of all children before the expiration of their attendance at school has been required, and the few deaths from small-pox which appear from time to time in the returns are confined to infants or to persons born under the former *régime*; while in Vienna the deaths are in some years as many as eight or nine hundred, and in Prague the mortality is, relatively to the population, even higher. It is a remarkable fact that since 1872, not a single death from small pox has occurred in the entire German army.

When the Act of 1872 was passed, amid the alarm caused by the recent epidemic, whatever prejudice against vaccination may have existed in the minds of the lower classes, neither the medical profession nor educated persons generally apprehended any danger of the communication of syphilis or the risks of erysipelas, &c., or deemed them other than insignificant. As, however, is always the case when the demand for lymph is great, a want of care in its selection seems to have prevailed, and from time to time the most lamentable accidents followed. Dr. Lotz has col-

lected no fewer than fifty separate cases affecting in all seven hundred and fifty individuals, and as solitary instances of syphilisation are less easy of proof, the real number is probably much greater. These occurrences have raised a strong public feeling, not so much against vaccination in itself, as in favour of the general substitution of animal for human lymph, in which even disbelievers in vaccination like Drs. Lotz and Böing have joined. Three successive Committees of the Imperial Parliament appointed to enquire into the increase of syphilitic disease, especially infantile, have reported in its favour, and their recommendations were confirmed by a resolution of the full House in June, 1882.

Last summer accordingly the Chancellor of the Empire appointed a Commission, which consisted exclusively of medical men, including some of the most eminent members of the profession, representing the Imperial Board of Health, the Statistical Bureau, the Medical Department of the Army, and the Provincial Sanitary and Vaccination Authorities. Three of the leading anti-vaccinators, among whom was the notorious Dr. Böing, were placed on the Commission, not with the view of making any concession to their party, but as a guarantee that no evidence unfavourable to the existing practice should be suppressed or withheld. Whether they have been converted by the overwhelming proof of the benefits of vaccination remains to be seen, but they were among the most earnest advocates of the universal employment of calf lymph. The Commissioners have issued a report with elaborate tables showing the death-rate from small-pox in the principal cities and armies of Europe, and demonstrating in a most conclusive manner the beneficial effects of recent legislation in Germany. Several of these tables were reproduced in the *British Medical Journal* three weeks ago. Some of the facts adduced in reference to the dangers of infection were of the highest interest. The Commissioners considered the transmission of tubercle as unproven, but within the limits of possibility, especially when one takes into account the large proportion of children of the poor in towns who suffer from one or other form of tubercular or scrofulous disease. The communicability of bovine diseases they rejected as imaginary. In fact, they confined their attention to syphilis, primary and secondary (*spät*) erysipelas, and septic (*wund*) infection generally.

As regards syphilis, one case brought to their notice is most instructive. It is commonly believed that if a child has been so far cured as to present no external evidence of disease, and the vesicles run a perfectly normal course, no harm can result from employing it as a vaccinifer. But at Lebus in 1876, fifteen female scholars were syphilised by vaccination from a child whose skin was perfectly clear, and in whom the vesicles on the eighth day presented a normal appearance, the only trace of the disease being the scar of a boil which might have been of an innocent nature. A subsequent examination of the person of the mother revealed no signs of syphilis, but it transpired that she had had a miscarriage, a still-born infant, and a child that had died after a few weeks of "pemphigus," the vaccinifer being the fourth and only living infant. These facts had been concealed from the vaccinator,

but when mother and child are to all appearances healthy, such concealment is only too easy. Probably the English practice of vaccinating within three months provides a considerable safeguard, since it is very unlikely that all evidences of syphilis should have disappeared so soon, and in cases where older children are presented for vaccination, the certificate of postponement required by our law, even if it substitute a euphemism for the proper designation of the cause, is calculated to arouse the suspicions of a cautious practitioner. Where, however, the local authorities are remiss in looking up defaulters, such cases are not unlikely to occur. The distinction between the two forms of erysipelas drawn by the Commissioners is one on which Dr. E. Ballard has long insisted; erysipelas may be (1) the direct consequence of the use of unhealthy or decomposing lymph and run a course concurrent with the vaccination, or (2) may follow infection from other and extraneous sources, the vaccination merely offering like any other wound or breach of surface a means of access for the poison. For the latter the vaccinator is in no way responsible, and it cannot reasonably be urged as an objection to the operation.

The Commissioners sum up the advantages of employing human lymph as consisting in the simplicity and almost constant success of the operation, as well as the costlessness of the supply, while the objections are as stated, the dangers of syphilitic and other poisoning. In favour of calf lymph are the absolute security it affords against syphilis, and the greater security against primary erysipelas, &c., if the operation on the calf be performed with antiseptic precautions. The objections, on the other hand, are the somewhat larger percentage of failures, the difficulty attending the preservation of the lymph, which does not retain its vitality nearly so long as humanised vaccine, the elaborate arrangements required, and the expense involved in keeping up a constant succession of calves. All these, however, would, they believe, be reduced to a minimum by the establishment of vaccine stations, under the management of experienced medical directors, while each calf may be made to furnish lymph sufficient for from eight hundred to one thousand vaccinations, and the public vaccinator and private practitioner would alike be spared the disagreeable and unsatisfactory task of enquiring into the antecedents of their vaccinifers. While recommending the gradual extension of such institutions with a view to the ultimate disuse of human lymph, the Commission did not feel justified in advising the immediate prohibition of the latter, for as one member remarked, he could not wish a more perfect ideal of a source for lymph than an absolutely healthy child of healthy parents, whose family history was well known to him. They have also issued a series of model by-laws or instructions to local authorities and public and private vaccinators, dealing with every detail of the arrangements of vaccination stations, the prevalence of infectious diseases, the supply and preservation of animal and human lymph, the performance of the operation, &c., as well as schedules for the notification of cases of small-pox in a district whether

fatal or not. With a few of the recommendations, as, for example, that an infant vaccinifer should not be under six months old, we cannot entirely agree, but taken as a whole, the report is one of the most valuable and important documents on the subject that has yet appeared.

## REVIEWS AND NOTICES OF BOOKS.

---

### A SYSTEM OF THERAPEUTICS.<sup>1</sup>

THIS system of therapeutics, of which the first three volumes have now appeared in an English dress, is, we are told, the first work of the kind published in any language; and we may add that it is only to the writers of one language that the idea of publishing it would ever have occurred. The undertaking is, indeed, German to the backbone, and may best be described by a word very popular in Germany, "colossal." The monographs which make up these volumes are certainly not "chips from a German work-shop"; they are figures of heroic size, left in the rough with the marks of the workman's chisel upon them; often left, too, in such a shape that one cannot always carry away a very favourable idea of their authors' sense of proportion. The essays are admirable in their scope and completeness; they bear witness to a patience and industry of research and thought which we can only admire and envy. They exhaust the subject—and now and then the reader. They will be seized upon with avidity, as so many German books have been before now, by the medical book-writers of all countries, to furnish them with data and ideas. We shall come upon them again, worked up into small volumes with catch titles, appealing for popular favour for themselves and authors. Containing, as they do, a review of the most recent work in their respective departments, constituting a register of all that has been suggested or discovered or done therein, they will henceforward be indispensable as books of reference to the lecturer on therapeutics, while they will be scarcely less valued by the well-educated and scientific physician, for whom they were essentially written. They are intended "not merely to inform, but to suggest reflection and to prompt original work"; they will, therefore, be welcome to many a young enquirer, ambitious of discovery, or of such fame as consists in seeing his name quoted in *Centralblatts* and *Periscopes*. For the average English reader of medical literature we fear they will prove indigestible. Sad to confess, the English reader, as a rule, has an exiguous stomach for medical literature; bulk non-plusses him; he likes his literary fodder predigested and concentrated. Few of the articles in Ziemssen's system have any pretence to being easy or quick of digestion. Each, complete in itself, has a certain organisation, some a very complicated one; but it is not an organisation that strikes one as being very efficient in function, not a good working organisation. Every fact is there that is either

<sup>1</sup> Von Ziemssen's Handbook of General Therapeutics, in seven volumes. London: Smith, Elder and Co., 1885. Vol. I. (Translated by Dr. E. F. WILLOUGHBY); Introduction by Prof. von ZIEMSEN; on the Dietary of Sick and Dietetic Methods of Treatment, by Prof. J. BAUER; on the Koumiss Cure, by Dr. STANGE. Vol. II. (Translated by Dr. MATTHEW HAY); Antipyretic Methods of Treatment, by Prof. C. von LIEBERMEISTER; Antiphlogistic Methods of Treatment, by Prof. TH. JÜRGENSEN; Epidemic, Endermic and Hypodermic Administration of Medicines, by Prof. A. EULENBERG. Vol. III. (Translated and annotated by Dr. BURNEY YEO); Respiratory Therapeutics, by Prof. M. J. OERTEL.

available, or required, to guide us to a practical issue, but in many cases we have to ferret this issue out, and in some even to deduce it for ourselves. We are Philistines enough to wish in all sincerity that the translators had cut the ground from beneath the feet of future bookmakers, and given us the gist of the monographs in a series of short essays, relegating the evidence and experiments on which the conclusions, if any, are based to the small print of an appendix. By so doing they would have produced a work probably of greater usefulness, and certainly of greater popularity. The handful of teachers and investigators would still have been able to draw upon the work in its original German.

One thing that repeatedly and not unpleasantly strikes us in reading these volumes is the leading part played by English physicians in the past in the suggestion of new modes of treatment, and the small mention made of them in the elaboration of those innovations. In the first volume we read that after centuries of neglect "the high value of dietetics as an aid to therapeutics was brought anew to light by that great practical physician, Sydenham." No allusion is made to Cheyne, but Graves' influence is duly recognised, and even Banting and his medical adviser, W. Harvey, receive considerate mention. In the second volume Currie, of Liverpool, is admitted to be "the real founder of the systematic cold water treatment of fever," while his degenerate successors are blamed for clinging so firmly to their old prejudices and convenient routine. Due credit, however, is awarded them for enforcing the necessity of giving proper nourishment in fever. Under the question of blood-letting Marshall Hall's services are thoroughly admitted, and the great part played by English investigators, from Lowell and Timothy Clarke in the 17th century to Blundell in the 19th, in working out the problem of transfusion of blood is equally recognised. Coming to the next subject we find Alexander Wood, of Edinburgh, admitted to be the real inventor of hypodermic injection, a method of treatment which was thoroughly worked out in England during the four or five years that elapsed before its introduction on the Continent. Again, in the third volume, we find that it was an English physician, Bennet, who, about the middle of the 17th century, first studied respiratory treatment scientifically and introduced it into practice, declaring it to be the best remedy against phthisis. His successor, Willis, elaborated a system of inhalation, and a century and a half later Alexander Crichton was the first to revive Bennet's treatment of consumption, and to recommend the inhalation of the vapours of tar and turpentine. Even the method, now so generally neglected in England, of using compressed or rarefied air for curative purposes, was first introduced by an English physician, Heushaw. In short, it is painful in reading these volumes to contrast the frequent mention of the older British school of medicine with the almost absolute silence as to the activity of their successors. It may no doubt be true that the authors of these monographs seem much more familiar with their own than with modern English literature. It is also true that until recently political conditions were far more favourable to scientific investigation in England than in Germany. But, making every allowance, and even throwing in antiseptic surgery as a grand make-weight on our side, we cannot but recognise that the modern English school of physicians have not the same activity, inventiveness, and resource as their predecessors. Let us hope they make up for it in that ripe judgment which Professor von Ziemssen declares to be important above all things in matters of therapeutics.

The first volume of the System deals exclusively with what its editor terms dietotherapy, and besides

exhausting the general question of diet in disease, also discusses the grape-cure, the milk and whey cure, and the Koumiss cure. Dr. Bauer fills some 300 pages with a minute exposition of the theory and practice of nutrition in health and disease. The several sections of his work are of very unequal degrees of merit, and his style the reverse of attractive. Familiar as we are with the original, we cannot but express our sympathy with the translator in his self-imposed task of rendering into readable English the tedious tautology of Professor Bauer, whose style possesses all the faults commonly though erroneously held to be characteristic of German literature in general. Compared with Bauer's, the highly complex sentences, the ultra-Ciceronian construction of style, averaging three full stops in a page, of some authors, are in a certain sense works of art. The later chapters on special dietetics and dietetic methods of treatment are, to say the least, disappointing, and the wearisome repetitions involved in detailed analyses of numerous hospital dietaries with and without extras might have been spared with advantage. For those who have not access to König's great work, the elaborate tables of the composition of the several articles of food will be useful, but the value of the present volume consists in its exhaustive examination of the problems involved in the physiological action of the several food-stuffs in the organism, the digestion and utilisation of food, and the mutual relations of food and work, or as it has been called, the balance sheets of the intake and output in the animal economy. Very few indeed will read these chapters without learning much that will be new to them, for the views of Liebig, albeit somewhat modified, still hold their ground in this country in the teachings of Playfair, E. Smith, &c. Though the conclusions of the Munich School, of Pettenkofer and his pupils, especially Erwin Voit, may yet be in some minor points corrected by future research, there can be no doubt as to their substantial accuracy. It is now generally admitted that the excretion of urea is not increased by muscular exercise, while the elimination of water and carbonic acid, as well as the intake of oxygen, are enormously augmented; whence it appears clear that no waste of muscle substance is involved, and that, consequently, contrary to the vulgar notion, increased muscular activity demands an increased amount of carbohydrates and fat, not of albumen, *i.e.*, of bread and butter, not of meat. The demand of the organism for nitrogenous food is, in fact, a constant quantity proportioned to the actual development of the muscular frame, and not to the amount of labour performed, any excess above this merely adding to the urea to be excreted. The true value of gelatin, E. Voit's hypothesis of circulating albumen, the origin of fat directly from the albuminates, only indirectly aided by the non-nitrogenous food-stuffs acting as *sparmitteln*, the almost entire absence of digestive and absorptive power in the rectum, the low nutritive value of the vast majority of beef-teas, meat-extracts, &c., the importance of taking into consideration the percentage of any article of food that is really *utilised* in forming an estimate of its *nutritive* value, and many other questions on which English writers on diet are for the most part silent, are here clearly and thoroughly discussed. We wish, however, that some reference had been made to Dr. W. Roberts' work on the Peptones, and Prof. Haughton's Researches in Animal Physics. Dr. Stange's essay on Koumiss and the Koumiss-Cure might well have been condensed to a title of its present dimensions, reiterating as it does the same story of the composition, preparation and therapeutics of Koumiss according to different authorities in almost the same words, *usque ad nauseam*.

The second volume introduces us to some of the most important and fascinating subjects in the whole range of therapeutics, viz., the cold bath in fever, antipyretic medicines, blood-letting, transfusion and the hypodermic administration of drugs. Professor Liebermeister's article on antipyretic methods of treatment is one of the most satisfactory and practical articles in the whole System. His defence of the cold bath treatment of fever is very able. Most English physicians will decline to accept his rule that a heat-abstractor is always necessary when the temperature in the rectum exceeds 103°, but they will welcome the reasonableness of his advocacy, and the way in which he softens down the crude evangel of the cold bath. He only claims for the antipyretic treatment the power of changing the continued fever in severe diseases into a strongly remittent one, and so of preventing the dangers to the organism of a long-continued high temperature. Of late years Dr. Liebermeister has confined his efforts to making the remissions of a fever stronger and longer continued, rather than to combating its exacerbations. For this purpose he recommends that the baths should be principally employed during the night, when the temperature of the patient is usually on the decline, and the lower the temperature falls the colder should the bath be. He prefers the really cold bath to the gradually cooled bath of Ziemssen. Liebermeister regards antipyretic medicines as merely supplemental to the bath, and he protests against the tendency of some physicians to put the somewhat inconvenient cold water treatment in the background and to rely upon the new antipyretics alone. Of these new remedies the translator, Dr. Matthew Hay, gives some concise particulars in an appendix.

Dr. Jürgensen's essay on Blood-letting and Transfusion is very German—that is to say, it might with advantage have been reduced to one-third of its present bulk. He admits that an exhaustive answer cannot be given to the question whether there is really any germ of truth in the tradition of more than 2,000 years in favour of blood-letting; and certainly if Dr. Jürgensen has not succeeded in giving this exhaustive answer in the eighty odd pages he has devoted to the subject, anyone else may well despair of success. His practical conclusion that blood-letting is "seldom, perhaps never, imperative," will not generally commend itself to the English physician; but the following sentence with which the article concludes is sufficiently sound: "Every physician who is accustomed to consider the blood as an organ of the body will ask himself whether in reality the welfare of the whole body requires the sacrifice of a part. He will make such a sacrifice only when it is needed in order to carry out the chief task of the therapist, viz., to assure the continuance of life itself." Dr. Jürgensen's attitude towards transfusion is equally cautious. He maintains that it ought never to be performed unless a reason which is scientifically supportable can be adduced for it. He qualifies the usual dictum, that only a life directly in danger must be preserved by the introduction of new blood, by pointing out that the remote dangers of severe hæmorrhage, e.g., fatty degeneration of the most important organs of the body, may be prevented by a seasonable transfusion. We cannot follow him through his long discussion of the special indications for transfusion in different diseases and accidents, but must content ourselves with saying that, long as it is, it will well repay perusal. Professor Eulenberg's article on endermic, epidermic, and hypodermic administration of medicines is as exhaustive as the preceding essays, but there is nothing very new in it. His summary of the indications for the use of the hypodermic syringe is sensible. It is to be preferred to administration by the mouth (1) where we wish to produce a rapid and energetic general medicinal effect

as in acute poisoning, imminent suffocation, internal hæmorrhages, &c., or in severe disturbances of innervation and in general diseases which come on in paroxysms, as in neuralgia, asthmatic attacks, and intermittent fever; (2) where we wish to combine a specific local effect, as in neuralgia and reflex spasms; (3) where internal medication is contra-indicated. The separate account of the different drugs available for hypodermic use is very complete. The whole of the second volume has been translated and annotated by Dr. Hay, who, in both respects, has done his work well. His use of the word "decubitus" (p. 54) to represent bedsores is, however, to say the least, confusing, though warranted by French custom.

The third volume consists of some 700 pages in which Professor Oertel says all that can be said, and a great deal more than we imagined could be said, on the subject of respiratory therapeutics. In long-windedness, in repetitions, and in complexity of form his treatise far outstrips the preceding ones. And yet it must be admitted that if the reader has only patience enough to search them out, he will find plentifully scattered through the volume many practical hints of great value, such as we have a right to expect from Dr. Oertel. The first parts deals with the more or less familiar subject of inhalations of chemical and pharmacological remedies, and besides a thorough discussion of their mode of action, and the different apparatus for applying them, contains detailed accounts of the drugs available, and of the special maladies in which they are indicated. The substance of some of the more important parts of these articles has already been published in this journal in Dr. Burney Yeo's clinical lectures, and need not now detain us. What will perhaps strike the English reader as the most novel point in this section of the volume is Dr. Oertel's treatment of pharyngeal diphtheria by carbolic acid. This treatment is, of course, only the corollary of the author's discovery of the *micrococcus diphtheriæ* as described in his article in Ziemssen's "Special Pathology and Therapeutics"; but there can be no doubt as to the boldness with which it has been carried out in practice. It consists in applying by the steam spray a five per cent. solution of carbolic acid—a strength, be it remembered, which takes the skin off any but the coarsest hands—every hour or two for from five to ten minutes, the patient being allowed to swallow any fluid that accumulates in the mouth and pharynx during inhalation. The inhalations are to be taken less frequently or intermitted altogether as soon as the urine shows a green colouration. By this method Dr. Oertel has obtained "perfectly satisfactory results in 51 of the most severe cases, more than two-thirds of which, I must say, would have proved fatal formerly under any other treatment." The second part of the volume consists of a long and wearisome discussion of pneumatic therapeutics, a subject which is very unfamiliar in England, and which we fear will not become the less so as a result of the present disquisition. This review, however, has already grown to such portentous length that we must refer the reader to the volume itself, or recommend him rather to wait until some book-maker of superabundant energy has condensed it into a readable form. In taking leave of the three volumes we must cordially congratulate the translators on the way in which they have fulfilled their arduous labours. As to the distinguished authors, we bear willing testimony to the "never yet exemplified effort" which must have attended the production of their monographs. Their laboriousness and profundity deserve our warmest recognition. But we may without ingratitude express the wish that they had possessed a less Talleyrandian idea of the function of language, or, at any rate, a less exaggerated notion of their readers' intelligence and application.

## ABSTRACTS AND EXTRACTS.

### ERYSIPELAS AND PUERPERAL FEVER.

AN important paper on the relationship between these two diseases, from the pen of Professor Gusserow, of Berlin, appears in the *Archiv für Gynäkologie* (Band XXV, Heft 2). He remarks that it has been believed, especially in England, that erysipelas and puerperal fever were closely allied, if not identical. This doctrine rested on the propositions which were assumed to be facts, that erysipelas and puerperal fever were found to prevail together; that puerperal fever could produce erysipelas, and erysipelas puerperal fever; and that anatomically, according to Virchow, in some forms of puerperal fever the changes in the cellular tissue of the pelvis were identical with those produced by erysipelas. Dr. Gusserow thinks that our knowledge on the subject is very superficial and defective. The observations adduced in support of the propositions above mentioned, although enough to make imperative the greatest care in protecting the lying-in woman from the contagion of erysipelas, are yet far from being sufficient to prove the pathological theory which is based upon them. Dr. Gusserow is of the opinion that there is no connection between puerperal sepsis and erysipelas. In the first place, a great number of cases of erysipelas during pregnancy have been seen, and our author has seen erysipelas come on in pregnancy, and the patient delivered while the disease was at its height; and yet there was nothing abnormal about the lying-in; the patient suffered from ordinary erysipelas, and nothing more. He has seen erysipelas come on during pregnancy; the pyrexia lead to the death and expulsion of the child, and the mother subsequently die; when the *post mortem* showed that the puerperal process was simply a complication of the erysipelas, no sign of disease of the genital organs being found, but *post mortem* appearances like those usual in erysipelas. Dr. Gusserow has also seen erysipelas appear as a complication in childbed, but it ran its course just as in any other subject, the course of the lying-in being in no way influenced by it. He has seen erysipelas coming on during childbed prove fatal, and the *post mortem* appearances were then simply those of fatal erysipelas, no sign of disease of the pelvic organs being present either during life or after death. Instances have moreover been recorded in which, during an epidemic of puerperal fever in a lying-in hospital, some patients have been affected with erysipelas, and other cases in which erysipelas and puerperal fever co-existed in the same patient. Both as to symptoms and *post mortem* appearances the phenomena of the two diseases were quite distinct; they were combined, but did not modify one another. Lastly, Professor Gusserow urges that we have now the proof, in the existence of a special micrococcus peculiar to it, that erysipelas is a specific disease. He has failed in experimental inoculations of the erysipelas-coccus under the skin and into the peritoneal cavity, to produce phenomena anything like those of septicæmia. The erysipelas-coccus produces erysipelas, and nothing else. Redness and swelling of the skin, which undoubtedly are sometimes present in septicæmia, ought not to be called erysipelas unless the erysipelas-coccus is present.

**LEPROSY IN CHINA.**—In his report on the health of Tamsui and Kelung for the four years ending Sept. 30, 1884, published in the last issue of the *China Customs Medical Reports*, Dr. Johansen writes as follows:—"The most interesting disease among the Chinese population here is leprosy. It seems astonishing that so little trustworthy information about this disease exists. It shows itself in an acute and chronic form, and attacks about 1 per cent. of the whole population, male and female. During the four years I have remained in Tamsui I have seen in the Chinese Hospital here above 150 cases, the total number of patients being about 8,000 in this time. My observations have led me to the following conclusions:—The acute form is more rare than the chronic, and attacks otherwise

healthy people, or, oftener, people suffering from chronic leprosy. The disease begins with a strong fit of ague, during which the temperature rises to 105° or 106°. This high temperature lasts during the whole attack, generally about eight days; then remissions begin, and the fever subsides gradually. During the fit of ague the patient gets red patches, particularly on the forehead and face, and also on the extremities, but rarely on the chest or abdomen. These patches look very like urticaria. They do not itch, but are very hot and tender on pressure. Many of them exude lymph, and even pus; the epidermis is softened and destroyed, the skin presenting the appearance of acute eczema. Some patches remain in this stage of their development; in the majority, however, the destruction goes on, and they form extensive superficial ulcerations. After about two weeks these ulcerations heal, and leave a cicatrix, which is more or less anæsthetic. The disease seems not to be contagious. The much more frequent chronic form of leprosy has often been pronounced a contagious disease; but this is certainly untrue. In over 40 cases I have made direct enquiries about the origin of the disease, and have found no case in which the patient could trace his affection to infection from another leper. If leprosy was a contagious disease, how could it be possible that in nearly every village exist one or two isolated cases who very often do not know what they are suffering from, because they have never seen another leper? Moreover, I have not found a single case in which a leper had a leprous wife or children, or where a leper had been accused of having infected a healthy man. Syphilis has been often called the cause, or one of the causes, of leprosy; but this is not the case. I saw a child of 7 years, a leper, whose parents were both healthy; the child had sisters and brothers, older and younger than herself, enjoying perfectly good health. In one case a leper acquired a hard sore while under treatment; a roseola syphilitica made its appearance in due time on the abdomen, which was covered with leper spots. I have seen many lepers with secondary or tertiary symptoms dependent on disease contracted before or after they fell sick of leprosy. Leprosy extends equally over the whole north end of Formosa, and the conditions of life of the mountaineer who fights with the savages and of a fisherman in Kelung are sufficiently different to make it impossible that they could suffer from the same disease in consequence of one fault in their diet or one peculiarity of the soil. Chinese doctors as well as laymen consider the disease to be the consequence of drinking rice spirit. Only the similarity of the red swollen face of a drunkard to the face of an unhappy victim of leprosy seems to have led to this idea. Among all my cases there was not one that could be definitely classed as belonging to either of the forms described in text-books. After the disease has lasted some months, every leper presents the following appearance. General health little or not at all affected; face covered more or less with dark red spots, sometimes approaching the appearance of a European face through accumulation of all colour on the cheekbone, the rest of the skin being whiter than that of the ordinary Mongolian of good health; ears shapeless and insensible to touch. These spots in the face get larger as the disease progresses; the subcutaneous tissue develops great masses of small tumours (this gives to the face the well-known hideous leonine appearance), or they disappear and leave white anæsthetic patches. There are fewer of these spots on the body and on the upper part of the arms and legs. Below the elbows and knees we find again more. The backs of the hands and feet are generally quite covered with them. The fingers are often of very dark colour; the finger tips clubbed. In the majority of cases we find that some portion of a limb has been lost through destruction of a joint. Under the ball of the foot or under the heel is a deep ulcer without any granulations or tendency to heal. Upper and lower extremity as far as elbow or knee have lost sensibility to touch and to pain. I can recommend ehaulmugra oil as a remedy in this formidable and mysterious disease. We are in the habit of giving the oil as we get it sent from London, in pill form, each pill containing 5 grains. The patient takes three pills daily after his meals, and continues this treatment for about six months. The best recommendation of this

treatment is the fact that nearly all our patients who have commenced have carried it out to the end, coming often from long distances to fetch their pills every month. An improvement generally takes place after one month. In some cases it was quite surprising to see the spots gradually getting paler and disappear, or sensibility coming back to places which had been anæsthetic for years. The most trouble is to get the indolent ulcers on the soles to heal up, as Chinese generally neglect to keep their wounds clean, and cannot or will not stop walking."

**ENTERORRHAPHY.**—After a brief summary of the operative procedures which have been devised in this direction from the time of Travers to the present day, Mr. Stanmore Bishop (*Medical Chronicle*, September) describes the operation which he proposes, but which as yet he has not performed upon the human subject. The portion of intestine to be removed having been cut out by scissors together with a triangular portion of mesentery, the edges of the latter are brought together with cat-gut sutures. A small round straight needle is then threaded with Chinese twist or silk, being placed exactly in the centre of the thread, which when double should measure about 80 centimetres long. The subsequent steps are thus described: "Then with dressing forceps the lower edge of both sides is seized, and the needle passed from left to right, and through the base of the fold thus formed, as near to the mesentery as possible; the double thread is then drawn through until 6 centimetres remain on the right side. One of the threads on the left side is to be cut 6 centimetres long; the needle is then passed from left to right through the same fold, at a distance of 20 centimetres from the first puncture. Two free ends and a loop remain on the left side, two ends free and two connected with the needle on the right. By gently drawing upon the loop, one of each of the two last pairs are seen to move; these are then drawn up so as to bury the loop in the mucous membrane on the left side, and are reef-knotted on the right; the two ends are then cut off close to the knot. The free thread left in the first puncture is now drawn under the free extremities of the upper bars of the clamp, so as to be out of the way, and is reserved for the latter part of the operation. The needle is now carried back again from right to left through the base of the fold, and a similar loop is thus formed, this time on the right, and knotted on the left. In this way, as the suture progresses, a series of loops consisting each of a single thread tied alternately on the right and left sides is formed, the threads of each loop passing through the same punctures as those of its neighbours on each side. It is thus impossible that any part of the intestinal circumference shall be unguarded, except the minute openings made by the needle and filled by the thread." Mr. Bishop claims that as the stitch is made it draws in the serous membrane, so that when finished the threads are really inside the restored lumen of the intestine, and the knots are really all inside. When half the circumference of the bowel is finished, Mr. Bishop recommends to commence again from the mesenteric border, tying one end of the fresh thread to one of the free ends of the first thread. In finishing the entire suture the last loop is made by tying the two free ends on one side together; the loop thus formed is then drawn up on the other side, folding in the serous coats of both sides, and the knot being made, the two threads left are cut off close, the bowel becoming absolutely closed.

**GUNSHOT WOUND OF THE KNEE WITHOUT FRACTURE OR PERMANENT INJURY TO THE JOINT.**—The *Boston Medical and Surgical Journal*, June 25th, gives the case of a patient, æt. 52, who was accidentally wounded during target practice, the ball from a thirty-two calibre pocket rifle striking him on the inner aspect of the left knee just as he was turning and had the joint partially flexed. The entrance wound was situated about 1 inch below the lower inner margin of the patella, and when the limb was made to assume the position it presented at the time of the accident, the puncture appeared to be in a line between the articular surfaces of the joint. The probe entered the joint, only a little synovia escaping. Careful search on the other side of the knee revealed a foreign body directly beneath the outer edge of the patella. This

proved to be the bullet, battered into an irregular pyramidal shape. Dr. Bridgeman decided not to interfere unless symptoms demanded it. The joint was fixed and constantly irrigated with carbolic water. Pain and swelling were moderate, without heat or swelling, and the pulse and temperature remained normal. The splint was kept on for three weeks, and the gradual use of the joint was then permitted. At the end of three months the only complaint was a slight amount of stiffness and weakness of the knee, and this chiefly after over-exertion. In six months the joint was practically as sound and as well as its fellow for ordinary use. Some years previously a knee-joint penetrated by the tine of a pitch-fork had recovered equally well. Numerous authorities and several experiments on the cadaver tend to prove that, during certain flexions of the knee, solid bodies can pass in an antero-posterior and even in an obliquely lateral direction through the joint without inflicting fracture, and scarcely more than grazing the cartilages of the articular surfaces.

**CREASOTE WATER FOR BURNS.**—Dr. Squibb, in his *Ephemeris*, remarks that the officinal aqua creasoti, a simple solution 1 per cent. of wood-creasote in water, is like similar solutions of carbolic acid and of cresol, a most effective local anæsthetic and topical dressing for burns and scalds. It is no better than the solutions of carbolic acid or coal-tar creasote for this purpose, but it is quite as good, so that whichever is most accessible or most convenient may be used. This creasote water, as made by the above formula—or diluted with an equal volume of water, or with more water for delicate surfaces in women and children—and applied by means of a single thickness of thin muslin or worn-out cotton or linen, such as handkerchief stuff, and the application renewed from time to time, as the return of pain requires it, will relieve the pain of burns and scalds in five or ten minutes, and will maintain the relief as long as the applications are properly renewed, or until the painful stage is over. In view of the importance of this preparation for the treatment of burns, Dr. Squibb expresses surprise at the general adherence to the old and comparatively useless dressings.—*Boston Medical Journal*, May 14.

## SPECIAL CORRESPONDENCE.

### INDIA.

(From Our Bombay Correspondent.)

*Hospital and Dispensary Relief in Bombay—Sanitary Difficulties at Calcutta—The "Unemployed-Pay" Question again.*

August 31.

MR. MOORE, C.I.E., the Surgeon-General with the Government of Bombay, has submitted the administration and progress report of the civil hospitals and dispensaries for the year 1884. During the year under report the administration was under Dr. Beatty, Mr. Moore's predecessor, and the report is drawn up by Dr. Patterson, the Secretary to the Surgeon-General. There are now 208 of these institutions, as compared with 202 in the previous year; the increase being due to the opening of new dispensaries in certain districts. Of these 47 are maintained by provincial funds, 33 by local and municipal funds, 25 at the cost of private individuals or associations, while the rest are supported from private subscriptions supplemented by grants from provincial or local funds. In the hospitals there were 29,045 in-door and 327,128 out-door patients treated during 1884, as compared with 29,420 and 304,455 respectively in 1883. In the dispensaries the figures are 7,357 in-door and 1,127,640 out-door in 1884, and 6,835 and 1,031,539 in 1883. The increase in the number of in-patients was but slight, while the increase in the number of out-patients treated was considerable. The proportion of in-door to out-door patients was 1 to every 11. Most of the dis-

pensaries have but limited accommodation for in-door cases, and the ratio of these is accordingly small. The average daily attendance of out-door patients was 3,053.6 at the hospitals and 11,750.2 at the dispensaries. During the year 4,182 major surgical operations were performed, viz., 1,517 in the hospitals in the City of Bombay, 1,557 in those of up-country stations, and 1,239 in the dispensaries. Of minor operations there were 76,546. A "note" by Mr. Wellington Gray, L.M., L.Ch., on the antiseptic treatment of wounds, is appended to the report, but there is nothing of special interest in it with which the average general practitioner is not acquainted. This "note" the Government, however, desire "should be circulated as widely as possible among medical officers in the Presidency."

The sanitary, or rather I should say insanitary, condition of Calcutta, has been for some time past attracting the attention of the Lieutenant-Governor of Bengal and the Government of India. The report of the Special Sanitary Commission appointed by Government, at the instance of a public memorial, has been published, and the Chairman of the Calcutta Municipality has written a reply. He maintains that the Government are not empowered under the Municipal Act to carry out the recommendations of the Commission, and the reason he is pleased to assign for this contention is that the Commission has not made out a case that the conservancy and cleansing of the town are defective or inefficient to an extent that would be prejudicial to public health. This is as strange as it is mortifying, because in the Report of the Commission, the most palpable and glaring defects are brought conspicuously under notice. Besides, the very high mortality in Calcutta, from cholera, typhoid fever, dysentery, &c., shows beyond a doubt that it is high time that a slothful body like the Calcutta Municipality should be brought to a sense of their duty and responsibility. The Commissioners point out the tenacity with which the cholera clings specially to the filthiest parts of the city. They report that "the cleansing and drainage is defective." They go on to say: "It will be seen from the recorded notes of our inspections of different parts of the town, that there are still many localities in an extremely insanitary state. Such localities are for the most part to be met with in the north of the town in *gowalla bustees*, or in the neighbourhood of filthy tanks. When they occur they cannot be regarded as other than plague-spots, the early obliteration of which is indispensable to the public health." Again, "Notwithstanding what has been effected in the last few years, we are not prepared to say that the cleansing and conservancy generally is at all what it might be. Foul drains, foul tanks, foul privies—these unfortunately are only too common. Much rubbish remains unremoved. Waste lands are soiled to a deplorable extent." Curiously enough, while the Sanitary Commissioners point out the unfiltered and impure water-supply to the masses, they remark that the wiseacres (the expression is mine) on the Municipal Board have actually been wasting a million gallons of filtered water daily in watering the streets and in flushing the drains. They strongly urge the absolute necessity of putting an end to the filthy pools of sewage which exist in the name of tanks for supplying water for ablution purposes as also for drinking. In every million parts of this tank-water, analysis shows the presence of 500 parts of chlorine and 48 of ammonia. Such being the state of things, it is no wonder that public opinion condemns the masterly inactivity displayed by the Municipality.

The subject of "unemployed pay" of surgeons-major of the Indian Medical Service, to which I alluded in a recent letter, is causing some agitation by anonymous letters appearing in the *Pioneer*. The writer of one of these adduces some very cogent arguments in favour of surgeons-major who do not hold permanent appointments, at least, drawing the same rate of pay as surgeons-major of corresponding standing on the medical staff. He allows that the "unemployed pay" presses more on surgeons than on surgeons-major, because the former are more likely to be without appointments, but at the same time he maintains that "this grade pay is inadequate and unjust no matter what the rank of the officer drawing it. If a rate of pay is

unjust for a year, the same rate is unjust for a day. If it be unfair to put twenty officers on an inadequate rate of pay, it is unfair to put one. The Government has listened to the most numerous body because they can shout the loudest. No one grudges the surgeons having obtained their rights, quite the contrary; but that should not be a bar to the surgeons-major obtaining theirs." "It is to be hoped," says the same correspondent, "that surgeons-major (and surgeons also, who will one day be surgeons-major themselves) will exert themselves in every way to have this glaring injustice removed as soon as possible. I would suggest that all concerned, and every officer of the Indian Medical Service concerned, should have questions asked in the House of Commons, and that they should also petition Parliament."

## GENERAL CORRESPONDENCE.

---

### DR. WATNEY AND THE CONTAGIOUS DISEASES ACTS.

[To the Editor of the Medical Times.]

September 19th, 1885.

SIR,—You would oblige me by inserting this letter in your next issue. I have long disliked the Contagious Diseases Acts, and expressed myself as opposed to them. There is no interest shown on the question in the constituency for which I am canvassing.

I am, Sir, yours, &c.,

HERBERT WATNEY.

1, Wilton Crescent, Belgrave Square.

---

### THE VOCAL REGISTERS IN MALE AND FEMALE.

[To the Editor of the Medical Times.]

SIR,—It is now many years that I pointed out in the *Orchestra*, and in the *Medical Press and Circular* (1873), that the male and female voices are fundamentally identical, and that the acoustical differences discerned arise from second causes, reinforcement. It is gratifying to me to find Dr. Gordon Holmes in your April issue of this year supporting this view.

I am, Sir, yours, &c.,

CHARLES LUNN.

Edgbaston, September 18th, 1885.

---

PROFESSIONAL DISEASES OF THE SKIN.—In his lecture on this subject, by which he intends the diseases produced by following various occupations, M. Guibout (*Gazette des Hopitaux*, No. 91) observes that whether these manifest themselves in the acute or chronic form, they are always attended by special characteristics which enable us to distinguish them. (1) Unlike syphilitic or herpetic affections (chiefly represented by eczema and psoriasis), they exhibit no tendency to become generalised, arising in fact from purely local causes. (2) Unlike herpetic affections, they are not pruriginous, that is to say, do not give rise to itching. (3) Nor do they give rise to any unity of lesion; that is to say, on the same parts we may have a union or confluence of lesions of different kinds, such as the patches of eczema in the midst of the papulae of lichen and the pustules of ecthyma. (4) They have no durability, tenacity or disposition to relapse, for the local influences once removed, they sometimes get well of themselves without treatment, and when once cured they do not return without renewed exposure. (5) They exert no evil influence on the general health. (6) They are neither contagious or inoculable.

## INVENTIONS AND IMPROVEMENTS.

### THE IMMEDIATE APPLICATION OF PLASTER OF PARIS IN FRACTURES OF THE FEMUR.

MR. E. COTTEBELL, of Bicester, has recently devised an apparatus for treating fractures of the shaft of the femur in adults by means of the immediate application of the plaster of Paris bandage. It is a modification of Sayre's suspension apparatus. Counter extension is made from the axillæ by means of a broad padded leather chest belt and perineal band. Extension is made from the foot by means of a boot fastened to an iron foot plate, which rotates by means of a screw, and which can also be extended by similar means. The sound leg rests upon a step formed by the box, in which all the apparatus except

the length of the two limbs should be measured from the anterior superior iliac spine to the lower border of the patella, and any shortening may be remedied either by tightening the perineal band, or by the extension screws attached to the foot plate. When the limb is judged to be in accurate position, a roller of flannel should be applied to the limb and pelvis, padding the ischial and femoral tuberosities with a little cotton wool. The flannel should be begun just above the boot and carried well over the pelvis. The plaster should now be carefully applied over the flannel. In order to strengthen the part over the groin and at the seat of fracture, strips of tin should be included in the bandage over these parts. When enough plaster is judged to have been laid on, and the splint is well set, the foot piece and perineal band may be removed, and the patient laid in a recumbent position, care being taken not to break the newly set plaster. The perineal band should be removed by [unbuckling it from the chest

the tripod will easily pack. The method of using this apparatus is as follows:—Whilst the patient is lying down, the belt can be applied to the chest, and the step being placed under the centre of the tripod, the patient is carefully lifted so as to rest his *sound* foot upon the step, leaving the injured one hanging over the side, but being held steady by an assistant. The cross bar is now lowered and attached to the chest belt by means of the straps, and then by pulling the cords the patient is to be supported, but not raised from his sound leg. The foot piece being raised to its full height, is now fastened on to the foot of the injured limb, by means of the boot, which has been previously fastened to the lid of the box by thumb screws. Should there be any rotation outward of the lower fragment, this can be remedied by rotating in the boot, to the sole of which is fixed a screw arrangement for this purpose. Having got the foot into position, with plenty of extension,

belt, and then drawing it downwards. When the patient has been laid down, an assistant should hold the foot at right angles to the leg, and the surgeon having enveloped it in flannel, puts on a plaster of Paris boot. It is necessary to include the foot and ankle in the plaster of Paris, in order that we may avail ourselves of this most reliable means of keeping up extension, for as the limb will naturally shrink from disuse, the condyles and muscles of the calf will offer but little resistance to the action of the strong muscles of the thigh, and more or less shortening of the limb will consequently ensue. This immobile apparatus should be worn for about six or seven weeks, the patient meanwhile getting about on crutches, having a patten, about four inches high, placed on the boot of the sound leg.

The apparatus can be obtained of Messrs. Maw, Son & Thompson.

**BRAND'S MEAT PEPTONES.**—Messrs. Brand & Co. (11, Little Stanhope Street, W.) have recently introduced to our notice some samples of their meat peptones. After the lectures of Dr. Roberts, of Manchester, on the useful part that can be played by peptones in the feeding of the sick, it is unnecessary to say anything on the general question of peptones as an article of invalid diet. Suffice it to say that the peptonized beef, veal, mutton and elieken prepared by Messrs. Brand & Co. are not at all unpleasant to the taste, as peptones are apt to be, and that we have found them very useful in cases of obstinate sickness, as well as for rectal feeding. In fevers and prolonged illnesses, where the digestive powers are enfeebled and the main indication is to introduce into the system sufficient nutriment, the peptones will be found a valuable addition to the ordinary sick-diet. We have also received from Messrs. Brand, and examined samples of "Peptonized Osseine," containing peptone of the nutritive portion of meat-bone, "Ivory-Jelly," and "Malto-beef Lozenges," all of which have been very skilfully prepared, and will find a useful place in the invalid dietary.

**ACKERMAN-LAURANCE'S "BRUT ROYAL" CHAMPAGNE.**—This wine, which is already pretty well-known to the profession, is a light Saumur, free from added sugar and alcohol, and, according to the result of Sir C. Cameron's analysis of a bottle bought in the open market, also free from tannic and excess of other acid. It contains extremely little sugar, and is therefore suitable for the many cases in which sugar is not well borne by the stomach or the organism. It may be prescribed with advantage to the gouty and rheumatic. For those who prefer a dry wine, it is a pleasant drink, and extremely reasonable in price even for a Saumur.

**FRY'S CONCENTRATED SOLUBLE COCOA.**—The well-known firm of Fry and Sons, of Bristol, have recently introduced an improved concentrated cocoa, prepared by a new method. The sample examined by us dissolved rapidly and completely in hot water, a great advantage in a cocoa, and formed a very pleasant drink. It is free from starch and any other foreign addition, and contains only a small proportion of the natural fat of the cocoa bean. It is therefore eminently suitable for invalids, as well as for that steadily growing portion of the population who cannot take tea or coffee.

**DANIELSSON AND Co.'s CLINICAL FIGURES, &c.**—The outline figures published by Messrs. Danielsson & Co. (late Lebon & Co.), of 23, Southampton Buildings, Chancery Lane, are admirably adapted for their purpose. They consist of a series of diagrams of the head, brain, spinal cord, thorax, abdomen, limbs, and, in short, of all the regions of the body girdled at the back, which, when properly filled in, would constitute a most valuable addition to the clinical record of a case. The same firm have also issued a pocket case book arranged for brief notes with temperature chart of fifty cases. The prices at which these are issued place them within the reach of all.

**CORSETS.**—Every surgeon must meet with cases in which some sort of corset is more or less necessary to give either temporary or permanent support to the back. We have lately had experience of corsets made by the Misses Wells, of 56, Welbeck Street, and we are very well satisfied with the result. We find that their stays are made to fit patients very comfortably and without pressing unduly on the ribs, and in special cases they are carried high up the back, giving good support to the shoulders. They are the only corsets with which we are acquainted, and our experience is not small, which combine the requirements of the surgeon with those of the *modiste*. They are very suitable for weak backs, and even for ordinary wear, so long as ladies will wear corsets.

**LACY'S ISOLATION SHEET.**—Mr. W. G. Lacy (24, Ringford Road, Wandsworth) has devised an isolation

sheet for covering the door of the sick-room in infectious cases, the chief merit of which is that it can be thoroughly moistened in a few minutes with a disinfectant solution contained in a small tank fitted over the door. The whole apparatus can be purchased and fitted up for less than a pound, and it no doubt constitutes a much more satisfactory means of securing isolation than the usual sheet with its attendant bucket and brush.

**MARSHALL'S SEMOLINA.**—Many doctors order semolina without knowing what it is or how it is made. In reality, it is a coarse flour made of the best part of the wheat grain, with all the external covering removed, and consequently it contains all the constituents of good bread. It bears the same relation to fine wheaten flour that coarse oatmeal does to fine, and it makes good porridge as well as good puddings. We have given the semolina prepared by Messrs. Marshall Bros. (Morrison Street, Glasgow) a prolonged trial, and find it a most satisfactory food for children and invalids. The results of the analyses of this food-stuff by Dr. Stevenson Macadam and Prof. Ferguson, give a much higher proportion of albuminous compounds than is set down to coarse wheaten flour in the usual tables, and a higher proportion even than is found in oatmeal. In short, semolina as prepared by Messrs. Marshall is an economical, palatable, and nutritious article of diet.

## OBITUARY.

### JOHN GAY, F.R.C.S.

THOUGH nearly two years—a long period in these busy and fast-moving times—have passed since Mr. John Gay was compelled by grave illness to retire from all professional work, the tidings of his death on the 15th instant, at his residence in Belsize Park, Hampstead, will have caused vivid regrets, touched by numberless recollections of past kindnesses and gratefully remembered services, social and professional, to a very wide circle of friends. Indeed, but few of the metropolitan surgeons of the last fifty years, outside the small number of the exceptionally eminent, were more widely known or more popular than was John Gay. Throughout his career, he was an enthusiastic and able surgeon, and an ardent student of anatomy and pathology; while his happy temperament, his many social gifts, his genial character, his generosity, and his wide hospitality gained him troops of friends, and made his friendship highly valued by a large society of notable persons, including not a few of the lights of the artistic world.

Mr. Gay, who was descended from a good old family, of Devon county we believe, was born at Wellington, in Somersetshire, in 1813; and after receiving a good general education, he commenced the study of medicine by the old and valuable way of apprenticeship; and when he thus had been partly trained and educated for his chosen profession, he entered as a student at the school of St. Bartholomew's Hospital, where he clerked under Peter Mere Latham, and carried off the first surgical prize given by Mr. (afterwards Sir William) Lawrence. In 1834 he became a member of the Royal College of Surgeons, and in December, 1843, he was among the prominent surgeons upon whom the honour of the newly-created Fellowship of the College was first bestowed. In 1869 he was elected into the Council of the College, and again in 1878, but he did not attain the honour of the Presidentship. In 1836, two years after he had obtained the membership of the College, Mr. Gay was appointed one of the surgeons of the Royal Free Hospital, and for several years he laboured to maintain and advance the reputation of that charity; but a time came when he felt obliged to resign his connection with it; and in 1856 he accepted the post of Senior Surgeon to the then just founded Great Northern Hospital, an appointment which, to the great advantage of that Institution, he held up to the day of his death.

As Mr. Gay was ever an eager student and a close observer, and was devoted to his profession, he was naturally also a somewhat frequent contributor to its literature; but we cannot afford space for the mention of more than a few of his writings. He had already made his mark as a successful operator and an original observer, when, in 1848, he published what perhaps may be regarded as his most important work, namely, his volume "On Femoral Rupture, its Anatomy, Physiology and Surgery": he there advocates a modification of the operation for the division of the stricture external to the sac, in such a way that Mr. Erichsen, in his "Science and Art of Surgery," speaks of Mr. Gay's method as being "little more than the taxis, with the addition of a superficial incision." In 1853 he brought forward his well-known plan for facilitating the healing of indolent ulcers, otherwise intractable, by incisions in the skin and fasciæ of the healthy structures surrounding them; and this method is fully described in his "Memoir on Indolent Ulcers and their Treatment" (1855). In 1868, Mr. Gay delivered the Lettsoman Lectures of the Medical Society of London, taking for his subject "Varicose Disease of the Lower Extremities: its Physiology, Pathology and Treatment." In 1877 he contributed to the *Lancet* some papers, the result of much careful research and close observation, on "The Anatomy and Physiology of the Venous System in the Lower Limb in Relation to some of its Diseases—Gout, Gangrene, Dropsy, &c.," and so lately as in 1882 he published an original and suggestive monograph, "On Hæmorrhoidal Disorder." He wrote the elaborate article on "Cleft Palate" in *Costello's Surgical Dictionary*; and contributed numerous papers to the Royal Medical and Chirurgical Society, the Pathological Society and the medical press.

Mr. Gay was a Fellow of many learned societies at home and abroad. He was Consulting-Surgeon to the Idiot Asylum at Earlswood, and to the Soldiers' Daughters' Home, Hampstead; and Surgeon to several assurance societies, and to the Metropolitan, North London, and London, Tilbury and Southend Railways. He has left a widow, one daughter and two sons—one of whom, a second John Gay, is already a member of our profession.

#### FRANCIS HARRIS, M.D., F.R.C.P.

FRANCIS HARRIS was born December 1st, 1829, in Southwark, for which borough his father was sometime M.P. He began to study medicine at Caius College, Cambridge, and at St. Bartholomew's Hospital; and took the degree of M.B. in 1854. He was House Surgeon to the Hospital for Sick Children in 1856-7; was admitted M.R.C.P. Lond. in 1857; and afterwards went to France and Germany for further study. Returning, he was elected Obstetric Physician to St. George's and St. James' Dispensary, and Assistant Physician to the Children's Hospital in 1859. The same year he took the degree of M.D. and chose for his thesis, "The Nature of the Substance found in the Amyloid Degeneration of Various Organs of the Human Body." In this paper, which was printed in 1860, and which may still be read with interest, he maintains "that the reactions of these substances (corpora amylacea and amyloid degenerations) with iodine and sulphuric acid indicate their analogy, not their perfect identity, with the substances of the amylaceous group." The Dispensary he soon gave up, together with the intention of applying himself to obstetrics. He was next appointed Demonstrator of Morbid Anatomy, and soon afterwards Assistant-Physician and Lecturer on Botany at St. Bartholomew's. About this time he married. In 1865 he resigned his Children's Hospital and the Lectureship. In 1868 he was elected Physician to St. Bartholomew's. He now began to suffer from pulmonary emphysema and catarrh, connected with a disposition to gout. These infirmities increased upon him somewhat quickly, insomuch that in 1874 he resigned all his hospital duties and retired from practice; leaving behind him the reputation of great mental power and practical sagacity, which would have raised him to eminence had he been able to devote himself sedulously to his pro-

fession. Henceforth he passed most of his time in the country, upon an estate which he possessed at Lamberhurst, where he found that he could live and breathe more easily than in London. Here his kind heart and love of hospitality gained him many friends, by whom his death is sincerely lamented. In 1882 he passed through an attack of pneumonia, and it was a recurrence of this disease which put an end to his life on September 3rd, 1885.

### MEDICAL NEWS.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, September 10th, 1885:—

Thomas Peachey Allan, The London Hospital; Thompson Wilberforce, M.R.C.S., East Rigton, Bondray, near Leeds.

*Preliminary Examination in Arts.*—The following candidates passed this examination on the 10th, 11th and 12th of September, 1885:—

*Second Division.*—S. E. Baxter, \*H. L. Brownlow, C. C. Clark, \*C. E. Colpus, \*A. C. Curtis, \*G. G. Giffard, C. H. W. Hammich, \*L. D. Heather, E. W. Herrington, G. P. Jacobson, \*A. Lucas, C. E. A. MacLeod, E. C. MacLeod, \*A. Quennell, F. W. Rix, and W. Thompson.

Those marked thus \* also passed in Elementary Mechanics.

The following passed in Elementary Mechanics alone:—

W. C. Aylward, A. K. Barrett, A. T. Coleman, J. B. O. Richards  
E. M. Williams, P. M. Yearsley, S. D. Wakefield.

The following passed in Geometry alone:—

H. D. Nichol.

The following passed in Latin alone:—

R. O. Satchell.

The following passed in all subjects except History and Geography:—

W. F. Pakeshott.

The following passed his examination in the Science and Practice of Medicine, Surgery and Midwifery, and received a certificate to practice, on Thursday, September 17th, 1885, viz.:—

Arthur Jno. Helen Montague, Uxbridge House, Uxbridge.

At the recent examination for the prizes in Botany given annually to young women by the Society of Apothecaries, the successful candidates were—

1st, Lilian Jane Clarke, A Gold Medal; 2nd, Emmiline Florence Carder, A Silver Medal.

DR. DE CHAUMONT ON SANITARY PROGRESS.—At the opening meeting of the Sanitary Congress at Leicester on Tuesday, Dr. de Chaumont, the President of the Sanitary Institute, delivered a most interesting address. He said the Institute did not wish the Congress to be a mere meeting of experts in the various branches of hygiene, but to make it the occasion of bringing home the subject to the community at large. The beneficial effects of sanitation were nowhere more evident than in the army. Thirty years ago the soldiers at home died at the rate of 18 per 1,000, whereas now the rate was only 6.28. The result was that, calculating sickness and death, there was a saving in the home army of two battalions per annum. When he entered the army there were dying of consumption alone more men in two years than now died from all causes whatsoever in three years. Equally valuable results had followed good sanitary measures in India and the West Indies, and, putting on one side some pestilential spots which were specially dangerous to human life, they might confidently say that there was hardly a spot on the globe where men might not be kept in health and vigour by proper attention to hygiene. Alluding to the important work done by the Sanitary Institute in granting certificates of competence on passing examinations to those officials who are entrusted with the carrying out of local sanitary work, Dr. de Chaumont said that it was a remarkable fact that at present there was no official recognition of the competence of any of the officers connected with sanitary

work. He earnestly hoped that the time was not far distant when it would be compulsory on all sanitary officials to show undoubted proof of their competency for office. The present system of uncertain tenure must be abolished, and the country divided into large combination districts sufficient to occupy the entire time of a competent medical officer, who should be well paid and irremovable except by the Local Government Board. The importance of a Health Department of the State was becoming more and more evident, and there could be no question that unity in administration would add greatly to the efficiency and materially diminish the expense of sanitary work. A premature death was reckoned overhead as a loss of 100*l.*, and if it was the head of the house and the breadwinner it was evidently much more. There were 750,000 deaths every year in the United Kingdom, about one half of which were deaths of children or of persons in the unproductive periods of life, and of the remainder nearly one-third were distinctively preventable. Could those deaths be prevented they would save, he calculated, a sum of 25,000,000*l.* per annum, or little short of the amount they paid yearly for the interest on the national debt. Most sanitarians agreed that the death-rate was capable of being reduced to 15 per 1,000 by the reduction of preventable disease, and in that case the mean duration of life would be 54 years instead of 41, while a reduction to 12 per 1,000 would raise the mean duration of life to 65; 11 per 1,000 would raise it to 70; while a ratio of 8 per 1,000—a rate seriously contemplated by Mr. Chadwick—would bring it up to 93; and a fractional amount below 8 would establish the ideal 100 years which was now held to be the normal life of man. Having shown the reduction in the mortality in specific diseases by means of improved sanitation, Professor de Chaumont proceeded to deal with the question of cholera. Epidemic cholera, which had lately committed such ravages in Spain, and might possibly reach our shores by-and-by, was a disease which carried great dread to the public mind. The terror which cholera inspired was due to the appalling suddenness of its invasion as well as to its great proportionate mortality. He had known 22 cases die out of 24 attacks, or about 92 per cent., but his experience as a whole had been that about 63 per cent. died, or very nearly two out of three. In the recent epidemics, the death-rate had been much less. In Spain it had only been one in three; but even this was bad enough. Supposing Spain to have a normal death-rate of 22 per 1,000, then there would be about 1,000 deaths per day as the usual death-rate; but from 1,500 to 2,000 lives had been lost daily from cholera alone, and altogether up to the end of August some 80,000 persons or more had perished in a population of 16,000,000, so that the death-rate was being more than doubled. In this country our normal death-rate was about 16,000 a week; if cholera prevailed in the same ratio as in Spain, we should be losing some 25,000 lives per week from that cause alone, and the total death-rate would be between 40,000 and 50,000. This naturally led them to consider what condition we were in to resist this formidable invasion. Cholera had visited Europe six times, including the present epidemic, namely, in 1832, 1849, 1854, 1866, in which years it prevailed in this country; but in 1873 and up to the present time in the existing epidemic it had not been able to make a footing. It was chargeable with the death of 180,000 or 200,000 persons in the United Kingdom, and this number divided by the 54 years gave 3,700 a year. But in those 54 years the deaths from fever were higher in the aggregate, and even in epidemic years the deaths from fever sometimes equalled those from cholera. For instance, in 1854, there died in England and Wales from cholera 20,000 persons, and 19,000 from fevers, while in the last two epidemics the total cholera deaths were 38,000, while the total fever deaths were 40,000, without including scarlet or other eruptive fevers. Altogether the deaths from fevers in the United Kingdom during these 54 years could not have been less than 1,500,000, or eight times the mortality due to cholera. They had thus had a constant enemy to deal with, the mere familiarity with which had bred a certain amount of contempt, while on the other hand the impressive onslaught of cholera had raised them from time to time to more vigorous action, to such an extent, indeed,

that they might say that cholera had been more of a blessing than a curse, and that it had saved many more lives than it had taken. The utter futility of quarantine by land or sea had been proved most clearly, and they had wisely in this country devoted expenditure to internal sanitation, to the provision of good water and good drainage. Judging by the past they had good hope for the future, for they were far better situated for resisting an epidemic than they ever were before. In conclusion, the President referred to the question of vaccination, and he wished it to be distinctly understood that in his judgment vaccination was one of the greatest boons ever conferred upon humanity. Leicester had constituted itself a principal centre of opposition to vaccination, and he believed that it was insisted that sanitation was sufficient to prevent small-pox. With special regulations and strict isolation they had been able to keep the town very free from this disease, and he should be a bad sanitarian if he did not recognise the value of both these measures, but he would point out that they were now working with a population that was for the most part already vaccinated. What it might be when an unvaccinated population had accumulated was a very different thing, and he feared they would have a rude awakening. It was an entire mistake to suppose that a prophylactic measure, such as vaccination, was antagonistic to general hygiene. On the contrary, they went hand in hand, and they were now too fully convinced of the advantages and paramount importance of general sanitation to be likely to fall so far back into error as to neglect it.

METROPOLITAN HEALTH RETURNS.—Dr. Tripe, Medical Officer of Health of the Hackney district, has just made his annual report. Dr. Tripe points out that, notwithstanding the increased density of population, the death-rate of the district is below that of London as a whole, being 18 per 1,000, as against the general rate of all London of 20.3. The deaths from zymotic diseases numbered 850 in the year, pulmonary diseases, other than phthisis, caused 603 deaths, and tubercular diseases caused 515 deaths. The zymotic diseases mortality of the last period was higher than the two previous years. In connection with the ill-condition of the river Lea, it is significant to remark that diphtheria caused an unusual number of deaths. Typhoid fever was also more prevalent than usual. Dr. Tripe deals with the epidemic of small-pox which visited the district especially, and he allows that many unnecessary deaths occurred through children being unvaccinated, and he enters into details at great length in support of his contention that the existence of the Eastern Asylum was responsible for some of the spread of the disease. That the sanitary officers found much work to do is shown by Dr. Tripe's record that upwards of 6,000 houses were inspected by them, and 1,663 premises and houses where nuisances existed were visited. Dr. Gwynn, the Medical Officer of Health for the Hampstead district, reports that the death-rate for the year was 12.5, slightly exceeding that of the previous year, which was 11.26. The deaths from small-pox and other zymotic diseases were equal to 1.9 per 1,000 of the population, against 3.34 in the metropolis at large. Diphtheria was more fatal than in any year since 1878, the deaths having been 19, against an average of 10; but the disease had been epidemic in London generally during 1884. The epidemic of small-pox in Hampstead in 1884 had not been equalled in severity since the great epidemic of 1871. From April to December there were 25 deaths of parishioners from that disease, against 38 in the two years' epidemic of 1876-78, and six in the epidemical period of 1881-82, although in London in 1884 it had only destroyed one-third of the number that succumbed in 1877-78. In 1880-81, when the Asylums Board hospital was closed, the deaths of Hampstead parishioners from small-pox only equalled 2.1 per 1,000 of total deaths; but in the epidemic of 1884, when the hospital was open, such deaths equalled 20 per 1,000 of total deaths, the largest number of deaths occurring around the hospital. Under the name of the "Wandsworth District," the whole of the Surrey southwestern localities, spreading from the borders of Lambeth to Roehampton, are included in one administration of a local board of works, and the six medical officers of health of

the several sub-districts have just presented an interesting series of reports. The population numbers very little short of a quarter of a million, spread over Battersea, Clapham, Balham, Tooting, Putney, Streatham, Wandsworth, and Roehampton. The death-rates over the several parts of the district are of a satisfactory character. The death-rate of the whole Surrey suburban district comprised in the area under the Wandsworth Board of Works came to the low aggregate of 17.85 per 1,000 of the population—a rate 2.49 below the rate of London generally. The death-rate, like the birth-rate, greatly varies according to population in various parts of the district. In Battersea, where the population numbers about 25,000, and the density of population to area is 53.4 to an acre; the death-rate is 17.75; while in Clapham and Putney (with Roehampton), with a density of population respectively of 32.1 in Clapham and 6.6 in Putney, the death-rate is only 13.7 in the 1,000 of population. In Streatham, where the density of population is only 8.4 to the acre, the death-rate is 15.3, and in Wandsworth, where the density of population is only 12.4 per acre, the death-rate is higher than that of closely-inhabited Battersea, being 18.77.

**THE EPIDEMIC OF TYPHOID AT WIESBADEN.**—The *Neue Freie Presse* of Vienna has published some facts with regard to the ætiology of this outbreak. Owing to the constant increase of Wiesbaden, which is now a city of over 40,000 inhabitants, it has been from time to time necessary to add to its water supply. The source from which it has been sought to obtain these additional supplies has been in the neighbouring Taunus Mountains, the new springs being brought into connection with the existing waterworks. Recently an underground gallery or tunnel about a mile in length was excavated into the hill known as the Münzberg, with a view to tap fresh springs and convey their waters to the town. The work of extending this subterranean passage is still going on, so that numerous labourers are kept for considerable periods within the gallery. Along the bottom of the passage are planks, beneath which a stream of water can be heard, and this water was for some time habitually fouled by the workmen employed. At the beginning of the month of July this water from the tunnel was carried into the principal reservoir of the town waterworks. Soon after, in the same month, cases of typhoid fever occurred in the town, and their number increased from day to day until the outbreak assumed the form of a real epidemic, and the number of cases officially announced amounted to over 60 a day. The disease broke out simultaneously in various parts of the town remote from each other, the cases being less frequent in those streets where the city water supply was least used. The circumstances therefore appeared to indicate that the epidemic was spread by the waterworks. The authorities of the place, on ascertaining the facts, caused the source of contamination to be stopped as soon as possible, and thereupon the epidemic began to decrease. But the damage was done. Schools were closed, and visitors as well as many natives took to flight. The water in the Münzberg tunnel was found to contain near the spots where the water flowed out of the earth only a few bacteria in each cubic centimetre, but at the mouth of the tunnel the same quantity of water contained several thousands of these microbes. The epidemic may now be regarded as extinguished.

**MEDICAL OFFICERS OF HEALTH IN SCOTLAND.**—In a paper on this subject, read before the Fifeshire Medical Association, and published in the *Edinburgh Medical Journal*, Dr. Robert Spence expresses himself as follows: "In place of the present numerous and local officers, I would have appointed by a central sanitary authority, such as the Board of Supervision, district medical officers, responsible to the central authority, and free from the distraction of private practice and the influence of local parties. The number required would be determined by the area and population and general requirements of the district, and the salaries should be sufficient to enable them to devote their entire time to the duties of the office. This would also involve a very small sacrifice on the part of the ratepayers. Taking our own country, for example, one farthing per pound on the total rental, landward and burghal,

would yield about 1,100L., and that, with the salaries (small as they are) at present paid to the burgh medical officers, would yield enough for two district officers, sufficient, I should suppose, for the country. Here again, I fear, the medical men would be the losers, for the general community would very soon be repaid over and over again by diminished doctors' fees and druggists' bills. This plan is very simple on paper, but I doubt that here its simplicity ends. The tendency at present seems altogether in the direction of increased local government. Against this I have nothing to say in ordinary affairs, but, unfortunately, disease is not local in its effects, however local in its origin, and I think if anything is to be managed by central and imperial authority it is the public health. Religion is provided for by the State; we have had for long a special department to look after the interests of trade and commerce; education has tardily received efficient State recognition; and is it too much to hope that the time will yet come when we shall have a really effective Department of Public Health?"

**THE VOLUNTEER MEDICAL CORPS.**—The terms upon which members of the Volunteer Medical Staff Corps, of which Surgeon-General Sir Guyer Hunter has been appointed honorary commandant, were enrolled, have been promulgated from the War Office. The capitation grant will be allowed on certification from the Commanding Officer and Adjutant that men are duly enrolled in the Corps; that they do not belong to Regular, Militia, Yeomanry, or Army Reserve (including Enrolled Pensioner) Forces, and are not enrolled in any other Volunteer Corps; that they have attended during the year ending the 31st October a certain number of drills ordered by the Commanding Officer of not less than one hour's duration; that they possess a competent knowledge of squad, company, and bearer column drill, and were present at the annual inspection, or if absent, had leave of the Commanding Officer. The number of drills for a recruit in his first year has been fixed at 16 ambulance and 20 other drills, including the inspection; if absent from the latter with leave or from sickness, two ordinary drills have to be added. In the second year the recruit must put in the same number of drills as in the first, or such number—not less than eight ambulance and nine other drills—as will, with the number performed in the previous year, amount to 32 ambulance and 42 other drills in the two years. In subsequent years eight ambulance and nine other drills will be required, with two additional ordinary drills if absent from the annual inspection; and extra drills, probably about six, will be required for instruction with pack equipment. Squad drills, at which not less than four rank and file are present, may be reckoned when necessary to complete the number of company drills, but when so reckoned they can only be counted in the proportion of three squad drills in place of one company drill. To constitute a bearer-column drill towards efficiency at least 850 of all ranks must be present, of whom not less than twelve must be officers and sergeants. Attendance at a brigade drill or review may be counted as a drill; and to constitute a company drill for efficiency at least 16 of all ranks must be present, of whom not less than two must be officers or sergeants.

A LADY Dentist has commenced practice in Amsterdam with the intention of devoting herself to the care of the teeth of women and children.

**THE PADDINGTON CANAL DUST WHARFS.**—The toleration of a nuisance which, at length, is recognized as little short of a scandal, came before the Paddington Vestry last week. It appears the deposit and sifting of the dust and other refuse hitherto carried on at wharfs north of the Canal Basin, has been extended to the south side of it, in close proximity with St. Mary's Hospital, and the spot on which the dust carts are discharged of their unwholesome contents only 80 yards from the windows of the Accident Ward, thus offering a serious interference with the ventilation of the ward. The Sanitary Committee recommended the Vestry to require the immediate removal of the nuisance. Dr. Stevenson, the Medical Officer of Health, reported the necessity for this course, which was strongly urged by

Dr. Danford Thomas and others, and it was remarked that the whole of this dust business should cease to exist in the parish; moreover, to permit its extension in the area over which it was conducted would be seriously detrimental to the usefulness of St. Mary's Hospital, while additional vested interests would accrue, which must be satisfied when the authorities did their duty, by entirely clearing the nuisance away. The Vestry decided, by a large majority, to insist on the removal at once of the dust business from the south side of the canal, and the medical officer was instructed, if necessary, to take legal proceedings to accomplish that object. The initiation of this first step augurs well, we hope, for the ulterior measures necessary to be taken to effect the abolition of a nuisance jeopardizing the health of this populous district.

DR. FRANK WOODBURY, the Editor of the *Philadelphia Medical Times*, has been elected Professor of Materia Medica and Therapeutics in the Medico-Chirurgical College of Philadelphia.

CORONERS' COURTS.—A good deal has, from time to time, been said, and very properly, in condemnation of the unsuitable places and accommodation provided for holding coroners' enquiries. The ventilation of the subject, however, has, no doubt in many instances, led to satisfactory results. But there appears to be plenty of room for similar improvements. Whether military authorities generally under-estimate the dignity of the coroner's office we will not venture to assert, but a dispute arose, a few days since, between the coroner and the authorities at the Station Hospital at Portsea. An inquest was to be held on the body of a private soldier, found dead outside a house of ill-fame. The coroner and jury arrived at the military hospital, and were shown into an apartment which appeared like a scullery, filled with smoke, and told that was the place set apart for the coroner's enquiry. He protested against the insult offered to him and the jury, and threatened to adjourn the inquest to the magistrate's room in another part of the town. The timely arrival, however, of Surgeon-Major Rooney, who admitted the smoke was very bad, averted the carrying out of the threat, and ultimately the surgeon-major directed that the library should be got ready for the coroner and jury. There the inquest took place, although the coroner intimated that he should bring the insult, which he insisted had been offered to himself and the jury, under the notice of the Secretary of War.

INSANITY IN THE UNITED STATES.—Apart from several large county asylums in the United States there are 80 State and 40 private institutions for the care of the insane, with a proper capacity for about 40,000, but containing 53,192, leaving some 45,000 lunatics to be cared for elsewhere. The proportion of insane is greatest in New England, but the increase has been most rapid in the Western States. In the State of New York there are 35 institutions for the care of these unfortunate people, accommodating 11,343 patients, while it is said that there are 4,000 provided for at home.

ANOTHER MEDICAL CANDIDATE FOR PARLIAMENT.—Dr. Alfred Carpenter, of Croydon, it is stated, will be Liberal candidate for the Reigate Division of Surrey, in opposition to Sir Henry Trevor Lawrence.

STAFF-SURGEON DR. GAFFKY.—The announcement in the Military Orders, the *Allgemeine Medicinische Zeitung* observes, that Staff-Surgeon Dr. Gaffky has been removed from the active list and placed in the reserve, would under other circumstances have excited great surprise; but in fact he has himself resigned his post, in order that he might become one of the regular staff at the *Reichsgesundheitsamt*, where he had hitherto only acted as an assistant. As one of the first and most able of the pupils of Geh. Rathes Prof. Koch, he accompanied him on his expeditions to Egypt and India for the investigation of the cholera, and on his return received an honorarium of 15,000 marks. As Koch's assistant he has of late been employed in the bacteriological department of the *Gesundheitsamt*, and now that his leader has retired (having been appointed Director and Professor in the new Hygienic Institute of the University), Dr. Gaffky, it is expected, will receive his appointment at the *Gesund-*

*heitsamt* and be made a *Regierungsrath*. The work at the *Gesundheitsamt* will be somewhat modified, as much of the work hitherto done there will in future be more naturally conducted at the Hygienic Institute.

THE POPULATION OF FRANCE.—The French Ministry of Commerce has just published some interesting statistics respecting the state of the population of France in 1884. From these we learn that while the number of births of illegitimate children has increased, that of the births of legitimate children has decreased. The death-rate has also risen. Last year there were 937,758 births and 858,784 deaths, making an excess of births over deaths of 78,974. This, with one exception, is the smallest increase since 1872. Indeed, since 1877 the increase has, with one exception—that of 1881—been smaller than in any of the five preceding years. One notable fact brought out by these statistics is the marked increase of the death-rate in Brittany, of which no explanation is as yet forthcoming.

PROFESSOR SENATOR.—The Berlin Correspondent of the *Canada Medical Journal* for September, states that during the interval which elapsed between the date of the death of Professor Frerichs and the filling up of the post vacated by his successor Professor Leyden, the clinic was conducted at a short notice with such distinguished ability by Professor Senator, that it was expected by many that he would be appointed to the post vacated by Professor Leyden, but which has been bestowed on Professor Gerhardt, of Würzburg. It is rumoured that the anti-semitic bigotry at present prevailing in Germany was indirectly the cause of Senator not obtaining the appointment. During his short course he achieved high popularity; and at the *Festcommers* (a banquet defined by the correspondent as consisting of indifferent beer in unlimited quantities, bad music, and worse singing), indignation was expressed that while so able a professor existed in the Berlin University, another should be brought from a distance.

THE MERCER'S HOSPITAL, DUBLIN.—An urgent appeal is made by the Governors of this Institution for public assistance, in consequence of the liquidators of the Munster Bank having called upon the Governors to pay off a debt of 1,455*l.* 8*s.* 6*d.*

SOUTH LONDON SCHOOL OF PHARMACY, 325, KENNINGTON ROAD, S.E.—The following prizes were presented to the successful competitors, on Saturday, the 19th Sept., 1885:—Senior Chemistry: Medal, F. W. Taylor; Certificate, J. B. Nicholls. Junior Chemistry: Medal, Andrew Craig; Certificate, A. L. Wood. Botany: Medal, J. B. Nicholls; Certificate, E. L. Ralling. Materia Medica: Medal, John Tirrell; Certificate, J. Burgess. Pharmacy: Medal, Robert Pyle; Certificate, J. W. Carr. Extra Certificates of Merit to Messrs. Jackson, Lewis, Minter, Moore, and G. H. Taylor.

CALF VACCINATION IN SWEDEN.—From a report issued by the Swedish Sanitary Committee we learn that since the introduction of a system of supply of calf lymph to the chief towns in 1883, a large number of persons have been vaccinated with it, and the results have been in every way satisfactory. The original supply of lymph was brought from Belgium, and there are now establishments where the calves after being inspected by competent veterinary surgeons are vaccinated. The lymph from these is supplied both to public and private vaccinators. In the summer of 1884, in Stockholm alone 500 children and 3,000 adults were vaccinated direct from the calf.

A VOLUNTEER MEDICAL STAFF CORPS, WOOLWICH.—With the sanction of the Secretary of State for War, it is proposed to raise a detachment or company by the Volunteer Medical Staff Corps of London for the Woolwich district, for the purpose of forming a branch of the Volunteer Medical Association. The object of the Corps is to occupy towards the Volunteer Force a similar position to that held by the Medical Staff Corps towards the army, and upon the highest scale of efficiency, including field hospital and bearer company's work, to organise a system of ambulance work.

