Painting Peach House (W. H. M.).—We consider it most imprudent to paint a Peach house inside when the trees are in flower, and should not expect a good crop of fruit after the process.

Greenhouse Rhododendrons (C. H. B.).—A selection of varieties and cultural notes were given in this Journal, page 564, December 29th, 1887.

Cinerarias (G. H.).—The blooms are fine, one especially so. The fasciated stem is curious, and it may be worth trying to preserve both by suckers and seeds.

Lilium candidum Diseased (J. C.).—The disease is caused by a fungus (Peronospora), concerning which we hope to publish some particulars shortly, as similar examples were recently submitted to the Royal Horticultural Society's Scientific Committee for examination. The course you propose to adopt is the best under the circumstances.

Hardy Lilliums (An Old Subscriber).—The following do well with us outdoors:—L. candidum, L. croceum, L. longiflorum Harrisii, L. tigrinum splendens, L. auratum, English-grown bulbs being planted, and L. lancifolium or speciosum varieties. If more are wanted add L. chalcedonicum, L. testaceum, L. Humboldtii, L. superbum, L. colchicum, L. Thunbergianum, and L. umbellatum fulgidum.

Peaches not Setting (R. C. W.).—Many blossoms have failed to set on trees grown against walls in the open air this spring, chiefly, no doubt, in consequence of frosts accompanied by cold easterly winds being prevalent during the blossoming period. Netting and similar light coverings do not, nor cannot, ensure good crops of fruit in all seasons and districts, but are serviceable during the majority of seasons, and often effectual.

Dandelions on Lawns (F. B. Taunton).—We know of no better plan than the one that has been many times mentioned of dropping sulphuric acid exactly into the centres of the plants. It is usually kept in a stone blacking bottle, with wire round for carrying it, a stick with several notches cut in it an inch upwards from the end being plunged in for drawing out the liquid and applying to the weeds. It is quite useless if not placed full in the hearts of the plants, but one or two drops there burn down into the roots. The acid must not touch the hands, clothes, or boots, nor should the stick be rubbed on the grass, or brown unsightly marks will be left on the lawn. A handy workman soon becomes expert in the use of the acid. We have seen boys do more harm than good with it, and the work is not suitable for women.

Fig Trees Casting Fruit (A Subscriber).—The chief cause of Figs shedding their fruit is imperfect or non-impregnation, and arises from the trees not having a sufficiency of sun and air, the growths not being fully exposed to light so as to thoroughly solidify the growth as it is made, too high a temperature in the early stages of forcing, and an uncertain supply of water at the roots. With properly constructed borders Fig trees can hardly be overwatered after the fruit commences swelling until it changes for ripening. The fruit sent presents the appearance of being scorched at the apex, probably a consequence of the sun acting powerfully upon it whilst wet, air not being given sufficiently early to dissipate the moisture proportionately with the advancing temperature. It, however, was not fertilised, hence its falling.

Strawberries Dying—Peach Scalded (F. G.).—The Strawberries appear to be two or more years old—that is, offsets from old plants seem to have been potted, instead of runners having been rooted for growing into healthy young plants. Offsets from an enfeebled stock often collapse when the crop is advancing, the strain on the plants being too great for them to endure. Secure runners from young and healthy, not from old and semi-exhausted plants, and with good cultural attention they will not fail. There is nothing in your letter to enable us to form any definite opinion on the apparent scalding of the Peach. You do not say whether it was exposed or shaded, nor detail your practice as to syringing, temperature, and ventilation. It appears to be the Amsden, an American variety, and is perhaps superseded by the Alexander.

Roses under Glass (S. S.).—If you read Mr. W. Bardney's article on page 379 last week, you will observe that he advises portable roof lights or sashes, in order that they can be removed for ripening the wood, and inducing early and complete rest, when blooms are required in the winter or early spring; and there are few, if any, cultivators more entitled to be listened to on the subject, for we have seen Roses in his charge flowering as freely at Christmas and onward through the winter as at any time during the whole year. But Maréchal Niel is not grown for winter, but rather for spring flowering. When you ask whether "it is necessary to have the sashes removable, or whether ample top and bottom ventilation would be all that is needful," our reply is that we have seen equally good results under both systems. When we see as fine blooms as are sent into Covent Garden in April cut from plants under a fixed roof, the grower of them would not deem moveable sashes "necessary," though another grower who removes the sashes in the autumn and has similarly fine blooms might think his plan the better. It is thus a question of management. More Maréchal Niel Roses are probably cut from under fixed roofs than in houses from which the sashes are removed for a time. With the sashes portable you have a choice in the matter, as you can take them off or leave them on as you wish; but such a roof is more costly than a fixed one, and the Maréchal Niels referred to on the page quoted last week as being so well grown by Mr. E. Trollope were grown under a fixed roof. As the question then resolves itself into one of outlay and individual aptitude no one can be expected to settle the matter so well as yourself. As to shading, unless the glass is very inferior, and Roses are in good soil and under good management, they do not require to be shaded by covering the glass with anything at any period of the year.

Various (J. E.).—We have seen excellent beds of double Petunias, and on the other hand many that were not satisfactory. Much depends on the varieties that are grown and the weather. During a wet and generally cold summer double Petunias are seldom effective in beds, even in the south of England, or in Wales, where you reside. Last summer the plants flowered remarkably well in beds; but for massing, the single varieties are, as a rule, much more effective than the doubles, and exuberant growth is checked and floriferous induced by plunging the pots an inch or two over their rims in the beds, instead of removing them and planting in the usual way. The soil in the pots must not be dry when the plunging is done. Stout plants 3 or 4 inches through may be inserted about a foot apart. Marvel of Peru is not suitable for ordinary bedding purposes, though a mass may perhaps suit you. The flowers close in the daytime, except in dull weather, opening towards evening, and then diffusing a honey-like fragrance. The plants vary in height according to age, soil, and season, but generally attain a height of 2 feet, though we have had many bushes upwards of 3 feet high and the same in diameter. The tubers may be preserved from year to year. We have seen some nearly a foot in diameter. If your plants are seedlings, and you require to grow them in a mass, they may be planted 15 or 18 inches asunder. Zinnias grown in good soil and a warm position make brilliant beds. There is no better way of raising and planting them than you may find described on page 79 of our issue of February 2nd of the present year. Strong plants, similar to those there referred to, may be planted 9 inches apart. Smaller, such as we often see by less intelligent preparation, may be planted more closely, thinning them afterwards if needed. The Auricula sent is "peculiar" in colour, but not in being "unshaded as a self," because true selfs are not shaded, but many Alpines are.

Evaporation from Heavy Soil (W. R. R.).—The advice given in the book from which you quote is sound, as drainage and a loose ameliorated surface are the principal means by which heavy soil is made available in the highest degree for cultural purposes. Drainage by ridding the soil of water within 3 feet of the surface renders it drier, therefore warmer, which is demonstrated by grass land during a thaw, the surface immediately over the drains is freed of snow or "white frost" much sooner than in the spaces between the drains; in fact, the grass now (May 10th) over the drains a full yard wide is double the height of that on the intervening surface. The drains by carrying off superfluous water from the soil draw in, so to say, a corresponding quantity of air, which causes the water retained to be more divisible, hence sooner warmed. The air entering is particularly valuable as a direct source of fertility, and peculiarly so as supplying nitric acid for attacking stubborn substances, hastening the decomposition of vegetable and animal matter, making it sooner and in large proportion available as plant food. Decomposition means heat; stagnation, cold. It is an old and true saying that grass does not grow as it ought because the ground is "cold and wet," or, in other words, the grass does not grow because the soil is cold, and it is cold because wet. Evaporation only intensifies the effect of the cold temporarily, therefore is to be taken into consideration relatively with the condition of the soil and time of year, as evaporation from an undrained soil is different in effect to that taking place from soil efficiently drained. Evaporation means abstracting moisture and supplying its place by air, which at the time of year when cultural operations are practised is warmer than the water displaced; concomitantly soil deprived of water by evaporation is made drier and warmer because more absorbent of heat from the atmosphere. Evaporation from an undrained soil will tend to make the surface colder during the process, but no soil is in a fit state for cultivation that is allowed to contain stagnant water within 3 feet of the surface. Preventing evaporation or the escape of moisture with the heat absorbed by means of a mulch or covering of non-conducting material when required, is very different from preventing it by a close surface at all times of the year. Drainage on a heavy soil counteracts the tendency to a lower temperature by evaporation in summer. Throwing up the soil roughly in winter prevents its getting sodden, allows the water to pass more quickly to the drains, and the larger surface exposed admits of more rapid evaporation and subsequent absorption of heat. A loose surface of ameliorated soil is also the most efficient agent except mulching in resisting drought—that is, conserving moisture in the soil when needed in summer, because without the loose surface the soil would bake and crack, forming miniature chasms and larger rents through which the moisture escapes. A hard close surface is the great evil of heavy soil; it holds more water in the close state than in the loose, and its absorbing and retentive power both as regards heat and moisture are in proportionate ratio to its divisibility and porosity, and its wealth for cultural purposes is proportionate to its depth of ameliorated soil and the food assimilated therein.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (J. W. G.).—A double variety of Narcissus incomparabilis known as "Butter and Eggs." (S. K.).—A fine variety of Cattleya Mossiae. (S. P. E. S.).—The Narcissus is the double variety incomparabilis, known as Eggs and Bacon. It is totally different from N. capax. (J. W.).—Saxifraga oppositifolia and Sempervivum arborcum. It is not a Sedum. (T. W.).—Send us a specimen, and we will endeavour to give you its name. (J. C.).—No numbers were attached to your speci-

mens, the names cannot therefore be clearly indicated. The red flower is Kennedyya rubicunda, the white one Leptospermum scoparium. The Daffodil is a double Narcissus incomparabilis.

Stewarton Hive (A. R. C.).—The Stewarton hive, octagon or square form, can be had from Messrs. George Neighbour & Sons 149, Regent Street, London, whose advertisement appears in this Journal, and practical modes of management for these hives at all times are given in these columns. The Stewarton system is now recognised by all bee-keepers of note as the best.

Separators (J. G.).—In crates of sections. It is quite unnecessary to have pieces of wood, tin, or glass between sections. They obstruct the bees, reducing greatly the harvest of honey. They are meant to give flatness to the surface of the comb, but when managed properly the end is attained without them, to the great advantage of the bee-keeper, especially that of profit.

Bees Leaving their Hive (Inquirer).—In the absence of fuller information as to the whole history of the bees from the beginning, we can only conjecture what has been the cause of the bees leaving their hives, there being so many causes; but the one most probable is the queens were old ones and had been superseded by young ones last autumn, which had in all probability either missed fertilisation or had been lost when out for wedding purposes. Another cause which induces bees to leave their hive during the early spring is, if the hive has been kept too cold, to keep the bees in a normal state, a sudden warm blink of the sun rouses them into activity, and, becoming excited, they leave the hive. There are other causes, but not knowing all the facts we cannot give particulars.

COVENT GARDEN MARKET.—MAY 16TH.

GOOD supplies of all classes of fruit to hand. Vegetables of all kinds short, with the exception of Asparagus, which owing to the heavy consignments from the Continent is hardly cleared at low rates.

PRECISION IN FARMING PRACTICE.

If we required proof of the existence of a desire for improvement, and a lively apprehension that improvement in practice is possible among farmers, we have certainly had it during the last few months, for never before have we had so many applicants for advice about cropping and the selection and application of manure to farm crops. We have done the best we could for all our clients, and if our advice is accepted and acted upon in a literal sense it cannot fail to induce better practice and a proportionate improvement in results; for we have invariably insisted upon the primary importance of thorough drainage, cleanliness, and mechanical division, in order that the crop for which manure is used may derive full benefit from it. In addition to this we also require exact distribution of manure, and when chemical manure is used it cannot be applied with precision by hand, and the use of an implement is absolutely necessary. No implement which we have tried for this purpose is equal to the Excelsior drill. The quantity can be regulated to a nicety. It is drilled with seed just as regularly as the seed itself, or it is applied as a surface dressing alone by removing the coulters with a degree of precision that is perfectly delightful in comparison with the slovenly work done by hand. For example, if manure, consisting of a mixture of nitrate of soda, muriate of potash, steamed bone flour, and mineral superphosphate is sown by hand upon pasture, the heavy particles of soda and potash fall within a space only a few feet wide along the track of the sower, but the bone flour and superphosphate is carried some distance off by the slightest puff of wind. We have seen evidence of this repeatedly, and came upon a glaring example a few days ago upon some permanent pasture, where the grass along each track of the sower was of a deep green hue and robust growth, the intermediate spaces being of a comparatively weak growth and light colour. This difference arises from the speedy action of the nitrogenous manures, of which the greater portion of the surface was practically free. Sown by the drill this can never happen, for the manure is distributed evenly over the entire surface.

Frequently are we asked for a formula of the most suitable manure for certain crops. We always give it, but we are free to own that more or less than we recommend might probably be used with advantage. How are we to know this without that intimate knowledge of the condition of the soil to be treated, which the manager of each farm ought, but which he so frequently does not possess? Soil and seasons both exercise an influence for good or evil upon results. Knowing this as we do so well, how can we venture to give precise formulæ for general guidance? Science has been defined as precise or systematic knowledge, but in relation to agriculture it is best regarded as precision in degree. By all means let us strive for the possession of accuracy in every detail of farming, but do not let us forget how greatly results are influenced by atmospheric as well as soil peculiarities. If only we come to accord due weight to such natural influences, we shall not strive for unnecessary accuracy of weight and measure. It was for this reason, or rather this was one of our reasons for recently calling attention to the important fact that there is a residue in the soil of the fertility imparted by chemical manures after the crop of the year is harvested. It is true there may be some loss of nitrates from this residue in a wet winter, especially from light soils, and this must be taken into account in spring when calculations are made of the quantities of different manures required for the season. No doubt the marvellous results obtained by Mr. Cook at Fritcham Abbey by the use of muriate of potash for Barley has induced very many farmers to try it, and has led to much disappointment. Yet

good has undoubtedly been done, by showing how the want of enough potash, phosphorus, or nitrogen in the soil may prevent a full development of a crop.

Precision, then, in farming practice is best regarded as a relative term. Let us take care that it leads us to avoid all shams either in manures or seeds, that we use pure manures and pure seeds, that our practice all round is sound. We may be asked, Of what use, then, are the reports of agricultural experiments? We reply, They are invaluable if taken as guides to practice, provided there is no blind following of any of them. If a farmer would excel in the practice of his calling he must bring intelligence and common sense to bear upon it, and must prove for himself what or which are the best sorts and methods of manures and their application to the soil. But we may insist upon close accuracy in the preparation of the soil for the reception of manure and seed. Drainage, either natural or artificial, there *must* be; mechanical division of the particles of the soil there *must* be; weeds also *must* be kept down. Do these three simple primary conditions to precision in farming practice receive the attention they merit? If any of our readers had been with us on the day we write this article, when we walked over three farms of an aggregate area of nearly a thousand acres, they would have had ample evidence that they do not.

WORK ON THE HOME FARM.

Corn-hoeing still continues being done as briskly as possible, and we have had to urge the men doing this upon Wheat to greater exertion, for it has grown so fast that we feared the hoeing might not be finished before the Wheat became too high for such work. Rapidity of growth has been most remarkable where the top-dressing of chemical manures was given early in showery weather. We fully intended using the Excelsior drill for this work over the Wheat, but finding the soil too wet and soft for horses to go upon it hand-sowing had to be resorted to. We mention this as showing how no inflexible rule can be laid down for general practice. Farmers more than any class are subject in their work to conditions of weather, and when these prove adverse we have to make the best of them. We have seen reports in daily papers that the Wheat plant is backward in growth, and therefore a short crop was inevitable. Seeing as we do frequently much of the great corn-growing district of East Anglia, we cannot agree with this statement. Some Wheat is undoubtedly backward, but very much more is fairly forward. Thistles, Docks, Coltsfoot, Charlock, and Couch Grass have we among corn sown upon land taken in hand last Michaelmas, and we have every horse and man we can spare at work upon them, for never was the weather more favourable for the destruction of weeds, and true economy prompts the employment of all available labour power now to destroy these robbers of the fertility of the soil.

Since the weather has become more favourable to the promotion of free growth in grass and other green crops, the price of sheep has advanced so much that we have known a profit of 10s. per head made upon hoggets purchased only a fortnight ago. Upon one of our farms we have decided to fold sheep upon a weak Clover layer, which would not afford a full crop for hay, and by folding we may obtain a better second crop either for stover or seed. We have finished folding upon Rye, which is now left for a second growth for harvest, as we do not require the land for roots; had we done so it would have come admirably to hand for such a purpose, after being so well manured by the flock in folds. A full crop of Rye seed and straw is not unprofitable, and it always meets with a ready sale.

REMARKS.

- 6th.—Fine, but with very little sunshine.
- 7th.—Cloudy till 11 A.M. bright and warm after.
- 8th.—Generally cloudy except for an hour or two at mid-day, and rather close.
- 9th.—Bright, fresh and cool.
- 10th.—Cloudy early, gradually clearing, and bright in afternoon and evening.
- 11th.—Bright and fresh.
- 12th.—Bright and warm.
- A week of fine spring weather, temperature just the average. Gr. ss frost on the 11th.—G. J. SYMONS.

WAYS AND MEANS.

WE have the satisfaction of knowing that our observations published last week, entirely in the interests of the Royal Horticultural Society, were not wholly fruitless. The requisite details as to the probable nature and extent of the Exhibition then in preparation in the Temple Gardens, with the prices of admission, were precisely what some of our readers desired to know, and the information reached them just in time for attending the Show. We have, moreover, reason to believe that some of them will shortly become Fellows of the Society, while others prefer to wait the issue of events. There is a very large number of persons, and perhaps a very large majority, deeply interested in horticultural pursuits, who cannot bring themselves to believe that showing should be the chief object of a horticultural society. They rather regard such gatherings as means to an end—gaining public countenance and wider support, that may be applied in some practical and useful manner in furtherance of the greater and ultimate object—improved and extended cultivation of plants and crops; encouragement in the production of new varieties by art and by enterprise; testing them and estimating their merits, then disseminating the information for the public benefit. That is the ideal entertained by many, and in all probability an increasing number, of what a horticultural society should be, more especially one established on a Royal, which of course means a national basis in this country, because charters are only granted to institutions that are founded for the public good. We not only believe such an ideal to be excellent, but capable of embodiment as an actual fact. It is not a sentimental notion, but a practical proposition, and it only remains to ascertain the best methods for carrying it into effect.

All the efforts made in the interest of the Royal Horticultural Society, including shows, small and large, and all the expenditure incurred in the transaction of business, are in accordance with the eventual object indicated. This has been clearly stated in our columns by a member of the Council of the Society and of the advising Committee, who said that all the arrangements for holding shows periodically were made for obtaining support, by which the gardens at Chiswick could be better maintained, and horticulture in its widest and most important aspects represented for national purposes. That view of presenting the case not having been, so far as we know, opposed, the principle may be admitted, and there only arises the question of methods. This is essentially, and most properly, debatable, and has in fact been publicly debated by members of the Council and Committee, and views expressed thereon. If there were no divergence of views there could be nothing to discuss; but such a millennium has not arrived in conducting the affairs of this or scarcely any other Society. There are majorities and minorities in every corporation of individuals working for a common object, even in the closest of cabinets, and the majority rule, though many an example has shown that the minority was sometimes right. The Council of the Royal Horticultural Society is not a secret conclave. It used to be considered so, and press and private lectures have on no subject been so frequent as on the unwisdom, to employ a mild term, of the directorate not taking the public into its confidence. Whether desirable or not, and we pass no opinion on the matter at this moment, the days of cabinet secrecy passed with the appointment

of the advising Committee, for there is a commingling of members of the two bodies, and matters that are to be brought before the Council are discussed with persons other than members of those bodies. Whether the Society will be much stronger at the end of the year, and in a better position for doing horticultural work on the lines acknowledged as correct, than it was at the beginning, of necessity remains to be proved. Our strong hope is that it will be, and we shall rejoice in the opportunity of giving credit to whomsoever it may be due for the good work done and the satisfactory results achieved.

The number of Fellows enrolled during the past few months is highly gratifying and very encouraging. The zeal exercised on behalf of the Society by friends on the Council and Committees, and not less so by the officials, has borne good fruit, and as there is no fear of a cessation of endeavour, the numbers may be expected to go on increasing. Many have joined, not with the object of having their money expended on shows and for distributing among professional showmen richer than themselves, but for raising a strong fund for the Society to be expended for conducting substantial work in the common interest of all. It is due to Fellows holding those views, also to a noble few exhibitors and supporters who have staged their products without expecting pecuniary reward, and who have done much more than that, to state that the guineas of gardeners are not expended in the form of prizes at shows they cannot see. It is fortunate the Society has such excellent supporters and nothing but good can result through letting the public know it. The secret of success rests in a sound system of finance. This does not consist in miserly hoarding, but in investments that as far as human foresight avails, and experience warrants, shall be remunerative. Nor does it follow that an effort must be adjudged a failure if it does not directly and immediately bring profit. Seed has to be bought and some expenditure incurred in tillage before the harvest can be reaped; but scatter good seed on good ground and a satisfactory return may in due time be expected.

The Exhibition of last week was a sowing of seed, good seed, in fresh ground and promising. What the immediate result of the Show may be we do not at present know. A financial balance in favour of the Society could not be expected under the circumstances, and if there should be a near approach in that direction it would be encouraging. The locality was most favourable for attracting the affluent to see what is being done in the work of cultivation, and it was pleasing, indeed almost surprising, to find such a large attendance, including many persons of distinction, on an unmistakeably rainy day. Moreover, the visitors as a body were new to the shows of the Society, which is a great point gained. They were not seen at either the Kensington or Westminster Shows, where faces were and are so familiar and fresh visitors the reverse of numerous. During the course of years thousands of persons in the aggregate have no doubt attended the scores of minor shows that have been provided at short intervals, and have not been impressed sufficiently for speaking of them with enthusiasm and arousing an interest in the work of the Society amongst their friends. The public come to a show under the auspices of the Royal Horticultural Society with great expectations. These would be realised last week, and visitors, of which the Baroness Burdett Coutts is an example, are so satisfied that they urge others to go also and to support the Society. One exhibition of a commanding nature, and in a favourable position, is calculated to be of greater service to the Society than a score of small gatherings, the nature of which the public do not understand and may misapprehend. Periodical meetings of horticulturists for the examination of new, rare, and special products are most important, and records of them interest the whole of the horticultural community and keep the work of the Society before the world; but exhibitions for the public must nowadays be of considerable magnitude to attract attention. Nurserymen appear to be fully cognisant of this, and take care that when the public are

specially invited to their home displays that they do not go away disappointed.

If an exhibition like that of last week can be provided so quickly and such a good attendance be secured on rainy days, what may be expected if exhibitors have long notice to prepare for an event made widely known, and which may be fortunately held when the weather is as propitious as it was on this occasion uninviting?

Since the foregoing was in type we have received the following information:—"At the meeting of the Society held on Tuesday, the Council received a short statement in regard to the result of the Temple Show, and thought that it was eminently satisfactory, bearing in mind the extremely bad weather which prevailed on the first day, and which prevented so many visiting it. Sir Trevor Lawrence, the President, read letters from Sir Henry Ponsonby regretting that Her Majesty had been unable to attend, and also from Sir Francis Knollys that the Prince and Princess of Wales would have had much pleasure in attending if they had not had previous engagements. A letter of thanks was ordered to be sent to each of the Judges." We are also informed that eighty-two candidates were proposed and unanimously elected Fellows of the Society.

FORCED STRAWBERRIES—HOW TO PREVENT BARREN PLANTS.

ACCORDING to the information given by "T. J." (page 405) in reference to his plants proving barren, the first mistake that he appears to have made was relying on two and four-year-old plantations for runners. Plants so raised lack that vigour which is necessary to the production of strong bold well-ripened crowns early in the season. The energies of the fruiting plants are divided between the production of fruit and runners, the former having the first claim. Early runners produced by old plants at the flowering stage are quickly brought to a standstill as soon as the fruit commences swelling, seldom making any progress afterwards until the crop has been removed and heavy rains start the plants again into activity. The result is that plants raised from these late runners have the growth to make at the time of year when it should have been made. From all the varieties named, except Vicomtesse Hericart de Thury, I should expect a very large per-centage of barren plants when subjected to such treatment. But this variety, if true, seldom fails to fruit, even if the plants are small, but the crowns matured, this being indispensable. If "T. J." provide a young plantation from fruitful plants, prepared by layering in small pots or by cutting off the runners and starting them in a frame, and when well rooted planting them out 1 foot apart in rows 18 inches asunder during the month of August, so that they would be well established before winter, he would have a plantation from which he would secure luxuriant runners for layering early in the season. The only attention after planting is to keep the ground free from weeds, make the plants firm in February, if lifted by frost, and then mulch the ground. If the soil is light and dry previous to the flowers appearing (which should be removed as soon as they are sufficiently developed) a good soaking of water may be given, or liquid manure in a weak state if the ground was not very fertile at planting time. A plantation of this description will produce runners, which if pegged on the surface of 5½ and 6-inch pots, according to the variety and the time they are required for forcing, will make strong well-rooted plants by the time runners would be ready for layering from old fruit-bearing plants. It must be kept in mind that two or three weeks' growth in the early part of the season is of infinitely more value than thrice the length of time in autumn. Runners that have their constitution impaired through being brought to a standstill by the strain of fruit-bearing to which their parents are subjected, recruit themselves in good soil when carefully and liberally watered and syringed; but this is accomplished too late in the season, for the result is, that they are in full growth when frost brings them to a standstill, when half their season's work has not been accomplished. Such plants, with few exceptions, are certain to prove barren, and even those that do fruit I have not a shadow of a doubt produce only weak flower stems.

This evil has been aggravated by a too rich material for potting that appears to have been used, as well as over-feeding. Would your correspondent in making a plantation outside go to the labour, trouble, and expense of adding one-third of manure to the soil as necessary for the growth and fruitfulness of the plants. Such a quantity of manure even on the poor land would do more

harm than good. What would it do outside but produce luxuriant growth at the expense of fruitfulness? The same effect would take place under pot culture in even a more marked degree, for being constantly provided with water the plants would be stimulated to grow faster and longer even than those outside. If I had rich soil from an old pasture that had been recently stacked I should hesitate to use any manure. But under any circumstances with good ordinary loam an addition of one-seventh of manure is ample. If the soil is inclined to be heavy a little coarse sand might be added, and the manure would consist of horse droppings passed through a half-inch sieve. The droppings would be sweetened by frequent turnings, the same as would be necessary in preparing them for making a Mushroom bed. If the soil were light cow manure would be preferred. A little soot sprinkled over the drainage would be beneficial to the plants and assist in keeping out worms while the pots were standing on the border. Feeding, with soil of this nature should not give much trouble, and stimulants should only be applied when the plants have made a fair amount of roots and are in vigorous growth. This should not be persisted in too late in the season or the growth would not be ripened, and thus all previous care and attention would be wasted. One or two dressings of artificial manure applied to the plants are all that are really needed. We seldom give more than one application, for if the soil is crammed firmly into the pots they should contain ample food for the plants until they are top-dressed ready for forcing.

Another source of failure may be due to the heat and moisture to which the plants are subjected. Moisture three or more times a day, if I am to infer that is syringing and watering, with a temperature of 60° to 70°, is alone sufficient to cause the best and most matured crowns that can be produced to prove barren. Under any circumstances the Strawberry must be started gently. Especially is this necessary when the crowns have not been well ripened. Hurry them, and apply a super-abundance of moisture, and leaves, "nothing but leaves," will be the reward. At first a cool structure only is needed for two or three weeks, then the temperature should not exceed 50°, with a little air daily until the plants show signs of movement, when it may be gradually increased to 55°, but not before the flowers are visible, and a higher temperature is not needed before they are set. It can then be gradually increased to 60° or even 70°. To move the plants from a temperature of 55° to near 70° is too sudden a change, and may alone be the means of small instead of large fruit.

The atmosphere should not be too moist nor too close before the fruit is set. The syringe may be used once or twice daily according to the weather. Early in the season once will be sufficient, but when the sun increases in power it may be done twice. The plants should be carefully watered at their roots, never allowing them to become dry, but, on the other hand, they should not be saturated. Early in the season they would not need water applied to the pots even daily. Later it might be needed once a day, and at this season of the year in all probability twice. At this period of the year the plants are better a good distance from the glass where the foliage can partially protect the fruit from the burning rays of the sun the same as they are in a natural state. Early in the season the exposure of the fruit to the feeble rays of the sun is a decided advantage, for a few sunny days will do more to bring it forward than a week's hard firing. Having the plants close to the glass later is one of those fancy notions that have laid hold too firmly of cultivators, and which must be modified in a marked degree if successful results are to be achieved. I will return to the subject of Strawberry forcing, as there have been many failures this year, and others should be averted.—WM. BARDNEY.

THE LAURUSTINUS.

JUST now this favourite shrub is at its best, being loaded with flowers, and where they are growing intermixed with the red-flowering Ribes, Aucubas, and common Laurels arranged near the front of shrubbery borders the effect is very pleasing. My object, however, is to ask for more attention to be paid the plants to prevent their running up too high, and causing them to become naked or bare of branches at the bottom, which does not add to their beauty. It is well known that after the shrubs become established they are liable to send up strong shoots which, if allowed full scope, will throw them out of their true character by depriving them of their lower branches. These strong growths should either be shortened or cut clean out soon enough to prevent the shrubs being disfigured by the operation. Again, where they are getting old and their lower branches showing weakness, one of the best plans I know of is to layer them during the autumn. These will throw up young growths, and the shrubs be thereby renovated in a comparatively short time, and as they are not deep-rooting a surface-dressing of manure will help them to make fresh roots and promote healthy growth. In town gardens, where this shrub is so largely used, the above treatment would much improve the many unsightly specimens we often see. I am of opinion that it is not a good plan to dig among such

surface-rooting shrubs as is the practice in most places, but instead advise more surface hoeing and manure dressing, especially where the subsoil is not good. My employer is a great advocate of this treatment for most trees and shrubs, and the appearance of them and the growth they make amply prove the value of the practice.—THOMAS RECORD, *Folkington Manor*.

CROPS THAT PAY.

BROCCOLI.—The ground from which late Broccoli has been cleared, previously produced a crop of second early Potatoes. These were planted 3 feet apart, the same as all the early and second early Potatoes that we grow, except those planted closely together on warm borders. The rows of Broccoli are, therefore, 3 feet apart, and being naturally hardy in consequence pass the majority of winters safely. The ground occupied by late Broccoli is generally reserved for French Beans, the variety being Canadian Wonder. The ground between the rows of Broccoli is liberally manured during January. By digging only in the centre of the rows no injury to the crop occupying the ground results, but on the contrary, when the plants begin growing the roots quickly take possession of the manure that lays near the surface, and which is only just covered during the process of digging. We have found by this treatment that the heads of the Broccoli are larger than would be the case if the ground was left unmanured until the crop had been cleared away. This is no small advantage in rendering the crop a profitable one when the produce is solely required for market purposes. But there are other advantages that attend this mode of culture that cannot be overlooked. To get the succeeding crop in at the proper time is one of the first steps towards success. To have the ground to dig and manure at the busy season of the year when planting should be done and work presses heavily is bad and thoughtless practice, yet it is too often followed, and failure is the result. By preparing the ground at the time stated the Beans can be sown before the Broccoli are removed from the ground, which leaves the rows 3 feet from each other.

Those who have been in the habit of planting Beans close together may think that distance from row to row is a waste of ground. Experience has proved that a plot of Beans closely planted will not yield more than two-thirds of the crop that will be obtained if they are given ample room for each plant to branch freely and fully develop itself. If the ground is in good heart and has been well manured the variety advised will meet in the rows before the season is over. We strive, however, to snatch a crop of Cos Lettuces from between them. As the Broccoli are removed the space where they have been growing is turned over and broken up with a fork, and the Lettuces planted at once 9 inches apart in the row. To insure their doing well and being off the ground before the Beans crowd them, the plants must be strong and ready for placing out directly the Broccoli are removed. If the plants are small and weak the prospects of success are by no means certain. If, however, the Beans display the least signs of crowding the Lettuces, this can be prevented without injury to the Beans by placing a few stakes along the row and running a cord from end to end on each side. The Lettuces, if they do well, may be estimated at one-third of what the ground would produce if entirely planted with them. In depending upon these the Beans are a profitable crop, for they seldom realise less than twopence a pound. While on the subject of Beans it may be stated that Scarlet Runners are a profitable crop in some localities, not if they are staked on the orthodox fashion. The stakes, and the labour of staking combined, the extra distance they must be planted apart, renders the crop next to a profitless one. If staked, to do them well they should be 6 feet from row to row, unstaked 3 feet, or another 6 inches at the most. Directly they show signs of running the points are clipped off with a pair of shears. If this practice is followed two, three, or more times during the season they will fruit abundantly and not exceed the height and width of Canadian Wonder. In spite of this the returns from a given portion of ground will not equal in most localities that obtained for French Beans grown on the same space. Generally a halfpenny or penny per pound less is paid for them.

Our object in growing early and second early varieties of Potatoes only, and planting them 3 feet from row to row, is not altogether for the purpose of securing a second crop, although this is a matter of no small moment in rendering ground remunerative that has to be worked with the spade. The main object, however, is to get the crop off the ground and into the market before those under field culture are ready for digging. The lowest price by this system may be said to be 5s. a cwt. instead of 1s. 6d. less. The price falls quickly after farmers once commence supplying the market in quantity. It is only natural to suppose that the system of closer planting which they follow, even if the price is

lower, pays better than the method of planting 3 feet apart. This, however, is not the case, for the tubers can be planted closer in the row than they practise, and the greater space allowed for development results in a heavier crop of tubers than they generally obtain. Crops by this method on our rich land are enormous, and profitable at the price that can be obtained for them, without taking into consideration the second crop.

CAULIFLOWERS.—One of the second crops from amongst Potatoes, and generally one that pays, never better perhaps than last year, that is where the crop proved a success, is Veitch's Autumn Giant Cauliflowers. To grow these well they must be planted on rich fertile land, or the heads are too small to find a ready sale in the market. The seed should be sown in a cold frame about the middle of March, so that sturdy well-hardened plants are ready for putting out at once. A shallow drill between the Potatoes should be drawn and the plants placed 18 inches apart. They then become established, and are growing freely before drought sets in to prevent them from making good stuff. Once they are well established and growing freely dry weather does not appear to do them much harm. As the Potatoes are dug, if they can be given a soaking, if the weather is dry, of liquid diluted with water from the drainings of the manure heap, and the soil in digging turned over the moistened portion of ground to prevent evaporation, a rapid growth will follow. Fine heads which will prove profitable will result.—MARKETER.

PREMATURE FLOWERING.

WHY vegetables "bolt," to use a technical phrase—in other words flower before they are expected—why ornamental plants are made to flower in profusion by one man, whilst by another they are termed difficult; why some trees fruit, and others apparently undersimilar conditions are barren; and, to close, why some shrubs flower and others do not. These are questions which may not be disposed of in a flippant way. Such is the position of this question; and here I must confess to the recklessness or bewilderment of that honest and free-hearted Hibernian, who, when asked where he was going, said he did not know until he got there.

VEGETABLES.—I need not run over the whole range of our culinary vegetables. I, therefore, must typify them by such crops as Celery, Lettuce, Cabbage, Cauliflower, and Spinach. A discussion concerning these will at once throw light on the rest. I take them in order. Celery sometimes "bolts." What is the predisposing cause? If anyone was to ask me what would be the readiest mode of compelling the young Celery plants to "run"—that is, to blossom, I should answer, "Sow them early, transplant them in very rich soil, and let them stand thus before being finally planted, until they are 9 inches in height;" such will be sure to "run" betimes in the autumn or winter. Lettuces that endure the winter, commonly called early spring Lettuces, are notorious for being a long time in use without advancing to the blossom state, and why? Simply through the comparative absence of those exciting causes which cause plants to assume the blossoming condition. But Lettuces sown in May on rich soil, and transplanted when stout plants, will in general "run" before they make good hearts. The only way to obtain good hearted Lettuce in the heat of summer is to sow them in drills on the richest soil in the garden, if loamy so much the better. There they may be thinned out to the proper distance, and with waterings when necessary they will produce heads as fine as in spring. The Lettuces are a short-lived race, and any check after rapid growth during the exciting heats of summer will be sure to induce this blossoming habit. In the cool of autumn and early spring they bear transplanting well, for that kind of elaboration which tends gradually to the production of blossoms goes on very slowly, the exciting causes of heat and light being at a low point.

And now we come to the Cabbage. These are not so notorious for bolting as some other vegetables, and their tendency to run to blossom is at all times increased by any spurious mixture in their blood. How this occurs is not particularly plain, but certain it is that they are more excitable when such is the case. But the true Cabbages, sown at particular periods, are unsafe in this respect. Let anyone sow his best kind in the first week of July, and the probability is that they will all, or many of them, bolt in the succeeding April. The fact is, that they grow with too much rapidity in the month of September;—too fast to form a heart in that young state;—and, being transplanted, which they must be, at the end of that month, they receive a sudden check on the heels of grossness, and this check at once lays the foundation for the blossoming principle. But how different the result if the Cabbage seed be sown in the middle of August. By the period the young plants are up—say, the early part of September—the summer heat has declined; consequently, the plants grow more steadily and are shorter jointed; and the over-exciting causes being reduced to a fair equilibrium, the whole tendency of the plant is to produce what is termed heart, and a good Cabbage is the result.

In passing on to Cauliflowers, I may observe, that these are liable to "button," a technical phrase; and, I beg it to be understood that I am by no means the inventor of this term. It has been used by our great grandsires, and, still being accepted by practical persons, I do not feel

myself in a position to coin new terms. I will, however, endeavour to show that science itself recognises the facts connected with it, although she employs another kind of phraseology to express it. The term buttoning signifies forming a blossom-bud, or tiny head, whilst the plant is young. One man sows Cauliflower seed, genuine, in the third week of August, in order to produce early spring Cauliflowers in May and June. He sows them on rich soil, and transplants them—what he calls strong fine plants—in October, in frames or glasses, providing again very rich soil for them; for all the world, says he, knows that the Cauliflower requires a generous soil. But, how puzzled may this man be to find in March or April that out of a dozen handglasses, containing half a hundred permanent plants, he will not have much more than a score of Cauliflowers after all his pains.

Another man will sow his Cauliflowers at the same time on poor soil, or one of a moderate character, and transplant them on similar soil, and not one will button; yet they were from the same samples of seed. Here, then, is another case in point. The fact is, that if Cauliflowers, like Celery, are once allowed to become gross, in the seed-bed, or where they are transplanted, and are removed afterwards, they are sure to possess a tendency to button.

Spinach is another susceptible vegetable in this way, and the last I shall name in this section. This plant is very much excited by heat alone, irrespective of rich soils. Indeed, in this case at certain seasons, rich soils are averse to that speedy bolting, or running to blossom. Spinach sown in August stands the winter; and, be it ever so strong, it scarcely makes an effort to run to blossom until April or May. But the same kind, sown in the first week of June, will produce a very different plant. The former, stout, robust, and exceedingly prolific of foliage, also averse to a blossoming tendency; the latter, just producing a few leaves, with a highly attenuated stem, and rushing forward to blossom with celerity. This plant is, perhaps, one of the best we possess, for exhibiting to a student the influences of those laws which govern the vegetable kingdom, by presenting to him, in their extreme effects, a first proof, or sound and lasting impression. Spinach happens to be extremely excitable, more so than most of our ordinary vegetables. Heat is the most exciting cause, and this, combined with much solar light, is doubly influential as to the blossoming tendency. Thus, good gardeners sow their summer Spinach in shady situations, and on rich soil, in order that the growth may be as slow as possible in the plant, whilst the root is supplied with all the accessories to robustness.

It may now be seen that heat and drought, and much solar light, are predisposing causes; and the influences of these are much enhanced by checks of any kind, and by poor soil. Heat, of course, is highly exciting, as also trying to the whole system of the plant. Heat, with deficiency of moisture, has a strong tendency to hasten the development of all annual plants; and those I have selected to illustrate this matter, may, I suppose, all be termed annuals, in one sense at least. Indeed, like a host of other things, they are annual or biennial, according to circumstances; and to exemplify the latter is, indeed, the chief design of my remarks. Heat, with much moisture, has a tendency to produce a profusion of exuberant foliage, provided the soil is good. This condition of crops is called "proud" by many farmers. "My Wheat is too proud," they will say, "it will go down."

And what makes Wheat or other straw crops go down? What produces this habit, causes a crop of Cabbage, Lettuce, Spinach, &c., to become lumbering, or to use a technical phrase, "to smother itself?" The fact is, that the plant is too succulent, has grown too fast, and assumed a character similar to that of overfed and excited animals. I had almost said there was a disproportion of woody fibre. Drought in itself, without a superabundance of solar light, has a tendency to promote this "bolting" by withholding the necessary supplies, and this, more especially, if the subject has been previously much excited by heat, moisture, and a fair supply of nutriment. Such a course may be fairly classed under the head "sudden checks," the tendency of which I will further advert to. Those who would fully understand the character and influences of sudden checks, after an excitable condition, may refresh their ideas by a consideration of the effects of root-pruning, ringing, and those other manipulations. Who thinks of trying to make a seedling fruit tree bear when only two or three years of age? And why not? Simply because there must be a fund of strength or maturity previous to any attempt at fruitfulness. But let a fruit tree of any kind after being planted some three years, be planted at a proper season, and under proper circumstances, and the roots pruned withal, and you may feel almost assured that it will be covered with blossom-buds. Here, then, is the sudden check after high excitement; and acting in a manner much in analogy with checks on our ordinary vegetables.

But, to revert to drought and its effects on the foliage of plants, the flagging of vegetables in cases of extreme drought plainly shows what a change must be induced in the system. A lean or hungry soil is another cause of bolting in vegetables, as before observed. Let us also examine this portion of the question. Such soils are generally "hired" to perform their duty by a little extra decayed manure; and, indeed, without it they would be all but sterile. The term "hiring" is much used in our north-western quarter to signify that the land in question is "ploughed out," to use a farming expression, or, in order to please the gardeners, let us say "dug out." But still these technical terms may need translating, to suit ladies and gentlemen of other localities, and it simply means in its practical acceptance, that the properties the soil acquired whilst in a rest state or pasturage are exhausted; there is scarcely

anything soluble left in it, the organic materials especially being used up.

Then there is the sudden check occasioned by transplanting things after growing somewhat gross, and I must offer a few remarks concerning it. Plants thus circumstanced have already a fund of sap in store, nearly equivalent to the demands of the fructifying principle, and the only thing necessary to induce the habit is a temporary and partial cessation of rapid growth, and that this is a sure consequence of summer planting is notorious to everyone. But our readers may like to know why this result should follow, and without attempting to flounder amongst abstruse phases of science, I may offer a simple explanation, which will, I think, be borne out by both science and practice. We all surely know that the principal functions of plants may be, for an off-hand purpose, reduced to two divisions—absorption and elaboration. As for the process of assimilation, or the appropriation of the elaborated sap, we may pass it by, taking it for granted that, as in the animal world, so in the vegetable, the frame is built up and the general purposes of nature carried out by a process of the kind. Now, there is at times, I conceive, a condition in which the root is able to satisfy the demands of the branch, and *vice versa*. When the former is the case what may we expect but a tendency to produce leaves and branches, and a postponed fructification; when the latter, a precocious tendency to the blossoming principle, which soon, of course, overtakes the supplies. And this applies to fruits, and even shrubs, as well as vegetables. Thus, even a common countryman, without any recognition of such facts, instinctively, as it were, cuts off a part of the exuberant foliage of his Cabbages, his Greens, or his Swede Turnips, and this, although performed by mere rule of thumb, happens frequently to be correct as to principle, inasmuch as it reduces the perspiring powers of the plant, thus avoiding too heavy a tax on the root action, now in a somewhat debilitated state. I mean, of course, when transplanting gross or leafy plants during warm weather.—R. N. E.

EELWORMS AS GARDEN PESTS.

We are inclined to think that these creatures occur more frequently in gardens than has been hitherto supposed, the mischief they do being attributed to other enemies as insidious which lurk in the soil of gardens and beds. In the course of 1886 we received several communications from a correspondent in this journal describing the annoyance and loss he was experiencing from the attacks of some mysterious insect, which was seldom seen and difficult to secure, but which seemed to be extending its ravages alike amongst flowers and vegetables. On examination it was found that the soil was infested with at least two species of the millipede tribe, *Geophilus longicornis* and *G. subterraneus*, and it also contained specimens of a species of eelworm in different stages of growth. These, by most, would probably be taken for extremely minute worms of the earthworm tribe. Their identification, however, was not then possible; they might have belonged to the species which Miss Ormerod has specially noticed in her annual entomological report, and which had previously been chronicled as occurring at the roots of garden plants, or if not, then to a species very similar in size and habit.

Doubtless the effects produced by this eelworm vary according to the nature of the plants it may attack, but to the Oat, upon which it has now been found for some years, it is injurious by causing the curious appearance known as "Tulip root," a diseased swelling at the base of the stem; the leaves also take a sedge character. Having been found besides swarming at the roots of the Teazle, there originated the earlier name of *Tylenchus Dipsaci*, but as it is now believed to visit a large number of plants, its appellation has been changed to *T. devastatrix*, alluding to its activity as a destroyer. During 1887 samples of this pest were obtained from Clover fields in counties lying as far apart as Kent and Linlithgowshire, farmers complaining of "Clover sickness" amongst their crops, a malady formerly ascribed to a fungus, and many fungoid spores were observable, but the abundance of eelworms also at the roots suggested they might be the cause of the mischief. Dr. R. Bos, a naturalist, who had frequented the *Tylenche* in the fields and gardens of the Netherlands, verified the Clover specimens sent him as being *T. devastatrix*. He has reported instances of its damaging Onion crops and feeding on the roots of meadow grasses, on Rye, and of course on Oat, both in England and on the Continent. Oats grown on sandy or gravelly soil are most affected, and in severe attacks the ear is never formed. This eelworm has been discovered on Carnations occasionally, a peculiar malformation which Dr. Bos styles the "Pine Apple growth," and Hyacinths have been infested, the effect being "ring disease." It was supposed *T. devastatrix* visited crops of Beans and Peas sometimes, but Dr. Bos thinks it does not touch these plants. Minute as are the eelworms, their length varying from the sixth to the twenty-fourth of an inch, so that some cannot be seen without a magnifier, it is believed each individual worm lives several years, and not only so, such is their vitality, that after being eaten by animals they will pass through them uninjured to recommence their attack on vegetable substances. Ordinary insect killers do not touch these eelworms, but gas lime proves effective, and also manuring with a mixture of the sulphates of ammonia and potash. It must be allowed that all the eelworms are not to be dreaded, for certain species appear to limit themselves chiefly, if not entirely, to decaying matter, and hence form a part of the great army of Nature's scavengers.—J. R. S. C.

SCUTICARIA KEYSERIANA.

At the Temple Show of the Royal Horticultural Society last week, Messrs. Sander & Co., St. Albans, exhibited a plant of a new *Scuticaria* from the Roraima district, and which was named in honour of the Lord Mayor of London, *Scuticaria Keyseriana*. It has the same habit as the other species, *S. Steeli*, *S. Hadweni*, and *S. Dodgsoni*, which are all South American, the leaves being

FIG. 55.—SCUTICARIA KEYSERIANA.

several feet long, cylindrical or quill-like, and pendulous; the flowers fleshy, with broad petals and sepals heavily spotted with purplish maroon on a yellowish ground; the lip broad, open, and streaked with a similarly dark colour on a lighter base. The plant is a handsome one, owing to the clear well-defined markings.