FATAL ACCIDENT TO A LIVERPOOL PRACTITIONER.—Mr. Arthur Clarke Walker, of Liverpool, was on the 15th

instant kicked to death by a horse in his own stable. He was well known and much respected in the neighbourhood in which he practised, and the large crowd that attended his funeral showed the deep and wide-spread regret occasioned by his death.

**INDIAN MEDICAL SERVICE.**—We learn that Mr. Cameron MacDowall, F.R.C.S., Brigade-Surgeon, whose attainment of a good service pension we recently announced, is now officiating as Deputy Surgeon-General in Bombay, during the absence on leave of Mr. Bruce. Mr. T. G. Hewlett, C.I.E., Deputy Surgeon-General and Sanitary Commissioner with the Government of Bombay, has been granted three months' leave of absence, and Mr. MacRury, F.R.C.S., S.Sc.C. (Cantab), is appointed to act for him. Mr. E. Tully, Acting Superintendent of Vaccination, Western Guzerat Circle, is also granted leave of absence. Dr. D. F. Keegan, Surgeon-Major, and Residency-Surgeon, Indore, has obtained three months' leave, and Mr. R. Caldecott, Medical Officer, 2nd Regiment Central India Horse, is appointed to act for him, and Mr. Lowdell officiates for Mr. Caldecott in that regiment.

**THE PRUSSIAN TRICHINA INSPECTION.**—According to Dr. Eulenberg the inspection of pigs for trichinae is carried on to a much greater extent than is generally supposed. In one year there were established in Prussia not less than 20,636 official inspection-stations. About four million pigs were inspected, among which were found 2,000 that were trichinons—that is, about one in 1,232. In Berlin there were 237,593 pigs examined, and the yearly expenses in that capital for this purpose amount to more than 237,000 marks. (11,850*l.*)—*St. Petersburger Medicinische Wochenschrift*, September 5.

**THE REJECTION OF A PARIS THESIS.**—The rejection of a thesis by the Paris Faculty of Medicine has recently caused much excitement, not indeed in the profession, but amidst the general public, in consequence of the fact having been published in the lay journals. It was the title of the thesis (Contribution to the History of Artificial Fecundation), and its preposterous statistics that led to the popular notice of its rejection, which was attributed by the papers to the squeamishness of the Faculty in relation to a subject which they considered as indecent. This proves to be all nonsense; for in a letter published by Prof. Pajot, he declares that the question of the morality of the thesis never arose, and that it was unanimously rejected in consequence of the utterly non-scientific character of the facts it professed to bring forward. As to the operation of artificial fecundation, although its performance should be quite exceptional, it has now obtained recognition by the Faculty and by the most recent writers on obstetrics and gynaecology. In the present case the writer of the thesis, 50 years of age, who is an *officier de santé*, desirous of obtaining the doctor's degree, states that during the last 10 years he has been consulted for 518 sterile marriages, in 56 of which the prolonged employment of medical means led to normal fecundation. In the remaining 466 cases artificial fecundation was resorted to, and in 143 of these with success. In 48 there was complete failure, and in 275 what is termed relative failure. It would indeed have been surprising had the Faculty allowed such a statement as this to have passed.

**A MODE OF GIVING A BATH IN TYPHOID FEVER.**—Professor Horatio Wood (*Therapeutic Gazette*, July 15th), in order to avoid moving the patient in and out of the bath, adopts the following procedure:—"The canvas of an ordinary bed-cot is to be made three or four inches wider than usual, and a broad board nailed at each end so as to hold the cot permanently open, and project above it several inches in the form of a head or footboard. This cot is then arranged alongside of the bed of the patient, so as to be on a level with it, and at the same time firm. Over it is spread an india-rubber cloth sufficiently large to cover it entirely and to fall above and below over the head and footboard. The patient, wrapped in a sheet, is then slipped on to the cot, the canvas sagging down, and when water is poured over the sheets, the man lies half immersed in a pool. The attendant is provided with two jugs, one containing water and the other empty, and with a large bathing-

sponge. The water in this pool, heated by the body, can be removed by the sponge, and fresh cold water soused over the body enveloped in the sheet. In this way, the water lying continually between the sheet and the body, as well as saturating the sheet, so envelopes the person that the effect of a cold bath can be achieved, and I have seen very rapid reduction of very high temperatures. If the bed upon which the patient lies be a very wide one, the mattress can be so arranged on one side as to sag down sufficiently to form a hollow for the pool, and in this way the bath be given."

**ETHERIZATION OF THE RECTUM IN CHOLERA.**—Rectal etherization has been practised in the Hospital in Granada in fifteen cases of cholera with the idea of killing the comma bacilli by surrounding them with an atmosphere of ether. Two of these cases were cured within twenty-four hours, one died, while the remaining twelve improved rapidly.

**NO LACK OF MEDICAL MEN IN GRANADA.**—It has been stated that there is such a lack of medical men in Granada, and that there large numbers of people have died without medical assistance. The *Correspondencia Médica* referring to this, says that it is quite true that many have died without the aid of any medical man, but the reason of it is that the Municipal Authorities treat them very badly, although expecting them, family men as they are, to run into danger like martyrs or like priests and sisters of charity, whose lives are supposed to be given up to doing good, and who have no one depending upon them for support; the same amount of self-denial can hardly be expected from the profession especially after the way in which it is treated.

**DR. GIMENO'S DEFENCE OF ANTI-CHOLERA INOCULATION.**—One of Dr. Ferrán's great supporters, Dr. Gimeno, a professor of the University of Valencia, in a lecture given before a Madrid Scientific and Literary Society, complains of the false statistics on which so many of the attacks on Ferrán's method have been founded. He himself produces statistics of the value of which he is satisfied, to show how cholera has been practically stamped out of a town in a few days when the great majority of the population have submitted to the process. It must be remembered that, according to Ferrán himself, the prophylactic effect of his inoculation does not begin to take effect for five days. The Town of Benifayó contained 3,615 inhabitants; before the inoculations were commenced there were from fourteen to eighteen deaths per diem. From the 24th to the 30th of June 2,313 people were inoculated, some of them a second time. From the 2nd to the 5th of July, thirteen of the non-inoculated and five of the inoculated died, and from the 6th to the 8th two of the non-inoculated and none of the inoculated. In another town containing 5,227 persons, 3,117 were inoculated between the 30th of June and the 3rd of July. From the 1st to the 5th of July, thirteen of the inoculated were attacked with seven deaths, but from the 6th to the 8th, none of the inoculated were even attacked.

**PRESERVATION OF SOLUTION OF COCAINE.**—In relation to Dr. Squibb's employment of salicylic acid for the preservation of cocaine, subsequent experience has seemed to prove that this substance, even in the minute percentage employed, adds to the irritant effects of the alkaloid. Dr. Squibb has therefore been trying the value of boric acid for this purpose. His researches have been going on for six months, and although these are not complete, enough has been ascertained to show that the employment of a 1 per cent. solution of this substance preserves the cocaine without producing any irritant effects.—*Therapeutic Gazette*, July 15.

**CHARITABLE BEQUESTS.**—Mrs. Catherine Watkinson, late of Earl's Colne, Essex, has bequeathed 200*l.* each to the Colchester Hospital and the Essex Idiot Asylum. Miss Martha Gape, late of St. Michael's, near St. Albans, Herts, bequeathed 50*l.* to the St. Albans Dispensary. Mr. Thomas Smith, merchant, late of Ashwood, and Mr. John Mitchell, merchant, late of Arugask, Fifeshire, have each bequeathed 1,000*l.* to the Dundee Infirmary.

**A NEW TEST FOR ALBUMEN IN THE URINE.**—In the *Medical Chronicle* for September, Dr. Thomas Harris details the results of a series of trials with a test first suggested by Dr. William Roberts about a year ago. The test consists of a mixture of one volume of strong nitric acid with five volumes of a saturated solution of magnesian sulphate. It forms a very dense fluid which is as clear as water, does not fume, and does not stain or burn anything with which it may come into contact. It is used exactly in the same way as the cold nitric acid test, and care should be taken in adding the urine to slope the test tube so as to avoid as much as possible a free mixing of the urine with the test solution. If albumen be present, a well-defined band will be formed exactly at the line of junction of the two fluids, its degree of opacity varying with the amount of albumen, but it is always sharply defined, and just at the junction. When the quantity of albumen is very small, some little time may be required for its development. This test also precipitates mucin; the ring thus formed appears just above the junction of the urine and test fluid; it is broader and less dense than that indicative of albumen, and shades off gradually above and below. This test further possesses the advantage of giving no reaction with the peptones, and it does not liberate iodine from the urine in the case of persons taking iodide of potassium to the same extent that nitric acid does, and is therefore suitable under such circumstances for the recognition of small quantities of albumen. Dr. Harris proposes to call this test the magnesian nitric test.

**POISONING BY MORPHIA IN AN INFANT.**—Dr. Judkins, of Cincinnati, reports (*New York Medical Record*, August 8) a case of morphia-poisoning in an infant 50 hours old, a quarter of a grain in solution having been given by mistake for the relief of colic. This dose was repeated an hour afterwards. Dr. Judkins saw the child two hours after the first dose had been taken and found it cyanotic, with very feeble respirations, three per minute, and a pulse hardly perceptible. Immersions in hot water and injection of whisky into the gastrocnemius were resorted to, strong coffee also being administered by the mouth and anus. After two hours of constant work, respiration increased in frequency, and the action of the heart became stronger. Eventually recovery took place, and when seen ten weeks afterwards, the child was quite well. The catheter had to be used several times during the first 24 hours, and three abscesses were produced by the frequent introduction of the hypodermic needle.

**EXAMINATION OF THE VOMIT IN SUSPECTED POISONING.**—The *Indian Medical Gazette* for July observes that a number of cases of criminal poisoning in India (and we may add elsewhere also), are supposed to escape detection owing to the vomited matter not having been chemically examined. In vain have medico-legal works and regulations insisted upon the necessity of forwarding for examination not only the stomach itself, but its contents and the vomited matter. The following case, taken from the Report of 1884, of the Bengal Chemical Examiner, illustrates the importance of the subject. The subject of the case mixed for his dinner some curry which had been left from breakfast with freshly cooked rice; and while eating the food was seized with a burning sensation in the throat, vomiting, and purging, and died next day. There were forwarded for examination the stomach, containing a thick rose-coloured fluid, two pieces of liver, the matter vomited, and some of the mixed curry and rice of which the deceased was partaking when seized with the violent symptoms. On analysis, no poison was detected in the stomach or its contents, nor in the liver; but aconite was found both in the vomit and in the food. The quantity which had become absorbed was evidently just sufficient in amount to cause death when superadded to the effects of the gastro-intestinal irritation. The quantity in the liver and stomach was inappreciable. The great bulk of the poison had been evacuated by vomiting, when it had excited locally its irritant effect upon the stomach. Hence, had only the stomach and its contents, as they existed at the time of the necropsy, been forwarded for chemical examination, the poison would not have been detected.

## APPOINTMENTS.

BERRY, GEORGE A., M.B., C.M., F.R.C.S.—Ophthalmic Surgeon to the Royal Infirmary, Edinburgh.  
BOUGHTON, WILLIAM BLOCKLEY, L.R.C.S. Edin., L.S.A. Lond.—Medical Officer to the Third District, Dursley Union, *vice* Mr. D. W. Morris, resigned.  
LITTLETON, PHILIP R., M.R.C.S. Eng.—Medical Officer to the Workhouse, Ashbourne Union, *vice* Mr. H. Greaves, deceased.  
McRITCHIE, DONALD, M.B., C.M., L.R.C.S. Edin.—Medical Officer to the Huntingdon District, Huntingdon Union.  
MEASURES, J. W., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Stansfield District, Todmorden Union.  
PASTEUR, W., M.D., M.R.C.P.—Physician to the North Eastern Hospital for Children, Hackney Road, E.  
ROXBURGH, DAVID, M.B., C.M.—House Surgeon to the Isle of Man General Hospital and Dispensary.  
SEMPLER, JAMES ROBERT, M.B., C.M. Glasg.—Medical Officer to the East District and to the Workhouse, Whitby Union, *vice* Dr. E. M. Taylor, resigned.  
SHEEHAN, JAMES CURTIN, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Laveulani District, Cosford Union, *vice* Mr. F. T. Barkway, deceased.  
SLOMAN, HERBERT, L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the South District, Farnham Union, *vice* Mr. S. G. Sloman, resigned.  
WARNER, F. A., M.R.C.S., L.S.A.—House Surgeon to the Belgrave Hospital for Children, S.W.  
WILLIAMS, W. T., M.R.C.S., L.S.A.—Medical Officer to the Hednesford District, Cannock Union.  
WILSON, FRANCIS, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Workhouse and the Third District, Keighley Union.

## VACANCIES.

BEDFORD GENERAL INFIRMARY.—Surgeon-in-Ordinary. Candidates must be legally qualified to practise both in Surgery and Medicine, and be duly registered. Applications and testimonials to be forwarded to the Secretary on or before October 8th.  
BERWICK-ON-TWEED UNION.—Medical Officer for the Workhouse, in succession to Mr. Thomas Fraser, resigned. Salary, £50 per annum.  
HARDINGSTONE UNION.—Medical Officer for the Bradfield District, in succession to Mr. F. W. Thurnam, resigned. Area, 10,961 acres. Population, 2,904. Salary, £45 per annum.  
MALE LOCK HOSPITAL, 91, DEAN STREET, SOHO.—House Surgeon. Salary, £50 per annum, with board and lodging. Candidates must be Members of the Royal College of Surgeons. Applications with copies of testimonials to be sent to the Secretary, Lock Hospital, Harrow Road, W., on or before September 30th.  
RISBRIDGE UNION.—Medical Officer for the Fourth District, in succession to Mr. G. R. M. Wright, resigned. Area, 9,029 acres. Population, 1,782. Salary, £14 10s. per annum.  
ROYAL UNITED HOSPITAL, BATH.—House Surgeon.  
SETTLE UNION.—Medical Officer for the Long Preston District, in succession to Dr. Lazenby, deceased. Area, 16,295 acres. Population, 1,620. Salary, £10 per annum.  
TAUNTON AND SOMERSET HOSPITAL.—Honorary Physician. Candidates must have taken the degree of Doctor of Medicine, or be Fellows or Members of one of the Royal Colleges of Physicians of London or Edinburgh, or of the King and Queen's College of Physicians in Ireland, and be duly registered under the Medical Acts. Applications, accompanied by qualifications and testimonials to be sent to the Secretary, on or before October 14th.  
WARRINGTON UNION.—Medical Officer for the Schools at Padgate, in succession to Mr. Spinks, resigned. Salary, £35 per annum.

## DEATHS.

GAY, JOHN, F.R.C.S., at 51, Belsize Park, Hampstead, on Sept. 15th, in the 73rd year of his age.

## NOTES, QUERIES, AND REPLIES.

### THE CASE OF DR. BRADLEY.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—I beg to forward a further list of subscriptions; will you kindly allow it to appear in the next issue of your Journal?  
I remain, yours faithfully,

ROBERT JEFFREYS.

*Eastwood House, Chesterfield, September 23rd, 1885.*

Dr. A. Halliday Douglass, £2 2s.; Dr. George Pearce, Dr. W. Vawdrey Lush, Mr. T. Jenner Verrall, Mr. H. Greeuway Howse, Dr. Edwin Rayner, Mr. T. Simpson, Mr. J. H. Ewart, Mr. A. E. Barker, each, £1 1s.; Mr. Sammel Lodge, 10s. 6d.; Mr. W. H. Beverley, 10s.; Dr. Charles W. Cathcart, Dr. A. Sloane, each, 5s.

### THE GRAHAM FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

DEAR SIR,—Kindly insert the following additional subscriptions to the Fund which is being raised for the family of the late Dr. A. F. Graham, of Liverpool. Further contributions to this charitable fund will be thankfully received by any Member of the Committee, or by

Yours faithfully,

JAMES BARR, Hon. Sec.

1, St. Domingo Grove, Liverpool, September 23rd, 1885.

Edward Lund, Esq., F.R.C.S.; W. B., each, £3 3s.; W. Marrant Baker, Esq., F.R.C.S.; J. A. Harris, Esq., M.D.; T. G. Harrower, Esq., each, £2 2s.; Dr. Henry Stear, £2; A. Butterworth, Esq.; Rev. J. E. Cleworth; Dr. James Hall (Preston); Rushton Parker, Esq., F.R.C.S., each, £1 1s.; A. B.; Mr. Drape, each, £1; Dr. John Brown (Bacup), 10s.

*F.R.C.S.*—The individual in question is not a medical practitioner.

*E. A. Stevens.*—Your conduct seems to have been perfectly justified.

*B. P.*—You will get it more cheaply through a bookseller.

*Fiat Mistura.*—Carbolic Acid and Spirits of Chloroform in equal parts.

*Acetabulum.*—If payment is made quarterly, the principal would be justified in demanding a quarter's notice, though it is questionable whether he could enforce it.

#### COMMUNICATIONS RECEIVED—

Professor GAIRDNER, Glasgow; Mr EDMUND OWEN, London; Mr. J. D. CAMPBELL, London; Dr. CHAPMAN, Paris; Dr. T. MAXWELL, Woolwich; THE SECRETARY OF THE MASON SCIENCE COLLEGE, Birmingham; Mr. GERARD SMITH, London; OUR BOMBAY CORRESPONDENT; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; THE HON. SECRETARY OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY; Mr. CHAS. LUNN, Edgbaston; Dr. CHAS. DULLES, Philadelphia; THE SANITARY COMMISSIONER OF THE PUNJAB, Lahore; Dr. WILLOUGHBY, London; Dr. EARDLEY-WILMOT, Leamington; Dr. HERBERT WATNEY, London; OUR BERLIN CORRESPONDENT; OUR LIVERPOOL CORRESPONDENT; Mr. PLOWRIGHT, King's Lynn; Dr. NORMAN CHEVERS, C.I.E., London; Dr. FOWLER, Glenlivet; THE REGISTRAR-GENERAL FOR ENGLAND, London; Mr. E. WOOTON, London; Mr. ROBERT RAE, London; Mr. STONE, Wimbledon; Mr. JAS. DIXON, Dorking; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; Messrs. CASSELL & Co., London; Mr. GEO. COWELL, London; THE SECRETARY OF THE SOUTH LONDON SCHOOL OF PHARMACY, London; Mr. R. JEFFREYS, Chesterfield; Mr. N. C. DOBSON, Clifton, Bristol; Mr. H. C. FOX, Stoke Newington; THE HON. SECRETARY OF THE GRAHAM FUND, Liverpool; Mr. WHEELER, Ilfracombe; THE PRESIDENT AND FELLOWS OF THE ROYAL COLLEGE OF PHYSICIANS, London; Mr. READ, Harbury, Leamington.

#### BOOKS RECEIVED—

Quarterly Bulletin of the Clinical Society of the New York Post-Graduate Medical School and Hospital—Tabular Statistics of One Hundred Cases of Urethral Stricture treated by Electrolysis, etc., by Robert Newman, M.D.—A New Bandage for Fixation of the Humerus and Shoulder-Girdle, by Charles W. Dulles, M.D.—Eminent Doctors, by G. T. Bettany, M.A. (Camb.), B.Sc. (Lond.), F.L.S.—Histoire du Choléra aux Indes Orientales avant 1817, par J. Semmelink—Alpine Winter in its Medical Aspects, by A. Tucker Wise, M.D., F.R.C.P., M.R.C.S.—Imperial Maritime Customs in China—Medical Reports for the half-year ended September 30, 1884—Report of the Manchester Royal Infirmary and Dispensary, etc., from June 25, 1884, to June 24, 1885—Report of the Chelsea Vestry for 1884—Proceedings of the Geographical Society of Australia in Fitting-out and Starting the Exploratory Expedition to New Guinea—Complete Laceration of the Perinaeum and Part of the Recto-Vaginal Septum, etc., by A. B. Cook, A.M., M.D.—Zur Impfung mit Animalen Lymphe, von Dr. Kornfeld, Grottkau—Health Lectures for the People, Vol. VIII.—Clinical Studies on Diseases of the Eye, by Dr. Ferdinand Litter von Arlt, Translated by Lyman Ware, M.D.

#### PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Weekblad—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—Journal of the American Medical Association—Revue de Médecine—Revue de Chirurgie—The Dublin Journal of Medical Science—Journal of Cutaneous and Venereal Diseases—Scienze Mediche—The Daily Free Press, Sept. 15, 17, and 21—The Norwood Review, Sept. 19.

### HOSPITAL OPERATING DAYS.

**Monday.**—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopaedic, 2 p.m.; Chelsea Hospital for Women, 2.30 p.m.

**Tuesday.**—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

**Wednesday.**—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopaedic, Great Portland Street, 10 a.m.

**Thursday.**—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

**Friday.**—St. George's (ophthalmic operations), 1½ p.m.; Guys, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

**Saturday.**—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF THE NEW BUILDINGS OF THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

By GEORGE COWELL, F.R.C.S.,  
Senior Surgeon to the Hospital.

SIR RUTHERFORD ALCOCK AND GENTLEMEN,—I hardly know whether I ought to be the more gratified or the more dismayed that it has fallen to my lot to deliver the first lecture in this the chief theatre of our new School buildings. In either case my thanks are due to my colleagues for the honour that they have conferred upon me, and although it would have given both you and me greater pleasure to have listened to the Senior Physician of the Hospital, Dr. Sturges, it was his wish that I should occupy this place, and I should ill discharge the duty that has devolved upon me if I did not recognise to the full the importance and responsibility of the task and the difficulty of adequately performing it. Accepting this responsibility with some reluctance, I yet feel that it is no mean privilege to be permitted to inaugurate not the opening of an ordinary winter session, but the commencement of a

Vol. II. 1885. No. 1840.

new era in the history of our School. It is both a privilege and a pleasure within these walls the many old friends who are with us to-day, the past and present students, my former and present colleagues, and the new students who come amongst us for the first time—to welcome you all to the large and commodious buildings in which we are assembled, and to congratulate you on the possession by the Westminster Hospital of a local habitation for its school, worthy in all respects of its high purposes, on the possession of theatres and laboratories, of a museum and a library, in which its career of usefulness to the community at large may be conveniently and successfully fulfilled.

I think, perhaps, that I shall be pardoned if, instead of speaking of the subjects that have to engage the attention of the medical student and the usual topics of an introductory lecture, I speak to you mainly of how it has come to pass that we are opening to-day this excellent new building. I have written a short account of the Hospital and School for the first volume of our Hospital Reports, and therefore it is not necessary now to give you more of the history of the school than is required to establish a few important facts that are necessary to the purpose that I have in view, that of establishing our *raison d'être* in this place.

Although our hospital dates from the year 1719, our medical school was not established until 1834, the year in which the present hospital was opened in the Broad Sanctuary. The first introductory lecture was

delivered by Mr. Guthrie on the 1st of October in that year, and this is the 51st anniversary of it. In the early part of the century the only hospitals that had medical schools attached to them were St. Bartholomew's, the London, Guy's, and St. Thomas's. All the rest of the medical schools in London were private schools, not attached to hospitals, although some of them were attached to dispensaries. Of these private schools there was a large choice. The most famous of them were Grainger's School in the Borough, frequented chiefly by St. Thomas's and Guy's men; the Aldersgate Street School, attended by London Hospital and St. Bartholomew's men; the Great Windmill Street School, founded by William Hunter; the Little Windmill Street School, at which Messrs. Tuson and Guthrie used to lecture; and the schools of Brookes, Dermott Lane, and several others. Students in those days first selected the hospital that they wished to attend, and then the school or schools which appeared to be most conveniently situated in relation to the hospital, or which possessed the most popular teachers. The advantage of an intimate connection between hospital and school only gradually became recognised. Managers of hospitals used to be opposed to the patients being in any way utilized for teaching purposes. How completely this was formerly the case is well shown by the records of our own hospital. Nearly a century before the establishment of the medical school we find a minute forbidding the surgeons "to take any cub or cubs, or receive any fee or reward for admitting any persons to the practice of the infirmary," as it was then called, "their apprentices excepted." The rule was gradually relaxed and then removed. We find the same objection animating the minds of the managers of the large infirmaries of the Metropolitan Asylums Board at the present time, and instead of at least one of these excellent institutions being attached to each hospital possessing a medical school, and periodically used for teaching purposes, a large amount of valuable material, maintained at great cost to the ratepayers, is not permitted to make that return to the community which it would do if it were available for the training of doctors for the service of the public.

But to revert to the period of private schools: a change of feeling was gradually growing, and in the third and fourth decades of this century we not only find all the hospitals establishing medical schools of their own, but two new flourishing schools, University and King's Colleges, soon discovering the necessity of making the circle of medical training complete, and exerting themselves to obtain funds to build themselves hospitals for the express purpose of teaching. Our School was founded in Dean Street by Mr. Guthrie and Mr. Hale Thompson, surgeon and assistant surgeon to the hospital, Dr. Robert Bentley Todd, afterwards the distinguished teacher of physiology at King's College, and several others, and although the Committee of the hospital had sanctioned its being called the Westminster Hospital Medical School, the opposition to it on the part of some of the staff and others was so strong that the Governors on a ballot declined to permit it, and it was therefore called the Westminster Medical School. In 1841, however, the majority of the Governors at last recognised, to quote the words of their own appeal, "the paramount importance of a School of Medicine in connection with the hospital." The school premises were bought up, and from that time to this the school and hospital have been more or less closely connected, the school receiving the name of the Westminster Hospital School of Medicine.

The occupation of Dean Street lasted only fifteen years. In order to carry out the construction of Great George Street and Parliament Street, the Westminster Improvement Commissioners in the year 1848 served a notice of ejection on the

school, and in the following year Dean Street and its buildings were swept away, and premises were obtained close to Princes Street, not far from the back of the hospital, and here the school was constructed and opened in 1849 with an introductory lecture by Mr. Benjamin Phillips, F.R.S., one of the surgeons to the hospital and the lecturer on surgery.

The school was, however, in three years again homeless. The Commissioners of Her Majesty's Woods and Forests in granting a 40 years' lease had retained the right of terminating it at 12 months' notice if the land were required for Government purposes. That contingency speedily arose, as the Government of the day determined to build the Stationery Office at the back of the Hospital, the site including the school buildings. Fortunately, the Governors of the hospital came to the rescue, and, in spite of very considerable opposition, the school buildings were constructed at the back of the hospital on hospital ground. The third new school was commenced in June, 1852, and was opened in October of that year with an introductory lecture by Dr. Basham. Thus, then, it was that the hospital became the home of the school for the 33 years which terminated with the last summer session. It has seen many vicissitudes, but in its popularity, in the number of its students, in the completeness of its teaching, it has, I venture to believe, steadily advanced in spite of many difficulties. With the increase in the number of the students and the sub-division of the subjects taught, additions to the school buildings became necessary from time to time until the whole of the ground at the back of the hospital was covered with laboratories, and it became apparent not only to the Lecturers of the school, but also to the Governors of the hospital, that any further improvement of the school buildings and any extension of the out-patient and casualty departments were impossible from want of space.

Much has of late years been done by the Governors to improve the efficiency of the hospital. The first step taken, and a most important one, was to improve the nursing. I remember well the opposition and discussions that took place in the Board Room of the hospital on this matter. The nursing, with little exception, was thoroughly bad. A false economy had prevented any increase in the wages of the nurses, with the inevitable result of obtaining the supply from a lower and lower class. It is not surprising that amongst the nurses at that time were found some of the class immortalized by Charles Dickens, who were capable of drinking the patient's brandy, and, if need be, of even utilising the patient's pillow for their own comfort. All this was swept away. The new nurses were women of a higher class, properly trained for their work. The cost of the nursing was doubled at a single bound, but never was money better spent. The advance that has taken place in sick nursing during the last 12 or 15 years has been most remarkable. The work has attracted a class of women than whom none perform their duties with more devotedness, with more zeal, and with more efficiency. I am glad to say that Westminster has profited to the full from this advance. No one was more keen in this reform, or more gratified with its success, than the late Dr. Francis Anstie, whose early and irreparable loss to both hospital and school we have never ceased to regret. But this success was largely due to one who has most ably steered us through the opposition which has threatened all our reforms, one who has truly been the hero of a hundred fights, I mean our Chairman of to-day, Sir Rutherford Alcock. To him our indebtedness in the past is immeasurable, and our thanks may very appropriately be expressed in this building, for without Sir Rutherford's valuable aid these walls might never have been erected.

One reform leads to and necessitates another. Improved nursing required increased accommodation for nurses, and by very contrast made our long recognised sanitary defects more apparent and more urgent of destruction. The next considerable reform that was carried to a successful issue was the series of sanitary improvements effected by means of towers and bath-rooms, the construction of an additional story, the laying down of polished parquet floors and the provision of isolated wards, improvements so well known to Westminster men that I need not occupy your time by describing them. Suffice it to say that these improvements carried out by the Governors and friends of the Corporation from the plans of Mr. Stephen Salter, at the considerable cost of some 18,000*l.*, brought our hospital up to date in sanitary matters, I believe that our wards will now compare favourably with those of any hospital in the Kingdom. They are as healthy and as airy as is possible in a hospital surrounded by a large population.

These improvements rendered the wards for the in-patients, and the accommodation for the nurses all that could be desired, but little or nothing had been done for the out-patients and medical school. These two departments were literally hugging each other to death, and their defects were rendered only more apparent by the improvements already effected. It was evident that room for growth must be obtained for both in the only way that was possible, viz., by the purchase of a site outside the hospital for the accommodation of the school, and the utilization of the space vacated for the construction of a convenient out-patient department.

The proposal to purchase a new site was first publicly announced by H.R.H. the Prince of Wales, who, when presiding at a dinner held at Willis's Rooms, five and a half years ago, described the defects of both out-patient rooms and school buildings. Again a large majority of the governors took up this question, and generously supported the appeal that was made for funds. There was some delay in finding a suitable site, land being very dear in Westminster. We long entertained the hope that a site sufficient for our purpose might have been obtained at a reasonable cost in Princes Street, close by the hospital, and there are several reasons why this position would have been desirable. At last, the site on which we are now assembled was offered to us. It is five minutes walk from the hospital, and close to the site in James Street and Castle Lane, occupied for 101 years by the old Westminster Hospital. Although it is a little further from the present hospital than some of us desired, still its size and situation had much to recommend it, and the freehold was secured by the hospital for about 4,600*l.*, the school and staff, however, contributing largely towards it. The next step was, of course, to get plans and a rough estimate of the cost of the required building. These were supplied by Mr. Salter, who had previously most kindly discussed other sites with us, and had even submitted plans for one or two of them, and we found that our building would probably cost some 9,000*l.* in addition to the cost of the site. This was a serious outlay to face. The President and Governors of the hospital have most generously helped us to raise a good part of it, and the rest will be lent to us at a moderate rate of interest, and our thanks are due to all who have helped us, either as contributors, or as members of the House Committee, and they are especially due to His Grace the Duke of Westminster and to Sir Rutherford Alcock, and the other members of the Building Committee who have helped us to carry our work to a successful issue. I am sure that the whole of the Governors are now thoroughly alive to the advantages of having a medical school attached to the hospital,

that they recognise the fact that the more efficient the medical school can be made, the more efficiently the work of the hospital will be performed, and the better resident officers, and dressers and clerks they will get. Both hospital and school will be great gainers by the opening of this building. The governors will at last be enabled to construct an out-patient department worthy of the institution. The required new buildings will not only afford greatly extended accommodation for out-patients and casualties, but also space for a new chapel, and more rooms for the use of resident officers and nurses. The hospital has raised only a small portion of the 8,000*l.* that will be required for the erection and completion of these proposed buildings. The governors of the hospital have done so much for us, that I should be indeed glad if some old pupil or friend of the school could be the means of obtaining a substantial part of this sum. Even our own wants are not yet satisfied, although they must be second to those of the hospital. The school has many expenses and scholarships, which have to be met before the teachers, however hard they may work, can receive one penny of remuneration. Its expenses will be largely increased in this place. It does not possess, like some of the larger schools with which it has to compete, any endowment, except for a few of its prizes, and an endowment fund of some 5,000*l.* would place our school in a satisfactory financial position. There is one other addition to the hospital which is very near my heart, and I will take this opportunity of making it known, viz., a home in the country, not too far away, for our convalescent patients. There are many persons who take great interest in this class of institution, and if their attention could be drawn to this want of ours, an immense boon might be conferred upon many of our hospital patients.

I must not omit to say a few words about the excellent building that Mr. Salter's admirable plans have provided for us. Mr. Salter had several difficulties to overcome, one being the peculiar shape of the site. His object has been to give us a compact, conveniently arranged, moderately sized building with a maximum of light and air in its various rooms, and especially in the laboratories and theatres. I think that your verdict to-day will be decidedly a favourable one. There are two theatres besides the one in which we are assembled, one seated for 60 students, the other for 50. The dissecting room is well proportioned, and being at the top of the building is light and well-ventilated. The museum, I think Mr. Salter will tell us, is the feature of the building: it adjoins this theatre, and I will leave you to judge for yourselves as to its merits. I will only say that it is a great contrast to the museum that we have vacated in the hospital. The laboratories, and especially those for histology, are splendidly light. The committee room and the library are large handsome rooms, and the rooms of the students' club, where meals can be obtained without leaving the building, and which will be set apart for the social work of the institution, just as all the rest are intended for genuine hard work of a more strictly scientific kind. I may add that the building has been constructed solidly and well by the contractors, Messrs. Higgs and Hill. I trust that this brief description of our new building will convey to you the idea of one harmonious whole, sufficiently extended to prevent departments in any way clashing, and yet presenting the compactness of a small school, a characteristic which I trust that Westminster will ever retain.

And here let me pause for a few minutes to remind the younger students, and especially you who are entering upon your medical career to-day, that the comfortable and convenient arrangement of our new building and the hygienic condition of the rooms are

matters of great importance to you. This building will, to a great extent, be your home for nearly four years. With the exception of the vacations, you will spend the greater part of every week-day in it. You will know every part of it, acquire a preference perhaps for certain rooms associated with favourite branches of study. Let me advise you to regard it as a home, and to remember that the years that you spend in it will be the most important in your lives. I think it is Southey that says that, "Live as long as we may, the first twenty years form the greater part of our lives. They appear so when they are passing; they seem to be so when we look back to them; and they take up more room in our memory than all the years which succeed them." It is the last portion of that period which you will spend here, and it is worth remembering that your subsequent career, your success in life, will depend very much upon the way in which you utilise them, the extent in which you succeed in making yourselves at home in this place. Introductory lecturers are wont, on these occasions, to speak of the nobleness of the profession upon which you are about to enter. I will give you credit for having already formed a high opinion of that profession; but whether or no you expect to deserve the description given by Homer to Machaon, one of Agamemnon's surgeons, when he called him *ισόθεός φῶς*, you will approach more nearly to the god-like light the more completely you utilise the four years that you spend in this place.

There are two qualities that will help you more than any others not only to ensure your own success, but to uphold the dignity of your profession. They are *enthusiasm* and *chivalry*. Let me begin to-day to inspire you with *enthusiasm*, enthusiasm for the profession that you have chosen; enthusiasm in the lecture room, in the laboratory, and at the bedside. I believe that one reason why teaching by lecture has held its ground, and especially in medical schools, is the necessity for the personal communication of enthusiasm from the teacher to the taught. The best lecturer is he who has a power of creating enthusiasm in the individuals of his class, a power which is unequally distributed, but which all teachers should cultivate because of its extreme importance. Enthusiasm will attract you to work at once, and prevent the wasting of the first session, a loss which you can never make up. Enthusiasm will lead you to study to the very bottom of each subject that you take up, whether it be in natural science or in the more practical subjects, the pathological and clinical study of disease. Enthusiasm will enable you to estimate the proportionate value of these branches of study, and whilst leading you to secure every opportunity of studying pathology, will also prevent the fascinations of pathology from over-shadowing the cultivation of clinical observation. It is well to recollect that the duty of a physician is not merely to scientifically explain disease, important as this unquestionably is, but it is also to cure disease, or at all events to alleviate its distressing results. It is too much the fashion of the schools to forget this. Science and pathology are most valuable means to an end, but they lose half their value unless they be supported by a sound clinical and therapeutical experience. It is through such experience only that the facts that pathology teaches can be applied to the advantage of mankind.

Of equal importance with a spirit of enthusiasm is the spirit of *chivalry*. Do not think that chivalry is extinct. As exercised by the knights of old, by a Lancelot or a Douglas, it may be; but much of the principles which guided them ought to guide us, for to no profession or calling is the exercise of such principles more becoming. Chivalry means sympathy with suffering, fearlessness of danger, prodigality of

trouble, forgetfulness of self. I am proud to think that these are characteristics that adorn many a member of our profession. Even public acts of chivalry are by no means rare. Many an army-surgeon has won the distinction of the Victoria Cross. It was only the other day that Dr. Rabbeth, the house-surgeon at the Royal Free Hospital, lost his life by applying his lips in a case of diphtheria to a tracheotomy tube which had become blocked immediately on its introduction. Without discussing the question as to whether it was the right means of freeing the tube, we cannot but be proud of such an instance of professional heroism and forgetfulness of self.

One other instance that I will mention, occurred at the unfortunate battle of Majuba Hill. Arthur Jermyn Landon, a young army-surgeon, whom I knew well both as a boy and as a student at St. Bartholomew's Hospital (I wish that he had been a Westminster man), was wounded by a rifle bullet through the spine. His lower extremities were completely paralysed, and he knew that he had not many hours to live. Whilst lying upon the ground in this condition, he heard a wounded soldier, not very far from him, groaning in great pain. Landon, mortally wounded as he was, dragged himself along the ground to the side of this poor fellow, and administered to him a hypodermic injection of morphia with the effect of giving rapid relief to his suffering. This, again, was something more than chivalry, it was the grandest heroism. Sir Spencer Wells, who alluded with pride to this occurrence in the last Hunterian oration at the College of Surgeons, said also that Landon's photograph had found a cherished place in the photographic album of the Queen.

Gentlemen, it is not necessary to allude to such noble examples as these to show that there are higher reasons for enthusiasm in our work, higher reasons for seeking proficiency in our calling, than the desire for mere individual pecuniary success. The relief of suffering, the exploration of truth, the acquisition and extension of knowledge are each an inspiration. Professional success doubtless is a truly laudable object to have in view. Do not think me so Utopian as to believe that this can often be other than the main object in our choice of a profession. But I assert that this very object will be best and most easily attained by the possession of a real sympathy with suffering, and a genuine desire to attain and use the best knowledge within our reach for its relief. It is a miserable view to take of our profession to look upon it, to use the words of Francis Bacon, as "a shop for profit and sale, and not as a rich storehouse for the glory of the Creator, and the relief of man's estate." This, then, is what I mean by the chivalry of our profession. It is a spirit which will not only give us a zest for our work, and diminish the tendency to be always putting a money value on the aid that we are able to give, but it enables us to exercise our profession in some small degree in the spirit of the Great Physician, Who has promised that love to one of the least of His, is very love to Him. There is one other reason why chivalry is worth cultivating. It is an efficient check to carelessness. It has been truly said that more blunders in practice result from want of pains than want of knowledge. A full sympathy with our patients will render such mistakes impossible.

If I may offer you one other piece of advice, it is to cultivate some subject of interest outside your profession. It is difficult to exaggerate the advantage of this. It is the necessary tendency of the course of training for any particular profession to throw the mind into a narrow groove. You can only obtain that healthful variety so essential to the perfect health of mind and body, by seeking some other pursuit, such as cricket and football, for your muscular exercise, and

the study of some branch of art, of music, of history, or even of some special branch of science to exercise and expand your mental powers. The great object is to cultivate and exercise those powers and thoughts that are not exercised in your special work. It is only in this way that you can secure a breadth to your powers of mind and to your methods of looking at even the subjects of your own profession. With some such occupation your very holidays and intervals of recreation will be rendered more enjoyable, and made to contribute in no small measure to the culture of your whole being. Many of our profession neglect healthful recreation of this kind, and yet they are the very men to whom the reading of poetry and works of imagination, as well as one or other of the fascinating objects of study above mentioned, would go far to relieve and render harmless the vexations and anxieties of professional work. It has been well said that it is by careful culture such as this that we come to recognise the presence of emotions, yearnings, aspirations of our spiritual nature.

“ We live by admiration, hope and love ;  
And, even as these are well and widely fixed  
In dignity of being, we ascend.”

I have been carried into a digression of greater length than I had intended, but at least I have the satisfaction of feeling that I have discharged a duty, that of saying a few earnest words to show how our new students may pursue a real education and make themselves doubly welcome to us. Let me now return to our new school buildings. It may be asked, it has been asked, why, in the present unsettled state of medical education, have you expended this large sum of money in constructing these new buildings? Why, when a strong desire has been manifested to separate the early scientific portion of the curriculum from the later more practical portion, did you not organise yourselves into a practical and clinical school, instead of seeking to provide yourselves with all these new rooms for teaching Anatomy, Physiology, Biology and Chemistry? There is an old proverb that threatened men live long. It possesses a ten-fold force when applied to institutions. When I had the honour of delivering the introductory lecture in the old theatre, twelve years ago, I ventured to use the following words: “ I trust that the day is not far distant when the College of Natural Science will be distinct and separate from the Medical School. A few colleges in London would suffice for teaching Anatomy, Physiology, Chemistry, Natural Philosophy, Zoology and Botany, and then the hospital school proper would not be entered until the student had become more or less well grounded in the subjects I have named, and had passed his primary examination.” Twelve years ago this opinion was held by a few. It is much more widely held now, so far as separating the primary science subjects from those that are more strictly medical is concerned, and there is a strong desire for a regulation compelling the student to pass in the former, before commencing the study of the latter. The feeling, however, in favour of confining the teaching of the primary science subjects to a few large colleges is passing away with the necessity.

The reason for this is that the character of the method of medical teaching and learning has been progressively changing. Formerly, in the absence of books, and when theory rather than practice held full sway, the simple method of lecturing had to suffice for the conveyance of information to the student. It was, in short, his only method of learning. But now that cheap—often too cheap—literature has opened up a fresh means of acquiring information; it is to his text-books rather than the lecturer that the student too often turns. Admitting, as I am bound to do, the value

of such books, I cannot, however, assent to the proposition that lectures can be replaced by them; rather are they accessories to the professor and his course. Though leaving the necessity, if possible, stronger than heretofore, that the lecturer should be of the very best, it nevertheless does not prevent the possibility of a small school furnishing as good, or at least proportionately as large, a staff of capable lecturers as the larger institutions. Again, next to the abundance of text-books is the extended method of teaching by demonstration. Every subject has now its practical class, and the demonstrator, formerly found in the anatomy class only, is the right hand of almost every lecturer. Now, surely the method of demonstration and tutorial teaching is from the nature of the case self-limited. Whilst a lecturer may address his hundreds, the demonstrator and tutor must be confined to his tens, and for such purposes a staff of assistants often drawn from the larger colleges may without much difficulty be secured, leaving the smaller school in this respect no whit inferior to its more extensive neighbours, rich though they be in laboratories and plant. It may be said further that the desire of studying natural science is so rapidly extending that medical schools having the necessary laboratories and plant, such as ours now possess, will have to admit science students to some of their classes, or establish special classes for their accommodation.

It has been said that there are too many medical schools in London, and that their numbers should be diminished by closing the small schools or by the union of those that are contiguous. From the arguments that I have already advanced, it will be seen that this statement now obtains, and that with a progressively diminishing force, only so far as the systematic science lectures are concerned. It is only in these that there is any advantage in large classes, whilst small classes are essential for all tutorial, practical, and clinical teaching. A few years ago it happened that a number of the chairs in this School were vacant at the same time; and it appeared to a few of us to be a favourable opportunity, not likely to occur again, of ascertaining the possibility of such an amalgamation. The idea seemed at the time to be a right one, and it was undoubtedly wise to avoid the great expense of a site and building, although in many respects amalgamation was opposed to our own interests. Before filling up our vacant chairs, therefore, a few of us took steps to ascertain the feeling of a few leading members of the staff of a neighbouring large school. The overture was by some favourably received, but it was soon found that many private interests stood in the way of a union which was only possible if approached in a public-spirited manner. I only mention this attempted negotiation to show that the question of fusion had not escaped us, and that we had not been blind to the probable advantage of large classes for systematic teaching with a double set of demonstrators, clinical teachers and clinical appointments.

One of the strongest arguments in favour of the annual delivery of introductory addresses at the medical schools, is the value of the opportunity which it affords of saying a few words on questions of public interest and importance. As a profession we have few occasions of public speaking. We give our advice to individuals, and but rarely to communities. The busy lives of medical men and the nature of their vocation prevent their taking much active part in public questions, and lead them to avoid pressing forward their opinions in the council room or in the public press. But deliberative assemblies require medical advice and guidance in many social and sanitary questions. It would be well if medical men everywhere recognised their duties as citizens, and took an active part in the ordering of their towns or parishes. Membership of

the House of Commons is not compatible with a busy practice, but that assembly wants a larger infusion of medical knowledge. There are many defects in the laws relating directly or indirectly to public health, which might probably have been avoided by the aid of a greater medical experience. Professor Virchow is a most able and useful member of the German Parliament, and I am glad to see that Mr. Erichsen, after having obtained every possible honour as a surgeon, is seeking a seat in the next House of Commons. Apart from any political side that he may take, he cannot fail to prove a most useful member.

It is impossible at the end of an introductory address to enter upon the many questions relating to public health in which improvement is required, and in some of which this country is far behind others. The water supply, the drainage of towns, the dwellings for the poor, the cleansing of our houses and streets, the isolation of infection and medical relief, are all questions of national importance about which medical men ought to speak with no uncertain voice.

There is one important question which has of late been exercising the public mind, that of the restraint of lunatics. Not only have several actions against medical men for signing the necessary certificates been won, and in some of them damages obtained, but an action against the master of a workhouse for detaining a supposed lunatic was also sustained. The immediate result of this litigation has been to strike with something like dismay those who have hitherto been expected and willing to incur the responsibility of certifying as to the mental condition of persons of unsound mind, and of such as required to be detained under care and treatment. The result in the future seems likely to be disastrous. The law no doubt requires alteration in many respects, but it is important that no lunatic should be confined except on a medical certificate, whatever other safeguards it may be thought proper to add. But whilst "it is important that personal liberty should not be improperly interfered with by any abuse of the power," the exercise of the power is so important to the community that it has been held that "the medical man should not be held responsible for any mere error of judgment." In the fear of the former, judges and juries seem to have lost sight of the importance of the latter. Without convicting medical men of having acted improperly, they have failed to protect those who seem to have acted honestly and with due care. Under these circumstances can medical men be expected in future to sign certificates? I fear that they will require a large amount of public spirit to do so without a deed of indemnity from the responsible friends of the patient. And will not the result be, that many who are dangerous to themselves and others, and many who, in their own interests, ought to have a chance of recovery by being placed under proper treatment and care, will remain at large? This is no imaginary difficulty. It has already become a real one. But this is not all, for the remedy in such cases has been for the time destroyed. Lunatics found in a public place without proper attendance were at once removed by the police to the nearest workhouse, with a view to their detention until they could be drafted off to an asylum, but after the recent case, no master of a workhouse dare admit such a lunatic within his walls. A short Act was passed at the end of last session, to legalise the detention of wandering lunatics, but it will be some time before confidence is fully restored. This is not the time to discuss so large a subject as the reform of the law of lunacy, but I hope that our profession will have an opportunity of being heard, as it has much to say in mitigation of existing defects, and the dead-lock

into which those defects and the courts together have brought us.

There is another subject to which I will ask your attention for a moment—the great risk which is daily run by the travelling public from the defects of colour-blindness. In travelling by rail and sea, we place our lives in the hands of pilots and sailors, of guards, engine-drivers, and signalmen, who are obtained from a class of men of whom over four per cent. are colour blind, that is, unable to distinguish between red and green. As these are the colours generally in use in signalling on both ship and rail and by night and day, it may easily happen that a danger signal is unobserved, and a lamentable accident, resulting in the loss of many lives, be the consequence. The frequency with which danger signals were overlooked led Professor Holmgren to bring this matter before the Swedish Government, and that country has set the example, which ought to be followed by all others, of enforcing a careful examination of the colour perception of every candidate for posts in which the power of correctly interpreting signals is essential to the safety of life. Beyond the establishment of a rule of examining their employés by two or three railway companies, no steps have been taken in this country, and the government can hardly escape some responsibility for the lives that are daily risked and often lost by the neglect.

Several interesting facts with reference to the prevalence of colour blindness were ascertained by an enquiry that was instituted five years ago by the Ophthalmological Society of Great Britain. Colour blindness is rare amongst women, only four in a thousand (.4 per cent.), and even in these the defect is very slight. Amongst men the defect is much more pronounced, occurring in 2 per cent. of the educated class and 4.16 per cent. of the artisan class, or taking men generally 3.5 per cent. These defects are usually inherited, but are very much a matter of the education of the colour sense. These two facts are supported by the rarity of the defect in girls who are early brought in contact with colours, as their mothers were before them, and by the prevalence of colour blindness in isolated classes. Thus amongst male Jews the average is 4.9 per cent., amongst male Friends 5.9 per cent., amongst the deaf and dumb 13.7 per cent. As a rule, the poorer the condition of life the higher the average of colour blindness. There would seem to be indicated, then, a twofold remedy: the education of the colour sense in our elementary schools, and legislation to prevent the employment of the colour blind on our ships and railways.

There is a question which has of late been agitating the London medical world, I mean the establishment of a medical degree for the great mass of the London men. In Scotland the majority of students take the M.D. or M.B. degree. There are four Universities, whence men of average ability can obtain them: those of Edinburgh, Glasgow, St. Andrew's, and Aberdeen. In Ireland there are two Universities conferring these degrees: the Dublin University whose degrees are of a high standard, and the Royal University whose degrees are like the Scotch degrees, attainable by the rank and file of the profession. In London we are very unfortunately situated in this respect. The degrees of the University of London are of a high order, and deservedly so. I am quite willing to admit that the University of London has done much to raise the standard of medical and scientific education, still I think it would be greatly to the advantage of that body, and to the diminution of cramming, if several alterations could be made in its regulations such as a diminution in the number of subjects required for the matriculation, a decided relaxation in the severity of the preliminary scientific examination, and arrangements for holding most of the examinations twice or

even thrice a year. But even if these improvements could be carried into effect, the standard of these examinations is of a high order and beyond the power of the average student without expensively prolonging the period of study. Of late years men have been getting discontented with the titles M.R.C.S., L.R.C.P., and there has been a growing desire amongst them to obtain a University degree. If they do not possess the ability and industry or the long purse required to secure a degree of the University of London, where are they to obtain one? It may be said that they do not deserve to have one; but it must not be forgotten that they see their brethren obtaining degrees with facility in Scotland and Ireland, and even in Durham and Manchester in this country. I maintain that the examinations of the Colleges of Physicians and Surgeons in London are together equivalent to the examinations of most of the Universities that I have mentioned, and yet they confer no degree, only a long array of mystical letters, whilst the equivalent Universities confer the coveted degrees. Is it fair to the students, to medical education, to the valuable museums, libraries, and medical schools of London, that this anomaly is permitted to exist? Is it not surprising that it has not been removed long ago? Three schemes are at present before the profession.

(1) The very simple one of conferring upon the two colleges jointly the power of granting the degree of M.D. to those who have passed the conjoint examination. (2) The establishment of a teaching university with the power of regulating the teaching in four faculties and of granting ordinary degrees in them. (3) The institution of a third division at the examinations of the University of London, the first and second divisions being of the same standard as at present and the first considered as conferring honours. I think that it would be highly advantageous if both the first and second of these schemes could be carried into effect. The material in London for teaching Law, Science, and Arts, as well as Medicine is so vast that there is room for several universities side by side. There are several in some of the capitals and large cities of Europe, and we have seen that in Dublin there are two, and it is idle to suppose that one university can be sufficient for the largest city in the world and the centre of a thickly populated country. It is mainly because there is only one, that there is a tendency for students to go elsewhere for their medical degrees. I have already expressed my opinion of the University of London, and would strongly deprecate in any way watering down its degree examinations and therefore the value of its degrees. I would rather see established one or more universities of a less exalted pass standard. Such a course would give an immense impetus to teaching. I do not believe that the University of London would in any way suffer from the competition. Men of ability would continue to seek degrees of the higher value, and the increased number of students that would be attracted to London would directly benefit the old University. There need be no difficulty in the choice of a name. Westminster is known as widely over the civilized world as London, and a University of Westminster would speedily wrap itself in some of the most cherished associations of the country. The Dean and Chapter of Westminster and King's College would greatly extend their influence by the establishment of such a University, and the medical and other schools in and around Westminster could not fail to be benefited by an association with it.

But, gentlemen, I have done. I have said sufficient to show that there is a vast field of enterprise for the medical statesman. I fear that I have wearied you with the length of my remarks, but, on an occasion like the present, one is addressing a far larger audience than is gathered within these walls. I must, in conclusion, ask

you who have kindly listened to me to accept my thanks for your patience and attention. To all our students, I desire in the name of my colleagues to express a hearty wish for your success, both here and in the future practice of your profession. I trust that it may be an object with you all to strive to be a credit to the school of your adoption. If you keep this in view you will not only succeed in your work, but you will secure what you will value in after life, the esteem both of your teachers and of your fellow students.

As it is our wish that this may be realised by each one of you, so I am confident is it yours, that commencing under the happy auspices of to-day, this school in its new home may flourish.

Floreat Schola Medicæ Nocosomii Westmonasteriensis.

---

## INTRODUCTORY ADDRESS

DELIVERED AT THE OPENING OF THE MEDICAL SESSION  
AT THE MIDDLESEX HOSPITAL.

By J. KINGSTON FOWLER, M.A., M.D. Cantab.,  
Senior Assistant Physician to the Hospital, and Lecturer on  
Pathological Anatomy in the Medical School.

GENTLEMEN,—In appearing before you as the representative of my colleagues to address you at the beginning of another session of work, I cannot but feel the responsibility and difficulty of my position. Responsible it is; for, meeting many of you as I do to-day on the threshold of your student life, I might, had I the gift of eloquent speech, influence you for good throughout its course; difficult, because the frequent recurrence of the occasion has well nigh exhausted the topics which suggest themselves as suitable to it.

Let me at the outset offer you a hearty welcome to the school which you have chosen as your medical *alma mater*, a school which, if not in point of numbers among the first, in the earnestness of its teachers and the opportunities it offers you for obtaining a thorough and practical knowledge of your profession, stands second to none. To those who have to-day cast in their lot with us I would say that, whilst on our part no effort shall be spared to fit you for the work that lies before you in the future, we look to you by honest work to do credit to your teachers, and by your conduct worthily to maintain the reputation of our school.

We have met to-day to celebrate a golden wedding—the union of the Middlesex Hospital with its medical school—for in October, 1835, fifty years ago, the medical school of this hospital was opened by an introductory address by Sir Charles Bell, one of its distinguished founders. It was a union of autumn with spring, but, happily, the leisure of fifty years has given no cause for repentance on either side; domestic differences have, no doubt, from time to time arisen, but no serious rupture has ever occurred in those friendly relations which have throughout existed between the authorities of the Hospital and Medical School, and which were never more cordial than at the present time. For this we are much indebted to the representatives of the Governors, and, without a tinge of flattery be it said, to none do we owe more than to the gentleman who now so ably and courteously fills the office of Chairman of the Weekly Board.

The harmonious co-operation of the various elements which are associated in such an institution as this is secured by the sphere of action of each being well-

defined; the lay element, supreme in all matters of administration, the medical body consulted and deferred to on those subjects on which it alone can speak with authority, the nursing staff no "imperium in imperio" claiming independent action as part of a distinct profession, but occupying a position of honourable subordination. You do not need to be reminded to whom we are indebted for the efficiency and harmony which prevail in that most important department of the hospital.

It seems fitting that at this fiftieth anniversary of our foundation we should at least recall the honoured names of those to whom we owe our existence as a school. One, James Moncrieff Arnott, the Nestor of the profession, has but lately passed over to the great majority at the ripe age of ninety-one years; another, Sir Thomas Watson, the Macaulay of medical literature, preceded him by a short time only. Arnott was appointed Assistant Surgeon to this Hospital in 1831, and Surgeon two years later; Watson became Assistant Physician in 1827, both whilst holding office here were appointed to Professorships at King's College, a school which, though it has taken from us of some of our ablest teachers, has given to us others not less distinguished. A third, Alfred Shaw, still remains one of our consulting surgeons, a good friend, to whom our museum owes much, and who, as I lately found, notwithstanding his years, still takes a lively interest in everything connected with the scene of his former labours.

Our founders do not appear to have had any very lofty aims in view, for Sir Charles Bell, in the address to which I have alluded, states that the school was established in order to counteract the effects of a rival party, who had deprived of its pupils the Middlesex Hospital, the Governors of which were no sooner fully informed of the fact than they enthusiastically came forward and supplied the funds necessary to institute a medical school in connection with the Hospital. In one of the medical journals of the time some further light is thrown upon our birth by the following not too friendly notice—"The amount of the fees received at the Middlesex Hospital has diminished so greatly since the opening of the hospital of the London University that at the last division of profits only about fifty pounds a-piece fell to the share of the medical officers. The energies of these gentlemen have accordingly been roused, and being feelingly sensible that a reaction in favour of Middlesexism is impossible in the absence of those lectorial temptations to the student which are held forth at all the other hospitals, a plan has been arranged for the formation of a school connected with the charity." The reference to "lectorial temptations" reminds us of the stormy opposition which attended the institution by the licensing bodies of compulsory courses of lectures.

But, gentlemen, it matters little to us at the present day what were the motives which actuated the founders of our school. Had they been as lofty as apparently they were mundane, it would not have endured had it not proved itself no mean rival of those older and more wealthy institutions with which it has had to compete. That it has endured, and that today finds it more prosperous, and with a larger number of students than at any previous period, is the best tribute that can be given to the wisdom of its founders and the earnestness and success of its teachers.

Sir Charles Bell, in his introductory address, referred to the evidence which he had lately given before the Parliamentary Committee on Medical Reform, and on turning to the report it is curious to note how many subjects which at that time agitated the medical world, and which were discussed in the medical press with a warmth and wealth of epithet compared to

which the style of the present day is but as iced milk and water, remain still unsettled.

One of the first questions put to Sir Charles Bell was, "Do you approve of the present mode of choosing the members of the Council of the College of Surgeons?" The answer was, "Upon the whole I by no means approve of it." Sir Charles supported those who wished that every Member should have a voice in the election of the Council of the College. Whether, however, if he were now alive he would support the present agitation is not so certain, for the point in dispute, though similar, is not quite the same.

The germ of what is now called the one-portal system, and which seems by-the-by likely to remain for ever only a germ, was at that time present to some minds, for we find one member of the Committee asking whether two boards or one are the fittest in point of number to examine candidates for general practice. With the answer given we shall, I imagine, nearly all agree: "I see no necessity for more than a single Board."

Here is another question put to Sir Charles Bell which touches on a question still of much interest to physicians: "Is there any such marked distinction between the practice of the physician and surgeon as the names would import?" "Is not a large share of the practice of most of our eminent surgeons in reality medical?" The answer was, "Most of us take it as the stream flows. The public does form strange opinions and inferences, and they will make a doctor out of a surgeon in spite of all distinctions and designations." This recalls to one's mind Lawrence's celebrated definition of a surgical case as "a patient with a guinea in his pocket."

The public are as little able now as of yore to distinguish a physician from a surgeon, for should a junior member of the former class hint to sympathising ear that (probably owing to the prolonged activity and very moderate honoraria demanded by his seniors) his own great talents have not met with that ready recognition which is their due, he is consoled with the suggestion that an ancient dame of fabulous wealth may some day have the misfortune to break her leg hard by his door, when his fortune would be assured. I confess that to me it has always seemed easier to say where medicine ends than where surgery begins. Chronic bronchitis is a well-known surgical affection; measles is, I believe, at times included.

I must quote yet another question which occurs in this examination. Sir Charles Bell was asked, "Would it be desirable in your opinion that there should be a Board appointed in London to confer medical degrees with power to grant the license to practice, or should there be two distinct bodies having these separate duties entrusted to them?" Strange, indeed, that after such a lapse of time this should in nearly the same terms be the burning question of the day.

From many quarters there comes a demand that greater facilities should be afforded to the students of the London schools for obtaining a degree in medicine, and various schemes have been proposed for meeting this want. Year by year an increasing number of English students are leaving the London schools and betaking themselves to or beyond our northern border, whence in due course they return, having by "no immoderate exercise of intellect or learning" acquired an university degree, whilst others no less able or diligent who study in London find themselves at the end of their curriculum with the diplomas of the Colleges of Physicians and Surgeons, distinctions which in my humble opinion are just as honourable, and the possession of which affords as good a test of a man's professional ability as the degrees I have alluded to. But, unfortunately, it is said that the public cannot be got to understand this, and show an undue apprecia-

tion of the holders of titles. This complaint comes no doubt chiefly from the provinces, where competition appears to those who are struggling to be the keener, because their knowledge of each other and of their possible clients is more intimate.

London, with its vast population, undoubtedly affords opportunities for the study of disease which are unrivalled and unapproached by any other place in the kingdom, and it cannot but be a source of regret that students should be attracted from such a centre of clinical teaching by the temptation held out to them elsewhere of obtaining a degree upon easy terms. The amount of learning to be required from a candidate for a degree in medicine must, so long as there are many universities, remain a purely arbitrary quantity to be fixed in each case chiefly by the examiners. If the standard be a very high one it is obvious that it can only be attained by the few who require but little incentive to work; the many, seeing that the task is beyond their powers, will content themselves with some inferior title. Such an university will attract the one able man, but it will leave untouched the ninety and nine, many of whom, could they have caught but a glimpse of the goal before them, would have striven for the prize of a degree.

The older universities have wisely solved the difficulty of retaining at the same time the allegiance of talent and mediocrity by fixing such a standard for the ordinary degrees as shall place them within the reach of men of average merit, whilst in their honour examinations full scope is given for the display of abilities of a higher order. The value of honours and degrees in medicine as in arts is and will probably for long remain a matter to be determined by the judgment of the initiated; the general public are as ignorant on this as on all other subjects connected with the profession, and as little able to estimate the value of a degree as that of the various opinions they may receive about their ailments from different medical men. The under-graduate who, having come out of the mathematical tripos at the head of the junior optimes, the lowest class, informed his father that he had taken the highest place open to him, as he was not old enough for the senior optimes, and all the wranglers were married men, had very accurately gauged his parent's probable knowledge of such matters.

University honours and degrees serve to fix a man's place in the profession in the early part of his career, and are rightly considered when he is in competition with his fellows for any post of honour, in which case we look not only to his degree, but from whence he obtained it, and where he was placed in the class lists, and he receives full credit for his attainments, but beyond this such distinctions are of small value in themselves, and their possession will as little ensure success in medicine as in any other profession. For this, qualities of a very different and perhaps less distinguished order are necessary, and it often happens that the man who in his youth was unable to master more than a very limited amount of mathematics is found far ahead of the senior wrangler in the practical business of life. There may perhaps be something in the mathematical mind that is antagonistic to the world and its trivial round, for it is said, I know not with what truth, that on the rare occasions when great mathematicians unbend at the festive board, a favourite sentiment is "May pure mathematics never be of any use to anybody."

I confess that I am not one of those who wish to see every one in the profession the holder of a degree in medicine, for if the acquirement of this distinction is to be so facilitated that its possession is to become universal is it not obvious that it will cease to have any value?

Already we hear suggestions that hospital physi-

cians should cease to use the title of "doctor," a proposal which has something to recommend it, for, if it did nothing else, it would at least relieve one from a good deal of that painful and unremunerative therapeutic process which is known to our legal friends as administering an interrogatory. In this matter it has always seemed to me that the surgeons enjoy a great advantage; they are not on a casual introduction at the mercy of any hypochondriacal individual who desires their opinion on the latest and most extensively advertised nostrum, or with unconcealed satisfaction relates the last supposed triumph of a noted boue-setter. That such a change as this is by no means impossible was lately made clear to me when staying with one of the best known practitioners in a large town, the possessor of the coveted title from the highest source. On my remarking that he did not use it to attract the attention of the casual passer by in the manner which custom has unfortunately sanctioned, he replied, "No, all the decent men here call themselves Mr.; it is a distinction."

"Very curious is it," says Trench, "to watch the varying fortune of words, the honour which in tract of time they exchanged for dishonour, the extent to which it has fared with them as with persons and families, some having improved their position in the world and attained to far greater dignity than seemed destined for them at the beginning, whilst others in a manner quite as notable, have lost caste, have descended from their high estate to common and even ignoble uses. Titles of dignity and honour have naturally a peculiar liability to be some lifted up and some cast down." Notwithstanding that I feel strongly that the present rage for titles and degrees is an evil, I am convinced that it is a still greater misfortune that for the sake of a degree a student should be attracted to a school where clinical teaching can hardly be said to exist, or where the chances are nearly a hundred to one against his obtaining a resident appointment, without which, in my opinion, no man can be saved from great ignorance. We should cordially welcome any development of scientific teaching which, whilst tending to bring the profession into closer relations with the older universities, gives promise of our regaining that wide culture which was the distinguishing merit of the older school of physicians, and offers the advantage of social intercourse with men pursuing various branches of learning.

It is, however, much to be hoped that the authorities of these schools will be animated by the same wise views which have regulated the most recent development of this kind at the University of Cambridge, and will not be induced by their success in the teaching of the natural sciences to commit the great mistake of attempting to found complete medical schools—centres of scientific work they should be, but centres of clinical teaching they can never become. Let us hope that the full discussion of the various schemes which are now before us will result in the institution in London of a medical degree which shall maintain in the purely professional subjects the high standard of the older universities, and for which the requirements in the collateral sciences shall not be beyond the reach of men who are fully worthy of such a distinction.

The coming session marks the beginning of important changes in our curriculum intended to meet the requirements of the Conjoint Examining Board of the Colleges of Physicians and Surgeons. One of these, the foundation of a Lectureship in Practical Medicine, is to me a source of peculiar gratification, for I have long urged the necessity of such a step, and I feel sure that in the able hands of my colleagues, Dr. Coupland and Dr. Douglas Powell, it will be the means of removing the reproach under which, I fear, this, in common with other medical schools, has lain of

sending many men into the profession almost ignorant of medicine as distinguished from surgery. For this the College of Surgeons has much to answer, in that for many years it maintained a ridiculously inadequate examination in medicine. Happily now that it has thrown in its lot with the College of Physicians, a change has come o'er the scene, and the examination in medicine will cease to be what was little more than a farce. I well remember that in my student time the casual perusal of portions of a small black-bound manual with red edges, and the aid for an evening or two before the examination of an experienced coach, were considered quite sufficient preparation to justify a man in presenting himself at the College of Surgeons with some confidence as to the result.

Whilst, however, in the class of Practical Medicine you are learning to use and rightly value the many instruments of precision which we now daily call to our aid in the investigation of disease, do not forget that nature has given you in your own bodies senses which you may by assiduous cultivation transform into instruments of much precision. For there is great danger that in this mechanical age much of that *tactus eruditus* which was the boast of the older school may become a lost art. Strive to make a thermometer of your hands, a sphygmograph of your fingers, and, above all, learn, as my old and revered master, Sir William Fergusson, in his northern brogue would often say, to "use your eyes, mon!"

In the new class of practical midwifery you will be taught a subject which will probably when you enter upon practice transcend all others in importance. Let me urge you all to make full use of your opportunities of gaining a thorough knowledge of it; failing to do so, you may have reason bitterly to repent such negligence hereafter.

At the end of each session of Parliament a proceeding usually takes place which has come to be known as "the massacre of the innocents"; it consists in lightening the political ship by throwing overboard such cargo as cannot safely be carried further. We have this year, in obedience to the behests of the conjoint Colleges, been compelled to lighten the burden of medical lectures by throwing overboard three poor innocents—Botany, Chemistry, and Materia Medica—subjects which may now be studied previous to entry at a medical school. Studied, however, they still must be, either here or elsewhere, and those of you have done wisely who have already devoted to them a preliminary summer session. To my colleagues who have thus been deprived of some of their pupils, I would offer the consolation that they will now have a class, all of whom are drawn to them by an earnest desire to learn, not driven by the fear of an unsigned schedule, whilst they will be relieved of the presence of those gentlemen who occupied high places in the theatre, but were content with a more modest position in the class lists; who decorated themselves with the botanical specimens, devoured the edible preparations of the materia medica, and whose chemical combinations too often resulted in an explosion.

I shall offer no apology for mentioning a subject which, although it lies somewhat without the scope of this address, is one of the greatest importance to the profession, and is at the present time attracting considerable attention. Recent events have brought prominently under notice certain defects in the laws under which persons of unsound mind are placed under care and control, and although to you as students such matters are not of importance, as practitioners of medicine they may soon become so. It is not my intention to use this occasion as an opportunity for defending any medical men who may have been guilty of irregularities in signing certificates of lunacy, but it is a mistake to imagine that the proposed

changes in the law are needed only in the interests of the public; they are required with far greater urgency in the interests of our profession, whose members are called upon, by no wish of their own, to discharge most difficult duties, and who will if they are wise demand in no uncertain tones the protection of the law in the honest fulfilment of the obligations it has cast upon them. It cannot be too often repeated that the profession is in no way responsible for the present state of the law, which it did not make, and which it has no desire to uphold, and from which it has suffered far more than has the public by any irregularities that may have occasionally occurred in carrying out the statutes.

It appears to me that in any reform of the Lunacy Laws there are four important principles to be kept in view: 1st, that no man should be deprived of his liberty except by a judicial proceeding; 2nd, that no impediment should be placed in the way of a patient being brought under treatment in the early stages of the disease when the chances of recovery are most favourable; 3rd, that except in special cases and with proper safeguards no medical man should be pecuniarily interested in the detention of a patient and at the same time the judge of the necessity of such detention; 4th, that the medical men acting honestly and to the best of their judgment, and observing the requirements of the Act, should be protected from actions at law.

The Bill for the amendment of the Lunacy Acts, brought in by the late Lord Chancellor, but relinquished owing to circumstances beyond his control, contains a provision adopted from the Lunacy Law of Scotland, that except in cases of urgency a person not a pauper shall not be confined as a lunatic without an order of a county court judge, stipendiary magistrate or justice. This provision has been met with the strongest opposition by the Earl of Shaftesbury, the Chairman of the Lunacy Commission, on the ground that the fear of publicity attendant upon the intervention of a magistrate would prevent the treatment of mental disease in the early stages, and he intends to resign his office if it be carried. Whilst deeply regretting the loss of such valuable services, I think it is the duty of the profession, for its own protection, most strenuously to insist on this principle being maintained—not, however, in the form in which it appears in this Bill, whereby no additional security is given to the public, as it is not made obligatory on the magistrate to visit the patient, and should he do so there is no provision that he shall be accompanied by an independent medical expert with whom he may consult. This alone would make his intervention of any value, for the mere overlooking of certificates by a magistrate would be no real safeguard against possible abuse of the Act, and would probably cause the loss of valuable time.

It is admitted by all who have considered the subject that the time has come for the extinction of private asylums kept by medical men or laymen for profit, and the more speedily this is effected the sooner will public confidence on the administration of the lunacy laws be restored. I would with much deference suggest the following plan as one likely to meet with the approval of the profession, and at the same time secure that no sane or merely eccentric person is deprived of his liberty. The petition of the relative or friend, and the certificates of one or two medical men should still be required, but such certificates should only be valid for forty-eight hours from the time of the patient's arrival at the asylum. A rota of visiting justices should be attached to every public asylum, and on the admission of a patient notice should be sent to one of them to attend and investigate the case. This he would do with the aid of the medical superin-

tendent, who should have an official appointment as an Assessor in Lunacy. The patient would be personally examined, and his condition compared with the statements in the certificates. If satisfied that he was a fit person to be kept under care and control, the justice would sign an order to that effect, and would at the same time give a certificate to the certifying medical men which should when pleaded be a bar to any action brought against them by the patient on his recovery. The magistrate if not satisfied could order the temporary detention of the patient pending further evidence, and could also withhold his indemnifying certificate if he were of opinion that the patient had been detained without good cause.

It is true that the amended Bill contains a clause to the effect that any medical practitioner who in good faith signs a certificate shall not be liable to any civil or criminal action, but that merely provides a defence to an action; what is wanted is a bar to an action, as the injury is done when the action is brought, almost irrespective of what may be its result.

The medical superintendents of the large public asylums are all men of the highest standing in their branch of the profession; they are entirely disinterested in the detention of anyone, and I can see no good objection to giving them this consultative voice in the determination of the patient's mental condition. The private asylums so long as they exist, should be placed under proper control as regards the admission and discharge of patients.

This mode of proceeding has the advantage of introducing the civil officer in a manner that would not be felt as an intrusion by the patient's friends; it gives him the assistance of a trained expert who would have no interest in the result of the enquiry, and protects the medical practitioner who has acted honestly and to the best of his judgment when placed in what must always be a most difficult position.

One other omission in this Bill may be pointed out. It is not recognised that for the safety of society and the true welfare of the patient his discharge should be made as distinctly a judicial proceeding as was his original detention, requiring the intervention of the magistrate who would as before have the advantage of the opinion of the medical assessor.

If this Bill should pass without a protecting clause no respectable practitioner will run the risk involved in signing a certificate of lunacy. I have quite recently heard of a case in which twenty medical men had been applied to and all had refused to sign a certificate; to do this under present conditions would in my opinion almost in itself amount to an act of lunacy, and I have no hesitation in advising any of you who may be about to enter upon practice to refuse in all cases. The law has fortunately provided other means of placing the insane under control; let us therefore leave this unpleasant duty to those whose position compels them to undertake it, until such time as the Legislature shall in its wisdom pass an Act for our protection as well as that of the public.

Some of you, gentlemen, are about to enter upon the study of anatomy and physiology, the two great subjects which form the very basis of the art and science of medicine, the one dealing with the arrangement of the various structures which form the human body, the other treating of the functions of its tissues and organs. To them you cannot, in the early part of your student career, too earnestly devote your attention. If you would grasp the spirit in which you should set about the study of anatomy, let me urge you to read those classical lectures by the late Mr. Hilton on the Therapeutic Influence of Rest, and the diagnostic value of Pain Lectures so admirably clear and well reasoned that they cannot fail to interest you, even if you find in them much that you cannot as yet

either understand or appreciate. There you will see how a subject too often taught as a mere aggregation of separate and rather dry facts may become in the hands of a master a very harmony of structure, each seemingly unimportant detail having its application to the daily needs of practical work.

You will meet some who will tell you that such details are of no importance but to an operating surgeon, and that if acquired will soon be forgotten. True it is that in proportion as you learn them without seeking to understand their practical bearing on the diagnosis and treatment of disease, so quickly will they pass from your memory, but that their acquisition is in any sense a useless labour is an opinion held only by those who are without experience, or who having it, have failed to profit thereby.

Few diseases could be mentioned, no matter of how purely "medical" a type, on which some light is not thrown by the application of anatomical facts. Perhaps pulmonary phthisis may occur to you as such an one, but putting aside the bare knowledge of the general position of the lungs within the chest, it would, I think, be possible if the occasion were fitting, to convince you that a knowledge of the exact relation of the different lobes of the lungs to the chest wall is essential to a complete understanding of the progress of that disease which, in most cases, follows a line of march so regular, that given its appearance at one spot its previous course may be demonstrated and its next point of attack foretold. Spare yourselves, then, no pains in this study, being well assured that as students you will be rewarded by success in your examinations, and hereafter, as practitioners by the confidence begotten of precision in diagnosis.