CATTLEYAS.

ALL that are in flower should, if practicable, be arranged by themselves, so that their flowers can be kept perfectly dry. When mixed with the general stock of plants and the syringe used, it is very difficult to keep them from becoming spotted. They last longer in good condition when a cooler and drier atmosphere can be given them during the time they are in bloom. This provision is beneficial, not only as far as the lasting of the flowers is concerned, but those not in flower can be given the treatment they

require, which it is impossible to do without injury to the flowers more or less when the whole are mixed together. Those growing and rooting freely should occupy the warmest position in the house where a close moist atmosphere can be maintained, and the plants syringed twice on fine days. During dull weather the syringe need not be used; in fact, only when the water that lodges in the new growths can be evaporated with certainty once in every twenty-four hours. When this is done no injury to the young growths will result from water lodging in them. On fine days this can be readily prevented by giving air early in the day at the top of the house. Those that have not yet started into growth should be watered carefully, but more liberal supplies will be needed from the present time. Plants growing in baskets and on blocks with little or no moisture-holding material about them must have constant attention. Syringe plants in this condition liberally, so as to thoroughly soak the wood to which the roots cling; merely dewing them over is useless, for the moisture is gone very soon afterwards. Plants subjected to such treatment seldom make satisfactory progress, but if well soaked and syringed they will do well and perfect strong stout pseudo-bulbs.

COOL ORCHIDS.

ARTIFICIAL heat can be dispensed with for the occupants of the Odontoglossum house, except on solitary nights when the thermometer falls very low. The atmosphere must be kept moist by throwing abundance of water about every available part of the house. Dry atmospheric conditions are detrimental to these plants, and can be avoided if the house is kept close and shaded instead of admitting air liberally when drying winds prevail. More liberal ventilation will be needed than has been the case up to the present time, which will entail greater care in keeping the necessary quantity of moisture in the atmosphere. The plants should have abundance of water at their roots, and no harm will be done them if some is applied to the foliage. They must not be unduly shaded, but every ray of light possible should be admitted to them, so that their growth will be short and stout. It is necessary only to protect the plants from bright sunshine. A close confined atmosphere combined with overshadowing will draw up the foliage so weakly that it will not have strength to maintain an upright position. Pseudo-bulbs made under such conditions seldom flower satisfactorily.—N. G.

ROYAL HORTICULTURAL SOCIETY.

SUMMER SHOW IN THE TEMPLE GARDENS.

MAY 17TH AND 18TH.

LAST week we gave a brief indication of the character of this Show, but a few more details of such a remarkable Exhibition will no doubt be welcomed by many of our readers. Most unfortunately the weather was of the worst possible character on the opening day, rain falling with scarcely any cessation. It was better on the second day, but showers were frequent. Exhibitors came forward in greater numbers than seemed to be likely at one time, and the exhibits throughout were of a most interesting description and high quality. Large as was the space provided it was adequately filled.

The entrance marquee, 200 feet long and 30 feet wide, was devoted mainly to the groups of market plants in competition, hardy plants, cut flowers, and fruits. The groups were arranged upon the grass on the right hand side, and a very bright and varied effect they afforded. A stage upon the opposite side contained the cut flowers, while it was found necessary to have a central stage also for miscellaneous collections, and some groups of cut flowers which could not be accommodated at the side. This tent was remarkably well filled, and the inspection of the numerous exhibits occupied the visitors a considerable time.

By far the most beautiful portion of the Exhibition was, however, contained in the spacious marquee at right angles with the one just mentioned, and as this was 160 feet long by 60 feet wide it afforded ample room both for plants and people. The central stage running the whole length of the marquee had one side filled with Orchids, one of the most extensive and handsome displays of these varied and beautiful plants that has ever been provided in the metropolis. Some of the important amateur and trade collections were represented, and the plants throughout were distinguished alike by their vigorous health and their profusion of flowers. The other side of the central stage was filled with miscellaneous groups, Pelargoniums, &c., while around the sides of the marquee were some scores of specimen Roses, from huge bushes 6 or 7 feet high to compact little plants in small pots, all bearing abundance of blooms. The Orchids, Roses, groups of plants, and the cut flowers were in fact the great features of the Exhibition, and were alone worth a long journey to see.

On Thursday the Show was visited by the Lord Mayor of London, accompanied by the Lady Mayoress, the Right Hon. W. E. Gladstone, M.P., and J. Chamberlain, M.P., with many other distinguished persons, and the attendance was much better than could have been expected in such unfavourable weather.

ORCHIDS.

A magnificent group of Orchids was contributed by Baron Schröder, The Dell, Egham (gardener, Mr. Ballantine), and the silver cup

awarded as the first prize in the class was an appropriate recognition of its merit. The principal plants were the following, but every one staged was of exceptional character, the strong growth and high colour of the flowers being very marked. *Cymbidium Lowianum* had seven long racemes of large flowers, the tip very deeply coloured. The specimens of *Odontoglossum vexillarium* were extraordinary alike for their fine healthy condition and the number of their flowers; they were literally masses of bloom, and they varied in colour from the deepest of the rubrum type to some nearly pure white. *Cattleya Skinneri* was represented by two handsome plants loaded with flowers, one variety of unusually rich colour, and in contrast with them were valuable plants of the pure variety *alba*. *Odontoglossum Roezli* was notable in the fore part of the group. Of *O. crispum* there were some of the choice varieties for which the Dell collection is famed. *Masdevallias Veitchiana grandiflora*, *Harryana armeniaca*, apricot coloured; *Lindeni* and *Chelsoni*; *Cattleya Regnelli* with seven large flowers, and the dwarf pure white *Aerides Williamsi* (certificated) were a few other good plants amongst many others of scarcely less interest.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorling (gardener, Mr. Bickerstaffe), exhibited a group of Orchids, for which also a silver cup was awarded, and though the plants were smaller and less effective individually than the preceding they comprised some of the most interesting in the Exhibition, and all were in excellent condition. Very conspicuous was a plant of *Lissochilus giganteus*, having a flower stem 8 feet high, the flower-bearing portion 12 inches long and crowded with large, soft, rosy-tinted flowers. The peculiar *Selenipedium Lindeni*, or *Uropedium*, as it is better known, which is like a *Cypripedium caudatum* without a lip, had several of its remarkable flowers with long green striped sepals and still longer, narrow, dull purplish petals. *Catasetum Christyanum* had some strange brown and green flowers with fringed lips; *Acanthophippium bicolor* had twelve flowers, white tipped crimson; *Spathoglottis Kimballiana* is a distinct effective plant with large yellow flowers at the apex of a long stem; *Cypripedium caudatum* had thirteen fine flowers; *Cyrtopodium Andersonianum* had a three-branched panicle of yellow flowers; *Oncidium Marshallianum*, two beautiful panicles, with *Dendrobium Brymerianum*, *Oncidium undulatum*, *Masdevallias*, *Odontoglossums*, and innumerable others. Some very handsome varieties of *Anthurium Schertzerianum* were also sent from the Burford Lodge Gardens, the fragrant Violet-like *Tinnea aethiopica* and the New Zealand Forget-me-not, *Myosotidium nobile*, which few succeed in growing well.

In the classes for nine Orchids and a group of *Cattleyas* and *Laelias* Mr. J. Cypher, Cheltenham, was the only exhibitor, and he was awarded first honours in each case, securing a silver cup for the nine Orchids. The plants were the same as those with which on the previous day Mr. Cypher was equally successful at Regent's Park, and they need not be particularised. It must be mentioned, however, that the superb varieties of *Laelia purpurata* in both classes were greatly admired.

A beautiful group of *Odontoglossums* from H. M. Pollett, Esq., Fernside, Bickley (gardener, Mr. W. Parks), won the premier award in that class. The plants comprised capital examples of *Odontoglossum Edwardi*, *Halli*, *Andersonianum*, *Pollettianum*, *crispum*, *Wilckianum*, and *Ruckerianum*, tastefully arranged with *Adiantums*, and the collection altogether was an extremely pleasing one. F. Wigan, Esq., Clare Lawn, East Sheen (gardener, Mr. D. East), showed a choice group of Orchids and Ferns. Major Lendy, Sunbury House (gardener, Mr. S. West), was first with a collection of Orchid flowers, and J. Hemwerde, Esq., Elliott Place, Blackheath (gardener, Mr. G. Barker), showed two large plants of *Cattleya Mendeli*, one having eighteen flowers, and the others a less number.

Messrs. F. Sander & Co., St. Albans, arranged an exceedingly beautiful group of *Odontoglossums*, *Cattleyas*, and Ferns. The varieties of *Odontoglossum* comprised some of the most distinct and handsome in cultivation, together with the grand varieties of *Cattleyas*, *C. Mossiae londinensis* and *C. Mendeli Rothschildiana*, with the new *Scuticaria Keyseriana* noted in another page. A silver cup was awarded for this group, and to Messrs. H. Low & Co., Clapton, for a pretty group of Orchids, and Messrs. H. Page & Son, Teddington, also had a group of *Cattleyas*, *Odontoglossums*, and *Oncidium Marshallianum*.

ROSES.

As already mentioned these formed an important portion of the Exhibition, and the plants were excellent in all respects, well clothed with foliage, and bearing substantial blooms. Messrs. Paul & Son, Cheshunt, won a silver cup as first prize in the class for twelve Roses in pots, these being much the largest specimens shown, 4 to 7 feet high, and about the same in diameter. The varieties were Charles Lawson, John Stuart Mill, Catherine Soupert, Centifolia Rosea, Celine Forestier, Cheshunt Hybrid, Beauty of Waltham, Edouard Morren, Juno, Madame Victor Verdier, Magna Charta, and Comtesse de Serenyi. Messrs. Jackman and Son, Woking, were second, and secured a silver Banksian medal, as besides their twelve specimens they had a group of similarly creditable plants. Mr. C. Turner, Slough, was third, his Roses being neat compact examples of good varieties, about 3 feet in diameter, very useful, but too small in comparison with the others. Mr. Wm. Rumsey, Waltham Cross, showed in the same class, his plants being highly commended.

A non-competing group of Roses in pots and cut blooms from Messrs. W. Paul & Son, Waltham Cross, won the exhibitors a silver cup, and occupying a portion of one side and the end of the large marquee this collection had a wonderfully fine appearance. Numbers of choice varieties were shown, but the distinct new hardy Tea Rose Sappho,

certificated at Regent's Park on the previous day, was notable amongst them, together with the rich crimson H.P. Crown Prince, both Waltham Cross seedlings.

GROUPS.

The groups staged in the classes provided by the schedule, and those of a miscellaneous character not in competition, occupied considerable space and formed one of the characteristics of the Exhibition. With a group of plants occupying a space not exceeding 150 square feet Messrs. J. Laing & Co., Forest Hill, were first with a highly effective well arranged contribution similar to that so much admired in the centre of large marquee at Regent's Park on Wednesday. Palms and Crotons formed the background, with large Azalcas, Aralias, Caladiums, and Dracenas, smaller plants of *Odontoglossum crispum*, *Cattleyas*, brilliant Tuberos Begonias, Pimeleas, and *Gloxinias* occupying the body of the group, with a margin of *Odontoglossum* and *Caladium argyrites*. *Gloxinia Madame Bleu*, which has been certificated elsewhere, is a pretty variety, crimson edged white.

The competition in the class for groups of plants from market growers was remarkably keen, and the collections of well-grown, useful, and brightly coloured flowering or elegant foliage plants, added largely to the interest and beauty of the Exhibition. Three silver cups were offered by the Duke of Bedford in this class, and one for cut flowers, those for groups being won by Mr. William Icton, Barnes and Roehampton, and by Mr. J. Sweet, Newbridge. Mr. Icton's collection comprised tall handsome Palms with a margin of *Dracena Lindeni* and *Isolepis*, simple, yet very attractive, and a suitable position was assigned it in the large marquee near one of the entrances. Mr. Sweet's group was chiefly composed of flowering plants, decorative *Pelargoniums*, *Fuchsias*, *Cinerarias*, *Heaths*, yellow *Marguerites*, *Myosotis*, *Heliotropes*, &c., and though groups of this character often have a rather glaring and even startling appearance, the bright colours were so well placed, and softened by sufficient dwarf Ferns, that it had a satisfactory effect. Mr. E. Rochford, Cheshunt, was second with a rather more formal but bold group, *Hydrangeas* forming the chief feature, in contrast with miscellaneous flowering plants and Ferns. Mr. H. B. May was also second for a group of Ferns, Crotons, and a few other foliage plants arranged with the greatest taste, and though no flowering plants were employed, it found as many admirers as the two first prize groups. Messrs. J. & J. Hayes, Lower Edmonton, were third for a well contrasted array of flowering plants.

Calceolarias from Mr. James, Farnham Royal, gained the first honours in this class, the flowers large, and of the varied rich colours and delicate markings that distinguish his plants. For a group of *Pelargoniums* Messrs. J. & J. Hayes were first, their plants including some admirable varieties, one named *Fanny* being of a delicate pale pink, of compact habit and very free. The groups of hardy plants were practically the same as those at the preceding day's show, and the prizes were awarded in the same order—namely, to Messrs. Collins Bros. & Gabriel, Hampton; T. S. Ware, Tottenham; and Paul & Son, Cheshunt, the first-named winning their position by the larger size and greater effectiveness of the plants shown, the other two having more numerous and smaller plants, but several of much interest. Considerable difference of opinion respecting the respective merits of these collections was, however, expressed, and many persons preferred the second group to the first.

Nine well-flowered Azalcas from Mr. C. Turner secured him the first prize in the class, but he had no opponent. The plants were of medium size, but the varieties were either new or included some of the most effective, such as *Cordon Bleu*, M. Thibaut, the double white *Madelinc*, *Comtesse de Flandres*, *Apollo*, *Etendard de Flandres*, *Chelsoni*, *Jean Vervaene*, and *Vervaeniana*. In a large Exhibition of this character a few Azalcas are almost indispensable, as they afford a remarkably massive and brilliant colouring, but many of the giant specimens have an overpowering effect.

Pelargoniums, too, of the show, fancy, and decorative types are welcome additions at this time of year, the nine premier specimens from Mr. Turner comprising the best of those he had at Regent's Park, flat-trained specimens, 4 to 5 feet in diameter, and extremely well flowered. The show varieties were *Prinee Leopold*, scarlet; *Lady Isabel*, purplish with maroon blotch; *Kingston Beauty*, white with purple blotch; *Amethyst*, crimson, dark upper petals; and *Matin*. The fancy varieties were *Princess Teck*, *East Lynn*, *Fanny Gair*, and *The Shah*. Messrs. J. & J. Hayes were second, with capitally grown plants of the decorative market type. *Princess Maud*, *Duchess of Bedford*, *Goldmine* very bright and showy, *Triomphe de St. Mande*, and *Lady Blanche* were some of the best.

One of the most simple yet tasteful groups in the Exhibition was that from Messrs. J. Veitch & Sons, Chelsea, and for which a silver cup was awarded. Those employed were dwarf compact Japanese Maples in all their diversity of foliage both in form and colouring, about a dozen strong examples of *Lilium Harrisii* with large heads, massive pure white trumpet like flowers, a number of the rich and showy Tree *Pæonies*, side plants of *Hydrangea paniculata grandiflora*, and a front plant of *Arundo donax variegata* beautifully striped with pure white and green. The Maples were exceedingly graceful, the most distinct forms amongst them being *palmatifidum*; *flavescens*, yellowish; *dissectum*, red, deeply divided; *decompositum*, finely cut and handsome; *sanguineum*, large deep red; *japonicum aureum*, golden, fine leaves; *linearilobum*, dark purplish red, linear regularly spreading segments; *septemlobum elegans*; *purpureum* dark reddish purple, fine; and *roseo-marginatum*. The numerous delicate shades of green, yellow, and red of the leaves in these Acers render them great favourites both for outdoor planting and

decoration under glass. The chief of the Tree Pæonies were *Rosea*, salmon scarlet; *Incarinata*, salmon, very large flowers; *Reine Elizabeth*, bright red large flowers; *Berenice*, purple; and *Carolina*.

Mr. B. S. Williams, Upper Holloway, was awarded a silver-gilt medal for an extensive well arranged group of miscellaneous plants, comprising both flowering and foliage specimens from stove and greenhouse with Orchids. *Dracenas*, *Crotons*, *Anthuriums*, and *Azaleas* formed the background and greater part of the group, and amongst them the following plants were notable—*Lælia purpurata*, very fine; *Eurycles australasica* with white flowers and *Eueharis*-like leaves; *Phoenix rupicola*, a tall graceful Palm; *Nepenthes Mastersi* with deep red pitchers produced most freely; *Calanthe veratrifolia*, pure white flowers in good heads; *Davallia tenuifolia Veitchi*, an elegant Fern with finely divided fronds; the peculiar *Ataccia cristata*, with small dull purplish brown flowers in a dense head, large erect bracts at the back, and long drooping filaments; *Ochna multiflora*, with red persistent calyx and green fruits; the neat white *Gloneria jasminiflora*, and the white *Azalea Miss Buist*, a useful variety of the *Amœna* type, *Imantophyllums*, *Amaryllises*, *Crinums*, and *Dracæna Lindeni*.

Messrs. J. Laing & Sons, Forest Hill, were awarded a silver-gilt medal for a group of well grown *Caladiums*, about sixty plants 4 feet high and as much in diameter, the leaves well developed and deeply or delicately coloured. Some of the more noteworthy were—*Candidum*, white with green veins; *Madame Imbert Kæchlin*, yellowish green with red spots; *Duchesse de Montemart*, white; *Ibis Rose*, pale rose; *Charlemagne*, large, red; *L'Automne*, green and white, bold; *Princess Royal*, red, edged with greenish yellow; *Luddemanni*, green dotted white, red veins; *minus erubescens*, red edged green, dwarf and small, a good companion for *argyrites*. Messrs. Laing & Sons also had a pretty little group at the end of the centre stage near the entrance.

Messrs. H. Cannell & Sons, Swanley, contributed groups of *Tuberous Begonias*, comprising several distinct novelties, both single and double; and of *Calceolarias*, representing the Swanley strain, notable for compact habit, large and variously coloured flowers; and several stands of *Zonal Pelargoniums* of dazzling colours. Messrs. J. Carter & Co., High Holborn, showed a group of excellent *Cinerarias* and *Primulas*, both admirable strains. W. Clay, Esq., Kingston, sent a group of *Pelargoniums*. Mr. R. Drost, Kew Nursery, Richmond, had a group of *Palms*, *Ferns*, and *Lilies of the Valley*. W. Mellor, Esq., Chingford, Essex (gardener, Mr. J. Nicholson) contributed a pretty group of *Caladiums*, very neat plants. Mr. T. S. Ware, Tottenham, had a group of *Tree Pæonies*, *Tulips*, and *Daffodils*. Mr. G. Poulton, Edmonton, exhibited an effective group of *Coleuses* and *Lilium longiflorum* and *candidum*. Messrs. J. & J. Hayes, Edmonton, had a group of *Pelargoniums* and *Hydrangeas*; Mr. G. Braid, Winchmore Hill, a group of *Pelargoniums*; and Mr. H. B. May a group of *Calceolarias*, *Mignonette*, and *Adiantums*.

CUT FLOWERS.

In two-day summer shows the cut flowers are usually the most satisfactory portion of the exhibits, but at the Temple perhaps the only advantage of the wet dull weather on Thursday was that the flowers lasted well until the end of the second day, and looked almost as fresh and bright as when first staged. Though these exhibits are always interesting, they rely more upon their individual attractions than general effect, as they cannot be arranged to much advantage upon long straight tables. Messrs. Barr & Son, Covent Garden, had a very extensive contribution of *Daffodils* and *hardy flowers*, a choice selection of the former in all the types, and the most distinct of the latter for general garden culture, *Saxifraga pyramidalis*, *Anemone fulgens*, *Doronicums* and *Irises* forming prominent features. A silver cup was awarded for this group, and a cup given by the Duke of Bedford was awarded to Mr. Poupart of Twickenham for a collection of market flowers, comprising *Lilies of the Valley*, *Narcissus poeticus* and *biflorus*, *Forget-me-nots*, *Trollius*, *Tulips*, *Anemones*, *Wallflowers*, and *Campanulas*. In the class provided for *hardy flowers* by the Society, Mr. T. S. Ware won first honours with an excellent collection of *Daffodils*, *Tulips*, *Lilies*, the double bright red *Anemone Le Brillante*, *Lupinus Nootkanus*, the white *Ranunculus amplexicaulis*, and the yellow *R. speciosus*, with many others. The second place was taken by Messrs. Paul & Son, Cheshunt, who had a varied and interesting collection, including representatives of most of the best hardy plants in flower at this time of year. The only other class specially for cut flowers was that for twenty-four *Roses*, in which Mr. Rumsey, Waltham Cross, took the lead with admirable blooms of both *Teas* and *Hybrid Perpetuals*, Mr. C. Turner and J. Walker, Thame, following in the order named.

From Mr. J. Walker's farm at Whitton came a remarkable collection of fancy, *Parrot*, and other *Tulips*, which were as much admired as any other exhibit in the same tent. *Daffodils* and *Doronicums* from the same grower were also good, and a silver-gilt medal was awarded for what was one of the best contributions of cut flowers in the Exhibition. Messrs. Hawkins & Bennett, Twickenham, had a pretty group of double *Ivy-leaf Pelargoniums*, *Adiantums*, and *Lilies of the Valley*, the latter arranged in a central half-circle and two side pyramidal groups. The *Lily of the Valley* was the *Victoria* variety, for which this firm is noted. Mr. P. H. Garcia, Covent Garden, was awarded a silver-gilt medal for handsome bouquets of *Roses*, ball and bridal bouquets, crosses, and wreaths. Messrs. J. R. Pearson & Son, Nottingham, had a collection of choice *Zonal Pelargoniums*, which were highly commended; Mr. Virgo sent some flowers of *Myosotis dissitiflora grandiflora*; and Messrs. G. Smith & Co., Commercial Road, Pimlico, exhibited samples of a simple stand for flowers of semi-globular form, with perforations for holding water and flowers. (See page 431.)

FRUIT AND MISCELLANEOUS.

Comparatively few samples of fruit were staged, but there were several good collections of Apples. A. H. Smee, Esq., The Grange, Wallington (gardener, Mr. Cummins), sent thirty-six dishes of Apples and Pears very well kept. Messrs. G. Bunyard & Co., Maidstone, had thirty-four dishes of Apples, and Messrs. J. Cheal & Sons had thirty dishes of Apples. Mr. G. Munro, Covent Garden, showed examples of Channel Island produce, including fine Melons, Grapes, and Peas. The Right Hon. Lord Braybrook, Audley End, Saffron Walden (gardener, Mr. J. Vert), exhibited two dishes of fine fruit of President and Sir Joseph Paxton Strawberries. Mr. J. B. Thomas, Covent Garden, had an important and interesting collection of fine Australian Apples in excellent condition, King Pippin, Blenheim, Ribston, and Cox's Orange Pippins being the varieties. Belgian Black Hamburg Grapes, Jaffa Oranges, Mangoes, Chinese Litchees, Madeira Bananas, and American Cranberries were also represented. Seakale from Mr. W. Poupart, Twickenham, and Asparagus from Mr. W. Lobjoit, Putney, completed the exhibits.

COMMITTEE MEETINGS.—MAY 22ND.

ON Tuesday the Fruit and Floral Committees met in the Drill Hall, Westminster, and though there were few exhibits they comprised some of unusual interest. The attendance of visitors was very small.

FRUIT COMMITTEE.—Present: H. J. Veitch, Esq., in the chair; and Messrs. J. Lee, W. Marshall, G. T. Miles, J. Burnett, A. H. Pearson, P. Crowley, J. Cheal, and T. B. Haywood.

Mr. D. Campbell, The Priory Gardens, Roehampton, sent some fine examples of Asparagus. Two fine even fruits of Cucumber Tender and True also came from the same garden, and cultural commendations were awarded for both. Mr. H. Merryweather, Southwell, Notts, showed fruits of Bramley's Seedling Apple, well kept and good in colour.