Physiology now covers such a vast field, that you cannot hope, in the short time you can devote to it, to gain more than a knowledge of its leading and well-ascertained facts; but the more thorough your insight of the functions of the various organs in health, the clearer will be your view of disease which is but disturbed function and disordered growth. In this as in all your studies, aim rather at a knowledge that is accurate than comprehensive, for the main roads of science should be well known before its bye-paths are explored.

Many of you are already engaged in clinical work in the wards; now is the time when you may, if you will, fit yourselves for winning what are after all the real prizes of student life, the resident appointments. I would fain hope that you are using to the full the opportunity which will never return of gaining in actual contact with disease, where alone it can be acquired—such a practical knowledge of your art as will stand you in good stead in time to come. To this your lectures and reading are but a preparation; by such means the principles of medicine may be learnt. Not so the art. That each must to a great extent teach himself, educating by constant practice his powers of observation, thinking and reasoning over what he has seen.

Surgery by the clearness of its aims, the directness of its methods and the brilliancy of its results, allures you, as it has done those before you both here and elsewhere, from the study of medicine, wherein to the unpractised eye and ear of the beginner, all seems to be darkness, uncertainty, and impotence. And to some extent you are right; doubtless in your mind's eye there is a picture of some poor crippled fellow creature doomed for life to hobble by the aid of stick or crutch, about some country village, an ever-present reminder at your gates of your want of surgical skill; whilst who will know of that pleural effusion you failed to recognise till perhaps a lung was rendered useless for ever, or of that case of typhoid fever which for three weeks was ordered solid food

until perforation of the intestine put an end to the scene? It was said of a painter who became a physician that he had done well, for before, the faults of his work were seen, whilst now they would be unseen. For himself, perhaps, he did well; for his patients it may have been otherwise.

My surgical colleagues will, I feel sure, forgive me for asking that a share of your patronage may be accorded to the medical wards, for surgery is now conjoined with medicine, and we stand or fall together. Forgive me for hinting that some few of you by confining their—may I say clinical—observations to a contemplation, through a smoky cloud, of the patients to be seen enjoying the air of our garden, are losing valuable opportunities of studying acute disease, as unfortunately most of such cases are already in the stage of convalescence.

Those who have been or may be so fortunate as to gain one of the prizes I have spoken of, a resident hospital appointment, of which, by-the-by, we can boast, as many as some places where the students are numbered by thousands to our hundreds, should regard it as a great opportunity, on the use you make of which success or failure in the future will in no small degree depend. To you also, for the time being, the good name of the hospital is entrusted; see that its reputation does not suffer in your hands. You are in a position of much responsibility; exercise the authority deputed to you with moderation and gentleness, determined that if, as must happen, some should leave the wards committed to your charge, with suffering unrelieved, none, as far as in you lies, shall go away cherishing aught but kindly feelings towards the place which has been to them a haven of refuge in trouble and sickness.

Some whom I address to-day are about to enter upon the active duties and trials of professional life, well prepared, let us hope, by diligent study for the responsibilities that lie before them, for I can conceive no position to an honest man more distressing than to have the health and happiness of any of his fellow-creatures committed to his charge, whilst conscious that he is unfitted for the great trust that is confided to him.

If when life's work is over you find that neither wealth nor fame is yours, still one noble ambition may have been realised, that of having maintained untarnished the honour of your profession and your name.

"The honours of a name 'tis just to guard,  
They are a trust but lent us, which we take  
And should, in reverence to the donor's fame,  
With care transmit them down to other hands."

---

## PART OF THE INTRODUCTORY ADDRESS

DELIVERED AT THE SESSIONAL OPENING OF THE  
MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE,  
LEEDS.

By JONATHAN HUTCHINSON, F.R.S.,

Emeritus Professor of Surgery to the London Hospital.

AFTER addressing a general audience on the uses of knowledge, Mr. Hutchinson concluded as follows:—I have left but little time for what, perhaps, ought to have been the chief part of my discourse, that is, for addressing remarks to those present who are now commencing the study of medicine. If, however, what has been said as to the scope and aims of study in general has been made clear, it is not needful that I

should add much in reference to that of medicine in particular. I shall, however, do injustice to my own feelings if I neglect to congratulate the medical students present upon their choice of a profession. The study of medicine has an advantage over many others which are adopted as means to livelihood, in that it is itself full of scientific interest. To this it may be added, that it is a pursuit to which no knowledge comes amiss. You can scarcely secure knowledge in any direction without finding that it may be made collaterally useful in your daily pursuits. Carefully avoid taking a too narrow view of the life's work which is before you. First, unquestionably, and as a thing which admits of no excuse for its neglect, you are to acquire a matter-of-fact familiarity with the common diseases and accidents to which the human frame is liable, and their means of remedy. In these matters you must put aside all crotchets, and seek to become, as far as possible, compendiums of empirical knowledge, and embodiments of common sense. Your first duty is to advise people for the best when they are ill, and from this duty there must be no shrinking whatever. Your vocation will not, however, end here, for your training will have fitted you to assist in the formation of social opinions in a great variety of directions. The influence of food and clothing on health; the hurtfulness, or otherwise, of such articles as tobacco, tea and coffee; the desirability, or otherwise, of abstinence from alcohol; the relative value of different climates to different states of health; the causes of mental disorders; these, with many others, are questions upon which it is important that trained medical observers should form and express sound opinions. I need not remind you of the invaluable services to sanitary science which have been rendered by a Leeds surgeon, who has, at the same time, maintained a very high position in the profession which he adorns. If you would speak from more than mere conjecture or caprice, if you are honestly desirous that what you say in daily conversation shall be helpful to those who hear it, you will find incentive for hard work in many directions. Acquaintance with the structure of the world in which we live, the peculiarities of soil and atmosphere, a wide knowledge of the history of man and his development in civilisation, a familiarity with plant-life and with the facts as to health and disease amongst the lower animals, will each and all in turn prove of great value. In addition to all this, you will, I trust, many of you, become, in the several districts where your future life may be cast, leaders in the cause of general scientific education. Our profession is, indeed, in this matter, little less than a sort of unendowed Church of Science, sending its pastors and teachers to reside in the most various and distant parts of the world, and become bearers of the torch of knowledge wherever they may go. Nor have I the least doubt that the usefulness of our profession in this way is destined to large increase.

There are yet other subjects upon which I might offer you my unfeigned congratulations. You have had the good luck to be born in Yorkshire, and you have wisely followed it up by becoming students in a Yorkshire college. I feel sure that you will never have cause to regret either of these important steps in life. Leeds has always held a high position in respect to her medical men. Talent, indeed, seems to be hereditary here after a fashion which we do not witness anywhere else; and the Heys, Teales, and Chadwicks follow each other in line like princes in their own right. Nor, I may safely add, did the repute of the Leeds School of Medicine and Surgery, great as it has been in the past, ever stand higher than it now does.

I might congratulate you, also, upon good fortune in respect to the times upon which you are entering. Whether we regard the development of our own pro-

fession or the general progress of mankind, unquestionably we live in an age of most unusual interest. Great advances have been very rapidly made, and there is every indication that still better things are to follow. At the same time, it is impossible not to both see and feel that problems of no ordinary difficulty are being forced upon us for solution.

I have invited you, gentlemen, to dignify the calling of medicine which you have chosen; permit me now to invite you to dignify yourselves who have chosen it. I remember well a story which is told, I think of John Foster, that he having once, in a fit of melancholy, declared that the world was a "wild beast, untamed and untameable," his friend reminded him that, at any rate, he himself was part of it. "Yes," he rejoined, "a single hair at the end of its tail." I prefer, I may confess, and I am sure that he would have done so in a cooler moment, the comparison with which I began my address, when we likened individual men to single leaves on a mighty pine-tree. As each leaf in quietness and confidence does its duty, so may it be with us. To every student here I would say, and say very earnestly, "to thine own self be true." In hours of lassitude or moment of temptation remember this maxim, and, acting upon it, all good things will follow. Do not think lightly of your own individual value in the world's work, and always think hopefully of the world's progress. The world, you may feel sure, never had a more happy day than that in which you were born. Lest you mistake my meaning, let me hasten to add that it will be happier still on the day you die; and permit me to take leave in urging the reflection that the ratio of its gain in happiness will depend, in some degree, now and for ever, upon how you live.

## INTRODUCTORY ADDRESS

DELIVERED AT ST. MARY'S HOSPITAL ON THURSDAY,  
OCTOBER 1ST.

By AUGUSTUS J. PEPPER, M.S.,

Surgeon to the Hospital.

[Abstract.]

AFTER some general remarks, the lecturer proceeded as follows:—"I pass now to the consideration of a few of those questions which are largely exercising the mind of our profession, and which, in the future, must greatly modify its public obligations. As regards medical education and examinations, so far as I am able to judge, there never was a time when greater tension existed than at present. An unsuccessful attempt was made by the expiring Parliament to carry into law what is familiarly known as the 'one portal system'—a system which would tend to equalise the severity of the professional examinations in the three kingdoms, and the value of the corresponding diplomas conferring the right to practise. It is well known that not a few gentlemen who fail to pass the ordeal—or fear to try it—of one or other of our English colleges, betake themselves over the border with a reasonable expectation that they will bring back the equivalent of their railway fare and other pecuniary outlay. There would be no reason to complain of this if our Scotch brethren kept their licentiates among themselves, since we are willing to concede that they are the best judges of the value of their continued existence and of the marketable price of the

cure of their infirmities. I know there are many distinguished members of our profession practising in London and elsewhere under the ægis of a Scotch qualification, and I do not for one moment intend my observations to be taken as the indication, much less the measure of personal disrespect, nor, again, would I insist that the examinations for the Scotch diplomas are not generally speaking sufficiently stringent; that may or may not be, I only say that a system which places two institutions of very unequal merit as regards their credentials on a practical equality is wrong in principle and ought to be abolished. In addition to the fact that many English students go to Scotland for the diplomas granted by the colleges and faculties, a large number, justly ambitious of possessing a university degree, repair thither for their professional training. This has become a question of vital importance to the future interests of our London schools, since year by year the exodus increases. It has been proposed that the London University should lower its standard so as to enable it to counteract the attractions of the Universities of Scotland. But remember, if you please, what that proposal means. It means that an institution, founded by Royal Charter with the intent of fostering scientific education, shall resort to a miserable subterfuge because, forsooth, the degrees of other universities can be obtained on easier terms. It means that a noble cause shall be sacrificed to one of the most despicable traits of human character. Speaking for myself, as a member of the London University, I would rather it ceased to exist and be henceforth only a name and an influence, than that it should be made the scape-goat for what so-called educational reformers please to consider the exigencies of the situation. There is a powerful movement on foot in favour of establishing a Teaching University for London which, instead of simply granting degrees to candidates from affiliated schools, shall designate, direct, and control the curriculum of instruction. Such a scheme, if carried out on a comprehensive basis and with due regard to the interests of existing institutions, would confer a distinct boon upon our profession and the community at large; but if, on the other hand, it is to be made subservient to the real, if not avowed, designs of those whose chief desire is to raise up a successful rival against the Scotch universities I hold it would be our bounden duty to oppose it to the utmost.

The advantages accruing from the study of general literature were next discussed. "There are occasions frequently recurring when the strain of mental exertion can be relieved by varying your intellectual pursuits. It is a pleasure and solace to turn from the dry details of the text-books to the charms of poetry and the romance of fiction, and though the former are essential to give precision to knowledge, the latter add an interest which make it endurable and enduring. The action of the superior oblique muscle of the eye, as learnt at lecture, is to the student of anatomy a mere fact and nothing more, and a few days will probably suffice to free his memory from a burden imposed neither by choice nor desire. But who would or could forget the bewitching lines of Longfellow:

"She gives a side glance and looks down,  
Beware! she's fooling thee."

It is curious our standard works are all but mute on the physiology of expression with which the organ of vision is so richly endowed, and yet almost every bodily and mental state in health and disease speaks through that silent voice. Wherein consists the merry twinkle of the impudent school-boy or the languishing looks of the love-sick maiden? Why is the eye so listless and dull in collapse, so brilliant in hectic fever so staringly vacant in coma-vigil? Here

is matter for thought, worthy alike the philosopher and the practical physician."

The subject of moral and mental training was then dealt with. "I am not one of those who hold that youth can better withstand the temptations of life by being kept in ignorance of the dangers which pervade our social atmosphere. The best security against disaster is the forecast of its approach, and the knowledge of its accustomed guise. Do not misunderstand me: I would have you avoid all appearance of evil, but at the same time I would have you taught the way to recognise it. Remember the most dangerous snares are hidden beneath the softest blandishments. In the struggle for supremacy, whatever the object pursued, some will outstrip others, but none need despair of success. Therefore, lose not heart, but continue the race according to your lights and ability. Should you grow faint by the way, turn once more to the pages of Lytton, and read again, 'That in the lexicon of youth there is no such word as fail.' Bear in mind, however, that the tide which is to carry you to the goal of your ambition, will serve you only at its flood, and that you must keep a constant look-out for its approach, for the waves of the ocean of man's opportunities break not in warning notes upon the rocks of his indolence, but ebb and flow in silence, unseen by all, save those who wait and watch patiently for the sign."

## INTRODUCTORY ADDRESS

AT

THE SHEFFIELD SCHOOL OF MEDICINE,

DELIVERED AT FIRTH COLLEGE ON OCTOBER 1.

By R. J. PYE-SMITH, F.R.C.S.

[Abstract.]

AFTER welcoming the new students, the lecturer congratulated them on their choice of the profession, and dwelt on the nobility of its aims and practice. Referring to the risks from disease and from unjust actions at law, he said, "But all these and other risks must be loyally accepted by all who would enter the profession of medicine. We must operate in spite of possible untoward consequences to ourselves; we must attend epileptic patients, in spite of their vagaries perchance falling terribly upon us; we must examine persons represented to be of unsound mind, and faithfully sign or refuse to sign certificates of lunacy to the best of our judgment, in spite of the annoyance and loss such duties may possibly entail upon us. In all such respects it should be true of the surgeon as of the Christian—

"He holds no parley with unmanly fears,  
Where duty bids he confidently steers."

The lecturer then proceeded to advocate a year's preliminary study after leaving school and before entering as a medical student. Among other subjects to be taken up at this period he laid special stress on biology, and the use of the microscope, and mentioned also drawing, photography, carpentering, shorthand writing and cooking. He recommended also the study of meteorology and climatology, and advised attendance on a course of instruction in first aid to the sick and injured and in nursing, as given in connection with the St. John Ambulance Association. Address-

ing the first year's men again, he urged them to the early formation of good working habits, and showed how the special senses required cultivation as well as the various faculties of the mind, whilst not omitting congenial recreation and rest. Having dwelt on the special importance of anatomy and physiology as the foundations of the healing art, he sketched the curriculum as now required for the double diploma of the conjoint examining board of the Colleges of Physicians and Surgeons, and then warned the students of the possibility of their turning out ill by neglecting the opportunities before them.

Turning next to the older students, he congratulated them on entering upon their clinical studies, and insisted on the importance of paying special attention to pathology and to diagnosis whilst attending the hospitals. He warned them against conceit and pretending to cure when they knew they could not, and against a spirit of cynicism "bred of a knowledge that medicine is not an exact science, and is therefore liable to mistakes, together with a lack of clear and trustworthy perception of what may be definitely known, namely, those scientific principles and well-ascertained facts on which so much of medicine depends." A just, though modest, confidence could be acquired and maintained only by habits of diligent self-education, and they should invoke Duty in the words of the poet—

"The confidence of reason give,  
And in the light of truth thy bondman let me live."

The lecturer then proceeded to address some remarks to the lay part of his audience. Having expressed gratification at the prospect of the incorporation of the Medical School with the Firth College, he based an appeal for pecuniary help for a new building on the beneficent objects of the profession and the poor pecuniary rewards of its practitioners as compared with other professions and commerce. He pointed out the advantages to the community of having a flourishing Medical School in their midst, and traced the history of the present movement for more adequate accommodation. The plans for the new school were exhibited, and it was stated that some 2,000*l.* more are needed before it can be built. He spoke of the help afforded to the school by hospitals, and impressed on their managers the duty of seeing that no waste occurred in the materials for instruction at their disposal. Referring to experiments on animals, he applied Ruskin's words to the anti-vivisectionists:—"The first passions that come are the vain, the false, the treacherous; if you yield to them they will lead you wildly and far, in vain pursuit, in hollow enthusiasm, till you have no true purpose and no true passion left." And he predicted that Pasteur's work on hydrophobia would strike a mortal blow to this ignorant and inhuman opposition to scientific investigation. He also urged the public to withhold objections to *post-mortem* examinations in cases where the medical attendant considered them important. He credited the future spread of elementary physiology with deterring the public from trusting in any of the surviving systems of quackery, and with putting them in a position to estimate rightly the uses and the abuses of specialism in practice. In conclusion, he reminded the students of the motto of the school, *Ars longa, vita brevis*, and said, "In steady perseverance in your work cultivate modesty in manner, exactitude in habits, sobriety in thought, truthfulness in speech, courage in action, and, above all, honesty in purpose. Now is your golden opportunity for preparation, and if you will now lay up a store of knowledge it will, by right application, become wisdom, as fuel becomes fire, and you shall in due time be initiated into

"The secrets and the mysteries whereof  
The bounds are space, the time, eternity."

REPORTS OF  
HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL  
AND  
NORTH EASTERN HOSPITAL FOR CHILDREN.

TWO CASES OF STRANGULATED HERNIA  
IN INFANCY.

(Under the care of Mr. R. J. GODLEE.)

CASE I.—Herbert G. C., aged 6 weeks, was admitted into University College Hospital, on August 10th, on account of an irreducible swelling in the right inguinal region. The bowels had not been opened for a week, but the patient had seemed to be in his usual health till the day before admission, when severe sickness set in, and it was at this time that the nurse first noticed the presence of the inguinal swelling. A dose of castor oil was given, and the child was brought to the hospital on the morning of August 10th.

On admission, a "lump" soft and fluctuating was found in the inguinal region, which, on manipulation, gave a sensation of crackling. As all attempts at reduction failed, an incision about two inches long was made over the upper part of the swelling. After carefully dividing the skin and subcutaneous fat, the sac of the hernia was exposed and incised, whereupon a small quantity of blackish fluid escaped. The gut was dark red in colour, and could not be pressed back into the abdomen until the neck of the sac had been notched with a blunt-pointed bistoury, although the constriction was not very tight. The cord and vessels were carefully separated from the surrounding structures and an aneurysm needle passed round the sac, the neck of which was then tied with a strong chromic catgut ligature. The pillars of the external abdominal ring were then stitched firmly together with fine catgut sutures; after an india-rubber drainage tube had been inserted, the wound was closed; an antiseptic dressing of iodoform wool was applied. The testicle and epididymis, when examined, were both swollen and of a dark purple colour. The bowels were opened in the evening. No blood in the stools.

August 11th.—There is some rise of temperature, 102°. Wound healthy, and there is a slight sanious discharge. The scrotum and testicle are somewhat swollen and very tender, indicating some orchitis.

August 13th.—The temperature is now normal. The child takes the breast very well. Wound is nearly healed. The drainage tube was shortened to half-an-inch. The orchitis is better.

August 15th.—Tube removed.

August 18th.—Patient discharged with a light truss.

CASE II.—Albert L., aged 5 weeks, was admitted into the North Eastern Hospital for Children on June 26th with symptoms of vomiting and constipation. There had been severe vomiting for two days, and latterly the vomit has been yellow and offensive. Bowels have been slightly open once. The child has not taken the breast for the past two or three days.

On examination he was found to have a hard painful elongated swelling in the right inguinal region and right side of scrotum, which had only been noticed for one day, and which could not be reduced.

Under chloroform, Mr. Godlee cut down on the swelling and opened the sac; the testicle was found swollen; a loop of intestine, about as large as a filbert, and very much congested, was also found. This latter

was reduced and the wound sewn up; a small drainage tube being placed in the lower part of the wound, a dry dressing of iodoform and iodoform wool was applied.

July 29th.—The wound has almost healed, the same dressing to be continued; the child was made outpatient. The temperature ranged between normal and 99.6° Fahr.

*Remarks.*—Strangulated hernia in very young children is not a common affection; and it is one which presents a few considerations of interest. I have met with one or two cases besides the two here reported, but at not quite so tender an age (a few months for example), and in all, on opening the sac, it has been found that the constriction was much less tight than is ordinarily found in a strangulated hernia in an adult, and there has been no difficulty in passing a probe, or even something larger than a probe, through the neck of the sac alongside the gut. But, notwithstanding this, it has not been always easy to reduce the gut, which has generally been congested, and sometimes, as in the first case, it has been impossible to do so without notching the neck of the sac.

All the cases have been boys; and in all it has been found that the testicle was swollen and purple; looking in fact, like a large bilberry. All have suffered more or less from orchitis afterwards, but it seems doubtful whether this depends upon the previous constriction of the cord or the manipulation during the operation; for it is a matter of common experience that, after performing the radical cure in infants, an attack of orchitis is by no means an uncommon occurrence.

The question may be asked—seeing that the constriction is generally so slight, should we persist in efforts to reduce the contents of the hernia? For my own part I should answer, No. The operation for radical cure in children seems to be quite free from risk, and the child afterwards is in a much more comfortable condition than before, and in a safer position for the rest of life. I am, therefore, inclined to grasp the excuse for performing the operation, rather than to allow the child to run any possible risks that may result from too forcible manipulation or prolonged delay. In saying that the operation is free from risk, it is of course implied that strict antiseptic precautions be taken; and it is quite possible to do so, even in this region, so near the genitals of a baby. Whether or not the spray be used at the operation is, I believe, a matter of small moment, provided the parts be thoroughly purified beforehand, and the sponges and instruments and hands during the operation. Afterwards a most efficient dressing may be made by luting down a piece of salicylic wool or iodoform wool over the wound, and applying over this a large mass of the same material, which is secured by a bandage and protected from urine by a piece of gutta-percha tissue in which a hole has been cut for the penis. The outer mass of wool should be changed at least daily for the first few days.

In conclusion, I would mention two cases I have met with in infants, in which the sac of a hernia contained only a much enlarged and congested testicle. In one the testicle itself was tightly nipped at the external ring, and in the other the cord only was constricted. In both, the spermatic vessels were very short, so that the testicle could not be brought into the natural position. In both there were all the symptoms of strangulated hernia, which were relieved by the operation. In the second of these two cases, the question could not help arising whether or not the operation was perhaps simply dealing with a case of orchitis in a partially retained testicle; if so, it is interesting to note that all the symptoms disappeared after dividing the constriction at the neck of the sac.

## APPOINTMENTS FOR THE WEEK.

*Wednesday, October 7.*

OBSTETRICAL SOCIETY OF LONDON, 8 p.m.—Specimens will be shown by Mr. Doran, Dr. Wm. A. Duncan and others. Papers—Dr. Matthews Duncan, "The Hypertrophies of Lupus of the Female Pudendum"; Mr. Hutchinson, F.R.S., is expected to take part in the discussion; and Dr. Thin will speak on the histological aspect of the subject; Mr. S. D. Hine, "Case of Obstructed Labour in which Spontaneous Version followed an Unsuccessful Attempt to Deliver with the Crotchet after Craniotomy."

HUNTERIAN SOCIETY, 8.30 p.m.—Mr. Rivington, on "The Radical Cure in Operations for Strangulated Hernia."

*Friday, October 9.*

CLINICAL SOCIETY, 8.30 p.m.—Dr. Sawtell, "A case of Hæmatemesis and Melæna in a Newly-born Child"; Mr. Barwell, "A case of Gastrostomy"; Mr. Clement Lucas, "Two cases of Strangulated Umbilical Hernia, treated by Excision of the Sac and Skin Covering"; Mr. Charters Symonds, "A case of Trephining for Compression by a Clot derived from a Lacerated Meningeal Artery, suggesting temporary or permanent closure of the Carotid as a means of controlling the Hæmorrhage."

*Medical Times and Gazette.*

SATURDAY, OCTOBER 3, 1885.

THE Medical Session was opened at the London hospitals on Thursday; silently at four of them, and with speeches at the rest. At the provincial schools addresses were delivered only at Leeds and Sheffield. Leeds has again had the honour and pleasure of hearing the best of all the addresses, London or Provincial, as it had two years ago when Dr. Allbutt was the lecturer. The audience at Leeds being a mixed one, Mr. Jonathan Hutchinson's address was mainly of a general character the small segment of it which we print elsewhere being the only part addressed to medical students as such. The rest of it, in which the speaker brought forward "certain thoughts and suggestions as regards the future of education and the increase of knowledge, on which my mind has often dwelt with pleasure and profit to itself," was, in suggestiveness, in boldness of thought, breadth of sympathy, and beauty and fitness of language, an address to be gratefully studied and remembered. No other man in the profession could have written it.

MR. HUTCHINSON began by working out the old Homeric simile—

*Οἷη περ φύλλων γενεή, τοίηδε καὶ ἀνδρῶν*

from which he drew the lesson of the "beneficence of the law of individual death." Thanks to this law, the human family, like a tree, attains increasing growth, and perpetual youth, successive generations taking up the work of their forerunners, and "eager to do or die," in turn submitting to the same fate. But men differ from leaves in their power of receiving by direct communication with their predecessors "a vast wealth of impulse and power, which has not as yet assumed a form in which its acquisition by inheritance is possible." This is education, a laborious and

endless task, but one which admits of the prejudices, the narrow formularies, and the erroneous conceptions of the past being more easily laid aside. "No process of cleaning the battered soot-begrimed leaves of last season could compete with Nature's plan, which covers the tree with new and untarnished foliage." The rest of Mr. Hutchinson's address was more or less a working out of this pregnant idea. In a most beautiful and characteristic passage he showed the use of knowledge—real living knowledge—as the parent of sympathy and love, the seed of that plant of which wisdom and love are the flower and the fruit. We are not sure that Mr. Hutchinson is quite sound in his psychology, or justified in concluding that the power of loving wisely, well and strongly is always proportionate to the intellectual development of the being, but that is a question out of our range in these columns. We will only add that as the matured thoughts of a man who has studied Nature in many aspects deeply and faithfully, Mr. Hutchinson's address deserves to be reverently read by all. It is Darwinism grafted on to a Wordsworthian stock.

AT King's College, the Session was opened by the Bishop of London with an address which was enough to make the late Dr. Jelf turn in his grave, so freely has the Church, in the mouth of its most advanced speakers, reconciled itself to the teachings of science. We do not think that Dr. Temple's speculations about life will quite hold water, when they come to be leisurely tested; but it is a pregnant sign of the times that they should even have been put forward. The latter part of his address was devoted to a sketch of a religious practiser of the art of healing in his studies and his life, in the course of which the attitude of the Liberal churchman to vivisection was enunciated. There was a passage in the address which appeared to show that the Bishop is a little bitten with the psychological research mania, though it was admitted that the influence of mind on matter is not yet a ripe subject for scientific investigation. *Quâ* sermon, we prefer Mr. Hutchinson's to Dr. Temple's.

AT St. George's Hospital, Mr. Timothy Holmes called the attention of the students to the best method of study, and impressed upon them the enormous advances which medicine had made of late years as a practical art. He advocated an extension of the period of study, the federation of the dispensaries and infirmaries with the hospitals, so that students would undertake the actual treatment of disease by being put in charge of dispensary and infirmary cases under proper superintendence, and a reform of the constitution of the Royal Colleges by the admission of the Fellows and Members to a direct voice in their management; further, an amalgamation of these Colleges into one great institution, which could deal with authority with the many pressing medical questions of the day.

FOR the conversazione to be held this (Friday) evening at St. Mary's Hospital, in connection with the opening of the new wing, a full and varied programme has been provided. For the lovers of art there will be displayed numerous Chinese and Japanese curiosities,

as well as specimens of Doulton ware, water colours, oil paintings, engravings, tapestries, prints, brasses, a statue in the chemical theatre illuminated by the electric light, and the out-patients room will be decorated as a Japanese hall, where tea will be served *à la Japonaise* under the immediate superintendence of a Japanese young lady. Those who are more scientifically disposed will turn their attention to Dr. Maguire's demonstrations of micro-organisms and disease germs, or to the various microscopical specimens which will be provided for their delectation, whilst new varieties of gas lamps, electrical apparatus, a new mechanical clock, the combination chromatic stereoscope and Thistleton's electric machine will no doubt all receive a due share of attention. The bands of the Grenadier Guards and of the St. George's Rifles will enliven the proceedings, and Mr. Edward Plater's Glee Union will contribute in the same direction. Last, but by no means least, we must not omit to mention that Mr. Clifford Harrison will give a series of recitations in the Board Room.

THE Sanitary Congress resumed its sittings at Leicester, on Thursday week, with an address from Mr. Percival Smith, the President of the Section of Engineering and Architecture. Mr. Smith drew attention to the large sums that had been spent on sanitation throughout the country since the establishment of the Local Government Board, nearly thirty millions having been borrowed for the purpose in thirteen years. The education of the people in the appreciation of sanitary work of all kind had also, he said, been most encouraging. With regard to the dwellings of the poor, he deprecated the erection of huge blocks in such close proximity to one another as to shut out sun and air. He concluded by urging that much still remained to be done in the way of sanitation, especially in educating the people to appreciate all that tended to healthiness of body and mind. Mr. J. Gordon, of Leicester, subsequently read a most interesting paper on the drainage of continental towns, in which he showed that the adoption of the English water-carriage system was steadily progressing on the Continent. A brisk discussion followed, in the course of which surprise was expressed that the works in question had, in many cases, had very little effect on the mortality, and Dr. de Chaumont explained that the sewers were not used efficiently for sewage by the people in continental towns, and this accounted for a large amount of typhus, diphtheria, and other diseases which prevailed much more extensively on the Continent than in England. In the Sanitary Science Section the Countess de Viesca read a paper on sanitary house management, in which she advocated a higher degree of sanitary knowledge and activity on the part of the lady of the house—a novel, but needed preachment. In the evening, Mr. Ernest Hart delivered a lecture on the essentials of local government reform, in which he contended that the reforms required to bring local government into its proper function, concisely stated, were the simplification of the primary area, the creation of one authority for all local business, the creation of County Boards, the reorganisation of the local government officials, and the consolidation

of local finance. A more vigorous and intelligent public opinion on local government, however, had yet to be created in many places, and until it was created the action of the authorities would be more or less hesitating.

ON Friday, the last day of the Congress, Dr. Maxet, the President of the Chemistry, Meteorology, and Geology Section, read a very interesting address on the distribution and effects of carbonic acid in nature, and its sanitary relations; and a second paper on the influence of altitude on the chemical phenomena of respiration, in the course of which he stated that experiments he had made led him to the conclusion that people might live for months or years at altitudes not exceeding 6,000 feet or 7,000 feet in the Alps, and there was no doubt but that after a time the body could accommodate itself to the influence of altitudes much above 10,000 feet. A discussion subsequently took place on the burial question. In the Engineering Section smoke abatement and plumber's work were the subjects of debate. At the closing general meeting Professor de Chaumont, the President, said this had proved one of the most successful meetings which they had held; after which votes of thanks were passed to the Local Committee, and to the Mayor and Corporation of Leicester, and the Congress came to an end.

AT the last meeting of the Metropolitan Board of Works two resolutions, having respect to the pollution of the River Lea, were carried unanimously. One, moved by Mr. Runtz, that a Bill be introduced into Parliament next session for the inclusion in the metropolitan area of Tottenham and other districts adjacent to the metropolis and bordering on the River Lea; and the other by Mr. Cook, urging *inter alia* the construction of proper intercepting sewerage works along the Lea Valley to prevent the pollution of the river by the entrance of sewage in any part of its course. The latter is in the highest degree desirable, since we may be permitted to doubt the sufficiency of the "purification" effected in the sewage of Luton and Hertford, while that of Tottenham and the adjacent districts appears to be, if possible, made fouler by the process to which it is submitted, and it is quite compatible with the former. Of course, as we maintained in a note some weeks since, and as Mr. Runtz has admitted, the existing sewers of the Metropolitan system are incapable of accommodating such an accession of sewage; but Tottenham, &c., are practically parts of London, and when constructing the long culvert to Thames Haven it would be easy for the Board of Works to adapt it to the reception of both. The same remarks apply to the rival scheme of Messrs. Denton and Jones for the extension of the same culvert to Canvey Island and the utilisation of that island for the disposal of the sewage by irrigation and downward intermittent filtration. We fear, however, that unless the East London Water Works Company have further resort to wells, the diversion of such a body of water as is represented by the sewage of the places in question would seriously reduce the volume of the river, and give rise to fresh evils.

THE death-rate in London last week reached the marvellously low figure of 13·8, which is considerably below any record hitherto made. The deaths between the ages of 5 and 20 give the average figures; but at all the other periods there was a very decided decrease in the numbers. The deaths from zymotic diseases were 100 below the average, and give a rate of

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past nine weeks.

1·8. There were 11 deaths from small-pox and 18 from diphtheria. It is a sign that the public alarm about hydrophobia has not been without foundation, that three deaths were attributed to this cause. The mean temperature of the air was 3·4° below the average of the past twenty years. In the provincial towns the public health was almost as satisfactory as in the metropolis, the highest death-rate, viz., 23·4, being attained at Preston, and the lowest, viz., 10·0, at Bristol.

BOTH in Spain and in Sicily the cholera appears to be steadily declining. The deaths in the former country have not, however, yet fallen below 200 a day, while in the province of Palermo they had reached nearly 100 a day until Tuesday, when they fell to 68. The epidemic is still severe outside Gibraltar, where there is much distress amongst the workpeople owing to the cessation of work caused by quarantine arrangements. The comparative immunity of the Rock is attributed, probably with justice, to the excellence of its sanitary arrangements.

ON Friday last, a dinner was given by the medical profession of Dundee to Sir Andrew Clark, who passed his early years as schoolboy and medical apprentice in that town. The occasion was cannily laid hold of

for again ventilating the project of establishing a medical school in connection with the Dundee Infirmary and the University of St. Andrew's; and Sir Andrew Clark devoted the greater part of his speech to the proposal, to which he gave a cordial support. "It was," he said, "not only right for Dundee to found a medical school, but it was the duty of Dundee to do so. The foundation of such a school would enable their most venerable University of St. Andrew's to complete and crown the work in which she was now engaged. It would enable them to supplement her education without disturbing her present educational course; and, furthermore, it would probably enable that university to revive the traditions of her ancient glories. There were reasons for believing or supposing that it was undesirable to found a medical school in Dundee at present; but he had examined these reasons, and he said of them that they were either too feeble or too few, or in a very high sense too selfish, to receive serious consideration at the present time." In conclusion, Sir Andrew Clark said that, in anticipation of its being founded soon, he would propose the toast of "The Medical School of Dundee," and he would express the hope that it would turn out many thoroughly practical trained men for the noble work of medicine; that it would contribute to the advancement of every just interest of that great community, and still more largely to the advancement of knowledge and the relief of human suffering. The toast was most cordially received, and replied to in suitable terms by Professor D'Arcy Thompson.

MR. CARTER, the coroner for East Surrey, gave some extremely gratuitous advice to poor persons in the course of an inquest held on Monday. The subject of the enquiry was a baby, some thirty hours old, who had been delivered by a student in connection with the maternity department of St. Thomas's Hospital. The verdict was "Death from inanition through the want of power to partake of food," which, in the case of a baby not two days old, looks very much like nonsense. No doubt the student in question was remiss in leaving his patient unvisited for thirty hours after the confinement, though there is no mention of his being sent for, but the coroner's generalisations from this single case were entirely uncalled for. It was a great pity, he is reported to have said, that poor persons, not able to pay for medical aid at confinements, went to the hospitals at all. His own advice to them was to get an order for the parish surgeon's services and have proper attention. Had that course been pursued in the present case, the death, as in numbers of other cases, could have been certified, and the county saved a great expense. Apart from the fact that parish-surgeons are not always impeccable, it is obvious that the coroner's sweeping condemnation of hospital maternity departments is entirely undeserved. We venture to say that women confined from a hospital have quite as good a chance of being well looked after as those who go upon the parish. And if there is any difficulty in their case, they have a much better chance, the best skill in London being at their disposal. Mr. Carter thinks

that his plan would save the country a great expense, but has he ever calculated what it would cost the rate-payers if the parish authorities undertook all the work now gratuitously performed by the hospitals? Besides, students must practise midwifery somewhere. If they did not learn it in connection with the hospital, they would have to learn it elsewhere, perhaps as private pupils of the very parish-surgeons to whose skill and attention Mr. Carter has given such a high and no doubt deserved testimonial. From every point of view the coroner for East Surrey has distinguished himself.

THOSE of our readers who were interested in the account we gave last week of Dr. W. W. Myers' attempt to form a small medical school in connection with the Manson Memorial Hospital at Takow, in the island of Formosa, will be glad to hear of the progress that is being made towards providing the Chinese with medical text-books in their own tongue. Ten years ago Dr. Dudgeon, of Pekin, entered upon the arduous task of translating Holden's Osteology and Gray's Anatomy into the language of the Flowery Land, and the translation has recently been published in eighteen Chinese volumes, in addition to two volumes of plates comprising 600 cuts. The work is entitled *Chuen ti t'ing k'au*, or Complete Investigation of the Human Body, and is published at the expense of the Yamên, or Chinese Council for Foreign Affairs. The letterpress is printed from moveable type, and is issued from the Pekin College Press, which has been occupied upon it for the last two years. The plates have been cut on wood by native artists from the drawings of Dr. Dudgeon's senior hospital assistant, and those which we have seen are very fair specimens of wood-carving. In the Osteological part, which is a translation of Holden, the nomenclature has been largely drawn from a thorough study from native medical works. The publication is prefaced by autograph letters from leading Chinese officials, eulogising Western medical science, as well as by an author's preface. The latter contains a strong plea for the right of dissection, which has hitherto been denied in China, on the ground that the human body is sacred, and its mutilation a crime against one's parents. In addition, the first volume also contains a translation of Professor Turner's article on Anatomy in the Encyclopædia Britannica. Notes are scattered through the volumes, pointing out where Western ideas differ from native medical knowledge. The Chinese are very proud of their own medical science, but it rests mainly on the doctrine of the pulse, the dual principle, the five elements, and it is to be hoped that the publication of this translation will tend to sap the general confidence in a system so insecurely founded, and to pave the way for the introduction of Western medicine, and the general acknowledgment of its superiority.

DR. DUDGEON, we hear, has also ready for the press copiously illustrated translations of Marrant Baker's "Kirke's Physiology," and likewise a Medical Vocabulary in English and Chinese, arranged alphabetically and according to subjects, of all the technical, ana-

tomical and physiological terms occurring in the two works, besides all the anatomical terms occurring in the native medical works and in Kanghi's dictionary. This will prove a most useful book of reference for all future translators and instructors of Chinese medical students. Some years ago the same author published an anatomical atlas in quarto, and two volumes of medical essays which have been instrumental in drawing the attention of the native practitioners to the importance of Western medicine. The Chinese Government gave its sanction many years ago to the establishment of a Chair of Anatomy and Physiology, which has been occupied by Dr. Dudgeon, but it was only last winter that permission was granted to begin lectures on clinical medicine and surgery. There is every prospect of a medical school being now established, with the view of providing proper practitioners for the service of the army, navy, and palace. Twenty-six more students have been added to the language department, and more are shortly to be admitted, with higher Chinese qualifications, and altogether on a more advanced basis.

THE latest bacillus is that peculiar to beri-beri or *Kakke* of the Japanese, for the discovery of which we are indebted to Dr. Wallace Taylor, of Ozaka. Having recognised a spore in the blood of *Kakke* patients, he proceeded to cultivate it as follows: a sterilized culture fluid of meat infusion was inoculated with the blood of some of the patients, and from these pure cultures were obtained by successive inoculations for from eight to twelve removes. Then animals were inoculated from these cultures and after a period varying from five to twelve days the animals developed symptoms of *Kakke*. Spores were found in the blood of these animals, and most of them died. The micro-organism was also found in the urine of *Kakke* patients, in canal water used for drinking purposes, in the soil, and in rice. Experiments showed that the spores were not destroyed during the process of cooking rice, or during digestion. It seems probable, therefore, that one of the sources of the disease is the eating of rice infected with the disease, more especially as it appears to be a common practice amongst the Japanese to eat their rice cold.

DR. MACLEAN, of Netley, has written to the daily papers to appeal for contributions on behalf of Dr. Warburg, the deviser of the well-known febrifuge. It was in compliance with Dr. Maclean's advice that Warburg, some years ago, allowed his formula to be published in the *Lancet* and *Medical Times*. This publication was followed by disastrous results to the inventor, who now at the age of 81 finds himself in embarrassed circumstances. Dr. Maclean therefore invites all "who have derived benefit, perhaps had their lives saved by this remedy, to assist the man who has given to tropical medicine a powerful weapon to contend with a disease that kills twice as many victims as cholera and small-pox put together." The Government of India, some time ago, took the very unusual step of marking their sense of the value of Warburg's Tincture by a grant of 200*l.* to the discoverer, and it would be only becoming on the part of the English Government if they would give him a

pension on the Civil List. Still, whatever is done officially, it behoves the public and the medical profession as well, to gratefully mark their sense of the rectitude of Dr. Warburg's conduct in divulging his formula, and to make up to him as far as they are able for the loss that he has thereby incurred. It is a matter of expediency as well as of good feeling to prevent this example of unrecompensed service from going down to posterity to deter future discoverers from making their discoveries a free gift to the world. Contributions to the Warburg Fund may be sent either to Major-General F. Cotton, 13, Longridge Road, S.W., or Captain Ralph N. Taylor, United Service Club.

DR. BRISTOWE writes to us as follows:—In reference to your remarks a week or two ago concerning convalescent homes, and the trouble that their managers often seek needlessly to impose on medical practitioners, I enclose, in corroboration of your observations and for your amusement, the accompanying form as it was sent to me about four months ago, together with a narrative of the circumstances connected therewith. A short time before, at the end of a long hospital visit, and when it had become imperative on me to hasten away to fulfil other engagements, I was requested to fill up a copy of this form on behalf of one of my hospital patients, who was in every sense a fitting person to be sent to a convalescent home. I answered the first six questions without difficulty. But, when I came to the seventh and eighth, I found that in order to answer them I should have to read a whole page of printed matter. Under the circumstances I was unable to do this; and, as an answer to them, wrote that I had not time to read them. I complied with the further requirements, and the patient was received. Not long afterwards the pretended proof was sent to me. I need scarcely say that I did not reply to it. But I handed it to my class and to the nurses, and we had a hearty laugh at its feeble insolence.

In an admirable little book, entitled "A Schoolmaster's Retrospect," Mr. Maurice C. Hime, M.A., LL.D., strongly advocates the advantage of a medical training to a schoolmaster. Whilst fully agreeing with him that those employed in educating the young should have some knowledge of physiology (everybody should have some knowledge of it), we are not quite clear as to the desirability of every schoolmaster having gone so far as to take the degree of M.B. as Mr. Hime wishes. Having taken this degree, he would, he contends, be the more fitted to decide such questions as the best means of ventilating a school-room, the best hours for meals, the best food to take at meals, the best division of hours for teaching, the boundary lines that divide proper pressure from over-pressure or under-pressure, the proper amount of bodily exercise and the best kind of such exercise, the shape, and size, and requirements generally of a suitable school infirmary, the best mode of disinfecting, all questions relating to sewerage, etc. Information as to some of these points can be gained from the experience of others, and the medical officer of the school would be the proper person to consult as to the

rest. In an earlier part of the book, Mr. Hime is at some pains to adduce several cogent reasons why a schoolmaster should not be a clergyman, but should be specially trained for an educational career; we believe his remarks are equally applicable to the case of a medical man, and we very much doubt whether a medical education would afford at all the kind of training that Mr. Hime so properly considers necessary.

In a most interesting little brochure lately published, entitled *Medical Experiences in India*, Surgeon-Major Maunsell shows not only what a grand field for observation India offers, but how by the aid of a little determination and plenty of common sense difficulties which would have proved insuperable to many may be faced and surmounted. Having interested himself especially in diseases of the eye whilst at home on furlough, Surgeon-Major Maunsell on his return to India in 1881, found ample scope for the prosecution of his new study. The first difficulty he had to deal with was the reluctance of the natives to submit to operation; at last, however, an old man with double cataract was prevailed upon, and both cataracts having been successfully removed at one sitting, there was no further hesitation on the part of the natives in that locality. As an instance of the extent of his practice in the matter of cataract, we may mention that in one village in three consecutive days he performed 35 extractions, of which 32 were successful. In all his operations he was single-handed, at any rate so far as skilled professional assistance was concerned, and he was invariably his own chloroformist. In the course of eleven working months extending over a period of a year and a half, he performed 267 extractions, of which 22 were failures. Of course cataract was not the only eye-disease which came under his observation; indeed, cases of all sorts were met with, and notably not a few of night-blindness. A tabular statement is appended giving the sex, age, mode of operation, and result in each case.

It is somewhat satisfactory to know, from a recent prosecution at North Shields, that the Board of Trade are on the alert for those who transgress the Merchant Shipping Act. One of the provisions of that Act declares that in the case of illness or injury on board ship requiring medical advice, the fact of the occurrence of such a case shall be duly recorded in the official logbook. For neglecting to comply with this regulation, the master of a ship, which had brought a boy suffering from typhoid fever from Malta to London, was very properly prosecuted, and on conviction fined forty shillings. We hope this sentence will deter other masters from endeavouring to conceal cases of illness when they may feel tempted to do so; no possible good can be gained by the concealment; whilst in the case of cholera, for instance, an infinity of harm might result.

FROM the annual report of the Nightingale Fund for 1884, which has just been placed in our hands, we learn that after an existence of nearly a quarter of a century this school for training nurses continues to be in a most flourishing state. Thirty-one probationer nurses received appointments during the year, making

a grand total of 467 who have passed out of the school as certified nurses since its foundation. The intellectual standard of the several probationers is reported to have been good, and in fact to have been somewhat above the average, and the lecturers, Dr. Bristowe, Mr. Croft and Dr. Bernays, all spoke favourably of the knowledge shown by the pupils in their respective subjects. From a financial point affairs are equally satisfactory, and the fund has a large and increasing balance at its bankers.

THE death of Lord Shaftesbury at the advanced age of 84 removes one of the most eminent philanthropists of the present century from our midst. His labours on behalf of factory children culminating in the Ten Hours' Bill, and still more the prominent part he took in establishing refuges for homeless children, and especially the foundation of the *Chichester* and *Arethusa* training-ships for boys, have made for him an undying name in our annals. But by the medical profession he will be best remembered as the staunch supporter of the great reforms which were instituted in the treatment of lunatics in the first half of the present century. When the Board of Commissioners in Lunacy was created in 1829 he was appointed to it, and was its Chairman to the day of his death.

By an oversight last week, we stated that the Harveian Oration would be delivered by Dr. Quain, at the Royal College of Physicians, on October 18th; it should have been the 19th, as the former day falls on a Sunday.

#### THE FIRST OF OCTOBER.

ANOTHER First of October with its flow of eloquence and commonplace has come and gone, and some hundreds of young men, with the happy carelessness of school still aglow in their eyes, are straining at the leash, eager to get to work with their scalpels and as yet undaunted by the prospect of the long drudgery that lies before them. The teachers meanwhile are eagerly scanning the entry lists, anxious to learn how many of these raw young colts it will fall to their or their colleagues' lot to bit and bridle with Quain or Gray. In a week or so the curiosity of the elders will be set at rest, the enthusiasm of the *débutants* will be in process of defervescence, and all, or all but a few, will have settled down to that steady grind which, proverbially, "does it." In no other profession is there anything at all to compare with this general start off. In the church and in the law, in engineering, in literature, and in art, men get away in dribblets, unconscious often as to who is in the running until they knock against each other at the winning-tape. There is some excuse, then, for making a good deal of the First of October; there would be excuse for making a good deal more of it than we do. It is eminently sensible and eminently English (which comes to much the same thing) to make a speech to each new batch of students, giving them a broad view of their future course, telling them by means of what energies and endurances they may reach the end of it, and what they may expect to find when they get there. Such a course, implying as it does a dozen different speeches

addressed every year to as many fresh batches of students, has its obvious inconveniences, and we have wondered before now why the Medical Council or some such authoritative body has not followed the time-honoured example of the Church, when it found itself in a similar difficulty, and composed a common liturgy or a book of homilies for general use on such ceremonial occasions. Still in spite of the inconveniences, of which so much has been written heretofore that we forbear to press them, the system is on the whole more sensible, and, as we have said, more English than the modern innovation of inviting all and sundry to an evening entertainment, with a foreign name, at which the very men in whose honour it is held are swamped and silenced by a garrulous crowd. Surely to the freshmen a First of October *conversazione* is something of a mockery; and we do not doubt that if it were put to them, whether they would prefer sitting and listening to a speech in the singular, or standing and listening to speech in the plural, they would unhesitatingly give their votes for the former. That, at any rate, is a ceremony in which they have some part, even if a silent one, to play.

The older schools which, with a lack of conservatism rather unusual in such time-honoured and prosperous bodies, have given up their October addresses, can hardly perhaps be expected to restore them. But we may hope that their example has already done all that it was capable of, though we fear from what Professor Schäfer said at University College that that Institution has some idea of following in the wake of its older rivals. Yet even Mr. Schäfer, abolitionist as he is, admits that the October addresses have some uses, while Mr. Cowell, in his lecture at the new Westminster Hospital School, showed both explicitly and by implication how fully he valued the opportunity thus afforded him, of delivering a medical opinion on questions of public interest and importance; and the speakers at other schools, by dealing largely with those questions, bore witness to a like appreciation on their part of the function entrusted to them. Possibly when the roll of the new Parliament is called, the profession may find itself in the possession of better and more frequent opportunities of influencing public opinion than it at present enjoys; but the questions on which medical men are justly entitled to speak with authority are rapidly coming into such prominent importance, that if medical opinions are as wise and sound as we take them to be, we need not be nervous about having too much of them. Dr. Fowler very aptly pointed out in his address that more than fifty years ago, when Sir Charles Bell gave his evidence before a Parliamentary Committee on Medical Reform, the questions under discussion were exactly the same that we are discussing still. The fact might perhaps be put forward as a proof of the futility of October addresses, fifty years of them having left us exactly where we were. But it must be remembered that those questions which have not advanced are just those on which medical opinions, or at any rate medical interests, are not entirely unanimous; whereas the questions on which the medical voice is undivided have advanced towards their solution by leaps and

bounds. If we examine the addresses of this year, we find that on some points, such, for instance, as the necessity for lunacy reform, especially in regard to the protection of medical men, the speakers are of one accord; whereas in other questions, such as the provision of a degree for London students, the opinions expressed are much less unanimous and much less decided. The obvious conclusion from this is that the Government will soon probably grant the one reform, but will wait until medical opinion is more homogeneous before giving us a helping hand towards obtaining the other. The moral is that October lecturers would do well to consult together beforehand, and to take care that, as they all speak at once, they should all say the same thing—assuming, of course, that they all want the same thing, which is perhaps not always the case.

### ANTI-VACCINATION FALLACIES AND TACTICS.

THE recent Conference on vaccination at Leicester has given rise to a brisk correspondence in the columns of the *Times*, Drs. de Chaumont, Corfield and Seaton complaining that the position they assumed and the arguments they brought forward had not been fairly represented by the reporters of that journal, and other gentlemen making various explanations of a more or less personal nature. But there is one letter so characteristic of the mode of reasoning adopted by the opponents of vaccination, that we feel it a duty once more to denounce the tortuous and unscrupulous statements which constitute their stock-in-trade. We refer to that of the notorious Mr. William Tebb, though whatever pleasure Alexander may have felt when "Thrice he vanquished all his foes, and thrice he slew the slain," to us it is unspeakably wearisome to refute for the fiftieth time the misstatements and to expose the fallacies of men who are unamenable to reason. Why, we would ask, do the antivaccinators obstinately refuse to look the statistics of the last ten years of German small-pox in the face? Simply because they dare not! The new vaccination laws enacted in that year, and in force throughout the empire, mark an era in the history of small-pox in that country. Instead of this they harp for ever on the severity of the epidemic which raged in 1871-2 there, as in all parts of Europe, a severity which we have no wish to question since it brings out in stronger relief the amazing results of the new law.

Mr. Tebb calmly declares that when Professor Corfield refers to the triumphant results produced by the German Vaccination Law of 1874, and the immunity from small-pox consequent therefrom, he "is seriously in error on both points." To prove that the laws of 1874 have not led to any such reduction of the deaths from small-pox as Dr. Corfield maintains, he proceeds to quote the higher mortality of 1871 over 1870. He asserts that "compulsory vaccination laws of the most stringent character have existed in the greater part of Germany since the beginning of the century," giving dates varying from 1807 in Bavaria to 1835 in Prussia. This assertion has been so often

contradicted that he ought to know it to be false, except as regards Nassau, and one or two minor states and the army. In these the results have been all that could be desired. It is needless to repeat the striking contrast presented by the German and French armies in the late war, when the former lost under 230 and the latter over 23,000 men by small-pox—indeed, the deaths occurring among the French prisoners formed in some German towns no small proportion of the total mortality. In Frankfort, again, such a thing as a fatal case of small-pox has not been known for many years, the result of really stringent vaccination, just as much as the immunity at present enjoyed by Leicester is of isolation. Elsewhere, however, the laws were, as regards the civil population, the very reverse of stringent. Even in Bavaria vaccination was not compulsory until the end of the second year, by which time a large number had evaded the law by removal, and very many had died of small-pox while still unvaccinated. In Hamburg, Dr. J. Voigt, the Director of the Vaccine Institute, states that it was very rarely performed until the child attained the age of six years, when it was required by the school regulations.

In 1871-2 small-pox raged throughout Europe, and in Germany it was aggravated by the presence of over 200,000 badly vaccinated or unvaccinated prisoners from Sedan and Metz. The contrast again seen between the Nassau towns and Frankfort on the one hand, and those of other states, especially Prussia, on the other, betrayed the illusory character of previous legislation, and led to the promulgation throughout the newly constituted empire of the laws which had proved so successful in Nassau, with the addition of compulsory re-vaccination before the close of the period of attendance at school. Of course the adult population are not directly affected thereby, but they do enjoy an indirect benefit by lessened exposure to infection. We can well afford to decline any questionable evidence in our favour. We know that vaccination, however generally performed, is not to be wholly credited with the low mortality which marks the years immediately following any epidemic whether of small-pox or of other infectious diseases, when they have exhausted themselves on the more susceptible portion of the population, but in this case such concession actually lends additional force to our contention, for it is after the new law had fairly come into operation that the most marked improvement appears in the German returns, and when in every other country small-pox was beginning to re-assert itself. Thus the deaths from small-pox in Berlin from 1863 to 1870, while the population was rising from 600,000 to over 800,000, had varied between 100 and 620 annually; in 1871 and 1872 they were 3,552 and 1,128; but from 1873 to 1880, during which period the population increased to 1,200,000, they were respectively 93, 20, 34, 14 (7 of these being unvaccinated infants), 2, 5, 2 and 2. It is true that an outbreak in 1881 caused 50 deaths (of which 22 were unvaccinated and mostly infants), but the numbers since have been as low as in the few years preceding this solitary epidemic, if it deserve the name.

In the terrible year of 1871 at Hamburg, over 3,700

persons died of small-pox, but not one successfully vaccinated child under five years of age, and the deaths since that time have averaged 5 per annum, chiefly unvaccinated infants. Even if the absolute immunity enjoyed by Frankfort be in part attributable to its exceptionally good sanitary conditions, no reason beyond the difference in the laws relating to vaccination can be assigned for the fact that while in Berlin, Hamburg, Danzig and other densely peopled towns of Germany, the deaths from small-pox have for several years not exceeded units, in Vienna they amount to 800 or 900 annually, and in Prague are relatively to the population even higher. In the German army there has not been a death from small-pox for the last ten years, while in the Austrian, the mortality per 100,000 has varied between 10 and 67, and in the French between 8 and 28. In London and Paris, after the great epidemic of 1871-2, the mortality fell for a time simply or chiefly from exhaustion, but in each city it soon recovered from the temporary depression, and in our metropolis it assumed the proportions of an epidemic in 1877-8, in 1881, and again last year. In Paris this was delayed till 1879-1881, the mortality in 1880 being as high as 104 per 100,000. In Vienna it has exhibited only a partial remission in 1879, and has persisted with the exception of the years 1878-80, at or over 100 per 100,000 annually, and with a slight remission in 1880-1, the same may be said of St. Petersburg. In the whole of the German Empire, on the contrary, small-pox has ever since the year 1874 sunk to such insignificant proportions as to have become, if not actually extinct, a negligible quantity regarded as a cause of death.

It is impossible to find words too strong to describe the obstinacy which refuses to face these facts and to listen to any statistics from Germany subsequent to the year 1872, that is, less than fifteen years old, or the dishonesty which would put forward the mortality of 1871 as an answer to claims advanced on behalf of a law passed three years later. Once more we repeat that prior to 1874, *infant* vaccination was not compulsory in that country in any true sense of the word, the laws were the reverse of stringent except in one or two of the minor states, and if we wish to judge of the results of really compulsory vaccination *and re-vaccination* we must take into account the statistics of the last ten years. That a man who can thus distort the plainest facts should fall into a fallacy common to all his party need not surprise us. Mr. Tebb, when he quotes from the Registrar-General's report, that of the 121,147 persons who died of small-pox in England and Wales between 1854 and 1883, no fewer than 51,472 were under five years of age, "when vaccination is said to retain all its virtues," assumes that all these infants were vaccinated, whereas, next to young adults whose primary vaccination has lost much of its influence and who have not been re-vaccinated, the heaviest mortality is everywhere found among infants who have not been vaccinated at all. If, as we have no doubt, the vast majority of these fifty thousand infants and young children had not been successfully vaccinated, we have in this fact the strongest conceivable argument in favour of the earliest possible performance of the operation.

### THE ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

It is perhaps rather venturesome to hope that this Report for 1884 will be amongst the last issued by the Local Government Board as such, but if a thorough re-organisation of local government throughout the country is to be the first task of the new Parliament, we may trust that the formation of a Ministry of Health will constitute an integral part of the scheme of reform. A mere glance at the reports annually issued by the present Board is enough to convince one that the importance and multiplicity of the interests entrusted to it are such as to render it advisable if not obligatory, that the department should forthwith be placed under a Minister of cabinet rank. It may, perhaps, seem a matter of indifference whether the authority of the Board is exercised in the name of a President or of a Minister, especially when it can command the services of a statesman like Sir Charles Dilke, who signs the present report. But considering the difficulties which are always arising between the central Board and various opiated, and often recalcitrant local authorities, it is of great importance that the head of the former should be able to advise and to command with all the authority and prestige that the State can possibly endow him with. A committee which sat during the year under review decided that the present clerical staff of the Board "is quite inadequate for the numerous and important duties which now devolve upon it," and in consequence of this report, alterations were made with the view of adding to the efficiency of the department. It is to be hoped that these changes may be but the prelude to the formation of that Health Department which Dr. de Chaumont so forcibly advocated in his recent address at Leicester.

The present Report is divided, as usual, into three parts, dealing respectively with Poor Relief, Local Government and Public Health, and Local Taxation. The second division is that which mainly concerns us, but we may state with regard to the first part that in the year under review the mean number of paupers relieved in proportion to the population was the lowest on record the absolute number being actually less by 50,000 than in 1874, in spite of the increase in the general population. The number of paupers relieved, however, still amounted to 765,914, and they cost 8,402,553*l.*, or 6*s.* 3*¼d.* per head of the population. Compared again with 1874, the ratio of able-bodied paupers to 1,000 of population relieved in 1884 was less by 1.2. But if paupers have diminished in numbers, lunatics have increased, partly, no doubt, owing to many being classed under the latter head who, in previous years, were classed under the former. The total number of lunatics relieved in January, 1884, at the cost of the poor-rate, was 68,736, or nearly 16,000 more than on the same day ten years previously. The metropolitan pauper returns are still more favourable than those of the country at large, the ratio per 1,000 of population having decreased in ten years from 34.3 to 25.1. Yet the fact that in London nearly 100,000 persons (or one out of every forty inhabitants) have to be maintained at the public cost is a sufficiently painful commentary on our political organisation. One of the most inter-

esting features in the attempt to break the back of hereditary pauperism by the timely care of the young is found in the system of boarding-out pauper children. This system has been slowly growing in importance, until in 1884 those so provided for numbered 1,043, and it is reported to be working most satisfactorily as regards nearly all the children. One of the inspectors reports that "a healthier looking lot of children could scarcely be found." The medical supervision of the paupers of the country is entrusted to 4,063 medical officers, whose annual salaries amount to 146,216*l.*, or about 36*l.* per head. Under these circumstances it is perhaps surprising to learn that only 6 of the 4,063 were dismissed or required to resign during the year on account of irregularities in the discharge of their duties.

The part of the Report dealing with Local Government and Public Health gives us a still higher idea of the enormous powers wielded by the Board; for while the work connected with poor relief is steadily declining with the decrease in the number of paupers, the duty of superintending the public health must necessarily increase in proportion to the spread amongst the population of the desire for health. In his address at the Leicester Congress last week, Mr. Percival Smith called attention to the fact that, while the loans for sanitary improvements sanctioned in the 23 years before the Local Government Board was instituted amounted only to some 10,000,000*l.*, in the first thirteen years of the Board the loans amounted to nearly 30,000,000*l.* These figures give us some idea of the amount of local activity in matters of sanitation. In fact, the local debt of the country, much of it incurred in health-giving works, amounted in 1883 to the vast total of 159,142,926*l.*, or more than one-fifth of the national debt, whereas in 1875 it was less than one-eighth of our national indebtedness. It is in urban districts that by far the largest debts have been incurred, thirteen times more money having been spent in twelve years by the former than by the latter, viz., twenty-six millions compared with two millions. The health of the country, we learn, is watched over by 1,136 Medical Officers of Health, viz., 520 for Rural, 582 for Urban, and 26 for Port Districts. Under them there are 1,037 Inspectors of Nuisances, and the two sets of officers cost the Board nearly 70,000*l.* per annum.

The Report, after dealing with the condition of the Thames, described by its inspector as "a huge sewage tank which for now many months has not been cleaned out;" the pollution of the Lea, and other rivers; and the Canal Boats Act, of the working of which it speaks rather diffidently; proceeds to deal with two subjects of great interest to the medical profession, viz., the adulteration of food, and vaccination. During the year 1884 nearly 2,300 analyses were made by some 250 analysts, and the proportion of articles found adulterated was 14.4 per cent. of those examined. That is not unsatisfactory so far, but it is very unsatisfactory to learn that in most of the small boroughs and in many of the rural districts the Sale of Food and Drugs Act is practically inoperative. The article found most frequently adulterated was spirits, though, as the adulterant was invariably

water, there is perhaps not much cause for indignation. Coffee and butter came next, chicory being the main addition to the former, and beef or pork fat the chief adulterant of the latter. Over 10,000 samples of milk, or nearly half the whole specimens of food and drugs examined, were analysed, and 1,761, or rather more than one-sixth, were condemned. But only in one case was any addition of solids detected. Tea, on the other hand, and sugar were found seldom, if ever, spurious, while bread was only adulterated in two per cent. of the specimens analysed. So that out of the five chief articles of consumption at the breakfast-table of the poor, two only, coffee and butter, proved unworthy of implicit confidence. As regards the results of the analysis of drugs, we have given an extract from the report in another column. The vaccination statistics of 1882, contained in the Report, must be dealt with hereafter, as the full returns will be published separately in the supplementary volume containing the Medical Officer's Report. We will only add here that of 807,584 children born in 1882 who survived, 94.5 per cent. were registered as successfully vaccinated, while of the remaining 5.5 per cent. the Board has no evidence. That one person out of every twenty born should be left unprotected from small-pox shows how far our present system is from complete efficiency.

## CLINICAL PAPERS.

---

### XXV.—ON THE USE OF ERGOT IN LABOUR.

THERE are two things that are apt especially to strike one in reading the older works on obstetrics and in talking to the practitioners whose procedure is founded on those works. The one is the importance which is attached to simple retention of the placenta without adhesion, and the frequency with which it is assumed to occur; the other is the tendency to rely upon ergot as an oxytocic agent. The experience of modern obstetricians with regard to the one and their practice with regard to the other, are entirely different from what was taught within quite recent times, and from what is still experienced and practised by many who have never come under the influence of modern precepts. It may be stated without hesitation that simple retention of the placenta, resisting the usual methods of removal by expression or traction, or both combined, is seldom if ever met with in modern midwifery practice; while the administration of ergot to hasten birth in cases of feeble uterine contraction has been almost entirely superseded in practice by other agencies, manual pressure, galvanism (largely and successfully employed by individual practitioners) and instrumental delivery. Two cases which have lately come under the notice of the writer incline him to believe that there is more than a mere casual connection between these two changes in midwifery experience and practice. Possibly the connection may be acknowledged in some of the many handbooks of obstetrics, English

and foreign; but if so the lesson taught therein has not duly impressed itself on the mass of general practitioners of the old school. The first case alluded to was that of a young and healthy primipara who was rapidly and unexpectedly delivered of a dead child at the end of the seventh month of pregnancy. The practitioner, finding a dead child in the bed, and fearing hæmorrhage, for reasons difficult to determine, at once administered a drachm of liquid ergot. On attempting to remove the after-birth, some twenty minutes later, he found the cord grasped by the rigid os and the entire placenta still in utero. The os would not even admit a finger. The help of the writer was requisitioned, and by his advice the woman was put deeply under chloroform. Still, in spite of persevering efforts, the rigid os resisted all efforts to introduce even a finger-tip, and in the end the attempt was given up. Some twelve hours afterwards the placenta was found lying in the vagina, compressed into a hard ball of the size and shape of a large lemon. In the second case the rigidity of the os was not so marked, but the placenta resisted all attempts at expression and traction, though on giving chloroform the contraction of the os was overcome without much difficulty and the placenta thereupon easily removed. In this case ergot had been given by the practitioner in attendance in order to hasten delivery, and he had been making unsuccessful attempts to remove the placenta for three hours.

Neither of the cases corresponded to the so-called "hour-glass" contraction of the uterus of which we read so much in obstetric literature, but see so little in obstetric practice. Hour-glass contraction—a condition almost certainly due to the neglect of the practitioner to keep the womb well in hand after the expulsion of the child—implies rigid contraction of the internal os, with flaccidity of the body of the uterus. In the above quoted cases, however, the whole of the uterus was in a state of tonic contraction; there was none of the alternate balling-up and loosening of the uterine tissue which one feels after an ordinary labour. In the first case, too, the condition of the placenta when removed suggested that it must have been subjected for some hours to prolonged and powerful compression, the contraction of the womb being so continuous and efficient, that not a single clot was passed with or after the placenta. Now this tonic contraction of the uterus is the very result which we know and wish to be produced by ergot; it is its power of producing it which renders ergot such a valuable hæmodynamic in post-partum hæmorrhage. At the same time it is this very action which has driven it almost entirely out of the field as an oxytocic. Until the placenta has come away, we look for alternate contraction and relaxation of the uterus, and by substituting for this action the tonic contraction produced by ergot we are running counter to Nature (a wise interpretation and imitation of whose aims and methods form the only sound principles in midwifery practice), and risking injury either to child or mother. It cannot be too deeply impressed upon the student of obstetrics that only under most exceptional circumstances is it advisable to give ergot unless one can assure oneself that both child and placenta are likely

to be delivered before the uterus comes under the action of the drug.

Before concluding this paper it may be worth while to add a few practical remarks on the removal of the placenta. Next to the precautional use of antiseptics, the expression of the placenta by the left hand and the subsequent care of the womb probably constitute the most important reform in the modern treatment of normal labour, lessening as they do respectively the opportunity of infection by the practitioner, and the liability to post-partum hæmorrhage. There is, however, one danger in connection with expression of the placenta, which has been frequently pointed out, but which has not been taken to heart so generally as it might be. When the placenta is expressed it comes away rapidly, drawing the membranes after it. The latter are thus very liable to be clipped by the contracting os, and if the placenta is not received by the hand, or if being received it is drawn away too suddenly, a piece of membrane is very apt to be torn off and left behind—a very undesirable, not to say dangerous result. The safer practice is to receive the placenta in the right hand, and if there is any drag on the membranes to hold it and to wait half a minute or more until the contracted os relaxes and the membranes come away easily. Following this procedure, there will be seldom any necessity, though it may sometimes perhaps be safer, to twist the membranes into a rope as the text books direct.

## REVIEWS AND NOTICES OF BOOKS.

---

*Diseases of the Tongue*; by HENRY T. BUTLIN, F.R.C.S. London: Cassell & Co. 1885, pp. 451.—This is one of Cassell's Clinical Manuals for Practitioners and Students of Medicine, and may be taken as a representative volume of the series. The subject is exhaustively treated in many ways, and some of the more important diseases are admirably illustrated in chromo-lithograph. Beginning with accidents to the tongue, the author next proceeds to consider congenital defects, and then, seriatim, every disease that has ever been seen or recorded. If it were possible to find any fault with so admirable a compilation as the one before us, it would be on the score of the paucity of pathological details and the absence of illustrative drawings of these conditions. Few surgeons are better qualified to supply both the details and the drawings than Mr. Butlin. The descriptions of the clinical facts are in large part transcripts with criticisms and remarks by the author. In such facts our literature and text-books abound, but in the minute pathology of the conditions described they are sadly deficient, and the want is in no way supplied in the volume before us. One of the most interesting and most valuable chapters in the book is that on the after-treatment which operations on the tongue require. The author says: "Until a comparatively late period, the after-treatment of patients who had suffered amputation of the whole or part of the tongue was little studied." He also refers to the fact that in two well-known works on the antiseptic treatment of wounds, no mention of those of the tongue is made. The majority of our readers, we imagine, either as students or practitioners, will remember how penible most of their tongue cases were, with their horrible fœtor, and incessant dribbling of decomposing discharges from the mouth. Various plans, including drainage through the floor of the mouth, have been tried with but very partial success. And not only from this standpoint is this fœtid discharge disagreeable, poisoning

the room or the ward and rendering it offensive to every one in it, for there is the danger of septic pneumonia, by far the most frequent cause of death in fatal cases. The breathing air passing over this decomposing surface gets charged with disease germs, and moreover, the discharge itself finds its way into the larynx, and thence to the lungs, and so sets up the fatal complication. The most recent and the best treatment now consists in feeding the patient entirely for some days on nutritive enemata, and keeping the floor of the mouth packed with iodoform gauze. This treatment was proposed first by Wölfler, one of Professor Billroth's assistants; he carried it out successfully in 17 cases of various operations on the tongue; not only was there no fatality, but the inconveniences were reduced to a minimum, and from first to last, there was no fœtor. The mode of dressing is as follows: Strips of the gauze, about the width of two or three fingers, are placed in the cavity of the mouth with a pair of forceps; all the angles of the wound are filled with it without exercising any undue pressure, but so as to cover the whole surface of the wound. The strips of the gauze interlace with the surface of the wound, and in the next few days cannot be separated from it without the occurrence of bleeding. If the strips are properly placed, there is nothing more to be done to the wound, for they may remain there six or eight days until they fall out. Only the superficial layers, which become sodden with the saliva and the food, need be removed from day to day. Wölfler does not feed his patients by enemata, but apparently through the mouth from the first. This, we think, is a mistake. It is better to give peptonised food *per rectum*, as long as possible; a few drops of opium help to quiet the patient as well as the rectum. If the latter become irritable, the use of a soft œsophageal tube is to be commended. In this manner, the dressing in the floor of the mouth is kept dry and healing goes on more rapidly; but if food must, for some reason, be given by the mouth, it will be found advantageous to take out the superficial strata of gauze, to cleanse out any mucus which may have collected about the fauces, and then to give the food. Immediately afterwards the mouth may be well-cleansed with boracic or some other solution, and then re-packed with the iodoform gauze. The whole work under review is exceedingly interesting, and will doubtless be highly appreciated by the practitioners and students of medicine to whom it is addressed. When the complete series of manuals has appeared, we shall be in possession of an admirable library, one of the chief advantages of which will be that in a small space will be given not only the writer's own experience (which is sometimes not very great), but that of the best known authorities on the subject, compiled up to the latest date. It is obvious, therefore, that for such a series to maintain its present popularity and value, the editions must follow each other with fair rapidity, on account of the rapid march of events, and of the vast improvements which this march brings with it.

*A Practical Treatise on Diseases of the Kidneys and Urinary Derangements*; by C. H. RALFE, M.D. London: H. K. Lewis, 1885. It is always a misfortune for an author when his book is just forestalled by someone else who treats of the same subject and from the same standpoint. Dr. Ralfe appears to be in that unenviable position, though through no fault of his own, for within the last few months a well-known monograph on this subject has reached a fourth edition, whilst another great authority has finished, after many years of labour, his masterly treatise on the same topic. However, the function of the critic is not to institute comparisons, but to judge of each book on its own merits. At the outset we must confess that the opening chapter on the general symptomatology of kidney disease did not give us a favourable impression of the work. We very much doubt the advisability of endeavouring to compare such widely different conditions as are here dealt with; diabetes and chronic Bright's disease should surely be kept quite distinct, whereas here their symptoms are taken consecutively, in reference, for instance, to the ophthalmoscopic changes where they have absolutely nothing in common. If the first chapter is thus open to objection, the next chapter sees

Dr. Ralfe at his best. It deals with the clinical examination of the urine, a subject in which the author is thoroughly at home, and which he has handled in a manner that leaves nothing to be desired. The author speaks much more decidedly than do most of his predecessors, as to the pale granular kidney being the final stage of the large white; but whether we agree with him in this matter or not, we must all allow that it is often very difficult to draw a line histologically between intra and inter-tubular changes. Dr. Ralfe speaks favourably of the solvent treatment of small uric acid calculi that have just been passed into the bladder, but if they are so small as would seem to be necessary for successful treatment in this way, surely a very slight measure of surgical interference would get rid of them more effectually and far more speedily. Several times throughout the book the use of Davy's lever is mentioned as an aid in diagnosis, for instance, to determine from which kidney pus is being discharged, but no directions are given for its use. No doubt the student can find out how to apply the lever so as to control the common iliac artery by reference to a surgical manual, but this will not tell him the exact relations of the ureter, and even if he has remembered them from his anatomical days, he will still want to know how he is to feel sure that he is compressing the ureter, and how long such compression must be kept up in order that the diagnosis may be made. We hope that in a subsequent edition Dr. Ralfe will be a little more explicit on these points. And in that edition, we hope too that the very numerous grammatical and clerical errors which disfigure this one will be removed.

*Medical Reports of the China Imperial Maritime Customs*; Special Series, No. 2. 28th Issue. London: P. S. King & Co., 1885. This number of the Reports, which we owe to the far-sighted initiative of Sir Robert Hart, and which we sincerely hope will be kept up by his successor, is not inferior in interest to its predecessors. It deals with the two middle quarters of 1884. Many cases, some of which we shall take the opportunity of quoting in full hereafter, are carefully recorded by the Customs Medical Officers, whose opportunities of observing disease under novel conditions are certainly unique, and to whom a powerful incentive to observation and thought are doubtless afforded by the publication of their reports in a collected form. On almost every page of the present number one meets with interesting facts. Thus, Dr. Henry calls attention to the liability of Chinese women who deform their feet to accidents, resulting in two cases under his observation in Pott's fracture. Dr. Jamieson records a very interesting case of enlarged heart, weighing 34 oz., with mitral and aortic incompetence, the possessor of which had never complained of illness till his sudden death. Dr. Rennie reports a case of typhoid fever, with death on the tenth day at a temperature of 106.2°, in spite of baths, and a case of hepatic abscess treated by Manson's operation. Dr. Myers contributes some very sensible remarks on the use of alcohol in health and disease. He remarks on the peculiar inability of the Chinaman to withstand any affection localised in his bowels. "I have repeatedly seen a Chinaman, purged once or twice, exhibit a condition of shock which could scarcely be worse if he had received a severe abdominal wound; while if the latter had really been the cause, his chances of speedy recovery, with often few or no unfavourable symptoms, would be infinitely better than with a foreigner similarly wounded." Of Dr. Myers' Report on the teaching of native students at the Manson Memorial Hospital we spoke last week. Dr. Lowry's report contains some careful observations on bubonic plague; and the volume closes with a note on Distoma Hepaticum, by Dr. Wallace Taylor, supplementary to that which appeared in the previous issue of the Reports.