Mr. A. Ward, Stoke Edith Gardens, Hereford, sent samples of a seedling Broccoli, and C. Hoare, Esq., Hackwood Park, Basingstoke, showed remarkably fine fruits of Hackwood Park Tomato (cultural commendation). Messrs. T. Pascall & Sons, South Norwood, showed samples of propagating pans, perforated and other pots.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair; and Messrs. J. Fraser, J. Walker, H. Herbst, W. Goldring, W. H. Lowe, G. Paul, R. Dean, B. Wynne, H. Ballantine, J. Dominy, H. M. Pollett, J. O'Brien, E. Hill, A. J. Lendy, W. Holmes, G. Duffield, and J. Laing.

From the Royal Gardens, Kew, came a group of interesting plants comprising the following:—*Exacum macranthum*, three plants in 48-size pots, each bearing six to eight heads of brilliant blue flowers, the large yellow anthers contrasting strongly with the petals; *Lotus peltorhynchus*, a species from Teneriffe with linear glaucous leaves and bright red flowers towards the points of the drooping branches; *Disa racemosa* (*D. secunda*), a species with long spikes of large bright rosy flowers, the upper petal hooded over the lip; *Ansellia africana nilotica*, a variety with neat flowers, narrow yellowish sepals and petals spotted and barred with brown and a yellow lip; *Phaius Manni*, from Assam, having bright brown sepals and petals, the lip crimson in the centre and light at the tip and margin; *Diaerium* (*Epidendrum*) *bieornutum*, with five racemes; the curious small brownish *Masdevallia triaristella*; *Primula Rusbyi*, with small bright purple flowers and lanceolate serrated leaves; *Haberlea rhodopensis*, a dwarf plant with numerous trusses of small *Streptocarpus*-like flowers, the tube purple, the limb pale, nearly white; *Onosma tauricum*; *Aster Stracheyi*; *Acradenia Franklani*, from New Zealand, with small starry white flowers; the graceful papilionaceous *Bossia liniphylla*, with small orange and red flowers clustered along the slender branches.

In addition to the Orchids certificated, Messrs. Veitch & Sons, Chelsea, sent a plant in flower of *Dendrobium porphyrogastrum*, a hybrid between *D. Huttoni* and *D. Dalhousieanum*, of a pale mauve tint, the lip flat and slightly darker.

R. B. White, Esq., Arddaroch, Dumbartonshire (gardener, Mr. Kidd), showed a plant of *Cattleya Mendeli alba* with three fine pure white flowers (vote of thanks), also a plant of *Cattleya Mossiæ superba*, with large flowers and richly coloured lip. F. G. Tautz, Esq., Studley House, Hammersmith (gardener, Mr. Cowley), sent a plant of *Cattleya Wagneri*, the flowers large white, the lip orange in the throat; also *Cattleya Mossiæ Studleyana*, with white sepals and petals, the lip very pale crimson, and orange veined in the throat.

E. Ellis, Esq., Manor House, Wallington (gardener, Mr. Glover), exhibited a group of Orchids, including plants of *Angræcum Sanderianum* with two racemes of white flowers, *Thunia Marshalliana*, strong, *Oncidium Marshallianum*, with a large panicle of bright yellow flowers, *Cattleya Lawrenceana*, with fine spike, and *Cattleya Schroderi*.

Messrs. J. Laing & Sons, Forest Hill, exhibited a handsome group of *Caladiums*, *Palms*, *Gloxinias*, *Tuberous Begonias*, and *Ferns* very effectively arranged. *Gloxinia virginale* has pure white flowers produced very freely (vote of thanks). The interesting *Rose*, *Madame George Bruant*, said to be a cross between *Niphotos* and *R. rugosa alba*, it has large semi-double white flowers and neat foliage (vote of thanks). *Clivia sulphurea* has large flowers and trusses, orange yellow (vote of thanks), and *Marquis d'Albertas* silvery centre, green margin, and pale red spots (vote of thanks). (Silver medal).

G. F. Wilson, Esq., F.R.S., Heatherbank and Oakwood, Weybridge, sent a stem of *Lilium roseum* with twenty flowers, *Pinguicula caudata*, seedling *Auriculas*, several interesting *Primulas*, and the pale yellow *Roses* *Isabella Gray* and *Cloth of Gold*. Messrs. Paul & Son, Cheshunt, exhibited some choice hardy plants and *Roses*. For a dwarf American

Phlox with neatly formed pale mauve flowers a vote of thanks was accorded. The Siberian Edelweiss, *Leontopodium sibericum*, differs from the ordinary form in its smaller greenish white heads. The "Fairy Borage," *Eritrichium nanum*, light blue, very small; *Pulmonaria paniculata*, bright blue or pink bells; *Cortusa Mathioli grandiflora*, and *Geum miniatum*, *Polemonium himalayense* (vote of thanks) were well shown. The Roses comprised the new Lady Alice, bunches of *Maréchal Niel*, and plants of the new Fairy China Rose, Red Pet. Mr. Gordon, The Nurseries, Twickenham, had a large group of Japanese Maples and Pæonies (silver medal), and R. H. Alexander, Esq., Gifford House, Rochampton (gardener, Mr. Springthorpe), had a group of *Calceolarias*.

Messrs. H. Cannell & Sons, Swanley, showed forty plants of *Calceolarias*, compact healthy plants, very dense and healthy, the flowers large, well formed and of rich varied blooms. (Silver medal).

Messrs. Kelway & Son, Langport, Somerset, exhibited nine boxes of single and double Tree Pæonies, very fine blooms, varying from the palest to the deepest colours. (Silver medal).

Mr. John Forbes, Hawick, N.B., exhibited a large collection of Pansies, representing many very handsome varieties. (Bronze medal).

Mr. Duffield and Mr. J. Hall, Cambridge, exhibited Carnation flowers (vote of thanks), and Mr. W. H. Scott, Nunfield, sent a plant of a good variety of *Odontoglossum Andersonianum*. (Vote of thanks).

CERTIFICATED PLANTS.

Disa racemosa (Royal Gardens, Kew).—This Orchid is also known as *Disa secunda*. It is a South African species, with tall spikes of large bright rosy flowers, the upper petal hollowed and partly surrounding the lip.

Aerides Fieldingi alba (Baron Schröder).—A fine pure white variety of a well-known Orchid.

Prostanthera lasianthos (C. Ross).—An old plant that is very seldom seen, though it was well grown at one time. The slender branches are furnished with narrow lanceolate leaves, and clusters of white woolly flowers spotted with purple in the throat, like a small edition of a *Catalpa*.

Alsine verna plenissima (Froehel).—Diminutive white double flowers on a little grass-like tuft.

Rose Sappho (Wm. Paul & Son).—A hardy Tea Rose which we have previously noted.

Anguloa intermedia (Veitch & Sons).—A hybrid between *A. Clowesi* and *A. Ruckeri*, the flower of moderate size, creamy and blush, with numerous pink spots.

Epidendrum James O'Brien (Veitch & Sons).—A hybrid between *E. erectum*, purple, and *E. rhizophorum*, brilliant scarlet, the resulting colour being a kind of rosy-crimson, quite intermediate in tint, and much like *rhizophorum* in size and shape.

Cypripedium bellatulum (H. Low & Co.).—A grand *Cypripedium* of the *C. Godefroyi* type, but much superior to any variety yet seen. The flowers on an imported plant were 2½ inches across, white or creamy, heavily spotted with crimson maroon, the petals broad and finely shaped. Dried flowers are said to have been obtained 4½ inches in diameter.

Abutilon vitifolium (Kelway & Son).—Shown as a half-hardy shrub, the leaves evenly triangular in outline, the flowers pure white, 2 inches in diameter.

Tree Pæony Prince Albert (W. Gordon).—A large-flowered single variety, bright crimson, very showy.

Arnebia echinoides (Paul & Son).—A fine pan of this beautiful and well known plant was shown, the flowers large, bright yellow spotted with maroon between the lobes when first expanding, afterwards fading.

Caladium Comte de Germiny (J. Laing & Sons).—A dwarf compact variety, leaves bright red with a few silvery spots.

Begonia Princess Maud (J. Laing & Sons).—A double Tuberous Begonia with beautifully formed flowers, pure white.

Begonia Baroness Rothschild (J. Laing & Sons).—A single Tuberous Begonia with well shaped flowers, white centre, edged deep crimson.

Haberlea rhodopensis (Royal Gardens, Kew).—A dwarf plant from Macedonia, like a *Ramondia* in habit, but with tubular Streptocarpus-like flowers, about 1 inch long, the tube purple, the limb of five lobes, pale nearly white. They are borne in small trusses of three or four flowers each.

MELONS AND CUCUMBERS AT CARDIFF CASTLE.

"A TOURIST" when describing the noted gardens at and surrounding Cardiff Castle, incidentally alluded to my visit at about the same time as he was there, and although forestalled by him to a certain extent, it was yet left for me to describe our friend Mr. Pettigrew's most successful method of growing Melons and Cucumbers.

Melons, Cucumbers, and Pines are all grown in one large span-roofed house designed and erected by Mr. Pettigrew. This most serviceable structure is 60 feet long, 22 feet wide, and 13 feet high in the centre, is lightly yet strongly constructed, supported by iron pillars, and very effectively ventilated. A central pit, probably about 10 feet wide and well heated, is devoted to fruiting Pines, and a grand lot there were ripening off in October—Queens, including Mr. Pettigrew's favourite Ripley selection and Moscow Queens, plenty of them weighing 6 lbs., and Smooth Cayennes still heavier. Between the walks and front walls other narrow well-heated pits are formed, and it is in these that the Melons and Cucumbers are grown. Nowhere else probably are less pains taken with the compost for Melons, and nowhere else are better

crops grown. In the narrow pits just mentioned a depth of about 18 inches of the best loam available (and that as far as I could learn is poor and void of fibre) is firmly packed. Sometimes much of the old soil is used, a little fresh being added to enliven it up somewhat. As a matter of fact very little importance is attached to the compost, the aim always being to encourage a constant and brisk root action, no drying off being ever thought of. Strong plants are put out 4 feet apart, and the stems at once enclosed with an earthenware collar about 8 inches in diameter and 2 inches deep, the bottoms being rather wider than the top. Two squares of glass are cut so as to fit over these and neatly up to the stem, and with the aid of this capital invention Mr. Pettigrew can safely defy the much-dreaded canker. Most practical gardeners are aware that Melons are very liable to canker at the collar or portion of stem just above the ground, too much moisture being the principal, or it would appear the only cause of this. Nothing is more annoying to a cultivator than the loss of a plant, or it may be a whole row of plants, just when a fine crop of fruit is swelling off. Our remedy for this is high planting and careful watering, a little mound of soil about the stems being kept as dry as possible. At Cardiff Castle, however, it is almost impossible to wet the soil about the stems; at any rate, if ordinary care is exercised. These collars or rims are, I believe, made specially for Mr. Pettigrew, but it is a pity so excellent an idea cannot become general property.

Each plant is taken up with a clear disbudded stem up to the trellis, and they are then trained unstopped up the roof, the laterals being laid in right and left and stopped at the second or third joint beyond the fruit. Afterwards they are only stopped occasionally beyond fruit, or where necessary to avoid crowding, and are allowed to extend about 9 feet up the roof. One or more fruit are set on them as soon as possible, others at intervals, or according as the plants are capable of swelling them off. In this manner a succession of fruit are obtained on each plant. Any time during the Melon season fully grown or nearly ripe fruit, and more in various sizes, down to those newly set, may be seen at Cardiff Castle on the same plants, this being more like Cucumber than Melon culture. Water is given freely as well as liquid manure whenever the borders are at all dry, and I noticed a mass of fibrous roots on the surface. The fruit are early and simply supported and cut before they crack badly, their full flavour being developed on a warm, dry shelf. I do not remember which are Mr. Pettigrew's favourite Melons, nor is this very material, as all varieties are amenable to the same treatment.

Cardiff Castle, raised by Mr. Pettigrew, is the only variety of Cucumber grown in the garden, and anything better for private places it would be difficult to find. It possesses a good constitution, is very prolific at all times, and the quality of the fruit is of the best. As a rule the fruit scarcely average 12 inches in length, and if only they could be generally grown as long as the Telegraph it would also become a favourite with market growers. With this again very little trouble is taken, the plants keeping in good health and very productive when rooting for many months in the comparatively small amount of loamy soil just alluded to. A high temperature is naturally maintained if only for the Pines, and plenty of head room coupled with the good attention the house receives at the hands of the Messrs. Pettigrew and Son does the rest. Altogether this mixed fruit house is much above the ordinary level of similar structures, and worth a long journey to see.—W. IGGULDEN.

— THE WEATHER.—"B. D.," writing from Perthshire, says:—"The weather has been warmer during the past week, with a good deal of rain. On the 18th and 19th a severe thunderstorm visited many parts of the country, bright warm weather following." To this we may add that after the steady downpour on Thursday last in London two or three very warm or rather hot days were experienced, since which the weather has been somewhat dull and cold, with frost on one or two mornings.

— THE GARDENERS' ORPHAN FUND.—It has been decided that the Promenade Fête in the Covent Garden Flower Market on behalf of this Fund will be held between the hours of nine and twelve on Wednesday evening, June 6th, and that Messrs. Deal, Dickson, Assbee and Richards be appointed to carry out the necessary arrangements.

— THE death is announced of MR. FRANCIS RAUCH, Inspector of the Imperial Gardens, Laxenburg, in Lower Austria, which occurred on the 13th inst. When a young man he and his brother were both engaged by the late Mr. Loudon, and both being excellent artists as well as good botanists, they contributed very materially in the production of the works upon which Mr. Loudon was at the time engaged, especially the "Arboretum et Fruticetum Britannicum."

— **MAIDENHEAD HORTICULTURAL SOCIETY.**—We are requested to state that in consequence of the death of J. Hibbert, Esq., the President of this Society, the annual Show on August 16th will not be at Braywick Lodge as announced, but in the grounds of Ray Lodge, Maidenhead, by kind permission of Miss Lassell.

— **WAKEFIELD PAXTON SOCIETY.**—At a recent meeting of this Society, Mr. T. Garnett, gardener to Miss E. G. Mackie, and one of the Honorary Secretaries, read a very interesting paper on "Some Peculiarities of Climbing Plants," which he read before the members of the Naturalists' Society some time ago, and it was most attentively listened to. A short discussion ensued, in which Messrs. Waite, Cordon, and others took part. Mr. B. Whiteley proposed a vote of thanks to Mr. Garnett for his essay, and said that he did not know anyone who had done so much to promote the success of the Paxton Society as Mr. Garnett. The motion was supported in very eulogistic terms by Mr. Thomas Senior, solicitor, a former President of the Society, and was heartily carried.

— **SEEDS FOR SONG BIRDS.**—Messrs. James Carter & Co. desire us to state that they have made arrangements for supplying the bird-loving public with seeds in packets of various sizes. One of these has been sent to us; it is very attractive, and we doubt not the contents are, as represented, excellent for the purpose in view.

— **HOOPER & CO., LIMITED.**—At the annual general meeting of Shareholders in this Company recently held, the Chairman, C. Adams Hooper, Esq., explained that, as shown by the accounts, the business of the Company was in a highly efficient and satisfactory condition, that after deducting all the salaries and expenses of management there remained a net profit upon the capital of the Company for the six months ending December 31st last of about 9 per cent., and recommended that a dividend at the rate of 6 per cent. per annum should be declared, the remainder being carried forward. After a few remarks from Shareholders present, approving of this proposal, a resolution was unanimously passed that such a dividend should be paid within fourteen days. The old-established business of Messrs. E. G. Henderson and Son, with the Pine Apple Nursery, Maida Vale, is now the property of the Company, of which Mr. Henderson is a Director; also the wholesale seed business of Mr. James Farrar, formerly carried on at Primrose Street, Bishopsgate; a branch establishment is to be opened in Paris, and another shop is secured in connection with the present one in the Central Avenue of Covent Garden Market.

— **ROYAL METEOROLOGICAL SOCIETY.**—The usual monthly meeting of this Society was held on Wednesday evening, the 16th inst., at the Institution of Civil Engineers, 25, Great George Street, Westminster; Dr. W. Marcet, F.R.S., President, in the chair. Mr. J. W. Gatwood and Mr. N. Simmons were elected Fellows, and Prof. D. Calladon an honorary member of the Society. The following communications were read:—1, "Report of the Wind Force Committee on Experiments with Anemometers conducted at Hershams," by Mr. G. M. Whipple, B.Sc., and Mr. W. H. Dines, B.A. A whirling apparatus with arms 29 feet radius was rotated by means of a small steam engine. On the arms of the whirler four different anemometers were placed. Each experiment lasted fifteen minutes, the steam pressure remaining constant during the run. For the Kew Standard Anemometer, with arms 2 feet long, the experiments give a mean value for Robinson's factor of 2.15, and for two smaller instruments the factor is 2.51 and 2.96. Mr. Dine's Helicoid anemometer gave very satisfactory results, the mean factor being 0.996. 2, "On the Measurement of the Increase of Humidity in Rooms by the Emission of Steam from the So-called Bronchitis Kettle," by Dr. W. Marcet, F.R.S. The author described a number of experiments which he had made by steaming a room with a bronchitis kettle, and ascertaining the rise and fall of the relative humidity from readings of the dry and wet bulb thermometers. He found that the air in the room could not be saturated, the relative humidity not exceeding 85 per cent.

— **MR. W. SMITH** writes from Nantwich—"Have any of the readers of the Journal noticed the habits of the little migratory bird known as the WHITE THROAT? I have been very much amused with a pair of them during the past week in what was to me quite a new feature in their habits, although I have noticed their annual migrations from childhood, and am now grey with age. Here, in the country, in Cheshire, every homestead is fringed with Damson trees in the land-

scape at great distances by their pure white blossoms. It is on some of these trees that I have seen these little birds 'gathering honey from every opening flower.' At first I could scarcely believe my eyes, I thought they were insect-hunting; but no, they were sipping nectar. They put their bills carefully into the centre of each flower and held it there a second or so, then off they went to another. This was to me amusement blended with instruction, for I concluded that they acted as fertilisers of the flowers."

— **WE** are informed that the extensive collection of **FLORISTS' TULIPS** grown by Messrs. E. H. Krelage & Son at Haarlem, Holland, will be in bloom towards the end of the present month and early in June. The beds, which comprise an area of 7000 square feet, will be protected, and persons who are interested in these handsome flowers are invited to inspect the display. We are also desired to state that at the same time may be seen a collection of "one-coloured breeders unrivalled for variation and brilliancy of colours. These varieties have not yet been sold, but eventually some of them can be offered to the public. Here are represented in colours, ranging from pale porcelain to the darkest violet, from soft rose to the most brilliant red, from light brown to glossy black. These Tulips have very large well-formed flowers borne on strong stems. Grown in quantity they would give to our gardens a new feature at a time when striking colours are so much wanted. The black and the darkest red shades in this collection are really unique, and seem to be of great horticultural value."

— **GARDENING APPOINTMENT.**—Mr. W. Gibson, for the last three years foreman at Farington House, near Preston, has been appointed gardener to H. Harris, Esq., Steventon Manor, Micheldever, Hants.

— **ARTIFICIAL MANURES.**—"R. H." writes:—"I wish to congratulate your correspondents on the way they have both conducted the discussion on the above subject, and I hope they will continue the controversy, as will be convenient to themselves. I am greatly interested in it, and have no doubt many more will benefit by it."

— **THE** schedule of **THE HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY** has just arrived, and announces that this year's Show is to be held in the Artillery Barracks, Park Street, Hull, on Thursday and Friday, November 22nd and 23rd. Liberal prizes are provided in forty-seven classes, including another 15-guinea challenge cup and £15 as first prize in the class for forty-eight blooms, twenty-four incurved and twenty-four Japanese, not less than eighteen varieties of each. With regard to this cup a change has been made in the conditions. It has to be won only twice now, not necessarily consecutively, to become the property of the exhibitor, instead of twice consecutively, or three times altogether, as with the cup competed for last year and previously.

— **PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY.**—A large gathering of the above Society was held at the "Green Dragon Hotel," Guildford Street, Leeds, on Tuesday, the 15th May, for the purpose of presenting a testimonial to Mr. Wm. Sunley, the Society's able Secretary, who for the period of twenty-one years has held that office. The meeting was presided over by the President, Mr. James Inman, the vice-chair being occupied by Mr. William Harrison, the Vice-President. After the Chairman had made the presentation a number of the members spoke of the great services rendered by Mr. Sunley, and attributed the present splendid position of the Society to be due in a great measure to him. One of the most pleasing features of the evening was to see Mr. Sunley and the Treasurer of the Society, Mr. Thomas Jamieson (who has held that position for twenty-one years) shake hands over the table and say for the whole of that period nothing had arisen to cause any misunderstanding between them. The testimonial consisted of a beautiful timepiece and pair of ornaments supplied by Mr. Dyson of Briggate, and an illuminated address prepared by Mr. Massey, Printer, Upperhead Row. Amongst the gentlemen present were Mr. R. Featherstone, nurseryman; Mr. S. May, Mr. Wm. Green, and Mr. J. R. Beckwith, seedsman. A most enjoyable evening was spent.

BELVOIR CASTLE GARDENS.

EVER since reading an account of these gardens by the "oldest correspondent" of the Journal, "D., Deal," I have had a lingering desire to see them, and at last have had an opportunity of gratifying my thirteen-years-old wish, for on referring to my encyclopædia of gardening in the

form of eighty half-yearly volumes of the *Cottage Gardener and Journal of Horticulture*, I find the descriptions to which I refer were the result of a visit towards the early part of May, 1875. My run down to Belvoir was in the early part of May, 1888, and it came about in this way. Not long ago, as some readers may remember, a provincial nurseryman prevailed on me to introduce him to the Homes of Flowers and of Fruit, Messrs. Caunell's and Mr. Ladd's establishments at Swanley. So pleased was he with the day out, and feeling himself, as he intimated, somewhat indebted to me, like an independent man that he is, began casting about to see in what way he could be level with me, and get out of my debt. Of course, he was never in it; but that was his way of putting the matter, and it suited me very well. My friend, travelling somewhat widely, and having many good friends, including the Duke of Rutland's talented gardener, Mr. W. Ingram, I had a summons to arrive at Grantham Station at 9.15 A.M., on, as it proved, a bright May morning, and I should be met and escorted to Belvoir. But how was that to be done? The 7.40 A.M. from King's Cross does not stop at Grantham, and to cross ten miles of London and reach the Great Northern Terminus at 5.15 in the morning was no joke to a late riser and bad walker; but I had to be at Grantham all the same at the

scene was enchanting. And all this done for the gratification of one man—the Duke! No, it was done by the Duke and Mr. Ingram, as a work of pleasure to them no doubt, but the beauty to be shared fully, freely, and every day without let or hindrance by the people. No wonder the ducal family is popular in the neighbourhood and for miles around. But I am going too fast, and had better begin at the beginning.

Mr. Ingram received us with great courtesy, and soon made us at home in his embowered residence; and it is a treat of no ordinary kind to spend a few hours with a gardener who has travelled so far, and whose attainments are so widely recognised. As a geologist he may fairly be described as the leader among gardeners, and he appears to be as conversant with what is beneath the soil and the disposition of the strata almost everywhere as with the vegetation on its surface. His knowledge of the science of rocks and soils has been of no small value, both in the formation of rockeries and the arrangement of plants and trees, as well as culturally. In the creation of his effects and the conduct of its work he does not grope his way experimentally, but goes direct to his object. No grotesque conglomerations are perpetrated in the formation of "rockwork" on the slopes which constitute the attraction of the place, but he hides his art in the close alliance with

FIG. 56.—BELVOIR CASTLE.

appointed time. One of those happy thoughts that seem occasionally to be born to the lame and the lazy came to the rescue, and an inner voice suggested, Why not go down to Peterborough the previous afternoon, see the Conifers at Orton Longueville, spend the night with Mr. A. Harding there, and go on by the 8.30 in the morning, which is due at Grantham exactly at 9.15? The plan was carried out, and we measured trees, and had a very good time in the garden till the nightingale's trill interrupted the work. How the measuring was done, with the heights determined, will perhaps be told another day. We must first go to Belvoir.

The drive from Grantham is seven or eight miles; that is the aristocratic way, and leads through a pleasant district to the front entrance to the Castle; but as we were not aristocrats, and as the Nottingham train was waiting, we went on to Redmile, a seventeen minutes' journey, and entered the demesne by the back door, so to say, after a drive I was told of two miles, but I think a pedestrian would vote them long ones. The route is through a flat country, the Vale of Belvoir, across which the north-east wind rushes keenly in spring, retarding the growth of the grass and the trees. It is a cold late tract of land, and the outlook somewhat dreary, but when we mount the hill on which the Castle stands and descend the southern slope, which is further protected by a thick hanging wood, the change is almost startling. It is winter on one side the promontory and the treeless, summer on the other, with Rhododendrons blooming and flowers, flowers everywhere; borders filled with them, beds crowded to overflowing, rocks sparkling with colour; and as the sun streamed through the trees, and the shadows waxed and waned from fleeting clouds, the

Nature. When he prepares mounds for alpine plants for their culture solely, he aims not at the picturesque, but considers their requirements. There are examples of what may be said to be the useful and also of the ornamental in rockery mounds, both answering their purpose, the former unpretentious and agreeable, the latter equally unpretentious, yet imposing.

We first enter the home garden, an enclosure of an acre or two in front of the chief range of glass. This is a fine type of an herbaceous garden of the olden time. The space is occupied with beds of varying length and about 4 feet wide, the level expanse being broken here and there by elevations for alpine plants. The species and varieties of border and alpine plants are very numerous. Many old familiar kinds are there, and others less familiar, but all appropriate to their positions, each in turn revealing its attractions, and the whole rendering the garden interesting, and more or less beautiful, according to the season, all the year round. Here is a rough jotting of a few plants just as we find them, and they fairly represent the diversity of the garden. Each has space for displaying its character, while the strong are not allowed to overrun the weaker and crush them out of existence in an unequal struggle for supremacy:—

Doronicums austriacum and *plantagineum*; *Pyrethrums*, double and single; *Chrysanthemums triptens*, fine for summer and autumn blooming; *Alyssums saxatile* and *argenteum*; *Pinks*, *Cloves*, and *Picotees* in great variety; *Campanulas Hendersoni*, *glomerata*, and *G. F. Wilson*; *Anemones stellata*, *blanda*, *apennina*, *Robinsoniana*, very beautiful; *Morina longifolia*; *Eryngium giganteum*; *Phlox frondosa*, *Nelsoni*; *Erigerons macranthum* and *grandiflorum*; *Erysimum pulchellum*; *Pæonies* in variety; *Delphiniums Belladonna* and *nudicaule*; *Lychuis*

chalconica fl.-pl., and *L. viscosa* fl.-pl.; *Iris* *corifolia* and *sempervirens*; *Megaseas purpurascens* and *ligulata*; *Iris* *ochroleuca*, *stylosa*, and *pumila* varieties; *Polemonium azureum* and *Richardsoni*; *Violas* in variety; *Orobis vernus*; *Sedum spectabile*; *Rocket* (*Hesperis*); *Geum coccineum*; *Centaurea montana*; *Achillea ptarmica*; *Physalis alkekengi*; *Gypsophila paniculata*; *Galax aphylla*; *Onosma taurica*; *Statice*, *Trilliums*, *Alstromerias*, and *Narcissuses*. This list, a fragment of the whole, and representing the mixture, gives an idea of this interesting garden.

On one of the rockery mounds the following plants are thriving, showing how well they are adapted for exposed elevations, and that they find the essentials for their growth. The mounds are in three tiers, or the top and two ledges:—Upper part—*Campanula soldanella plena*, *Coronilla iberica*, *Origanum pulchellum*, *Dianthus superbus*, *Veronica solanifolia*, *Dentaria polyphylla*, *Lithospermum prostratum*, *Dianthus deltoides alba*. Second ledge—*Ranunculus amplexicaulis*, *Dianthus cinnabarinus*, *Hutchinsia alpina*, *Primula hirsuta*, *Viola alpina*, *Anemone stellata*, *Dianthus neglectus*, *Androsace lanuginosa*, *Dianthus Seguieri*, *Sedum causicum*, *Dryas octopetala*, *Anemone Robinsoni*, *Dianthus Candolleana*, *Thymus montanus albus*, *Androsace lanuginosa*, *Saxifraga Maenabiana*. Third or bottom ledge—*Androsace coronopifolia*, *Aralia*

matter of right and by force of habit, unthinkingly essayed to cross the lawn, whereupon a loud protest arose against the transgression, and they were put into their proper place forthwith. They apologised for the momentary forgetfulness, and did not offend again. On Mr. Ingram speaking to the Duke the next morning of the exemplary conduct of the people, His Grace expressed his pleasure, remarking he "understood the only offenders were Lady Adeliza and Mr. Ingram."

Passing the Castle, as it is seen in fig. 56, on the right, the walk curves along the side of the hill on the extremity of which the building stands. The great ridge of rocks, which at some far past period rose out of the sea, are somewhat horseshoe-shaped, and clothed with timber, as they have been for generations; on the north and west side—the outer rim of the shoe—densely, forming a wood; along the inner curve, from the west almost round to the east, the trees have been thinned, and under them the great slanting, and in places almost precipitous, bank is studded with flowers. Daffodils and others suitable for establishing in the grass and clefts of rocks have been planted annually, and the effect of this steady persistent work of years is precisely as if the flowers had crept onwards by natural increase right along the slope for about a quarter of a mile. The walk along the declivity bends about, as paths usually do along steep hillsides. Honeysuckles, wild Clematis, and

FIG. 57.—THE PLEASURE GROUNDS.

Veitchiana, *Draba helvetica*, *Erinus alpinus*, *Gentiana verna*, *Cyclamen Coum venum*, *Androsace Laggieri*, *Lychnis alpina*, *Primula formosa*, *Saxifraga oppositifolia*, *Sanguinaria canadensis*, and *Alpine Auriculas*. *Sempervivums* and *Sedums* fringe the supporting rock.

Twisting walks between shrubs lead from this garden to the walks, beds, and slopes in the pleasure grounds, from which not even a gate bars the way to whoever may desire to enter them. During all hours of daylight on Sundays and week days the public have free access, and they can rest on the green banks or wander about at will enjoying a combination of arboreal, floral, rugged, and pastoral scenery such as it is rare to find associated, and almost blended, for one merges into the other in a manner that it would puzzle even Mr. Ingram to draw lines of demarcation. Excursionists come from the busy towns of the midlands and the north to the number occasionally of 4000 or 5000 at a time. They are not watched by keepers nor directed to go this way nor that, but are simply trusted, and the knowledge of this has the effect of transforming them for the time being into guardians, and it is rare indeed to find the sprig of a tree broken or a flower plucked from the thousands they could so easily stoop and gather. It is only under exceptional circumstances that notices request visitors to keep on the walks, such as immediately after a torrent of rain, when an army of sightseers rushing up and down the lawn, for there is not much of it level, would soon do serious damage, and it is the rule to allow the utmost possible latitude to all comers. As evidence of the respect accorded to the expressed wishes of the nature mentioned Mr. Ingram recalls an amusing episode. Walking round with one of the ladies of the Castle, and mixing with the crowd unknown, they, as a

other appropriate rambling plants are arched over here and there in rustic fashion. Flights of a few steps in different places conduct from the higher to the lower levels, and each of these descents are flanking banks of Violets—an excellent idea, well carried out. The air is fragrant with them in the spring, while right and left and ahead, looking along and across the curve, masses of bright spring flowers are seen everywhere glistening between the trees.

Only near the Castle the lawn is kept smooth like velvet, the grass in the pleasure grounds being mown much less frequently, as extreme trimness there would be out of character, and too "cockneyfied" for the natural grandeur of the surroundings. Near the Castle are beds quite cushioned with spring flowers—*Myosotis*, *Aubrietias*, *Anemones*, *Arabis*, *Saxifragas*, and Mr. Ingram's ennobled *Oxlips*, that stand out bright and clear from the surrounding cushions of contrasting colour. A little further we come to another group of beds, and a plateau of gravel surrounded by evergreens equally gay but not formally planted. Some weeks ago they were bespangled with *Winter Aconites*, with *Hellebores* pushing above them; then in turn come other bulbs, such as *Hyacinths*, *Tulips*, and *Narcissus*, rising above and between dwarfer spring flowers such as those above mentioned, and others that are in beauty during the spring months. Beyond this we come to more freedom in arrangement and less trimness, the garden gradually merging into a beautified wood on the right upwards, and on the left downwards receding and melting away to the flat, pastoral, tree-studded country that stretches away southwards, where the wild waves in remote ages washed up and left their debris on the beach, where the rocks grew and subsequently the trees and flowers. When it is stated that the tops of the forest trees in

this old sea bed are far below the roots of those on the bold protecting semi-circular range, it will be understood how sheltered the position is, and suitable for early spring flowers.

In their disposition the natural configuration of the ground has been steadily kept in view, and to this all arrangements have been subservient. In one place they recede into the hill on the right, a portion of which has at some time fallen away to make room for them; in another they fall away into the lower ground to the left, as if they had ridden off on a landslip; indeed, some of the mounds that recede into the lawn below are landslips turned to account, and here the geological knowledge of Mr. Ingram has been displayed, for by the lack of it Nature could not have been followed with such fidelity, rock building would have been overdone, and incongruous heaps piled up unmeaningly. In some places the soil has been upheld, forming terraces with beds on the sloping ground below. This is somewhat gardenesque, the link, so to say, between the smooth and trim at one end of the promenade and the wildness at the other. But the terraced portions look more pleasingly irregular now than when the sketch (see fig. 57) was made. The work was new then, but mellowed with age now, and the sharp edges worn off; besides, as "D., Deal," hoped it would be, there has been an extension of the free and more natural in planting and a restriction of the formal, and he would be delighted with Belvoir now. The sketch was obtained by him and the engraving introduced in the following words, and I can imagine no others more appropriate—"One likes to linger on these slopes, and the clever sketch by Mrs. Ingram, who is an artist of no slight merit, will give some idea of the situation; and as one stands on the upper portion and looks down on the carpet of green, backed by the feathery growth and elegant foliage of the Birch it is hard indeed to tear oneself away; but beautiful as the combinations of flowers were, the wilder and more natural portion of the garden pleased me most." So it did me, and, as I have said, it is that which Mr. Ingram is extending. Apart, however, from individual proclivities in that respect, the talents of Mrs. Ingram must be recognised. They are even more evident in her combined studio and drawing room, her landscape, architectural and animal paintings all commanding attention by their undoubted merits. But to return to the garden. To enumerate the plants employed by Mr. Ingram in furnishing the beds and on the rockery mounds and slopes were to form a catalogue of all that are suitable for the positions. For massing from 8000 to 10,000 Aubrietias are planted, and as associated with the large-trussing early flowering lemon and yellow Belvoir Oxlips, the effect is admirable. The Belvoir Yellow Wallflower is practically supplanted by the Oxlips, these being hardier, earlier, and more lasting. Aubrietias are a great feature at Belvoir, where most or all the species and varieties are grown, while others of great decorative value have been raised from seed—one, a rose tinted form of *A. græca*, being particularly attractive. But the most attractive of all is *A. Leichtlini*, which was received from Mr. Max Leichtlin in return for some sent to him by Mr. Ingram, and will be referred to again.

Besides or among the plants previously mentioned as typical of the Belvoir collection a few attracted attention—namely, *Vesicaria utricularia*, resembling an Alpine Wallflower, and *Androsace coronopifolia*, a gem of a plant with lax umbels of small white flowers; *Cardamine rotundifolia*, white, early and graceful; *Oxalis Acetosella*, the blue variety in lovely tufts; *Narcissus Leedsii* Duchess of Westminster, the queen of the collection; *Saxifragas cymbalaria* and *peltata*, *Tiarella*s, *Edelweiss*, and Alpine Daisies that are so suitable for rockwork, up some of which we clamber and find at the top the "last tree" that is found in northern latitudes on the way to the North Pole—*Salix herbacea*. Flattened by the snow for ages the tree retains its prostrate form in temperate climates. Its upright growths are only a few inches high, and at a few feet distance one of the "trees" reminds of a mass of Creeping Jenny. Mr. Ingram brought it from Greenland's icy mountains, indeed many plants at Belvoir were collected by him in different parts of Europe. But as we have got to the "last tree" it is time to depart, and in doing so across the lower grounds we find *Camellias* growing and flowering as they have done for years, also a fine specimen of one of the Indian *Rhododendrons*, perhaps *R. Falconeri*, with huge clusters of buds. And what can this Vanilla-like perfume come from that pervades the air? It is from the elegant Box-like bush or tree that stands on the open lawn, *Azara microphylla*; and as we pass under it and look upwards we see myriads of yellowish miniature flowers in the axils of the leaves. This evergreen was sent out a few years ago by Messrs. Veitch & Sons, and is usually grown against walls. The Belvoir specimen is much the finest I have seen in the open, and is worthy of the position it occupies.

We have a rush through the houses in which very old Vines bear in abundance Grapes of superior quality, a peep into half a dozen plant houses, a walk down the fine kitchen garden, in which Potatoes are earthed at the time of planting by being laid in rows on the ground and ridges of soil taken from between the rows and piled over them—the best plan with cold strong land; a look into the reserve ground, where Mr. Ingram makes worthless clay land fertile in a year or two in the same way that Nature does in a thousand, for he spreads on the surface leaves and all kinds of vegetable refuse a foot or two thick, covers it with soil, and soon has a rich mass of what plants like, and in which Primroses and others grow luxuriantly. This is an instance of Art improving Nature with the best results. The garden walls are well covered with trees, including Peaches, which ripen good crops, as they might in hundreds of other gardens where "they cannot be grown now." Growing Peaches on open walls bids fair to be a lost art at no distant date, but there are a few gardeners left who retain it and

grow good crops further north than Leicestershire. There are useful orchards, and Mr. Ingram advises all who want fine standard Apple trees and plenty of good fruit to plant Bramley's Seedling. Excellent accommodation is provided for young men in the gardens, with incentives for improvement, and Mr. Ingram is proud of the good positions some of his pupils have obtained in various parts of the world. And now I wish to record my obligations to all—guides and entertainers—who contributed to the pleasure of the day—a few hours spent in such good company in such a fine garden being a real treat to—A LONDONER.

ROSES IN WINTER.

WHEN plants have to be raised for winter flowering a start cannot be made too early in the season, provided growers have no young plants on hand to commence with. Moderately young wood in a half ripened condition will strike freely if inserted amongst sand in pans or pots and covered with bellglasses. The cuttings only require two joints, none of the foliage need be removed, and the top eye only left above the sand. Insert them directly they are severed from the plant, well water, and place them in a temperature of 65°. If gentle bottom heat can be given them all the better, but it need not exceed 10° higher. In three weeks they will be rooted, and should be placed singly in 3-inch pots in a compost of loam and leaf mould in equal parts with a liberal quantity of sand added. The varieties before named do well on the Briar, but are preferable on their own roots, because they throw up more freely from the base, *Niphetos* excepted, for it is a weak grower. If the stocks are grafted at home they should be housed some time before the operation is performed to induce activity of the roots and the sap to flow freely. When in this condition cut them down as closely to the rim of the pot as possible, and the scion, which need only possess one eye, should be securely tied on. Take care to fit as nicely as possible the slanting cut on the scion with that on the stock. They can be rubbed over with grafting wax, or a little clay rubbed in with the finger will do equally well. Neither is absolutely necessary. Then place them in a close house, or better still in the propagating frame, where they can be kept close and moist until the stock and scion are united. When this takes place the scion soon begins growing, and care is needed in hardening the plants to bear full exposure in a structure having a temperature of 60° to 65°.

In a few weeks from the time of grafting they will be ready for placing in 5-inch pots, and in doing so bury the union of the scion and stock so as to give them a chance of emitting roots from the junction. They will do this with much greater freedom when they are buried early after grafting than if the greater portion of the season has elapsed before it is done. These plants, as well as those on their own roots, should be grown on under warm conditions until the end of June, when they may be gradually hardened to cooler treatment, although they should be grown under glass the whole of the season. The grafted plants will grow most rapidly at first, and by the time named most of them will be ready for 8-inch pots, while those on their own roots will be much smaller in pots 2 and 3 inches less, and will fill their pots with roots by September.

It may here be mentioned that plants can be purchased directly they are grafted, or when placed in 5-inch pots, in which they will be well established by May. After that time strong plants can be had in larger pots. The earliest worked plants are generally shifted, for there is a demand for plants of extra size towards autumn. If purchased in 5-inch pots transfer them into 8-inch, and if grown under glass they will increase wonderfully in size during the next two or three months. Up to this stage all the flower buds as they appear should be removed.

In September it must be decided whether the plants are to be repotted or planted out. Those intending to grow them in pots should place them into others 2 inches larger—that is, those on their own roots into 8-inch, and the worked ones into 10-inch. The balls of roots in potting should not be disturbed further than the removal of the drainage from the base and loose soil from the surface. The soil this time must be pressed a little firmer than was needed during the earlier pottings, the same care being exercised in planting them out, and the soil of the border should be pressed firmly about them. At this stage of the plant's growth the critical may be inclined to ask two questions—First, Would not the potting advised, or planting out, be better postponed until after the turn of the year? secondly, Would not the roots keep better in the smaller pots than amongst a quantity of soil that is unoccupied? Our answer to both questions is, Decidedly not. Keeping the plants in pots they have filled with roots will quickly bring both the roots and growth of the plants to a standstill, which is not desirable. Our object is to keep them growing freely for at least a month or six weeks after planting them out, so that they will become well established in the border or pots ready to make a vigorous growth early in the season. The roots will remain in better condition, because we do not intend them to be inactive during the whole of the season, and there is not the slightest fear of their not remaining fresh and healthy provided those in charge do not saturate them with water.

The house must be kept close for ten days or a fortnight after the Roses are potted or planted out, and during the remainder of the season should be shielded from cold by closing the house early and applying heat when needed to keep a temperature at night of 55°. Fire heat is very rarely needed until the end of October, and often not for some short time afterwards; but this is a matter that depends entirely upon the weather. Those on their own roots will now appear to make the greatest progress, and frequently towards the end of October they commence throwing up strongly from the base.

After the beginning of November any blooms that the plants show may be allowed to expand, for I have never observed that it does them any harm. From young plants of this description I have frequently had a good supply of useful buds up to Christmas, but for the purpose in view the plants should not be encouraged to produce flowers after the beginning of December. They should have three weeks' or a month's cool treatment towards the close of the year. The last growth should harden fairly well before this is attempted; in fact, the plants will show signs of standing still, and when this takes place cool airy treatment should be given them. Frost should be excluded, so that the whole of their foliage can be preserved uninjured, which will insure the roots remaining active.—WM. BARDNEY.

(To be continued.)

BATH SPRING SHOW.

MAY 16TH.

THE second of the series of five shows annually held at Bath took place in the Sydney Gardens, and on the whole was a very successful meeting. Unfortunately the weather was far from being favourable to the full enjoyment of an open-air "floral fête," a few cold showers having the effect of keeping many visitors away. Two very large tents and two smaller ones were fairly well filled with the various exhibits, plenty of room being allowed, as usual at Bath, for promenading.

STOVE AND GREENHOUSE PLANTS.—In the classes open to him, Mr. Cypher, Cheltenham, was simply invincible, his most noteworthy exhibit being in the class for twelve plants, these being of unusual excellence even for him. The best nine flowering plants were staged by Mr. W. Long, gardener to C. Gardiner, Esq., Brislington, among these being well-grown specimens of *Pimelea decussata*, *Erica Cavendishi*, *Clerodendron Balfourianum*, *Azalea Bernhard Andreas alba*, and *Anthurium Schertzerianum*. Mr. H. Jones, gardener to Canning Doherty, Esq., Bath, was a creditable second, his best being *Erica Cavendishi*, *Bougainvillea glabra*, *Rhynchospermum jasminoides*, *Hibiscus striata*, *Genetyllis Hookerianum*, and *Rhododendron Gibsoni*. Mr. G. Tucker, gardener to W. P. Clark, Esq., Trowbridge, was third with rather small plants. Mr. J. F. Mould, Pewsey, was well first for six specimens; Mr. C. H. Keel, gardener to Col. Landon, second; and Mr. W. C. Drummond, third. In the class for a single plant Mr. J. Cypher was placed first with an immense and grandly flowered *Pimelea spectabile*, and Mr. Long second with a good *Anthurium Schertzerianum*. The best four Heaths were staged by Mr. Cypher, these consisting of neat, well-flowered specimens of *Ventricosa coccinea minor*, *depressa*, *Victoria*, and *aristata major*. Mr. W. J. Mould was a good second. There was only one class for fine-foliaged plants, the prizes being offered for a group of fifteen varieties; Mr. Cypher was easily first, his best being *Kentia australis*, *Cycas revoluta*, *Cycas circinalis*, *Kentia Fosteriana*, *Kentia Belmoreana*, *Pritchardia pacifica*, and *Phormium Veitchi variegata*. Mr. Curry, gardener to Col. Pepper, Salisbury, was placed second, but ought to have been third, the numerous *Crotons* included in his group being very indifferent plants; Mr. W. J. Mould was third. Ferns were well shown by several exhibitors, but most of the plants were rather small. The best fifteen varieties were staged by Mr. G. Tucker, among these being creditable specimens of *Dicksonia antarctica*, *Athyrium Goringianum tricolor*, *Asplenium Nidus-avis*, *Adiantum cuneatum*, and several *Gymnogrammas*. Mr. W. J. Mould was a good second, and Mr. W. C. Drummond third. Mr. H. Jones was placed first for nine Ferns, these including good plants of *Alsophila excelsa*, *Dicksonia squarrosa*, *Platilobium rotundifolium*, and *Adiantum farleyense*. Mr. W. Marchant, gardener to Jerome Murch, Esq., was second for a healthy group. Mr. Drummond was first, and Mr. Brown, gardener to C. Baily, Esq., Frome, second for a specimen Fern, both having fairly good *Dicksonias*.

AZALEAS.—These are always a feature at this Show, but it was generally considered that they are not nearly so well shown as they formerly were, huge specimens having to give way before young plants of superior varieties. Mr. W. Long was first for twelve varieties, having fine freely flowered specimens, about 6 feet high, of such old favourites as *Charmar*, *Mrs. Turner*, *Roi Leopold*, *Iveryana*, *Duc de Nassau*, *Stella*, *Criterion*, and *Souvenir de Prince Albert*. A third prize was awarded to Mr. Keel. The best nine specimens were staged by Mr. J. Cypher. Captain Haskett Smith was first for six varieties, Mr. W. J. Mould second, and Mr. W. C. Drummond third; and Mr. Lond first, and Mr. W. C. Drummond second for a single specimen.