*Operative Surgery in the Calcutta Medical College Hospital*; by KENNETH McLEOD, M.D. London: J. & A. Churchill, 1885, pp. 351. This work consists of a tabular record of all the cases of surgical operation which have come under the author's treatment during five years' service as sur-

geon to the Calcutta Medical College Hospital, together with short notes of such cases abstracted from the more detailed histories kept in the wards. The record includes a grand total of 800 operations with a death-rate of 14·7 per cent., among these there are 27 operations for vesical calculus, with 4 deaths; 18 hernias, with 9 deaths; 129 cases of elephantiasis of scrotum, with 23 deaths; 10 cases of epithelioma of the penis; 41 excisions of joints, with 4 deaths; 38 primary amputations, with 9 deaths. Dr. McLeod is a strong advocate of the antiseptic treatment in surgical operations; he says the details given in his chapters "amply sustain the conclusion, and there is no difficulty in appreciating these local changes, for the phenomena of a septic repair differ fundamentally and entirely, more especially in bad subjects and bad hospitals, from those which characterise septic repair. In the case of good subjects and good hospitals the difference may not be so apparent." He then refers to the difficulties of securing aseptic occlusion in India, so much depending on the surgeon's assistants and surroundings. The book contains most interesting cases, together with Dr. McLeod's views thereon. Altogether the work before us is a record of which the author may be justly proud, and on which we cordially congratulate him.

*Clinical Lectures on Scrofulous Neck*; London: J. & A. Churchill, 1885.—In this little volume Dr. Clifford Allbutt and Mr. Pridgin Teale have issued two clinical lectures delivered by them at Leeds during the past year, and originally published in our columns. Their collaboration has been very successful, and now that the surgeon is so often called upon to operate on parts of the body that were once left almost exclusively to medical treatment, we may expect to find such division of labour a more frequent, as it certainly is a most convenient, arrangement. Dr. Allbutt deals with the medical aspect of scrofulous glands in his own inimitable way, and leads up to Mr. Teale's practical description of their treatment by extirpation. The substance of the lectures was communicated to the International Medical Congress in 1881, but many of the cases were inadvertently omitted from the Transactions. The details of these are now given, and Mr. Teale tells us that his more recent cases abundantly confirm the experience previously gained. The operation advocated is an admirable instance of treatment based on a sound and enlightened pathology, and deserves to come into much more frequent use than it has hitherto done.

*Elements of Surgical Pathology*; by AUGUSTUS J. PEPPER, M.S., M.B. Lond., F.R.C.S. Second Edition: Cassell & Co.—We gave a considerable space to a review of this book on its first appearance, and we need do little more now than congratulate the author on having given heed to our criticisms, and amended his work in the directions we indicated. The chapter on "Inflammation," which we mainly fell foul of, has been entirely re-written, and now forms a much more satisfactory introduction to the study of surgical pathology than it did as it originally stood. Besides this, the whole work has evidently been subjected to painstaking revision, and new sections have been added on acute rickets, foetal rickets, Raynaud's disease, progressive obliterative arteritis and spondylolisthesis—most of them subjects of much recent attention. A new and useful chapter on cell-multiplication is also appended. We have therefore much less hesitation now in recommending the work to advanced students than we felt on perusing the first edition.

## ABSTRACTS AND EXTRACTS.

### FROM THE FOURTEENTH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

*Small-pox in London in 1884.*—From the beginning of the year, small-pox, which during 1883 had been at a low level, began to show signs of increase. The number of patients admitted during the year into the hospitals and

hospital ships of the Metropolitan Asylums Board was 6,900. In February the hospital ship *Atlas* began to receive cases. In April a tent hospital for convalescents was opened at Darent. In May the managers hired from the Poplar Board of Works the infectious hospital built by them some years since at Plaistow. In June the second hospital ship, the *Castalia*, was prepared for the reception of patients. The maximum number of patients under the care of the managers was reached on July 3rd, when it amounted to 1,391. From that time the numbers fell rapidly till the close of the autumn, when they again increased. On the last day of the year there were 1,060 patients under treatment. There are now three ambulance stations, in telephonic communication with the offices of the managers in Norfolk Street. To these offices all cases of small-pox are at once notified by telegram, with a statement whether the disease is of a mild or severe type. Severe cases are taken to the land hospitals, whilst mild cases are removed at once by ambulance to the river side, two ambulance steamers being used for their conveyance to the ships at Long Reach. When convalescence begins the patients are removed to the camp at Darent, in which as many as 1,000 patients have been accommodated at one time. Some difficulties have been experienced in the administration of this large camp; and, during the interval which will probably elapse before the next visitation of the disease, further consideration of the question of the provision to be made for convalescent patients will be necessary.

*The Adulteration of Coffee.*—Coffee continues to be one of the chief subjects of adulteration, and about one-fifth of the samples examined were reported against. The peculiarity in one case was that the berries were actually shown to the inspector, and were ground in his presence, so that there seemed to be no likelihood of adulteration. Chicory, however, was found on analysis to be present, and the vendor was fined. It is possible that this fraud was due to the revival of an old practice of compressing chicory by machinery into the size and shape of coffee-berries. These sham berries are mixed with real ones, and the purchaser, who sees what he believes to be coffee being ground before his eyes, is hopelessly deceived. As chicory only costs threepence or fourpence a pound, the fraud is very profitable. It is no rare thing for so-called "coffee" to be sold which proves on analysis to be composed of one-fourth part of coffee added to three-fourths of chicory.

*Adulterated Drugs.*—Of 442 samples of drugs analysed during the year no less than 64, or 14·5 per cent., were reported as adulterated. The chief subject of analysis was sweet spirits of nitre, of which 106 samples were examined and 36 were condemned, no less than 20 being either wholly or almost wholly destitute of nitrous ether. We may probably assume, however, that in a greater or less proportion of these cases the deficiency was due, not to intentional dilution, but to the accidental escape of volatile spirits which had originally been present. Of 35 samples of quinine all were genuine, but 2 samples of tincture of quinine (out of 9) were reported against. Similarly 13 specimens of powdered rhubarb were pronounced pure, while 6 out of 17 samples of tincture of rhubarb were found wanting both as regards the strength of the extract and the proportion of proof spirit.

*A Vaccination Census.*—Among the measures taken by Boards of Guardians may be specially mentioned a very comprehensive investigation instituted by the Guardians of St. Pancras with regard to the vaccination of the residents. A staff was organised consisting of ten gentlemen connected with University College Hospital, who were appointed to institute, under the direction of Mr. G. W. Collins, L.R.C.P., a house-to-house enquiry throughout the parish. They visited 21,885 inhabited houses and obtained statistics with regard to the vaccination of 141,620 persons. The enquiry elicited some interesting information. It showed that, of 25,917 children over one and under ten years of age, no less than 25,692, or more than 99 per cent. had been vaccinated, while of 112,425 persons over ten years of age, 71,213 or 63 per cent. had been vaccinated once, 39,835, or 35½ per cent., had been vaccinated more than once, and only 1,377, or less than 1½ per cent., were unvaccinated. As regards the incidence of small-pox on vaccinated, re-vaccinated, and unvaccinated persons

respectively, the results of the enquiry were as follows:—Of the 71,213 persons over ten who had undergone a single vaccination, 2,013 or 2·8 per cent. were found to be marked with small-pox. Of the 39,835 who had been re-vaccinated, only 29, or 0·08 per cent. were so marked. But of the 1,337 unvaccinated no less than 857, or 62·2 per cent., bore unmistakable traces of that disease.

*Compulsory Notification of Infectious Disease.*—The system of compulsory notification of infectious disease is steadily growing. In our last Annual Report we enumerated thirty-four towns, with an aggregate population of more than two millions and a half, where it had been already introduced. We have now to add that the towns of Chester, Croydon, Dewsbury, and York adopted similar provisions in their Local Acts of last year, and that Bills containing clauses of the same kind, and applying to Eastbourne, Hastings, Ramsgate, Sunderland, and Wakefield have been submitted to us prior to their introduction into Parliament in the Session of 1885.

**IMPORTANCE OF THE THERMOMETER IN EPILEPSY.**—Dr. Legrand la Saulle delivered a lecture, of which the following is a portion (*Gazette des Hopitaux*, No. 78), at the Hospice de la Salpêtrière:—"I have just lost a young epileptic under conditions well worthy of being reported, demonstrating as they do the clinical and exceptional value of the thermometer in epilepsy. But, first, let me lay down as a principle this fact, that it is not possible when an epileptic has undergone great amelioration under the bromide treatment to suspend the use of the salt for a certain time without the patient being exposed to grave convulsive relapse. All the provisional immunities so slowly acquired may suddenly disappear, and the patient in some hours, in two or three days, or, at a maximum, in nine days, may have to pay the balance of his comitial arrears and lose his life. Several years of great relative security, due to a daily perseverance in an invariable dose of the bromide, may give place to a sudden catastrophe. A suspension somewhat too prolonged of a medicine become indispensable for the maintenance of the silence of the neurosis, notwithstanding apparent health and the integrity of the intellectual faculties—and all is done. When an epileptic has been under the influence of bromide for a long period, he continues, after the cessation of the therapeutical agent, still, though less and less, to eliminate the bromide by the urine. After the 15th, the 16th, or even the 17th day no more is found, or only mere traces. If the patient had fits no longer, he may yet have one or more in the short space of time that had elapsed since his emancipation from the bromide slavery. But if the benefit of the treatment persisted (which is not very rare) for a month, six weeks, two, or even three months, there is still reason not to partake of a deceptive quietude. The enemy is there, all ready to strike. For a certain number of years I have always insisted on these particulars which are so special, on these minutiae, and ordinarily I exercise the greatest vigilance in the control of my own prescriptions; but in consequence of an intercurrent disease while taking the bromide, leading to a suspension of the medicine, I have witnessed twice in the same patient a most dangerous state of the disease. On the first occasion she recovered, but on the second she succumbed. This patient entered the Salpêtrière, at the age of 17, in November, 1881, and up to the end of that year there were counted 38 convulsive attacks and 13 vertigos; and during 1882 there occurred 132 attacks and 81 vertigos. In January, 1883, she became the subject of typhoid fever, and the bromide of potassium (of which until then she had taken from 4 to 5 grammes daily) was suspended. Twenty-five or thirty days afterwards she had completely recovered from this and was very merry, when she was suddenly seized with a fit, and had 1,646 attacks within the next three days. She got better, however, and renewed the bromide. During 1884 she had 259 attacks and 9 vertigos. In January, 1884, becoming dyspeptic, with symptoms of biliary calculi, the bromide was again suspended. On 7th February she was going on very well, and had resumed her ordinary little occupations in the ward, when she fell down in a fit, and on the 16th she died, after having suffered 2,074 attacks. She

had traversed quite a typical condition of epilepsy, and the most unfavourable prognosis had been given much more on account of the gradual elevation of the temperature than for the multiplicity of the fits. Thermometrical indications acquire here so great a prophetic value that their revelations cannot be too strongly insisted upon. An epileptic who habitually has a temperature of 37·5° C. may very well have one of 38° during and a short time after an isolated attack. If this has been a severe one, it may rise to 38·2° or even 38·5°, the pulse at the same time increasing to 80 or 86 and the respiration to 23-27. But when a series of attacks appear it is a very different matter. The multiplicity of the attacks, which is sometimes so extraordinary, is of the greatest importance in the convulsive period of epilepsy; but it is the elevation of temperature which should arouse the attention of the practitioner. Dr. Bourneville, who has contributed so much towards making known the clinical importance of the thermometer in diseases of the nervous system, has seen, for example, a little patient who, in the course of five days, passed from 38·3° to 42·1°, and another from 37·6° to 41°, the figure of 41° being quite hyperpyretic. The temperature increases in general from the first attacks, mounting up in proportion as these attacks are multiplied, especially when the faculties are enfeebled or abolished. At the end of this convulsive period the temperature may have advanced from 40° to 41°, and then death supervenes; but in a certain number of cases 39·5° is not exceeded, and then the stupor may disappear, consciousness return, the temperature speedily falling to 39°, 38° or even 37·8°. In the meningitic period of the disease, after the convulsions have become rare or have ceased, the temperature may diminish; but it may undergo another elevation, and then the condition is highly perilous, especially if the other symptoms are simultaneously exasperated. But even in this meningitic period if the temperature has not become hyperpyretic (40·5°, 41°, 41·3°), the collapse has diminished, the tongue has become moist, and especially if the temperature has sensibly diminished, all may yet be well. This epileptic condition may oscillate between three and nine days, and Dr. Bourneville has never seen it exceed the latter. In three-fifths of the cases the termination is fatal. In fine, thermometrical indications possess an undeniable value in the prognosis, and this fact is not as yet sufficiently known."

**ANTIPYRIN.**—Dr. Ziteke writes in the *Therapeutic Gazette*, for August: "Collapse, which so often accompanies kaïrine and makes its administration dangerous, seldom or never follows the administration of antipyrin. In one of my cases, where antipyrin was given for more than eight days in considerably large quantity, I observed that the temperature fell to 96° and remained so for several hours, though no other alarming symptoms were present. The pulse was full, the sensorium undisturbed, the respiration regular, and the patient was always ready to take the offered nourishment. Hence, I think that this fall of temperature, which sometimes follows large doses of antipyrin, and which was duly observed also by Docent von Hofer, Dr. Batek, Prof. Prizbram, and others can hardly be called a collapse, as all the pathological signs of collapse are usually wanting, and because the temperature after having been low for several hours begins to rise to its normal stage again. The sweating stage, which is so often observed in the wake of kaïrine and other drugs, is of no consideration after the administration of antipyrin. Sometimes it may be observed, yet it is usually the case in such diseases in which hyperhydrosis is one of the most common symptoms. In such cases small doses of agaricine or of atropine if administered are able to check the excessive sweating. Finally, as to the exanthematous symptoms which follow large doses of other drugs, they were also observed after a prolonged use of antipyrin. The eruptions were of widely different shape and form, some resembling measles, others scarlatina, or even the common form of urticaria hæmorrhagica. In some cases, however, it is impossible to lay the exanthema at the door of the drug, whilst in others, it is without the slightest doubt its effect. In such cases, however, the exanthema usually disappeared as soon as the administration of the drug was ceased. From all this we can derive the one

firm conclusion, that in antipyrin we have found a powerful antipyretic, very valuable in the treatment of the many acute febrile disorders, because its action is sure and because its administration is far more safe than that of many drugs now used by the profession."

**CHLOROFORM AS A HÆMOSTATIC.**—Dr. Betz, in his *Memorabilien*, 1885, No. 5, relates two cases of uterine hæmorrhage, in which he found chloroform of great utility in its arrest. The first of these occurred in the person of a robust woman, 33 years old, delivered of her second child under chloroform. Owing to the delay of the passage of the head, notwithstanding violent pains, the forceps was applied, and after the removal of the placenta, fearful hæmorrhage ensued, so that the reporter did not dare remove his hand which he had introduced into the uterus as a plug and a stimulus to action. The contraction soon subsided, and hot water injected by the side of the hand failed to reproduce it. Chloroform was now poured on a sponge and passed into the uterus, and some was also poured on to the abdomen. On the introduction of the sponge, a severe burning pain was felt along the genital passage, strong contraction of the uterus took place, and the bleeding ceased. A delicate woman, 23 years of age, formed the subject of the second case, being at about the fourth month with her third child. During eight days she had slight hæmorrhage and pains, and on the ninth a fœtus was expelled, succeeded by a mass of black coagulum. Hæmorrhage followed and resisted all the ordinary means, and the patient became cold and pulseless. A plug was made of cotton wool, and after being wetted with a mixture of chloroform and ether was passed up and held against the os by the fingers. Severe burning pain was produced from the vagina to the abdomen, and in a very short time contraction of vagina and uterus, with arrest of the hæmorrhage, ensued. The action of chloroform, Dr. Betz observes, differs from that of the ordinary astringents, not inducing coagulation of the blood as they do, but causing narrowing and closure of the blood-vessels in consequence of muscular contraction. When chloroform is not at hand alcoholic injections may be resorted to. The use of chloroform in this way may supersede the hypodermic injection of ether.

**URETHRAN IN INSOMNIA.**—Dr. R. v. Jaksch, privat-docent and assistant in the first medical clinic in Vienna, has made a number of observations on animals and in the wards on the action of urethran lately described by Dr. Kobert, of Strasburg. It is a white crystalline substance without smell, and something like saltpetre in taste. It dissolves readily in water, and has the formula  $\text{NH}_2\text{CO}_2\text{C}_2\text{H}_5$ . It does not appear to be a poison, as when given to rabbits in doses equal to a two-thousandth of their weight, no ill effects were observed; 110 observations were then made on its hypnotic effect on 20 different patients with various diseases associated with a greater or less degree of insomnia. Amongst them were cases of phthisis, chronic rheumatism, paralysis with cardiac disease in which both morphia and chloral were contraindicated, carcinoma of the rectum with carcinomatous peritonitis causing severe pain, and aneurysm of the aorta. The author at first gave doses of .25 gramme (about 4 grains), but found that that quantity produced scarcely any decided hypnotic effect. He then increased it to .5 gramme (about 8 grains), and with this, which nearly always succeeded in giving the patient a few hours quiet sleep, sometimes commencing immediately after the dose was taken, and sometimes being delayed for an hour or an hour and a half.

**PERFORATION OF THE CERVIX UTERI BY LAMINARIA TENTS.**—Dr. C. C. Lee relates (*New York Medical Journal*, July 25th) the case of a middle-aged single woman, under treatment for what was believed to be a sub-mucous fibroid attached to the anterior wall of the uterus, a short way above the internal os. Laminaria tents, carefully used and frequently changed, were introduced into the elongated cervix in order to favour exploratory and operative measures. The uterus was slightly anteverted. Two tents produced perforation on the anterior surface of the cervix at the vaginal junction. He had heard of two other cases in which a similar accident had occurred during the employment of laminaria tents.

## SPECIAL CORRESPONDENCE.

### THE NEW HYGIENIC INSTITUTE IN BERLIN.

(By Our Berlin Correspondent.)

THE foundation of this Institute has attracted much interest in scientific Europe, chiefly because a large part of the new building has been devoted to the formation of a Bacteriological Laboratory, the conduct of which has been placed under the direction of Dr. Koch as Professor of Hygiene in the Berlin University. From the great resources of this laboratory, both from a research-work and from a teaching point of view, there would seem to be reasonable ground for believing that in the future it will obtain a world-wide reputation similar to that now enjoyed by the Physiological Institute in Leipzig, and therefore more than ordinary interest attaches to the circumstances under which it has been instituted.

Until recently Dr. Koch was director of the old "Health Office" in Berlin, but was often (I believe) in that capacity more or less directly involved in work not strictly bacteriological. Recognising his great ability and the desirability of freeing the hands of such a man as far as possible, the German Government converted a large building in the Kloster Strasse into a Hygienic Institute, placing in it a bacteriological and chemical laboratory and a museum (the latter two departments not yet complete). The bacteriological department at least has been placed under Dr. Koch's direction, whilst his former assistant retains charge of the old "Health Office." The appointments of this bacteriological laboratory are superb. Under the professor's direction are five permanent assistants, and in addition other students who are working there at special bacteriological subjects.

With characteristic forethought the German Government determined not only to give Dr. Koch a magnificent laboratory, but also to place it within the power of almost every professional man in Germany to receive a thorough and practical bacteriological education. Those who work there are divided into three classes:—(1) The ordinary students who are taught for two hours three times a week during a semester. (2) Qualified practitioners who are admitted for from four to six hours daily for a month. (3) Qualified practitioners and others who desire to work at special subjects, and who are provided with a special place in the laboratory in which they can work for at least one semester. The fees for admission are to an English mind very low. For classes (1) and (2), 3*l.*; for class (3) 5*l.*, and absolutely no distinction is made between foreigners and Germans. It was one of these monthly courses (2) that the writer has just taken part in, and amongst the twelve students who had entered for that course there were representatives from Russia, Norway, Australia, America and Canada. The work done in these monthly courses is essentially practical, since the student is expected not to be ignorant of the theoretical branch of the subject. He is compelled to do almost everything for himself; to prepare his own gelatin meat infusion, bread cultivation material, blood serum, potatoes, etc., and this for the most part not once or twice, but over and over again until he can almost mechanically effect their successful preparation. With his own materials he is taught to make almost every known variety of cultivation, and to repeat them *ad nauseam*. He observes microscopically all the chief micro-organisms from micrococci to moulds. He is shewn the manner in which inoculations are made, and then repeats them for himself, next cultivates the organisms from the blood and tissues of the dead animals and again repeats the inoculations and cultivations. He is never asked to believe anything "on faith," but on the contrary is requested to thoroughly satisfy himself that what he is taught is true.

Thus, after one month's hard work, he is fairly well grounded in bacteriological method, and to repeat the witticism of a Danish bacteriologist, represents a spore going out into the world to reproduce its own species in a

suitable soil. The bacteriologist concluded by hoping that all the new cultivations would be "Rein-Culturen."

In conclusion, I should remark that the fidelity in detail, and what may be called "abstract honesty of purpose," evidenced in the daily work in the laboratory by all the officials, cause one to feel that the confidence of the German Government was well grounded; and I would echo the query of your former correspondent, and ask, Where in England could I receive such instruction on any terms whatever, and whose fault is it that I cannot do so?

## GENERAL CORRESPONDENCE.

### CENTENARIANS.

[To the Editor of the Medical Times.]

SIR,—I am endeavouring to collect information respecting centenarians, and shall be much obliged if any of your readers who may be acquainted with such a person, will be so good as to send me notice of the same. I shall also be glad to hear of persons who have attained or passed the age of ninety.

I am, Sir, yours, &c.,  
G. M. HUMPHRY.

Cambridge, September 30th, 1885.

### OBITUARY.

#### THOMAS SHADFORD WALKER, M.R.C.S.

It is with much regret that we report the death, on the 27th ultimo, of Mr. T. Shadford Walker, the well-known ophthalmic surgeon of Liverpool. Although it was known to his more intimate friends that he was in delicate health, his sudden death from apoplexy at the early age of 50 years has been a sad surprise to his professional brethren. Mr. Walker was born at Burslem, in Staffordshire, where his father practised as a surgeon. He was educated at King's College, London, and became M.R.C.S. and L.S.A. in 1858. In that year he was appointed house-surgeon to the Liverpool Infirmary. In 1861, Mr. Walker entered private practice, and obtained an assistant-surgeoncy to the Liverpool Eye and Ear Infirmary. In 1870 he became surgeon, and a short time ago consulting-surgeon. His reputation in ophthalmic surgery was deservedly great around Liverpool, and his practice in that specialty exceptionally large. He did not write much on professional subjects, but devoted his spare time to the study of art, and was famous as a collector of china, manuscripts, Wedgwood ware and other articles of *vertu*. He held the office of President of the Liverpool Medical Institution, and was a Vice-President of the Ophthalmological Society and an energetic member of the Liverpool Art Club.

### MEDICAL NEWS.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, September 10th, 1885:—

Stephen Moffatt Hay, Moorefield, Ontario, Canada; Edward Herbert Young, 13, St. John's Street, Stamford, Lincolnshire.

THE METROPOLITAN ASYLUMS BOARD.—On the first meeting of the Board since the recess, on Saturday, a letter was read by the Secretary, asking for a contribution to a testimonial fund to Mr. Elliott, a member of the Board, who had interested himself in promoting the Local Government Board enquiry into the management of the

Eastern Hospitals, which the letter alleged had caused a reduction in their present precept of 60,000*l.* In reply to this statement the Chairman read the estimates to Lady Day 1885-6, showing various anticipated reductions in the expenditure. A discussion ensued, during which it was urged that a reply to the calumnies upon the managers be issued. As to the Elliott testimonial, it was argued that the circular contained untruths and fallacies, and it was moved that it lie on the table; but an amendment, "that it be referred to the General Purposes Committee to report thereon if they thought proper," was carried by the chairman's casting vote.

SMALL-POX AT MONTREAL.—Montreal is suffering from a small-pox epidemic, which continues to spread with apparently hopeless severity. There were no less than 201 deaths from this disease last week, besides 70 in the adjoining municipalities. It is believed that there are now between 2,000 and 3,000 cases in the city. There are probably 100,000 persons in Montreal who have not been vaccinated, and the opposition and bigotry shown by the French population are unabated. They assert that the infection came from the slums of London, and they attempt to bribe the physicians to issue false certificates. The attempt on the part of the health officers to enforce the Compulsory Vaccination Act led on Monday last to rioting, which, at one time threatened to become serious. The offices of the Local Board of Health, as well as of one or two newspapers which had steadily pointed out that the epidemic of small-pox was due to the action of the French Canadians by their bigoted opposition to vaccination, were attacked by the mob and the windows broken. The houses of Dr. Lachapelle, a member of the Provincial Board, of Dr. Laporte, the public vaccinator, and of a druggist who sold vaccine points met with a similar treatment. On the following day the police proved equal to the occasion, and several of the ringleaders were arrested, and the latest accounts state that no further serious trouble is anticipated. Meanwhile, the small-pox is gaining ground, and in the first three days of this week, caused fully as many deaths as in the whole of last week.

BRITISH MEDICAL ASSOCIATION.—The medical profession of Brighton, held a meeting on the 26th ult., at the Dispensary, Queen's Road, which was numerously attended, and presided over by Dr. Withers Moore, to appoint a reception committee for working arrangements for the visit of the British Medical Association to that town next year. The appointment of an influential committee was the result.

THE ARMSTRONG ABDUCTION CASE.—The name of a respected medical practitioner, Mr. W. R. Cheyne, having been dragged into the above case, the editor of the *Pall Mall Gazette* has written to the daily papers to assert from his own knowledge that Mr. Cheyne had nothing whatever to do with the case of the girl Eliza Armstrong. "I much regret," adds Mr. Stead "that the name of this gentleman should have been brought into a business of which he knew nothing and with which he had no sort of connection, direct or indirect."

CHARITABLE BEQUESTS.—Mrs. Susannah Brookshank, late of 5, Arundel Terrace, Brighton, has bequeathed 500*l.* to the Samaritan Fund of the Sussex County Hospital, 200*l.* to the National Hospital for the Paralysed and Epileptic, Queen's Square, Bloomsbury, and 100*l.* to the Brighton Blind Asylum.

CONVALESCENT HOMES.—Miss Rawson, of Nidd Hall, has given 3,500*l.* for the erection of a convalescent home at Harrogate, in connection with the Bath Hospital, and the Earl of Harewood has presented the site (four acres) and 100*l.* towards the building fund. It is stated that the memorial to the late member for Wakefield—Mr. R. Bownas Mackie—will be a convalescent home, or an extension of the School of Art in the town.

ST. JOSEPH'S HOSPITAL FOR CHILDREN, DUBLIN.—This hospital (founded in 1872) for the treatment of sick children of the poor, received gratuitously, has been recently enlarged, to meet the increasing demands upon it. During the past year 235 cases were treated in the wards.

**VOLUNTEER MEDICAL CORPS AT WOOLWICH.**—A preliminary meeting, the first of a proposed series of meetings to establish district corps throughout the country, was held at Woolwich on the 25th ult., with the object of enrolling 100 men of the Volunteer Medical Staff Corps for the West Kent district. Sir James A. Hanbury, K.C.B., Principal Medical Officer of the Home District, presided, and there were also present Surgeon-Commandant Cantlie, Dr. M'Dowell, Principal Medical Officer at Woolwich, Surgeon-Majors Mansell, Maxam, Galway; Surgeons Wilson, Stephenson, W. H. Smith, Purvis, and a number of the principal civilians of the district. Sir Jas. A. Hanbury remarked that they had met with the object of providing a medical service for that portion of the great volunteer force belonging to the Woolwich district. It was at first proposed to establish a Volunteer Medical Association for West Kent for promoting the development of ambulance work in the volunteer service; and secondly to enrol a Volunteer Medical Staff Corps Company, consisting of 100 men, for the West Kent district. There was no question as to the importance and necessity of such a service, and he had not the shadow of a doubt that the movement which they were inaugurating would spread over the length and breadth of the kingdom and colonies. The great volunteer force, comprising nearly 220,000 men, demanded the establishment of this corps, and it was a movement deserving the cordial support and co-operation of all who had the interests of the Volunteer Army at heart. After some discussion, it was unanimously resolved that an executive committee should be appointed to raise a Volunteer Medical Staff Corps of 100 men for the West Kent district, and it was decided to ask the commandants and surgeons of the various volunteer regiments in West Kent to join the committee.

**QUARTERLY HEALTH RETURNS.**—Dr. Alfred Hill, the Medical Officer of Health for Birmingham, has a satisfactory account to give of his district for the second quarter of this year. The total number of deaths was 2,093, giving a rate of 19.57 per 1,000; as compared with the corresponding quarter of last year, there was a slight rise in the deaths of infants under one year, and of persons over twenty; whilst there was a very marked fall in the deaths of children between one and five years, and a decided fall amongst those between five and twenty. The death-rate from the zymotic diseases was remarkably low, whooping-cough alone causing anything like the usual number of deaths. In Bristol during the quarter under notice Dr. Davies reports that there were 1,043 deaths, giving a rate of 19.2 per 1,000; this shows an increase over the returns for the corresponding quarter of last year, which is attributed partly to the greater prevalence of measles and whooping-cough and partly to an increase in diseases of the respiratory tract. The town was fairly free from small-pox, scarlet-fever, diphtheria, and enteric fever during the quarter. In Hastings the report of Mr. Knox Shaw states that there were 155 deaths, equivalent to a death-rate of 12.98. The deaths from pulmonary complaints and from tubercular diseases figure largely, whilst only five deaths are included in the group of zymotic diseases.

**GLASGOW WESTERN MEDICAL SCHOOL.**—Dr. J. T. Carter, the Lecturer on Anatomy at this school, writes to draw our attention to the fact that the existence of the School was ignored in our Students' Number, an omission which we regret. The School has been in existence for five years, during which period most of the subjects of the Medical Curriculum have been lectured upon. The number of students attending the classes shows a steady increase. During the ensuing session Lectures on Anatomy and Demonstrations will be given by Dr. Carter, while Dr. McVail will lecture on Medicine, Mr. D. N. Knox on Surgery, Dr. W. L. Reed on Midwifery and Gynæcology, and Mr. J. W. Downie on Diseases of the Ear and Throat. The fees for the classes are moderate, and the students are able to take out the requisite hospital attendance and clinical instruction at the Glasgow Western Infirmary for the sum of 21*l.*

**THE FEVER EPIDEMIC, ASHFORD SCHOOLS.**—It is announced that the epidemic has nearly disappeared.

The later cases were chiefly of a mild type, and with the exception of 18 children and 7 officers, the patients are convalescent. 296 persons contracted the disease (263 children, 23 officers, nurses and servants, including the superintendent, and 10 labourers), and the deaths comprised 12 children and three of the officials. This low mortality is attributed to the great care bestowed by the staff on the patients. It is stated that the investigations and observations of the medical officers, Dr. De la Motte and Mr. Warwick, have brought to light a number of new and unexpected facts connected with the origin, dissemination, and treatment of typhoid, and the results, when tabulated, may be expected both to form an interesting contribution to the pathology of the disease, and to materially modify many previously entertained theories on the subject.

**STATUE OF SIR JOSIAH MASON.**—At Birmingham, on Thursday, October 1st, Sir John Lubbock unveiled a marble statue of the late Josiah Mason, which has been placed in the square between the Science College and the Town Hall. He afterwards delivered an address, in which he eulogised Sir Josiah Mason's wisdom and beneficence, and dwelt upon the importance of scientific instruction, not only as a branch of culture, but as essential to the future material development of the country.

**THE LATE DR. NICOL MARTIN, OF HUSBOST, GLENDALE.**—There was removed by death last week one of the oldest proprietors in the Highlands—the venerable Dr. Nicol Martin, of Glendale. Born in the first year of the century, Dr. Martin had attained the age of 85 years. He was the descendent of an old Highland family who had long resided in the Island of Skye, and he himself had personal recollection of the country and of its people from the period of his earliest observation. He graduated early in the medical profession, and spent many years abroad, having been during a long period a member of the College of Electors of British Guiana. On returning to this country he applied himself to the management of his estate, Husabost, which forms a portion of the district of Glendale in Skye, and in which reside many crofters and cottars, who were among the foremost in the land agitation. His professional acquirements were largely taken advantage of by the people among whom he resided; for years he prescribed and dispensed for the crofters and cottars free of any charge, and thus exercised a benevolent care over them.

**BIRTHS AND DEATHS IN FRANCE IN 1884.**—According to the *Journal Officiel*, the births amounted to 937,758 and the deaths to 858,784, being an increase of population in 1884 of 78,974, the increase in 1883 having been 96,000. This diminution is due to the epidemic of cholera which caused nearly 17,000 deaths, and the two departments in which this diminution was greatest (Bouches-du-Rhône and Var) were those in which the most numerous deaths from cholera took place. The department of the Nord continues to be that in which the greatest preponderance of births occurs, there having been 50,950 in 1884 to 35,563 deaths. The results furnished by the department of the Seine are much less satisfactory, there having been only 80,270 births to 72,535 deaths. Of the 87 departments of which France consists, only in 48 do the births exceed the deaths in number, the contrary being the case in the 39 others.—*Lyon Medical*, September 27.

**CONSANGUINEOUS MARRIAGES; THEIR EFFECT UPON THE OFFSPRING.**—Under this title, Dr. Witherington communicated an interesting paper to the Massachusetts Medical Society, which has since been published in full in the *Boston Medical Journal*, for August 20 and 27. Its length precludes our doing more than recommend its perusal to those of our readers who are especially interested in the subject, as containing an able examination of the conflicting views held in relation to it. The author likewise furnishes tabulated particulars which he has obtained concerning more than 100 instances. His general conclusion is that consanguineous marriages are not attended with the mischievous consequences which have been on insufficient grounds attributed to them.

**HAY-FEVER ASSOCIATION.**—Congresses and Associations are indeed just now rampant. The *New York Medical*

*Record* states that the annual meeting of the United States Hay-Fever Association was held at Bethlehem, N.H., on the 1st September.

**CONFISCATION OF CHOLERA-BACILLI.**—Professor Rummo, who had been for some weeks in Spain studying Dr. Ferrán's cholera inoculations, brought away with him four glass cylinders containing some of Ferrán's cholera culture. On his arrival at Naples the municipal authorities, getting to know of this, immediately despatched an official to his laboratory, who at once confiscated the four bottles. These, after being securely sealed, are now deposited in a subterranean vault of the municipal buildings. It is understood that the authorities will not allow Professor Rummo to perform any inoculating experiments with this material.—*Allgemeine Wiener Medicinische Wochenschrift*.

**EARLY TRANSMISSIBILITY OF VARIOLA.**—Dr. Lanee-reaux related at the Académie de Médecine (*Semaine Médicale*, September 9), some cases of variola which occurred in his service in the persons of patients who had entered for quite other diseases. The disease was introduced into the ward by three patients who were admitted into it by error, and were removed as soon as this was discovered. But as these cases which had transmitted the disease were sent out again the first day, or at latest on the second, of the eruption, they evidently show the erroneousness of the opinion generally entertained that small-pox cannot be transmitted until after the second or third day of the eruption. Small-pox, in fact, as well as measles, and probably scarlatina, is transmissible from its earliest period. The period of incubation in the three cases here referred to was exactly eleven days.

**THERAPEUTICAL APPLICATION OF CAFFEINE.**—Dr. Mays, Professor of Experimental Physiology and Therapeutics at the Philadelphia Medical College, as the result of a series of experiments on frogs (*Therapeutic Gazette*, Sept.), comes to this conclusion: "It is very evident that caffeine has a profound tendency to contract and give tone to muscles by stimulating their motor nerves. And since it exercises this power in the human organism chiefly on the unstriated muscles of the heart and the circulatory organs, it is very obvious that its therapeutic application lies in the direction of cardiac affections. Clinical experience undoubtedly teaches that within a certain sphere of these diseases it is superior to digitalis. Not that it will ever supplant the indispensable digitalis, but caffeine has the power of producing the same and sometimes better results without exposing the patient to the risks of the toxic action of digitalis. This is an important consideration. I certainly believe that on account of its tardiness the action of large doses of digitalis is very much underrated. It is slow in making itself felt, but when this comes it exerts its supremacy in a 'death-like grip,' and usually protracts its stay. Caffeine, on account of its immunity in even comparatively large doses is not only a safer agent, but also quicker in its action, as is plainly shewn by the profuse diuresis which closely follows its administration. It acts most beneficially on a weak heart: in valvular insufficiency depending more upon imperfect irritability or contractility of the heart-muscle than upon a loss of valvular urea—although I have seen it act very kindly in permanent mitral and aortic valvular incompetency, with incomplete compensatory action of the left ventricle."

**NAPIER (NEW ZEALAND) AS A HEALTH RESORT.**—Napier is situated on Scinde Island, which lies on the east coast of the North Island of New Zealand, near the southern extremity of Hawke's Bay. From a pamphlet recently issued by Mr. W. I. Spencer, who writes after a seventeen years' residence in Napier, we learn that the climate is a favourable one for invalids, not quite so hot or so enervating as that of Maderia. Limestone clay and sandy beds constitute the chief strata, the soil being porous and drying quickly after rain. Napier is fairly accessible from all parts of the world, the journey out from England taking about forty-five days. The general health of the population is good; typhoid fever, which used to be common, has almost disappeared, and malarial affections are extremely rare. Pulmonary affections are uncommon, whilst Mr. Spencer speaks of cases of advanced phthisis that have done well after their arrival in the colony.

**VENOUS INJECTION OF SALINE SOLUTION.**—Ziemacki and Kotelnikov recently injected a saline solution into the veins of a patient who was intensely anæmic from extra-uterine pregnancy in the Female Clinical Hospital in St. Petersburg. A great improvement occurred in the pulse after the injection, but the patient sank in four days time.

**FILARIA MEDINENSIS IN A PATIENT FROM TASHKENT.**—Professor Bogdanovski, of St. Petersburg, has extracted a worm (*Filaria Medinensis*) 110 centimetres long from the leg of a man of 36, who had returned nine months previously from Tashkent, where he had been residing for five months. Nothing was seen of the patient subsequently.

**CANCER OF PYLORUS SUCCESSFULLY EXTIRPATED.**—In a Polish medical journal, a case is mentioned by Dr. Baronez which occurred in the clinic of Professor Mikulicz, where a cancer of the pylorus was extirpated by Wölfler's method of gastro-enterotomy, and the patient recovered.

**ABUSE OF DISPENSARIES IN NEW YORK.**—These, according to the *Medical Record* of New York (August 15), seem to be more considerable in that city than with ourselves, and that owing to their being more used for teaching purposes. This induces the medical officers to allow the attendance of many persons whose means do not justify their presence there, in order that a better choice of cases for the various clinics may be obtained. "The patients are not the only ones to blame for the existing state of free medical service. It is the physicians also who attend the clinics, most of whom are professors or instructors. To them patients who will well illustrate diseases are at a premium. They are sought after with eagerness, and devices are resorted to to secure them. It is often a matter of how to induce people to come to the clinics rather than how to make them stay away. Dispensaries, too, are multiplied every year, and once started their managers desire to make them successful. Success is measured by numbers, and any inducement is offered to the moderately poor to avail themselves of free medical services." As to the patients themselves, designated here as "dispensary tramps," they are of every sex and age, and have made the rounds of almost all the dispensaries. They become connoisseurs of doctors and their methods of treatment. Some of them are very much puffed up with pride if their ailments have been such as to draw the attention of distinguished members of the profession, and to have brought them forward in the college clinics.

**IODOFORM.**—In the *Therapeutic Gazette*, August 15, Dr. Charles Pettit Stout gives the following directions as to how iodoform should be prescribed:—(1) To make a deodorized powder the iodoform must be in a very fine powder, likewise the chemical used to deodorize, and very thoroughly incorporated and let stand for one or two months in a glass-stoppered bottle. (2) To make ointments, take the deodorized iodoform and mix with vaseline or cosmoline, as the best base for the ointments. (3) In making into a pill mass add glycerine, which will keep the pill moist for a long time, owing to the hygroscopic properties of the glycerine. (4) To make suppositories, melt the ol. theobromæ at a gentle heat and stir in the deodorized powder, and pour into moulds of usual size. (5) To make the ethereal solution, add deodorized powder to the ether: can use one drachm to ounce of ether, or more if desired. (6) To make nasal bougies, cut a slender piece of fine strong sponge, about one inch and a half long, roll between two boards with pressure in shape of a thin cylinder, place a piece of strong silk through one end, and melt by gentle heat the vaseline or cosmoline with the white wax, and stir in the deodorized iodoform; keep stirring, and immerse the sponge and withdraw and cool and immerse again, and repeating until large enough (but stirring constantly), or about the size of a goose-quill; then hang up by silk until cool; then coat with a solution of gelatine containing about ten per cent. of glycerine, which will easily melt at the temperature of the body. The bougie should be introduced into the nasal cavity at night and withdrawn the next morning. One will do for several applications. (7) Can also use the deodorized iodoform by mixing with solution of collodion or solution of gutta-percha, by mixing the powder with either solution and painting the parts and let dry, then

paint over the first with the pure solution. By this means we prevent the iodoform from volatilizing by this impenetrable coating and secure the action of the deodorized iodoform.

**INDIA AS A FIELD FOR OPERATIVE SURGERY.**—The *Indian Medical Gazette* for August calls attention to the wide field which the Civil Department of the Indian Medical Service presents. "Having spent a few years in regimental duty, the young surgeon can generally obtain an appointment in the Civil Department. If, now, the bent of his desires be in the direction of operative surgery, he will soon obtain a wide field for his labours amongst the teeming population of this country, provided he be sympathetic in manner, bold and self-reliant in undertaking single-handed the most difficult operations, and painstaking and careful in carrying out the details of after treatment. . . . Often has it been matter of surprise to us that young medical men at home, endowed with ample pecuniary means, have not entered the Indian Medical Service with the object of accumulating an amount of surgical experience in a few years which it would take them a quarter of a century to gain while acting in a subordinate position on the staff of a London hospital. Pecuniary considerations would not debar them from resigning after eight or ten years' service, and they would return to England early in life, having performed more important operations than most of the senior surgeons of the London hospitals." In proof of the truthfulness of what he says, the writer points to the figures published in Surgeon Major McLeod's *Operative Surgery*, derived from the returns from Bengal, the North-Western Provinces, Oudh, and the Punjab during the years 1878-82. During these five years 13,724 cataract operations were performed in the North-West Provinces and Oudh alone, while 9,261 cases of stone were treated in Bengal and the above-named provinces. Amputations, excisions, and the removal of large tumours are also well represented. He also calls attention to the fact that the English writers on surgery in their statistical tables entirely ignore the work done in India.

**HEARING BETTER IN A NOISE.**—Dr. Sexton brought under the notice of the New York Practitioners Society (*Medical Record*), the case of a man who when 7 years of age had undergone destructive inflammation of both ears from scarlet fever. In his youth he was quite deaf, but hearing began to return as he approached manhood. Eventually he became stoker to a railway locomotive, and was promoted to the position of driver. For many years he ran his engine without any complaint; but when the railway employes were examined as to their power of hearing, he was dismissed. After drifting about he came under Dr. Sexton's notice at the Eye and Ear Infirmary, when it was found that he could not hear a loud voice at the distance of a few feet, and was unable to understand anything that was said to him. The man, however, stated that when he was on the engine he could hear better than his stoker whose hearing was normal, but the moment he left the train he could hear nothing. An artificial drumhead was introduced into one of his ears, and he was immediately able to hear ordinary conversation, and he at once obtained a place as a stationary engineer, and a drum head having been placed in the other ear he was also able to hear with it. Dr. Sexton observed that it is only in cases in which the drum-head of the ear partially remained that this device is of service; but in the greater number of cases of chronic catarrhal inflammation of the ear, the drum-head remains. When hearing is better in a noise the drumhead is usually present, but it is very loose; the equilibrium having been lost there is consequent defect in the transmission of mechanism. In such cases, loud vibrations, such as are experienced in a carriage or train, drive the drumhead in, bringing the ossicles together. Other sounds are taken up, and the subject is able to hear very well. In the above case only the upper segment of the drumhead was present, which failed to drive the ossicles in except during the presence of strong vibrations.

**SPONTANEOUS RUPTURE OF THE STOMACH.**—Dr. Clarke, of the Eden Hospital, Calcutta, records in the *Indian*

*Medical Gazette* for August, two examples of this rare occurrence which came under his notice very soon after each other. The first a Hindoo, 22 years of age, was in the hospital for slight ague when he suddenly fell into a state of collapse without pain or vomiting, and died twenty-three hours afterwards. The second case was that of a woman, who was supposed to have died of cholera, with somewhat uncertain history. "These cases were instances of rupture of the stomach, and not a mere perforation of its walls. Its coats in the first case were atrophied and thin, but in the second they were healthy; and in neither were they softened or eaten away in irregular patches by the action of the gastric juice. In both, the stomach was empty at the time of rupture; and in both the gastric juice acted on the spleen, digesting off its capsule and peritonæal coat, and thus allowing the escape of blood into the abdominal cavity. I think that there can be no doubt but that the rupture in both cases took place before death. The seat of rupture was on the anterior wall. The mucous membrane and peritonæal covering could be traced up to the margin of the rent, and did not present any marked degree of irregularity; and there was an absence of softening, erosion, or rupture on the posterior wall of the stomach."

#### APPOINTMENTS.

EMBREY, GEORGE, F.C.S.—Analyst for the City of Gloucester, *vice* Mr. John Horsley, resigned.  
GORDON, GEO., A. S., L.R.C.S. & L.R.C.P. Edin., L.F.P. & S. Glas.—Assistant Medical Officer to the Infirmary, Croydon Union.  
PATTON, A. S., M.B., B.Ch. Dub.—House Surgeon to St. Mark's Ophthalmic Hospital, Dublin.  
POTT, F. H., M.R.C.S.—Resident Medical Officer to the Boscombe Infirmary, Bournemouth, *vice* George H. Dawson, M.R.C.S., L.R.C.P. Edin., resigned.  
PURSLOW, C. E., M.B., M.R.C.S.—Resident Obstetric and Ophthalmic House Surgeon to the Queen's Hospital, Birmingham; *vice* A. F. Messiter, M.R.C.S., L.R.C.P., whose term of office has expired.  
WALSH, WILLIAM A. S., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Holt District, Martley Union, *vice* Mr. H. Hill, deceased.

#### VACANCIES.

BEDFORD GENERAL INFIRMARY.—Surgeon-in-Ordinary. Candidates must be legally qualified to practise both in Surgery and Medicine, and be duly registered. Applications and testimonials to be forwarded to the Secretary on before October 8th.  
ECCLES AND PATRICROFT HOSPITAL.—House Surgeon. Candidates must be duly qualified. Salary, £60 per annum, with board and furnished apartments. Applications and recent testimonials to be sent to E. H. Roe, Esq., Patricroft, Manchester, not later than October 3rd.  
HASTINGS UNION.—Medical Officer to the Third District, in succession to Mr. W. G. Jones, resigned. Area, 10,293 acres. Population, 5,221. Salary, £150 per annum.  
OWENS COLLEGE, MANCHESTER.—Professorship of Physiology. Candidates to forward applications and testimonials to the Council of the College, under cover, to the Registrar, not later than Nov. 9th. Further particulars can be obtained on application to the Principal of the College.  
ST. ASAPH UNION.—Medical Officer to the St. Asaph District and to the Workhouse, in succession to Mr. F. L. Heaton, resigned. Area, 19,260 acres. Population, 4,241. Salary, £67 per annum. Salary for Workhouse, £40 per annum.  
STRATTON UNION.—Medical Officer to the South District, in succession to Dr. W. Stuart, resigned. Area, 27,430 acres. Population, 2,907. Salary, £60 per annum.  
TAUNTON AND SOMERSET HOSPITAL.—Honorary Physician. Candidates must have taken the degree of Doctor of Medicine, or be Fellows or Members of one of the Royal Colleges of Physicians of London or Edinburgh, or of the King and Queen's College of Physicians in Ireland, and be duly registered under the Medical Acts. Applications, accompanied by qualifications and testimonials to be sent to the Secretary, on or before October 14th.  
THIRSK UNION.—Medical Officer to the Pickhill District, in succession to Mr. David Mickle, deceased. Area, 4,098 acres. Population, 611. Salary, £10 per annum.  
WIGTON UNION.—Medical Officer to the Ireby District, in succession to Mr. T. R. Denham, deceased. Area, 19,840 acres. Population, 2,060. Salary, £11 per annum.

#### DEATHS.

BAGSHAW, E. L., F.R.C.S., at 13, St. James's Square, Bath, on September 22nd, aged 76.  
BROWN, HENRY J., F.R.C.S., at 20, Foregate Street, Worcester, on September 22nd, aged 66.  
CONCANON, W. A., M.D., at Brisbane, Queensland, on July 30th.  
DRIUIT, WILLIAM, F.R.C.S., at Westfield, Wimborne Miueter, on September 27th, aged 65.

HOCKIN, G. T., M.R.C.S., L.R.C.P., L.M., at Southport, Queensland, Australia, on September 23rd, aged 27.  
 LEE, ALFRED ROBERT, M.R.C.S., etc., at 71, Highbury Hill, N., on September 29th, aged 37.  
 PAYNE, EDWIN, M.D., at 19, Gilmore Road, College Park, Lewisham, on September 23rd.

## NOTES, QUERIES, AND REPLIES.

### THE CASE OF DR. BRADLEY.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Will you kindly allow the following list of subscriptions to appear in the next issue of your Journal?

I remain, yours faithfully,

ROBERT JEFFREYS.

*Eastwood House, Chesterfield, September 30th, 1885.*

Dr. W. H. Broadbent. Mr. Timothy Holmes, each, £2 2s.; Mr. Clement J. Hawkins, Dr. W. H. Taylor, Mr. R. J. Pye-Smith, each, £1 1s.; Mr. Edward J. Betts, £1; Dr. Ptolemy S. H. Colmer, 10s. 6d.; Mr. A. Hamilton, Mr. Frank S. Goulder, Mr. Allen Wearing, each, 10s.

### COMMUNICATIONS RECEIVED—

Prof. G. M. HUMPHRY, F.R.S., Cambridge; Dr. FOWLER, London; Dr. J. S. BRISPOWE, London; Dr. G. E. HERMAN, London; Dr. HUXLEY, Maidstone; Prof. E. A. SCHÄFER, London; Mr. A. J. PEPPER, London; Dr. J. H. PACKARD, Philadelphia; Dr. LEOPOLD CASPER, Berlin; Dr. W. H. ALLCHIN, London; Messrs. HODGE & Co., London; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; THE SECRETARY OF THE MEDICAL SCHOOL, LONDON HOMŒOPATHIC HOSPITAL; THE DEAN OF THE MEDICAL DEPARTMENT, KING'S COLLEGE, London; Mr. B. F. WATKINS, London; THE MEDICAL OFFICER OF HEALTH OF THE PORT OF LONDON; OUR BOMBAY CORRESPONDENT; THE SANITARY COMMISSIONER OF THE PUNJAB, Lahore; THE SECRETARY OF THE LOCAL GOVERNMENT BOARD, London; Mr. HUTCHINSON, F.R.S., London; Mr. J. T. CARTER, Glasgow; THE SECRETARY OF THE COLLEGE OF MEDICINE, Newcastle-on-Tyne; Mr. COWELL, London; Mr. SELL, London; THE SECRETARY OF THE NIGHTINGALE FUND, London; THE SECRETARY OF THE OBSTETRICAL SOCIETY, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE EDITOR OF THE LIVERPOOL JOURNAL OF COMMERCE; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE HON. SECRETARY OF THE HUNTERIAN SOCIETY, London; THE DEAN OF THE LONDON SCHOOL OF MEDICINE FOR WOMEN; THE SECRETARY OF THE CLINICAL SOCIETY, London; THE DEAN OF ST. MARY'S HOSPITAL MEDICAL SCHOOL, London; Mr. N. C. DOBSON, Clifton; OUR LIVERPOOL CORRESPONDENT; Mr. R. JEFFREYS, Chesterfield; Dr. ALFRED MEADOWS, Bournemouth; Dr. W. J. COLLINS, London.

### BOOKS RECEIVED—

Transactions of the Sei-I-Kwai—Napier (N. Z.) as a Health Resort for Pulmonary Invalids, by W. I. Spencer, M.R.C.S. Lond.—Medical Communications of the Massachusetts Medical Society—Medical Dictionary, by Joseph Thomas, M.D., LL.D.—Report on the Health of Bolton during the year 1884—Atlas of the Cutaneous Nerve Supply of the Human Body, by Jacob Heiberg, M.D., &c.—The Blot upon the Brain, by William W. Ireland, M.D. Edin.—Moisture and Dryness; or the Analysis of Atmospheric Humidities in the United States, by Charles Denison, A.M., M.D.—The Encyclopædic Dictionary, Part XXI.—A Guide to the New Pharmacopæia (1885), by Prosser James, M.D.

### PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Weekblad—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—Journal of the American Medical Association—The Therapeutic Gazette—The American Journal of Obstetrics—The Medical World—The Hospital Gazette—Revue Médicale—Revista de Medicina—The Ophthalmic Review—The Journal of Mental Science.

## HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.; Chelsea Hospital for Women, 2.30 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## I.—ON THE CAUSE AND DISTRIBUTION OF CALCULOUS DISEASE.

By CHARLES B. PLOWRIGHT, M.R.C.S., F.L.S.,  
Surgeon to the West Norfolk and Lynn Hospital,

*A Comparatively Stone-free District in Norfolk—  
Influence of Salt as an Article of Food.*

It has long been a favourite idea with me that a careful study of the distribution of our Norfolk stone cases with regard to the geological formation of the various villages in which they have occurred would throw light upon the ætiology of the disease, and although previous attempts to elucidate the cause of the prevalence of calculus in Norfolk have been comparatively unsuccessful, still the attempt was worth making now that the county has been so recently gone over by the staff of the Geological Survey. Through the kindness of Mr. Cadge I have been able to avail myself for this purpose of the records of the Norwich Hospital since its foundation in 1771, as well as, in part, those of the Yarmouth Hospital, together with his own private cases and those of some other Norwich surgeons. In addition to the above, the records of the Lynn Hospital and of several private practitioners in Lynn and in the

county have been made use of, together with a list of some 140 cases for which I am indebted to Professor Humphry, of Cambridge. Altogether something over 2,000 cases, with the locality whence each was derived, have formed the basis upon which the following communications are based. It soon became evident during the course of this investigation that a knowledge of the distribution of the disease in other parts of the kingdom was necessary, and that other causes must be taken into consideration which could not properly be studied if attention were confined to Norfolk. It also happened that by a study of the distribution of the disease in a limited area, as in Norfolk, certain reasons for its frequency or rarity suggested themselves, which it was obviously desirable to corroborate or disprove by appealing to wider sources of information.

The small hospital at King's Lynn, during the fifty years of its existence, has drawn its cases, as all hospitals do, not only from the town in which it is placed, but also from the surrounding country district. It has long been a subject of remark amongst the Lynn surgeons that there was one district from which a stone case never came, namely, from Marshland, and although this is not absolutely true, yet it is a fact that the disease is very uncommon in this district. I therefore resolved upon a careful investigation of this point in the hope that it might throw some light upon the ætiology of the disease. The district of Marshland, as limited in the present enquiry, consists of a tract of flat alluvial country of a triangular shape, bounded on

the east side by the river Ouse, on the west by the river Nene, and on the north by the Wash. It comprises an area of about 160 square miles, and in great part, almost within historic times, has been reclaimed from the sea, which, even now, is kept back by a series of banks. Its population, of about 16,000 persons, is purely agricultural. Taking a corresponding area on the east side of the Ouse (excluding the two townships of Lynn and Downham, the population of which, together, is 21,795) we find a similarly agricultural population of about 17,800. Taking all the records of stone cases (including those of Norwich, which date from 1772) I find that some<sup>1</sup> twenty cases have occurred in Marshland against 100 in the eastern area. By confining ourselves to the last twenty years, 1865-85, we find these two areas east and west of the Ouse have produced a very dissimilar number of calculous cases—

West of the Ouse (Marshland), pop. 16,634, 5 cases.  
East of the Ouse " 17,825, 21 cases.

Of course this does not represent every stone case which has occurred during this period, but only those which I have been able to trace. Since the foundation of the Lynn Hospital in 1835, 129 cases of calculus have been admitted; of these only 14 came from the west side of the River Ouse. Again, the rarity of the disease in Marshland is further shown by the admissions for the last 20 years. Only one case has been treated from Marshland, against 51 from the east side of the River Ouse. This Marshland case is further interesting, inasmuch as it was a child of 4 years whom I cut in 1880. The parents were not natives of Marshland, but migrated from a village on the east side of the river about a year before the child was born, and he had symptoms of stone from his birth.

Between these two areas no noteworthy difference exists in the amount of rainfall, temperature, wind, ozone, &c. As much beer is consumed on one side the river as the other, and there is the same difficulty in obtaining milk, yet the amount of disease is so different. If each case be marked by a dot on an ordnance map, the abrupt manner in which the disease stops on the east bank of the river is very conspicuous. It is difficult to conceive of any other than a water-spread cause thus being limited by a river, especially when we remember that the land on the east side of the river is somewhat the higher, so that its natural drainage is into the river, but not beyond it.

Such being the circumstances of the case, the question naturally suggests itself whether the immunity which the inhabitants of Marshland enjoy is due simply to the absence of some stone-producing cause operating on the east side of the river, or whether there is anything in the Marshland drinking-water which acts as a preventive to the disease. For the following case bearing on the subject I am indebted to Mr. Cadge. A gentleman, whose father and grandfather suffered from stone, lived in two Norfolk villages till he was 17 years of age, and suffered all the time more or less from gravel. For the next 12 or 14 years of his life he resided at Marshland (Tilney) and in the fen district (Wisbech and Ely), during which time he had no gravel whatever. He then removed to another Norfolk village, where his old urinary troubles again affected him to such an extent that he developed a calculus which was crushed by Mr. Luke; he was perfectly cured, but in the course of a few years he developed a second stone, which Mr. Cadge crushed in 1861, removing an ounce of hard uric acid calculus in 17 sittings.

The natural water supply of Marshland is surface water only—ditch-water, in fact—there being no

streams and comparatively few wells. Of late years this has been supplemented—(1) by rain-water stored in cisterns; (2) by a water supply to Wisbech, which is conveyed across Marshland in an iron main, and of which the villages through which the main passes have availed themselves. So impregnated is the soil with salt that only a few wells yield potable water—at least such is the case in that part of Marshland between Lynn and Wisbech. For the purposes of the present enquiry I collected the following 19 samples of surface waters from Marshland, the amount of chlorine in which Mr. F. Sutton, F.C.S., of Norwich, has determined for me:—

	Chlorine grains per gallon.
Terrington St. Clement's	Post Mill Pulk .. 8.12
" " "	Road Side Pit .. 162.8*
" " "	Seaking's Well .. 67.2
Tilney All Saints	Savage's Well .. 110.6
" " "	Holborn's Pit .. 56.0*
" " "	Reeder's Well .. 36.4*
" " "	Gregory's Pit .. 10.08*
Tilney St. Lawrence	Peek's Well .. 33.6
Walpole St. Peter's	Stacey's Well .. 151.2*
" " "	Cozen's Well .. 129.3*
Walpole St. Andrew's	Road Side Ditch 1274.0*
" " "	Timble's Well .. 49.0
North Lynn	Clark's Well .. 127.4
West Lynn	Rayner's Well .. 36.4
" " "	Ellis' Well .. 22.4
Clenchwarton	Cotton Row Pit 10.64
" " "	Bartle's Pit .. 336.0
Elm	Canal .. 319.2*
" " "	Clamp Pits .. 11.2
	Average 155.3
	= 253.95 grains of salt per gallon.

Of the above, those marked with an asterisk are not used for drinking purposes. To show, however, how salt water must be before it is rejected by the inhabitants of Marshland, Bartle's pit and Savage's well may be instanced, in both of which the water tastes so strongly of salt that one would think it quite undrinkable, yet I was assured these were both excellent waters when "one pail-ful is mixed with two of rain-water." The average amount of chloride of sodium in the eleven of the above waters at present used is 108.6 grains per gallon.

If now, for comparison, we take 11 samples of potable water from the corresponding area on the east side of the river, we shall find a very marked contrast. The following samples were collected from various wells used by persons who suffered from calculus during the last 30 years. Mr. Sutton has determined the amount of chlorine in them as follows:—

	Chlorine grains per gallon.
Watlington	S. Nobbs' Well .. 8.40
" "	E. Moore's Well .. 3.60
West Bilney	Paw's Cottages .. 3.60
" "	Baek's Well .. 2.24
Rnneton Holme	Jerry's Well .. 7.80
West Winch	Hunter's Well .. 3.00
Seteh	Newell's Well .. 11.60
North Wootton	The Run .. 2.20
Ashwicken	Robert Smith's Well .. 1.40
Middleton	Shaw's Well .. 2.80
King's Lynn	Water Supply .. 2.20
	Average 4.44
	= 7.22 grains of salt per gallon.

Because Marshland is a stone-free district and its waters contain salt, yet it by no means follows that presence of salt is the cause of the absence of stone, for there are very few districts in England where salt is so abundant in the drinking waters, and yet there are

<sup>1</sup> The actual numbers are 18 and 94, but about the time the Lynn Hospital was started a lithotomist of considerable local note practised at Downham, of whose cases I have no record, although I know he operated frequently for stone.

many in which stone is still more uncommon. Still the fact remains that on one side of a river where the waters are salt, there is less stone than on the other where this is not the case, and it occurred to me that this line of enquiry was worth following up. If the presence of salt in the drinking waters has any tendency to lessen the frequency of calculus, we should expect to find that a deficiency or an abundance of this substance in the dietary of the inhabitants of other parts of the kingdom will have a similar effect. For this purpose it occurred to me that if there was anything in the above supposition, an increase in the number of calculus cases would be apparent during the time the salt tax was imposed.

Salt was taxed<sup>2</sup> in the time of the Commonwealth, at the rate of  $\frac{1}{2}d.$  per gallon; in 1694, this was increased to  $3d.$ , and again in 1698, to  $6\frac{1}{2}d.$ , but being always an unpopular tax, it was taken off in 1730. Two years later, however, it was re-imposed by Walpole. The duty was subsequently raised by Lord North, during the war of American Independence, to  $5\frac{1}{2}d.$  per bushel. In 1798, Pitt raised it to 10s. per bushel, at which rate it was continued until 1825, when it was again raised to 15s. or about thirty times the value of the salt itself. The excessive duty on salt lasted from 1798 to 1823, when it was reduced to 2s., and finally taken off altogether in 1825. We may therefore speak of the salt tax period as extending from 1798 to 1823.

I have endeavoured to obtain from various hospitals in England an account of their yearly admissions of stone cases, before, during, and after the salt tax period, but hitherto with only very limited and partial success. That a distinct increase in the number of stone cases did actually occur in many hospitals during the period of the salt tax, as compared with the preceding years, is shown by the following statistics<sup>3</sup> which show the percentage of yearly admissions, before and during the salt tax period.

	Before the Salt Tax.		During the Salt Tax.	
Canterbury ...	1793 to 1798	·6	1798 to 1815	1·2
Leeds ...	1776 to 1797	3·5	1797 to 1817	4·4
Worcestershire ...	1767 to 1779	1·04	1792 to 1817	2·0
Cambridge ...	1766 to 1799	0·4	1799 to 1817	4·0
Leicestershire ...	1771 to 1779	0·3	1801 to 1813	3·0
Cheshire ...	1735 to 1779	0·02	1787 to 1817	0·4
Shropshire ...	1747 to 1779	0·2	1800 to 1813	1·5
Liverpool ...	1749 to 1779	0·2	1807 to 1817	0·9
Average ...	...	·78	...	2·15

Part of this increase is doubtless due to the increase of the population of the county generally, but this does not explain the whole of the phenomena. If we take Leeds for an example:—

1767 to 1777	..	..	24 cases
1777 to 1787	..	..	62 "
1787 to 1797	..	..	23 "
1797 to 1807	..	..	42 "
1807 to 1817	..	..	46 "

Upon the other hand, we must take into consideration the fact that although the general population, and consequently the gross number of stone cases, may be increasing, yet the hospital accommodation of any particular district may have increased in a greater degree by the establishment of fresh hospitals among which the cases have been distributed. Thus, between 1750 and 1760, Bristol had 83 cases, while between 1780 and 1790 only 36. Now, between 1750 and 1790, hospitals were established at Gloucester, Oxford, Salisbury, Hereford, Birming-

ham, and Bath (2), which places were 35, 70, 53, 50, 87, and 12 miles distant from Bristol respectively. If the salt tax and not the increase in the population be the cause of this increase in the number of stone cases, we shall expect to find a corresponding decline taking place after the duty was removed. How long the effects of the salt famine would take to eliminate themselves it is not easy to say. The tax was finally removed in 1825, and the official registration of deaths did not begin till 1837, but it is certain that deaths from calculus have steadily declined since registration commenced.

Half-year ending 31st December, 1837, 180 deaths :

1837 =	360	1840 =	303
1838 „	320	1841 „	261
1839 „	299	1842 „	304
(Deaths from 1843 to 1846 not abstracted)			
1847 =	265	1851 =	204
1848 „	202	1852 „	208
1849 „	218	1853 „	224
1850 „	250	1854 „	183

The introduction of anæsthetics, however, took place about 1850, which would tend to lessen the deaths from the disease, by inducing patients more readily to submit to early operation.

Dr. Thursfield<sup>4</sup> has extracted the cases of calculus treated at the Shrewsbury Infirmary, between the years 1747 and 1877. He found 118 cases were treated from the town of Shrewsbury itself in the 114 years. If this 114 years be divided into two periods of 57 years preceding and subsequent to the year 1820 (exclusive of 15 years of which the records are wanting), it appears that 81 cases occurred prior to 1820, but only 38 after that date. These cases occurred in the residents of Shrewsbury, which in 1801 had a population of 13,812, and in 1881 of 30,400, so that the salt tax period produced a far larger number of cases than did the subsequent period in spite of the increase in the population.

The records of the Norwich Hospital showing the admissions for stone, year by year since 1772, afford much the most valuable evidence, because not only is the population known, but also the dates at which neighbouring hospitals were established. The annexed chart shows this at a glance. We here see that a distinct increase in the number of cases occurred during the salt tax period and a subsequent diminution after its removal—a diminution which steadily continued in spite of the population of the county doubling itself. The only hospital likely to diminish the Norwich cases was the small one of 22 beds at Lowestoft, established in 1820, 23 miles distant. I do not know whether it had so many as 22 beds when it was started, but it would hardly be likely to draw away many cases considering the prestige the Norwich Hospital always has had for stone cases. Lynn Hospital (48 miles) and Yarmouth (24 miles) were not started till 1835 and 1839 respectively. The decline had, however, set in long before the two latter hospitals came into existence. On the chart is also shown the population of Norfolk. This, in 1801, was 270,000; by 1841, when the disease had fallen almost to its lowest, it was 412,000, or nearly double, so that the amount of increase in hospital accommodation is more than compensated for by the increase in the population. We also see by this chart that for the last 30 years (1855-85) the admissions into the Norwich Hospital have risen very considerably, although the population has fallen slightly between these dates. This is accounted for by the fact that a large number of young adults annually emigrate from the country,

<sup>2</sup> For these particulars I have to thank Mr. A. Grant, of Somerset House.

<sup>3</sup> The above statement has been calculated from the data given in Mr. Smith's paper in "Medico-Chirurgical Transactions," Vol. xi.

<sup>4</sup> Report on Borough of Shrewsbury by the Medical Officer of Health, May 14, 1877.

leaving the old men and children—the two stone-producing elements of our population. Between 1851 and 1861, 60,000 of the inhabitants of Norfolk left the county to seek employment elsewhere, and the

same efflux of the adult population has continued ever since. Although there are no census returns prior to the beginning of the present century which are available for the explanation of the rise between 1777 and

1781, yet this can be fairly accounted for, I think, by the growing reputation of the hospital, attracting to it the accumulated stone cases of the pre-hospital period. The cases are shown on the chart biennially; this is done partly to shorten the diagram, and partly to counteract the great elevations and depressions occurring in alternate years, which are mainly compensatory of one another. The average annual number of admissions for stone is 12·8 (*i.e.*, 25·6 biennially).

The salt tax was practically imposed for 26 years, (1798 to 1824); now, if we compare the annual average admissions before, during, and after the salt tax period we find them to be :

	Average Annual admissions.	Population of Norfolk.
Before the Salt Tax . . . 1772 to 1797	11·7	1801 = 273,479
During the Salt Tax . . . 1798 to 1823	15·7	1821 = 344,368
After the Salt Tax . . . 1823 to 1849	9·8	1841 = 412,664
(Emigration of Adults) 1849 to 1875	15·9	1871 = 434,791

It is worth while to remark that the salt counties of England are very free from calculous disease, as Mr. Cadge pointed out with regard to Cheshire.<sup>5</sup> I find that for the 10 years 1872 to 1881, the deaths from calculus per 100,000 of the population (1881) were in Cheshire 3·21, against 28·3 in Norfolk. In Durham, another salt county, the deaths for the same period were only 4·91.

The amount of salt consumed in various places and by various classes of the community differs somewhat. Thus, Thudicum<sup>6</sup> in speaking of the amount of chlorine in the urine, says: "Sailors who have lived on salt rations for the greater part of their life spent afloat, will discharge an extraordinary amount of chlorine in their urine, because the ordinary food of our kitchen is insipid to them without the addition of an amount of salt that would make an ordinary person ill. Such men may be seen dipping sweet cake into salt, and this inclination generally lasts for the remainder of their life on land."

In various parts of England, the amount of salt food consumed probably does not differ very greatly. With regard to the amount of calculous disease in Scotland, our knowledge is at the present time very incomplete; from an extended enquiry into this matter, I am, however, in a position to say that the disease is more uncommon than the Registrar General's returns would lead us to suppose. I have received a large number of communications from medical men practising in the North of Scotland, including Orkney, Shetland, and the Hebrides, from which it appears that in the last-named places especially, salt fish enters largely into the dietary of the poorer classes, and that they enjoy a great immunity from the disease. I intend in a future communication to publish in detail the valuable information these gentlemen have given me, as it is in itself a history of the distribution of the disease in their part of Great Britain. I would here remark, however, that salt is an essential ingredient in porridge for one thing, and for another that the Scotch people use this condiment more freely in the dietary of children than we in England do.

If the consumption of salt as an article of food has any power of lessening the frequency of calculus, it occurred to me soon after I began the present investigation that this must have been noticed by other observers. It was very satisfactory to me to find that this is really the case. Mr. Coupland Hutchison<sup>7</sup> has shown that in the navy during the early part of the present year, calculus was exceedingly rare. He found

that from 1st January, 1800, to 1st January, 1816, the navy comprised annually 162,000 men and boys from the age of 9 to 60 years. During these sixteen years only eight cases of calculus occurred amongst the above, and of these only five originated at sea. That is to say, 1 case in every 518,400 males— $162,000 \times \frac{1}{5} = 518,400$ . Mr. Hutchison says this immunity is most marked amongst the sailors (not the officers) of the navy, "who live for months on highly-salted beef and pork," and who thus acquire such a taste for salt that "it is incredible to see what quantities of salt the seamen will use with their fresh beef." It would have been very interesting to have compared the relative infrequency of the disease as it then existed with the present more generous diet of the navy, but Sir John Reid, the Director-General of the Medical Department, informs me this cannot be done, as the cases of calculus, although now very uncommon, are not separated in the returns from other urinary diseases. Dr. Yelloly<sup>8</sup> has suggested that the statistics above quoted are fallacious inasmuch as the navy is manned by adults in good health, and at an age least likely to afford cases of calculus (14 to 50). But Mr. Hutchison points out that the limit of age was at the time he wrote really greater, viz., 9 to 60, and moreover we must remember this was during war-time when governments are always less jealous about the health of recruits, and, in point of fact, at the time in question, employed the press-gang in order to obtain men for the navy: an agency which would unceremoniously over-look physical defects far more obvious than a tendency to urinary calculus.

Mr. Hutchison<sup>9</sup> in a further communication shows that from 1st January, 1816, to 1st January, 1828, 331,000 men and boys were employed in the navy, of whom 21,910 were invalided from various causes, but not a single case of stone occurred amongst them; and from 30th November, 1830, to 30th November, 1836, the navy consisted annually of 30,000, of whom 2,000 were boys, and that during these six years only one case of stone or gravel occurred, which was a case of renal calculus.

If we, upon the other hand, look for a class of the community from whose dietary salt is conspicuously absent, we shall find it in infants and young children of the poorer classes. The children of the upper and middle classes have very generally added to their milk or milk-food a small quantity of salt, especially amongst those, and they are a pretty numerous class of the community, who are guided by the writings of Mr. Chavasse. The fact that the children of the poor suffer more from calculus than those of the rich has been pointed out by Mr. Cadge,<sup>10</sup> who indicates that it may be due to a deficiency of milk in their diet. But milk is deficient for the diet of infants and young children in all parts of England; but it is only in Norfolk and Suffolk that they so specially suffer from stone. Again, in Marshland milk is exceedingly difficult in many of the villages for the poor to obtain, as I can testify from a personal residence; yet the Marshland children escape stone, while the children on the opposite side of the Ouse suffer from it.

From the foregoing it would appear that there is a considerable amount of evidence indicating that the presence or absence of salt in the dietary has a determining influence upon frequency or rarity of calculus. It remains for us to consider in what way this is brought about.

In the first place, I think it is pretty evident that the more salt a person consumes the greater is the amount of thirst he will experience, to allay which,

<sup>5</sup> Address in Surgery, *Lancet*, Aug. 15, 1874, p. 233.

<sup>9</sup> "Medico-Chirurgical Transactions," Vol. xvi, pp. 95-120.

<sup>10</sup> Address in Surgery, *Lancet*, 15 Aug., 1877.

under ordinary circumstances, he will drink a larger amount of fluid than would otherwise have been the case. This is such a self-evident fact that the dishonest publican who adulterates his beer with salt does so to make his customers imbibe more freely; at any rate, he gets the credit for thus acting. Be this as it may, we all know a meal of salt fish or salt meat makes us thirsty. It is equally obvious that the more fluid that passes through the kidneys in a given time, the more dilute will be the urine, and hence the less chance will there be of its solid parts separating in the form of gravel or calculus. So plain, then, on this score is the action of salt, that it might have been dismissed without further comment, had it not been for the statement of Kaupp and Flack, as given by Parkes,<sup>11</sup> that "the urinary water is not increased, is even lessened in man." I have not had the opportunity of referring to the original statement<sup>12</sup> of these authors, but it is possible that, during the experiments made by these gentlemen, for some purpose unknown to me, they refrained from gratifying their increased thirst. When a quantity of chloride of sodium is taken, as with ordinary meals, the whole of it does not pass out with the urine: a portion of it emerges within six hours (Buchheim); another part is retained for some time, and then appears in the urine, so that in 24 hours two-thirds have passed out: while a considerable portion (one-third, Bischoff) never appears in the urine at all, but is either retained for a longer time, or emerges by the skin, or, if there be diarrhoea, by the intestines, or occasionally by the saliva (Percy, Wright), or by the milk during suckling (Harnier).<sup>13</sup>

The same author observes<sup>14</sup> that during childhood everything shows a very rapid kidney excretion, and in this respect the kidney only participates in the activity of the lungs and of the skin. This is clearly seen from the subjoined table, which shows the amount of kidney excretion to a given weight of the body during twenty-four hours in children of both sexes between the ages of three and seven years, compared with adult males:—

	In Children.	In Male Adults.	Excess in Children to each Kilogramme.
Water ... ..	59 c.c.	23 c.c.	36 c.c.
Urea ... ..	0·973 grm.	0·500 grm.	0·473 grm.
Urea and Volatile Salts	0·279 "	0·151 "	0·128 "
Chlorine ... ..	0·303 "	0·106 "	0·202 "

From which it appears that the amount of chlorine to body-weight of children in health is nearly three times that of the male adult; hence the obvious necessity of supplying this important element in their food for one thing, while for another the greater amount of total solids per kilogramme explains the well-known fact of their great liability to urinary concretions.