ORCHIDS.—A tent was devoted to a display of these, though the competition was not so keen as last year. The best prizes were offered for a group of Orchids arranged for effect, on a space 12 feet by 6 feet, Ferns and foliaged plants allowed. Mr. Kerslake, gardener to the Rev. E. Handley, Bath, was well first, his group being very superior in every way. Various choice *Cattleyas*, *Lælias*, *Dendrobes*, *Vandas*, *Odontoglossums*, *Oneidiums*, *Masdevallias*, *Calanthes*, and other Orchids were shown in a fresh condition, plenty of Ferns and Palms serving to

set them off to the best advantage. Mr. R. B. Cater also had a very excellent group, in which *Dendrobes* and *Cattleyas* were most prominent, and was awarded the second prize. The Rev. E. Handley was the only exhibitor of six varieties, and fully deserved the first prize awarded. This exhibit consisted of a good plant of *Odontoglossum vexillarium giganteum* with about sixty-five flowers, *Cattleya Skinneri* carrying twelve strong spikes, a large pan of *Cypripedium Lawrenceanum*, and good specimens of *Vanda suavis*, *Cattleya Mendeli* and *Lælia purpurata*. Mr. Handley was also well first for four varieties, these consisting of *Vanda suavis*, with two strong spikes; *Cattleya Mendeli*, carrying six good spikes; *Lælia purpurata*, with seven spikes; and *Cypripedium*, with six fine flowers. Sir A. E. Ramsay, Bart., Cheltenham, took the second prize with very creditably flowered plants, *Cattleya Mossiae* being especially good, while the third prize went to Mr. W. J. Mould. The last named had the best single specimen, a strong plant of *Aerides Fieldingi*, with two grand branching spikes of bloom; the Rev. Handley being second with *Lælia purpurata*, bearing twenty-three beautiful flowers. The Rev. Handley was again first in the class for a new or rare plant, staging a small piece of *Oypripedium Sanderianum*; the second prize going to Mr. G. Pymm, gardener to Mrs. Gouldsmith, Trowbridge, for *Cattleya Mendeli superbissima*.

ROSES.—These were particularly well shown, a small tent being fairly filled with them. There were four competitors with a group arranged for effect on a space 8 feet in diameter, pots not to exceed 10 inches. The Rev. E. Handley was first with a capital lot of plants with fine blooms arranged in a circular group. Mr. R. B. Cater was a good second, and Mr. F. Baskerville, Clifton, third. Mr. Handley was also first for six varieties, having fine well flowered specimens of *Earl of Pembroke*, *Mdlle. Thérèse Levet*, *Merveille de Lyon*, *Edward Morren*, *Madame Lacharme*, and *Souvenir d'un Ami*. Mr. Cater followed, his best being *La France* and *Souvenir d'un Ami*. The third prize was awarded to Dr. Budd, Bath.

SOFTWOODED PLANTS.—A capital lot of show *Pelargoniums* were staged, all being remarkably fresh and well flowered. The best nine varieties were staged by Mr. G. Tucker, these consisting of *Triomphe de St. Mandé*, *E. Perkins*, *Virgin Queen*, *Rob Roy*, *Beauty of Kingston*, *Royalty*, *Mary Mallet*, *Lady Isabelle*, and *Digby Grand*. Mr. H. Jones followed closely, equal third prizes going to Mr. W. J. Mould and Mr. H. Weston, gardener to Mrs. Wiltshire. Mr. A. A. Walters, Bath, was the only exhibitor of six varieties, and was awarded the first prize. The best six *Cinerarias* were shown by Mr. M. Cole, gardener to S. Tredwell, Esq., Bath, Mr. W. Burridge being second, and Mr. W. Marchant third; Mr. M. Cole was also first for six good *Calceolarias*, the second prize going to Mr. W. Robinson, and the third to Mr. G. Tucker.

CUT FLOWERS.—A beautiful lot of cut Roses were shown, but owing to the crush no names could be taken. Mr. R. B. Cater was a good first for twenty-four blooms in twelve varieties, beating the Rev. E. Handley, who took the second prize. The first prize for twelve blooms was awarded to Dr. S. P. Budd, Mr. T. Jolley being second, and Mr. F. Hooper third. Messrs. A. T. Hall and W. Meddick were the prize-winners with Tulips, and Messrs. A. G. Way, E. Dury, W. G. Meddick, W. Meddick, and Col. R. T. Hare were successful with Pansies. The competition with twenty-four varieties of cut flowers was good. Mr. G. Howe, gardener to Lewis Fry, Esq., M.P., had an exceptionally beautiful collection, and was placed first. Mr. W. Fidler, gardener to the Baron de Tuyl, being second, and Mr. W. Pumphrey third. Messrs. Garaway and Co., Clifton, obtained the first prize for a hand bouquet, this being rather a novel arrangement, in which strong spikes of *Odontoglossum Alexandræ* played a conspicuous part. Mr. C. Winstone was second, and Mr. E. Thomas third. The last-named was first for a vase, and Mr. R. Bush second.

FRUIT AND VEGETABLES.—Strawberries in pots were not so good as usual. Mr. W. Robinson, gardener to Lord Justice Lopes, was first with creditable plants of *President*, the second prize going to Mr. J. Shelland, gardener to W. Hill, Esq., who had *Oscar* in fairly good condition, and the third to Mr. J. Watson, gardener to the Rev. C. C. Layard. In the class for a dish of Strawberries Mr. G. Pymm was well first with grand fruit of *James Veitch*, Mr. W. Robinson being second with *President*, and Mr. W. Fidler third. Mr. R. Bush was first for a dish of Apples, staging well kept *Malakofna*, the second prize going to Mr. J. Weston for *Wellow Pippin*, and Mr. W. Leaney, gardener to W. War, Esq., was third with *Balchin's Pearmain*. A capital lot of vegetables were shown, and of these the best nine varieties were staged by Mr. W. Evry, Bath; Mr. G. Garaway, Bath, being a good second. For six varieties Mr. J. Ricketts was first, and Mr. J. Weston second. Mr. S. Tredwell had the best brace of Cucumbers, a fine seedling of his own raising, and named *Upland House Seedling*. Mr. Robinson was second, and Mr. T. Jolly third. Mushrooms were well shown by Messrs. Pymm and E. Hall, French Beans by W. Robinson and W. Fidler, Asparagus by G. Garaway and J. Long, Peas by G. Garaway and J. Watson, and Potatoes by W. Robinson and J. Curtis, who took the prizes in the order named in each instance. Mr. A. Miller, gardener to Walter Long, Esq., M.P., Rood Ashton, staged, but not for competition, a very fine dish of selected *Old Red Tomatoes*, which fully merited a cultural commendation.

CERTIFICATES OF MERIT.—Messrs. G. Cooling & Sons, Bath, arranged a very pretty group of Orchids and other choice flowering plants, interspersed with Palms and Ferns. They also had a fine stand of cut Roses in large bunches, the best represented varieties being *Niphetos*, *Catherine Mermet*, *The Bride*, *Alba rosea*, and *Dupuy Jamain*. A certificate of merit was awarded this group, and to the same firm for

the beautiful single white Himalayan Rose, a variety that ought to become very popular among lovers of single varieties. Messrs. Veitch and Sons also arranged an effective group of plants, conspicuous among which were several very pretty Japanese Maples, as well as several Orchids, Rhododendrons, Azaleas, and other flowering plants. They also had plants of the new *Boronia heterophylla*, a showy bright crimson variety, sweetly scented, and very floriferous. Numerous photographs of rockwork, and the prize plan of the People's Park, Poole, were also shown by this firm, to whom also a certificate of merit was awarded. A similar award was made to Mr. A. A. Walters, Bath, who had a large group of *Pelargoniums*, *Mignonette*, and other popular plants.

MANCHESTER SHOW.

MAY 18TH TO 25TH.

THE Whitsuntide Show in the Botanic Garden, Old Trafford, Manchester, is regarded in the north and over a considerable portion of England as one of the great horticultural events of the year, attracting exhibitors and visitors from long distances. The Society which possesses the garden named, with their Secretary and Curator, Mr. Bruce Findlay, have concentrated their efforts for many years past upon this Show, and though smaller ones are held at intervals during the year, that at Whitsuntide is made as representative as possible by means of a comprehensive schedule and liberal prizes. The Show which opened last Friday is no exception to the rule as regards being a full, important, and beautiful display, but a change seems to be coming over shows of this character, and they have to be viewed more as spectacles than examined very closely in detail. At one time Manchester was famed for its large specimen plants, and we have seen some magnificent exhibitions there in which stove and greenhouse plants, Ferns, fine-foliage plants, and Orchids were represented by the grandest example of cultural skill that could be seen in any portion of the kingdom. The owners of some of these have left the neighbourhood, others have died, and the collections have been dispersed, so that now there are comparatively few who possess collections of the giant specimens which have graced so many exhibitions. Grouping and miscellaneous collections are taking the place of the specimens to some extent, but no show held in spacious tents or buildings seems complete without them. Classes with substantial prizes must always be provided in the schedules of these exhibitions for the specimens, but for a great portion of what may be termed the "filling up," group classes must be depended upon.

Though differences in the style of the Manchester Shows have been gradually arising, that just held was quite as remarkable as ever for the good culture displayed by the condition of the smaller plants exhibited, and there can be no question that a healthy, well-furnished or profusely flowered plant of moderate size is far preferable to a giant defective either in foliage or flowers. In another respect the Show was fully equal to many of its predecessors—namely, in the general effect and varied interest, and the garden is exceptionally favoured in this matter, owing to the capital buildings that are devoted to the purpose. Some alterations and improvements have been recently effected as the result of the great general Exhibition held in the garden last season, and one of the most important of these is the extension of the building, which was formerly covered with canvas on the occasion of the shows, but now permanently glazed. This was 360 feet long by about 60 in width, but it has been increased by an annexe at the lower end over 200 feet long and of similar width, giving a total length closely approaching 600 feet. At the upper end there was formerly a high bank with a path at the top from which a good view of the Show could be obtained. This was all cleared away for last year's Exhibition, a refreshment and dining room being new added to that end. Along the sides of the building are the banks, alternately and irregularly projecting or retiring, so as to form prominent points for groups or plants of importance, and bays or recesses for others of less interest, the centre being occupied by a succession of circular, oval, or variously formed beds and mounds, upon which Palms are arranged, surrounded by groups or collections of plants of various kinds. It is a matter of opinion whether too many of these central groups have not been employed, as these in part partially obstruct the view of the others, and when seen in succession from one end, unless the colours of the plants are judiciously contrasted, blended, or relieved by foliage, they have a discordant effect. To our mind these might be advantageously reduced both in size and numbers, but under any circumstances it is far the finest building in the country devoted to horticultural exhibitions. A covered communication has also been effected between the upper end of this building and the Exhibition house, a span-roof structure, 80 yards long and 30 or 40 feet wide, adequately heated, and devoted to Orchids or other tender plants. This also is unique, for at no other summer show can choice plants be exhibited with the same safety as at Manchester. For many years the Whit Show has been celebrated for the display of Orchids, and on the occasion under notice they constituted a special feature, but generally characterised like the other classes mentioned by the absence of large specimens. So far, however, from this being a disadvantage the appearance of the house was more pleasing to many visitors, as there was less formality. The foliage plants, with the principal stove and greenhouse plants, were arranged behind the Orchids, and the collections not for competition occupied the central table.

ORCHIDS.—In this house the most interesting class was that for a group of Orchids, Ferns, and foliage plants arranged for effect, a mode of exhibiting Orchids that we have frequently commended, and which

has received much more attention from the framers of schedules in the past few years than formerly. By far the finest exhibit in this class was the group from A. Heine, Esq., Fallowfield (gardener, Mr. J. Cragg), who wins this season the champion of the amateur classes for Orchids, as he secured no less than six first prizes. The group had an irregularly undulating foundation of *Adiantums* and a background of Palms, smaller Palms and other fine-foliage plants rising from the bank of Ferns, with such Orchids as *Cattleyas*, *Dendrobiums*, *Odontoglossums*, *Lælias*, *Cypripediums*, and *Masdevallias*. Two remarkable specimens demand a word or two—namely, *Dendrobium Paxtoni* and *D. Devonianum*. The former was a wonderful mass, about 7 feet high, and as much in diameter, and it bore innumerable racemes of its rich golden flowers, having a fine effect in the centre of the background. *D. Devonianum* was equally notable in its way, for very seldom is this graceful Orchid seen in such perfection. It was growing in a basket elevated on a pedestal around which drooped scores of long growths crowded with soft tinted flowers. T. Statter, Esq., Stand Hall (gardener, Mr. R. Johns), was second with a collection of healthy, well-flowered Orchids and *Adiantums*, but they were not arranged to the best advantage, and too many *Crotons* were employed. The Duke of Sutherland, Trentham (gardener, Mr. Blair), took the third place, *Masdevallias* being conspicuously bright in this group. Mr. Heine's exhibits occupied a large space in the house, as may be gathered from the fact that he had forty-one specimens besides those in the group just mentioned, comprising the first prize plants in the classes for ten *bonâ fide* specimens, twelve and six Orchids, ten *Cattleyas*, and three *Vandas*. It is unnecessary to particularise all these, but some of his best specimens were *Cattleya Skinneri* and the variety *alba*, *Lælia purpurata* in several beautiful varieties, *Dendrobium densiflorum*, *Calanthe veratrifolia* with twenty-two spikes, and *Vanda teres* with sixty large flowers. In some of these classes Mr. Heine was the only exhibitor, but Mr. R. Elphinstone, Stretford, was second with twelve Orchids, and Mrs. Hodgkinson, Bowdon (gardener, Mr. D. Boardman), secured a similar position with ten *bonâ fide* specimens, his finest plant being *Brassia verrucosa majus* having sixteen long racemes. In the nurserymen's classes for Orchids Mr. H. James, Norwood, and Mr. J. Cypher shared the honours, the former taking the second prize for a group, and the first for ten Orchids in flower; Mr. J. Cypher following in the last-named class, a rather unusual position for him, but he had evidently concentrated his Orchid strength at Regent's Park and the Temple.

STOVE AND GREENHOUSE PLANTS.—Mr. J. Cypher had the class for twelve stove and greenhouse plants to himself, but he would have proved a formidable opponent for any other competitor, his specimens being in beautifully fresh condition and profusely flowered. An extraordinary example of *Pimelea spectabilis* attracted the attention not only of the public but the most experienced plant growers and exhibitors present, and it was pronounced to be one of the finest ever shown. It was nearly 6 feet high, at least 7 feet in diameter, every shoot terminating in a large head of white flowers. The plant had evidently been grown quickly and vigorously; it was not too formally trained, and it was altogether a superb example of skilful culture. A plant of *Erica ventricosa magnifica* 5 feet in diameter was scarcely less commendable for its health and beauty. Mr. Cypher was also first with six *Ericas* and eight fine-foliage plants, followed in each case by Mr. H. James. S. Baerlein, Esq., Didsbury (gardener, Mr. G. Williams), had the best ten fine-foliage plants in the amateur class, showing large Palms, Cycads, and *Cordyline indivisa*. Mr. Baerlein was also first with six *Dracenas*, Colonel Wingfield, Shrewsbury, and Mr. W. Hayes, jun., Sale, being second and third, and with Palms and *Yuccas* he won similar honours. Azaleas and *Ericas* in the amateur classes were of an ordinary character, second and third prizes being accorded to Messrs. Baerlein; J. Brown, Heaton Nursery; and S. Lord, Brooklands. For ten Pitcher Plants and *Sarracenias* Mr. A. J. A. Bruce, Chorlton, secured first honours with good plants, and Mr. H. James had the best twelve *Dracenas*.

Several non-competing groups or collections were staged in this house, the most extensive and beautiful being that from Mr. B. S. Williams, Upper Holloway, who has for many years contributed liberally to the attractions of the Show, but he has rarely had a more interesting collection than on this occasion. Large numbers of choice and new Orchids, together with a selection of the most effective stove and greenhouse plants, of useful size for decorative purposes or growing into specimens. Messrs. R. Ker & Son, Liverpool, had a group of highly coloured *Crotons* and other plants. Mr. J. Charlesworth, Heaton, Bradford, showed a group of *Odontoglossums*, Palms, and Ferns; the Liverpool Horticultural Company exhibited a large and beautiful group of Orchids and Ferns lightly and tastefully arranged, and Mr. W. Owen, Northwich, had a group of *Cattleyas* and Ferns.

The principal competing groups were arranged in the long exhibition building, two classes being devoted to them—namely, one for nurserymen and the other for amateurs. The trade groups were required to be arranged in a space not exceeding 250 square feet, and Messrs. R. P. Ker & Son, Liverpool, were awarded first honours for a brilliant and handsome group, the *Crotons*, for which the firm is noted, being extremely well coloured. Rhododendrons, *Ericas*, Azaleas, and other bright flowering plants were employed with abundance of Ferns and foliage plants, but it would be somewhat of a relief, and would certainly not have lessened the attraction of the group, if a few less *Crotons* had been used. Mr. J. Mason, Ashton-in-Mersey, was second with a group in which a tasteful style had been adopted, but the material apparently was not adequate for carrying it out satisfactorily, for it was somewhat weak and deficient in colour. To the amateurs'

groups 150 square feet each was allotted, four competitors entering the class. Mr. S. Baerlein led with a light and tasteful composition of Adiantums, Rhodanthes, Crotons, Pelargoniums, &c. Mr. S. Lord followed with a varied group not quite so light as the preceding; Mr. G. B. Blair, Whalley Range, and Mrs. Hodgkinson taking third and fourth place. With hardy herbaceous plants Messrs. J. Dickson & Son, Chester, were the principal exhibitors in the nurserymen's class. In the class for forty alpines Messrs. Paul & Son, Cheshunt, were first, and amongst amateurs Mr. J. Dickens gained a similar position. For thirty hardy herbaceous and bulbous plants R. P. Gill, Esq., Woodhayes Hall, Ashton-on-Mersey (gardener, Mr. Plant), was first with a capital collection of showy pan of the blue Ajuga genevensis being conspicuous. Roses from Messrs. Paul & Son, Pelargoniums and hardy Ferns from Messrs. C. Ryland & Co., Ormskirk, were all good, as also were the amateurs' hardy Ferns from Arthur Bitley, Esq., Pendleton, and Mrs. Hodgkinson, who were first and second respectively.

Cut flowers were principally Pansies and Roses; the former were chiefly from local growers or fanciers; Mrs. Mellor, Chorlton-cum-Hardy, Mr. G. Robinson, Sale, and Mr. J. Dickens, Higher Broughton, winning the leading prizes. Exceptionally beautiful blooms of Tea Roses shown by J. Marshall Buckley, Esq., gained the exhibitor the first prize, and it is seldom that such substantial Rose blooms are seen at this time of year. The varieties were Princess of Wales, Alba rosea, Madame de Watteville, Grace Darling, Anna Ollivier, Comtesse de Nadaillac, Hon. E. Gifford, Niphetos, Souvenir d'un Ami, Marie Van Houtte, Madame Welche, and Catherine Mermct. Colonel Wingfield, Onslow, Shrewsbury (gardener, Mr. Lambert), sent a box of thirty-six grand flowers of Maréchal Niel Rose, of great size and substance and rich colour.

Fruit was not very abundant, but it was better than might have been expected at such an early date in a late season like the present. Sir W. Pease, Bart., M.P., Hutton Hall, Guisboro' (gardener, Mr. J. McIndoe), was the principal exhibitor, taking first with eight dishes, third with black Grapes, second with two Pine Apples, first with one Pine Apple, with Peaches and green-flesh Melons, all the samples staged with creditable productions. P. J. Thellusson, Esq., Doncaster (gardener, Mr. Chuck), was first with white and Black Grapes, the former even bunches of Duke of Buccleuch, the berries large and very clean; the black Grapes were Black Hamburg, well finished for early Grapes. W. Bretherton, Esq., Chorley (gardener, Mr. F'Anson), followed in the white Grape class with Foster's Scedling, small.

The miscellaneous exhibits were as follows:— An extensive and beautiful group of greenhouse plants from Messrs. Wm. Cutbush & Son, Highgate, Azaleas, and the graceful Saxifraga pyramidalis freely employed being striking. Messrs. F. & H. Dickson, Chester, had a pretty group of Maples and Carnations; the white Madlle. Carle, the yellow Mrs. Reynolds Hole and Lilac Charles X. were employed with capital effect. Mr. J. Hayward, Cheadle, showed a group of Rhododendrons and other plants. Messrs. W. & J. Birkenhead, Sale, had a group of Tree Ferns and dwarf Ferns of various kinds, arranged to form a central group. Messrs. J. Waterer & Co., Bagshot, had large banks of Rhododendrons. Messrs. Ryder & Son, Sale, had a group of Primula Sieboldi varieties, and outside Messrs. C. H. Frettingham & Son, Beeston, had a fine exhibit of Conifers.

TUBULAR FLOWER HOLDERS.

MESSRS. GEORGE SMITH & Co., Commercial Road, Pimlico, exhibited their new receptacles for displaying cut flowers at the Royal Horticultural Society's Show last week. The flower holders are solid disks in the shape of a dome, either round or oval, with flat base, in which are sunk forty to fifty tubular orifices gradually inclining outwards from the centre. When flowers are to be arranged, the tubes are filled with water, and the disk is placed on an ornamental plate of wide diameter (preferably of glass or terra cotta), which retains any overflow of water, and supports the outer leaves. The sprays of flowers and foliage are inserted in the tubes one by one, according to the taste of the arranger—the highest in the centre, others inclining outwards, and the lowest resting on the margin of the plate. As will be perceived even a few flowers may be arranged to the best ad-

vantage, while, if numerous, their effect need not be spoiled by overcrowding. The engraving on fig. 58 represents the disk arranged with flowers; fig. 59, showing the disk singly, and the same placed on the plate ready for arrangement. We are informed there was a great demand for these articles at the Show in question.

GARAWAY'S CLIFTON NURSERIES.

THERE are no better known nurserymen in the west of England than the Messrs. Garaway. When I first knew them they were inclined to continue on the old lines, keeping hundreds of old-fashioned hard-

FIG. 58.

FIG. 59.

wooded plants in pots. These are nearly all disposed of, only enough being kept to meet chance orders. Neither fine-foliaged plants, if we except such useful Palms as Arecas Baueri, rubra sapida and lutescens, Chamærops excelsa, Cocos Weddelliana, Cycas revoluta, Euterpe edulis, Geonomas gracilis and intermedia, Kentias Belmoreana, Canterburyana, and Fosteriana, Latania borbonica, and Seaforthia elegans, nor hardwooded plants, are in great demand in this part of the country. What are principally wanted are flowering plants, and more especially those producing choice white flowers. These are now being largely grown by Messrs. Garaway, nearly every house being crowded with serviceable young plants, all clean, healthy, and saleable. A double advantage attends the growth of these plants. Quite recently a show house fronting an important street has been built, and with this has followed an enlargement in the cut flower trade, wreaths, crosses, and bouquets being daily in demand. This enables the proprietors to profitably utilise all their surplus flowers, and at Easter time, when my visit was paid, many more flowers could have been sold than were available. Gardenias are always useful, these highly fragrant beautifully white flowers being good alike for bouquets, wreaths, and crosses. Of these there is a good bank of plants, the favourite varieties being G. florida and intermedia. Another useful companion for Gardenias is

found in the *Tabernæmontana coronaria flore-pleno*, this when in good health producing a profusion of pure white semi-double and sweet-scented flowers, but not quite so large as *Gardenias*. Some *Eucharises* that have been in bad health are under treatment. All the best bulbs are placed singly into 5-inch pots, and four smaller ones are placed in the same sized pots. All are plunged in a brisk bottom heat, and with plenty of top heat, shade, and moisture in the atmosphere should soon become well established. Bulbs thus treated frequently start vigorously, smaller side bulbs being formed in a few months, and if they are gradually shifted into larger pots useful plants result. *Paneratiums*, of which the best is *P. fragrans*, also do well under somewhat similar treatment. These are less liable to succumb to the attack of the bulb mite, and their elegant flowers produced at various times are much appreciated for bouquets and wreaths. *Ixoras* in variety and *Euphorbia jacquiniæ-flora* are found very serviceable, and it is almost needless to add a fine plant of *Stephanotis floribunda* on the roof of a large stove more than pays its way. All other more or less popular stove flowering and fine-foliaged plants are cultivated, regard being paid to those most suitable for dinner table and house decoration. A good selection of Ferns is kept in stock, but the invaluable *Adiantum cuneatum* is in the ascendant, nothing yet being found to surpass it for cutting from. *Asparagus plumosus nanus* and *A. tenuissimus* are also good additions to a house principally devoted to Ferns, the cut sprays from these being very elegant and most durable.