That salt is an important element in our food is so well known that one would hardly think it necessary to repeat it; but there has been a tendency manifested by a certain class of pseudo-physiological valetudinarians to decry its utility. I am therefore the more pleased to note that Dr. Lionel Beale<sup>15</sup> speaks out strongly in favour of an increased consumption of salt as an article of diet, and it would seem that the admissions of stone cases into the Norwich Hospital bear out his remark that the salt tax was "cruel and unprincipled." Our knowledge of the geographical distribution of calculus is very imperfect, but we do know that the disease is very prevalent in

the East Indies, and that the salt tax in India in 1882-3 produced something over 6,000,000*l.*, a sum not very different from that which during the same year accrued to the revenue from the opium tax, about the iniquity of which we hear so much.

Chloride of sodium has been spoken of by physiologists as being a universal solvent, not only of the comparatively few crystalloid substances met with in the body, but also of the colloids, fibrine, albumen, mucine, etc. As early as 1844, Bence Jones showed that the solubility of urate of ammonia was doubled by the presence of sodic chloride.<sup>16</sup> The presence of potassium chloride has a similar effect on the solubility of urate of calcium.<sup>17</sup> It therefore seemed desirable to ascertain whether chloride of sodium affected in any way the solubility of uric acid. My friend, Mr. Henry C. Brown, A.I.C., was kind enough to undertake this investigation. The following is Mr. Brown's account of the experiments: An excess of pure uric acid in the form of a fine white powder (purchased from Becker and Co., Maiden Lane), was digested for three hours with frequent agitation at a temperature of 100° F. in (1) distilled water; (2) a solution of '615 per cent. sodium chloride; (3) a '86 per cent. solution; (4) a 1·3 per cent. and (5) a 2 per cent. solution. The solutions were filtered at the same temperature, and 50 cc. of each filtrate evaporated and dried in a water bath till the weights were constant. From these, after deducting the amount of sodium chloride, the following table was calculated:—

Dissolves at 100° F. in—

Pure Uric Acid.	Distilled Water.	Per cent. Solution of Sodium Chloride.			
		'615	'860	1·300	2·060
1 part.	8·333 parts.	4000 parts.	2630 parts.	2330 parts.	2000 parts.

The strengths of the salt solutions were taken so as to represent to some extent the extreme variations in the quantity of chloride of sodium in the urine of healthy adult males as given in Dr. Thudicum's table.<sup>18</sup> From the above it is apparent that at the temperature of the body a very small quantity of salt greatly increases the solubility of pure uric acid, and, further, that an increase in the amount of salt proportionately increases the solubility of the uric acid. Speaking roughly, one part of pure uric acid requires 8,000 parts of distilled water at the temperature of the body to dissolve it, whereas the addition of one-half per cent. of salt doubles its solubility, while two per cent. quadruples it. If our sailors consume anything like the amount of salt they are credited with doing, they are not very likely to suffer from uric acid deposits.

We must, however, go a step further; between the cayenne pepper deposit of uric acid in urine and the formation of a compact calculus there is a great gulf—a gulf, however, which has been bridged over by the researches of Dr. Ord, Dr. Vandyke Carter, and Mr. Rainey, the general outcome of which has been to demonstrate the fact that the presence of a colloid at the moment various crystalloid bodies pass into their crystalline forms so modifies the crystalloid that, instead of becoming a crystal, the body separates in a coherent form. Certain colloids act more powerfully upon crystalloids in the production of this coherent form than others. For example, Dr. Ord found albumen much more powerful in its action upon uric acid than gelatine. But the action of an equally diffused low percentage of albu-

<sup>18</sup> Thudicum's "Pathology of the Urine," 1877, p. 563.

men in urine is so slight that, although the form of the crystals may be altered, yet there is no tendency for the uric acid to become aggregated into a calculus. Hence the rarity of calculus in Bright's disease, where, although the urine contains albumen, yet, being equally diffused, aggregation does not take place. Thus we find that those counties where Bright's disease is very common do not produce many stone cases.

The relationship of calculus to other diseases, as evinced by their geographical distribution, I must leave for a future communication, and would only here remark that the study of the disease from this standpoint is not only one of great interest, but one which throws light upon its ætiology. The action of sodium chloride in preventing the coagulation of the blood is well known, and the presumption is that this salt has a similar action with other colloids. If this be the case, we have no difficulty in understanding the rarity of calculus amongst those who consume salt freely. Dr. Ord tells me that "whatever tends to keep the colloids diffused will oppose the formation of calculus, for while mucus equally diffused does little more than round the edges of the crystals, precipitated it at once becomes the bed of spheres and agglomerations of spheres."

The conclusions I would derive from the foregoing are:—

(1) That there exists in Norfolk a district (Marshland) in which calculus is much less common than in other parts of the country.

(2) That in Marshland the natural water supply contains a large proportion of salt.

(3) That calculus was relatively more common during the period of the salt tax than before or after.

(4) That the disease is rare amongst sailors who consume much salt.

(5) That it is more common amongst the children of the poor from whose dietary salt is almost absent, than amongst those of the middle and upper classes where this is not the case.

(6) That the disease is common in India where salt is taxed.

(7) That the presence of salt greatly increases the solubility of uric acid.

(8) That the consumption of salt by increasing thirst ensures a larger amount of fluid passing through the urinary tract, and therefore lessens the probability of calculus.

(9) That by keeping the colloids equally diffused salt tends to prevent the crystalline solids of the urine from agglomerating into calculi.

And lastly, that the facts above stated warrant us in recommending a more liberal consumption of salt by those who are in any way threatened with calculous disease, either by hereditary tendency or by premonitory symptoms—especially those at the two extremities of life who reside in calculous districts. Particularly does this apply to infants and young children—the former, of course, through the mother, for we know that sodium chloride is one of those salts which freely passes from the maternal system into the mammary secretion.<sup>19</sup>

#### SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—

A general meeting of this society was held in the rooms of the Medical Society last Tuesday, the President, Dr. Norman Kerr, in the chair. Papers were read by Mr. Carsten Holthouse and Mr. C. G. Robertson. In the discussion which followed, Drs. Poole, Williams, Yeo, Robertson, Jabez Hogg, and Edwards took part.

## PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,  
President of the Health Department, Social Science Association.

### DISEASES OF THE CIRCULATORY SYSTEM.

(Continued from page 430.)

#### *Aneurysm.*

DURING the past forty years, I have been allowed full opportunity of regretting that my medical brethren should neither have controverted nor adopted the observations which I published in 1845,<sup>26</sup> on the causation of those "true" aneurysms which are dependent upon dilatation of the arterial walls.

They were not mere theoretical speculations, but were the outcome of much attentive study of arterial disease in the dead-house and in museums. All my subsequent observation has confirmed their general accuracy, and I venture to believe that they still deserve attention.

I think that we, the young morbid anatomists of 1845, were not uninstructed in the subject of "*Arterial Tension*," vide Dr. Goodhart's admirable Bradshawe Lecture for the present year. Our writings show that, in the system of the gin drunkard, we had learnt to perceive the existence of chronic blood impurity maintained by a constant supply of turpentine, juniper, white-vitriol and alcohol. Hence the over-taxed kidneys and liver became diseased. Impediment to the circulation through their capillaries gave rise to undue tension resulting in dilatation and hypertrophy in the arteries and left heart—we assigned far more importance to the dilatation than to the hypertrophy, viewing the latter rather in its compensatory than in its morbid aspect. Imperfect elimination of urea and bile elements produced a tendency to endocarditis and degeneration of arterial tissue. We had made a special study of the various conditions which lead to morbid tension in the pulmonary artery. The dependence of permanent dilatation of that vessel and of the right heart and venous system, leading to dropsy, upon over-work, intemperance, chronic bronchitis, emphysema, mitral disease, &c., was a matter of daily observation.

*Aneurysm of the Ascending Aorta.*—Preps. 636 and 638 represent aneurysms of the ascending arch in natives.

An apparently healthy captain, having taken his usual morning walk, returned to his quarters at the Military Club, Calcutta, and was found dead in his bath-room—a very small aortic aneurysm having burst into the pericardium. An East Indian(?) medical subordinate died from an almost precisely similar cause.

I used to think that the progress of an aortic aneurysm through the chest was quite as capricious, as regards its direction, as that of a musket bullet. But the study, chiefly of cases observed in India, convinced me that although the mode of expansion of a thoracic aneurysm is modified by various circumstances, its progress, which is generally to the surface, is ruled by definite laws. The following cases fairly display the principal modes in which aneurysms of the arch and descending aorta advance.

I collected a valuable series of plaster of Paris casts, taken by the late Mr. Bowser, from patients of mine, showing aneurysms of the ascending aorta, chiefly in natives, pointing forwards at and to the right of the sternum, absorbing bone, costal and clavicular cartilages,

<sup>19</sup> Carpenter's "Principles of Human Physiology." Edit. 8, 1876, p. 1057.

<sup>26</sup> *General and Aneurysmal Dilatation of the Aorta; especially with reference to their Pathology and Treatment.* The London Medical Gazette for August, 1845, pp. 725 and 769.

and, in two cases, opening by slough and allowing fatal hæmorrhage. A wealthy and rather noted Hindu gentleman, advanced in life, died with a large pulsating aneurysm about to point on the right of the sternum. I heard that, when his body burnt on the pyre, the sac burst throwing a column of blood into the air. It was manifest from the symptoms, although there was no autopsy, that the death of that truly eminent physician, William Twining, was caused by the opening of an aneurysm of the upper part of the ascending arch into the substance of the right lung. This occurred in a patient of my own.

A case which, as far as my reading and experience go, was unique occurred in the practice of my friend Dr. T. Watkins Wilson.<sup>27</sup> A man, æt. 28, born in India of English parents, a free liver, had suffered for 12 months from no other distress than a pain in the left deltoid muscle immediately under the acromion process, which prevented him from raising his arm. He then became subject to palpitation, difficulty in breathing, a feeling of constriction in the throat, and a pain to the left of the sternum. There was increased and extended dulness in the præcordial region. The first and second sounds were distinct, but feeble. Following the first was a bruit most audible at the upper part of the sternum. The features were full, bloated and congested. Gradually respiration failed on the left side, and the whole of that side of the chest became dull. The thoracic suffering became very intense, and he died in a paroxysm of dyspnoea. It was found—

(1) That there was congenital transposition of the viscera, the liver lay on the left side, the spleen on the right.

(2) That an immense aneurysm, half filled with solid fibrine, occupied the usual site of the heart; the heart with an adherent pericardium was on the right side, displaced, and thrust back behind the lung; the left lung was perfectly collapsed. Serum occupied the pleural cavity. The aneurysm appears to have arisen from the back part of the ascending aorta, and to have made way laterally to the left.

*Aneurysms of the Cross of the Aorta.*—A very delicate young officer, a younger son of one of the greatest literary men of this century, whose death was also from arterial disease, died from a large aneurysm of the upper part of the aortic arch. The sac would nearly have received two fists; I never saw such extensive arterial disease in a person under 25 years of age. The parts were so matted together that, as the specimen lay before me, it took me several minutes to understand it. He was in the Officers' Hospital, but was standing with his foot on a chair, talking and laughing, when he suddenly fell and expired.

In No. 2 of the "Indian Annals of Medical Science," I have detailed fully the very remarkable case of a ship's captain, aged 29, in whom I found during life evidence of the existence of an aneurysm of moderate size obstructing the three primitive branches of the aortic arch.

Under the heading of Diseases of the Organs of Respiration, I shall have to report in detail the case of a Greek who had symptoms of acute laryngitis caused by a little aneurysm arising from the crown of the aortic arch attaching itself closely to the trachea in its upward course, and attempting to open into that air passage. I vainly attempted to save life by tracheotomy. I had to watch the sufferings, ending fatally in a few hours, of a poor European in whom an aneurysm was found to be making its way into the bronchus, nearly as happened in the case of Liston, the great surgeon; save that, in the latter, there was a premonitory gush, followed by a considerable interval of apparent health, in which I took a patient to him.

He looked pallid, but as he took me by the button-hole, I thought that his was one of the noblest and most scholar-like faces I had ever looked upon. Mr. R. O'Shaughnessy published, at p. 306 of the *Calcutta Medical and Physical Transactions*, a case in which aneurysm of the arch of the aorta was mistaken during life for aneurysm of the right carotid. I was asked to examine a young and well-built Queen's soldier, who had a pulsating swelling as large as a hen's egg at the root of the neck. It lay in the course of the left common carotid, and had much the appearance of an aneurysm of that vessel; the application of a ligature distally was in contemplation. It, however, appeared to me that it was an aortic sac. My colleague, Dr. Chuckerbutty, had a patient, a youngish native man, in whom there was a huge pulsating sac arising from the aortic arch, and occupying the whole of the front of the neck. On placing my hand upon it, my first feeling was one of astonishment,—where was the larynx, of which there was no sign in front? A projecting mass lay *just below the left angle of the lower jaw*. This was the larynx with its appendages, which had been pushed aside in the gradual upward progress of the aneurysm. Respiration was quite easy. I showed this to my class, saying that it appeared to give an additional physiological reason for the fact that our upper air passage is not an immoveable bony tube.

*Aneurysms of the Descending Aorta.*—A much esteemed European officer, a well put together dark man, apparently under 35 years of age, was treated by the late Dr. Edward Goodeve, for spitting of blood. There was extensive dulness under the left clavicle. At this spot, I think, a little moist crepitation was noticed. It was considered singular that there should be such extensive lung mischief, with excessive hæmorrhage, where all other signs of phthisis were absent. He went home, appeared to recover, and married. On his return to India, after several months' absence, he appeared well, and, I believe, did not seek medical advice. I recollect to have seen him walking and leading his wife's horse; a considerable exertion in that climate. After sunset, on what was noted to have been a singularly hot day, he was about to walk out with his wife when he fell, bringing up blood, and expired. I carefully examined the diseased structures. An aneurysmal sac, of globular form, larger than a fist, proceeding from the front of the descending arch just as it turns, had burrowed into the substance of the upper lobe of the left lung which it had not pushed away, but had almost completely destroyed by absorption. The amount of dulness and the profuse hæmorrhage were clearly evidence that the aneurysm had occupied that position and had bled largely before he went to England, and that Nature had made an attempt at cure, which was valid for many months.

Preparation 665 is from a European woman, a patient of mine. It displays an aneurysm of the extremity of the arch of the aorta *opening into the œsophagus*. Death did not result from hæmorrhage, although a little blood was spat up, but from pressure upon the trachea and consequent suffocation. The fatal attack of asphyxia was precipitated by a drinking bout. Many years ago, I saw, at the South London Medical Society, a fresh specimen in which the firm and even coagulum of an aortic aneurysm had completely removed an oval portion of the œsophagus, upwards of three inches in circumference. Death had not been caused by hæmorrhage, but the tumour encroached so much upon the passage as to cause dysphagia. It was clear that, if a probang had been used, as was then a frequent practice, the sponge would have entered the aneurysmal sac. I saw a very remarkable case of this kind in Calcutta.

<sup>27</sup> "Indian Annals of Medical Science," No. v, p. 362.

A European, rather past middle age, had difficulty in swallowing. There had not been hæmorrhage, but he was anæmic. Thus, his nose was quite pale, but there were large red vessels upon it, as if he had formerly been extremely florid. Some time after he came to me, the medical friend who had consulted me brought to my office an earthen vessel which appeared to contain more than two pints of blood which had come up at a gush. Not long before that time I had been in the habit of making close examination of aneurysmal clots. With this blood there was at least a handful of partially decolorised laminated clot which had unquestionably come from the sac of an aortic aneurysm, probably through a large opening in the œsophagus. The man was doubtless well cared for; there was no recurrence of hæmorrhage, and he went to an employment at Diamond Harbour, where he died about a year afterwards, it was said of some bowel complaint.

I had long in my ward a middle-aged European who had been a soldier. His chief ailment was a harsh dry barking cough, which it was distressing to listen to. Examination *post-mortem* confirmed the diagnosis that this was due to the pressure of an aneurysmal sac on the left recurrent laryngeal nerve. He was so irritable and quarrelsome a person that I found it very difficult to keep him in the state of quietude which his condition demanded. After a time, the cough abated, and he appeared to be mending, but he died from acute pneumonia, occasioned, I believe, by mechanical interference with the pneumogastric nerve.<sup>28</sup>

An unhappy European sailor was for some time in my ward with an aneurysm of the descending thoracic aorta which had destroyed several ribs posteriorly on the left side, and formed a tumour so bulky that two hands could scarcely cover it. He went out, got drunk, fought, and was severely beaten, and returned to hospital for a time, still he did not die under our observation.

Preparation 678 represents a most interesting case which occurred in my ward. An elderly American master mariner became absolutely paraplegic only a few days before his death. The lower extremities had entirely lost sensibility and power of motion. He, however, declared that once, during the night, he found himself able to use his legs. I told my class that this state of things could only arise from one of three causes—1 and 2, strumous or malignant disease of the bodies of dorsal vertebræ. I considered that the man's occupation and grand physical development, together with the absence of any spinal projection, discountenanced struma; while his aspect and the fact that the cord had temporarily recovered its powers obliged us to put aside the second cause; whereas all indicia countenanced the opinion that—3—an aneurysm had destroyed the bodies of the vertebræ and was compressing the cord. It was found that an aneurysm of the thoracic aorta had largely destroyed the bodies of ten dorsal vertebræ. One of the lower bodies had become so completely absorbed as to expose the dura mater. Higher up, two bodies had been destroyed, also exposing the dura mater; and, still higher up, a portion of the body of another vertebra was disintegrated down to the same tunic. The huge sac was filled with a very dense coarsely-laminated coagulum. In one spot, the sac was about to open into the left lung. At first it appeared possible that the idea of temporarily restored power of motion occurred in a dream; but he was positive that he

had moved his legs. The truth of this appears quite possible, considering the manner in which the cord was compressed by the aneurysm, whose volume was liable to be diminished from the quiet state of the circulation during sleep.

In 1845<sup>29</sup> I suggested that the chief general indications which it is necessary to fulfil in conducting a rational plan of *medical treatment in cases of aneurysm of the aorta* are as follow:—<sup>30</sup>

To reduce, as far as is practicable, the volume of the circulating fluid; but in such a manner as to lessen the proportion of its watery constituents without diminishing the fibrine or producing debility in the system.

To render the circulation through the visceral arteries, general capillary system, principal venous trunks and lungs as free as possible.

To maintain the muscular power of the heart.

To encourage the deposition of *thin* layers of plastic coagulum within the aneurysmal sac.

These principles have always guided my practice. For many years I used to tell my students that the greatest hope of prolonging his life that we can offer to the subject of aortic aneurysm is to afford him absolute REST, which he can best obtain in hospital, where I generally succeeded in keeping my patients with aneurysm until they died. Latterly, I employed the iodide of potassium treatment, but I was unable to attribute any effect to it. While it is, in these cases as in all others, the physician's obvious duty to prolong existence as much as possible, I have always admitted to myself that, in following this line of practice, we distinctly add to the sum of the patient's sufferings. For many years, my wards were very rarely without cases of aortic aneurysm. Only one of my patients died suddenly in hospital; but, as time advanced, the sacs increased in bulk and gradually made their way towards the surface and beyond it. Assuredly, if I were the subject of aortic aneurysm, I should accept, as a mercy, the visitation of sudden death vouchsafed as the alternative of months of suffering, while the mass, in growing, causes the destruction of everything which stands in the way of its advance.

I saw only one case of *Aneurysm of the Common Carotid* in a native man. Death occurred suddenly by cerebral embolism.

Preparation 696 is "*an aneurysm of the right common carotid* of a native, about an inch-and-a-half above its origin from the innominate. Close to its entry into the cavity of the aneurysm, the lining membrane is slightly infiltrated with yellow atheromatous deposit. The tumour is globular in shape."

Preparation 697 is from a Lascar, and displays aneurysm of the left common carotid at its bifurcation, extending along the external carotid. The common carotid was ligatured. The man lived a month. Death occurred from sloughing of the whole of the left side of the neck, which the description does not account for. The left cornea had sloughed.

Preparation 698 is one of great interest. It is from a man of 30, in whom, a year previously, the right carotid was tied by Professor Mott. The disease was aneurysm in the right orbit caused by an accident. He returned to England, and the swelling not having disappeared, the left carotid was tied. He died anasarctous, with albuminuria. The account of the condition of the vessels and of their irregular distribution is interesting.

Dr. John Shortt<sup>31</sup> tied the common carotid success-

<sup>28</sup> When I commenced the autopsy, it appeared to me that, although the aneurysm was large, it was so completely filled with firm evenly-deposited laminated clot, as to give the idea that nature had made a valid attempt at "cure." I removed the mass entire, hoping in vain for leisure to examine it fully.

<sup>29</sup> *London Medical Gazette* for August 29th of that year, p. 774.

<sup>30</sup> As revised in my treatise on the Treatment of Diseases of the Heart and of Aortic Aneurysm, Calcutta, 1851.

<sup>31</sup> "*Indian Annals of Medical Science*," No. xv, p. 269.

fully in a native prisoner, æt. 34, for aneurysm of the external carotid.

Mr. Edward A. Birch ligatured the right common carotid artery with catgut in a Chumar, æt. 40, for aneurysm of the internal carotid. The operation was followed by headache, left hemiplegia, and mental confusion. The power of speech was lost and recovered. This was a typical case of those disorders of the cerebral circulation which I have shown, in the 36th volume of the *London Medical Gazette* for 1845, to have resulted in many cases where the common carotid has been tied. He eventually made a good recovery.

Baboo Preonath Bose has reported<sup>32</sup> the case of a Hindoo hawker, æt. 32, suffering from a large aneurysm of the *Right Internal Carotid*, who had the common carotid tied by Mr. S. Bowen Partridge. There were no unfavourable symptoms for seven days; then the right eye "became suddenly and uniformly congested, and in the course of 48 hours was entirely destroyed." Hæmorrhage occurred on the separation of the ligature. On the thirteenth day a ligature was placed around the innominate trunk.

The patient sank principally in consequence of pneumonia, a rather frequent result of operations for tying the arteries of the neck.

In the chapter on Diseases of the Nervous System I have spoken of the case of a Hindoo gentleman of high caste, in whom the presence of an aneurysm of a *cerebral artery given off from the left internal carotid* was evidenced by a remarkable bruit.

Mr. A. H. Hughes successfully ligatured the *Subclavian artery* for axillary aneurysm in a native policeman, æt. 25.<sup>33</sup>

There is on record<sup>34</sup> the remarkable case of an Indian major, æt. 33, who died suddenly from an aneurysm of the *Left Subclavian* opening into the left pleura.

A native woman died from *Aneurysm of the Abdominal Aorta* in my ward. She was extremely thin. There was considerable abdominal fulness and a soft swelling, the strong pulsation of which was very apparent, showed a little below the left hypochondriac ridge. After death from rupture, the sac was found to be an immense one, having upon it several rounded diverticula, one of which had advanced to the abdominal wall over the lesser curvature of the stomach, and had formed the pulsating tumour.

Preparations 679 to 683 are five typical cases of aneurysm of the abdominal aorta, but there is nothing to show whether the sufferers were Europeans or natives.

I do not think it needful to cite all of the many reported cases of aneurysm of the smaller arteries in Europeans which appear in our Indian literature, but I may allude to that of a young soldier in whom I saw my friend, Dr. Gordon Hardie, tie the *External Iliac* with perfect success, although there were marked evidences of a most extraordinary amount of disease in the poor fellow's arterial system generally; and to that of a well-conditioned looking European seafaring man who, while under treatment for other disease in my ward, noticed a swelling which I found to be *Popliteal Aneurysm*. Gangrene of the limb occurred, and he sank after amputation. I saw a nearly parallel case in Guy's Hospital.

In 1837<sup>35</sup> Mr. Richard O'Shaughnessy ligatured the *External Iliac* in a Calcutta Hindoo, æt. 40. There was a femoral aneurysm about the size of a large orange. The aneurysm appeared to be cured, although

when the case was reported, six weeks after the operation, the ligature had not yet come away.

There is a singularly interesting case<sup>36</sup> in which Dr. Parry successfully ligatured the *External Iliac Artery* in a European soldier in whom sloughing (of syphilitic origin) in the groin produced diffused aneurysm of the femoral.

Kenneth Mackinnon just mentions (p. 8) the case of a native in whom "*aneurysm of the External Iliac or one of its branches* underwent a cure by sloughing."

Sir Joseph Fayrer tied the *External Iliac* with success for femoral aneurysm in a West Indian negro, æt. 34, who had been several years in India.<sup>37</sup>

In a case where an aneurysm of the femoral artery ruptured at Poupart's ligament, the late Mr. Cutcliffe ligatured both the *External Iliac and the Femoral* arteries, using carbolised catgut.<sup>38</sup>

Many years ago, at Guy's Hospital, I watched the case of a man who, upon being admitted with an actively pulsating aneurysm of the femoral as large as an orange just below Poupart's ligament, was attacked with typhus. On his recovery from the fever in about six weeks, the aneurysm had undergone spontaneous cure.

I believe that the first surgeon who tied the femoral for *Popliteal Aneurysm* in India was Dr. Adam Macdougall, who operated with complete success in 1822 on a Hindoo ordnance driver.<sup>39</sup>

Kenneth Mackinnon noticed that the same operation was performed successfully at Madras on a sepoy. This was probably the case reported by Mr. J. Lawrance.<sup>40</sup>

Sir Joseph Fayrer tied the femoral, at the superior third of the triangle, in a Burmese, aged 26, suffering from popliteal aneurysm. The whole of the sac sloughed away. Three days afterwards profuse hæmorrhage occurred from the cavity which had contained the sac. The common femoral was then tied about an inch and a half higher up. Thenceforward he made a good recovery.

Mr. F. F. Allen tried pressure and flexion in a native (Goorkah) corporal, aged 50, with popliteal aneurysm. He then tied the femoral in Scarpa's triangle with perfect success.<sup>41</sup>

Mr. C. P. Costello reported<sup>42</sup> the case of a native soldier in whom he successfully treated an idiopathic popliteal aneurysm by combined pressure and flexion.

Surgeon Major P. Sinclair Laing cured popliteal aneurysm in a European soldier of 30, who had served nearly seven years in India, by flexing the limb.<sup>43</sup>

Dr. John G. French<sup>44</sup> gives the very interesting case of a Mussulmann in whom he tied the artery in Scarpa's space for a false traumatic aneurysm of the femoral, wounded by duck-shot.

Dr. K. D. Ghose employed digital compression successfully for popliteal aneurysm in an up-country Hindoo aged 40.

The cases which I have quoted show clearly enough that aneurysm occurs in the natives of India nearly as it does in Europe; there, however, remains the not-easily solved question—Is arterial disease as frequent in India as it is in the United Kingdom? Kenneth Mackinnon, writing from

*mo-fussil* (country) experience, stated it as the result of his observation that arterial disease is rare in India. Allan Webb, having read nearly all that had been published regarding disease in India, and writing with large experience of the Calcutta hospitals, held a contrary opinion. Writing earlier than these eminent authorities did,<sup>45</sup> Richard O'Shaughnessy said that he was "strongly persuaded that aneurysm is much more common in India, and that there are more lives lost by it among the natives than is generally supposed; as, from their total ignorance of the formidable nature of the disease, they apply to the native quacks in the bazaars, who, taking the swellings for simple abscesses, puncture them." I find that, in 1881, there were only 6 admissions for aneurysm and 3 deaths out of an average strength of 114,612 sepoys; while, during the same period, the European army, with a strength averaging 58,728, had 9 deaths from aortic aneurysm, and sent away 9 cases of aneurysm invalided or for change. The result of my own experience is that aneurysm is a rare disease in the natives of India, although I saw many cases in Calcutta, the largest city.

Cases of *Arterial Plugging* are noticed in the chapter on Malarial Cachexia, Vol. ii for 1883, p. 736. I never saw or heard of a case of *Senile Gangrene* in a native. There are not many very aged Europeans in India. I saw only one case of this disease in an Englishman.

#### *Diseases of the Venous System.*

Mr. Charles N. Macnamara has alluded to the case of a European soldier, the subject of general fatty disease, in whom "the *Superior Vena Cava* was ruptured just at its junction with the auricle."<sup>46</sup> A soft yellowish jagged spot, about the size of an eight anna piece (shilling), appeared in the descending cava just at the point where that vessel enters the heart. There was, at the centre of this spot, a small opening through which fatal hæmorrhage had occurred. The walls of the vein in this locality had entirely lost their normal structure, being replaced by fat. The remainder of the vessel, as also the coats of the aorta, the heart, liver, and kidneys, were all in a state of fatty degeneration.

Dr. John Shortt gives<sup>47</sup> the case of a native Christian butler, aged 50, a fat man, said to be intemperate, who fell suddenly, and was fifteen minutes dying. "A circular rent about the size of a shilling was found in the superior cava within the pericardial sac, and near its termination in the the upper part of the right auricle. Half an inch of the cava round the rent had its serous coat destroyed, and the surrounding tissues were infiltrated with blood."

Mr. George Harper has given<sup>48</sup> the case of a European riding-master, aged 45, an unhealthy man of temperate habits, in India for 25 consecutive years. His horse, becoming restive and making a sudden twist round, he was obliged to use great muscular exertion of the lower extremities to enable him to keep his seat. Immediately after this, he felt the right leg stiff and uneasy, and the whole of that extremity became highly ecchymosed from the ileum to the ankle. He survived the accident 41 days, during which his health steadily declined. A circumscribed strongly-pulsating tumour, nearly the size of a goose's egg, was felt immediately above and opposite the umbilicus, over which there existed a distinct bruit. It was suspected that aneurysm of the abdominal aorta or common iliac existed. He suffered greatly from

constant lumbar and abdominal pain, and from attacks of dyspnœa, and latterly there was colliquative diarrhœa. No arterial lesion was discovered *post-mortem*, but the *Vena Cava* was enormously distended for about two inches before passing through the hepatic fissure, and was filled with a large clot of blood. The rectus femoris was ruptured, and it and nearly all the muscles of the thigh and leg had large clots in and about them.

It is not stated whether Prep. 702 is from a native or a European. There is "*Obliteration (embolism) of the Inferior Vena Cava* opposite the termination of the renal veins." At this point the vein is three times its natural thickness. The tumour is about an inch and a quarter across and two inches in length. "Above this the vessel is thin, atrophied, and cord-like." Nothing is said regarding the manner in which the collateral circulation was carried on.

Two cases of obstruction to the inferior cava have occurred within my personal knowledge. In one of these I dissected the tissues of the enormously enlarged external epigastric veins, and found that, unlike any other integumentary veins, these generally small and unimportant vessels are constructed precisely as the inferior cava is, evidently with a view to enable them to act vicariously for that trunk when it is unable to do its own work.<sup>49</sup> For the other case see Phlegmasia Dolens in Diseases of Pregnancy.

For observations on *Venous Plugging* in Malarious Cachexia see Vol. ii for 1883, p. 736.

*Varix* is not common among natives. Throughout my India career I generally looked the natives well over wherever I went, and thus often noticed remarkable evidences of disease. Among the hundreds of thousands of bare legs which I must thus have glanced at, I can only recall to mind one very striking example of varicose veins in the leg of an Ooriah *palkee-bearer*.

(To be continued.)

#### NOTES ON A CASE OF CONGENITAL SACRAL TUMOUR.

By H. W. PHILLIPS, M.B., M.R.C.S., Bolton-le-Moors.

BEYOND the acknowledged rarity of such tumours the following case presents features both peculiar and novel, that render it one of especial interest. I should say at starting, that its position was not exactly such as to warrant altogether the name of sacral, being rather lumbo-sacral, or, to be more precise, occupying a region corresponding to the three or four lower lumbar and upper two or three sacral spines; nevertheless, in its anatomical structure it has seemed to be in close affinity with the tumours which have been described under the above head.

On June 12th, of this year, a child was brought to the Bolton Infirmary on account of a swelling on its back, which we were told had been there since its birth some three years ago. On examination this swelling was found to be situated low down in the back, rather to the left side of the spine, and having the relation to it above indicated.

When palpated the tumour was felt to be distinctly lobulated, the individual lobules being large in size, some four or five in number, and attached deeply on their under surface. The outermost of these, that is, the one to the left edge, on firm pressure was felt to slip from beneath the fingers through an opening in

<sup>45</sup> In 1837, *Calcutta Medical and Physical Transactions*, Vol. viii, Pt. ii, Appen. p. 223.

<sup>46</sup> "Indian Annals of Medical Science," No. v, p. 182.

<sup>47</sup> *Ibid.*, No. xv, p. 186.

<sup>48</sup> *Ibid.*, No. xv, p. 256.

<sup>49</sup> *London Medical Gazette*, August 8th, 1845.

the muscles of the back into the abdomen, leaving an empty collapsed bag of skin. From the general contour and feel, this reducible part of the tumour came to be recognised as the left kidney. As the spine disappeared beneath the tumour's edge the tips of the processes were felt to become flat and smooth, and a tendency in them to become cleft could be doubtfully made out. The legs of the child were small and probably unnaturally weak, though the child possessed a considerable degree of control over their movements. Its general health was feeble, though otherwise good.

The case was considered to be one of congenital misplaced kidney, associated with a condition closely resembling spina bifida; and, seeing that there was no prospect of improvement by time, but rather the probability of further trouble as development advanced, an antiseptic exploratory incision was made, in order to ascertain the exact nature of the tumour with a view to a further operation for its relief.

It was now found that the lobules to the right of the tumour, and overlying the cord, were cysts with very firm fibrous walls, connected deeply with the meninges of the cord through a wide cleft in posterior wall of the spinal canal, and, in the case of one which was opened, communicating freely with the subarachnoid space.

Further procedure under these circumstances was deemed inadvisable; the cyst was therefore closed, and the wound brought together with sutures.

For some days after this the child progressed favourably; on the tenth day, however, it became cross and fretful and refused its food, convulsions followed, exhaustion rapidly supervened, and death resulted.

The *post-mortem* revealed a state of matters very similar to what was anticipated from the above noted facts. In that part of the spinal canal corresponding to the lower lumbar and upper sacral vertebrae there was a wide cleft due to a complete absence of both laminae processes. At the bottom of this cleft lay the cauda equina enclosed in the spinal membranes, and attached to the posterior surfaces of the membranes were a number of tough fibrous cysts of varying sizes, containing pale straw-coloured fluid. The cavity of but one of these cysts, namely, that one opened in our exploration, was in actual communication with the sub-arachnoid space. These cysts formed, together with fat and areolar tissue, the bulk of the tumour. To the left, however, of the spinal cleft, and in the position corresponding to the reducible portion, there was found the left kidney lying in fat, with immediately beneath it a cleft in the muscles through which it could be returned into its natural position in the abdomen. The organ itself was apparently perfect and healthy, as were the rest of the viscera. In the fat between the kidney and the cysts, a curious piece of cartilage was discovered, which both in shape and position had apparently some relationship to the imperfect spinal canal.

In a somewhat hasty search I have been unable to find any recorded case in which the state of parts resembled this, and as it has seemed to me of peculiar interest from the curious malposition of an important organ like the kidney, I have thought it right to put the case on record.

---

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH.—By the opening of a fever hospital, by the Town Council, considerable additional accommodation has been provided for the treatment of sick children in this institution. Four wards with 16 beds each, and one with 8 beds, are now available for cases of a general description, providing accommodation for 72 children. It is noteworthy that free admission is given to suitable cases, and no introduction is necessary.

## CUMBERLAND INFIRMARY, CARLISLE.

### CANCER OF THE ŒSOPHAGUS — GASTROSTOMY—PARTIAL SUCCESS.

By H. A. LEDIARD, M.D. Edin.,  
Surgeon to the Infirmary.

THIS case is recorded from notes taken by Mr. Francis Smith, who watched the progress from the time that the stomach was opened, and carefully superintended the artificial feeding to the end.

Henry P., aged 54, a tanner, was sent to me by Dr. Highet, of Workington, with a statement that the man had dysphagia, emaciation and probably malignant disease.

I found that no bougie of any kind or size could be passed further down than thirteen inches from the teeth, whilst the patient was able to swallow only liquids. No lump was felt anywhere, and there was absolutely no pain, even on passing a bougie down to the obstruction. The patient was very emaciated, but able to go about well enough, and his chief complaint was that of constant hunger. The symptoms had been coming on for some months, but he had kept at work almost up to the time of his admission.

I held a consultation on August 26th, that is, one week after his coming in, and it was agreed that gastrostomy offered the best prospect, and that there was no time to be lost.

On August 28th I proceeded to open the abdominal cavity under the left costal arch in the position generally chosen. The left lobe of the liver was soon reached, and the stomach lay immediately below. Silk and catgut stitches were used to unite the stomach to the wound, care being taken to pass the needle through skin, muscles, and peritonæum, and finally through the muscular structure only of the stomach, and this left an area, about the size of a half-crown, of stomach-surface exposed. Listerian dressings were used. Little or no sickness or pain followed; all nourishment was given *per rectum*.

On September 2nd some of the stitches were taken out, and as the margins of the wound were rather angry-looking from stitch tension, the opening into the stomach was postponed.

On September 4th the remainder of the silk sutures were taken out. The stomach, which was found covered with an opaque tenacious lymph, was incised with a tenotomy knife, and a small india-rubber tube inserted. A considerable amount of bile escaped from the tube when the plug was out.

September 5th.—About  $\frac{3}{4}$  iij of warm beef tea were introduced into the stomach with a glass syringe, and, so on for the following days, gradually increasing the quantity until a short time before death. The patient took in the course of a day milk O ij, beef-tea O ij, and two eggs, being fed at intervals of two hours. Besides this, on account of a very parched condition of the mouth, he was allowed lemonade and iced water, which he was able to swallow; but anything of thicker consistency he rejected. The wound improved in appearance and a larger tube was inserted.

September 11th.—Temperature for first time rose above normal to 100° F., and on examining chest it was found that air entered with difficulty, with here and there musical rhonchi.

September 12th.—Viscid mucous expectoration, but no increased dyspnoea.

September 14th.—Patient at night was sleeping, but at same time the breathing was carried on by gasps; this condition became worse during the night, and he sank. It must be observed that nearly from the time of admission artificial rectal alimentation was resorted

to successfully, and continued until he took a sufficiency of nourishment by the stomach wound. Pain was as absent after operation as before, but the gradual change noted was a slow desiccation of the body with shrinking of the skin and absorption of fat; this was not checked by the operation, whereas the thirst was aggravated.

*Autopsy.*—No organs abnormal, excepting firstly, the lungs, the right upper lobe of which was consolidated from old pneumonia, and presented a cavity in its centre, about the size of a hen's egg. There was no tubercle or cancer. The bronchial tubes were filled with thick muco-purulent secretion, and the mucous surfaces congested. The omentum was studded with nodules of cancer, varying in size from that of a millet seed to that of a cherry stone. No peritonitis and no ascetic fluid. *The special disease.*—Traced from above, the œsophagus appeared perfectly normal until within three inches of the diaphragm, when some difficulty was experienced in freeing it from surrounding structures, the aorta in particular. At this point, the walls were thickened and indurated with cancer growth, which encroached upon the lumen of the tube, so that it was difficult to pass a small catheter readily through. The stomach, which was small, was attached to the abdominal wall by its anterior surface, and about three to four inches from the pylorus, by a circular mass of adhesions which was sharply defined and limited to the region of the wound.

*Remarks.*—As far as the surgery of the case is concerned, all went well; very little time was lost, for the sequence of events was as follows:—Admission—August 19th. Consultation—August 26th. First stage of gastrostomy—August 28th. Stomach opened—September 4th. Artificial feeding commenced—September 5th. Death—September 15th. Operation a month earlier would have insured a less emaciated and starved patient to operate upon, but the surgeon in this instance had to deal with the material at hand. I cannot feel that this patient's life was either abbreviated or lengthened by what was done, for although large quantities of nourishing liquid food were introduced into the stomach, yet a corresponding result in strength was not realised. I have no modification to suggest in operative detail, but advise keeping to the lines laid down, providing always that the stomach itself is opened as a separate operation, when healing and adhesion are well advanced. The cancerous mass has not as yet been examined microscopically.

THE IMBECILE ASYLUM, CATERHAM.—Dr. G. Stanley Elliot, the medical superintendent, in the annual report just issued, after giving the statistics of the admissions, and the patients under treatment, the discharges (14 had recovered) and the mortality, during the year, shows there were left 2,009 under treatment, 1,078 females and 931 males, and he points out that many patients admitted had, antecedent to their admission, been detained at home, and thus, by the mistaken kindness of their friends and relatives, recovery was doubtful. Cases, he says, which came under treatment within the earlier months of the disease recovered in the proportion of 70 per cent. (excluding epileptic, paralytic, and congenital cases), whereas in cases of from three years and upwards duration of the disease there were only three per cent. of recoveries. Hereditary predisposition, epilepsy, and drunkenness had proved, as usual, the most formidable trio in the causation of the insanity of the admissions, and, he adds, "I have no hesitation in stating my conviction that the majority of our afflicted population owe their sad mental condition either directly or indirectly to alcoholic intemperance."

## APPOINTMENTS FOR THE WEEK.

*Friday, October 9 (this day).*

CLINICAL SOCIETY, 8.30 p.m.—Dr. Sawtell, "A case of Hæmatemesis and Melæna in a Newly-born Child"; Mr. Barwell, "A case of Gastrostomy"; Mr. Clement Lucas, "Two cases of Strangulated Umbilical Hernia, treated by Excision of the Sac and Skin Covering"; Mr. Charters Symonds, "A case of Trephining for Compression by a Clot derived from a Lacerated Meningeal Artery, suggesting temporary or permanent closure of the Carotid as a means of controlling the Hæmorrhage."

*Wednesday, October 14.*

BRITISH GYNÆCOLOGICAL SOCIETY.—Specimens by Dr. Fancourt Barnes, Mr. Reeves, and others; Dr. Jamieson, "Ruptured Perineum"; Dr. Heywood Smith, "Hernia of the Ovary."

ROYAL MICROSCOPICAL SOCIETY, 8 p.m.—Dr. Maddox, "On the Feeding of Insects with Bacilli"; Mr. T. B. Rosseter, "On the Gizzard of the Larvæ of *Corethra pleunicornis*."

*Thursday, October 15.*

OPHTHALMOLOGICAL SOCIETY, 8.30 p.m.—Living and Card Specimens at 8 p.m.; Mr. W. Lang, (i) "Detached Retina in Yellow Spot Region, re-shown"; (ii) "Pemphigus of Conjunctiva"; Mr. Spencer Watson, "Granular Lids and Vascular Cornea treated by Peritomy"; Dr. J. B. Lawford, "Tuberculosis of Choroid"; Mr. G. Anderson Critchett, "A case of Orbital Cellulitis"; Mr. Walter Jessop, "On a case Exhibiting Definite Movements of the Pupils with the Action of the Extrinsic Muscles of the Eye"; Mr. E. Nettleship, "A case of Fatal Meningitis after Excision of the Eye-ball"; Mr. Simeon Snell, "Foreign Bodies in the back part of the Eye with Preservation of Sight."

*Friday, October 16.*

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 p.m.—Prof. W. H. Corfield, President, Inaugural Address on "The History of House Sanitation."

## Medical Times and Gazette.

SATURDAY, OCTOBER 10, 1885.

THE Obstetrical Society of London reassembled after the recess on Wednesday evening last. The chief business of the meeting was the consideration of a paper on the hypertrophies of lupus of the vulva, by Dr. Matthews Duncan, a sequel to a former paper by him on the ulcerations of the same disease. Dr. Duncan's remarks on the proper subject of the paper were supplemented by records of six cases, each illustrated with a coloured drawing. The discussion was opened by Mr. Jonathan Hutchinson, who, in a most courteous and appreciative speech, after expressing his sense of the great value of the excellent clinical description of the disease given in the paper, urged his own view, which was, that the disease was in no way related to ordinary lupus, but was

really one of the manifestations of tertiary syphilis. One of the cases was described by the author himself as "syphilitic lupus," and in the histories of every one of the others there were points strongly suggestive, if not demonstrative of by-gone syphilis. Dr. Duncan's views were supported by Dr. Thin, on histological grounds, and by Dr. West. Among those who did not altogether agree with him were Drs. Playfair, Galabin, and W. A. Duncan. Dr. Duncan replied with a warmth of manner and strength of language somewhat out of tune with the politeness and moderation of Mr. Hutchinson's criticism. To accept as evidence of syphilis the facts upon which Mr. Hutchinson dwelt, Dr. Duncan said was the most unreasonable thing he had ever heard. He did not assert that the disease he described was identical with *lupus vulgaris*. It was a distinct disease, about which there was a large literature; and the term "lupus of the vulva," as denoting it, was convenient and well understood.

THE annual conversazione at Guy's Hospital, held on the evening of the 1st of October, would appear to gain in popularity with each succeeding year. Owing to the large area of space at their disposal, however, the organisers of the entertainment are enabled to distribute their objects of interest in such a way as to avoid that inconvenient overcrowding of their guests which forms such an unpleasantly prominent feature of some of the other medical gatherings of the year. The usual lavish decorations, supplied by prominent firms, and a more than usually large collection of objects of art and interest were displayed throughout the lower medical wards and museums under the searching glare of the electric light, the various buildings being connected by means of covered ways. A novel effect was produced by the illumination of the hospital grounds with coloured lamps, many hundreds of which were distributed, after the manner of the popular exhibition at South Kensington, along the margins of the pathways and flower beds. The prizes gained by students during the past year were distributed by the Treasurer in the Anatomical Theatre in the presence of an enthusiastic audience, a special ovation being accorded to Dr. Wilks who was present for the first time in the character of Consulting Physician to the Hospital.

IN Spain the daily number of deaths from cholera has fallen to about one hundred, and in Sicily to about half that number. There are still scattered cases in Italy and France, and a correspondent of the *Standard* states that there have for some time been cases at Nice, which have been kept dark. The same correspondent gives a quaint explanation of prejudice against doctors strangely widespread among the poor of southern nations. The patients and their friends see "Poison" on the bottles of laudanum used for cholera, and at once assume that the doctor's aim is to kill them and so stamp out the germs of the disease. But, of course, even the most ignorant peasant must know that if such were the doctor's intention, his bottles would be made to look as innocent as a Florence flask. We suspect that the rage against medical men is due to

the fact that the mortality is so much greater and medicine so much more impotent in cholera than in other diseases. Hence, under a new and appalling experience, an ignorant mind may easily rebound from confidence to angry distrust.

THE special correspondent of the *Times* continues to send home most able letters from the chief cholera-stricken towns in Spain, the reading of which we hope will give a little of that impetus to the Mansion House Fund which it so sorely needs. His account of the way in which the epidemic was met by the inhabitants of Saragossa and Barcelona, gives us a much higher idea of the "self help" of the Spaniards than we previously held. But the sanitary condition of both cities, and of the villages around the former, is deplorable. At Saragossa there are no sewers, and the houses are mostly drained into deep pits dug in the porous soil beneath the houses. The liquids percolate away, and the solids are removed from time to time, generally in an open cart. The drain-pipes are untrapped, and a silver spoon left on the sink soon covers itself with sulphide. At Barcelona there are sewers, some built centuries ago and in excellent condition, others built recently and already leaking; but the sewers are only intended for slop and rain-water. As a matter of fact they receive the fluid that overflows from the cesspools, but they are so thoroughly ventilated that there is little chance of sewer-air making its way into the houses. Barcelona has an insufficient water-supply, but Saragossa draws its water from high up the Ebro by means of a canal, which was projected in the time of Charles V. as a means of uniting the Atlantic with the Mediterranean. This comparative purity of supply probably accounts for the small cholera mortality in the city as compared with that in the villages around.

THE principal physician in charge of the Cholera Hospital at Barcelona assured the *Times* correspondent that he was able to save 95 per cent. of the cases brought under treatment before the algide period, but hardly 30 per cent. after it had fully developed. Most of the patients brought to the hospital were in a very dangerous condition; and of the deaths that occurred 75 per cent. had taken place within 24 hours of the arrival of the patient. With respect to the treatment, he found that, to produce the reaction, friction with rags steeped in frozen water, followed by sub-cutaneous injections of ether, was most effective. To stop the diarrhoea doses of tannin and enemata of dilute perchloride of iron were useful; but most successful of all was the hypodermic administration of laudanum, which was thus retained in the system and checked the vomiting. To maintain the purity of the air, ozone was discharged in the dormitories, and all dejections instantaneously disinfected. There were three doctors, three assistants, a chemist, and from eight to twelve nurses; and of these attendants only one had been ill, and then but slightly. Altogether, continues the correspondent, energetic measures have been taken at Barcelona to cope with this epidemic, and if equal zeal is displayed to remove the cause, Barcelona will become one of the healthiest towns of the Mediterranean.

WE have before us a complete list of the office-bearers of the Washington Medical Congress, as appointed by the new organizing Committee, and the number and importance of those who have declined to serve under the altered circumstances are even more striking than we had imagined. The President, Dr. Austin Flint, retains office; but of the Vice-Presidents, four, viz., Dr. Stillé, Dr. Skillman, Dr. Atlee and Dr. Wendell Holmes, have withdrawn. The Secretary-General, Dr. Packard, has also withdrawn, and been replaced by Dr. Davis, of Chicago. Of the General Committee, Dr. Billings, Dr. J. M. Browne, Dr. Engelmann, Dr. Minis Hays, Dr. Christopher Johnston, Dr. Thos. F. Wood, and Dr. N. Senn have expressed their unwillingness to serve. Amongst the officers of Sections, *i.e.*, amongst the men on whom falls the scientific as distinguished from the ornamental function of the Congress, the withdrawals are still more numerous. They include thirteen out of the seventeen presidents of sections, thirty vice-presidents, eleven secretaries, and more than eighty Members of Council. Some of the sections remain mere skeletons. Medicine, for instance, loses its President, Dr. Da Costa; four Vice-Presidents, Dr. McCaw, Dr. McSherry, Dr. T. F. Rochester, and Dr. Weir Mitchell; one Secretary, Dr. W. Osler (our Gulstonian lecturer of last spring) and ten members of the Council. Surgery loses its President, Dr. Yandell; three Vice-Presidents, including Dr. Agnew and Dr. Gross; and a Secretary, Dr. Collins Warren. And much the same is true of several other sections. At present there is no sign of anxiety to return on the part of those who have retired; indeed, every week brings intelligence of fresh withdrawals. So that unless some golden bridge can be found over which the retirers may return, or the mischief-makers retire, the Congress will be, with a few brilliant exceptions, a Congress of mediocrities, of no value whatever from a scientific point of view. The *New York Medical Journal* tells us "that the 'new committee' has utterly failed to repair in any degree the breach of concord which its creation precipitated upon the American profession, and which, in the view of the great majority of well-informed and fair-minded men, has entirely done away with the possibility of a successful meeting of the Congress in this country in 1887." And it asks whether it is incumbent upon the officials of the Congress to wait much longer before withdrawing the acceptance of the American invitation. "Our own conviction," adds our contemporary, "is that both the interests of the Congress and those of the American profession would be decidedly furthered by prompt action on the part of our European colleagues," in which conviction we heartily concur.

At the meeting of the Metropolitan Board of Works on the 2nd inst., Mr. Runtz introduced a deputation from the Association for the Preservation of the River Lea, headed by Mr. Charles Russell, M.P. These gentlemen explained that no scheme could be considered satisfactory or final that did not provide for the complete exclusion of sewage from the Lea, a non-tidal river, interrupted by locks. Such works would require from two to five years for their execu-

tion. Meanwhile, as a temporary abatement of what had become an intolerable nuisance, injurious to health and seriously depreciating the value of property, they proposed that the Tottenham sewage should be conducted by a new sewer into the Springhill sewer of the Hackney district belonging to the Metropolitan Board of Works and joining the main outfall sewer near Old Ford. The Tottenham Board were prepared to construct the junction sewer between their present outfall and the head of the Springhill sewer at their own cost, and the Hackney Board had no objection to the proposal. The sewer would be used only during dry weather, the sewage reservoir at Tottenham serving as storage basins whenever the volume of sewage was larger than usual and storm waters would be allowed to discharge into the Lea. Of course the arrangement would be but temporary, and the junction sewer would be closed when the permanent works should be completed.

THOSE who have followed the returns of the Registrar-General each week, will be prepared to learn that the death-rate for the third quarter of the present year in London was 18.1, as compared with 20.0, the average for the preceding nine years. Last week the death-rate rose from the abnormally low point it had reached to 16.0, but the deaths notwithstanding were 160 below the corrected average for the week. The increase over the previous week was equally present at all ages, and does not appear to be attributable to any one special cause, save and except perhaps the weather, which was, for the most part, remarkably

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past ten weeks.

cold, and to which we may ascribe the extra 50 deaths from respiratory diseases. The epidemic of small-pox is steadily diminishing; there were only 18 new cases

during the week, the total under treatment at the close of it being 131, 7 deaths having been recorded. From measles there were 20 deaths, a number slightly exceeding the average, and from scarlet fever 14; whooping cough produced 22 deaths, and enteric fever 16, whilst diphtheria, which seems to have taken a permanent and high place in our weekly bills of mortality, reckoned 24 victims. The deaths from diseases of the respiratory system and from phthisis were in excess of any return during the previous 13 weeks. In the provincial towns the lowest death-rate was 12·3 at Bolton and the highest 26·0 at Oldham. In Liverpool measles caused 9 deaths, and scarlet fever and diphtheria 6 deaths apiece.

OUR Paris Correspondent writes:—The founder, and for a long time the leader, of the French school of histology, Professor Charles Robin, died on Tuesday last of apoplexy, at the age of 64. The history of Professor Robin was for a long space of time the history of medical microscopy itself, and he stood prominent as the representative of that branch of study, in opposition to Velpeau and other practical and clinical teachers, who endeavoured to cast ridicule upon the microscope and histology as viewed in relation to medical science. The triumph of Robin appeared complete, when, in 1861, a chair of histology was created at the Faculty of Medicine, of which he became, of course, the first occupant. His success was great at first, but he soon became unpopular with the students on account of his extreme severity as an examiner; while, on the other hand, the clerical party, then predominant, were incensed at the so-called materialistic tendencies of his lectures and writings. The combination of these two hostile forces led to violent scenes, in which the Professor was hissed, abused, and prevented from speaking. At a later period he regained his popularity through the petty persecutions of the clerical party, which, among other annoyances, excluded him from the list of persons qualified to sit upon a jury, although at this time Robin was unquestionably one of the most celebrated men of science in Europe. He had become, in spite of strenuous opposition, a member of the Institute in 1866. When the Senate was created, in 1870, Robin was named a Senator by his native department (Ain). He remained a member of the Assembly till his death, although in politics, like many scientific and literary celebrities, he was content to play a dumb part. Indeed, both his qualities and defects made him unfit to play the part of a Demosthenes; he had neither the eloquence nor the assurance which are the stamps of the political orator, and which are seldom developed by a severe process of scientific training. Robin was one of the chief disciples of Auguste Comte, and one of the founders of the celebrated *Société de Biologie*, along with his intimate friend Claude Bernard. He was also closely connected with Littré, and became with him one of the joint editors of the *Dictionnaire de Nysten*, which, although in the beginning a mere vocabulary of words employed in medical science, became a stumbling-block to orthodox believers, and a sort of gospel to the followers of positivism, through the extreme boldness of some of its definitions, those

for instance, of *Ame, Homme*, and a few others of the same description. In private life Robin was a most amiable and disinterested man. All his pupils were much attached to him, and he will be sincerely regretted by his numerous friends. The Chair of Histology at the Faculty of Medicine, left vacant by Robin's death, will probably be disputed by numerous candidates, among whom the most prominent are Drs. Lancereaux and Mathias Duval and Professor Ranvier.

ON Tuesday next and the three succeeding days, Dr. Symes Thompson will deliver his annual course of lectures at the Gresham College. We are glad to notice that he has chosen a more suitable subject for his course than was the case on a former occasion when we called attention to the anomaly of a professor of medicine lecturing on the manufacture of poultices and such things. This year he will treat of diseases of the heart under the following heads: influence of heart disease on the tissues of the body, influence of disordered nerve supply on the heart, influence of deteriorated blood on the heart and influence of the organs of circulation and respiration on each other. The lectures are free, and commence each evening at six o'clock.

THE idea that medicine is destined to take a large share in reconciling Eastern nations to Western culture, is one which, tardy of birth as it has been, is not the less flattering to our profession. It remains to be seen, of course, whether medicine will be any more successful in winning converts than missionaries and merchants, but it has this advantage, that its gifts are more immediate than those of the one class, and more freely given than those of the other. When one surgeon, single-handed, can operate successfully on 245 cataracts in eighteen months, as Surgeon Major Maunsell did in India, the people must be blind indeed not to realize the advantages held out to them by Western Science. In recent numbers we have given very hopeful intelligence of the prospects of Western medicine amongst the Chinese; but it is in India that the field is most free. In one Presidency alone, as our Bombay correspondent has told us, over 3,000 in-patients and 10,000 out-patients are treated daily at the hospitals and dispensaries, but as yet the large proportion of the immense female population throughout the Peninsula has been shut out from the advantages of modern medical science. The Zenana Medical Mission has, no doubt, done good work amongst the women of India, 61 pupils having been taught at the school with a view to entering upon the work. It is hoped that this movement may be extended and consolidated, and at a meeting held at the Mansion House on Tuesday, a special appeal was made for 2,000*l.* to "facilitate the affiliation with a London general hospital, and thus prepare the way to become a recognised medical school, to make some payment to the lecturers, to make more complete the departments of instruction, and to more widely assist the candidates unable to fully pay for board, residence, and instruction." We forbear to criticise the policy of organizing another school of medicine for women in London, when the existing one is hardly yet securely founded; but, in any case the Zenana Medical Mission can

hardly expect to do more than touch the fringe of a great work. If the women of India are ever to be endowed with the benefits of scientific medicine to any appreciable extent, it must be by means of an effort framed on a larger scale and endowed with a more liberal revenue. This effort is now being undertaken by the National Association for supplying medical aid to the women of India, into which Lady Dufferin has recently thrown herself heart and soul.

THE objects of what is to be known as the Countess of Dufferin's Fund are:—“(1) Medical tuition, including the teaching and training in India of women as doctors, hospital assistants, nurses and midwives. (2) Medical relief, including (a) the establishment, under female superintendence, of dispensaries and cottage hospitals for the treatment of women and children; (b) the opening of female wards under female superintendence in existing hospitals and dispensaries; (c) the provision of female medical officers and attendants for existing female wards; (d) and the founding of hospitals for women where special funds or endowments are forthcoming. (3) The supply of trained female nurses and midwives for women and children in hospitals and private houses.” To carry out these objects it will be necessary, according to the prospectus of the Association, to provide scholarships for women under tuition or training, to give grants in aid of institutions that provide satisfactorily for the medical training of women, and to procure in the first instance from Europe or America a sufficient number of skilled medical women on adequate salaries. In time it may be hoped that the Indian female medical schools will furnish what is required. The central Committee will undertake to engage competent medical women for the charge of female medical schools and wards if desired to do so by the branches or affiliated societies, but will make it their special care to supply the wants of those places which are outside the sphere of any such local organisations. The Association has done wisely in not interfering with the bodies already at work in the field which it proposes to occupy; but there is no doubt that much economy of labour may be secured through the guidance of a central body, highly patronised and liberally endowed. The prospectus of the Association has been drawn up with statesmanlike forethought, and it properly insists on all its *employées* working in harmony with, and where necessary in subordination to, the medical officers of this Government, upon whose goodwill and support the eventual success of the scheme must so largely depend. We need hardly say that the project is one which has our warmest support. Here, surely, is a work in which women innumerable may find that outlet for their pent-up sympathies and activities which has been so long and so loudly demanded. They will be able henceforward to take a fair share in that moral conquest of the peoples of the earth, which seems to be the Saxon's birthright. We shall see!

INCREASED accommodation at the Children's Hospital in Aberdeen having become absolutely essential, the building of a new wing was undertaken, and is now

rapidly approaching completion. By its space will be provided for thirty additional patients, so that there will be fifty-four beds exclusive of those in the fever block. All the modern improvements in the way of ventilation, heating and drainage have been adopted, and the walls of the wards are plastered with a hard cement, so that they can easily be kept clean. The kitchen is wisely placed on the second floor, and the laundry is in the extreme basement, the out-patient room being between it and the ground floor. The medical wards, two in number for boys and girls, containing twelve beds apiece, are on the ground floor; and the surgical wards, with a similar number of beds, are on the first floor, and adjoining them is a small ward for eye cases. Provision can also be made for the separate treatment of patients when it is considered necessary, and doubtful cases can be isolated downstairs until their true nature is revealed. The fever block is about seventy feet from the main building, and is quite complete in itself, so that the risk of infection spreading from it to the patients in the rest of the hospital is reduced to a minimum.

THE position which Gravesend occupies in respect to the metropolis is such that its sanitary state must ever be a matter of the greatest importance to us all. In 1877, owing to defects in sanitary arrangements as well as to the prevalence of scarlet fever and enteric fever, Mr. Netten Radcliffe was deputed to enquire into and report upon the sanitary state of the town, and now, after a lapse of eight years, the Local Government Board have sent Mr. Shirley Murphy down to see what steps the sanitary authority may have taken to remedy the defects to which its attention was then drawn. Mr. Murphy found that a Sanatorium has been provided for infectious cases, and an ambulance for the removal of persons so affected; but the Sanatorium does not answer its purpose very well, and a proper hospital is about to be erected; no proper means have been provided for disinfecting the clothes and bedding of those who have become infected. The water company's service has been much extended, and to this Mr. Murphy attributed the diminution in the amount of enteric fever, which, however, is still endemic. The chief defect is in regard to the arrangements for excrement disposal: the existing sewers, with a single exception, are old brick drains intended for storm water and surface water only, and are utterly unsuited for anything else; so that, for the most part, cesspools are the only means of dealing with excremental refuse, and as these are in close proximity to the houses and often to the wells, they constitute a most serious nuisance. A certain amount of paving of courts and alleys has been done, and the surface drainage of the town is more efficient than it was before; but the dwelling-houses, especially in the lower parts of the town, are still ill-ventilated, badly constructed, and badly arranged.

DR. W. OSLER's address at the Annual Meeting of the Canada Medical Association on the growth of a profession is of more than passing interest. The difficulties in regard to preliminary and general education which we have experienced have been felt in

Canada ; and it is a just cause of complaint that men can come across to this country and obtain a diploma which places them on the register in their own country, and enables them to evade the regulations of their own university. In one point Canada differs from the mother country, in that there is no reciprocity between the different provinces ; this, undoubtedly, has its disadvantages as well as its advantages, but there are, doubtless, not a few teachers in London who would be glad if there was no reciprocity between the three divisions of the kingdom. We hear a good deal about the disproportionate number of licensing bodies and medical schools that we have, but in Canada they are far worse off in this matter, for with five million inhabitants they have eleven complete schools, four of which have some seven hundred students between them, leaving the remaining seven schools to share a couple of hundred students. As Dr. Osler says, such a state of things can end in but one of two ways : either several of the schools must die of inanition before long, or they must be supported by extraneous aid ; and Dr. Osler considers that the time has arrived when a strenuous appeal should be made to the public for assistance to build laboratories and provide apparatus for the smaller and less wealthy schools. An ill-equipped school is, in his opinion, an evil thing, and he holds that the provincial boards should refuse to recognise those schools which are not provided with all the apparatus necessary for a modern medical course, and that no new school should be permitted to be established until the promoters had satisfied the board that they had suitable buildings and hospital accommodation, and sufficient funds to carry on their undertaking.

---

#### STRAY THOUGHTS ON THE ADDRESSES.

It is impossible for anyone who may have heard or read the admirable addresses delivered by Mr. Hutchinson and Mr. Holmes on the opening day of the session to think lightly of the system of introductory lectures. They may be an anachronism, as Professor Schäfer calls them, though we doubt whether they are more so than nine-tenths of the systematic lectures which succeed them. But anachronism or not, we should wish to see some equally efficient instrument provided for drawing forth the utterances of men like the two we have mentioned, before we would willingly consent to their abolition. It may be conceded that many inaugural addresses are less interesting to their audience than to their authors ; it may be granted that one has to labour through an intolerable deal of mud before laying hold of one diamond. But that is the way of things in this world, especially in this world's literature, where much tasting has to be done for every morsel of savour and refreshment. In short, two such lectures as those delivered at Leeds and at St. George's form in themselves a sufficient plea for the continuance of the system.

In import and purpose the two addresses were as wide as the poles asunder. The one, addressed to a general audience, dealt with the large, perhaps the largest, problems of human life ; the other, delivered

to a professional gathering, concerned itself with the small problems of a single profession. Yet each was equally liberal and advanced in tone, indeed equally radical, if by radical we mean diving to the roots of things without fear or favour for the musty conventions which the dead years have heaped around them. The only thing that discourages one in reading such addresses is the suspicion of their futility, an admission of which the abolitionists are welcome to make as much as they please. Ours is a profession, we fear, of brave words and halting actions. In the North, for instance, an ex-President and Councillor of the College of Surgeons is canvassing as the Liberal candidate for a Parliamentary constituency, and demanding all sorts of reforms in the medical profession ; in London an ex-vice-president, in weighty and well-weighed words, anathematizes the management of the institution for which he was until lately largely responsible ; while at Leeds, halfway between the two, a Councillor and probable future President of the same College sets all hearts aglow with the hope of those better things that are to follow on a root-and-branch reorganisation of our whole system of education. And yet at the Council-table in Lincoln's Inn, these three late colleagues, elsewhere so bold in speculation, so unembarrassed by convention, so eloquent and persuasive in speech, are reduced to impotence by the passive resistance of a bureau. To use Mr. Hutchinson's metaphor, the College of Surgeons is a tree whose leaves are always soot-begrimed. There the law of individual death (or retirement) loses its beneficence. Elsewhere the old leaves fall and the spring comes—*ἔαρος ἐπιγίγνεται ὄρη*—with its new crop ; but at the College President succeeds President, and Council follows Council, and the whole tree, which might grow into such beauty and strength, stays stunted in the tub into which it was transplanted nearly a century ago. Surely the time has come to break up its tub, and to give its roots space to grow wherever they may find hold and nourishment.

To return from this digression, we heard from Dr. Wilks, at Cardiff, that he, like most men, had to spend his later years in working out and communicating the ideas formed in the flush of youth. This imaginative activity of early manhood might well have been quoted by Mr. Hutchinson as another proof of the beneficence of individual death. An unrecruited patriarchal generation, though versed in all lore, would soon find itself at a stand-still for the want of imaginative force. There would be no progress, for progress implies a constant succession of new minds. Another important lesson, indicated rather than demonstrated in Mr. Hutchinson's address, is that no good work done, either in practice or discovery, is ever lost. The good as well as the evil that we do lives after us, is *not* interred with our bones. This truth, which is made so much of by the modern positivist school, is not a new one to the medical profession. It found expression in the words which Dr. Caius more than 300 years ago had engraved on the monument of Linacre, and subsequently upon his own—"Vivit post funera virtus."

Turning to the practical parts of the addresses, we find the speakers thoroughly at one in most directions,

though on single points they manifest not unimportant differences of opinion. All are agreed that the knowledge imparted by education should be real. It should be a matter of heart-conviction, says Mr. Hutchinson. Subjects should not be "got up" as cram, but learnt as a part of daily knowledge, says Mr. Holmes; and almost the whole of Mr. Schäfer's address is a plea for that practical training which can alone impart reality to knowledge. On the other hand, Mr. Hutchinson and Mr. Schäfer are at variance in the importance they attach to the school-study of the dead languages, though with regard to living languages they are agreed. On neither point, however, do they speak as experts. In regard to clinical instruction we are glad to find two of the lecturers advocating reforms, on the importance of which we have frequently insisted; but while Mr. Holmes would increase the clinical material at our command by utilizing the infirmaries and dispensaries, where the students would be able to undertake the personal charge of patients, Mr. Schäfer recommends the better utilization of our existing material by allowing the student to walk whatever hospital he may please. On many other points a comparative study of last week's addresses is most interesting; but we have not space to consider them. We will only add that every one who is interested in medical reform should carefully read and consider Mr. Holmes' well-considered programme, and that all who concern themselves with the larger uses of knowledge and the tendencies of modern thought should give the same careful study to the address of Mr. Hutchinson.

---

#### THE BRITISH PHARMACOPŒIA AND ITS CRITICS.

Now that the first burst of congratulation on the termination of their labours has died away, the compilers of the new Pharmacopœia are being blessed with more attention than they are likely to appreciate. Every week some fresh error of omission or commission is brought to light where all at first seemed so correct. The most melancholy thing, however, is that the criticisms, no matter how just or well founded, all labour under the same defect, viz.: that they are too late. The new edition of the Pharmacopœia has been struck off, and we shall have to make the best of it with all its faults for the next ten years or so, whether we like it or not. A want of uniformity is perhaps the gravest of the faults that have thus far been pointed out, two of the critics having drawn attention to this defect in regard to the tinctures. Dr. Kilner shows that of the seventy-two tinctures, only twenty-three enjoy an identical range of dose; whilst Mr. Barford reminds us that the total range is from five minims, which is the minimum dose in about ten of them, to a maximum of an ounce in one, the tincture of rhubarb. This, however, does not cover all the shortcomings in regard to the tinctures, for the quantity of crude material used in their preparation shows quite as great a variation as exists in the dosage, and, further, the dose of the tincture does not by any means always correspond to the dose of the original drug. Dr. Kilner instances, in

illustration of this point, the case of cubebs, where the dose of the tincture is from 30 to 120 minims instead of from 240 to 960, as would be the case if the dose had been made to correspond with that of the crude drug. Again, the dose of tincture of digitalis is from 10 to 30 minims instead of from 4 to 12, which would be the proper equivalent to the dose of the powder. Dr. Kilner's remedy appears both simple and feasible. All the tinctures whose smallest dose is less than half a drachm should have a corresponding dilute solution, and all whose minimum dose is larger should have a concentrated solution prepared, so that there should be a uniform minimum dose of half a drachm. The tinctures which, if this suggestion were accepted, would require alteration might be designated "fortior" or "diluta" as the case might be, so that they could be readily distinguished from the original tinctures, which would still be retained. There can be no doubt that such a simplification would be an immense boon both to prescribers and to students, who at present have to master the composition and strength of tinctures by brute force of memory, as they do not appear to be arranged on any system that lends itself to easy remembrance.

The want of uniformity is shown in other things besides the tinctures. In the case of arsenic, for instance, as Mr. Barford points out, the three preparations have different maximum and minimum doses. Mr. Barford has another fault to find with the editors, and it is one of almost equal importance with the previous one. It concerns the needlessly complicated processes which have been introduced to replace some of the older and simpler methods. His illustration is drawn from the dilute solution of sulphuric acid, which is now prepared by the elaborate aid of a graduated glass and a thermometer, instead of simply by adding the acid to water in a beaker; moreover, there is less than no need for the new precautions, inasmuch as the directions are that a sufficiency of water is to be used, and as this is a vague term not to be interpreted alike by two consecutive persons, it is obvious that we need not be too careful about the other steps of the process.

Dr. Robert Lee falls foul of five out of the six vapours that have made their appearance in the new volume, though at the same time he rejoices that the compilers have been sufficiently well informed to put them in at all. If it is worth while to have preparations of this class in the Pharmacopœia at all, and we apprehend there cannot be two opinions in the matter, it would be just as well that they should be of such a strength as to be of some value. How far the vapor olei pini sylvestris comes up to this standard he leaves us to decide for ourselves from the following statement: forty drops of the oil of fir-wood are to be added to water to make one ounce, of this one-eighth (equivalent to five drops of the oil) is added to half a pint of cold and half a pint of hot water, so that the strength of the vapour is 1 in 1,920; if that really was the proportion during an ordinary inhalation, the benefit that the patient would actually receive would indeed be infinitesimal. The vapour, however, is much stronger in the first minute of inhalation than afterwards, and the best plan in practice is to add a fresh quantity of the oil as the first becomes exhausted.

We must admit that many patients cannot tolerate a stronger vapour than that produced by five minims of the oil to a pint of water, which is the proportion recommended in most of the special pharmacopœias designed for use in throat hospitals.

Dr. Murrell is dissatisfied with the directions regarding the preparation of the hypodermic injection of apomorphina which state that "the solution should be made as required for use." No doubt when in the presence of a case of opium poisoning it is desirable that no time should be lost, but it savours somewhat of exaggeration to say that many a valuable life will be sacrificed to a blind belief in the wisdom of a pharmacopœia simply because it does not advise that the solution of apomorphia should be kept ready for use. It is a pity that Dr. Murrell has not lighted upon some drug a little more in general use for an illustration of the directions that he finds inexplicable. Nine-tenths of the profession, we will venture to say, have never used apomorphia at all, and we are somewhat puzzled to explain how any one practitioner finds occasion to have it in constant use.

Dr. Prosser James, who has certainly lost no time in bringing out a very useful little guide, has not much fault to find with the new Pharmacopœia from a therapeutical point of view. He contents himself with disputing the grammatical and classical knowledge displayed by the General Medical Council in the substitution of *semen* for *faba* when speaking of calabar bean, and in the translation of the favourite rhamni purshiani cortex as "sacred bark"; a line of criticism in which it is not necessary for us to follow him.

Such are a few of the criticisms that have already been made on the new Pharmacopœia. Some of them no doubt are well founded, and it is an immense pity that they were not made a year ago in the form of suggestions. Perhaps next time that it is intended to revise the Pharmacopœia it will be found possible to let the proof-sheets be accessible to the public for some little time prior to the final revision. The General Medical Council no doubt contains many able men, but there is hardly one member, we should say, who has a right to seriously consider himself abreast of modern ideas on therapeutics, and we cannot but feel that a little outside criticism before instead of after the publication of the volume would be productive of happy results.

---

#### THE LISSON STREET SCANDAL.

It is obviously difficult in the extreme for any one, however independent and conversant with like questions, who has not the power of summoning witnesses and administering oaths, to form a satisfactory judgment on transactions and facts, all palpable evidence of which has been obliterated, and regarding which he has only the statements on the one hand of anonymous correspondents, who may be actuated by personal motives in withholding their names, and on the other, the self-exculpatory explanations of the parties implicated, when sitting in judgment on their own conduct. Yet such is often the position of those whose duty it

is to direct public opinion through the press; it has, in the present instance, devolved on the editor of the *Times*, and we cannot decline the same responsibility. The facts of the case are simply these: a person signing himself "Sanitary," whose identity has not yet fully transpired, wrote in the leading journal an account of certain houses in the parish of Marylebone, which he described as being overcrowded, structurally dangerous, and in a horribly filthy condition; fifty persons in one house, together with a number of visitors to a club room, using a single closet, which was without water, required to be frequently cleared by the hand, and communicated with a foul cess-pit in the yard beneath the back windows. At times, when the pan was filled with excreta above the seat, the excess of slops was stored in pails about the yard, the state of which was sometimes past description. The rooms were not only overcrowded, but let at high rent, a small room without a window, for instance, at 4s. per week. Challenged to name the place he referred to, he at once stated that the houses in question were Nos. 33, 35, and 37 Lisson Street, that the first had been bought by the owner of some property in the rear for demolition to make a way to a building he was erecting, but that the others belonged to a member of the Metropolitan Board of Works, Mr. Brown, of Fulham; and he maintained that the Board had been guilty of a breach of trust, and of complicity with the owner in evasion of the law, in that while they had left the purchaser of No. 33 to pull it down at his own cost, and to erect a wall adjacent to the party wall between it and the next house, they had, after condemning No. 35 under the Dangerous Structures Act, neglected to enforce their own order for fifteen months, shoring the building up at the public expense, until the owner, having completed his arrangements to his own satisfaction, found it convenient to give his tenants notice to quit a house from which he had been drawing rents after its condemnation.