Among plants grown in the intermediate house there are none more useful in the winter months than *Bouvardias*, and a good stock of these are being propagated. The double white *Alfred Neuner* is the most serviceable, and the pink sport from it, *President Garfield*, is also very pretty and serviceable. *Triomphe de Nancy*, if I remember rightly, was recommended as a good double scarlet, and among singles the best are *Vreelandi* and *Humboldti corymbiflora*, white; *Elegans* and *Dazzler*, scarlet; and *Queen of the Roses*. I also noticed a large stock of the spring flowering *Crassula jasminæa*. This succeeds admirably on a greenhouse shelf, is of dwarf bushy habit, and rarely fails to produce abundance of pure white sweet-scented flowers not unlike a *Bouvardia* in appearance, and even more serviceable and durable in bouquets and wreaths. This and the "Little Pet" *Roses* (*Rosa polyantha*) are plants that should commend themselves to amateurs especially. The latter, of which the best are *Mignonette*, rosy pink, *Parqueritte* and *Little Pet*, white, are suitable for small pots, and if given a light position in a greenhouse will yield a long succession of tiny double blooms in clusters. At Messrs. Garaway's they are principally grown in 5-inch pots, and a long row of them were flowering beautifully. A good selection of *Tea Roses* are also largely grown both for distribution and to afford cut blooms. Some of the most popular and serviceable are *Niphetos*, *Madame Lambard*, *Safranot*, *Souvenir d'un Ami*, *Catherine Mermet*, *Anna Ollivier*, and *Isabella Sprunt*. *W. F. Bennett* and *The Bride*, the last-named being a valuable white sport from *Catherine Mermet*, will also be largely sought after when their merits are better known. Of *Maréchal Niel* it seems impossible to propagate too many plants, and I noticed a fine healthy lot in pots worked on the *Manetti* stock.

At Easter time white *Azaleas* are especially valuable, and of these they have a capital collection of bushy untrained plants, and which are the best to cut from. The preference is rightly given to the semi-doubles, notably *A. Borsig* and *Deutsche Perle*, both early and good; *Narcissiflora*, very early and serviceable; *Raphael*, a good grower and free; *Reine du Portugal*, extra fine, but with a little green and crimson in some of the flowers; and *Bernhard Andreas alba*, the last named being the finest double white for Easter time, and of vigorous habit. Good single whites are *Cérés*, *Reine des Blanches*, *Étendard de Flandres*, very fine flowers, and *Alba illustrata*, the latter producing large bunches of flowers. *Bernhard Andreas*, dark violet purple, semi-double, and very free; and *Souvenir de Prince Albert*, peach rose, margined with white, semi-double, late, and very free, are also worthy of special mention. A number of dwarf hybrid *Rhododendrons* in pots were beautifully in flower, and these as well as forced *Azalea mollis* are well adapted for conservatory decoration early in the year. In addition there were numerous perpetual flowering *Carnations*, well-grown *Cinerarias* in excellent variety, *Primulas*, *Hyacinths* by the hundred, and among which were many extra fine spikes; *Narcissi*, *Spiræas*, and *Arums*. *Lilium candidum* is also largely grown in pots, and gently forced so as to have plenty at Easter. The bulbs were potted in November, started coolly and introduced into gentle heat in batches. *Lilium Harrisii* later on will be very fine, but as a rule the flowers are rather too large for wreaths and crosses. *Lilium eximium* and *Gladiolus The Bride* are both admirably adapted for pot culture, and these can be had in bloom at Whitsuntide.

Chrysanthemums are made a specialty at Garaway's, thousands being sold every season, and several hundreds are being forwarded for producing fine blooms. Greenhouse *Pelargoniums*, again, always seem to do well with them, one house being filled with healthy half-specimens, and a still larger one with stocky plants in 5-inch pots, the majority of which will be sold "in the trade." Herbaceous *Calceolarias* look remarkably well, very few of the plants presenting the sickly yellow appearance very commonly met with. Many thousands of *Dahlias* are already potted, the semi-double or *Cactus* varieties being most in demand, and other houses were filled with bedding *Pelargoniums*, *Colcuses*, *Tuberous Begonias*, *Fuchsias*, and other popular plants. Pot Vines are largely and well grown, those from cut-backs naturally being the strongest, and large supplies of *Peach* and *Nectarine* trees are grown in pots for fruiting in orchard houses. In addition to the Clifton

Nurseries the Messrs. Garaway have also large nurseries at Keynsham, where all the shrubs, forest and fruit trees, *Roses*, and other hardy plants are grown.—VISITOR.

AURICULAS.

SCOTTISH PRIMULA AND AURICULA SOCIETY.

THE second Exhibition of the above Society was held in the Calton Convening Rooms, Edinburgh. The room itself is very suitable, comfortable for flowers, and convenient for visitors; cool, quiet, dustless, airy without draughtiness, and admirably lighted from above by clear daylight without direct sunshine. Hence the *Auriculas* at Edinburgh had every advantage, which is almost past hoping for in the dreary dinginess of London and the highly compound murkiness of Manchester.

This Show was decidedly superior to the Society's first Exhibition in 1887, when very many flowers were damaged in transit, one leading grower suffering the severe torture of seeing his box of plants coming upside down from the ferry to the train upon a porter's handbarrow. They could have won high, but all they did was to escape with bare life, and the Exhibition room became for them the hospital where their injuries were carefully attended to. Mr. B. Simonite and myself, who were asked to judge, thought the flowers very good under the difficult circumstances and slow development of a late season. The classes were also well filled by the thirteen exhibitors of *Auriculas*. Plants were well grown, and there were bright flowers in many of the stands; but in some instances there were pips too far beyond their best. In these the tube was dead, and an *Auricula* pip is done for, critically, when it is "down in the mouth."

Some of the exhibitors had put their trust in a multitude of pips, more than could be displayed effectively, more than the plant could finish well, and more than could possess good properties. Each pip should be both fairly seen and be fair to see. It is better that they should stand slightly apart than so overlap one another's features that admiring eyes only see one or two full moons, and the rest in various phases of eclipse.

It is seldom indeed that we have need to slaughter a good pip to reduce the surplus population. I cannot recall an *Auricula* among the "edges" that will produce sufficient perfect pips to form a confused ball of bloom. When it is thus confused it is by the crowding of inner pips, which are innately feebler in size and inferior in form and proportions of the colour zones. These take up valuable space, which timely thinning will allow to be filled with more effective flowers; and as in a bunch of Grapes at thinning time, killing will eventually be found no murder.

Varieties vary much in their power of producing good pips; *Prince of Greens* or *George Lightbody* have been seen with eight or nine fine ones, while *True Briton*, after two or three superb white edged ones, will complete the truss with things horrible.

In the particulars given me by the Hon. Secretary there are, I see, only the names of the winning flowers. Perhaps he will kindly supply, and the Editor kindly accept, a supplement of my notes with a list of the winning exhibitors; for both the growers north of the Border and the flowers they grow will be welcome intelligence to all who feel keen interest in the *Auricula*.

Some of the flowers were old faces that are fading into memories further south; but it was a refreshment of old associations to see them again, and they were much as I had ever known them. There was *Page's Champion*, lovely in its green edge, but with the ground colour inconstant, two shades of maroon, and with the petal segments cutting into the circle and the paste. *Booth's Freedom* with its pure and darker green edge and rich black velvet ground, but with the old fault of an angular paste, always the worse the better the flower is grown.

Old Ringleader was very brilliantly done, but one of those that suffered from a congestion of the pips. *Ashworth's Regular* was larger in the pips than I have ever seen it, but it could not manage purity of body colour, the meal creeping over it. Such flowers as *Stapleford Hero*, *Meteor Flag*, *Lady Sophia Dumaresque*, *Countess of Dunmore*, and *Fair Maid*, a pale and ghostly old white edge, with every feature shrouded in a faint veil of meal, I saw with the feeling that these were shadows of the past. So also seemed *Earl Grosvenor* and the dark self *Vulcan* and *Ivanhoe*, and others.

I trust it may not be thought that I would cast unkind reproach on these old flowers or think them a melancholy sight. I have grown and loved them all, and so have many more of us. Only the sight of them after long absence was touching. It was like re-visiting in after life some scenes of earlier days, to find a native village smaller, a hill less mountainous, a well-known stream less enchanting than it seemed, while yet one had not wandered far beyond.

As for the newer *Auriculas* they can but with comparative slowness come into circulation. They have to be both proved and multiplied, and that work is not rapid. But there need be no fear that they will be accepted except upon their intrinsic merits. No mere puff of the raiser will blow them into favour. They must compete with the best there are, and they in their turn, if they stand the test, will be the standards for the flowers newer still. Thus the standard rises and will ever rise.

A twofold good test for a seedling will be found in open competition and in stern severity at home. It is the kinder way not to be a little blind.

An interesting feature in the prize list were the collections of six

dissimilar selfs for a special medal. It was happily won by the exhibitor who last year had his chances shattered by the reversal of his box, in which there was not even hope left unescaped. That competition showed that six good selfs are not easy to show or bring in good condition in an awkward season. The premier flower of the Exhibition was a very bright Acme, not often seen so good, better up upon the stem than it often is, body colour evenly balanced on the petals, which it often is not, edge a good white, and tube lively, the five pips of even quality, and the petals prettily smoothed. Acme's edge is frequently no whiter than the grey-mealed foliage, and, contrary to law and custom, is at times a superb thing from an autumn bloom.

A premier flower for each class was eligible out of the whole of the stands and single plants, and in green edges the Prince of Greens, which bloomed so phenomenally last season and won so highly in the English shows, was here again the premier, though with a lessened splendour. Prince at his best, with his grand green edge, and jet-black ground colour, and round paste, but always weak if not "fishy" tube, unites the best with the worst property of the Auricula, and reminds me somehow of Hood's lament over the fanciful make-up of the mermaid—

"That joined, to best of human form
The worst end of a fish."

In grey edges Alderman Wisbey in that character was the premier flower, none of the leading greys being in sufficient character and condition. In the selfs an exceedingly good and fresh complexioned Topsy, with more well-finished pips than this variety almost ever carries, had the post of honour.

In addition to the Auriculas, of which, in the Alpine classes I have no notes, there were six exhibitors of kindred and other plants, and among the Primula species was a very beautiful and varied collection from the Edinburgh Royal Botanic Gardens, also some very finely grown specimens of *P. obconica* completely sheeted in masses of bloom, some flowers being of a very large type.

I cannot but say how true and enjoyable were the warm welcomes and the keen enthusiasm of the florist brotherhood in the far north. It would have carried off even a poor show well, and it was nothing damped last year by manifold mishaps to the plants. There is a social floral atmosphere in which anything will grow, and the land, by tradition now waxing old, is a happy land for the Auricula.—F. D. HORNER, *Burton-in-Lonsdale*.

LIST OF WINNING FLOWERS.

For the gold medallion, presented by Mr. W. Straton, Broughty Ferry, for six self Auriculas, dissimilar—Heroine, Black Bess, Pizarro, Princess, Onward, Sapphire.

For six dissimilar Auriculas, one at least in each class.—First, Prince of Greens, Conservative, Ajax, Beauty, Frank Simonite, Mrs. Douglas. Second, Heatherbell, Black Bess, Colonel Taylor, George Lightbody, Ringleader, Prince of Greens. Third, Prince of Greens, Acme, Miss Gair, C. J. Perry, Dr. Kidd, and seedling green edge.

Four dissimilar, one in each of the classes.—First, Lovely Ann, Geo. Lightbody, Acme, Meteor Flag. Second, Heatherbell, Geo. Lightbody, Rev. F. D. Horner, Heroine. Third, Rev. F. D. Horner, F. Simonite, Rd. Headly, Lord Lorne.

Pairs, dissimilar in variety and class.—First, Geo. Lightbody, Stapleford Hero. Second, Lovely Ann, Sophia Dumaresque. Third, Lancashire Hero, Dr. Kidd.

Single Plants, Green-edged.—First, Rev. F. D. Horner; second, Booth's Freedom; third, Page's Champion; fourth, Lovely Ann; fifth, Colonel Taylor. Grey-edged.—First, Alderman Wisbey; second, Ringleader; third, George Lightbody; fourth, Trail's Beauty; fifth, George Lightbody. White-edged.—First, Beauty (Trail); second, John Simonite; third, Mrs. Dodwell; fourth, Frank Simonite; fifth, Earl Grosvenor. Selfs.—First, Topsy; second, Black Bess; third, Cathedral (Browning); fourth, Andrew Millar; fifth, Lord Lorne.

Premier of whole Exhibition.—Acme (white-edged). Premier green edge, Prince of Greens. Premier grey edge, Alderman Wisbey. Premier white edge, Acme. Premier self, Topsy.—F. D. H.

The list of prizewinners is published as we received it in the columns of a newspaper:—Probably the best cultivated specimens were shown by Mr. Ben Simonite, Sheffield. In respect of size and colour they were admirable. A leading prize—viz., a gold medallion given by the Secretary—was won by Mr. J. D. Kerr, Douglasfield, Dundee, for the best six self stage Auriculas. The following is the prize list:—

Six plants, dissimilar in class and variety.—1, W. H. White, Newcastle; 2, J. D. Kerr, Douglasfield; 3, W. Marshall, Ayr. Four plants, one from each class.—1, E. Adams, Swallow; 2, Jas. Black, East Calder; 3, W. H. White, Newcastle. Two plants, dissimilar.—1, E. Adams; 2, W. Kilgour, Blair Adam; 3, W. H. White. One plant, green-edge.—1, W. H. White; 2, 3, 4, and 5, W. Kilgour, Donne. One plant, grey-edge.—1, F. D. Kerr; 2, W. Kilgour; 3, W. Bairnsfather, Leek; 4, E. A. Adams; 5, W. H. White. One plant, white-edge.—1, W. H. White; 2, W. Marshall. One plant, self.—1, J. D. Kerr; 2, 3, and 4, W. Kilgour; 5, A. Scott, Forglen. Premier plant in each class.—1, W. H. White, green-edge; J. D. Kerr, grey; E. A. Adams, white; J. D. Kerr, self. Premier Auricula in Show.—E. A. Adams, Acme, white. Alpine Auriculas, six dissimilar.—1, E. A. Adams; 2, James Black; 3, A. Calder. Four dissimilar.—1, E. A. Adams; 2, James Black; 3, A. Calder. Two dissimilar.—1, James Black; 2, A. R. Henderson; 3, E. A. Adams. Polyanthus, three dissimilar, gold laced.—E. A.

Adams. Primula species, six distinct.—W. Straton, Annfield, Broughty Ferry. Three pots Primula obconica.—1, W. Henderson, Clermiston; 2, W. Straton."

THE NATIONAL CHRYSANTHEMUM SOCIETY'S PROVINCIAL SHOW AT SHEFFIELD.

A PARTY of officers and members of the National Society left London last week to visit Sheffield and complete some preliminary arrangements respecting the provincial show to be held in that town next November. The Committee and officers of the Sheffield Society took the opportunity of arranging to entertain their visitors at a dinner on Saturday evening last, and the idea was carried out in the earnest and thorough manner which distinguishes our northern friends. About fifty members and patrons of the Sheffield Society assembled at the "Clarence Hotel" at 7 P.M., Capt. Mark Firth presiding, the following being the representatives of the National Society present:—Mr. R. Ballantine (Vice-President), Mr. Wm. Holmes (Hon. Secretary), Mr. Lewis Castle, Mr. G. S. Addison, Mr. G. Stevens, and Mr. J. H. Laing. Of the local Society there were Mr. Duncan Gilmour, jun., Mr. Fenton, Mr. H. Outram, Mr. T. B. Hague, Mr. T. Haigh, Mr. Allison, Mr. Eadon, Mr. Broomhead, Mr. Ben Simouite, Mr. J. Udale, Mr. Walker, &c., and the Hon. Secretaries, Mr. W. K. Woodcock, Mr. J. W. Needham, and Mr. J. W. Jarvis.

An excellent repast was served by Mrs. M'Culloch, and after full justice had been done to it, the toasts were commenced by Mr. T. Haigh proposing "The National Chrysanthemum Society and Visitors." He said they all hoped that the new departure which had been taken by the National Society in coming into the provinces would bring it much into notice. The local society felt greatly honoured by the fact that the National Society had selected Sheffield as the town in which to hold its first provincial show, and he trusted it would be a complete success.

Mr. Ballantine was received with applause on rising to respond. He said it was a peculiar pleasure to him to be present to inaugurate a new departure in the history of the National Society, and he trusted that the commencement of all the meetings in other towns would be as pleasant as the commencement of the November Show had been in Sheffield. From the manner in which the deputation had been received, and from the correspondence which had passed with the local officials, he had no doubt whatever that the holding of the first provincial show in Sheffield could not fail to have a successful issue.

Mr. W. Holmes also responded, and met with a cordial reception. He expressed regret that they had not with them the President of the National Society, Mr. Edward Sanderson, and then said the kindness and hospitality they had received since their arrival in Sheffield had far exceeded their expectations. He also thanked them for the kind references made to the National Society, with which he had been connected from its beginning, and in working which he had taken a somewhat active part. He had watched their Society grow from a purely local into a national Society, but none of the steps taken in connection with it had been watched with greater pleasure and anticipation than the one they were now attempting—the holding of a provincial Show. Such a departure was suggested four or five years ago by Mr. Morton, of Darlington, but it was not entertained. The Committee were now unanimously of opinion that the attempt should be made, and then came the question, Where should the first provincial Show be held? The reply from the executive of the Sheffield Society was so satisfactory—so thoroughly business-like—as to leave no doubt in their minds as to which was the right town in which to begin the attempt. They knew that in Sheffield there were not only large numbers of florists who take an interest in Chrysanthemums, but that there were men who, like themselves, neither knew nor believed in the word failure. Hence the National Society had no hesitation in selecting Sheffield as the first town to be visited, and he hoped the pleasant meeting they had that day had was a happy augury of the success which would attend their first provincial Show.

Mr. G. S. Addison followed with the toast of the "Sheffield and West Riding Chrysanthemum Society and the Hallamshire Gardens Society," and spoke of the very great hospitality the visitors had received from the Sheffield Society. He should be pleased to meet the officials again in November. He had been told that in Sheffield they could grow Chrysanthemum blooms as big as they wanted them. They could not manage that in the south, but they could grow small and compact blooms. He hoped the Show would be a great success.

Mr. W. K. Woodcock, in responding, said the local Society had only been established four years, and they were very proud of the success it had already achieved. For that success they had to thank, in a very large measure, their esteemed President, Mr. Firth. Not only had Mr. Firth rendered them valuable financial aid, but he had used his great influence in many ways to promote the prosperity of the Society. He also bore testimony to the valuable aid they had received from Mr. Gilmour, Mr. Fenton, and other friends, and concluded by expressing the

hope that much good would result from the National Society coming to Sheffield.

The health of the Presidents and Vice-Presidents, proposed by Mr. Ledger, the patrons and subscribers by Mr. Eadon, and the Horticultural Press by Mr. J. Walker, were duly honoured. Mr. L. Castle in replying to the last named, regretted the unavoidable absence of Mr. J. Wright, Mr. Wynn, Mr. Gordon, and Mr. Dean, but intimated that all had promised their hearty support to the project.

Besides the invitation to the dinner the Sheffield Committee prepared a programme for two days' excursions, which proved most enjoyable. One day was devoted to a visit to Chatsworth Gardens and Park, a delightful journey by road over the moors in most favourable weather being thoroughly appreciated, and the pleasure of the trip was considerably increased by the hospitable reception accorded to the party by Mr. Owen Thomas. Upon the second day the party visited Oakholme, the residence of T. Wilson, Esq., who, with his gardener, Mr. Hannah, accompanied the visitors through the compact well furnished range of houses and neatly kept garden. At Mount View Mr. D. Ward received the party most cordially, and conducted them through his numerous houses devoted to valuable and well grown Orchids, of which there is now a fine display in flower. The residence of A. Wilson, Esq., Westbrook (gardener, Mr. Pidsley), was next visited; Eccleshall Wood, now undergoing a process of improvement, and then to Oakbrook, the residence of Mark Firth, Esq., where the gardener, Mr. Woodcock, entertained the party. A hurried visit to Mr. D. Gilmour's, Sandygate Rose Nursery, completed the tour, and shortly after 6 P.M. the members of the National Society left Sheffield, amply satisfied with their visit, which true Yorkshire hospitality and heartiness had rendered enjoyable in the highest degree.

The above brief reference to the gardens visited must suffice this week, but further details respecting the numerous attractions of the various establishments are promised for another issue.—ONE OF THE VISITORS.

HARDY FRUIT GARDEN.

APRICOTS.—Those under glass copings and further protected with blinds, have set remarkably heavy crops, and other trees only roughly protected have also a good sprinkling of fruit. It is very unwise to leave large clusters of fruit to mature, as in this case it is of little value when ripe, and all the tree's energies will have been exhausted in their production. They ought to be freely thinned at once, leaving them at least 4 inches apart all over the tree. If extra fine fruit are desired they ought to be gone over again later on, and any deformed or rather small fruit removed. Only when set very irregularly should the fruit be left rather thickly. The least that can be done is to remove all that are placed where they cannot possibly swell properly, or those pressing against the wall nails and old spurs. Fruit taken from the trees before stoning commences, or any not much larger than ordinary marbles, may be used in pies by those who appreciate them. It is also necessary to thin out the shoots, especially at the highest part of the wall and under the copings, the reserved or best placed foreright growths being stopped at the fifth or sixth joint, while yet it can be done with the finger and thumb. Old trees are constantly losing large branches as well as numerous spurs on the live wood, and there is no preventing this. All that can be done is to anticipate the evil, one plan being to always have some young trees coming on to take the place of those in failing health. Another remedy, especially for the loss of spurs, is to lay in a number of young shoots in the same manner as Peach trees are treated. Well-ripened young wood produces the finest fruit, and being nearer to the walls earlier dishes are obtained than from projecting spurs. Now is the time to select a number of well-placed shoots, these being laid in either over or between the older wood.

WATERING AND SYRINGING WALL TREES.—The rainfall as yet has been very far below the average, and it is doubtful if some wall trees get enough moisture at the roots even during a comparatively wet season. Especially is this the case with those under much projecting copings, or which are against a wall near which Elms, Beech, and other large trees are growing. There is no doubt that a close examination of numerous wall borders would disclose the fact that they are much too dry at the present time. Apricots, Peaches, and Cherries in particular need watering occasionally, and even Plums and Pears against hot walls will pay for a little similar extra attention. The whole of the space between the walls and vegetable crops growing on the fruit borders ought to be loosened with forks, and some of the surface soil thrown back in order to just bare the roots. This renders the work of thoroughly soaking the border with diluted farmyard liquid manure or soot, or some kind of special manure more effectual. Next the roots should be placed a layer of partially rotten manure, and the surface returned on to this. The former will be kept in a moist state by the soil, and, in addition to enclosing the moisture in the border, will also be a good food supply for the roots to take possession of. Red

spider usually follows in the wake of a long spell of clear days and cold days, and is already far too plentiful on the Peach and Apricot trees under fixed glass copings. Those improved copings with reversible action may in showery weather be so adjusted to admit of the rains washing the foliage, but the trees under the fixed coping must be frequently and heavily syringed, or otherwise the red spider will soon ruin the foliage, poor flavourless fruit being an almost sure consequence of this. A garden engine is of the greatest service for keeping down the red spider, and failing this the syringe must be forcibly used. If the nights are clear and cold the morning is the best time to damp them, but in warm weather it is advisable to syringe the trees both in the morning and also again towards evening. A good drenching should be given each time, this being a case where half measures are of no avail.

PROTECTED GOOSEBERRY BUSHES.—In many gardens the plan of fixing some kind of permanent protection over a quarter of fruit bushes has been adopted, it being found the cheapest and surest way of saving both the buds and fruit from the birds. Unfortunately these wire-netting-covered structures also exclude insect and grub-eating birds, and it may easily happen that caterpillars will do more harm to the trees than birds usually do. A bush badly infested with the grubs or caterpillars of the Gooseberry and Currant sawfly is quite stripped of leaves in a few days, and ruined for one season at least. All structures designed for covering a wall border or open quarter of fruit trees and bushes ought, therefore, to be so constructed as to admit of a portion of the fronts or sides being taken down or thrown open in some way as soon as they are in full leafage. Birds large and small, including our best friend the cuckoo, can then have free access to the bushes, and in country districts at any rate, will keep down the grubs. There is no necessity to uncover the roof, as they rarely enter in a downright direction, but soon find their way in and out at the front and sides. Cuckoos are naturally shy birds, and are busy among the fruit bushes early in the morning, and again when quiet is restored in the evening. One of these caught and placed in a "Gooseberry house" has been known to keep the whole of the usually much-infested bushes quite free from caterpillars.