"Sanitary's" statements as to the dangerous and insanitary condition of the houses are corroborated by a Mr. Sherwood, who describes himself as architect to the Salvation Army, and their unsafe and dilapidated state is admitted by the owner's surveyor as well as by the Board in the fact of their condemnation. "Sanitary" disclaims for the Salvation Army any collusion or even cognisance of his letters, but it is said that he is no other than a certain builder, who whether a member of that organisation or not, is at present employed by them in the construction of the neighbouring barracks, for which the speedy demolition of the houses in question was required. Be this as it may, it is curious to find that the army is everywhere a factor which must not be left out of our reckoning.

The matter was brought in the form of report before the meetings of the Marylebone Vestry on the 1st inst., and of the Metropolitan Board of Works on the following day. Each body felt itself aggrieved by the allegations, the former as responsible for the alleged insanitary, and the latter for the dangerous condition of the premises, besides being charged with misuse of powers and public moneys. At the Vestry meeting the utmost indignation was expressed at the letters of

"Sanitary," and a report was read, drawn up by Mr. Wynter Blyth, the medical officer of health, who stated therein that the number of occupants was grossly exaggerated, being but 34 in No. 37, which, moreover, was in a fair state of repair, that the w.c. was not "a nuisance," though without water, that there was a good drain, and that as regards overcrowding, &c., the premises, if not perfect, were certainly quite different from what was described in the *Times*. Of No. 35 he said nothing, since it had not been tenanted for some ten months. He had been informed that it was to be demolished, but found repairs in active progress. Only one voice was raised in defence of the letters, that of Mr. Verey, who suggested that the place had been put in tolerable order between the time at which attention had been called to it, and the visit of the medical officer of health. The members of the Metropolitan Board of Works were equally angry; they could not deny the dangerous condition of buildings they had long ago condemned, but laid the whole blame of their continuance on one of their own inspectors. As to the costs, it was asserted that the owners would be treated alike, and that as yet no account had been sent in.

"Sanitary's" description may have been too highly coloured, the plot may be a Naboth's vineyard which the army coveted as an approach to their barracks, and, like business men, were anxious to depreciate as far as possible; but the Board of Works' defence of their conduct strikes us as particularly lame. They admit having allowed one of their own number an extension of time beyond all reason, but try to throw the blame on one of their servants, whose position was certainly most embarrassing. And now, instead of at last enforcing their own order for the demolition of No. 35, they allow the same member to put into repair for the purpose of re-letting a house which more than a year ago they had condemned as unsafe. The whole thing is a painful comment on the existing system of Metropolitan Local Government. While vestries and the Board of Works are constituted as they are, jerry-builders and house jobbers will be strongly represented on the former and likely to find seats on the latter, and in such bodies there is an *esprit de corps* which saps the independence of those members who personally would be capable of rising to better things. Lastly, so long as medical officers of health are the servants of the boards, holding office at the pleasure of such men, it is utterly vain to expect that they can do their duty as they otherwise would, or avoid falling into the temptation to put as fair a construction as they can on the acts of those to whom they owe their position.

---

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At a meeting of the above Society held in the Faculty Hall, St. Vincent Street, on the 2nd inst., the following gentlemen were appointed office-bearers for the session 1885-86:—President—Dr. G. H. B. Maeleod. Vice-Presidents—Drs. David Taylor and Lapraik. Council—Drs. William White-law (Kirkintilloch), W. A. Wilson (Greenock), J. A. Lothian, William Patrick, M. Thomas, A. M. Robertson, S. J. Moore, and A. Wood Smith. Secretaries—Drs. Wallace Anderson and W. G. Dun. Treasurer—Dr. Hugh Thomson.

## ESSAYS ON MEDICAL CLASSICS.

### XII.—CURRIE.

JAMES CURRIE, the son of the minister at Kirkpatrick-Fleming, Dumfriesshire, was born in 1756. After leaving school he went into business, and was for some time in the employment of a firm in Virginia; but he disliked the work, and, being desirous of avoiding the troubles consequent on the outbreak of the American war, he returned home in 1776. In the following year he began to study medicine at Edinburgh, and after a three years' course, being in haste to obtain a military employment, he took the degree of M.D. at Glasgow. He was, however, too late to obtain the coveted post, and was on the point of sailing for Jamaica when he was taken ill. This altered all his plans; he remained in England, and in the following year (1781) settled in Liverpool, where he rapidly advanced in general esteem, and was soon appointed physician to the Infirmary. He became a Fellow of the London Medical Society, and read a paper there on tetanus and convulsive disorders. In 1792 he was elected F.R.S. In the following year he wrote a political pamphlet, which attracted much attention, on the ill effects of war with France. In 1777, when suffering from fever on board a ship from Jamaica, he had been greatly struck by Dr. Wright's treatment of his own, and another case of fever, by means of affusion of cold water; he put this treatment into practice in England, and tried it extensively, and in consequence of his success with it he brought out the work mentioned below, by which his fame was much extended both then and thereafter. In 1792 he became acquainted with the poet Burns; and when Burns died he edited his poems, with a biography and criticism, for the support of the poet's family. Though originally of a robust frame and constitution, he contracted pulmonary disease in 1784; he recovered to a certain extent by the use of horse exercise, his case being narrated in Darwin's *Zoonomia*; but after some fluctuations his health declined in 1804 to such a degree that he was compelled to seek a more genial climate at Clifton and Bath, in the latter of which towns he began to practise; in the following year, however, he died at Sidmouth from atrophy of the left lung and a flaccid dilated heart. Currie was distinguished for manliness and urbanity of manner, and for charm and variety of conversation, to which he united much good sense and sagacity. He was well equipped both for action and speculation. He was amiable, estimable, honourable, upright, and liberal, both in public and domestic life; he was decided without arrogance, was very highly esteemed by his friends, and gained the thorough confidence and attachment of his patients. His work by which we now remember him, and the contents of which we propose to summarize, is called "Medical Reports on the effects of Water, Cold and Warm, as a Remedy in Fever and other Diseases, applied to the Surface of the Body or Internally, &c." It appeared in 1797; a second edition in 1799; a third, with an additional volume, in 1804.

Apart from the attention always due to the observations of a skilful and observant physician, Currie's claim to remembrance rests chiefly on his warm advocacy of the use of cold water as a remedy of the first importance in severe cases of fever, and on his having been the first to employ the clinical thermometer accurately and systematically as an aid in diagnosis, and as a guide to treatment. His book, as its title indicates, is mainly occupied with an account of this single subject. A perusal of it is sufficient to convince us that its author was cultivated and well-read; he frequently quotes other writers, whether ancient, foreign, or modern, is familiar with the chief authorities, and we find him picking up stray facts bearing on the subject from all sources. He always pays most attention to those authors who have been sound and original observers; Hippocrates and Sydenham receive his highest praise. The latter, he says, recorded symptoms accurately, established important factors in treatment, and was a more cautious reasoner than his predecessors or contemporaries, but he had too many theories, which he took for self-evident principles. Currie evidently disliked any pronounced tendency to theory when invading the realm of practice, though he observes in one place that "to theorize seems the irresistible propensity of genius," which doctrine, combined with the remarkable absence of theory in his own writings, would lead one to conclude either that he had himself very little genius in his composition, or else that he kept his tendency to speculate remarkably well in check, for the rudiments of speculation are sometimes visible. He objects to "the eagerness of even eminent physicians to explain and systematize," and holds that "the science of life owes its corruptions more to the misapplication of learning than even to the dreams of superstition," and that the principles of the exact sciences when applied to medicine have served only to mislead and deceive. He had a higher opinion of Bacon's scientific achievements than has generally been entertained since Harvey's cutting epigram. A juster pathology than Sydenham's was, he thinks, established by Hoffmann. Cullen, Brown, and Darwin are passed in review. Among the ancients he is somewhat unsparing of Galen's elaborate and pedantic habits of thought, and he accuses him of introducing much corruption into medicine, but he read his work "for the pleasure of rescuing a stray fact buried under a mass of false theory." His own style is very plain, and he seldom bursts at all into enthusiasm or eloquence, although always striving to give due force to his views. Thus the greater part of his own reports can be read with much interest, though loaded with details of actual cases. There is no denying that the observations are ingenious and carefully made; he is always honest enough to give the true value of the method he employed, and not to omit to point out instances of failure. His arguments to prove his case are sound, and he is impartial and candid enough to alter his opinions in the later editions of his work, when they had been tested by himself or others and shown to be erroneous.

Living in Liverpool, where contagious fever was abundant and frequently epidemic, and therefore a common cause of death, both among the poor inhabi-

tants and the soldiers stationed there from time to time, it was natural that Currie's attention should be principally directed to this form of disease and to the choice of the best method of treatment. It seems to have been partly by chance that he was first led to the employment of cold water; his earliest idea on the subject being derived from Dr. Wright's account of the two successful cases above referred to. He cannot, therefore, be regarded as the originator, and perhaps scarcely as even the re-introducer of the treatment. It is well known that this method was practised by the ancients, being resorted to either occasionally or regularly by the Greeks, Romans, and Arabians, and it had been revived from time to time, according to changes of fashion, since those early days. Moreover, it had been adopted just before as a successful routine practice by Robert Jackson, with whom Currie had some rivalry for priority. Jackson, who had also stumbled upon it by accident, used it largely in combating the remittent fever of Jamaica, and found it of signal service, "the most important remedy in the cure of fevers of the West Indies, and perhaps in the cure of the fevers of all hot climates. Though not, perhaps, absolutely stopping the course of the fever, it generally restored the distinction between paroxysm and remission, diminished irritability, and imparted a degree of tone and vigour to the system, which was justly considered as a sign of safety." His chief dependence was placed on the cold sea water bath, in preference to bark, &c. So much had Jackson accomplished as early as 1777, as appears in his work on the fevers of Jamaica, published in 1791. Currie was not, however, indebted to him for the suggestion, except, perhaps, indirectly through Wright, for he did not become acquainted with his writings until later; and when he did, though the remedy he employed was the same, yet the principles on which he employed it were different and far more exact, and he used it in diseases of a different type. Thus, considering the success which Currie obtained from the careful and discriminating way in which he employed it, and bearing in mind that, though its claim to utility is at present widely recognised, the proper indications for its application, and the extent to which it may be carried out, are yet a matter of dispute, while it is still frequently neglected where it gives more promise of good than any other treatment; it is quite worth while to re-peruse Currie's remarks, and to glean the benefit of his experience in the matter, in which he bears the character of explorer and pioneer. At first he kept a register of all the cases in which he resorted to cold affusion, but after collecting them to the number of 153 he ceased to record any but the unsuccessful, in order to save time. He applied the treatment in hospital and army cases as well as in private practice.

There are many ways of using cold water, each with a different effect in controlling disease: tepid or cold, immersion, affusion, packing with compresses, &c., or merely sponging the surface. The cold bath and sudden cold affusion—especially the last—were Currie's favourite methods. He trusted to the effects of shock and cold combined to overcome the oppression which accompanies the early stage of fever and indicates

its severity. He preferred brine to fresh water, on account of its more stimulating qualities. The conclusions he arrived at as to the proper indications for adopting it were as follows:—Cold affusion is called for when the heat is above normal, and there is no sense of chilliness on the part of the patient, or profuse or long-continued perspiration. The greater the body heat the better are the results (hence the valuable aid Currie derived from the regular use of the thermometer). Its effects are greatest at the daily exacerbation of the fever, *i.e.*, from 6 to 9 p.m., and the benefit accruing is in proportion to the earliness of the disease; the affusion of a bucket-ful of cold salt water—repeated if necessary—will cut short an attack of typhus if given on the third or even on the fourth day. From his thermometric observations, he believed that the temperature was brought down thereby to the normal point; but as he only took the temperature under the tongue, this possibly may not be accurate. Guided by the good effects of cold air in small-pox, and knowing that cold water had been used beneficially in that complaint in China and India, Currie resorted to it also in that disease, according to the same indications, and his efforts were attended with a similar success. He found it of great use also in scarlet fever, especially at the beginning of scarlatina anginosa—the hottest fever of all; it may require repetition again and again, but in some malignant cases of scarlatina and small-pox there is very little heat, and accordingly cold affusion is not indicated. It is dangerous in the cold stage of fever, in which it may easily bring on alarming symptoms, but as soon as the pyrexial stage is established, it can always be resorted to with safety and benefit. On these lines it may be used with advantage in ague, while it is still more valuable and potent in the severer form of tropical remittent fever, as Jackson shewed, and in all fevers of hot climates. It is equally useful, if applied judiciously and at the proper time, in yellow fever. Rush adopted it in an epidemic of this disease, but finally abandoned it for evacuants—calomel and jalap—though, as he used it wrongly, *i.e.*, chiefly at the end, instead of at the beginning of the fever, he can hardly be said to have given it a fair trial. This rule is invariable; after prostration has set in, the use of cold, or indeed of any kind of shock, is inadmissible. It may be remarked here that, in his treatment of fever, Currie did not by any means exclude all other remedies, but gave opium, bark and alcohol freely to meet dangerous symptoms of debility and irritation. As an instance of his occasional plentiful use of alcohol, &c., a case of tetanus treated by him may be quoted, in which for thirty days were given 155 drops of laudanum, and five bottles of Madeira daily, besides much ale and several gallons of brandy in all. In milder febrile diseases Currie resorted to cold sponging freely. Noticing that the disagreeable sense of burning was seated principally in the palms, soles and temples, and believing that these sensations were the cause of a good deal of the disturbance, he took especial care to keep these parts cool and moist by vinegar and water. In the febrile and other diseases of children, he found tepid affusion a “blessed and invaluable remedy.” The same treatment was

found useful also in many cases of plague, but in dysentery it was useless.

At first he considered it unsafe to use cold in the presence of pulmonary complications, but he learnt in time that this objection was ill-founded. He did not believe it could do so much in inflammatory affections, where the fever is only symptomatic, and where the sensibility to cold is naturally increased; in these he found digitalis preferable. Hence we have not the advantage of his experience of the use and value of cold affusion in acute pneumonia. In endeavouring to give the rationale of the cold bath, he unfolded a rough theory of fever; he made it consist of a stage of debility, leading to a spasm of the peripheral vessels; the reaction produced by this resistance to the central power engenders a morbid degree of heat, which is thus a necessary part but not the origin of fever, though in itself it does harm. Cold affusion acts by relaxing the spasm, thus removing the excess of heat, at the same time acting as a general stimulus. Antimonial emetics and diaphoretics will produce equal relaxation, but are debilitating. Bleeding, of course, is still more effective, but is open to the same objections as depressant drugs. He looked on the maintenance of animal heat, irrespective of the external temperature, as the peculiar attribute of life; he showed that it exists to some degree even in the lower animals and plants; and explains how respiration, digestion and perspiration are the three functions on which life and living heat immediately depend. The unctuous sweat of the negro makes him more able to withstand tropical heat than the thin perspiration of the European; and in this way unguents, as used by the ancient Romans, especially after warm bathing, help to preserve health and strength.

Besides employing cold water in fevers, Currie tried it in other complaints, noting, however, that in the absence of fever, the constitution must be good, and without profuse and continued sweats. After the mode of Hippocrates and Avicenna, he used it with success in idiopathic tetanus (avoiding it in the symptomatic form), and with equal advantage in the convulsions of children, but with less success in epilepsy. He opposed the theory of the inflammatory nature of tetanus and hydrophobia, and either resorted to the cold affusion or plunged the patient headlong into a cold bath. He remarked that the best method was to resort to it during a paroxysm. He reports an obstinate case of insanity, ultimately cured by this seemingly rough treatment (a somewhat similar case, of acute mania, cured by immersion is reported by Willis), but he notes that in such cases there must be no organic disease, the circulation and digestion must be good, and the disease paroxysmal. He also used affusion in cases of alcoholic intoxication and opium poisoning. Besides employing cold externally, Currie methodically gave cold water freely as a refrigerant drink in fever, a plan, as he shews, as old almost as medicine itself; a useful auxiliary to stronger methods in the hot stage, but, like them, prejudicial in the cold and sweating periods. He made a series of experiments on the effects of immersion of the body in very cold water on the temperature, which are of some physiological interest, but not of any thera-

peutic importance. He found that tepid (87-97°) bathing sometimes cooled the body more quickly than cold, there being more evaporation and less reaction, and he suggests that it might be employed where sudden affusion would be dangerous. He also ascertained that there was no absorption by the skin, the body weight being unchanged by immersion in a bath; any absorption that goes on in this way being through the lungs. He has some useful observations on opium, pointing out that it produces sleep when the mind is vacant, the stomach empty, and external impressions are excluded; therefore it is aided in fever by cooling the stomach or the surface. Alcohol is the same, but more heating, less diaphoretic and less soporific.

Currie had the great satisfaction of meeting with more and more success, the longer he continued his system of treatment; and in a few years it became extensively adopted by other practitioners, many of whom bore testimony to its good effects.<sup>1</sup> He shewed that diseases arising from imprudently drinking cold water or cold bathing occurred only when the body was fatigued after severe exercise, and that these are fatal only when the body is much exhausted. Cold water is never so safe as when the body is immoderately heated. It is on these popular facts and the boldness of the proceeding, that the general prejudice against its employment at any time is principally founded, though of course it must be taken into consideration that its administration is often inconvenient and troublesome. In Germany, however, where the use of Currie's system has been often pushed of late years to an unreasonable extent, it is said that the popular prejudice against it is fast dying out, the friends of fever patients often demanding its application. The strange fact in the history of the treatment is that it should have passed out of use so entirely for years after its success appeared to have been demonstrated, and that it should have fallen to another nation to take it up, and work it out before we, the fellow-countrymen of Currie, would admit its usefulness. For this long "cold obstruction," we owe to Currie's name, henceforward, a grateful and proud regard.

N. H.

## REVIEWS AND NOTICES OF BOOKS.

### THORBURN ON THE DISEASES OF WOMEN.<sup>2</sup>

THE lamented death of the author of this book so quickly after its publication, gives a sad interest to its pages. This interest is the more melancholy because the book bears throughout evidence that it is the work of an experienced, sagacious and conscientious practitioner; one who has made it his duty to keep

<sup>1</sup> Currie's public spirit and interest in the general good of the people is shewn by the efforts he made to improve the sanitary condition of Liverpool, and his attempt to establish a lunatic asylum for the district.

<sup>2</sup> A Practical Treatise on the Diseases of Women, prepared with special reference to the wants of the general practitioner and advanced student; by John Thorburn, M.D., F.R.C.P., Professor of Obstetric Medicine, The Owen's College and Victoria University, Manchester, Obstetric Physician to the Manchester Royal Infirmary, &c., &c. With chromo-lithograph and over 200 illustrations. London: Charles Griffin & Co., 1885, pp. 575.

himself acquainted with the literature of his subject; who has striven to the utmost of his power to treat his patients rightly, and not merely successfully and profitably to himself; and who has felt the responsibility attaching to the teacher, and therefore kept in view, not simply the imparting of knowledge of medical art, but the making of upright and honourable practitioners. We have perused the book with pleasure as we noticed the characteristics we have endeavoured to describe. But we are compelled also to add, that it appears to us to fall short of the highest standard. It is not what is called an epoch-making book. It does not aspire to lead, nor do we think it will much influence, the tone of thought, or the practice of gynæcologists. The author has read much, and on the matters about which there is general agreement, he speaks with confidence, clearness, and accuracy; but where evidence is conflicting, and general opinion unsettled, he seems either afraid or unable to express a decided opinion. He generally gives both sides, and endeavours to steer a path between them by the aid of some incontrovertible general principles. This is a course with which we do not find fault. If the student follows the advice given to him, he will not go far wrong. But a book which is to influence opinion must do more than enunciate sound, but generally admitted, maxims. And the student is apt to think although the author does not recommend this or that measure, still it must be of some use, or he would not have described it. In gynæcology of late years, naming has outstripped knowing, and ingenuity of invention has been more apparent than carefulness of observation or exactness of statement. Hence there is more need for caution in judgment in this department than in almost any other.

In illustration of our remarks, we will make brief extracts which show the attitude of our author towards some of the current controversies and later novelties of gynæcology. With regard to the great question of Listerism, the author says it would be highly unbecoming in him to speak dogmatically; we must appeal to the future for guidance. Then he gives some excellent precepts as to surgical cleanliness, and says that if he were compelled to choose between the nail-brush and soap and water on the one hand, and germicide specifics on the other, he is not sure which he should prefer, but that the choice is unnecessary. As to the spray, his views are unsettled. In speaking of neurasthenia, the author wisely writes "that real uterine or pelvic disease may be the starting point; I have no manner of doubt . . . all this *may* be, and occasionally is, the case. . . . But, for the most part, and especially in the case of young and unmarried women, the relations of cause and effect are precisely the reverse. It is the anæmic or neurasthenic condition which gives rise to local pelvic congestions, to catarrhal discharges from uterus or vagina, to consequent displacements of the uterus even, and to the multiplicity of ovarian, uterine or pelvic aches and pains." We think it would be more accurate to say "to (the *symptoms* of) local pelvic congestions, &c." But putting this point aside, we are very glad to see a recognition of the fact, that pelvic symptoms are not always an indication of pelvic disease.

In speaking of dysmenorrhœa we find the following useful caution (p. 183): "Alcohol is perhaps the most popular remedy, and its use in dysmenorrhœa, and in alleviating the nervous depression of pregnancy, is an almost certain means in neurotic subjects of creating habitual female drunkards. I can trace scores of cases, from my own knowledge, to this source alone." Another wise remark, which the practitioner will do well to note, we take from p. 21. "The introduction of remedies into the cavity of the

uterus is not so light a matter as mere book descriptions might lead many a tiro to suppose. None but gynæcologists are aware how often its unskilful or unprepared-for employment leads to acute or subacute attacks which leave matters worse than before." A similar practical warning occurs at p. 219. "Intra-uterine injections . . . have often proved fatal . . . in able hands . . . I look upon them with the utmost suspicion, and would advise the young practitioner, at any rate, to have nothing to do with them in endometritis." At p. 238 the voice of truth and experience is again heard—"I have seen so much mischief produced by attempts to destroy hypertrophied portions of cervix by potassa fusa, in the hope that it would lead to absorption of chronic corporeal hypertrophy, that I can only use one word to express my advice in the matter—Don't."

Lacerations of the cervix, and Emmet's operation for their repair, are described at length; and the author lays down indications for the performance of this operation. But at the conclusion of his remarks on the subject comes the following sentence, which must rather damp the zeal of the beginner:—"I would further supplement the advice by recommending the practitioner who has successfully performed 'hysterotrachelorrhaphy' to dismiss from his mind the notion of having achieved a *cure-all*, and to remember that every single symptom attributed to the lesion under consideration may exist in its absence, and may remain or return in spite of its temporary remedial effect." This sentence may seem to some a round-about and cautious way of saying that the operation is really not a bit of good. Space, however, does not allow us to go on quoting; we have given enough to show the author's prominent qualities of candour, caution and good sense. It is a book which, on the whole, the general practitioner may safely trust to, as giving him a good picture of the present state of gynæcology, much sound advice, and many useful practical hints.

*School Hygiene and Diseases Incidental to School Life*; by ROBERT FARQUHARSON, M.P., M.D., etc. London: Smith, Elder & Co.—This is a book likely to do good in its generation. The hygienic code laid down by the school doctor often appears unnecessarily rigid to parents, who are naturally unfamiliar with many of the important facts upon which it is based; and the schoolmaster, standing between two fires, is sometimes tempted to pass over recommendations which appear almost revolutionary in favour of some *via media* which he thinks will be more pleasant, and hopes may prove as safe. Dr. Farquharson, writing with the authority of an all-round experience, and from the vantage ground of an independent observer, has striven to place parents, pupils, masters, and doctors *en rapport*, by sketching the conditions under which alone they can all work in harmony to their mutual advantage. The book does not profess to teach his profession to the practitioner, and is perhaps wisely reticent on most of those statistical details which are required in a work of reference; but the chapter on "The Duties of the School Doctor" contains some practical hints of value, to which the author's personal experience at Rugby lends added weight. Written in a pleasantly chatty fashion which conveys more information than is at first apparent, it is likely to be appreciated by the lay-reader, male or female, who would probably have been repelled by an abstruser style. The book can be thoroughly recommended to all parents and to all masters and mistresses of schools; if they appreciate its teaching and will be guided by its sound common-sense, there are better times in store for school children, and for school doctors also. If Dr. Farquharson had treated his subjects fully, he must have written an encyclopædia; he has done something of greater practical utility by publishing a manual which is worth reading and which can be understood by everyone. There are some evidences of hasty compilation and of imperfect proof reading which

can be corrected with advantage in a subsequent edition. Medical men will demur to the statement that the auditory meatus is better syringed by "pulling the ear forward," and there are still some schoolmasters south of the Tweed who have not bowed down before the increasing usage of "will" in place of "shall."

*Die Schall- und Tonstärke und das Schalleitungsvermögen der Körper*; von KARL VON VIERORDT.—Karl von Vierordt's name is known to all readers of German physiological literature, but we fancy there are few who are aware of the prolific nature of his work. His contributions, spread over a period of years, commencing in 1842 (when his first paper upon the pathology and therapeutics of strabismus appeared) until 1884, the year of his lamented decease, and amounting no to less a number than 115 original papers and published books, offer us another example of the amazing industry of German men of science. He is probably best known in this country, to the general medical public, by his text book of physiology, which first appearing in 1860, quickly ran through three editions, and reached its fifth edition in 1877. Devoting his researches largely to the physical problems of physiology, there is scarcely any branch of this science which he has not enriched by his labours, and his work has received grateful acknowledgment at the hands of English physiologists. The present volume deals with a number of physical researches to which its author had devoted many years of labour. Karl Vierordt did not live to see its publication, and the editing and production of the work have been ably undertaken by his son, Professor Herman Vierordt. Though dealing with subjects too abstruse to be of great interest to the general reader, the researches detailed in this work are of great value to the physiologist and those interested in physiological acoustics.

*Aneurysms of the Aorta*; by OSWALD BROWNE, M.B. London: H. K. Lewis, 1885.—Dr. Browne's thesis constitutes a valuable addition to the literature of the important subject with which it deals. It is based on a careful study of the *post-mortem* records of St. Bartholomew's Hospital during 17 years, giving a total of 88 completed cases of aneurysm of the aorta. Of these 31 affected the first portion of the arch, 29 the second, and 10 the third, the remainder occurring in some part of the descending aorta. Many interesting points are brought out in the course of this study—for instance, in the first part of the arch the pulmonary artery and vena cava superior are the parts most likely to be compressed, rupture is not common, when it does occur being either into the pericardium or right pleura. In the second part of the arch the trachea is by far the most likely structure to suffer compression, the left recurrent laryngeal nerve being sometimes involved; here, too, rupture is not common, being either into the left pleura, left bronchus or trachea. In the case of the third part of the arch the pressure falls on the vertebræ and œsophagus, rupture being common either into the left pleura or œsophagus. Aneurysms of the thoracic and abdominal portions are very liable to terminate by rupture. Dr. Browne has displayed considerable erudition in his references to the mention of aneurysms by the writers of the pre-anatomical period.

*Dental Surgery for General Practitioners and Students of Medicine*; by ASHLEY W. BARRETT, M.B. Lond. London: H. K. Lewis, 1885.—This little volume is one of Lewis's Practical Series, and it is to be hoped that its successors will be equally practical and to the point. Mr. Barrett has shown good judgment both as regards what he has inserted and what he has left out. He has given everything that the general practitioner of medicine ought to know about the accidents and diseases of the teeth and their treatment, without crowding his pages with dental pathology or dental mechanics. The chapter on irregularities in the positions of the permanent teeth is very good, and should prove useful to the practitioner, who is often quite competent to take upon himself the treatment of such cases if he only knew it.

*Health Lectures for the People*; Vol. viii. Manchester: John Heywood.—This, the eighth series of these useful popular lectures, contains those delivered at the Manchester Technical School during 1884-85. The subjects dealt with include soils and sites, entrusted to the chairman, Dr. Ransome; draining and sewerage; plans and sections; foundations and materials used in buildings; plumbing; decoration and furnishing; heating, lighting and ventilation; and last, but by no means least, the legal position of landlords, tenants, and sanitary authorities, by Professor J. E. C. Munro. The language used by the lecturers is free from technicalities, and they are so arranged that their hearers can hardly fail to have profited by them.

*Heiberg's Atlas of the Cutaneous Nerve-supply of the Human Body*; translated and edited by W. W. Wagstaffe, B.A., F.R.C.S. London: Ballière, Tindall & Co., 1885.—We favourably noticed the German original of this work some months ago, and are very glad to see it published in a form in which it will be more accessible to the English student and practitioner. Mr. Wagstaffe has introduced notes where they seemed necessary, and has added a preface in which he shows the indisputable value of an atlas of this kind. The book is one which every busy practitioner will do well to keep amongst his works of reference.

## NOTES ON FOREIGN HEALTH RESORTS.

### CORFU.

CORFU has for many years been familiar to the English as a winter residence for invalids suffering from pulmonary affections. But of late the Riviera, and, later still, Davos and sub-arctic climates of this nature, have been in fashion, and the beautiful island that a quarter of a century ago was the resort of numerous visitors whose chief object was to avoid the rigours of an English winter, is now deserted except by the sportsman and tourist. Other circumstances too, have combined to produce this result. English rule is now a thing of the past, and with it has departed the thousand-and-one advantages that those only who have lived for a lengthened period under a foreign flag are capable of appreciating. The facilities of travel have greatly increased, and a voyage to Australia is now an affair of almost as little difficulty as a trip to Paris. The consequence has been, that an enormous percentage of consumptives who, a few years ago, would have been distributed among the cities of the Mediterranean or the Adriatic, or, at the furthest, in Madeira or Egypt, are now filling the cabins of the Australian liners, and passing their winters in the Blue Mountains, or amid the lovely scenery of the north island of New Zealand. Yet Corfu hardly deserves the oblivion into which she has fallen, and if beautiful scenery, a tolerable amount of amusement, good cookery, and proximity to civilization go for anything in the choice of an invalid's winter residence, as even the most bigoted of climatologists will admit, it must be allowed that the island is possessed of many advantages which are by no means always found combined in other health resorts of wider fame.

Corfu is, from every point of view, the most important of the seven Ionian Islands. The others—Zante, Cephalonia, Santa Maura, Ithaca, Cerigo, and Paxo—are for the most part so ill-adapted for a prolonged visit, and so little likely to come under the notice of the invalid, except during a yacht cruise or a stay of an hour or so in a steamer, that no further reference to them is needed. An excellent service of steamers has rendered most of them accessible, but, even if the visitor has resolved on seeing something of them, he will in all cases make his head-quarters at Corfu. The island, from its somewhat central position, is a port of call for many steamers bound to Alexandria, the Levant, and other parts, and the harbour is rarely devoid of shipping. Most of the steamers, however, sail from the port of Trieste, and

should the traveller be arriving *via* Italy, he will have to time his arrival at Brindisi with care, or he may have to wait from three to five days at that most uninteresting of towns. This caution is necessary, as the Sicilian steamers, though nominally communicating with the Austrian Lloyd and Greek boats, often fail to do so. The latter vessels leave Brindisi at midnight on Friday, reaching Corfu about noon on the following day, and there is also another steamer every Monday, performing the voyage in the same time. The accommodation on both these lines is good and the passage seldom rough. Those who do not dislike the sea will probably choose the Trieste route, as avoiding the fatiguing railway journey through Italy. The Austrian Lloyd steamers leave that port for Corfu twice weekly, the direct vessel, taking rather more than two days, and the indirect exactly a week on the voyage. The latter is by far the most interesting route, and is not the less to be recommended from the fact of its lying for the most part within the shelter of the belt of islands that guard the eastern shores of the Adriatic. The cookery and accommodation obtainable in Dalmatia and Montenegro are by no means suitable for invalids, but thanks to the coasting steamers, the picturesque and interesting towns of those countries can be seen with comfort, as a stoppage of a few hours is made at each port. In this way, the traveller can visit Pola, with its magnificent Roman amphitheatre; the Byzantine and Venetian Gothic churches of Zara and Sebenico; the enormous Palace of Diocletian at Spalato; Cattaro with its lovely fiord and wonderful old Venetian fortifications, and the beautiful scenery of the Albanian coast. In addition to the above-mentioned direct and slow steamers, there are also other branches of the Austrian Lloyd which touch at Corfu.

Owing to the frequency and strength of the *Bora*—the terrible north-east wind which in winter renders the navigation of the Adriatic as dangerous as it is unpleasant—this route to the Ionian Islands should not be taken later than the beginning of October. It is perhaps even better to defer it till spring, and to choose it for the homeward voyage.

The approach to Corfu is one of the most beautiful in the world. The straits which separate the island from Albania are so narrow and so enclosed by the curve of the land, that they appear as a lake, and the stillness of the water and the snow-crowned mountains of the mainland heighten the resemblance to the Lago di Como. Were not descriptions of scenery *hors de propos* in these notes, Corfu is one of the few places that would tempt to them, but it may be shortly said that it is, without doubt, the most beautiful island of the Mediterranean. Boats meet the steamers to convey passengers ashore, but the sea is never rough enough to be unpleasant. The custom-house is merely an affair of a *pour-boire*, and the visitor, climbing a short, but steep ascent through narrow, picturesque streets, reaches a wide esplanade open to the south, in the neighbourhood of which most of the best houses are situated. The hotel most frequented by the English is the Hotel St. Georges. The Hotels d'Angleterre and Bella Venezia adjoin it, and are equally well situated, but they are more patronised by visitors of other nationalities. Living in the St. Georges is good, but somewhat dear. In 1884, twelve francs a day was charged for a small room and board; early breakfast (*café complet*) as well as lights being extra, which raised the price to fourteen francs. The other hotels would probably be cheaper, but not so good. The cooking is, on the whole, fair, about equal to that of a second-rate French hotel. Lodgings could probably be obtained, but it is doubtful whether they would be altogether satisfactory. There are, however, many villas in beautiful situations on the outskirts of the town, which, in the palmy days of the English occupation were peopled by our countrymen. Many of these have been allowed to fall into disrepair, but others in good order are still to be had at absurdly small rents. Servants are not difficult to obtain, and some speak either English or Italian, though it must be confessed that they are not numerous. Household necessaries, such as linen and plate, can be hired, and there is no doubt that this is the most economical mode of residence, although it does not offer such social advantages as hotel life.

Yachting is one of the chief attractions of the island.

Not only do many English yachts annually visit it for the shooting to be obtained on the opposite coast of Albania, but there is also a small fleet of vessels of from fifteen to one hundred tons ready for hire in the port itself. The charge made for a 35-ton cutter, with the crew provided, is 1*l.* per diem. There are between twenty and thirty of these craft, and most of them are let during the season. This commences in October, on the arrival of the woodcocks, and ends in March. The sheltered position of the island renders it peculiarly adapted for yachting, and even if the visitor be no sportsman, there are so many places of interest and beauty along the coasts, accessible only by sea, that it is a form of amusement as enjoyable as it is healthy. Every Monday the little fleet of vessels leaves the harbour, returning on the Saturday to rest and re-provision.

As may be gathered from the foregoing facts, the shooting, which is almost entirely confined to the Albanian coast, is rather overdone. Woodcock, snipe, duck, and wild fowl generally, can be obtained, together with an occasional wild boar, but on the whole the sport cannot be said to be particularly good, unless the sportsman care to adventure himself further inland, and risk the bad food, and a fair chance of meeting with brigands. If the patient sent to winter abroad is in tolerably good health, and is such an enthusiast as to make fair shooting a *sine qua non*, he would find Algeria more suitable, especially if a dry climate happened at the same time to be advisable. In May extremely good quail shooting is sometimes to be had on the island itself, but the advent of these birds is very uncertain, and the flights often stay only a few hours.

The walks, rides and drives about the island are extremely beautiful, and picnics during the winter season are, in consequence, very frequent. Horses can be hired for five francs per diem, and a carriage and pair for sixteen francs. The hotel prices are, however, considerably in advance of this, about twenty-five francs being the charge for carriages. An Italian opera company usually visits the town in the winter, and there are also occasionally plays in French and modern Greek. Lawn tennis is possible if, as is done by the officers of our ships, the net and other necessaries are imported. The English residents are so few in number that, for all practical purposes, it may be said that there is no other society except that obtainable in the hotels. In the season these are crowded, but those who intend to take a villa will have to remember that they will have to depend upon their own resources for their amusements. Bathing is but little indulged in, but there is tolerably good sea-fishing; and the visitor, if he be an artist, will find abundant employment for his brush in the picturesque costumes and beautiful scenery which everywhere meet the eye.

The season about Easter is probably more interesting in Corfu than in any other place in Europe. Our Easter Day is Palm Sunday with the Greeks, and from every part of the island, from Albania, from Zante, Cephalonia, and the rest of the seven islands, and even from Montenegro, the peasants flock into the town in hundreds, all wearing the gala dress peculiar to their district. On the following Saturday, at the instant of the citadel clock striking eleven, a lamb is slaughtered by every citizen in the town who can afford to buy one, and the gate-posts and lintels marked with its blood. Other customs, which would require more space than is at our disposal to describe, but which are equally interesting, are peculiar to this season and also to Corfu, but enough has been said to show that there is a good deal worth seeing, and it is worthy of remark that a good many travellers visit the island especially for the Easter ceremonies.

The English occupation of the islands, existing over a period of nearly fifty years—from 1815 to 1864—gave abundant opportunities of studying the climate. The winter weather sets in in October with northerly winds and a somewhat heavy rainfall. The early rains fall in September, and are commonly followed by pleasant weather lasting about a month. From October to April is the wet season; rain falling, on the average, about every other day. It should be mentioned, however, that the greater quantity of this falls in showers of short duration, and it is but seldom that entire days of rain are recorded. The rainfall

of Corfu itself varies considerably from year to year, but may be estimated at about 35 inches. Thunder-storms are not common, and occur most frequently in October.

The following table shows the number of days in which rain fell during the year, over a period of three consecutive years:—

January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
14	16	14	10	3	3	1	0	3	12	10	13
15	10	14	24	4	4	2	1	7	7	6	11
6	8	11	7	0	0	1	1	3	5	3	5

Fog is almost unknown, except upon the mountains; indeed, it would be hard to find an insular climate so devoid of it, unless we except the Canaries. Dew falls heavily in autumn, and also occasionally in the spring and winter. In summer it is rare.

March is often a very pleasant month, but towards the end of it, or at the beginning of April, the southerly winds blow frequently, and the weather is not so agreeable. The *scirocco*, or south-easterly wind, is warm and damp, the wet bulb of the hygrometer rarely sinking more than 5° during its prevalence. In summer it is unbearably hot and oppressive. At all times it makes its influence felt, even those in robust health feeling tired and disinclined for exertion. The majority of phthisical patients are distinctly the worse for it. During the month of April these winds blow for two or three days in succession, accompanied with clouds of dust. Then comes rain, after which there is an interval of three or four fine days, which, however, are generally overcast in the morning. Later on the weather is beautiful, and it may be questioned whether a spring so fresh and so exuberant is to be found in any other part of the world. Without the *scirocco* Corfu would be nearly perfect as a climate.

The thermometer in Corfu itself rarely, if ever, falls below the freezing point, and but seldom below 45° Fahr. Temperatures above 90° are equally rare. The mean annual height of the thermometer at the sea level is about 63° Fahr. Dr. Davy, in his work on the Ionian Islands, gives the following table of the mean monthly temperature recorded in Corfu between the years 1821 and 1827 inclusive:—

Months.	1821.	1822.	1823.	1824.	1825.	1826.	1827.
January...	52	53	52	52	52	53	54
February ...	53	49	53	54	51	50	53
March ...	56	53	56	56	51	55	55
April ...	63	59	59	56	57	57	57
May ...	74	66	68	65	66	61	67
June ...	74	76	75	71	69	70	71
July ...	79	80	79	77½	76	73	79½
August ...	84	84	80	81½	77	80	82½
September ...	78	82	79	80½	74	79	75½
October...	67	75	73	73	65	72	71
November ...	63	65	63	62	61½	66½	64½
December ...	59	58	54	58	61	59	60

The hygrometer shows the climate to be, on the whole, rather a damp one, although, during the prevalence of northerly winds in the summer, the difference between the bulbs is sometimes as much as twenty degrees. This, however, is unusual, but the hot winds, when they do occur, do not seem to affect prejudicially those patients suffering from pulmonary disorders.

PROFESSOR HAESER, of Breslau, author of a well known "History of Medicine," who was also well skilled in music, has lately died at the age of 72. The death is also announced of Professor F. Baekman, of Warsaw, where he had been professor of Pharmacy and Chemistry for many years.

## GENERAL CORRESPONDENCE.

### REFORM AT LONDON UNIVERSITY.

[To the Editor of the Medical Times.]

SIR,—While those bent upon revolutionizing the London University upon the lines suggested by the Association for Promoting a Teaching University for London are reflecting upon the cold reception their proposals met with at the last meeting of Convocation, and are considering what steps they will take to again urge the matter on the notice of the House, it would be well to see what have been some of the results of the recent meddlesome tinkering with the regulations relating to medical examinations.

The principle of allowing candidates to postpone one subject of an examination and take it up subsequently, that is, of taking an examination out in parts, is known only to the Medical Faculty; it is strange that this should be the case when we remember that, as a rule, medical students have far more time at their disposal than arts and science undergraduates, and, moreover, have a systematic curriculum prescribed for them. This principle was first permitted in the case of the Physiology of the Intermediate M.B. Examination; then the Logic of the M.D., which is now to be docked in deference to the expostulations of some candidates rejected in it, could be taken apart from the Medicine. Lately the principle has been extended to the Preliminary Scientific, and now a candidate may present himself in any two of the three subjects and postpone the other or *vice versa*. If a candidate takes all three subjects and fails in one, he is rejected in all; while if (knowing his own weakness) he purposely plucks himself in one subject or two by postponing them, he may pass in the remaining two or one. And to complete the absurdity: suppose a candidate twice presents himself in all three subjects, and each time fails in one, but not the same one, he is plucked in all. Yet wherein, I would ask, has this candidate (who has now passed in every subject) exhibited less knowledge than the successful student who has taken his examination in parts? This dangerous principle of a serial issue of London degrees I venture to think destroys the utility of an examination, whose function is to register a man's knowledge at a given time in certain cognate subjects bearing upon the Faculty in which he seeks to graduate.

Again, another recent concession to those desirous of "making London degrees more accessible to London students" was putting on an additional Preliminary Scientific in January, so that two are now held in the year, the other being in July. This change, laudable enough in intent, has been utterly futile, and has afforded no relief whatever. The reason is that a regulation of the Intermediate M.B. Examination requires that two years shall elapse between it and the Preliminary Scientific. Hence a successful candidate at the January Preliminary Scientific cannot proceed any earlier to the Intermediate than if, as formerly, he had passed in July, but has (according to the rules) done himself out of a chance of honours in reward for his additional exertions and premature success.

Another anomaly I would point out. It is provided in the Science regulations that anyone passing the Preliminary Scientific, who at the same time passes the Mathematics of the Intermediate B.Sc., or has *previously* passed the Intermediate B.A., is admissible to the B.Sc. Pass Examination. But a candidate who passes the Intermediate B.A. *after* the Preliminary Scientific is not so admissible. Why an advantage should be accorded to the student who learns his Mathematics before his Preliminary Science which is denied to one who merely reverses the order, possibly the Senate can explain.

Cases of this kind must constantly occur, and the officials at Burlington Gardens are doubtless being daily peppered

with brain-splitting conundrums of this character, which are the outcome of the pettifogging patchwork legislation which has recently been conceded to those who desire to "modify London University so as to adapt it to the requirements of the medical profession in England."

In former times a candidate either passed or was plucked, and if the latter, he had to set to work all over again; if it was hard, at any rate there was no doubt about it; but now-a-days, with the complicated and everchanging code of regulations, the man who prospers most is the artful dodger and the examination casuist.

The moral of all this is, that the Senate is too unrepresentative to know what is required, and being unrepresentative is weak in execution and out of harmony with Convocation and undergraduates. Indeed, the recent agitation for turning the University into a University of Teachers, when considered apart from the anxiety of its promoters to swallow up the Teaching Association lest it should swallow us, was but a clumsy expression of the need of senatorial reform.

As you have not, like your contemporaries, acquiesced in the spoliation of London University, I trust that, on behalf of students and graduates alike, you will advocate a speedy rectification of the anomalies which I have endeavoured to point out.

I am, Sir, yours, &c.,

WM. JOB COLLINS,

M.D., B.S., B.Sc., (Lond.).

1, Albert Terrace, Gloucester Gate, N.W.  
September 30th, 1885.

### CONVALESCENT HOME CERTIFICATES.

[To the Editor of the Medical Times.]

SIR,—In a recent number of your paper, you called attention to the excessive demands occasionally made upon the time and attention of doctors in the matter of filling up medical certificates for convalescent homes. The subject is one which has been much considered by the Convalescent Committee of the Charity Organisation Society, and so far as concerns patients who are dealt with by our society (2,000 since January 1st), the difficulty of which you complain has been very considerably reduced by the use of one simple form of certificate.

This form has been accepted as sufficient by the large number of homes to which the Charity Organization Society's patients are sent, and thus has substituted one approved form for the many different kinds which were formerly in use. It is to be hoped that a considerable extension of this system of a uniform certificate may take place, and that in time one form may be adopted almost universally by all convalescent homes for all their patients. These remarks do not for obvious reasons refer to institutions such as the Margate Sea-Bathing Infirmary, and the National Sanatorium for Consumption at Bournemouth, as these are special hospitals where a special class of disease is treated. I enclose for your information and inspection a specimen book as issued by the Charity Organization Society to the hospitals for their use, and I may add that, simple though it looks, it is the result of a great deal of thought and consultation with hospital physicians and surgeons. It is a matter of extreme difficulty to frame a medical certificate which shall be at once simple and concise.

I am, Sir, yours, &c.,

C. S. LOCH, Secretary.

Charity Organization Society,  
15, Buckingham Street, Adelphi, W.C.  
October 2nd, 1885.

## INVENTIONS AND IMPROVEMENTS.

### A NEW TRUSS ARRANGEMENT FOR THE COMFORTABLE AND STEADY SUPPORT OF DOUBLE INGUINAL HERNIA.

THE single truss of Messrs. Salmon and Ody, Strand, with its ball and socket joint, and long sweeping spring from the centre of the back to the further side in front, has stood the test of practical use for seventy years. Why not, therefore, by simple multiplication of the same instrument, give an equal boon to the sufferers from double hernia? This, under my direction, has been carried out with complete success. The subjoined sketch will show at a glance

this new arrangement. The two arms of the spring cross each other in front, without in the slightest degree interfering with each other's action. I find also, that by joining the two springs firmly together behind, great steadiness is secured. The springs by this arrangement are prevented from falling down over the hips, and allow free action to the legs and to the springs themselves. The advantage of having the springs in two parts is, that the maker can apply a stronger one either side if required. Other recommendations connected with the truss are as follows:—Trifling pressure over the hips; free motion of the body, with comfort in stooping. The perfect action of the ball and socket joints with the elongated springs (which press the pads inwards instead of outwards), enables much smaller ones to be used, and satisfies the great desideratum of not arresting the flow of blood from the extremities. To render this truss more comfortable, I considered it most desirable to construct an inexpensive elastic pad, which has been done by introducing coils of india-rubber tubing. It is well to remember that the *lower edges* of the pads, in front, should just rest on the bone below. Mr. Cantlie, of Charing Cross Hospital, has seen this double truss in action, and considers it most perfect.

HENRY ARMSTRONG RAWLINS, M.R.C.S.,  
Sutherland Avenue, Maida Vale, W.

### A NEW SANITARY CLOSET FOR COTTAGES.

DR. BYLES, the Medical Officer of the Eccleshill Local Board, and Mr. Hanson, engineer, Bradford, have recently devised a new sanitary closet for cottages, working-class dwellings, and other places where water-closets are inapplicable, which offers incidentally many advantages which will greatly reduce the cost and trouble involved in dealing with the removal of night-soil. It is well known that the cause of the intolerable smell arising from the ordinary privy is the fermentation of the liquid and solid excreta. In the "pail system" the evil is intensified by concentration in small vessels, and so serious is the nuisance caused by the removal of the pails and the emptying of their contents into the collecting vans, that the "pail system," from which so much was hoped, stands generally condemned. The difficulty is entirely overcome by the "Separator" closet, which does what has never hitherto been satisfac-

torily accomplished, *i.e.*, separates the fluids from the solids. How this is accomplished will be best understood from a description of the closet and its working. The bowl is similar in shape to the old w.c. bowl, *viz.*, a simple conical basin with no bottom. It is not a fixture, and, being quite independent of the other parts of the apparatus, may be instantly lifted out for cleaning. Underneath the opening is an iron tray or platform, having three or four parallel slots across its whole width. Immediately underneath the tray is a bell-mouth pot pipe communicating with the sewer. When the closet is used the urine passes through the narrow slots in the tray, and runs away into the sewer, the solid faeces and paper are left on the tray. By the pulling up of a handle, like the ordinary water-closet lever, a scraper is now made to pass over the tray, clearing off all that is left into an adjacent box or pail. The scraper is so made that the slots are cleaned at every pull of the lever, and they cannot possibly get choked. In its construction the apparatus is simple, strong and durable, while it can be supplied at a cost under 1*l.* The following are some of the advantages which the "Separator" closet offers:—(1) Effectual separation of solids from fluids. (2) Easy drainage of privies. (Drains cannot get choked.) (3) Slop water may with advantage be poured down the closet seat instead of into street gullies. (4) Dry cinders in the ashpit, free from all organic matter:—solving the difficulties with regard to "refuse destructors." (5) Overcomes the objections to the "pail system," because:—(a) The contents of the pail are solid instead of semi-fluid. (b) The pail is not immediately beneath the person using the closet, but on one side. (c) The pail need not be removed as often as in the ordinary "pail system," because its contents, not being constantly worked up with fluid, remain dry and inodorous. (6) Will save largely in the cost of removal when properly applied and fitted, as farmers will gladly take the dry excreta. (7) The expense of the apparatus and fitting is trifling. (8) The working parts are few and well protected, and there are no chains, pulleys, valves, cisterns, or ball-taps to get out of order.

Some of these closets have been in use for some time with perfect success, and we understand that the patentees are now prepared to deliver specimens to local sanitary authorities, and to give estimates for quantities.

HODGE'S TRUSS.—The chief feature of this ingenious truss (Hodge & Co., 18, James Street, Oxford Street) is the pad, which is made of soft inodorous vulcanized rubber, and in form is somewhat like a mushroom. The flat top ensures pressure on the margins of the hernial opening, on the principle insisted on by Prof. Wood, without enlarging the opening as conical pads are apt to do, while its resiliency ensures the pad keeping its place without exerting injurious pressure. The pad is perforated for ventilation and covered with chamois leather, and it can be moulded to any shape to suit the indication in individual cases. Pressure is regulated by a small screw on the convexity of the spring. We have no hesitation in recommending this truss.

THE PRINCE'S PORT.—Some recent writers on gout, having removed their ban from, and even recommended, the use of port wine by patients who are sufferers from that disease, one of the oldest firms in London, Messrs. Berry, Bros. and Co., of 3, St. James Street, whose name is very familiar to the medical profession, have brought under our notice a sample of port wine which adequately fulfils the conditions laid down by the writers in question. Having been kept in wood for from 50 to 60 years, it is thoroughly fermented and matured, and it also fulfils the condition laid down by Moore of increasing the acidity of the urine to a very slight extent. We will not take upon ourselves to express an opinion as to the advisability of prescribing port wine in cases of gout, but if the practitioner should determine to do so, he cannot find a wine more suitable to his purpose than that of Messrs. Berry, which is excellent in every way.

## MEDICAL NEWS.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, October 1st, 1885:—

Alfred George Francis, M.R.C.S., Southchurch, Essex; Frederick John Jaynes, M.R.C.S., Wormington Grange, Gloucestershire; George Henry Oliver, M.R.C.S., 73, French Gate, Doncaster.

On the same day the following gentleman passed his examination in the science and practice of Medicine, Surgery and Midwifery, and received a certificate to practise, viz.:—

George Francis William Ewens, Ealing House, West End, Hammersmith.

DR. CAMERON has been selected, by a large majority, the Liberal candidate for the representation of the College division of Glasgow in the next Parliament.

SURGEON-MAJOR A. STEPHEN, statistical officer to the Indian Government in the Sanitary and Medical Departments, has been appointed to act as Sanitary Commissioner in the Punjab.

BRITISH MEDICAL BENEVOLENT FUND.—The Hon. Dr. Beane, of Melbourne, who is now in this country, has made a third donation of £100 to the above charity.

PUBLIC BATHS IN EDINBURGH.—It has been decided by the Town Council to erect public baths on part of the old infirmary ground, involving an estimated expenditure of 11,080*l.*

THE PROPOSED HOSPITAL IN THE HOLLOWAY ROAD.—The Committee of Management of the Great Northern Central Hospital have received five competing plans of the new hospital. After selection of one by the Building Committee, the plans will be on view, open to the inspection of the subscribers and public at the hospital in the Caledonian Road.

ST. MARK'S OPHTHALMIC HOSPITAL, DUBLIN.—The building of the eastern wing of the hospital has been completed. The new wards will be utilized for the reception of patients as soon as funds are provided to purchase the furniture required. This extension will be a great boon, as the hospital is overcrowded with patients from all parts of Ireland.

ARMY MEDICAL SCHOOL.—The introductory lecture at the opening of the Winter Session of the Army Medical School at Netley, was delivered by Professor F. de Chaumont, F.R.S., on the 2nd instant. The principal subject of the discourse consisted of a review of the changes which had taken place during recent years in the organization of the Army Medical Department, and the influence of those changes on the functions of medical officers and on the health of the army. Forty-eight surgeons on probation had joined to attend the session, 40 being for the British Medical Service, and eight for the Indian Medical Service. Veterinary Surgeon F. Smith had also joined to attend the practical course of hygiene at the School.

OPENING OF EDINBURGH MEDICAL CLASSES.—This week the Practical Anatomy and Practical Chemistry classes of the School of Medicine, Surgeons' Hall, were opened for the session by Dr. Macdonald Brown and Dr. Stevenson Macadam, lecturers in Anatomy and Chemistry respectively. Since last year there has been added to the anatomical department a number of dissections of different parts of the body, and also frozen sections, these having been beautifully preserved and arranged in mounted cases or basins fixed into desk frames. The practical work of the Anatomy class under Professor Turner was also opened in the New University Buildings.

MEDICAL SCHOLARSHIPS.—At Guy's Hospital the entrance scholarship in Arts of 125 guineas has been awarded to Mr. Henry Woolmington Webber, and the entrance scholarship in science of 125 guineas to Mr. Frederick William Hall. At the London Hospital the entrance science scholarship of the value of £60 has been awarded to Mr. David Brown, and that of the value of

£40 to Mr. J. N. Collins. The open scholarships in natural science at St. Mary's Hospital Medical School, of the value of 60*l.* each, have been awarded to Messrs. G. Watson, A. F. Stabb, and G. A. Simmons; those of 50*l.* each to Messrs. C. E. Lansdown, H. A. Caley, and V. W. Low; and those of 50 guineas each for students of Epsom College to Messrs. J. J. Knox and S. P. Matthews. At Charing Cross Hospital the Entrance Scholarship of 30*l.*, tenable for one year, has been awarded to Mr. F. H. A. Taylor; and that of 20*l.*, tenable for one year, to Mr. J. H. T. Goodwin.

SMALL-POX IN MONTREAL.—The deaths in Montreal and the district from small-pox in September numbered 996, whilst during the last four days of that month and the first two of the present they reached 342. The Montreal mob, although all open violence is checked by the police and soldiers, still tear down the placards from the houses infected with small-pox; and the sanitary officials are only able to attach them under strong guards. A large military force guards the Exposition building, which has been made a small-pox hospital. On Tuesday night the guard here were attacked by a mob of some three hundred persons, but the rioters were easily dispersed without much damage being done.

THE LUNACY AMENDMENT ACT.—The anomalies of Acts of Parliament are proverbial. A nice point has been raised before the Guardians of Wirral (Cheshire) Union, under the Act passed at the close of last session, upon which they have sought the opinion and direction of the Local Government Board. In compliance with the provisions of the Act, a lunatic with suicidal tendencies was lately brought by a policeman to the Wirral Workhouse, and was refused admission, there being no accommodation for such a person, and no official available to attend upon him. By another clause of the Act a magistrate may commit such a lunatic to the workhouse, and the Guardians must admit him on such an order. The anomaly is that, under the second clause, the Guardians are empowered to refuse admission when there is no suitable accommodation, and by the third they are bound to receive a lunatic whether the accommodation exists or not. The Guardians have applied to the Central Authority, to inform them whether they are compelled to make special provision for lunatics.

STANLEY HOSPITAL, LIVERPOOL.—Lord Derby formally opened, on Tuesday, two new wings to the Stanley Hospital at the north end of Liverpool, to which his lordship presented the land required, together with 1,000*l.* to the general fund of the hospital. In responding to a vote of thanks, Lord Derby complimented the committee on the excellent sanitary and other arrangements of the institution. Hospitals, he said, rendered most important services to medical science, and in that regard all classes of society benefited by them. Of all forms of charity hospitals were the least liable to abuse. No doubt they were often used by those who were able to pay for medical service, but it was an abuse which might be checked in various ways; and in all our large towns there was abundant scope for all forms of medical charity. With regard to the manner in which such institutions were supported, he had been repeatedly struck by the small proportion which the subscribers to charities bore to the whole community, and he feared that too little regard was paid to the class who would gladly, if asked, subscribe small sums. He also deprecated the feeling which induced many not to subscribe at all rather than to figure for less than neighbours might think they ought to give. He concluded by expressing warm interest in an institution so intimately associated with his name and family.

SUGGESTIONS FOR IMPROVING THE STATUS OF THE PROFESSION IN BELGIUM.—Our *confrères* in Belgium are much exercised in their mind, about the increasing numbers of medical men yearly turned out by the universities, and the consequent overcrowding of the profession. A discussion has just taken place during a session of the Central Council of the "Fédération Médicale Belge," at which a report was presented by Dr. De Windt on the subject. At the close of the session a set of suggestions were drawn up, by Dr. Cloquet, for remedying the over-

crowding, and generally improving the status of the profession, amongst which are—(1) The re-establishment of the *examen d'élève universitaire*. (2) The modification of the programme of studies, so, *e.g.*, that only such accessory sciences should be studied as are really important to the medicine. (3) The establishment of courses of medical bibliography, the history of medicine and of dental diseases. (4) The suppression of the surgeon-dentists (*i.e.*, dentists without a medical qualification). (5) The establishment of medical societies with courts of honour, for the reference of disputes between medical men, or between them and their patients. (6) The establishment of a uniform tariff to which all medical men will be bound in honour to conform. (7) The organisation of a uniform service for the treatment of the poor. (8) The organisation of dispensaries or clubs, under the patronage of the State, in factories and amongst *bond fide* working men only.

PROVINCIAL HEALTH RETURNS.—From Dr. Sykes' report for the Borough of Portsmouth for 1884, we learn that there were 2,587 deaths, giving a rate of 19.22, which is slightly above that for the previous year. The cause of this mainly appears to be the great prevalence and fatality of measles which carried off 164 victims; this in great measure, and probably with perfect truth, Dr. Sykes attributes to the absurd practice of not including measles amongst the diseases notification of which is compulsory, and the opportunity therefore is never obtained of an early chance of stamping it out. Diarrhœa, too, proved rather fatal, otherwise the year in question was a fairly healthy one. Diphtheria and enteric fever were both unduly prevalent during the year, but did not prove remarkably fatal; they are probably both due to the polluted condition of the soil and the defective sanitary arrangements, which still in great measure exist. Mr. Sergeant's report for Bolton for 1884, discloses an increase in the death-rate, the total number having been 2,615, giving a rate of 24.0 per 1,000. Diarrhœa amongst the infants and pulmonary affections amongst the aged were the chief causes of the increased mortality. During the first half of the year there were 7 deaths from measles and in the last half 104. The other zymotic diseases did not give much trouble: of small-pox there were eleven cases, but no deaths; scarlet-fever caused fifteen, and diphtheria only two deaths. The compulsory notification scheme is in operation, and is found to render invaluable assistance in tracing diseases to their origin.

CONVERSAZIONE AT GUY'S HOSPITAL.—As usual, the medical session at Guy's Hospital was ushered in by a conversazione, which was attended by rather over three thousand people. The medals and prizes to the successful students were distributed by the Treasurer, at ten o'clock, in the Anatomical Theatre, which was crowded with ladies and gentlemen interested in the prize winners. In the course of his short speech, the Treasurer drew attention to the remarkable successes which Guy's had for some years passed obtained at the various examining bodies. Thus at the Intermediate M.B. Lond. University in July last, twenty-four, or a quarter of the whole number of successful candidates, came from Guy's; and in the honours examination, a quarter of those placed were Guy's men, and out of four exhibitions Guy's obtained two, and the marks qualifying for a third. At the B.S. examination, a third of the successful candidates came from Guy's, and a Guy's man qualified for the Gold Medal at the M.D. At the College of Surgeons, both at the Fellowship and Membership examinations, the percentage of the Guy's men passed was very high. Thus, at the Spring Primary, 37 out of 39 were successful. At the Apothecaries Society, the Surgical Scholarship of 100*l.* and the Silver medal for Botany both fell to Guy's men. After a few remarks from Dr. Wilks, the company returned to that part of the hospital devoted to the conversazione, where the pretty and elaborate electric lighting by Messrs. Woodhouse and Rawson, and the very tasteful decorations by Messrs. Morris and Co., excited universal admiration. Some of the most interesting exhibits were the instruments adapted for applying the electric light to medical purposes; Mr. Wilson Swan kindly exhibiting some of his own inventions. The various collections of microscopical objects was particularly good, Messrs. Gowan and Crook, students

of the hospital, showing some very beautiful bacilli. Messrs. Tooth gave a very fine display of pictures; and Messrs. Coote and Tinney's band was in attendance. The anatomical, comparative anatomy, and pathological museums were lit with the electric light, and in the latter, Dr. Goodhart showed all the pathological specimens added to the museums during the last year. The grounds were illuminated in the same style as the Inventories. All the company seemed to have enjoyed themselves thoroughly, and did not separate until a late hour, each carrying away with him as mementoes a very tasty programme and a leaflet containing an account of the work of Guy's Medical School for the past year.

UNIVERSITY COLLEGE, LIVERPOOL.—On Saturday last Lord Derby presided at the inauguration of the new session, and in addressing a full audience, said he need scarcely remind them that one important event of the year was the admission of the College to Victoria University. The effect of that change was that to all residents in or near Liverpool not only is higher education provided at a very moderate cost, but that the education would now bear the stamp of a University degree, the practical value of which to young men having to make their way in a profession they did not require to be told. He believed that as Victoria University became better known the number of its students would continually increase, and its hold upon the support and confidence of the public would be strengthened. He ought, however, to explain, because the matter was one on which misunderstanding was possible, that the union with the Victoria University did not in any way interfere with the independence and self-government of that or any other of the federated colleges. It was in University matters alone that any kind of central control was exercised. In regard to all local action, the college remained absolutely free, and in the decision of University matters each college which was a constituent part of the University enjoyed full and fair representation. After the Principal had made his annual statement, Professor Bradley delivered the inaugural address, in which he treated of the dangers of devotion to specialism in study. Lord Derby said that the address contained a most useful and well-timed warning against the danger to which they were all exposed by the tendencies and surroundings of the time. There was no use in saying they ought not to be specialists. They had got to be specialists if they meant to do anything. No man could now, like Bacon 300 years ago, take all knowledge to be his province. In these days the intellectual world was too wide for any man even to conceive such an idea. Men must resign themselves to undertake one small piece of work, to give their lives to it, and to be happy that they could succeed in doing even that thoroughly, remembering that after all each one was only a unit among some hundred millions who inhabited the surface of the globe. But it was just because they must be specialists in practice that they were bound to counteract the consequent tendency to narrowness by an enlightened appreciation of what other men were doing. That he took to be the practical moral of Professor Bradley's address, not that any of them tried to be a Jack of all trades, for they knew that would not work, but that they should learn to understand enough of pursuits which were not their own to be able heartily and sincerely to recognize the usefulness of those pursuits and the eminence of those who had become distinguished in them. His lordship then proceeded to deliver the prizes.

QUEEN'S COLLEGE, BIRMINGHAM.—At the annual conversazione last week, the Mayor (Alderman Martineau) after distributing the medical prizes to the successful competitors, reminded the audience that the medical profession in Birmingham had great traditions. It was a profession which had always held a high position in the community of Birmingham, and in whose roll were inscribed many honoured names—last, but not least, the name of him whose death they had lately had to deplore—Dr. Heslop. The medical profession gave a great deal of time for the benefit of the public. Many of them also moved in a wider sphere and gave useful service to the public outside their profession. In the public life of Birmingham an infusion of educated professional men had been of the

greatest possible benefit to the public service. He thought that the medical man should be above all and to the last a man of open mind, not running after new fashions and vague fancies, but ready to receive the new facts which came up from time to time, and to apply the principles of his science to them, and not be precluded by any ancient prejudice from taking new impressions. Dr. Sawyer, president of the Clinical Board, presented the clinical prizes and explained that, as president of the Clinical Board, he occupied a representative position with regard to the General and the Queen's Hospitals, which at present were happily united for purposes of clinical instruction. This union had been found in the past to conduce very much to the efficiency of clinical teaching in the town, and they trusted that the union might long continue. In addition to the prizes he had just distributed, prizes still more valuable had been awarded for clinical work—namely, resident appointments at the hospitals. Having expressed deep regret at the absence of his predecessor in office, Dr. Russell, whose serious illness was deplored throughout the medical profession, Dr. Sawyer congratulated the College upon the very substantial improvements and reforms that had been effected during the past year. He and his colleagues on the Council were deeply conscious that many improvements would have to be effected in the College yet before they could feel satisfied that they had placed it in its due position with regard to medical education. But they could point with pride to the improvements effected during the past year, more especially the improvements in their anatomical museum, which now contained a series of preparations and anatomical specimens unsurpassed in any museum in the country. Another great improvement had been accomplished in the election of a professor of pathology, with the special duty, scarcely fully recognised before, of demonstrating histriological subjects. They had also associated the College with the Birmingham Borough Lunatic Asylum, where their students might obtain knowledge the importance of which they would fully appreciate afterwards in practice. Mr. A. F. Clay, at the invitation of the Warden, stated that when Dr. Russell resigned the onerous duties of senior physician of the General Hospital, a Committee was formed to present to him a testimonial in the shape of an illuminated address. So well did the proposal commend itself that 109 past and present students of the College immediately subscribed to the fund. Having read letters from gentlemen who had subscribed to the testimonial, in which were expressions of the highest esteem for Dr. Russell, and of great gratitude to him for his kindly manner of imparting instruction and encouragement, Mr. Clay said that, though Dr. Russell's serious illness prevented the presentation of the testimonial even privately, the subscribers hoped to do something to perpetuate the name of their most industrious and most kind teacher, towards whom they cherished a feeling which could only be expressed by the word love. Mr. Clay then read a letter which had been dictated by Dr. Russell, and the usual votes of thanks were proposed and carried.

**SALICYLATE OF COCAINE HYPODERMICALLY.**—Salicylate of cocaine has been tried as a hypodermic injection in an obstinate case of trigeminal neuralgia by Max Schneider. It acted marvellously well; 0.4 gramme was injected under the skin of the cheek. This was repeated several times, and almost entirely relieved the pain and the distressing insomnia. Galvanism completed the cure.

**COCCUS OF VAGINITIS IN CHILDREN.**—A Hungarian physician has examined the vaginal secretions of a number of little girls who were suffering from all kinds of chronic diseases in a children's hospital, with the result that the coccus which existed in all was, according to the observer, identical with Neisser's gonococcus, and with that found in vaginal blenorrhœa.

**UTERINE SURGERY IN SPAIN.**—Seventeen myomatous tumours have lately been excised together with the uterus and left ovary, fallopian tube and lateral ligament, by Dr. Don M. C. Sabater, of Madrid. The patient did well. The total weight of the mass removed was 4 kilogrammes 480 grammes; the largest of the tumours weighing 3 kilogrammes 100 grammes, and measuring 25 × 20 × 21 centim.

**INOCULATION OF YELLOW FEVER BY MOSQUITOS.**—A Cuban physician has been successful in inoculating healthy persons with yellow fever. His plan is to make a mosquito which has recently stung a patient from the second to the sixth day of the disease to sting the person who wishes to be inoculated. A priest who had been inoculated and whose temperature was taken daily was found on the eighth day to be suffering from cephalalgic pain in the chest and fever, 38.2° C. In the evening he was worse, was covered with perspiration and had bloodshot conjunctivæ, the temperature being 39.1° C.; vomiting occurred during the night. He continued in much the same condition till the fourth day of fever, and when the colour of the eyes was decidedly icteric, the urine contained biliverdine and a little blood exuded from the gums on pressure. The pain had now ceased. The next day the patient was restless and the urine contained a trace of albumen. Both these symptoms disappeared on the sixth day, and on the seventh the temperature became normal. When two mosquitos were employed the symptoms were rather more severe, and lasted longer than when only one was used. The experiments were not always successful, four cases out of eleven being unaffected.

**THE SANITARY COMMISSION DURING THE WAR OF THE AMERICAN REBELLION.**—Mrs. Livermore, during some lectures which she had been delivering at Boston (*Medical Journal*, September 17) on the War of the Rebellion, referred to the immense benefits conferred upon the combatants by the exertions of the Sanitary Commission which was spontaneously formed on a large scale to meet the wants of soldiers beyond those supplied by the Government. It began its work with the permission of the National Government, but without any active co-operation until it had proved its ability to fulfil the objects it had been organised for effecting. She described the arrangements for distributing refreshments to troops in transit; the lodges, forty or more in number, which were in fact free hotels, open day and night to every soldier passing on furlough, and which on the average entertained 2,300 soldiers each night; and the hospital stores collected and forwarded. No army started for battle without a superintendent of the Commission, and a company of agents, men and women, and waggons packed with sanitary stores. No distinction was made between blue and grey uniforms, confederate soldiers being as kindly treated as those of the union. After the battle of Antietam, for instance, there were distributed 28,763 towels, bed-ticks and pillows, 30 barrels of linen bandages, 2,620 cans of condensed milk, 5,000 lbs. of beef, 3,000 bottles of wine, several tons of lemons, crackers, tea and sugar. The estimated value of the sanitary stores thus distributed during the war was 15,000,000 dollars, and the total amount raised and expended in the work of the Commission was 47,000,000 dollars.

**AN ILLEGAL MEDICAL CONTRACT.**—There occurred recently in the Michigan Supreme Court a curious case, wherein the validity of an agreement between a physician and his patient as against a railway company was in question. The physician, it appears, had agreed to accompany his patient, who had been injured by the defendant's cars, and explain to the lawyers and physicians employed by the company the character and extent of the injuries, he receiving as compensation an amount determined by the sum awarded as damages. This agreement the Court held to be illegal and void, though not on the ground that the injured man got more than he ought to receive. The Court decided the matter on entirely different grounds, which are fairly expressed by the following extracts from the judgment:—"He puts himself in a position where both parties are expected to rely on him and to act on what he says. When under such circumstances he makes a disclosure of his knowledge and opinions the subject of a contract, whereby his compensation is to depend upon the amount obtained by his employer by reason of the disclosure, it is plain that he puts himself in a position where it is his interest to exaggerate. . . . And, however honest a man's actual intentions may be, and however faithful he may be, there is a temptation to misrepresent and a direct danger that the misrepresentation will operate

injuriously to the parties dealt with." — *Philadelphia Medical Times*, August 22.

**MEDICAL WORKS IN THE LAW COURTS.**—"The vexed question as to the admissibility of medical books in court," the *Philadelphia Medical Times* (August 22) observes, "frequently comes up for new adjudication and interpretation. The most recent of the cases is found in one of the California courts, where it was held that medical works could not be read by counsel to prove the nature and probable effects of personal injuries. It was claimed that the Common Law rulings had been changed in California by the adoption of a new code, which declared that 'historical works, books of science or art, and published maps and charts, when made by persons indifferent between the parties,' were '*prima facie* evidence of facts of general notoriety or interest,' and the question was whether this legislation made medical books competent evidence. The discussion centred upon what could be termed 'facts of general notoriety and interest,' and whether medical investigation and experience, as recorded in text-books, come under this head. It was decided that they do not; but that such facts 'include the meanings of words and allusions, which may be proved by ordinary dictionaries, and authentic books of general literary history, and facts in the exact sciences founded upon conclusions reached from certain and constant data too intricate to be elucidated by witnesses when on examination.' Thus, mortuary or chronological tables, recognized standards of weights and measures and currency, are admissible. The rule as to medical works is thus stated. 'But medicine is not considered as one of the exact sciences. It is of the character of inductive sciences which are based on data which each successive year may correct or expand, so that what was considered a sound deduction last year may be considered an unsound one this year; and the very book which evidences the induction, if it does not become obsolete, may be altered in material features from edition to edition, so that we cannot tell in citing from even a living author, whether what we read is not something which this very author now rejects.'"

**THE LAST EPISODE OF THE FERRÁN INOCULATIONS FOR CHOLERA.**—Under this heading the *Union Médicale*, October 6, publishes an extract from a communication in the Spanish paper, the *Diario*, of Tarragona, concerning an alarming consequence that has followed the Ferrán inoculations at a small maritime locality called Cambrils, situated between Tarragona and Tortosa. No particulars of the number of inoculations that have been effected are given, but it is asserted that nine of the persons who had undergone inoculation had subsequently been obliged to undergo amputation of one or both arms in order that the gangrene which ensued might be arrested. At the time the communication was made there were two other persons about to undergo the same operation. A complete panic has arisen in the neighbourhood, especially among those who have undergone inoculation.

**CAPSICUM IN HÆMORRHOIDS.**—A case is mentioned by a correspondent of a Peruvian medical journal of a case of bleeding piles cured by capsicum. The patient was a man of 28 years of age. He was much distressed by passing variable quantities of blood after going to stool, and suffered a good deal from anal irritation and tenesmus. No tumour could be detected. He had formerly been in the constant and daily habit of using a violent purgative for ten months, and after he left it off, obstinate constipation followed, and it was under these circumstances that the hæmorrhage commenced. The writer tried all kinds of remedies and regulated the diet without producing any great improvement, and at last was contemplating surgical measures when he happened to mention the case to a hospital physician, who suggested a trial of capsicum, as he had himself been cured of a very obstinate form of chronic dysentery by its means, and he felt sure that it possessed the property of acting on the rectum. This was consequently prescribed with meals, and the doses gradually increased. A marked improvement soon was observed, and at the end of a couple of months a complete cure was effected.

## BIRTH.

At the College, Glasgow, the Wife of PROFESSOR GAIRDNER, M.D., LL.D., a Son, on the 1st instant.

## APPOINTMENTS.

GAYNOR, L.K.Q.C.P.I.—Resident Surgeon to St. Vincent's Hospital.  
HUTCHINSON, EDWARD, C.M. and M.D. Edin.—Medical Officer to the First District and to the Workhouse, Bridlington Union, *vice* Dr. C. F. Hutchinson, resigned.  
JOHNSTON, FRANCIS, M.B., C.M. Univ. Glas.—Senior House Surgeon to the Liverpool Northern Hospital, *vice* W. Horrocks, resigned.  
LAWSON, T. C., M.R.C.S. and L.S.A.—Medical Officer to the Second District, Shaftesbury Union, *vice* Mr. H. Sturrard, resigned.  
MILLER, R., M.B., B.Ch., T.C.D.—Junior Assistant Medical Officer to the Sussex County Asylum, Hayward's Heath.  
NEATE, CHARLES PITT WETHERALL, M.R.C.S. Eng., F.R.C.S. and M.R.C.P. Edin.—Medical Officer to the Stilton District, Peterborough Union, *vice* Mr. L. Thelwall, resigned.  
POWELL, J. J., M.B. Lond., M.R.C.S.—Senior Resident Medical Officer at the Royal Free Hospital.  
WASHBOURN, JUN., WILLIAM, M.R.C.S., L.R.C.P.—Medical Officer to the First District, Gloucester Union, *vice* Mr. A. P. Carter, deceased.

## VACANCIES.

OWENS COLLEGE, MANCHESTER.—Professorship of Physiology. Candidates to forward applications and testimonials to the Council of the College, under cover, to the Registrar, not later than Nov. 9th. Further particulars can be obtained on application to the Principal of the College.  
QUEEN'S COLLEGE, GALWAY.—Professorship of Natural Philosophy. (*For particulars, see Advertisement.*)  
ST. OLAVE'S UNION.—Resident Assistant Medical Officer, &c. (*For particulars, see Advertisement.*)  
TAUNTON AND SOMERSET HOSPITAL.—Honorary Physician. Candidates must have taken the degree of Doctor of Medicine, or be Fellows or Members of one of the Royal Colleges of Physicians of London or Edinburgh, or of the King and Queen's College of Physicians in Ireland, and be duly registered under the Medical Acts. Applications, accompanied by qualifications and testimonials to be sent to the Secretary, on or before October 14th.  
THE GREAT NORTHERN CENTRAL HOSPITAL, CALEDONIAN ROAD, LONDON, N.—Surgeon. (*For particulars, see Advertisement.*)  
WESTMINSTER GENERAL DISPENSARY, 9, GERRARD STREET, SOHO.—Resident Medical Officer. Salary, £100 per annum and furnished apartments. Applications, with testimonials to be sent to the Secretary, on or before October 12th.

## DEATHS.

CRANE, J. W., M.D., at Danett House, Leicester, on Sept. 30th, in his 81st year.  
MARKBY, THOMAS, M.R.C.S., L.S.A., at Stanley Villa, Zetland Road, Bristol, on Oct. 4th, aged 47.  
MOGER, ROBERT GEORGE, F.R.C.S., late of Highgate, on Oct. 1st, aged 78.  
MONCKTON, STEPHEN, M.D., F.R.C.P., at Maidstone, on Sept. 30th, aged 61.

## NOTES, QUERIES, AND REPLIES.

### A WAY OF MANAGING THREATENING PILES WITH SOME PROLAPSE OF THE BOWEL.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—There are two objects to be attained: to reduce the frequency of evacuation in order to give rest from straining, and to increase the bulk to be expelled. The daily effort over a few nut-like morsels is the cause of all the mischief. These efforts must be reduced and the bulk at the same time increased, for the expulsion of bulky well-formed fæces is no trouble, whilst that of small lumps is exceedingly difficult, and the great straining required causes the progressive advance of the disease. Thus, the indications are plain: give rest and obtain such a bulk as can be laid hold of by the bowel and expelled without undue force. I have tried this management for the last fifteen months with much advantage. After defæcation the bowel should always be neatly returned with the finger, which may be guarded with soft paper.

In this trouble formerly, after the daily evacuation there was always much remaining discomfort: the prolapse, so frequently urged, was never entirely over-gotten, but remained to tease. Now, there is at least one day of complete comfort, the day of non-evacuation. But sometimes the relief may not be perfect on evacuation day, some fulness remaining, more or less, during that day. Possibly this system of treatment may in the long run effect a full cure.

I am, Sir, yours, &c.,

J. E. H.

September, 1885.

## THE BRADLEY FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Please acknowledge the following contributions in the next issue of your Journal. And as it has been decided to close the subscription list on Monday, the 26th day of October, I shall be glad if those gentlemen who have not already paid their subscriptions, would kindly forward me their cheques as soon as convenient.

I remain, yours faithfully,  
RICHARD JEFFREYS.

Eastwood House, Chesterfield, October 7th, 1885.

Mr. Alfred Willett, Mr. Malcolm M. McHardy, each, £2 2s.; Dr. G. C. Dale, Mr. Matthew Hallwright, Dr. Arthur W. Orwin, each, £1 1s.

## COMMUNICATIONS RECEIVED—

Prof. GAIRDNER, Glasgow; Dr. J. SQUIRE, London; Dr. R. J. PYE-SMITH, Sheffield; Dr. HERMAN, London; Dr. WOLFENDEN, London; Dr. BENHAM, London; Mr. PLOWRIGHT, Shrewsbury; Dr. ALLCHIN, London; Mr. RIVINGTON, London; Dr. HEYWOOD SMITH, London; Dr. H. C. FOX, London; Dr. E. SYMES THOMPSON, London; THE ASSISTANT SECRETARY OF THE SOCIETY FOR THE STUDY AND CURE OF INEBRIETY, London; Mr. GEO. WILLIAMS, London; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; THE SECRETARY OF THE MEDICO-CHIRURGICAL SOCIETY, Glasgow; THE REGISTRAR-GENERAL FOR QUEENSLAND, Brisbane; Messrs. HODGE & Co., London; THE HON. SECRETARIES OF THE MEDICAL SOCIETY, London; THE SANITARY COMMISSIONER OF THE PUNJAB, Lahore; THE ASSISTANT SECRETARY OF THE ROYAL MICROSCOPICAL SOCIETY, London; Mr. POLAND, London; Mr. H. BYLES, Ecclehill; THE HON. SECRETARIES OF THE SOCIETY OF MEDICAL OFFICERS OF HEALTH, London; THE SECRETARY OF THE ARMY MEDICAL SCHOOL, Netley; Mr. H. A. RAWLINS, London; THE HON. SECRETARY OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, London; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; Mr. R. JEFFREYS, Chesterfield; Dr. W. H. BROADBENT, London; THE SECRETARY OF THE CHARING CROSS HOSPITAL MEDICAL SCHOOL, London.

## BOOKS RECEIVED—

Suggestions on some Symptoms of Renal Disease and their Management, by Charles W. Purdy, M.D.—Report of the Port of London Sanitary Committee, etc.—Address, by James T. Rudall—Reading Medical Dispensary, Report for 1884—Borough of Portsmouth, Report for 1884—Diseases of the Larynx, by Dr. J. Gottstein, Edited by P. M'Bride, M.D., F.R.C.P., F.R.S.—Die Diphtheritische Allgemein-Erkrankung und deren Behandlung, von Dr. Ed. Schottin, Dresden—Elements of Pharmacy, Materia Medica, and Therapeutics, Third Edition, by William Whitla, M.D.—A Summary of New Remedies, by Thomas M. Dolan, M.D.—The Diseases of Sedentary and Advanced Life, by J. Milner Fothergill, M.D.—A System of Practical Medicine, by W. Pepper, M.D., LL.D., and Louis Starr, M.D., Vol. III.—The History of Cholera in India from 1862 to 1881, by Deputy Surgeon-General H. W. Bellew, C.S.I.—Westminster Hospital Reports, Vol. I.

## PERIODICALS AND NEWSPAPERS RECEIVED—

## CLINICAL REMARKS ON PERITONITIS.

### CHRONIC OR SUB-ACUTE PERITONITIS IN THE YOUNG.

By W. T. GAIRDNER, M.D., LL.D.,

Professor of Medicine in the University of Glasgow.

(Continued from page 426.)

CASE.—*Very well-marked thickening, amounting to tumour of the Great Omentum, gradually resolved in two years, with extremely insignificant symptoms—Crepitus in right pulmonary upper lobe, arising under observation, and persisting during the entire course of treatment with little modification—Symptoms scarcely appreciable, and general health well maintained.*

THE case I have now to mention has been under my observation at different times since May, 1883; and although thus earlier in date than the others already referred to, I have placed it here last in order, because the chief physical facts connected with the abdomen can be more readily explained by recalling these others, than by appealing to anything in Lizzie C.'s own more

recent history; the last detailed notes of her case, in January and February, 1884, indicating that but for previous observations and the history, it would have been difficult at that time to demonstrate (as to a clinical class) that anything abnormal existed in the abdomen at all. I have, indeed, seen for and seen this girl more than once since that time, but only to satisfy myself as to her condition of quiescence as regards the abdominal disease, and also to observe again certain other facts which you, also, will find very interesting, if you take the trouble to follow the whole narrative continuously; for in no other way can the significance of the individual facts be properly understood. This girl, then, is in a certain sense "cured"; and her cure has lasted, as regards the abdominal disease, for fully two years; but I do not on this account say that she is absolutely, *i.e.*, pathologically as well as clinically, even now in a normal condition; on the contrary, there are certain abnormal facts, not at all obscure, and very rarely absent or difficult to discover, which, even if there were no symptoms at all present, and if there had been no history of prior disease, would necessarily induce great caution in speaking about her as "cured" in the most strict sense of the word. And it is precisely this contrast between the definiteness of the physical signs of disease, and the relative insignificance of the symptoms, that makes me anxious to bring the case under your attention.

Lizzie (or Elizabeth) C. was 9 years of age when she was first brought under my notice on the 7th of May,

1883, on account of a swollen abdomen; which, it may be said quite unreservedly, was at that time her only symptom, and, even after most careful examination and enquiry into the facts, was almost the only thing that could be ascertained about her suggestive of organic disease at all. Now, a swollen abdomen in a child may proceed from many causes, and is often regarded as a very trivial and unimportant disorder, *per se*. I do not say that you will be right in so regarding it; I would rather lead you to be very careful about all such cases, and not to dismiss them in the summary way they are often treated, with a little grey powder or a few doses of castor oil. No case could have been more trivial than that of Lizzie C., if judged by the amount of local uneasiness or of constitutional disturbance; for, from a note extending to more than seven pages in the Hospital Journal (Ward 6, T. pp. 222 *et seq.*), and mostly made by myself in presence of the class within two days of her first admission to the Western Infirmary, we can assure ourselves even now that the most thorough investigation was made at that date, and that neither in respect of complaints, nor in respect of physical and physiognomic signs, was there anything to beget even a suspicion of grave disease, except the physical condition of the abdomen; no hereditary syphilis, no scrofulous indications, no rickets, no chest symptoms of any importance, unless the cicatrices of a very old and obviously artificial eruption which may have pointed to some chest disease in early infancy, treated with antimonial or other ointment, but in the interval of years practically lost sight of and forgotten. She was said to have been always a healthy child, and her appearance confirmed it; she was, indeed, the very picture of health, nay, even of superfluous or "rude" health (as judged by her colour and general appearance) at the time of admission. She herself had first drawn attention to the swelling and hardness in the abdomen, about three months before, and she admitted that she had felt it "slightly sore." Her mother affirmed that, a few days after the swelling was first noticed, the girl was troubled with diarrhoea, at first pretty severe; but this had ceased after a fortnight, under merely dietetic treatment and without medical advice, and it had not recurred. Appetite and digestion, according to her mother's testimony as well as her own, remained unimpaired; and I may add that our experience in the ward tended in all respects to confirm these statements, in respect that her temperatures, carefully taken for weeks together, showed no signs of fever; and her body-weight, by no means apparently deficient even at first, went on increasing after admission.

And yet, with all these facts in her favour, more strongly so, even, than in the case of Jane M. (the first of this series that I placed before you), there was no doubt at all, in Lizzie C.'s case at this time, of the existence of a distinct tumour in the umbilical region, corresponding exactly, both as regards percussion and palpation, with the characters of a thickened great omentum as already detailed to you. The report, which goes into every element of the diagnosis as demonstrated to the class on 9th May, is open to your inspection; and I spare you the details here, simply because there is so much besides in the case to occupy us. The tumour was distinct and palpable, dense to the feel and superficially dull all over the umbilical region, so that it could not have been either faecal accumulation, or merely inflated intestines. The epigastric, hypogastric, and both iliac regions were comparatively soft and yielding, and quite normal to percussion. There was not, in fact, a single element in the diagnosis of thickening of the great omentum that was wanting in this case, and all the physical signs were present in even a more definite form in Lizzie C. than in any of the others; but there was no

evidence at all of fluid effusion at the time we first saw this girl, nor at any time afterwards. We judged it possible or probable, that there might have been such effusion at an earlier date; but if so (as in the case of Jane M.), it had been absorbed so as to leave no traces to physical diagnosis.

Had this case ended favourably at this point, and without any observations of interest other than those above mentioned, the case would have been mainly a reproduction, or rather an anticipation, of the facts presented to you in Jane M., with some non-essential variations of detail. Had this been so, I should probably have been satisfied with alluding to it briefly as such. But there is much more of clinical instruction in the case than this. The great probability, from the pathological point of view, of such a lesion as existed in Lizzie C. being of tubercular origin led to a more than usually, indeed an anxiously careful exploration of the lungs at the very first examination (May 9th). The result of this was that there was some ambiguity as regards the auscultation and percussion-signs, respectively, of the two apices; but on the whole we thought the right spex showed "a distinct deficiency, both as to quantity and quality, of the R.M., and even, perhaps, a little irregularity amounting to jerking. At the back," the report continues, "percussion of the right apex appears relatively impaired, and here also the R.M. is inferior in fulness to that of the left, but without r le or other alteration in quality." I emphasize one or two points in this report for a reason that will presently appear. Taken by itself, it amounts to a suspicion, but no more, of disease, probably tubercular, in the right apex.

Just a week after this, however (May 16th), I was again examining this patient, after noting carefully her satisfactory condition since admission as to the general symptoms. On this occasion my attention was attracted for the first time by "a fine and slight crepitus, probably of the mucous order, developed in the right apex since the previous careful observation, and audible very distinctly down to the second, and less so down to the third rib, accompanied everywhere by wheezing r les, but of no great intensity." The observations, in other respects, as to the relative fulness of the R. M., &c., on the two sides, were confirmed on this occasion.

I purposely caused a large number of persons to listen to these sounds, because, although it was possible that they might have been merely occasional and transitory, and therefore of no great importance, it was also possible that they might have a bearing on the diagnosis and prognosis of the case as one of tubercular disease both in the abdomen and the chest. The observation being made thus early and thus studiously with reference to this point, was followed up with the more freedom, because the state of the patient admitted easily of frequent examination. She was gaining in weight; she was free from fever and from pain; she had no considerable cough,<sup>1</sup> and no expectoration. Yet from that time onwards I can absolutely affirm that during the whole summer, when she was under daily observation up to the end of September, 1883, there was not a single occasion when the r le above referred to was found absent from the right lung in front, or even very difficult of detection. It had always nearly the same characters—a very fine clicking or crepitant r le, always much more distinct during inspiration, and sometimes only audible with forced inspiration, without any appreciable amount of tubular or other altered quality of the R. M. in the

<sup>1</sup> The precise fact, as noted, May 16th, is as follows:—"The ward sister, on being appealed to, has noticed a short cough without expectoration, but not such as to molest her, or to have attracted the child's own attention; which, therefore, may have been indefinitely present before admission."

right lung; but with, as above stated, a somewhat depreciated relative amount of fulness, and this both at apex and base. It perhaps differed from the crepitus of the early stage of pneumonia, but very slightly so, in being more of a moist character; and certainly much more in its long persistence without other alterations. All this was frequently the subject of clinical commentary, and of very repeated observation, not only by myself and my assistants, but by some of the other physicians of the Western Infirmary, and by occasional strangers. In not one instance did the râle altogether fail to be observed, although its area and its amount both varied. It was chiefly heard over the upper lobe, and never on the left side.

During her residence, on this occasion, of nearly four months, Lizzie C. gained in weight, in all,  $25\frac{1}{2}$  lbs., having been on admission 3 st. 2 lbs., and at her dismissal, 4 st.  $13\frac{1}{2}$  lbs. The condition of the abdomen very notably improved, without its being able to be said that the physical signs mentioned had altogether disappeared. Her cheerfulness, and her sense of well-being, were unimpaired throughout, and no local symptom seemed ever to cause her any uneasiness. Her cheeks were almost preternaturally rosy and fat, and it was only by becoming satisfied of the entire absence of fever that we acquitted her at times of a morbid flush; but I afterwards came to know that this peculiarity, and her altogether exceptionally good physique, had procured her an engagement at a theatre as a subordinate in a pantomime, and were by her mother and all her friends considered to be exactly in accordance with her condition from infancy onwards. I may add, that although partial sweats about the head and face appear once to be mentioned in the report, it was during warm weather, and was not considered, ultimately, to have been a fact of any importance.

Here, then, we have a combination of details, in the case of Lizzie C. which I have given you, so far, in a much condensed form, or abstract, from journals T and U of the female ward, inviting you to refer to these journals for yourselves, in case you should be of opinion that all the evidence of importance is not fully before you. I will merely say here that there is not a single point, in my opinion, in which the evidence of detail bearing on the peritonæal disease was not as carefully recorded, and as faithfully considered in reference to possible fallacies, as in any of the other cases here cited to you, or, as in the case of Jane M. and Mary Jane S., which have been mainly under your own observation. And you are not to suppose for a moment that any of these details are at all new to me, as I may presume some of them are to you.<sup>2</sup> On the contrary, cases of this kind in a general way (though that of Lizzie C. is certainly an exceptional one) have been constantly occurring to me for more than thirty years in hospital and dispensary practice, as well as in consultations among the more affluent classes; and the impressions about them that I wish to leave on your minds might be almost indefinitely illustrated out of the fifty or sixty journals which a decennium of the Western Infirmary has accumulated for our wards, as well as by reference to older experience in the Royal Infirmary here, and in the Edinburgh Royal Infirmary. What I wish to do now, however, is not to generalise prematurely, but rather to place before you the lessons of these four cases, thus successively presented in series, as elements out of which you may learn something more for your-

<sup>2</sup> Although in teaching clinically, I usually make but little reference to authorities, in dealing with demonstrable facts, it would be easy to show that in most of the text books the diagnostic characters and significance of thickening of the great omentum have been strangely overlooked; although the mere anatomical fact has long been known. Hence the prominence given to these points in the preceding papers.

selves. And it is to press home the lessons of Lizzie C.'s case that I now invite you to read with me more continuously the later reports, made when she could be hardly spoken of as a patient, but rather assent for at my request, in order to take stock (as it were) of her physical condition and progress.

On February 1st, 1884, I sent for this girl (she lives at Paisley, seven miles from this), and in the journal of Ward 6 (v. p. 169), we have a note which, as it is not long, I will quote almost entire:—"Speaking generally, it may be said that all the facts noted last summer are still more or less apparent; the abdomen being soft and elastic, but decidedly abnormal to percussion over the whole omental region; and the true intestinal note (*i.e.*, on superficial percussion) being only procurable towards the hypogastrium. The râle observed in the right apex is still appreciable, and perhaps more clicking and hollow in character, but still not so definitely altered as to suggest any well-marked new physical changes. The mother's account is as follows:—Lizzie complains of nothing, is always light-hearted and fit for all games with her companions, rising at eight in the morning and going to bed at eight in the evening without any appearance of undue languor, sleeps well at night, takes her food well, is never sick, has no diarrhœa and complains of no pain. As regards pulmonary symptoms her mother remarks that she may take a cold occasionally, and did so three weeks ago; and as the result of this a very little cough may be admitted as occasionally audible, but not so as to make the girl herself complain. [See footnote above, indicating exactly the same facts as at date May 16th, 1883.] She has preserved to the full the rosy appearance she had in summer, so much so, that the only question that can be raised is whether it does not incline to lividity. Her mother thinks her decidedly less fat than when dismissed last summer, but she has never noticed any feverishness nor sweating."

Again, on the 11th of October, 1884, I sent for Lizzie C., and on this occasion, and some later ones, much longer and more elaborate reports will be found in Journal X., p. 37, *et seq.*, the substance of which (condensing them very carefully to save repetitions, but omitting nothing essential) I will now endeavour to convey to you.

It appears that Lizzie C. suffered somewhat from headaches during the autumn of 1884; and as they disturbed her sleep she was on this account withdrawn from school in September, and put under medical treatment. There was, however, no uneasiness as regards the chest or abdomen, till the beginning of October, when she complained of pain in her right side, and on strict enquiry it appears she was possibly a little short in the breathing, but it was by no means a prominent symptom, and in the main, her mother adheres to the report made on February 1st (see above). She may have been a little feverish with the headaches, but otherwise there was no evidence of any constitutional disturbance. The physical facts were exactly as before, with the exception (which, however, was in exact accordance with the observation of May 16th, 1883) of a certain amount of distinctly wheezing râles audible on the right side. (It was presumed that these were on this occasion of recent origin.)

On the 11th October, 1884, Lizzie C. was found to weigh 5 st.  $2\frac{1}{2}$  lbs., as against 3 st. 2 lbs. at our first observation of her in May, 1883, and 4 st.  $13\frac{1}{2}$  lbs., at her dismissal in September; so that although she had not lost weight (but in fact gained about 3 lbs. between September, 1883, and October, 1884), it might be fairly maintained that there had been either an absolute or a relative loss of weight during some portion of the latter period, corresponding, in all

probability, with the illness above mentioned. It was, however, by no means very apparent to even a professional eye, that she was notably thinner or less in good health than on previous visits.

On January 5th, 1885, this girl was readmitted at her mother's request, chiefly on account of a "shortness of breath," with wheezing, especially at night. At this time she had gained 3 lbs. in weight since October, and looked certainly to my eye as well as ever (as a somewhat critical note made the next day informs me); the trace of "lividity" above incidentally alluded to being discounted (as it were) in consideration of previous knowledge of her appearance. The pulse was 80, regular, and of fair strength. The respiration barely 16 in the minute, and absolutely tranquil. Apart from the mother's statement, there was nothing to lead to any apprehension of renewed chest disease. It was, however, ascertained more fully than previously that Lizzie's father died of something that was called "bronchitis with inflammation of the windpipe" at the age of 30. He was a very intemperate man. Her mother also thought that there were traces, at least, of bronchial affections in the family.

The abdomen was found to have a maximum circumference at this time of  $24\frac{1}{2}$  inches, *i.e.*, one-and-a-half inches less than at the time of first admission, and almost four inches less than the absolute maximum noted on 28th August, 1883. Allowing for the developmental growth and improved condition of the child generally, this was considered a highly satisfactory note, and it was borne out in detail by a most critical estimate of the physical facts, which, as it was practically superseded at a later date by a much more compendious statement with almost identical results, I will not trouble you to read over. The râle, so often previously observed and discussed, was at this date made the object of a formal lesson at the bedside to the clinical class, and in the very ample report framed for the purpose of detailed instruction, and resting on all the previous observations, the following statements emerge: "Dr. G. remarks, with a view to the classification of this râle (1) That during the whole period of its singular permanence it has been heard, perhaps not quite exclusively, but always in an immensely preponderating degree, with the inspiration; (2) That while it has at different times and in different degrees suggested so much of the moist quality as to make it impossible to demarcate the râle from the moist râles, there has been no such consistent progress from dry to moist as is implied in Dr. Walshe's description of the dry and moist crackling rhonchi respectively (see 4th edition 'Diseases of the Lungs, &c.,' pp. 326-330, therefore, it was argued, there had been no evolution of the phenomena in the direction proper to, and according to Dr. W. eminently characteristic of, the progress of tubercle in the lung towards softening); (3) It appears, both to Dr. G. and Dr. Middleton, that there has been a little (but still only a little), increase in the tubular or bronchial quality of the R. M. in the right apex since the first observation; and this mostly, if not exclusively, in the region of the sterno-clavicular articulation; (4) It is difficult to say whether there has been any change in the percussion since the first observation in May, 1883."

On February 4th of this year we were able to record the results of a renewed daily observation of this case for a month in hospital as showing once more "quite satisfactory progress" in respect of the removal of the slight complaints indicated on her re-admission. "She says she has now no headaches. The pain on the right side is gone, and she appears to be quite unconscious of any wheezing or other notable symptom of pulmonary disease. Appearance perfectly good;

temperatures subnormal, rather than otherwise, but cannot be said to show anything worthy of remark. Apart from the history, there would be no reason at all for anxiety about the patient, or for detaining her in hospital. The abnormal facts in the abdomen are still just perceptible, but with so great an amount of difficulty that in the absence of previous history they would certainly be disregarded. It seems safe to say that the palpation is that of a normal abdomen in a plump, well-nourished child, with a good deal of fat in the abdominal wall. [The percussion still, however, appreciably abnormal.] The circumference is now  $26\frac{1}{2}$  inches, being two inches of increase since she was last admitted on January 6th, but this increase is probably commensurate with an increase in the general bulk of the body; at all events there is nothing whatever to lead one to suppose it abnormal." [The circumference in February, 1885, was in fact just over what was recorded as that of an abnormal or swollen abdomen in May, 1883; the difference being that normal development had taken the place of disease.]

As regards the chest, it was observed on Feb. 4th, 1885, that the same ambiguity which had been noted in May, 1883, existed in the percussion of the two apices. "The well-known râle was again found in the right apex in even a larger and more diffused form than ever before, and, though it is difficult to put into words changes of so extremely slight a character, the râle is certainly more of a moist order, and with larger bubbles than on most previous observations, and this is the more remarkable, as it is only a few days since Dr. G. and Dr. Beveridge, examining together, were struck with the paucity of the râle, and with its being rather difficult to catch, except at some points and on very full inspiration. To day, the râle is distinct at all points down to the third rib, and even occasionally a little below this, but during the examination by the class, it becomes much less abundant and more circumscribed, and is chiefly audible in the sterno-clavicular region. Wheezing is scarcely, if at all, appreciable. [The other characters of the R. M. did not differ from previous examinations, indeed, could not be said to indicate any advance in the disease even as compared with May, 1883.] Sputum has been entirely absent since admission."

On February 7th, this girl was dismissed for the second time, after exactly five weeks residence, greatly improved, and practically well<sup>3</sup>. The whole period of observation and treatment, taken together, in this case may be said to extend over more than two years, and it is likely, I hope, to be much further extended, for I have good hopes now that Lizzie C. may attain to womanhood, or even to mature age; and, having watched her case with so much interest thus far, I shall endeavour, if possible, not to lose sight of her entirely in the future.

(To be continued.)

<sup>3</sup> The very last reports of Lizzie C. through her mother, conveyed in a post-card dated August 31, 1885, are perhaps a little less favourable. "She has not slept much for the last fortnight, with pain in her head and breast. The swelling in belly is much about the same. The general health is good. Takes her food very well."

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—At the quarterly meeting of the governors of Addenbrooke's Hospital, it was announced that the late Master of Jesus College a few days before his death, had presented to the hospital a portrait of Bishop Turton, who was a great benefactor to that institution, bequeathing to the hospital at his death a twelfth part of his residuary estate. The portrait will be placed in the Board-room of the hospital.

## CYCLIC ALBUMINURIA — (ALBUMINURIA IN THE APPARENTLY HEALTHY).<sup>1</sup>

By F. W. PAVY, M.D., F.R.S.,

Senior Physician to Guy's Hospital.

ATTENTION has been recently given to a form of albuminuria which has been spoken of as "albuminuria in the apparently healthy," "physiological albuminuria," "intermittent albuminuria," and by my colleague, Dr. Moxon, in the Guy's Hospital Reports, Vol. XXIII, 3rd series, "Albuminuria in Adolescents." It is important that the albuminuria in question should be distinguished from the ordinary form of albuminuria, as the gravity of the two is diametrically opposed. Several cases have, during the last six years, fallen under my notice, and I have observed in them a character which has served as a ground of distinction, and enabled me to express an opinion at the commencement which has been verified by the advance of time. The character I refer to is the diurnal alteration that takes place in the condition of the urine. Examined at one period of the 24 hours the urine is found to contain, it may be, a large amount of albumen, whilst at other periods there is none, and what is observed one day is repeated with more or less closeness the next. These cases thus have a cyclic character belonging to them, and hence my adoption of the term "cyclic albuminuria" as the heading of this communication. It appears to me an appropriate one to employ for the purpose of classification. The description to be given of what is noticeable is as follows:—In the early morning the urine is free from albumen. Albumen then shows itself, it may be, at 9, 10 or 11 a.m., or not till the early part of the afternoon. After reaching its maximum it declines, and often by the evening it has disappeared. It is rare to find that it has not disappeared by bedtime. The period of diurnal appearance is, without too closely limiting it, pretty uniform for each case. Some days the amount may be observed to fall and then rise again. Also there may be considerable variation in the amount of albumen observed on different days. The condition noticed may go on not only for weeks and months, but even for years. It is not accompanied with any impairment of health, and there are none of the ordinary constitutional indications of the existence of Bright's disease present. In some cases I have noticed that there has been a sharp and unduly forcible cardiac impulse, but the pulse has been soft, and not hard and sustained as in Bright's disease. Such being the history belonging to the albuminuria in question, there is nothing to lead in a direct manner to its recognition, and it is generally in an incidental way that it becomes brought into view. The urine in other respects presents ordinary characters. No casts of tubules are to be observed but frequently oxalate of lime crystals are present.

The age in the cases that have fallen under my notice has varied from 9 to 49. Altogether I have seen 3 cases in children, viz., 1 at 9, 11 and 13. Two were boys, the other a girl.

It is not surprising that the condition should excite grave looks and the shrugging of shoulders on the part of members of the profession which give alarm to the patient, but there is nothing to show from the experience that has yet been gained that it is to be regarded as an early stage of Bright's disease, or that it leads on to anything serious.

The kind of albumen present in several of the cases has not been simply ser-albumen, but a mixture of caseiform or alkali-albumen with ser-albumen.

I do not propose at the present moment to offer any theory in explanation of these cases. Analogous phenomena are, however, noticeable in the case of persons the subjects of the phosphatic diathesis. Here the urine voided may be perfectly bright and clear in the early morning, whilst for a few hours after breakfast it is turbid from the deposition of phosphates, and becomes clear again in the afternoon, and remains so till the following day after breakfast when the same cyclic course of events is repeated. Again, without our being able to account for it by the operation of external influences, a diurnal variation occurs in a regular manner in the temperature of the body. An illustration is here afforded of a physiological cyclic change, and other illustrations showing the tendency in this direction might be adduced.

I will now supply the details of a few cases selected from those which have fallen under my notice.

In the spring of 1881 Mr. O. T., a tall, well-built, well-nourished, healthy-looking young man, 21 years of age, discovered the existence of albumen in his urine. He was engaged in practical chemical work, and was led to examine his own urine when suffering from a temporary attack of lumbar pain. To his dismay he found albumen present, and for some time was in a state of mental distress about it. When the case fell under my observation I desired that specimens of urine passed at different periods of the 24 hours should be brought to me for examination, and recognised the ease to be one of the class I am describing. Frequent examinations of the urine were made, and at one time this was done for three weeks on every consecutive day. What was observed was this: The urine passed on rising in the morning was never found to contain albumen. Sometimes as early as 10 or 11 a.m., but at other times not till about 2 p.m., albumen began to be perceptible. On first being found the quantity was slight, but went on increasing till usually about 6 p.m., when the maximum point was reached. It afterwards declined, and usually on going to bed the urine was free from albumen, or if it contained any it was only a trace. Breakfast was taken at 8 a.m., lunch at 2 p.m., and dinner at 6 p.m. Beyond the presence of albumen the urine presented normal characters except that it threw down oxalate of lime crystals. Casts of tubules were never found. There was no constitutional evidence of Bright's disease. The pulse was soft. There was undue cardiac impulse, but it was sharp and not heaving.

Such was the condition existing in 1881, and being desirous of knowing whether it had disappeared or not I wrote in March of the present year, and requested that I might be afforded the opportunity of again examining the urine. I received in reply as follows: "In answer to your request of yesterday I shall be very pleased to do anything I can to be of service to you. For a short time I tested my urine frequently with the same results. I then gave it up, as I found it only led to my getting mentally uneasy, so that for the last three years I have never tested for albumen. I will try and come to see you soon as you request. We are so busy just at present that I am afraid I cannot well get away during business hours. However, I will try one day next week, and, in the meantime will make a few more tests of the urine passed at various periods, and let you know the results when I see you."

On the following week I received a visit from Mr. O. T. He brought with him specimens of urine, and told me he had found that the old condition still

<sup>1</sup> Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Cardiff.

existed in the same form as before, the urine being free from albumen in the morning till about noon, the maximum amount being present between 4 and 6 p.m., and the urine being free again at bed-time, or if not absolutely free only containing a trace. I examined the specimens brought, and the results obtained confirmed this statement, but the afternoon urine contained less albumen than I had noticed previously. This might have been incidental. The bodily health was good in every way. There had been no illness during the four years that had elapsed, and no deviation from the state before observed was perceptible.

I have again procured specimens just previous to the Association Meeting, so as to bring the report of the case up to the present time. The urine passed at 8 a.m., July 20th, was free from albumen; that passed at noon contained a trace; that passed at 5 p.m. a considerable amount, and that on going to bed a trace. The same kind of condition that was before noted, therefore, still exists.

In July, 1883, Mr. T. W. R., 18 years of age, was brought to me by his father with the history that he had recently successfully gone through the examination for a Civil Service appointment in one of the British possessions, and on afterwards presenting himself for medical examination was not passed on account of the presence of albumen in his urine. He had been at Cheltenham College and had been reckoned as one of the healthiest there, engaging freely in the different sports pursued by the students, without the thought having occurred to himself or others that anything wrong existed with him. The urine passed at the time of consultation about the middle of the morning contained a slight amount of albumen. I desired that specimens passed at different periods should be sent for examination, and it was found that the early morning urine was free from albumen, whilst albumen was present in notable amount at 1 p.m., and absent again at bed-time. Examinations were made July 19th and 30th, and August 4th, 8th and 13th. They all agreed in showing the early morning urine to be free from albumen. The amount varied in the early afternoon urine, and by the end of the evening the urine had become free from albumen, or only contained just a perceptible trace. Microscopic examination revealed the presence of oxalate of lime crystals and no casts. The result of this examination was communicated to the authorities in Whitehall, and I was asked to meet the medical advisers (two of the most distinguished members in the profession) of the Board at a time appointed for the candidate to attend. This, as at the previous medical examination, was unfortunately for the candidate in the afternoon, and as was to be anticipated, the urine voided at this time for analysis contained albumen. Had it happened that the medical examination in the first instance had been conducted during the early part of the morning, the candidate would have undoubtedly been passed, for there was nothing against him beyond the condition of the urine that has been described. I expressed and recorded in writing my conviction, from what I had seen of other cases, that the candidate's condition was not to be looked upon in the light of ordinary albuminuria, and that it would not interfere with his continuing in the possession of health and ordinary working power. He was not, however, accepted. He had one more chance left him, which was to go in for the examination again in the following year, which his age just permitted. This he did, and came out in a higher position amongst his competitors than at the previous one. When he afterwards attended to be medically examined, his urine was free from albumen and he was passed. In the previous March it had been examined and was also found free. I have just (July 1st, 1885)

obtained an opportunity of seeing the person and examining the urine. Four specimens were brought derived from what was passed at 7.30 a.m., 1.30 p.m., 5 p.m. and 10.30 p.m. Under ordinary testing they would all be pronounced to be free from albumen, but with scrupulous attention the 1.30 p.m. and 5 p.m. specimens showed just a discoverable impairment of brightness, and the 5 p.m. specimen more so than the other. There had been an uninterrupted enjoyment of good health, and the bodily condition was in every respect satisfactory.

T. F. H., aged 49, consulted me in February, 1882, with the history that he was the subject of albuminuria, and that it had been noticed that albumen was present at one time and not at another. Although his bodily health had not suffered, he had been advised to give up hunting and shooting, and otherwise adopt an invalid mode of life. He had been in the habit of examining his urine himself with heat and nitric acid, and came with the statement that albumen was to be found between breakfast and lunch, but not in the early morning or at bed-time, or if at bed-time only to the extent of a trace. Finding by my own examinations that this statement was correct, I gave a different prognosis from that which had been given to him before, and recommended him to lead a prudent but ordinary mode of life, both as regards exercise and diet. I have watched the progress of this case, and examined the urine from time to time. I notice in my case-book that in June, 1883, all the five specimens brought were free from albumen. The last visit to me was in May of the present year, and again I see the report that no albumen was to be found. The general health was good.

In November, 1881, W. H., aged 19, was brought to me by his local medical attendant on account of the presence of albumen in his urine. He had already been taken to a physician, and the father had been alarmed by being told, in answer to an enquiry about the future employment of his son, that he had no future of any duration to look forward to. Investigation showed that in the early part of the morning the urine was non-albuminous. Soon after breakfast albumen began to be perceptible, and a little later on was more abundant. Usually at bed-time the urine was free from albumen, but sometimes a trace was found. In March, 1882, the condition of the urine was the same. There was no sign of any impairment of health. In December, 1883, I was afforded an opportunity of examining the urine again, and there was then an absence of albumen.

C. M., aged 19, appeared in good health, but albumen had been discovered in his urine when being examined for life assurance. I saw him in consultation in March, 1883, and it had been previously noticed by the medical practitioner that the albumen was not always present. The early morning specimen was free, whilst after breakfast albumen was found.

Last week a gentleman, aged 28, came to me with a letter from a medical practitioner. The letter is dated Liverpool, July 20th, 1885. It runs as follows: "About a week ago I found albumen in the urine of the bearer. The specimen I examined was passed in the evening, he having had a meat tea, and played a few games of lawn tennis. The albumen produced a decided milkiness with picric acid and heat, also with nitric acid, and left a deposit after twelve hours' standing equal to about one-tenth of the urine. The urine was acid; specific gravity 1,025; no sugar. No casts, but a very abundant deposit of octohedral crystals of oxalate of lime. The urine passed the following morning fasting had the merest trace of albumen. In the evening, a few days later, the albumen had returned. I had not examined it in the interim. The following morning, fasting, no albumen,

but after breakfast, consisting of sole and an egg, the albumen had returned in somewhat larger proportion. . . . . So much for the present condition. About four years ago his life was refused by an assurance society. I examined his urine at that time, and found some sugar in it—a very little, but he has heard the assurance medical examiner found albumen. He was treated by my late partner for some months, and you then saw him and found nothing wrong with his urine.”

Reference to my case-book shows that this person came to me in 1881 with the history that sugar had been found in his urine. At the time of his visit his urine was free from sugar. I put him upon a test diet for a few days—that is, desired him to partake freely of starchy and saccharine matters—and still finding his urine free from sugar, I told him that he might consider that he was not the subject of diabetes. He has now come to me as the subject of albuminuria, and my own observation shows, as had been noticed by the medical practitioner who sent him to me, that it is only during a part of the 24 hours that his urine contains albumen. The urine passed on rising in the morning of July 24th, was of specific gravity 1,030, with no albumen, and 6.804 per 1,000 of acidity. At 11 a.m. the condition was, specific gravity 1,024, considerable amount of albumen, and acidity 1.701 per 1,000. At 5 p.m., specific gravity 1,031, less albumen, and acidity 6.048 per 1,000. At bed-time, specific gravity 1,023, faint trace of albumen, and acidity 2.520 per 1,000. July 25th, on rising there was again an absence of albumen, the specific gravity was 1,030, and the acidity 6.930 per 1,000. Microscopically, the only abnormal condition discoverable in the several specimens was the presence of oxalate of lime crystals. Such is the information as yet obtained, and upon it I judge the case to fall in the category of those I have been describing. Much to the relief of the patient I expressed this opinion to him. He is of a highly excitable temperament, and was in an exceedingly anxious state about himself. It is curious that he should have come to me first with reference to sugar and now with reference to albumen, and I hope it will turn out that the encouraging terms in which I spoke to him with regard to the latter will prove as well founded as they did with regard to the former.

A case fell under my notice a few months back in which a first impression, based upon a statement of the patient that he was suffering from albuminuria, and that it had been observed that his urine was free from albumen in the early part of the morning, was found on full investigation to be erroneous. It was a case of a gentleman, 48 years of age, with a gouty family history, and a presumption that he himself owed his troubles to gout. Albumen had been discovered in his urine in 1879 when seeking advice from a physician regarding the most suitable Continental watering place to visit. Ever since this time albumen has been known to exist, and, as I have mentioned, the patient came to me with the statement that in the early morning the urine was free from albumen. He was the subject of alarming attacks of what he called faintness of so severe a character as to lead him to think that he was in imminent danger of death from stoppage of the heart. Upon one occasion, when driving in the park, an attack occurred, and he was taken to the house of Dr. Fothergill. I was glad that he fell into the hands of a person so capable of observing the nature of the condition existing, and I learnt from the patient that, notwithstanding the kind of feeling he experienced, his heart was found to be beating forcibly, and he told me Dr. Fothergill had referred the attack to contraction or spasm of the cerebral vessels. I see Dr. Fothergill present, and perhaps he remembers the case. As far as the general condition

was concerned, the symptoms were suggestive of the existence of gouty or granular kidney, but the urine was of normal quantity, colour, and specific gravity, and at its maximum only contained a slight amount of albumen. My own examination confirmed the statement that had been made, except that on scrupulous inspection the existence of a faint trace of albumen was perceptible in the morning urine. The microscope, however, revealed the presence of casts of tubules, and this carried the case at once out of the group I am describing.

In what I have stated about cyclic albuminuria I do not mean to imply that this is the only form of albuminuria which is associated with the apparently healthy state. On the contrary, I am of opinion that albumen may be persistently present, and yet not necessarily mean that a grave condition exists. I have seen cases which have afforded grounds for this conclusion. The subject is one which requires the light of further enquiry to be thrown upon it.

## CLINICAL LECTURES

ADDRESSED TO STUDENTS ON THE METHOD  
AND DATA OF MEDICAL DIAGNOSIS.

By W. H. ALLCHIN, M.B., F.R.C.P.,

Physician to the Westminster Hospital, and Joint Lecturer on the  
Principles and Practice of Medicine and on Clinical Medicine.

---

### LECTURE I.—INTRODUCTORY.

GENTLEMEN,—You are now entering—many of you for the first time—on that portion of your curriculum which is to immediately fit you for the practice of your profession. The value of the studies which have hitherto engaged your attention is both great and varied. Not only have you acquired thereby a knowledge of the structure and functions of the body, per-versions of which constitute disease, but you have also been trained to observe the facts that anatomy, chemistry, and physiology present, and to appreciate their significance and relationship to each other, and to comprehend the lines along which further advance is being pursued. These same powers of observation and reasoning you must bring with you here into the wards, for the problems that the patient offers are to be followed in the same method that you have elsewhere applied to health. The mention of this word health suggests at the outset one of the many difficulties you will meet with. What is health? what is disease? Where is the line that separates them? are questions you will frequently be putting, half involuntarily, perhaps, to yourselves, and which you will find impossible to supply a complete answer to. Health is a term which we arbitrarily employ to express that condition of the construction and working of the body, which prevails in the majority at any given time, and in which all the functions of life are performed in the completest manner. Very far from a satisfactory definition is this, I admit, but it is the best I can furnish you with, and though not attempting to express any more than you already know, claims, I think you will see, to be consistent with the line which you and I are about to work together on. You should not forget also that this term is a relative one; what may be a normal condition at one period of life may become a grave indication of disease at another. Then, too, there are individuals who offer exceptions to the generally recognised standard both of structure and function who

yet cannot be said to be unhealthy; such idiosyncracies complicate, even if they do not render impossible, any attempt to completely define health. Fortunately, the difficulty does not seriously interfere with us in our work, but nevertheless, I hold it to be desirable to remember that the nearer we do approach to an accurate conception of the normal state, the more precise will be our knowledge of the intimate nature of disease. With no sharp boundary line between the states you have been hitherto engaged in investigating, and that which you are now about to study, you might well ask where you are to begin? Occasionally you will see cases in the wards, and far oftener in private practice, when this query becomes very pertinent, for among the most difficult of the investigations we have to undertake, is to satisfy ourselves that there is nothing the matter with a person who claims to be ill.

Corresponding to the impossibility of defining health is the difficulty of defining disease. To say it is a departure from the healthy standard does not help us much, when we do not exactly know what that standard is; but at the same time if we remember that we mean by disease some perversion of function, slight or great, dependent on some defect of structure, obvious, or as yet with the means at our command irrecognisable, we shall be at least thinking and speaking in harmony with the currently accepted notions of physiology and pathology; and this whilst we quite accept the fact that between health and disease is a borderland not to be defined.

A case of disease that presents itself to a practical physician offers three aspects for consideration: first, there is its causation, or as we term it the *ætiology* of the malady. The pursuit of this line of enquiry on anything worthy to be called a scientific basis is a subject of quite recent development. So long as sickness was attributed to the malign influences of demons or to vitiated humours, a sound theory of causation was impossible. But now that we recognise that disease is dependent on some disturbance of those influences, whether intrinsic or extrinsic to the body, in obedience to which living matter liberates its energy, we are enabled to appreciate to a great extent *what* leads to disease, even when we do not know precisely *how* the cause may act. With the knowledge of the determining conditions of disease we are better prepared to prevent it, which is the first object of our art. We enquire into and ascertain as definitely as we can the cause that may have led to the production of a case of illness that comes before us, partly in order to add to our as yet very imperfect knowledge of *ætiology*, and so far benefit others, and still more particularly for the purpose of removing the cause, if it still exist, or counteracting it if possible—both important factors in the art of treatment. In studying the natural history of disease, its origin and evolution, the knowledge of its causal circumstances seems to be of prime importance. To this end many of our profession devote their entire life and labour, with what brilliant results, in the prevention and diminution of illness, the records of the Registrar-General amply testify.

For the moment I am concerned in telling you that, as a branch of medicine, it is fairly well marked off from that which deals with the detection and treatment of disease, and is pursued for the most part on lines of its own.

Next, not necessarily in order of time, for it is often only towards the end of the investigation or even later, that we are able to satisfy ourselves as to the cause; but next in the sense of another line of enquiry is the all-important one, "What is the matter with the patient?" the forming a diagnosis. This it is which will mainly concern us here. But I cannot too emphatically remind you that it is only a part of what

you have to do, a very important part, but only a part. There is the third aspect of your patient to be considered. Do not forget that you go to him for the purpose of relieving his suffering and curing him of his disease, towards the accomplishment of which diagnosis is only a means. There is a too prevalent notion that a physician's duties end with giving a name to the complaint after a careful and elaborate examination of the patient, but he who stops at this point can scarcely lay claim to the title "healer of the sick," however valuable may be his contributions to theoretic science. It is, I maintain, quite possible to hold this view, that making a diagnosis is but a means towards the end of treatment, and, at the same time, aim at the highest degree of perfection in the diagnosis itself. Being able to treat a patient successfully is not incompatible with the ability to accurately ascertain the nature of his malady. The best physician is he who can do both. You have arrived, if I may say so, at a very impressionable period in your work, when you will hear discussed, and discuss for yourselves, questions and problems which will insensibly tinge many of the views that you may hold through life, and upon which may depend your success, and what is of more importance, your power of doing good. I speak to you, therefore, earnestly on this point, knowing how easily a fatal scepticism in the power of our art may be acquired. I am not proposing at this moment to furnish you with grounds for a firm faith in the remedial efficacy of medicine; I trust that you will obtain them for yourselves in the wards of a hospital, always remembering that of necessity there is a very large proportion of cases which cannot be cured or even relieved, and to base your opinion only on the results here obtained would be manifestly unfair.

Let us now clearly understand what it is we aim at in endeavouring to ascertain what is the matter with a sick person. I think I can best lead you into the position I wish you to assume in regard to the enquiry if I illustrate it by a very simple case. Let us suppose that a man has met with an accident that has produced a simple fracture of one of the bones of his leg. He is brought to the surgeon ignorant of the nature of his injury, but conscious only of pain and an inability to use his leg. The surgeon recognises these two conditions, and seeks by examination of the limb to ascertain what organ—bone, muscle or nerve—it is which has suffered injury, and as a consequence has produced the pain and impaired power of movement. Knowing how the structures of the limb are normally arranged, he soon distinguishes in what way the parts before him are different from the normal, and on completely ascertaining the difference, so adjusts his treatment to allow of repair and cure. The sooner you appreciate the fact that identically the same line of procedure is to be adopted in any case of illness that you are called upon to treat, the sooner will you have acquired the conception of what medical diagnosis really is. It is, in brief, the endeavour to ascertain the structural defect that underlies every indication of impaired function, and the nearer it approaches to a perfect realisation of what the defect is, the more complete is the diagnosis. Let me say at once, that this desirable consummation is rarely attained; were it so, our art would be a perfect one, which it is at present far from being. Dependent as medicine is upon so many other branches of science, neither of them in any way complete, it is impossible that the one which includes the practical application in varying degrees of all should itself be perfect. In the vast majority of cases we have not the complete anatomical and physiological standard to refer to, such as the surgeon possesses in the case of a single fracture, and consequently so long as our standard of the normal is deficient, so long will uncertainty attend the accurate recognition

of disease. It is here enters the opportunity for difference of opinion so proverbially characteristic of our profession.

If such be our aim, how are we to attain it? what are the means at our command? First, you possess a foundation of anatomy and physiology, imperfect though it be, with which you will contrast, so far as you can, the abnormal appearances of structure and manifestations of function that you will meet with in the wards. There, also, you are acquiring simultaneously with your clinical work, either from your text books or your lectures, what is known as a systematic knowledge of disease — the classical standard collated from the records of many cases by many minds. To the standard so prepared we are in the habit of referring every case that comes before us, recognising the characteristics of agreement and distinguishing the points in which they differ. The value of this standard knowledge is undoubtedly great, but it is liable in some hands to be over-estimated, and to constitute subsequently the greater part of the mental stock-in-trade of the young practitioner who is discouraged at finding, when he is thrown on his own resources, that the maladies he is called on to recognise and treat do not conform to the easily comprehended cut-and-dried description that his book has led him to think he ought to meet with. For every so-called typical case that agrees in the main points with the description laid down, you will meet many that offer exceptions on few or many points, and nothing could be more fatal to your real progress than attempting to make such cases agree with the standard by slurring over or neglecting these exceptional features. Rarely, indeed, are two cases of disease absolutely identical in every particular, any more than are the individuals who are the subjects of the complaints.

Provided, then, with systematic information, you approach the individual case in the spirit of an impartial enquirer into the evidence that it presents. It now becomes your duty to obtain this evidence, to weigh and estimate its value, and to draw conclusions from it, thus forming your judgment or diagnosis. It is desirable to keep these three stages distinct, for very different attitudes of mind are involved in their performance, and unless careful, you are very apt to draw hasty and erroneous inferences to the impairment of your diagnosis and the detriment of your patient.

The evidences of disease that a patient offers are of two kinds. There are those which you recognise by means of your senses, sight, hearing, touch, smell, and taste—often called the objective signs. And there are the subjective symptoms, for the ascertaining of which you are dependent on the patient's own account. It is easy to see that the value of the results obtained may be very different: in the former case the accuracy of your information entirely depends upon yourself, on your own powers of observation, that is, of recognising what is before you, and of the skill with which you employ each of your senses with the help of such aids as the microscope, stethoscope, thermometer, &c.; on the other hand, you are at the mercy of the patient, whose power of either appreciating or explaining his own sensations is liable in most cases to be very imperfect. Partly by judicious questioning, partly by the orderly employment of your eyes, fingers, and ears, you will obtain from your patient a number of data which you connect together and form a judgment upon: as you come to acquire experience, you will, in many cases, almost surely perform these operations nearly simultaneously, but I strongly advise you at first not to attempt to piece the facts together to make a diagnosis until you have all the evidence you can get before you. As I have told you, different mental efforts are required, and by proceeding carefully you will be less likely to fall into the

error of making up your mind what the nature of the malady is that may be before you, and then squaring the signs and symptoms of the patient with your preconceived judgment. I am most desirous you should cultivate the habit of proceeding slowly and step by step; by so doing you will avoid many mistakes, and will thereby possess yourselves of the caution that is attached to real knowledge, as opposed to the timidity or rashness which a conscious ignorance begets.

Again I say, do not mistake me in supposing even by the most careful adherence to these or any rules, or the most skilful observations, that you will be able to form a complete diagnosis in every case that you meet with.

Often you will come across cases which are most obscure, that is, cases where either from a most imperfect history of previous condition or from inability to give any clear account of their own symptoms, or from the very nature of the objective signs themselves, or from all these circumstances combined, the arriving at a satisfactory diagnosis is impossible, and it may sometimes even occur that the case may end fatally, and *post-mortem* examination does not clear up the difficulty. All this only means an imperfection in our means and method of finding out, not that the diagnosis is intrinsically impossible. It is at this point that experience comes to be of value; it is able to furnish in reference to any given case not only accurately induced conclusions, drawn from the study of other cases, but also to supply certain empirical information the reasons for which are not so apparent, but which in the course of time, and by comparing one with another, may become transferred into the category of positive knowledge, incidentally in the progress adding to our pathological conceptions, and perhaps even those of physiology as well.

So far, then, as diagnosis is concerned, your work will at first consist in obtaining as complete a record as possible of your patient's state and progress, which is known as "case taking," and I propose to occupy your time by systematically enumerating the various heads of information that you are to enquire into, what questions you are to ask and how you should put them, and explaining to you the significance and value of the answers you obtain show you how to form a conclusion on the evidence you have collected.

Such a course must at once appear to you as being extremely formal, and herein lies the objection urged by many against the insistence of a too detailed scheme as being artificially precise and failing to take account of the numerous exceptions in dealing with which the student requires help. Doubtless the objection would be valid if the student were to become a slave of the scheme, instead of recognising that it is but a means for his obtaining the information he desires. Without a guide of some kind every case becomes an exception, and in the labyrinth of isolated cases the student loses his way and lapses into a vague and loose habit of thought and expression, most dangerous to the efficiency of a practical physician. I will admit, however, that here and there a student's previous training or natural disposition unfits him to accept with advantage a detailed scheme prepared for him, and yet may succeed in a path of his own choosing. But I believe such are rare exceptions, and in dealing with the majority I would counsel the acceptance of a plan as complete and precise as it may be made, reserving to yourselves the right to modify such scheme in your own way as future experience may suggest. There will be time enough for you to investigate exceptions when you have acquired a knowledge of the general course of disease. It may further be asked whether such a plan as I am about to give you is needful to be applied to all cases. Surely it may be said that there are many examples of disease, the nature

of which may be arrived at without the elaborate enquiry that my plan lays down. To such I would reply that, no doubt, so far as being able to give a name to many cases of illness that present themselves, a few questions and a very partial examination may suffice; but there is something else needful. The investigation of every sick person offers the opportunity of adding to our knowledge of the causation, the pathology and the symptomatology of the disease in question; and by carefully proceeding according to a definite plan, new features and facts come to be accumulated, and so far contribute to the natural history of the malady. Many a point, the significance of which is in no way apparent at first, becomes full of meaning in relation to other symptoms when noticed repeatedly. The more perfect your record of your case on every point, the more valuable does it become as a contribution to the completion of the classical standard and to determining the pathological alliance with other states. I shall propose to indicate to you what details you may, without impropriety, neglect, but, as a rule, it is safer to be too full than too meagre.

Again, I would say that the frequent repetition of thoroughgoing procedures engenders a habit that subsequently is often of great use, especially on those occasions when you may be called on to examine presumably healthy subjects for life assurance, for the services, and the like, when a hap-hazard investigation without order or system is likely to lead to many important points being overlooked. If, in my remarks, I appear to be too definite and positive, I beg you to remember that I am so, since I believe that such a position is the soundest for a teacher to assume. I am perfectly conscious that there are many exceptions to what I shall refer to as general rules, but I hold that the study of these exceptions should come later in your work, when you have already possessed yourselves of some positive knowledge.

---

REPORTS OF  
**HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY.**

---

ABERDEEN CHILDREN'S HOSPITAL.

---

CASE OF SARCOMA OF CEREBELLUM.

By A. MACGREGOR, M.D.,

Assistant Physician to the Hospital.

---

A. E., aged 11 years, was first brought to the Aberdeen Hospital for Sick Children early in May as an out-patient to get advice for frequent sudden attacks of vomiting accompanied with severe headache. Apart from these attacks, and not very marked, but increasing weakness, he felt well. The thoracic and abdominal viscera were apparently healthy. No dimness of vision was complained of, yet the ophthalmoscope revealed decided left optic neuritis with large and very tortuous veins. The right fundus was normal. The conclusion came to was that the boy was suffering from some kind of tumour of the cerebellum, and the result proved that this diagnosis was correct.

He was admitted into the hospital on 29th May, when his general condition, except that he was weaker, was much the same as when he was first seen. The left optic neuritis, however, was more marked, the

striated and beautifully mottled disc with the large tortuous veins making a very striking picture. The right fundus now showed the beginnings of similar changes.

*Family History.*—Patient is one of a family of ten, two of whom died of scarlet fever, and one of "water in the head." Father and mother are both alive and healthy, aged 47 and 49 years respectively. The mother is a highly nervous woman. Paternal grandfather at the age of 50 years, and two aunts aged 41 and 18 years respectively, all died of "apoplexy."

*History of Present Illness.*—The symptoms first appeared about six months before admission. The sickness and vomiting came on suddenly without any warning, lasted only a very short time, but were accompanied and followed by very severe headache. He had usually two or three attacks each week. During the first week after admission there was no vomiting and no complaint of headache, but the following week he had a severe attack, and the temperature which before was normal became sub-normal; and while he remained in the hospital the morning temperature was almost invariably 97° F., the evening usually 98°. After this there were at least three attacks in the week, and on one of those days the pulse was 56 per minute and irregular.

On 24th June, slight left facial paralysis was observed, and about this time also there was developed left convergent strabismus, which remained permanent. The eyeballs were evidently being protruded. He was taken home on 30th June. When seen about three weeks later, he was evidently much worse, the eyeballs seemed very prominent, the pupils were widely dilated, he walked with a much feebler step and frequently staggered, but a tendency to fall to one side more than another was not observed.

On 12th August, I found him in bed, lying with his head well thrown back. He complained of severe frontal headache and pain along the back of the head and neck. Pulse 56, pupils widely dilated and no reaction to light. He passed urine in bed, and now required to be supported when walking, having a tendency to fall forward. Vision, tested by reading, seemed normal.

On 20th August, at 5 a.m. he was suddenly seized with sickness, vomiting, and severe headache. The vomiting lasted only a short time, but he gradually became more and more comatose and died that evening.

*Autopsy.*—Permission was granted to examine the head only. The dura mater was nowhere adherent, the convolutions were slightly flattened, the veins and sinuses were distended with dark fluid blood. The brain seemed to lie on a bed of a dirty-yellow coloured fluid, which was also found in the ventricles in considerable quantity. The outer half or more of the left hemisphere of the cerebellum was found to be the seat of, or to have been replaced by, a tumour of a pale fleshy colour. After a week or two in spirit, the tumour measured 2½ inches long, 2 inches across its broadest part, and ½ inch thick; the brain matter proper formed a capsule for it, and it could be easily shelled out everywhere but on its inner side, where it was extending towards the middle line. Under the microscope it was seen to consist chiefly of small round cells and broken up brain elements.

---

UNIVERSITY OF ABERDEEN.—The University Court has appointed to be extra-professorial examiners for Graduation in Medicine for one year, the following, viz., Dr. John Alexander, of Glasgow; Dr. J. Maedonald Brown, of Edinburgh; Dr. Alfred H. Carter, of Birmingham; Dr. J. A. McWilliam, of London; Dr. A. D. Leith Napier, of Dunbar; and Dr. Francis Warner, of London.

## APPOINTMENTS FOR THE WEEK.

*Friday, October 16 (this day).*

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 p.m.—  
Prof. W. H. Corfield, President, Inaugural Address on  
"The History of House Sanitation."

*Monday, October 19.*

MEDICAL SOCIETY OF LONDON, 8.30 p.m.—The President  
(Dr. Ord) will deliver an address on opening the Session.  
Dr. W. H. Broadbent, on "Examples of Syphilitic  
Disease of the Brain and Nervous System."

*Tuesday, October 20.*

PATHOLOGICAL SOCIETY, 8.30 p.m. — Dr. Dickinson,  
"Malignant Tumour connected with Cranial Bones";  
Dr. Payne, "Bacilli from a case of Rhino-Scleroma";  
Dr. Hale White, "Ulceration of Gallstones into Stomach,  
causing Pyloric Obstruction"; Dr. Sainsbury, "Tumour  
from the Base of the Brain containing Skin"; Mr.  
Shield, "Cancer of the Bladder"; Dr. Gulliver, "Mul-  
tiple Hydatids of the Brain"; Mr. Barker, "Primary  
Lympho-Sarcoma of Tonsil"; Mr. Mansell Moullin,  
"Bladder and Rectum six months after Littré's Opera-  
tion for Imperforate Anus"; Mr. Lockwood, "Mal-  
formation of the Heart"; Mr. Eve, "Two cases of  
Sarcoma of the Tongue"; Mr. Alban Doran, "Broad  
Ligament Cyst"; Dr. Lediard, (1) Black Tongue (card),  
(2) Primary Sarcoma of Femoral Glands (card), (3)  
Intercondyloid Fracture of Femur (card); Mr. Shattock,  
Congenital Absence of Fibula (card); Dr. Bruce of  
Edinburgh will exhibit some Pathological Specimens of  
fine sections of Entire Viscera.

*Wednesday, October 21.*

MIDLAND MEDICAL SOCIETY (at Medical Institute, Edmund  
Street, Birmingham), 7.30 p.m.—Annual Meeting for  
Election of Officers.

*Friday, October 23.*

CLINICAL SOCIETY, 8.30 p.m.—Mr. Mayo Robson, "Two  
cases of Cholecystotomy," with remarks; Dr. Edward  
Seaton, "The Characteristic Symptoms of a Febrile epi-  
demic illness at a School"; Dr. Samuel West, "A case  
of Idiopathic Purulent Peritonitis in a child of ten,"  
with Autopsy; Mr. Walter Rivington, "Two cases of  
Ligature of the external Iliac Artery for Femoral Ancu-  
rysm."

## Medical Times and Gazette.

SATURDAY, OCTOBER 17, 1885.

THERE is little sign in this year's entries of any  
revival in the popularity of the London Medical Schools.  
At ten schools from which we have received returns,  
the aggregate entries of all kinds are this year 744,  
whereas last year the entries at the same ten schools  
amounted to 728! St. Bartholomew's Hospital  
holds its own well, counting 132 full entries against  
125 last year, or a total entry of 148 compared with  
one of 138 in 1884. In these figures, the students  
attending the London University class are not in-  
cluded. The total entry at Guy's hospital has increased  
in yet greater ratio, viz., from 79 in 1884 to 90 this

year. The entry at the London Hospital has fallen off  
by 22, viz., from 129 to 107, though the main decrease  
is in occasional students, the full entries having only  
fallen from 83 to 77. At St. Thomas's Hospital there  
are 89 full entries, an increase of three on last year's  
return; the occasional entries number 24, exactly the  
same as last year. Of the smaller schools the Westmin-  
ster Hospital shows the largest proportional increase,  
having exactly doubled its total entries and more than  
trebled its full entries, a result undoubtedly due to its  
improved facilities for teaching. With its 28 full  
entries and 8 occasional students, it now treads close  
on the heels of St. George's Hospital with its 31 full  
and 6 occasional entries; the full entries last year at  
St. George's were only 24. The full entries at St.  
Mary's Hospital are 52, an increase of nearly 50 per  
cent. on last year's returns; the partial entries, how-  
ever, have fallen from 21 to 15. Charing Cross has  
increased its full entries by six, from 46 last year to  
52 this year; the occasional entries being, last year 12,  
this year, 10. The main loss has fallen on King's  
College and Middlesex, the total entries at the former  
having fallen from 62 to 47, and at the latter from 43  
to 37. So as yet the tide of prosperity has not begun  
to flow.

THE first meeting of the Clinical Society was held  
on Friday, October 9th, a very considerable gathering  
of members being present to inaugurate the work of a  
new session. The new volume of the Society's  
Transactions was, according to the annual custom,  
presented to the meeting, and would appear fully to  
justify the appreciative remarks made by the President  
in so doing. The energetic Secretaries, Dr. Stephen  
Mackenzie and Mr. Godlee, must be congratulated on  
having brought out a work not only much larger, but  
also more complete than any volume that has yet  
emanated from the Clinical Society. An interesting  
account of a case of hæmorrhage from the stomach of  
a newly-born infant was read by Dr. Sawtell. The  
occurrence would appear to be quite unique; the cause  
of the bleeding was discovered after death in the  
presence of numerous minute hæmorrhagic erosions in  
the mucous membrane of the stomach. A discussion  
of more than ordinary importance was raised by a  
paper communicated by Mr. Clement Lucas on the  
treatment of the sac in operating upon cases of  
strangulated umbilical hernia. Mr. Lucas advocated in  
strong and positive terms the advantage of complete  
excision of the sac with the redundant skin about it,  
believing that the sac if left unexcised would become  
a fertile source of future danger. Several surgeons in  
the course of the debate gave an account of their own  
experience of the operation, from which it is satisfac-  
tory to note that a much larger proportion of success  
is obtained at the present time than was ever antici-  
pated in former days. Opinions differed, however, to  
some extent as to excision of the sac. Although the  
method was evidently adopted in most cases, some  
hesitation was expressed by the President and others  
as to its universal adoption as a rule of surgery.  
Another surgical paper involving a broad question  
was read by Mr. Symonds, in which he gave an account  
of a difficult case of hæmorrhage from a lacerated

meningeal artery. Whether in such cases it was better to trephine the skull and search for bleeding points or to proceed at once to ligature of a main vessel would appear by the light of Mr. Symonds' cases, and by two others communicated by Mr Howse, to be decided in favour of the latter method.

THE first meeting of the Session of the University College Medical Society, held on Wednesday, the 14th instant, was rendered notable by an address from Dr. Burdon Sanderson, the late Professor of Physiology, whose re-appearance for the occasion was warmly welcomed. The subject of the address was "The Story of a Life devoted to Science," and the life selected was that of the late Professor Cohnheim. The lecturer first gave an epitome of the events of his career, borrowed from the biography of Külme—how he rose almost from poverty, taking advantage of "the magnificent education Germany offers to her children," studying Anatomy under Kölliker, and Pathology under Virchow, then serving in the Schleswig-Holstein war, with the intention of afterwards practising medicine, when chance intervened, and he was offered and accepted the post of Assistant to Virchow. Thence he was promoted successively to the Professorships of Pathology at Kiel, Breslau, and finally Leipzig, when his health broke down, and he succumbed to the ravages of gout in 1884. His enthusiasm was so great that he said, the very day before his death, that if the cholera came to Leipzig, nothing would prevent his going to the *post-mortem* room, even if he should be carried there. On this illustrative history Professor Sanderson made several noteworthy comments. Borrowing an expression of Külme's, that the leading feature of Cohnheim's life was its distinctly known purpose and regulation according to that purpose, he rendered it "A really good man knows his aim and purpose, and is determined to carry it out constantly." He defined three prominent qualities in Cohnheim's character :—(1) The clear conception of his life's task, or scientific earnestness; though enjoying life and society nothing interfered with it. (2) The very special and characteristic attribute of the scientific mind—incapacity of holding contrary opinions at the same time, or intellectual truthfulness. (3) Independence, which is an outcome of the last. His life's task was to replace Virchow's Cellular Pathology by a doctrine based on the active powers of the corpuscles; and thus he was led to discover the phenomena of "emigration," which "reversed the whole doctrine of inflammation." Besides this, he advanced our knowledge of embolism, venous congestion, the pathological influence of the nervous system, &c.

IN applying the history thus told and analysed, Dr. Sanderson gave some sensible and shrewd advice :— "If any one thinks he has made up his mind to give himself up to scientific enquiry, he would for his part say—'Don't, or, at any rate, think twice about it.' Keep hold of medicine with one hand and science with the other, for medicine does good to others *and* to yourself, while the use of pathology is not recognised. Go on as if to fit yourself thoroughly for practice.

Enter it by the easiest gateway, and do not waste time on academical distinctions. Reside for a time in a hospital, and then you will be in a better position than ever before to decide whether you prefer science or practice. If the former, do not seek a junior hospital appointment, but choose a special subject for study, and after learning the language and the methods adopted, go to the best foreign school for that particular subject. After this, though a scientific career is easier now than formerly, there are very few ways in England of spending life as Cohnheim did. The medical profession does not sufficiently realize its value. Though research scholarships are good, it is bad to be induced to take up science for their sake." The lecture was full of interest, and calculated to arouse enthusiasm; but, with all admiration for the subject serving as illustration, it may be questioned whether it is desirable for us to take him as a model in every respect. The common sense of the profession may after all be right, that it is not good to make too sharp a demarcation between abstract science and practice, or only with very rare exceptions. Would Sydenham, had he lived now, have made it his chief end to watch the life and adventures of a small round cell?

THE first ordinary meeting of the Session of the Liverpool Medical Institution was opened by a few introductory remarks from the President, Dr. Gee. He referred in feeling terms to the death-roll of the past year, containing as it did the names of three old members of the Institution, viz., Drs. Gill and Spratley, and that of his predecessor in the Presidential Chair, Mr. T. Shadford Walker. In a short review of the work done in the previous session, Dr. Gee showed that considerable progress was being made in all the departments of the Society. He recommended the microscopical section especially to the support of the members, and pointed out the benefits resulting from patient microscopic research. After the address the upper suite of rooms was thrown open, and the meeting converted into a *conversazione*. Messrs. Alexander, Greves, Oxley and Parker showed numerous drawings and photographs of disease and injury, and dry and wet specimens of caries of the spine, rheumatoid arthritis and syphilis. Dr. Imlach showed a large uterine tumour just removed, and Mr. Frank T. Paul exhibited a beautiful series of photographs of English and Scottish scenery taken by himself. Specimens of new drugs and instruments were also shown, and the various articles were inspected with much interest by a large assembly. The rooms were decorated with plants and flowers kindly sent by Dr. R. F. Owen, of Tue Brook.

THE Midland Medical Society is evidently in the hands of a very efficient *impresario*. Last year Sir Spencer Wells was persuaded to go down to Birmingham to open its session, and deliver his excellent address on the Revival of Ovariectomy. This year the star whose services have been secured for the opening night on November 11th is Dr. Wilks. The Society numbers nearly 350 members, and will hold its annual meeting on Wednesday next, when the

officers for the session will be elected. Mr. Bartlett will retire from the Presidency, to be succeeded in all probability by Dr. Holmes Joy.

AT the Glasgow University, the preliminary examinations closed on Saturday last. They were attended by an exceptionally large number of candidates. At some of the sittings there were not many under 200 present. The professional examinations for degrees commenced on Monday, and will continue till Wednesday, the 21st. For the first (which includes Natural History, Botany and Chemistry) the number of candidates is 165. The names of 115 have been given in for the Second Professional Examination, which embraces Anatomy and Physiology (including Histology); while 71 candidates are this term attempting the third examination—Regional Anatomy, Materia Medica and Pathology. So that the large total of 351 candidates are at present under examination for medical degrees in Glasgow University.

THERE is no game of bodily skill exempt from a liability to certain special forms of injury; a proposition which lawn tennis illustrates with no less fidelity than the rougher exercises of football and cricket. It has dignified with the distinctive title of "lawn-tennis leg" an accident which, when it was a more rare event, had no more popular appellation than rupture of the plantaris tendon. And it has made even non-players quite familiar with another term, "tennis elbow" to wit, the diagnosis, treatment, and doubtful curability of which have exercised the pens of several recent contributors to the daily press. Almost all these communications are couched in a despondent strain, which is even observable, strange to say, in that of a sufferer, who, after several weeks' unsatisfactory use of ordinary remedies, happily bethought him of consulting "a well-known bone-setter." The bone-setter found—as he was morally bound to do—"that the point of a bone in the elbow was broken." Although after a week or two's treatment by fly-blisters, bread and milk poultices, and the sling, "the bone has set," the patient does not yet venture to do more than "hope the elbow will be all right again soon." Such an expression, may, however, be taken as affording antecedent probability of another variety of faith-cure.

No one who has had opportunities of studying cases of this injury can doubt that under the popular designation of "tennis elbow" are included at least two or three different lesions. A consideration of this fact should, in itself, lead patients to consult by preference those who make anatomical knowledge the basis of their diagnosis and treatment in surgical injuries. Dislocation of the pronator radii teres muscle, an accident originally described by Mr. Callender, and one very apt to be produced by the sudden and forcible pronation practised when making a back stroke, used to be distinguished as "lawn-tennis arm." But in popular speech the distinction is not always maintained between this and tennis elbow. The latter injury depends, according to the descrip-

tion given by Dr. Innes, on the constant jarring of the head of the radius against the condyle of the humerus. It is also very apt to occur when, as in serving under-hand with a twist, the radial head is, as it were, repeatedly ground against the humeral and the ulnar articular surfaces, the orbicular ligament being also strained by the specialised tension of all the muscles acting on the joint. Treatment will of course vary with the cause, and may, in a few cases, demand prolonged rest and special precautions on resuming play; but if based on a correct diagnosis, and carried out intelligently, it is very successful. There is no doubt that practitioners at large would do well, in their own interests, to make themselves more thoroughly *au fait* at dealing with these common, but vexatious accidents. Not only will they thus regain the *kudos* which eminent bone-setters may have acquired at their expense, but their patients will be more ready to believe in the cheerful assurance that "the small bone of the elbow"—whatever that may be—is neither "out" nor "broken." It is always well not only to know the truth, but to be able to apply it.

WE see that Dr. Crichton Browne is a candidate for the representation of Hackney, on the London School Board. Even Mr. Fitch would, no doubt, be glad to have Dr. Browne remitted to a position where his inconvenient eloquence would be more or less muzzled. While those who saw in the celebrated report on over-pressure in London Board Schools, a larger grain of truth than Mr. Fitch was pleased to detect, will be ready to admit that the public attention having been sufficiently aroused to a danger, Dr. Browne will be likely to do better work now as a sentinel inside, than as an independent scout outside the official circle. We only wish there were likely to be more doctors on the London School Board.

DURING the week the cholera has shown a slight recrudescence both in Spain and in Sicily. In the former country it has reappeared in the province of Albacete, and the daily deaths have risen from about 100 to 130. Madrid, however, is declared to have been free from the disease for a fortnight, and a solemn *Te Deum* was sung there on this account on Wednesday. According to the statistics of the Board of Health, the first case of cholera in Madrid occurred at the end of April. Between that time and the present month, there have been 1,654 cases and 1,051 deaths. The special Cholera Hospital has been closed during the last week. Observations prove that the death-rate among the patients admitted to it was smaller than among the persons attacked who refused to go to the hospital. Up to the 12th inst., official statistics show that in Spain, there were 266,323 cases and 97,382 deaths. Barcelona, Cadiz, Jaen, and Valladolid are now the only towns with more than ten cases or ten deaths daily. The long-delayed report of the Medical Commission appointed by the Spanish Government to enquire into Dr. Ferrán's inoculations has at length been delivered to the Ministers, and it is said to be unfavourable to Dr. Ferrán's procedure on the score both of its danger and its inefficacy. Towards the end of last week, cholera

broke out on board a Government vessel at Toulon, but we have heard of no further spread of the epidemic at that port. The authorities at various of the Mediterranean health-resorts have written to the English papers to reassure their chief patrons that they need not be deterred from visiting them by fear of cholera. Cannes and Algiers, it is stated, have been entirely free from the disease throughout the year; while the British Consul at Nice feels confident that the disease will entirely disappear from that town as soon as a fall of temperature occurs. The Mansion House Fund for the relief of the Spanish sufferers from cholera slowly grows, but has not yet reached 4,000*l*.

NOTWITHSTANDING a slight rise in the number of deaths in London last week, they were still 146 below the average. Of the zymotic diseases, whooping-cough did most mischief, causing 34 deaths, whilst scarlet fever caused 21, measles 17, diphtheria 14, and enteric fever 12. There were 8 victims to puerperal fever; and 10 (including 5 infants under one year) deaths

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eleven weeks.

from erysipelas. The mean temperature of the air was 47.6° or 5.2° below the average. The quarterly returns for the third quarter of the year as regards mortality in London have been made up, and give the following as to deaths from zymotic diseases: Measles comes first with a grand total of 610 deaths; next whooping-cough, 541; diphtheria, 237; scarlet fever, 185; enteric fever, 150; and small-pox, 136.

THE careful study which has been carried out in the pages of a contemporary, as to the results of the notification of infectious diseases in those towns in England

and Wales where a compulsory system of notification has been adopted, places beyond the possibility of doubt the great benefits which this system is capable of conferring upon the public health. Why measles and whooping-cough should have always been omitted in the classifications of infectious diseases drawn up for these purposes, we are at a loss to understand, except that it was feared by the supporters of the new scheme, that if they undertook too much at first the whole thing might be a failure, and they therefore omitted the two most prevalent of the infectious diseases as a temporary measure of precaution, to prevent the whole scheme being swamped from a too-extended sphere of action. The general public appear to have taken very kindly to notification, and it has nowhere met with opposition on their part. The profession, as is pretty well known, were strongly in favour of the duty of notification being imposed on the householder or occupier, and not on the medical attendant; but although in all the places into which the scheme has been as yet introduced, the duty of notifying has been practically imposed on the medical man, sometimes in conjunction with the occupier, it is satisfactory to know that it has been loyally carried out by the profession almost without exception. The towns from the statistics of which this study was drawn are thirty-four in number, and comprise about two and a-half million inhabitants, and every year the number of those who are, so to speak, under the protection of compulsory notification, shows a considerable increase. It appears, however, that at some of the towns the results that have been obtained in the way of diminished zymotic disease have not been at all commensurate with what might have been expected judging from the effects of compulsory notification elsewhere. In such towns there would seem to be an impression that notification is in itself sufficient, and accordingly the all-important isolation is left unprovided, and without this it is needless to say notification becomes a mere empty name, powerless to do good, and even doing harm by lulling the townspeople into a false sense of security.

ON Thursday, the 8th inst., Dr. Guy Percival L'Estrange Nugent was elected Physician to the House of Industry Hospitals, Dublin, in succession to the late Dr. Benjamin George MacDowel. Dr. Nugent graduated in Medicine and Surgery in the University of Dublin in 1878. He subsequently became a Demonstrator of Anatomy in the School of Physic, in Ireland, Trinity College, Dublin; and about two years ago he was appointed Assistant Physician and Pathologist to the House of Industry Hospitals in room of Dr. Stewart Woodhouse, now a Medical Inspector of the Local Government Board for Ireland. Dr. Nugent is a Fellow of the Academy of Medicine.

WE would fain hope that the vigorous letter of Lord Sheffield in the *Times* the other day, anent the insanitary state of Newhaven, would bring the powers that be in that hygienically benighted place to their senses. It appears that the sanitary shortcomings of

the town have been the subject of local comment for years past, but that nothing has as yet been done to remedy them. The Local Government Board, in consequence of a report of one of its own officers, requested the Local Board to proceed without delay to construct a proper system of drainage. This the Local Board have flatly refused to do; they are of opinion, in their reply, that this is an inopportune time to commence an extensive system of drainage, and they will wait until the times are better before commencing the undertaking. If the authorities flatter themselves that their town will prosper when it is a matter of common notoriety that its drainage system is unequalled in its defectiveness, it only shows that they are grievously ignorant of public feeling on these matters, and quite unfit for the responsibilities that have been entrusted to them. The only chance of regaining prosperity for their town, would be to have the drains put in the best possible state, and to take good care that it was publicly known that this had been done. Meanwhile, we hope the Local Government Board will show that its recommendations cannot be slighted with impunity by ordering the necessary works to be carried on and paid for by a special compulsory rate. What the sanitary defects are, we gather from the report of the local surveyor, who wrote in August last, that he had examined one hundred houses, and that he found that the sanitary arrangements were faulty and defective in the majority; the drains were foul, the traps ineffectual and in many cases stuffed up with flannel or earth, and often broken; the sinks were connected with the main drain; the ashpits were without covers, and several were in a state of fermentation. And yet the Local Board do not think the present time opportune for commencing an extensive system of drainage. Do they suppose that the drains will right themselves if only given sufficient time, or are they simply waiting till they are a little worse before applying the only remedy?

THE re-constitution of the Department of Clinical Medicine in the Medical School of Berlin has of late attracted considerable attention, and the arrangements, as finally concluded, give promise of something more than ordinary efficiency. The Chair vacated by the death of Professor von Frerichs has been divided between Professors Leyden and Gerhardt. To each of these Chairs there are now attached four assistants, two of whom are to be occupied with practical clinical work and treatment, and two with scientific investigations only. Amongst the names of those appointed to these offices are several which are already known to the medical world, notably, Dr. A. Fraenkel, Dr. Landgraf, Dr. Brieger, and Dr. Ehrlich. Provision is thus made for the systematic study of clinical medicine in a manner which has rarely been attempted before, and if only sufficient opportunities be afforded for students to learn for themselves as well as to be taught by others, the system cannot fail to bear good fruit in the future. The best clinical teaching in the universe is of little value, however, if the lessons of the classroom are not verified by the student himself at the bedside.

## LONDON UNIVERSITY REFORM.

THE holidays being virtually at an end, the various movements for assuring the higher development and status of education in London again begin to move. The members of the Lower House of the existing University of London have been convoked for the 3rd of November, to take up again the consideration of Lord Justice Fry's scheme of reorganisation, and before the end of the week we shall, in all probability, have learnt something more of the proposal of the Royal Colleges of Physicians and Surgeons to obtain powers for conferring a medical degree. Of the Association for Promoting the Establishment of a Teaching University we have heard little of late, its action being held more or less in suspense until Convocation of the established University has pronounced on the proposals which are before it. It is impossible for anyone to predict what action such a fluctuating body as London Convocation will take. The house which met at the end of July seemed certainly indisposed to swallow Lord Justice Fry's scheme as a whole; the expressed opposition to it was strong, and there was certainly a large majority in favour of further consideration and discussion of the subject. What will be the result of that prolonged consideration we are unable to foretell. On one point, however, Convocation appears to have made up its mind. Both the advocates and the opponents of reform express equal disinclination to promote any lowering in the standard of the London degrees. Whatever happens, we may take it for granted that the medical degrees given by the existing University will continue to represent, as they have hitherto done, the highest practicable amount of medical culture. From this determination, with which we fully accord, two things follow. First, the interests of medical education in London, and of the London medical schools, render it advisable, nay, necessary, that a medical degree should be instituted, which shall be accessible to such London students as would be accepted for graduation at the less rigorous of our British Universities. Secondly, it follows that no scheme for reforming the present University should be accepted which does not give the graduates, as distinguished from the teachers, a much more valid voice in the control of University policy than has been accorded them by Lord Justice Fry's committee.

It is abundantly evident that if the teachers are to have practically the entire management of the University, as the Committee propose, there will be no guarantee for the maintenance of the present high standard of the degrees. On this point the interests of the graduates and of the teachers are likely to be opposed. We do not say that they will be opposed, but it is clear that teachers who feel severely the competition of rival universities may be tempted to use their power in the University to increase the number of their pupils by enlarging the facilities for conferring degrees upon them. And unless their power should be balanced by an adequate representation of the graduates upon the Senate and the Boards of Studies, we very much fear that the almost unanimous desire of the graduates to maintain the standard of the

degrees might come to be disregarded. We may remind our readers that Lord Justice Fry proposes that of the 32 members of the new Senate 18 shall be representatives of the teachers, while the Crown and Convocation shall only have 7 representatives a-piece. Thus the teachers would always have a large working majority on the governing body of the university. On the Boards of Studies, which are intended to form the most influential element in the control of the University examinations, the representation of the graduates would be practically *nil*. We may be certain, however, that Convocation will never ratify a scheme which gives it only one representative on each Board of Studies. We need not here reiterate the arguments by which we supported the principle of giving the laity as distinguished from the teachers a substantial voice in the government of the University (see *Medical Times* for July 18th, 1885). But we are bound to state that mature consideration has not changed our opinion that the one great defect of Lord Justice Fry's scheme, which renders it unworthy of the support of Convocation, is that it places the University bodily in the hands of teachers, many of whom would have no interest in maintaining the prestige of the degrees or the high efficiency of the examinations.

Few will deny that there is a real necessity for re-organising the University of London. Even Dr. W. J. Collins, who, as the Randolph Churchill of Convocation, represents a small group of Tory-Democrat graduates, admitted in his letter to us last week the need for senatorial reform, though he stigmatised the present agitation as a clumsy expression of it. Dr. Collins' expressions are certainly anything but clumsy, but he did not attempt to deal with the real sources of the present discontent with the University. That he conclusively showed the inconveniences attending certain minor innovations introduced by the Senate, mainly at the instigation of the Lower House, we freely admit; and therewith by implication he demonstrated the necessity for a more intelligent control of the examinations. But we have not as yet heard, either from him or from any of his group, any suggestion as to the direction which, in his or their opinion, University reform should take. We regret also to see that no amendment containing any counter proposals to those of Lord Justice Fry is likely to be submitted to Convocation at its next meeting. Shortly after the meeting in July, formal notice was given of certain proposals for the reform of the University, which, in our opinion, were much more worthy of acceptance, and much more likely to be accepted by Convocation, than those of Lord Justice Fry and his committee. They had in view the realisation of the following objects:— (1) An enlargement of the powers directly exercised by Convocation; (2) An increase in the proportion of Senators to be elected by Convocation, and the limitation of the tenure of office in the case of all Senators; (3) The encouragement of mature study and original research among the members of the University, especially by the establishment of University lectureships of limited tenure, in different departments of learning and science; (4) The establishment of a Congregation of the University of London, consisting of (i) the Senate, (ii) members of Convocation (of such

standing and other qualifications as might be determined on), (iii) the examiners and other officers of the University, and (iv) representatives of such institutions in London and the provinces as might be in connection with the University. The last proposal is understood to have been shaped after the model of the Oxford Congregation, so far as a difference of circumstances would allow. We see with some regret that the above carefully considered proposals are not likely to come under consideration at the approaching meeting, for we think that the duty of Convocation would have been greatly lightened if those who object to the scheme of the Committee had thus formulated the broad outlines of the reform which would meet their approval and secure their votes. At any rate, we hope that at its approaching meeting Convocation will show itself determined to come to some final settlement on the question, and will not again postpone its anxiety for the reform of the University to the lower, if more imperious, desire for refreshment.

---

#### THE GERMAN EVIDENCE FOR VACCINATION.

IN a previous number we commented, in severe language, on the perversity and dishonesty of those anti-vaccinators who, when asked to explain the "triumphant results" of the German vaccination laws of 1874, refuse to look at the small-pox statistics of subsequent years, and quote the mortality of 1871-2 as proving the uselessness of vaccination, justifying their preposterous argument by alleging, in the face of repeated contradiction, that legislation as stringent had been in force for fifty or more years previously. One thing, however, they cannot deny, viz., that universal revaccination was not compulsory until then, and to it we attribute no small part of these results. Another class of anti-vaccinators, represented by Mr. Dudgeon in his recent letter to the *Times*, assume a somewhat less unreasonable position and one that admits at least of fair discussion. They argue as if London, which is never free from small-pox, and is subject to epidemics recurring every few years, were the type of a well-vaccinated community, and as if Leicester, which has hitherto enjoyed a comparative immunity from small-pox, stood alone among towns of its size in this respect, its freedom being in some way the result of its rejection of the practice of vaccination. To give any logical value to their argument, they ought to be able to show not only that the population is less vaccinated than that of most towns, but that it enjoys an immunity from small-pox greater than that of towns of like size but better vaccinated. This certainly is not the case, for a glance at the annual report of the Registrar-General will show that Leicester stands by no means alone. Nor is the cause to be found in its sanitary condition, for the high mortality from diarrhoea proves that this is far from perfect—indeed, in some respects must be worse than that of some more populous towns. It owes its immunity to its stringent notification of every case, isolation of the patient by removal to hospital, and, what has not been attempted elsewhere, though of more value than all, the practice

## REVIEWS AND NOTICES OF BOOKS.

### DOCTORS AND DOCTRINES.<sup>1</sup>

THERE is no denying the fact that doctors have not had their due from the biographer. It is scarcely possible to imagine a more interesting or more fruitful subject of biographical study than the lives and work of some of the great leaders of medical thought; to put oneself in their place, as every biographer worth his salt must do, to live as it were in, and amidst the thoughts of, their day, to con the substance and to imbue oneself with the spirit of their writings, and yet not to lose the temper of criticism in that of sympathy or admiration. To live this dual life, to understand as a contemporary and yet to judge as an aftercomer, is given to few; and of those few no one has yet touched the field of medicine, which lies before the future biographer a virgin acre, untrodden as yet except by casual book-makers and writers of articles for encyclopædias. The biographical ideal has undergone a wonderful development in recent years. It is not sufficient now to boil down a few old authorities, to add a sprinkling of extracts from contemporary literature, and to garnish with a brief summary of the views held by the subject of the biography and by a snippet or two of his literary style. The infinite conscientiousness of work, which except as an old and common attribute of genius, we have learnt from the Germans, has become an essential of all biography above book-maker's mark; but that modern English writers have been apt pupils in this respect is clear from the fact, generally admitted, that the best biographies of three of the greatest Germans have been written by Englishmen, only one of them a genius, to wit, Carlyle's Frederick the Great, Lewes's Goethe, and Seeley's Vom Stein. But besides industry in research, we demand in the modern biographer a sympathetic insight into the mind of his subject and a full knowledge of his writings, while last, but by no means least, comes that literary skill which is necessary to convey with pleasure and facility to his reader's mind the ideas that he has himself formed as the result of his labours.

Such being the standard by which every modern reader should, in our view, judge the written lives of great men, we cannot of course award the highest praise to Mr. Bettany's volumes. Probably, however, the author would not elect to offer himself for examination in that standard, and certainly if he did, the extent of the ground which he covers would be against his successfully passing it. Of the biographical studies which we have in view, no man of even extraordinary powers could possibly find force or time to furnish more than a strictly limited number. Mr. Bettany, however, gives us sketches of more than half the doctors of note from Linaere to Mr. Simon, a brief description of whose work appropriately ends the book. With this extension of effort, we are of course prepared to expect little intensity of idea, and the reader must not be disappointed if he misses those illuminating touches which show the hand of the master of his subject and of his art. Still, on the whole, Mr. Bettany has done his work well. He has evidently consulted many authorities, and made a judicious, if ample, use of the gum bottle. His work is well up to date, though that, we fear, in the present instance is a blemish rather than a merit. It is, indeed, a matter for considerable regret that Mr. Bettany has introduced the portrait models of any still living eminences into his show. Apart from the obvious inconveniences of this course, it is a literary anti-climax to lead us up from Harvey to Hunter and Jenner, and

on to Bright and Addison and other giants, only to drop us down and leave us amongst the specialists of to-day. To have dealt only with the dead would no doubt have robbed Mr. Bettany of two of the most fascinating subjects of medical history, antiseptic and abdominal surgery, the chief actors in which are happily still amongst the minority. But the time and space thus saved might with advantage have been applied to making his list of eminent doctors more complete, and his history of medical progress in England more connected. We should like, for instance, to have seen some mention of the founders of the English school of dermatology, Willan and Bateman, who certainly made a greater impress on their special science than Sir Erasmus Wilson, to whom Mr. Bettany gives a full share of pages. We notice too with regret the omission of the older writers on fevers, Currie, Huxham, Clutterbuck, &c., the first of whom certainly has quite as good a claim to the admiration of posterity as Murchison; even Dr. Latham is omitted. Then there is no mention of the great obstetricians, of Smellie, Gooch, Denman and Blundell, the last of whom ought certainly to be gratefully remembered for his work in connection with transfusion. Again, in a work dealing, as Mr. Bettany's does, with the contributions made by English doctors to medical progress, we might surely have expected to find a chapter devoted to "Dr. Alexander Wood and the hypodermic syringe." And if living men are to be admitted to Mr. Bettany's Walhalla, we think it will be generally felt that Dr. West, as the inaugurator of a new era in the treatment of children's diseases, should have been one of the first to obtain entry. The omission to give due credit to our modern pathologists is confessedly due to the author's reluctance to sketch his own colleagues at Guy's Hospital, but a book which omits the highly honoured names of Hutchinson, Wilks, Bristowe, and Moxon, can hardly lay a claim to completeness. After these criticisms, we owe it to Mr. Bettany to express the hope that he may find time to publish an additional volume, making good these regrettable omissions. So far as it goes, his work is good enough to make us desire that it should be complete, so that the English practitioner may have brought before him in a concise form the lessons to be derived from the study of the lives of his great predecessors and exemplars.

It is scarcely necessary to say what these lessons are, so often have they been emphasized by medical speakers. It can hardly, however, be too often reiterated that the one great lesson of all the lives which Mr. Bettany has sketched is the lesson of "hard work." Many, if not most of his models, we are told, rose early, some at three or four in the morning, and were late in taking rest, and the whole of their day was spent in an almost feverish activity. Dr. Stokes said, "My father left me but one legacy, the blessed gift of rising early," and most of those here classed with him as eminent doctors inherited the same legacy. In every case almost, we find the same eagerness for work, the same anxiety to be doing something. Even Sir Henry Holland expressed it in his incapacity for walking slowly. This love of activity, in itself the index of a fine physique, seems to have been in the past an essential to great success in the profession, and it is hardly to be doubted that it is as much an essential now-a-days, when the problems to be solved are far more difficult, while those ambitious to solve them are many times more numerous than in the larger times that are behind us. Sir Dominic Corrigan, reading "The Lives of British Physicians," drew from it the lesson that "there is but one road to excellence and success in our profession, and that is by steady study and hard labour." Sir James Simpson, dying after a life of unwearied activity, sighed, "I wish I had been busier." There are many,

<sup>1</sup> (1) Eminent Doctors: their Lives and their Work, by G. T. BETTANY, M.A. (Camb.), B.Sc. (Lond.), F.L.S. Two volumes. London: John Hogg, 1885. (2) Doctrines of the Circulation, by J. C. DALTON, M.D. Philadelphia: H. C. Lea's Son & Co., 1884.

no doubt, to whom the lesson is a hard one, because conscious of a physical or moral bar to great activity, they know it excludes them from transcendent success, whatever their other qualifications may be. Still, real success being largely awarded in exact ratio to work done, the lesson of work should not lose its motive force because it warns many that the highest reward is unattainable; or rather, is not the highest reward the consciousness of having worked up to the limit of one's strength and will?

We have coupled Mr. Bettany's volumes with a book of smaller scope, but of higher merit: Dr. Dalton's excellent exposition of the history of the discovery of the circulation. The subject is one which has been dealt with to wearisomeness by English writers and orators, but most of them have confined their attention to the final steps in the process, and have treated it too much from an insular standpoint. No one in this country can wish to minimize the merit of Harvey's work; but Dr. Dalton, by taking us straight back to Hippocrates and showing us the obstacles and uncertainties which impeded the discovery, raises the subject on to a higher plane, at the same time that he gives us a clearer and better view of Harvey's contribution to it. The book is one which bears witness to great faithfulness of research, and as the chief passages from different writers which bear on the subject are quoted in an appendix, we have before us all the data necessary for a judgment as to the general trustworthiness of Dr. Dalton's conclusions. The spectacle of transcendently great men like Vesalius groping in the dark after a fact which now seems to stare us in the face may serve to remind us that posterity may perhaps look with the same wonder on our present gropings. But the ever memorable fact that the secret was yielded up as soon as man left vain speculations and took to interrogating his fellows, living and dead, should strengthen our resolve to fight for freedom of research, while making the most of the freedom we still enjoy.

*The Westminster Hospital Reports*; edited by Dr. DONKIN and Mr. MACNAMARA, Vol. i. London: J. E. Adlard, 1885. It has been of late years so much the fashion to deery hospital reports, and to speak of communications in them as being buried, that we were not a little surprised a month or two ago to hear that another hospital was about to venture on a series. It is true that the societies are more numerous now than formerly, but there are many men who, for various motives, do not bring papers before them, though generally quite willing to give the world the benefit of their thoughts when allowed the opportunity of doing so through the unobtrusive medium of hospital reports. For instance, we will venture to say that very few of the papers in the present volume would have been brought before any of the societies during the forthcoming session, and yet they are all quite worth publishing, and will well repay perusal. The volume begins as is fitting with some account of the Westminster Hospital and School by Mr. Cowell, the Senior Surgeon; as he goes over very much the same ground as in the introductory lecture recently published in full in these columns, we need not further allude to this paper. According, as is usual, precedence to the physicians, we find that the medical papers are more numerous than the surgical. The first, by Dr. Fincham, contains the substance of two clinical lectures on pallor of the skin, and constitutes an excellent summary of the varieties of anæmia considered both in relation to their causation and treatment. Dr. Sturges follows with a paper on the use of hypophosphite of soda in the treatment of "tubercular" inflammation of children. After making due allowance for the fact that it is always difficult to be sure of the diagnosis of tubercle when the patient recovers or improves, it must yet be acknowledged that in the series of cases which Dr. Sturges here records, there were several in which few would have hesitated to attribute the symptoms to tuberculosis. Whether the patient would have equally recovered under other treatment must of course remain a little doubtful, but the beneficial results seemed to follow

so directly on the administration of the hypophosphite that it is the bounden duty of others to give the remedy a fair trial. Dr. Allchin, in his introduction to a course of clinical lectures, endeavours to trace the history of the foundation and gradual development of clinical medicine from remote times down to our own day. The next paper is by Dr. Donkin and is entitled "A Commentary on One Hundred and Five cases of Chorea." These cases all came under the author's personal observation, and were carefully investigated with regard to several definite points; for instance, the question of antecedent rheumatism, whether in the patient or in relations, the nervous antecedents and relationships of the disease, with especial note as to the nearness in point of time of the alleged fright or other shock to the attack, and the heart disturbances of chorea, the nature and duration of murmurs being especially studied. We have not the space to give to a detailed examination of this masterly paper, nor is this the proper place to attempt a criticism of it; we must content ourselves with saying that it is the ablest contribution to the theory of the non-rheumatic origin of chorea that we have met with. Dr. Hughes Bennett summarises the results of his experience in the treatment of epilepsy as being strongly in favour of the use of the bromides, which, even when they do not effect a cure, in a large proportion of cases give considerable relief. Dr. Hebb, in a short paper on quiescent tubercle, recounts some cases in which recovery had taken place after an attack of acute miliary tubercle of the lungs; unfortunately he was not able in any of his cases to determine the probable date of the attack. Turning next to the surgical papers, Mr. Cowell writes on the causes of failure after excision of the hip. He considers that the indication for the operation is the existence of grating in the joint when accompanied either by pain, profuse suppuration, or failure of health. Age is a very important question in regard to the operation. The younger the patient, the better the chances of a good result, and the older the patient, the worse. His most successful cases have been in children from three to six years of age, and he would not advise the operation at all after sixteen. The causes of failure are: (1) the external wound contracts so as to interfere with the drainage from the deeper part of the wound; (2) the limb becomes everted; (3) the limb becomes gradually shortened by the contraction of the muscles inserted into the femur. Mr. Macnamara has a short paper on the radical cure of hernia, in which he describes several successful cases, including one of congenital hernia in an infant of six months old. In regard to congenital hernia, if the parents were able to provide proper trusses, and look after the child, he would not operate before the child was nine years old, but would give it the chance of spontaneous cure; but if the parents were not able to take proper care, then he would operate as soon as the child had got over the period of dentition. The editors record jointly a successful case of nephro-lithotomy. Dr. Potter contributes a short paper on indefinite retention of a blighted ovum. Dr. Hall supplies a report from the throat department, and Dr. Fox does the same for the skin department. One of the most interesting communications is that from Dr. Dupré narrating the share he had in the investigation of the cause of death in the Lamson poisoning case; it forms a valuable appendix to the more elaborate document already published in the "Guy's Hospital Reports" by Dr. Stevenson. Dr. Dupré takes the opportunity to criticise the custom which has sprung up of late years for the Home Secretary to refer the appointment of an expert to the decision of the Presidents of the Colleges of Physicians and Surgeons; he objects to it on the ground that the questions to be decided are almost wholly chemical, and he submits that the President of the Chemical Institute ought to be joined with those of the two royal colleges in the selection of a person to carry on to the investigation. The latter part of the volume is devoted to short notes and cases by Mr. Boyce Barrow, Dr. Sutherland, Mr. Smale, Dr. Syers and others, and contains several valuable reports. On the whole, we would express the great satisfaction we have in welcoming this latest addition to periodical medical literature, and we hope that when next year's volume appears the papers will be of the same stamp, and that the number of subscribers will be doubled.

*Transactions of the Obstetrical Society of London*; Vol. xxvi., for the year 1884. London: Longman, Green & Co., 1885. Pp. 375. — This volume contains sixteen papers, besides descriptions of various specimens exhibited to the society. The longest paper, and the one which excited the most discussion, is by Dr. Graily Hewitt, "On the Severe, or so-called 'Uncontrollable' Vomiting of Pregnancy." This malady, according to Dr. Hewitt, is, like most of those to which women alone are subject, due to displacement or distortion of the uterus. His main arguments in favour of this view are: (1) that in most cases of severe vomiting, flexion, or version, with either incarceration of the uterus in the pelvis, induration of the tissues at the internal os, is present; (2) that the vomiting is often relieved by remedying the abnormal position or shape of the organ. This theory met with but slight acceptance. It was pointed out in the discussion, that anteversion and ante flexion (the displacements which Dr. Hewitt thought the most frequent causes of the vomiting) were so common that some reckoned them among the signs of pregnancy: that incarceration of the uterus in the pelvis as a consequence of anteversion or ante flexion was an impossibility, or at least incomprehensible; and that the relief which Dr. Hewitt found result from treatment of the displacement was neither frequent nor immediate enough to justify his conclusion. Mr. Hopkins Walters, of Reading, describes a remarkable case in which the entire uterus with its appendages was torn away from a patient by a midwife, and the patient recovered. In a very laborious and useful paper, Mr. Walters has collected a large number of cases in which a similar mutilation occurred, and points out their medico-legal bearing. Dr. John Williams, in an able paper on the corroding ulcer of the uterus, gives a full report of three cases of this disease, and discusses its pathology. He suggests that there may be two forms of the malady, one identical with lupus, the other allied to senile gangrene. The paper is the best and fullest account of the disease that has yet been published. Dr. Williams also contributes two smaller papers, one on a peculiar wart of the umbilicus, the other on the involution of the puerperal uterus in the absence of the ovaries. Dr. Matthews Duncan contributes a paper on foetal revolutions, and, in conjunction with Mr. J. B. Hurry, one on retroflexions of the pelvis. The former deals with the mechanism of labour, the latter with teratology. Dr. Playfair relates a case of recovery after thrombosis of the pulmonary artery; and Mr. E. S. Tait publishes an unpretending but useful paper on puerperal temperatures. Amongst other points, he brings forward evidence to show that pyrexia of short duration in the puerperal state may be produced simply by emotional disturbance. Dr. Arthur Mitchell expresses his conviction that emotional disturbance in the mother during gestation may be a factor in the production of idiocy in the offspring; and Dr. Kilner urges the benefits to be derived from the use of the induced current during parturition; but, in the case of both papers, the evidence brought forward is far from satisfactory. Mr. Doran publishes two pedigrees exemplifying a relationship which he believes to exist between prolapse of the uterus and hernia. Dr. Mathieson, of Ontario, relates a remarkable case of extra-uterine gestation in which, contrary to rule, he removed the placenta, checking hæmorrhage as he did so, by the application of a swab of perchloride of iron solution; and the patient did well. It will be thus seen that the volume contains no lack of interesting matter, and some papers which are substantial additions to our knowledge.

## ABSTRACTS AND EXTRACTS.

EXTERNAL TREATMENT OF ECZEMA AND PSORIASIS.—In some recent clinical lectures at the Hôpital St. Louis (*Gazette des Hôpitaux*, Nos. 85 and 88), M. Guibout gave an account of the external treatment of eczema and psoriasis. (1) *Eczema*: This, he observes, is the most frequent form of herpetic disease. It is essentially of an

inflammatory nature, and must, in its acute stage, be treated only by antiphlogistics and emollients. In that stage all ointments, even the most anodyne, must be avoided, owing to their liability to ferment and increase irritation, and for the same reason linseed poultices must be prohibited. So also cold baths, and alkaline and sulphurous baths, do mischief, and patients should not be sent to sea-water baths or for the employment of mineral waters, which may irritate either by their high temperature, their chemical composition, or their high degree of salinity. In fact, almost all mineral waters are dangerous in eczema, and it is only when the disease is on the decline that even the mildest can be safely applied. Those of St. Gervais being very mild are nearly the only waters which M. Guibout prescribes in sub-acute eczema. In the chronic form, the stimulant mineral waters may be used with advantage, but with caution. As emollient applications, cataplasms of well-cooked potatoe starch reduced to a jelly and very moist, may be applied three times in the 24 hours, or tepid bran baths or starched water, the starch being prepared beforehand, so as to be readily incorporated with the water. Lotions, when used, should always be tepid, never cold, and all objects of irritation must be carefully removed from contact with the skin. Additional difficulty occurs in treating eczema, when it occupies any hairy region of the body, owing to the increased irritation produced there, and the difficulty of applying emollients. As long as the disease lasts, therefore, the hairs of these parts must be kept cut short. When the genital region is attacked, the horizontal posture with immobility must be observed, care being taken that the diseased parts do not come into contact and are covered with cataplasms. Eczema of the lower extremities can never be cured, unless the parts are kept in a horizontal or somewhat raised position, motionless, and unimpeded by ligatures of any kind. The patient, in fact, should keep his bed, for if the limbs are allowed to be pendant, the eczema is never cured, while the parts become disorganized. When the eczema occupies the greater part of the trunk, or even the whole body, cataplasms are not available, and then we should have recourse to vulcanized caoutchouc, applied directly to the affected parts. This preserves them from all irritating contact, and keeps them at a uniform temperature, and as it were in a constant bath, owing to the impeded evaporation. Complete articles of clothing of this kind are made. They should be changed every 24 hours, washed in bran water, and exposed to the air until wanted next day. In the absence of the caoutchouc, the diseased surfaces may be painted several times a day with a liniment, laid on in thick layers, composed of equal parts of oil of sweet almonds and lime water; powdering the surface after each painting with unscented starch. A tepid bath of bran or starch should be taken daily or every second or third day. The treatment must be quite different in *chronic eczema*, which thickens and "pachydermizes" the skin, depriving it to some extent of its vitality. Stimulating, or even irritating topical applications are now indicated for the removal of the thick epidemic secretions which cover it. This object is to be attained by sulphurous or alkaline vapour baths, by paintings with oil of cade, by frictions with black soap or with sublimate lotions (1 part to 500 of spirit lotion) or by sulphur or boracic acid (10 parts to 100 of vaseline) ointments. (2) *Psoriasis*: Passing from eczema to psoriasis is like passing from summer to winter. In eczema all is hot and burning, while in psoriasis life is chilled and almost extinct—the *dartre morte* of the ancients—for which the most opposite treatment is required. The indications are to remove the hardened and thickened epidermic scales, to arouse the defective vitality of the subjacent dermis, and restore the suspended secretions. This is to be accomplished by means of frictions and baths. The two most useful substances for frictions are the oil of cade distilled from the resin of the *juniperus sabina* and pyrogallic acid. The former furnishes the most prompt, certain, and durable results. It is rubbed energetically twice a day over the whole body with the aid of a cloth pad, or flannel, soaked in the oil, a bath containing 400 or 500 grammes of carbonate of soda being also taken every or every other day, for the purposes of cleansing the skin, dissolving the oil which covers it, and imparting to it

a salutary stimulus. These measures should be continued until the complete disappearance, not only of the epidermic scales, but also of the hypertrophied crusts of the dermis, and of the coppery colour which still persists. But the oil of cade, advantageous as it is, possesses a most disagreeable and tenacious smell, stains both the skin and the linen, and sometimes induces a form of syçosis. The oil has then to be suspended, and the syçosis treated by emollients, and when this inconvenience has been removed, the stimulant effect of the oil must be abated by adding to it more or less almond oil. When this oil cannot be employed, pyrogallie acid in various proportions (5 to 15 per cent. of vaseline or lard) must be substituted. Being inodorous and colourless, it does not give rise to the inconvenience caused by the cade oil, but it is less energetic in its action, and must never be applied to parts exposed to the air (as the face or hands), as it induces in them a colour exactly like that produced by the skins of green walnuts, and which is very long in disappearing. When the psoriasis affects the head, the hair must be kept cut short.

**TRACHELO-RAPHÉ OR EMMET'S OPERATION FOR LACERATED CERVIX UTERI.**—Dr. Zinke, of Cincinnati, in a paper published in the *Medical Reporter* of Philadelphia, August 8, states that he issued circulars to a large number of the most prominent American and foreign gynæcologists containing queries as to their experience of the advantages of Emmet's operation. Analysing the replies which he received, he believes that he may draw the following conclusions:—(1) It is evident that the operation has been performed unnecessarily for symptoms similar to, but other than, those arising from lacerations of the cervix; further, that it has been done imperfectly, even without preliminary treatment, in many more. The failure to give relief, as reported by several, is due to these two causes. (2) That from our present knowledge we cannot arrive at any definite conclusion, from the fact that many of the so-called consequences of the laceration are not settled beyond dispute. (3) That every one should carefully select his cases and try every means to give relief before resorting to operation. (4) The operation should never be performed in cases of simple fissure, or in laceration of first or second degree. (5) In cases of eversion and disease of the cervical and corporeal cavity, or both, although attended with hyperplasia and displacement, it has sometimes been observed that all the symptoms abated, that all the parts returned to their natural condition, and that no laceration was discoverable after the employment of alleviative measures alone. (6) That there are some cases of extensive laceration that seldom give rise to any inconvenience. In these the operation should be deferred until symptoms calling for it arise. (7) Even when indicated, it should never be performed until the parts have been brought as far as possible into a healthy condition. (8) Near to and during the climacteric period, it should be postponed as long as possible, since in many cases the symptoms subside under proper treatment on account of senile involution, and never return. (9) The operation is justifiable in lacerations of the third and fourth degree, without complications, if there is a history of malignant disease in the family. (10) It may be performed with perfect propriety in young women as a preventative if the laceration is bilateral and extends up to the cervico-vaginal insertion or beyond it, even though there are no pathological changes. It is the duty of every one who observes a lesion of that extent to urge an operation. (11) It is justifiable in any degree of laceration, and in rare instances even in fissures, when there exists cicatricial tissue productive of reflex disturbances, annoying in character and not tractable under any other treatment. (12) It is absolutely indicated in all extensive tears of the os in which the cervix is everted, its mucous membrane and nabothian follicles diseased, and especially if there be granular or cystic degeneration present—the parts having been first restored to a healthy condition by palliative treatment.

**THE ACTION OF EXCIPIENTS.**—Dr. Hallopeau, at a meeting of the Société de Théraputique (*Gazette Hebdomadaire*, No. 32), in relation to the influence exerted by

excipients on substances incorporated in them, observed that he had been making some researches, the results of which plainly showed that a  $\frac{1}{10}$  of carbolic acid embodied in a pomade excited less irritation than  $\frac{1}{50}$  or even  $\frac{1}{100}$  part, when forming part of an aqueous or alcoholic solution. Carbolic acid dissolved in glycerine at  $\frac{1}{3}$  possesses no irritating properties, while, combined with vaseline, it will produce rubefaction at a  $\frac{1}{20}$ . Glycerine soap, containing 10 per cent. of carbolic acid, produces no irritation of the skin. Dr. Duhomme suggested that the difference in excipients arose from the more or less rapid concentration of the solution placed on the integuments. Water and alcohol evaporate much faster than fatty bodies, leaving the carbolic acid in, so to say, a state of nature. To this view Dr. Hallopeau demurred, since with vaseline, which is just as slow as fatty bodies, the irritant power is very marked. Dr. Campardon had remarked an analogous difference, according to the excipient employed in the preparation of boracic acid pomade for intertrigo. If the following formula be employed, viz., vaseline 30, boracic acid 2 grammes, with 10 drops of essence, no irritating effect is observed; but it is quite otherwise when the vaseline is replaced by a starch glycerole. Dr. Labbé observed that vaseline employed as an excipient in a great number of pomades prevents the absorption of the incorporated substance. Dr. Limousin said that vaseline is a very useful excipient in diseases of the eye, as not combining with the active substances with which it is mixed, it acts simply as a means of carrying the medicinal agent to the diseased part. Dr. Hallopeau observed that the white vaseline used at the hospitals is adulterated with paraffine, and contains numerous crystals easily discerned by the microscope; and Dr. Limousin added that the white vaseline being so easily adulterated, it was preferable to employ the brown, which may be easily purified and whitened by filtering it through animal black, without any injury to its purity.

**THE FORMATION OF RENAL CALCULI.**—In a paper read before the Ontario Medical Society, Dr. Groves says: "My own opinion is that with some rare exceptions the formation of primary kidney stone depends upon a predisposing cause which may be called the uric acid diathesis, and certain exciting causes incident to the food and surroundings of the individual, together with a precipitating cause without which stone is not deposited. The exciting causes determine the particular variety of calculus which may be found in any given case, but in the absence of the other two factors the exciting causes will not result in calculous deposit. The mere presence of the diathesis alone will not cause the deposit of stone, for many persons habitually pass large quantities of uric acid without the development of any form of calculus. Ultzman has demonstrated that when the urine is only mildly acid, uric acid is deposited in normal rhombic prisms, but that if the acidity be increased the crystals take the form of elongated, pointed and radiating rods, and that it is precisely these spiny crystals that are found in cases of calculous pyelitis. Dr. Ord shows experimentally that the form in which uric acid is deposited is often determined by the other urinary constituents. Eichorst cites a case where a gentleman invariably passed several uric acid concretions after drinking moderately of wine, and I have had under my care for some time a patient who is regularly attacked with renal colic during pregnancy, but at no other time. Persons who are exposed to the same influences and who are similarly nourished, always have the same character of kidney infarction. Thus in the fœtus and young infants, whose nourishment and surroundings are measurably the same, none but uric acid infarctions are found, but the conditions as to food and surroundings being changed other forms of deposit take place."—*Canada Lancet*.

**AN UNUSUAL CASE OF HEMIANOPIA.**—In the *Ophthalmic Review* for August, Dr. James Anderson records a curious case. His patient, a man aged 28, was seized with giddiness after undergoing great physical exertion, but did not lose consciousness. He had previously been suffering from fever and constipation. After the attack of giddiness he was laid up for four days, and he then found that he could not see properly; he also had slight loss of power in

the right limbs followed by movements which he could not control. He had never had syphilis. He came under observation two years after these symptoms first appeared. There was then no obvious loss of power, but marked loss of sensation in the right limbs. Taste, smell and hearing were natural. The knee-jerk on the right side was exaggerated. The heart and blood-vessels seemed healthy, and the urine normal. The patient could only see the upper half of objects; the movements of the eyes were natural. Examination with the perimeter showed that the lower half of the field of vision was almost gone, and that it was contracted above and at the inner side. There was a very marked family history of cerebral hæmorrhage. Dr. Anderson is of opinion that there was a lesion of the posterior third of the left internal capsule, also affecting the neighbouring fibres lying in the middle third which pass to the trunk and limbs. He declines to speculate on the lesion which produced the visual defect further than to point out that a symmetrical lesion of the optic nerves or a lesion of the upper and anterior surface of the chiasma would explain it.

**HYDROBROMATE OF HYOSCINE.**—Dr. H. C. Wood writes in the *Therapeutic Gazette* (September 15th): As a soporific, the drug is especially successful in those cases in which the insomnia is due to excessive cerebral action—cases in which there is a perpetual and uncontrollable succession of thoughts. Allied to this form of insomnia is the mental condition in which the sleep is excessively disturbed by urgent dreams. This, also, I have seen controlled by hyoscine. In one or two cases of intense fever with delirium the hyoscine has seemed to act very well in controlling the delirium. In two cases the symptoms have been such as to suggest that the drug exerts a paralytic action upon the recurrent laryngeals. One of these cases was in the person of a maniacal female, in whom the hypodermic injection of a large dose of the salt was followed at once by a paroxysm of suffocation apparently paralytic and laryngeal. The second case occurred in a child about 10 years old, suffering from very violent anginous scarlet fever with moderate laryngeal dyspnoea. Hyoscine was prescribed for the excessive insomnia which had lasted from the onset of the fever, with very good results so far as the insomnia was concerned; but so soon as the child came under the influence of the drug, the laryngeal symptoms increased with very great rapidity, and in the course of an hour or two death resulted. Whether the hyoscine was or was not the cause of this increased dyspnoea is of course uncertain; but two cases are assuredly enough to arouse suspicion.

**EXTRA-UTERINE PREGNANCY.**—Dr. Mann, Professor of Obstetrics in the University of Buffalo, in a paper which he read to the Medical Society of that city and published in the *Philadelphia Medical News*, July 11, after narrating four cases of extra-uterine pregnancy which had come under his notice, and reviewing the literature of the subject, arrives at the following conclusions respecting treatment:—"The rule of treatment, then, which I would deduce would be that if the fœtus is alive, destroy it at once by electricity, no matter at what age the pregnancy may be. If it is dead, and in the earlier months, leave it alone until some clear indications for operation show themselves. In the later months, after its death, wait four or five weeks and then remove it by laparotomy. The advisability of this latter recommendation might be questioned, but certainly the risks which a woman runs who carries in her abdomen a seven, eight, or nine months extra-uterine fœtus, are so great that a skilful laparotomy is preferable. The absorption or encysting of a large fœtus, while it may occur, is so unlikely, and the danger of rupture or of septicæmia is so great, that it hardly seems justifiable to allow her to run such a risk. Perhaps my single experience leads me to take too decided a view, but I should directly prefer an early operation to putting it off too long. Unfortunately, we have nothing on which to base a rule as to the exact length of time that we should wait, and the necessary data are obviously very difficult to get. More experience is necessary before deciding this point, but as I have already said, my experience and the opinion which I now hold,

would lead me to an early operation rather than to indefinite postponement and the expectant plan."

**UMBILICAL HERNIA; RUPTURE; EXTRUSION OF SEVERAL FEET OF INTESTINE; DEATH.**—Dr. Rennie records the following case in the *China Customs Medical Reports*, No. 28:—It occurred in a native infant whose mother died of puerperal fever. When first seen on March 3, 1884, the child was 27 days old, and his illness was doubtless due to improper feeding. For some days he had been much troubled with flatulence, and cried a good deal. Since the evening of the 1st March he had cried almost constantly, and on the following morning an umbilical hernia, about the size of an orange, was noticed. About 4 p.m. the coverings of the hernia burst, and the intestines commenced to pass out at the opening. On the evening of the 3rd March, he was enveloped in quilts, which the attendants said they had applied to keep the intestines warm. On removing the coverings it was found that the greater part of the small intestine had passed out of the abdominal cavity and, deeply congested, distended with gas, and smeared with a loose motion that had recently been passed, lay on the surface of the abdomen. After cleansing the parts with sponge and weak solution of carbolic acid in water, and removing some of the flatus by means of a small aspirator needle, the opening in the abdomen was enlarged (it was found impossible to return the bowel without doing so), the intestines replaced, and the wound stitched up with carbolised silk. Eight hours afterwards the child died.

**NEPHRECTOMY, ITS INDICATIONS AND CONTRA-INDICATIONS.**—Dr. Samuel W. Gross, in an elaborate paper in the July number of *The American Journal of the Medical Sciences*, based upon a study of nearly four hundred and fifty cases of different operations on the kidney, presents a careful analysis of all the facts pertaining to the surgery of this organ, and arrives at the following conclusions:—(1) That lumbar nephrectomy is a safer operation than abdominal nephrectomy. (2) That primary extirpation of the kidney is indicated, first, in sarcoma of adult subjects; secondly, in benign neoplasms at any age; thirdly, in the early stage of tubercular disease; fourthly, in rupture of the ureter; and, lastly, in ureteral fistula. (3) That nephrectomy should not be resorted to until after the failure of other measures, first, in subcutaneous laceration of the kidney; secondly, in protrusion of the kidney through a wound in the loin; thirdly, in recent wounds of the kidney or of the ureter, inflicted in the performance of ovariectomy, hysterectomy, or other operations; fourthly, in suppurative lesions; fifthly, in hydronephrosis and cysts; sixthly, in calculus of an otherwise healthy kidney; and, finally, in painful floating kidney. (4) That nephrectomy is absolutely contra-indicated, first, in sarcoma of children; secondly, in carcinoma at any age, unless, perhaps, the disease can be diagnosticated and removed at an early stage; and, thirdly, in the advanced period of tubercular disease.

**DIAGNOSIS OF GONORRHOEA IN THE FEMALE.**—Dr. Martineau, at a recent meeting of the Paris Obstetrical and Gynaecological Society, stated a most important fact by which specific can be distinguished from simple vaginal discharge. In the specific form, the discharge is always acid, while in the simple form it is always alkaline. It is very easy therefore, to decide by means of litmus paper whether a woman is or is not suffering from gonorrhœal discharge. This sign may also prove of value in cases of rape in deciding whether the person who committed the crime was then suffering from gonorrhœa, as any vaginal discharge proceeding from this cause would be acid.—*Philadelphia Medical News*, June 13.

**PARALYSIS FOLLOWING ON HERPES.**—A case is related in a Dutch medical journal of paralysis of the facial muscles on one side, with loss of taste on that half of the tongue, following on a painful attack of herpes affecting the whole side of the face. It was noted that the eruption and the pain ceased on the supervention of the paralysis. The observer, Dr. Waller, considers that the branches of the fifth nerve only were affected.—*Weekblad*.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 9TH, 1885.

THOMAS BRYANT, F.R.C.S., President, in the Chair.

THE PRESIDENT welcomed the members on their return to work, and presented the new volume of the reports, calling attention to its greatly increased size and its unusual value, containing, as it did, not only the full Transactions, but also the report of the debate on Charcot's disease and the report of the Spina Bifida Committee. He announced that at the next meeting of the Society a vote would be taken on the question of the serving of tea and coffee to the members before or after the meetings. No discussion would be held, but the matter would be put to the vote at once.

*Hæmatemesis and Melæna in which Blood was first Vomited 21½ hours after Birth; Fatal within 24 hours.*

Dr. SAWTELL read an account of this case and exhibited a preparation of the stomach, showing ulceration. A small male child, born April 9th, 1885, after a natural, but rather tedious, labour, suddenly vomited blood 21½ hours after birth, and, a few hours later, melæna succeeded. Up to this time milk was taken, and vitality seemed but slightly impaired. The discharge of blood continuing, much altered by admixture with meconium and mucus, the child rapidly sank, and died within twenty-four hours from the first appearance of blood. Besides general measures, sulphuric acid was given in tincture of cardamoms. *Post-mortem*, the stomach alone showed causal lesions—viz., small, but deep, round or oval ulcers on posterior wall of cardiac end, near the lesser curve. Dr. Sawtell remarked that, after some examination of the subject, he had failed to find any record of a similar case. He quoted Billard's paper in the *British and Foreign Medico-Chirurgical Review* for 1853, in which Rahn-Escher states that *softening* of the stomach and bowel is sometimes found. An interesting case observed by Dr. Richard Neale revealed no lesion of any kind. Dr. Edis, in the *British Medical Journal* for 1879, deals with *spurious hæmatemesis*; so also Dr. Thorburn. But records of true intestinal hæmorrhage in infants are so rare that Dr. West relates only three as occurring in his extensive practice, and only one of these in the new-born. Finally, Rilliet's elaborate essay does not give any cases of ulceration. The author inclined to the opinion that the ulcers arose from portal obstruction and erosion by gastric juice, and concluded his paper by pointing out the difficulty of diagnosis and treatment, and the truth of Dr. West's observation that the new-born suffer less from the effects of hæmorrhage than might be expected.

Dr. RADCLIFFE CROCKER thought that the case somewhat resembled those of purpura neonatorum, although in the latter the hæmorrhage was generally confined to the skin. It had usually been attributed to the sudden changes of the circulation at birth not being fully completed, temporary arrest of circulation in places being the result. The patches in the exhibited specimen appeared to be hæmorrhagic erosions, and there might possibly have been thrombosis of some of the vessels.

Dr. EDIS referred to the frequency with which hæmatemesis in new-born children was due to the swallowing of blood oozing from a sore nipple.

*Two Cases of Strangulated Umbilical Hernia, treated by Excision of the Sac and Skin Covering, with Suture of the Ring, after Reduction.*

Mr. CLEMENT LUCAS read the full notes of these cases. He began by stating that for several years he had been in the habit of excising the sacs when called upon to operate for strangulation in cases of hernia (of whatever kind), and that he had been led to do so, not so much for the purpose of producing a radical cure (though this was an advantage),

as to lessen the mortality from the operation. He regarded the sac itself as a danger, from its badly nourished texture, its tendency to suppurate or slough, and its liability to collect discharges, and guide them into the peritonæal cavity. To rid the patient of this abnormal, over-strained, ill-nourished, not only useless, but absolutely injurious, piece of tissue, should be the aim of every surgeon when called upon to operate for strangulation, after reducing the bowel. To speak of such a proceeding as "unsurgical" was a wanton misuse of the adjective. It was probably the only operation for radical cure that would bear the test of time. He regarded no operation for femoral hernia complete till the sac had been excised, even though the bowel might have been reduced before opening the sac. The same might be said of acquired inguinal. The congenital inguinal presented especial difficulty, as the whole sac could not be excised without sacrificing the testicle, but he usually excised the funicular portion, and rigid antisepsis was advisable. He was about to advocate much more radical measures in cases of umbilical hernia than were usually adopted, and he believed the mortality would thus be greatly lessened. The first case was of peculiar interest inasmuch as the operation was performed on a patient in an advanced stage of dropsy from Bright's disease. It might be studied with a case reported in the Guy's Hospital Reports for 1879, page 332. In that case he had twice operated on a femoral hernia, at an interval of eleven months, for strangulation during dropsy from heart disease. A married laundress, æt. 48, had suffered some years from winter cough, but till June, 1883, believed herself healthy. She then began to suffer from dropsy. In July, 1884, paracentesis abdominis was performed, when she was under the care of Dr. Wilks. She was tapped a second time in February, 1885, and a third time on April 9th, when eighteen pints of fluid were withdrawn. She then had very general anasarca, râles over both lungs, and dulness of the bases, urine depositing one-third albumen on boiling, and containing some blood. On May 22nd, at 4 a.m., the umbilical hernia, which she had had some years, became strangulated, and Mr. Lucas operated at 1 o'clock, having failed to reduce it by taxis. It was found necessary to open the sac, when a considerable quantity of fluid escaped, and a large piece of purple small intestine came into view. The opening was enlarged so far as to admit the finger into the abdomen, but owing to the water pressure behind it was found impossible by manipulation to reduce the bowel. Finding the obstacle to reduction was the peritonæal fluid, Mr. Lucas placed the patient on her side, and holding the intestine on one side with his finger passed through the aperture, allowed, in this way, three-and-a-half pints of ascitic fluid to escape. After this the bowel was easily returned. He then cut away the whole of the sac, and afterwards all the thin distended skin. Three stout chromicized catgut sutures were next passed through the margins of the umbilical opening to the peritonæal surface, tied and cut short. The skin margins were then brought together with wire sutures. Carbolic spray and antiseptic dressings were used. Sickness ceased at 10 the next morning, and the patient was comfortable. All the wire stitches were removed on the sixth day, and the wound appeared to be healed although the urine still contained one-third albumen and some blood. A few days later slight suppuration took place, and the cause proved to be one of the catgut stitches which came away unchanged on the fifteenth day. After this she gradually improved, and left the Hospital on July 25th, at which time there was no tendency to protrusion at the umbilicus. The second case was that of an exceedingly stout plethoric woman, æt. 52, who was admitted into Guy's Hospital on September 6th, 1885. She was married, and had four children. When lifting a heavy pole of clothes, eleven years ago, she first felt something give way at the navel. Since that time she had on four occasions required chloroform for the reduction of the hernia, which was of large size. The last time it was thus reduced was in August, 1884. At 10 a.m. on September 5th, as the result of a severe fit of coughing, the rupture became distended and irreducible. She was seized with severe pain over the stomach, and vomiting occurred soon after, and continued till her admission at 7 o'clock in

the evening of September 6th. Her bowels had not acted since the hernia came down. She was sick soon after her entry, bringing up dark greenish fluid. She was in much pain, and very restless. The hernia was of large size, and uneven on the surface, four inches by three in diameter, tense, devoid of impulse, and tender on manipulation. Taxis having failed both before and after the administration of chloroform, Mr. Lucas proceeded to operate at 9 o'clock in the evening. A vertical incision, about four inches in length, was made at the upper part of the tumour, and the sac being exposed, the ring was divided outside, and taxis again applied without success. The sac was then opened, and some blood-stained fluid escaped. The sac was found to contain a large mass of adherent omentum, forming an omental sac, within which the bowel was strangulated. After division of the stricture, several feet of dark-coloured intestine were reduced; the transverse colon then appeared in the sac, but it was not strangulated. Two large pieces of omentum were then ligatured with green catgut and cut away. The sac was next separated from its connections, and cut away, except at the lower part, where the adherent omentum made it impossible completely to remove it. Three stout green catgut ligatures were then passed through the edges of the aperture to the peritonæal surface, and the opening thus closed, the stumps of adherent omentum and sac being outside. The skin was cut away and its edges brought together with wire sutures and an aperture left for drainage at the lower front. Carbolic spray and antiseptic dressings were used. She had no sickness after the operation, and was quite relieved from abdominal pain, the abdomen remaining soft and free from tenderness. On the 10th there was a rise of temperature, and on being dressed some blood-stained discharge escaped from the lower part of the wound. After a week a slough came away, evidently the remnant of sac and stump of omentum. After this she rapidly improved, and had a normal temperature. Her bowels acted on the 15th. On September 23rd the drainage tube was removed. September 27th she got up and was practically convalescent. The cases illustrated the value of removing the sac and closing the abdominal aperture. Neither patient was in a good condition for operation, one being in an advanced stage of dropsy from heart disease, the other exceedingly fat and flabby. In both a large quantity of bowel was strangulated, and in one the hernia was much complicated by adherent omentum. In both some suppuration occurred, and in one sloughing; yet no suppuration extended to the peritonæum, as would probably have been the case had the aperture been left patent. Both patients recovered without any symptom to cause serious anxiety.

The PRESIDENT congratulated Mr. Lucas on his cases, and thought that they formed good examples of the modern form of treatment.

Mr. GOLDING-BIRD could not quite agree with Mr. Lucas in the argument by which he defended his mode of procedure, although he fully concurred in the practice of it. It was stated that by leaving the sac, a channel was liable to be formed through which septic material might take its way to the peritonæum. He thought that *post-mortem* evidence generally went to show that when peritonitis occurred it did not begin about the neck of the sac, but rather about the portion of intestine which had been strangulated. The argument hardly seemed good in the light of Mr. Lucas's second case, where a large slough had come away about the external wound; in that case some other cause than the excision of the sac must have been at work to prevent the return of pus into the abdomen. He had himself practised excision of the sac in all his own cases.

Mr. WALSHAM had had occasion to remove the sac in several cases. In two instances of umbilical hernia he had cut it away freely, paring the edges of the tendinous ring and bringing the lips together by means of carbolised silk, the use of which he should prefer to that of catgut. His cases had left the hospital without trusses, and no return of the hernia had taken place. He did not think that it was safe always to assume a radical cure, since it was never possible to make sure that such was the case.

Mr. MAKINS mentioned a case under his own care, in

which he had cut away skin and sac with a satisfactory result.

Mr. BALLANCE related the case of a patient of 50 years of age, in which he had found it necessary not only to remove sac and skin, but also to pull down and remove a considerable portion of omentum. He thought that in such a case it was better to remove as much as possible.

Mr. SYMONDS had operated on two cases of umbilical hernia, both of which were peculiar, in that they presented in two parts, lying side by side, the one protrusion being projected through the wall of the other. He had performed the operation advocated by Mr. Lucas in both instances with success, though the result, as far as subsequent protrusion was concerned, was not known. He considered that the edges of the opening must be ligatured if a radical cure was to be effected.

Mr. R. J. GODLEE asked whether the removal of the sac was, after all, a very easy proceeding? Generally the union of the sac to the skin in umbilical hernia was so very close that it was almost impossible to separate it. In one case he had failed to bring the walls of the aperture together from this very reason. He mentioned a rare kind of umbilical hernia in which the protrusion took place (in children) into the stump of the umbilical cord, and quoted a case in illustration of it.

Mr. HOPKINS referred to the case of an elderly person on whom he had operated for the relief of umbilical hernia by means of a semilunar incision.

The PRESIDENT observed that it was most cheering to hear of so many successful results in the treatment of what was undoubtedly one of the most difficult and dangerous forms of hernia. He thought Mr. Lucas's method was a great improvement, and should always be employed in cases where it was necessary to open the sac. He should be sorry, however, to adopt it as a rule for all cases, as in some he did not think it could be necessary. He had never performed it himself, but he had had successful results by the simpler method without opening the sac, and he thought the latter was more applicable to the cases of aged or very fat persons.

Mr. BARKER, referring to Mr. Godlee's remarks, thought that it would always be possible to remove the sac for at least an inch round the wound, and in his own cases had found no difficulty in doing so.

Mr. HOWSE thought that when so many successful cases of removal of the sac were brought forward together, there was some danger of the new rule becoming universal. He did not think it would be wise to adopt it wholesale, but would still judge each case on its own merits. He had not himself met with any case which required it. In recent cases where there was much omentum protruding, he thought that it would materially increase the risk, and there would be more danger of not being able to unite the edges. If a case could be operated on early, within a few hours, and no case should be allowed to wait when reduction had once failed, it generally did well. Removal of the skin and sac should be restricted to cases where there was either an excess of fluid or a foul-smelling omentum or a much-inflamed bowel. He thought that increased risk would attach to the operation if the rule of removal were to be universally adopted.

Mr. LUCAS replied in detail to most of the speakers, reiterating many of the views expressed in his paper. He looked upon the sac as a dangerous thing which ought by all means to be got rid of if possible. He expressed surprise at the conservative tone of Mr. Howse's remarks, and observed that the results of the so-called major operation were in reality simpler those of the apparently minor procedure.

*A Case of Trephining for Compression by a Clot derived from the Middle Meningeal Artery, and suggested resort to Compression or Closure of the Carotid as a means of arresting Hæmorrhage.*

Mr. CHARTERS SYMONDS read the following case: A man, aged 43, fell from a height of six feet, striking his head. He was admitted immediately into Guy's Hospital, and was seen shortly after in a totally insensible condition, with right hemiplegia, a pulse of 52, and failing. He had

two abrasions on the left temporal region, and a large extravasation of blood. Though there had been no conscious interval, Mr. Symonds immediately trephined on account of the hemiplegia and deepening coma. The site selected was rather posterior to that usually chosen, as here the chief injury seemed to have been received. On elevating the disc of bone a pulsating clot was exposed and removed. The bleeding was profuse, and to reach the laceration a great deal of bone was removed by Hoffman's forceps, two loose pieces of the sphenoid being found. Two lacerations were found in the vessel; one was closed by under-running the vessel with fine gut; the other by completing the division of the vessel and twisting both ends. The bleeding, however, still continuing, and the bone having been incised to the base, the hæmorrhage was finally arrested by under-running the artery with a piece of the dura mater, and making traction on the ligature carried out of the wound, and by a pair of torsion forceps pushed down into the farthest accessible point and given a half-twist. The operation altogether lasted two hours, and the man lost much blood. Recovery was immediate. As soon as the clot was removed the pulse rose from 40 to 64, and the muscles of the right foot moved; and at the conclusion of the operation the man could move his right arm and leg, and give his name and address. The next day he answered all questions and spoke rationally, and seemed to have completely recovered his consciousness. The same afternoon he became restless, and finally delirious, coma supervened, the temperature rose gradually, reaching 104.8 shortly before death, on the 26th, at 3.15 p.m., or fifty hours after the accident. At the *post-mortem* the dura mater over the exposed area was yellow and purulent, and there was general congestion. The temporo-sphenoidal bone on the right side was bruised, as was the cerebellum. The fracture ran from the site of the operation to the wing of the sphenoid, and there divided into two branches, one running over the orbital plate to reach the cribriform plate of the ethmoid, the other reaching the same point after traversing the optic foramen and sphenoidal fissure. In his remarks, Mr. Symonds said that his main object was to call attention to the paucity of information upon the best method of dealing with the bleeding vessel, and to suggest a resort to compression of the carotid from the moment such a case was seen, and to its ligation should, after trephining, other means fail to arrest the bleeding. Though no mention was made in our leading works of this method of arresting the hæmorrhage, he had no doubt that the idea had occurred to others before it had to him in connection with this case two years ago. He said that probably such severe hæmorrhage was not often encountered, and suggested that possibly the loss of the local pressure of the cranial contents owing to the non-recovery of the brain might partly explain it in this case. To the severity of the operation, to its great prolongation, and to the loss of blood he attributed the fatal meningitis, and did not think that the result affected the average success of trephining. As to whether it would be better to secure the external or common carotid, he thought that while ligation of the external would remove the special cerebral dangers attending closure of the common, its safety was yet to be established. He considered that with our present method of treating wounds less danger need be apprehended from secondary hæmorrhage, and he would therefore prefer to close the external carotid. Mr. Furneaux Jordan's suggestion to ligature the carotid instead of trephining, while it was thought effective, would, Mr. Symonds considered, be confined to those cases seen very early, and would therefore have but a limited application. The absence of the interval of consciousness was considered to be due to concussion, while the strictly localised character of the paralysis was unlike that seen in cases of cerebral laceration.

Mr. HOWSE read a short description of two cases similar to that recorded by Mr. Symonds, and at the request of the PRESIDENT, who remarked upon their importance, he agreed to communicate them to the "Transactions" of the Society. The following is an abstract of them:—

H. H., æt. 10: admitted July 26th, 1884, 12.30 noon. *Accident.*—Fell down fore-hatch, distance of six feet, eighteen hours before admission. *On Admission.*—In a

state of coma, which came on four hours after the accident. Pupils unequal; limbs rigid; convulsive movement of right arm and leg. *Operation.*—Three hours after admission trephining of left parietal eminence, removal of blood clot, fresh hæmorrhage. Digital compression of common carotid for three hours. *Progress.*—Moved right arm and leg on the evening of 26th; no hæmorrhage; went on well; no pyrexia. August 21st.—Wound healed; pupils equal; went into park; when walking drags both hips somewhat, though right the most; right shoulder tends to drop; reflexes equal; left facial paralysis. September 3rd.—Paralysis of right arm and leg has become worse. 15th.—Tonic contraction of right arm and leg. October 8th.—Right arm completely contracted; left facial paralysis persistent; general health perfect. November 20th.—Removed to medical ward. The second case was that of—

F. F., æt. 51, a carman: a healthy man. *Accident.*—Patient was loading a waggon with rags, the hook gave way by which he was holding, and he was pitched forward on to his forehead, falling about ten feet; brought immediately to hospital. *On Admission*, 11 a.m.—No sign of paralysis anywhere, was heavy and drowsy, but answered questions; much effusion under scalp, bleeding from right nostril, none from ear or mouth; pupils normal; pulse slow and laborious. 12.30 p.m.—Increasing insensibility, now quite unconscious, breathing stertorous; right hemiplegia with some amount of spasm. *Operation*, 2 p.m.—Mr. Howse trephined skull with largest sized trephine over the left parietal bone, towards the upper part. There was a large clot of blood between the dura mater and bone; this was removed; there was much hæmorrhage. Dressings were applied, and it was hoped the bleeding would cease under pressure and cold. After the operation the patient moved his arm and leg a little, but they still remained very rigid. He continued unconscious. *Second operation.*—Hæmorrhage continued, so at 5 p.m. the dressings were removed, and more bone was removed (mainly with Hoffman's forceps), and several branches of the middle meningeal were ligatured. This failed to arrest the hæmorrhage, so Mr. Howse cut down upon the external carotid artery, and ligatured it. Hæmorrhage immediately ceased. The patient, however, remained insensible, and died about 8.45 the following morning. *Post-mortem.*—Left parietal bone separated from frontal at coronal suture, the right also for about an inch, and then a fracture ran obliquely backwards across this for about three inches; bone not depressed. Some amount of clotted blood still remained on the dura mater. The under surface of left middle cerebral lobe was much bruised to depth of about half an inch. Viscera healthy.

### INDIA.

(From Our Bombay Correspondent.)

*The Governor-General on the Sanitary State of Calcutta*  
—Cholera and its Influence on Commerce—Sanitation  
in Bombay—The Scientific use of Condemned Criminals  
—"The Medical Register" and Indian Practitioners.

September 24.

THE subject of the sanitation of Calcutta continues to attract public attention there. The Report of the special Sanitary Commission appointed by Government has been submitted to the Governor-General in Council, and in his reply His Excellency very rightly regrets the acrimonious feeling which has been engendered concerning a subject of equal moment to all classes of the community. Considering its admittedly defective sanitary condition, it was of little or no practical importance whether the increase of cholera in Calcutta since 1880 was co-incident with the so-called "cholera wave." After alluding to the circumstances

which led to the appointment of an independent Sanitary Commission, His Excellency points out that the Municipal Commissioners themselves allow that there is much to be effected towards the improvement of sanitation; and it follows that they are bound to spend as much money on sanitary reform as they can. As to any question of remission of taxation, which curiously enough had been mooted, it would doubtless be a short-sighted policy until all sanitary defects had been effectually remedied. It need hardly be said that the advantages accruing from sanitary reform are immediate, so much so that the present generation might well be content to bear the burden. It certainly seemed not a little alarming, that while cholera mortality was increasing, the municipality went on reducing the sanitary estimates, drawn up by their own officers, by nearly 300,000 rupees. The Governor-General trusts that in future the public spirit of the Commissioners will lead them to recognise matters fully, and that their action will place it beyond the power of outside critics to impute to them indifference or a failure to justify the confidence of Government in entrusting to them the municipal arrangements of the metropolis of India.

The good effects that have resulted from what has already been done ought in themselves to encourage the Corporation to continue the good work upon a larger scale, and the public of Calcutta would, it is to be hoped, cheerfully bear the necessary burden. The Army Sanitary Commission once observed that the value of a single year's loss of productive labour which the existence of the present acknowledged evils entails upon the city would go far to pay for their riddance *in toto*. The important fact that the trade of India with Europe is seriously hampered by the quarantine regulations must not be lost sight of in this connection. These quarantine regulations are in force because of their supposed justification upon the continued prevalence of cholera in our large ports, and especially in Calcutta, which is regarded as the *nidus* of the disease. Every outbreak or rather re-appearance of the malady is, forthwith, followed by fresh restrictions upon commerce, and it has been found hopeless to get these removed or relaxed until the progress of sanitary reform has had a preventive influence upon the prevalence of cholera. The whole thing is in an unsatisfactory condition, and as mercantile interests are so largely at stake, it behoves the trading and shipping firms in England in particular, and Europe in general, to bestir themselves, and bring pressure to bear upon the lethargic Municipal Commissioners of Calcutta.

Calcutta, however, is not the only city that wants looking to. It is time that the good people of Bombay should awake to a lucid perception of the melancholy fact that they are not very much better off in this respect than Calcutta. The system of sewerage introduced a few years since at considerable cost, would seem to have some intrinsic defects of construction, the effects of which have been sadly manifest. Mr. Thomas Blaney, a local medical practitioner and Member of the Municipal Corporation, has discovered a *panacea* for this! He deprecates "closed sewers," and strenuously advocates "open sewers," and this in a tropical city!

That sewers must be properly constructed in this country with all the recent improvements which sanitary engineering, there can be no question, due weight being given to the influence of climatic agencies, and other points. The sewage must be carried away by means of water, of which there must be an adequate supply. Bombay has the superb advantage over Calcutta, of being a seaport; and with proper out-falls, I see no reason why sanitary work should lag behind when millions are wasted by the municipality. The carriage of sewage by water must be prompt and efficient, so that there can be little putrefactive change or generation of deleterious gases. Knowing the decrease in the mortality which has taken place, *pari passu* with sanitary advances in English cities, it would be simply foolhardiness and culpable inactivity on the part of the municipal bodies in this country to content themselves with the old arrangements.

The current issue of the *Indian Medical Gazette* has an interesting editorial article on "The Utilization of Condemned Criminals for Cholera Experiments," suggested by

an address by Mr. Cornish, F.R.C.S., recently printed in the same journal. Mr. Cornish says that "the suggestion has no element of cruelty about it, for it gives a few condemned criminals a chance of surviving otherwise unattainable, and only willing candidates would be allowed to become the subjects of scientific observation." He shows that from 300 to 400 persons are hung annually in India, and he thinks it could be arranged that a small portion of these victims of the hangman might be spared the final execution on certain conditions, their willingly submitting to experimentation, and should they survive that, their lives should be spared. There is nothing novel about this suggestion; it has been made more than once by the present writer, and also by Mr. Blaney, and others, of Bombay. It is sincerely to be hoped that it will be adopted ere long, and that Exeter Hall will not be allowed to mar the success of the only method of positive demonstration of the ætiology, &c., of cholera.

In the *Lancet* (August 29th) I notice a letter from Mr. W. J. Moore, C.I.E., Surgeon-General, Presidency of Bombay, complaining of the action of the General Medical Council in erasing his name from the *Medical Register* without his previously having received any sort of intimation on the subject of change of address. I would point out to the General Medical Council that it is absurd to put in force the rules applicable to members of the profession practising at home to those in the Public Services. It is, however, somewhat different in the case of practitioners resident abroad, and some members of the Indian Medical Service in civil employment with fixed addresses, which can be entered and altered in the *Medical Register*. It is to be trusted that they will take the above into consideration and amend this vexatious rule, and at the same time restore those names that have been erased for this reason to their legitimate places. I venture to think that Section 14 of the Medical Act (1858) needs this necessary alteration.

I understand that a movement is on foot to raise the standard of entrance from Matriculation to what is called the Previous Examination of the Bombay University, in the case of candidates entering upon their medical studies at the Grant Medical College in Bombay, and proceeding, after a four-years' course of study, to the Licence in Medicine and Surgery. Such a change, I am inclined to think, is to be welcomed. A course of, say, a year's study in Arts' Classes would do native medical students an immense amount of good, and would materially tend to facilitate their medical studies. It will at the same time enable them to acquire some knowledge in such important subjects as logic, natural philosophy, and languages.

---

[To the Editor of the Medical Times.]

SIR,—At the meeting of the Council of the Poor Law Medical Officers' Association, held at their rooms, 3, Bolt Court, Fleet Street, on Thursday the 8th instant (*inter alia*), the case of Mr. Isaac Flower, until recently Medical Officer of the Codford St. Peter district of the Warminster Union, Wilts, was taken into consideration and a resolution was come to, that I should lay the facts before the medical public through the columns of the *Medical Times*, &c., and in accordance therewith I have respectfully to request insertion of the following in your this week's issue. Mr. Flower was appointed district medical officer on the formation of the Union, 49 years ago, and has held office uninterruptedly during the whole of that lengthened period, to the satisfaction of the poor and the Board, before the latter of which he has never been arraigned nor his conduct in any way questioned. His salary, inclusive of all extras, was 100*l.* Last summer, finding that infirmities

were coming upon him which would interfere with the due performance of his duty (he has entered on his 75th year), he tendered his resignation, and at the same time made application for superannuation allowance. In due course the question came before the Board of Guardians for consideration. At such meeting Lord Heytesbury moved that a permanent annuity should be granted; this was negatived. It was then proposed that one year's salary should be given in the form of a gratuity; to this an amendment was made that the sum should be 50*l.* only. This being put to the vote was carried by 12 to 11; but we learn that up to the present Mr. Flower has not signified his acceptance of this insulting offer; he has, however, written to the Local Government Board stating the facts and asking their influence, and has received for reply "that it is entirely within the discretion of a Board of Guardians whether or not they will grant a superannuation allowance either for a limited period or otherwise to an officer on his ceasing to hold office, but they will, if he desire it, forward a copy of his letter for the consideration of the Warminster Guardians," a perfectly useless procedure, *per se*, as all that would accrue would be that the Board would direct that the Department's communication should be laid upon the Board-room table.

Having regard to the lengthened tenure of office, the high character of Mr. Flower, and his advanced age, this procedure of the Warminster Board of Guardians is in the highest degree unjust to this gentleman, and this brings me to the next point in my letter, where, let it be distinctly understood, I write for myself alone, and not under the direction of the Council. I refer to an increase of Medical Members of Parliament, by whose aid only can this permissive Superannuation Act be amended, as well as other legislative requirements affecting the pecuniary and social interests of medical men. I see that there are several medical candidates before the constituencies, and I further note that the two Scottish and the London Universities have candidates competing who are not of the medical profession. It is not to be expected that the present representative of the London University can be disturbed; but we surely can, if we like, wrest the two Scottish from the hands of lawyers or laymen. In the case of Edinburgh and St. Andrew's, we have an able, nay gifted, surgeon, Mr. Eriksen. I trust I shall not be held to be presumptuous in asking my fellow graduates to disregard all considerations as to whether this gentleman be a Liberal or Conservative, but vote straight for him solely on the ground that he is a high-class medical man. I would urge the same policy in every borough or division of a county where a medical man is a candidate, and I do so for the reason that there will be plenty of candidates left to take care of general political considerations, but unless we are up and doing on this occasion, we shall be in the future as we have been hitherto, without political influence in the councils of the nation, a want which I have experienced most strongly during the thirty years I have striven to secure medical, poor law, and sanitary reforms, through the action of the House of Commons.

I am, Sir, yours, &c.,

JOSEPH ROGERS,

Chairman, Poor Law Medical Officers' Association.

31, Montague Place, Russell Square,  
12th October, 1885.

## INVENTIONS AND IMPROVEMENTS.

### NEW AURAL SYRINGE, ADAPTED FOR SELF-APPLICATION.

By J. WARD COUSINS, M.D. Lond., F.R.C.S., Senior Surgeon to the Royal Portsmouth Hospital, and to the Portsmouth and South Hants Eye and Ear Infirmary.

THE brass instrument commonly employed for syringing the ears often renders this little operation tedious to the patient and troublesome to the surgeon. It demands the use of both hands. The syringe must first of all be charged, then placed in position within the aural orifice and discharged; it must now be removed, re-filled, and again inserted in the ear. This complicated series of movements often produces muscular weariness, especially when they have to be continued for any length of time. The new instrument is especially designed to overcome these inconveniences, and to make the operation easy of performance by the patient himself. It can be worked without any fatigue, and the elastic balls and valves are so arranged that only five or six contractions of the hand are required per minute to secure an efficient and continuous stream. The expansion of the hand ball is assisted by a recoil spring, and the force of the current is regulated by increasing or diminishing the number of contractions.