CLEARING BUSHES OF CATERPILLARS.—Where the natural enemies of caterpillars are numerous very little trouble is experienced in keeping the bushes clear of those destructive pests, but during some seasons a great difficulty is felt in keeping them under in many instances. Preventive measures, such as the removal during winter of much of the surface soil containing the cocoons from which the fly emerges, surfacings of lime and fresh tan are effective, but are of no avail so late as this. The fly first appears during April or early in May, and quickly deposits a number of eggs on the under side of the Gooseberry and Currant leaves. In the course of a week the grubs hatch and commence feeding on the leaves, their presence being denoted by numerous tiny holes in the infested leaves. If these are detected in time, picked off wholesale, and destroyed, those few escaping will work but little harm, and may be destroyed in a short time. When the caterpillars have been allowed to spread over the bushes they are not easily got rid of. Flour of sulphur is a capital remedy, this being either freely mixed with water and syringed over the trees sufficiently often to well coat both the upper and under side of the leaves with it; or the sulphur may, with the aid of distributors, be well distributed over the trees when they are moist with dew. Sulphur does not injure the fruit in any way, and is less objectionable than hellebore powder and a few other remedies. Hot water, with just sufficient soapy water or soapsuds to make it "oily," freely syringed over the trees is another good remedy. The leaves in a young state will stand it as hot as 100°, and later on the heat may be increased to 120° without injury to aught but the caterpillars. Smartly tapping the stems of the bushes and shaking the branches will dislodge many caterpillars, which can be caught on a sheet and destroyed.

FRUIT FORCING.

PINES.—Under good management Pine plants as a rule yield the finest fruits when they show their fruit ten to twelve months from the time the suckers are first potted, but some allowance must be made for autumn-potted suckers, which have to make a part of their growth under adverse influence. Plants that were finally potted last September will now be showing fruit, and if not, means should be adopted to effect it. Plants of that age not exhibiting signs of fruiting should be subjected to comparative rest for a period of four to six weeks, lowering the heat at the roots to 75°, and admitting air fully at 75° to 80°, and let the temperature fall to 75° before closing the house for the day. Very little artificial heat will be necessary, but it must be afforded if necessary to prevent the night temperature from falling below 60°. The plants must not be allowed to become excessively dry at the roots, but whenever a plant needs it afford water liberally. The smaller suckers of the plants referred to potted this spring should be kept growing until the pots are well filled with roots, when, if it be necessary, the plants can be subjected to the same course of treatment as advised for the larger plants, and these will afford a successional supply of fruit.

The strongest suckers potted last March should be in their largest pots. If they are not yet potted no further delay should be tolerated, as to retain them longer in small pots is debilitating and detrimental to their after growth. Recently potted plants should have a regular bottom heat of 85° to 90°, and be thoroughly watered after potting, and no more should be given until the soil becomes dry, as it is necessary to exercise more care than usual at this stage, the state of the individual plants being ascertained before its application.

Young stock will be making rapid progress, and should be regularly attended to in every particular, allowing such plants sufficient space for development, as nothing is so inimical to sturdy plants as crowding them together in their early stages. Ventilate early in the day at 75° to 80° to render the foliage dry before it is affected by the sun. Discontinue shading successional plants, but for fruiting plants with the crowns in close proximity to the glass a slight shade from powerful sun will be beneficial.

MELONS.—*Earliest Plants in Pits and Frames.*—When fruits are ripening they should be fully exposed to the sun by raising them on inverted flower pots. Place a piece of slate for the fruit to rest on, or the moisture arising beneath will cause it to decay. Admit air freely, and water only to prevent the foliage flagging. If a second crop is desired encourage about four shoots from each plant from the base of the stems now bearing, so that when the fruit is cut the old growths may be removed and young shoots substituted. These will show fruit freely on the first laterals, every alternate lateral being rubbed off to prevent overcrowding. If a top-dressing of fresh compost be given, supplemented with a good supply of moderately weak liquid manure at 90°, the plants will be assisted to make a vigorous second growth. A useful crop of Melons may be obtained by making up beds now of any spent material, which from mixing and turning will generate a gentle warmth, placing over it frames that may have been used for Potatoes, bedding plants, &c., placing in each light about two or three barrowfuls of rather strong loam mixed with some old mortar rubbish or road scrapings if deficient of grit, and pressing it down firmly. Into this when warmed turn out a strong healthy plant, pressing the soil firmly about the roots, and giving a good watering. If pits are employed the surface of the soil must be about a foot from the glass, and if the weather be bright shade for a few days after planting. Seed may yet be sown to raise plants for frames at present occupied by tender bedding plants.

In Houses.—When the fruit is cut from the earliest plants the old stem should be cut back to a strong shoot near its base, removing as much of the surface soil as can be picked out from among the roots, replacing with rather strong lumpy loam pressed well down, and giving a good watering. A moist atmosphere being maintained and the plants syringed in the morning and about 4 P.M. they will soon start freely, showing fruit in much less time than by planting afresh. If, however, the plants are affected with canker, or from carrying too heavy a first crop, a deficiency of water or attacks of insects are much enfeebled, it is better to remove them, thoroughly cleansing the house, placing strong plants in ridges or hillocks as advised in former calendars.

The weather of late has been all that could be desired to produce Melons of a rich flavour. The days have been bright though the air has been cold, necessitating the employment of fires, especially at night, as it is a great mistake to allow too great a difference between the night and day temperatures. Maintain 70° as the minimum at night, though 65° or even 60° will do no harm when the nights are unusually cold and the days bright, 70° to 75° by day being secured artificially, admitting a little air at and above the latter, allowing an advance to 85° or 90°, closing at 80° to 85°, but not so early as to raise the temperature to 90° or 95°. Keep plenty of moisture in houses containing young growing plants or those swelling the fruit, gently damping the foliage, walls, floors, and closing at about 3.30 P.M., or as early as safe. Feed plants liberally that have their fruit swelling, not allowing them to suffer through deficient supplies of water, and afford weak liquid manure. Fertilise all pistillate blossoms daily to set the flowers or fruit, ensuring a somewhat dry condition of the atmosphere, not using the knife during that period, but pinch out the points of the shoots one or two joints beyond the fruit. Earth up the plants so soon as the fruit is set and swelling, and examine the plants frequently for the removal of superfluous growths, not allowing them to interfere with the principal foliage. Shade as little as possible, and only to prevent flagging.

PEACHES AND NECTARINES.—*Early Houses.*—Hale's Early, closely followed by Early Alfred and Early York, make a capital succession to Alexander, Early Beatrice, and other of the very early Peaches, they being very much superior in quality, and those are followed by Royal George (still the most certain kind for forcing) which is preceded by Dr. Hogg by about ten days, it being a good setter, with large beautiful fruit of good quality and somewhat firm flesh, which renders it a good traveller. Lord Napier is the best as regards size of the early Nectarines. Admit plenty of air to the ripening fruit in the daytime, and at night also if a prolonged succession of fruit is required. When the fruit is all removed resume syringing to free the foliage of dust and red spider. The borders must be maintained in a thoroughly moist state, as it is important that the foliage be kept healthy as long as possible. The trees after fruiting should have the wood which carried the fruit cut away to the shoot at the base for next year's fruiting, excepting those needful for the extension of the trees, and if the trees are too full of wood thin well, so as to admit light and air to the shoots, and thereby insure their thorough ripening.

Succession Houses.—No great amount of artificial heat will now be necessary except in cold and dull weather, when it will be necessary, especially when the fruit is taking the last swelling or commencing ripening, to admit of a free circulation of air. Remove any leaves that shade the fruit too much, so that it may colour perfectly at the ripening period. The tying-in of the shoots must be regularly attended to, stopping the laterals at the first joint, and any shoots that cannot be allowed to extend without crowding or encroaching on others stop at about 14 inches, exception being made of extensions. Shoots retained

level with or past the fruit to attract the sap to it should be stopped to one or two joints at each break. Syringing must be vigorously followed up morning and afternoon to keep red spider under, and the inside border attended to frequently with water. Admit air early in the day, as with large panes of glass the sun often acts so powerfully on the foliage as to scorch it unless air has been previously admitted.

Late Houses.—Do not delay thinning the fruit. Very few more should be left after the fruits attain to the size of a walnut than will be required for the crop, up to which stage the thinning should be gradual, and avoid overburdening the trees, it being better to retain too few rather than too many fruits, as fine examples are always appreciated, whilst the indifferently swelled and quality-lacking are a source of complaint. It is a mistake to retain more shoots than there is room for; if the wood is not properly solidified as made, imperfectly formed buds result. Fumigate moderately on two or three consecutive evenings, having the foliage dry, for aphides, and for mildew dust with flowers of sulphur or use sulphide of potassium.

STRAWBERRIES IN POTS.—The early Strawberries have not been good. The lateness of procuring runners last season in consequence of the drought and its continuance, acted unfavourably on the plants after potting, so that they did not make and perfect as good a growth as was essential to the successful fruiting of the early forced batches. The succession Strawberries have been very much better, and are now affording good fruit. Copious supplies of water are necessary, especially in the early stages of swelling, for should the plants once lack that essential, the fruit may be so dried as not to swell kindly afterwards, and a somewhat moist condition of the atmosphere is necessary to obtain well-swelled berries, therefore avoid drying currents, especially of cold air. The plants should be watered two or three times a day according to the weather, and have liquid manure two or three times a week until the fruit commences colouring, after which give water only sufficient to prevent the foliage flagging. This, with plenty of air, is conducive of flavour.

PLANT HOUSES.

Calanthes.—The earliest plants if in small pots will be ready for shifting, as they are now growing and rooting freely. This should not be delayed until the small pots are crowded with roots. When once they are allowed to get into this condition it is better to feed them than place them in larger pots. With timely potting the roots take freely to the fresh soil, and increased vigour is soon perceptible. Do not over-pot these plants, for nothing is gained by so doing, but the reverse. The pots should be liberally drained, and the compost used of a light open nature. A suitable mixture is good fibry loam and peat in equal proportions, with the greater portion of the small particles removed, one-seventh of decayed manure passed through a fine sieve with charcoal and sand added liberally. After potting arrange the plants moderately close to the glass, and apply water carefully until they are rooting well in the new soil. Sturdy growth should be encouraged by admitting air judiciously, shading from the strong sun only. Later plants may be grown in the same structure, but be careful not to over-water those that have not yet made a fair quantity of roots.

Phajus grandifolius.—If these plants have been well cared for they will have passed the most critical stage of growth, and the roots should be extending freely in the pots. The young growths should be strong, and the expanding foliage free from spots. Too much water at the roots, and an injudicious use of the syringe in the early stages, are certain to spot the foliage and disfigure the plants for the season. Water may now be applied with greater freedom both to the roots and to the foliage, but be careful not to over-syringe them during spells of sunless weather. If possible grow them under the conditions advised for Calanthes. They can be grown well in a vinery, but are worthy of a better position if one can be found for them.

THE BEE-KEEPER.

THE MANAGEMENT OF SWARMS.

SWARMS may now be expected to issue. Where additional room is afforded swarming will be postponed, and, if room is continually given in advance of the requirements of the bees, obviated, unless the queen gives out in her egg-laying and so compels the bees, moved by the strong instinct of self-preservation, to raise a successor while there is yet time.

Every swarm should be fed for at least three days. This is a golden rule, and should never be broken unless combs of honey and empty combs are supplied in place of frames of foundation. In the former case the swarm at once becomes a stock and has a food supply; in the latter, the bees depend entirely upon their own exertions, and this, too, at a time when much honey is consumed in building comb or drawing out foundation. It may be urged that in

fine weather it is mere waste to feed a swarm. In practice, however, there is a manifest advantage in wise and judicious feeding. It gives a stimulus, and we may well believe encourages the bees to greater exertion. Plenty and laziness do not go hand in hand with bees. *Otium cum dignitate* is unknown to them. While an empty cell remains the bees will strive to fill it; therefore there is no necessity to fear—as some people seem inclined to do—that bees become lazy by assistance, and finding themselves assisted do not try to assist themselves. This argument—fallacious, ridiculous, and absurd—was seriously urged by an old bee-keeper, who had “observed”—or so he said—evil results from feeding. We ventured to suggest that in small hives a large supply of food given by a bee-keeper at a time when honey was coming in freely, might render the bees apparently lazy; but that they were in reality simply doing nothing, because they had nothing to do, the hive being glutted with honey. Overfeeding is a great injury to every stock. Extremes generally are injurious; but because unwise feeding leads to bad results it does not at all follow that judicious feeding will also be harmful. Now, the question is, What amount of syrup should be given to a newly hived swarm supplied with full sheets of foundation? We say that 10 lbs. of syrup distributed over one week is sufficient; but that if the weather presents any income from the fields a watch must be kept even after this amount has been given to see that the food does not run short. On the other hand, if the bees are able to work freely, and a plentiful supply of honey is coming in, less than 10 lbs. will suffice to give a swarm a start and to make them to draw out foundation and to start with good prospects on the “race that they must run.”

If it is intended to extract from frames in the body hive, the greatest possible care must be taken not to extract “syrup” and to sell it as honey. In fact, with honey at present prices, we should feel inclined to feed every swarm with honey, and not run the remotest risk of having syrup in the cells; but if the combs are not to be passed through the extractor, less care is necessary. With careful watching, however, sufficient syrup may be supplied to enable the foundation to be drawn out without enabling the bees to store more than an infinitesimal quantity of syrup. In fact, in cases where sealed combs are available, and it is desired to feed with syrup and not with honey, we would suggest that a frame of sealed honey should be placed on either side of the brood nest, and then sufficient syrup supplied to enable the bees to draw out the foundation, but not enough to enable them to “lay by for a rainy day.” The presence of the sealed combs prevents any chance of starving, and the bee-keeper is accordingly relieved from the anxiety which he might otherwise feel in feeding a spare quantity of syrup to a large swarm. These seem the general lines upon which this feeding of swarms should run. The individual may apply them and alter them, but he must bear in mind these facts:—

- 1, Without feeding, a swarm must die if bad weather immediately follow its issue and hiving.
- 2, Without a proper supply of food breeding is stopped by the inability of the bees to prepare cells for the reception of the eggs.
- 3, A little expense at the beginning brings a return in the end.
- 4, Syrup must never be extracted from the combs and sold as honey.

Feeding judiciously and at proper times is the golden key which unlocks the treasures of *Nature*. It opens to the bees the flowers of the field, and enables them to store their treasure house, and to yield to the bee-keeper a rich and plentiful harvest.—FELIX.

[In the last line of the first paragraph in the article on page 413 last week, for the word “bee” read “bird,” and the sentence will be intelligible.]

TRADE CATALOGUES RECEIVED.

Hooper & Co., Limited, Central Avenue Covent Garden, London.—
List of Designs in Makart Decorations.

TO CORRESPONDENTS

All correspondence should be directed either to “THE EDITOR” or to “THE PUBLISHER.” Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Pelargonium Leaves Spotted (*F. G.*).—To your question as to “Whether sour soil, overwatering, and want of drainage will cause the leaves to be spotted and curl,” our reply is in the affirmative. No plants can be kept healthy under such unnatural conditions.

Insects on Lilliums (*C. P.*).—The easiest and best way of destroying the aphides on your Lilliums is to fumigate them with tobacco smoke. Two light applications on consecutive nights will be better and safer than one strong dose. If this is impracticable, dew them with the syringe, and dust them lightly with tobacco powder. After it has destroyed the aphides wash it off with the syringe.

Auriculas (*A. S.*).—The flowers sent are border Alpines, and to such varieties as these before us names are not given, as they lack the requisite characters entitling them to that distinction. They are none the less attractive in borders and on rockery mounds suitable for the growth of the plants. Named varieties of Alpines grown and exhibited in pots by florists are entirely different, and superior in form, substance, and colour.

Melons (*W. J.*).—The plants that have been injured by fumigation will be checked in growth, and the fruit will not ripen so early in consequence, and may not be so large and good as if no such misfortune had occurred. Still much may be done by encouraging the development of some young leaves, avoiding overcrowding them and the best of the others, then with good management in other respects we do not think failure need be apprehended.

Gladioli and Wireworms (*H. C.*).—The specimens you send are wireworms. When present in the soil they appear ready to take possession of almost all kinds of bulbs, tubers, and fleshy growths. All we can suggest in your case is to provide counterbaits in the form of Potatoes, Carrots, and squares of fresh dug turf, burying these amongst the Gladioli and examining them every two or three days. We have known more wireworms caught in squares of turf than in roots buried at the same time for alluring them to destruction.

Mushrooms in Ice House (*Reader*).—You ask if you can grow Mushrooms in a disused ice house during the summer months? We are unable to say, not knowing your experience as a Mushroom grower; but we know of beds in a very cool building, that would make an excellent ice house, just commencing to bear, and which will, no doubt, yield an abundant supply of fine Mushrooms during the next three months. They grow well in a temperature between 50° and 60°, indeed lower than that, but their growth is slower. Some of the finest examples we have seen this spring were cut from a mound in the open, the surface of which was often crisp with frost. A disused ice house ought to be an excellent place for growing Mushrooms in during the summer.

Chemical Manures (*R. M.*).—This subject has been treated so fully, clearly, and frequently in our Home Farm department that it is difficult how it can be better presented to the intelligent reader. Consult a few back numbers and refer to a reply on page 371 (May 3rd) on manuring fruit trees, and you will find more information than we can possibly give apart from that which has appeared. If you want a simple mixture for general crops, superphosphate of lime and nitrate of soda may be tried, the former at the rate of six or eight, the latter about two or three cwt. per acre; but the exact quantity can only be determined by the condition of the soil. Chemical manures lose half their value if applied late in the season, and a term of hot dry weather follows, or rather the current crops do not absorb half their virtues.

Name of Insects (*W. H.*).—Your No. 1, the solitary specimen, is a centipede, *Lithobius forficatus*, not uncommon in gardens and houses, nearly related to those species which cause so much annoyance or peril to residents in hotter climates than ours. De Geer, having had this insect under close observation, gives it as his opinion that the bite is venomous, but it is doubtful whether the jaws can pierce the human skin even of a child. It kills and sucks the juices of many other insects, some larger than itself, the food not being vegetable. The other specimens (No. 2) belong to the too abundant species, *Julus terrestris*, a millipede of mixed diet. Probably the *Julidæ* feed chiefly on small insects, worms, and slugs, but they will also attack the roots of vegetables and hide in bulbs, doing much injury. Their destruction is often attempted by the application of soot, lime, nitrate of soda, and

diluted petroleum; their vigour, however, is considerable, and their ingenuity also in concealing themselves.

Plants for the Conservatory—Roses in Pots (W. S. S.).—If you had stated what convenience you have for growing plants other than the conservatory we should have been in a position to have given you a useful answer. If you write to us again stating your wants, with the additional information we require, we will gladly assist you. You can pot the Roses directly they have ceased flowering, provided they require only the removal of the drainage and shifting into larger pots without further disturbing the roots. The condition of the soil in which they are growing must guide you in this matter. If the soil is sweet, and you do not object to larger pots, they can be potted at the time named. By so doing they will be well established before the winter and in good condition for another year. If the soil is sour and the pots as large as you desire, you would have to reduce the ball by one-third or one-half of its present size. To do this directly after flowering might prove injurious, and it would be better not done before the end of July or beginning of August. Roses will do in the same pots for several years if liberally supplied with stimulants. The best practice, however, is to turn them out of their pots at the time stated, carefully reduce the balls one-third, and repot them in the same size pots. This insures good drainage, and provides food without recourse to stimulants. After the operation has been done the plants should stand in the shade for a fortnight and be liberally syringed to preserve their foliage in a fresh healthy condition to encourage root activity. For H.P.'s a suitable compost is good fibry loam with one-seventh of decayed manure added, with a 6-inch potful of quarter-inch bones, and the same quantity of soot to each barrowful of soil. If the loam is heavy add a liberal quantity of coarse sand; if light, a small quantity, or perhaps none will be needed.

Evaporation from Soil (W. R. R.).—Undoubtedly evaporation is accompanied by a lowering of temperature of the surface, through which moisture in the form of vapour escapes, and ice can be formed in summer accordingly. But in practical culture the escape of moisture from the soil by evaporation at certain seasons is advantageous, hence the beneficial effect of east winds in drying wet ground by evaporation in spring and rendering it amenable to tillage. The surface of the earth may be cooled somewhat during the process, but that is, at the time, and under the circumstances, the lesser of two evils, the greater, leaving the surface soil in a state of saturation. Loosening the surface soil—that is, exposing more and more of that below which is moist, in dry weather, and as the original surface dries, favours evaporation. If you place a quantity of wet soil on a bench in a dry potting shed, spread it out, and as often as the surface dries stir it to expose the damp particles below to the dry air, the bulk of the soil will be ready for use sooner than if it were pressed into a mass with a smooth firm surface and left undisturbed. In the most profitable market garden culture men are constantly employed in stirring the soil amongst Cabbages and Lettuces in dry weather in spring, not for killing weeds, because there are none, but for favouring the escape of moisture and admitting the air. This brings the crops a few days or a week earlier into the market, making a difference of £20, and often a good deal more, in their value per acre. If plants in pots are overwatered through ignorance or by accident, and are thereby endangered, stirring the soil is resorted to for favouring evaporation, and most gardeners know that Cucumbers, Melons, and other tender stemmed plants have been saved in consequence. A layer of loose dry soil in summer also arrests evaporation, but this would not be so if the soil were frequently stirred, each time bringing some of the moist earth below to the surface to become quickly dried, as obviously more moisture would then be extracted from the soil by evaporation in the process. Stirring the soil and maintaining a loose surface may therefore favour and arrest evaporation according to the manner in which the work is done. Sometimes we desire to promote and sometimes prevent the escape of moisture from the soil, and we act accordingly. We know the sandy Strawberry field very well to which you refer, and fail to see that it affords evidence in conflict with the teachings in the work you mention; and if the practice of the author is right, we do not quite see this proves his reasons for it very far wrong. There is no doubt much to be said on your side of the question, and if you have no objection to discuss the matter in our columns with the author of the paragraph that does not represent your view of the case, we will readily afford the opportunity.

COVENT GARDEN MARKET.—MAY 23RD.

MARKET quiet owing to the holidays, with prices lower.

AGRICULTURAL DEPRESSION.

STRANGE, most strange it is, that anyone paying ordinary attention to passing events should by any possibility take a wrong view of the cause and remedy of the agricultural depression. Yet we not unfrequently hear the most extraordinary reasons advanced for it, and which are altogether beside the mark. The work of our great agricultural societies is mentioned with a sneer; the value of the teaching at Cirencester and Downton is not simply questioned, but, with the presumptuous folly of that outspoken conceit which is the invariable concomitant of ignorance, it is termed worthless. Agricultural experiments, too, come in for a full share of condemnation, while chemical manures are said to have poisoned the soil, to have rendered it barren and worthless, and to have contributed more than anything else to the ruin of farmers. It was only a short time ago that we were assured a thousand acres of soil had been rendered worthless for agricultural purposes by the use of nitrate of soda, and one of our own barriffs objected to the use of fish salt as a manure because he thought it caused the soil "to run together and become hard." Yet this very individual has for the last three years been using potash and other salts extensively under our direction with very profitable results, but then he had never heard the term of salt applied to them.

Well, now, the only way to contend with such ignorance, if we notice it at all, is not by mere argument, but by the irrefragable proof of tangible results. At a meeting of the members of a farmer's club for a discussion of the relative value of manures, we

had been telling them, among other things, of the wonderful crop of Barley obtained at Flitcham Abbey by the use of muriate of potash, and we were much amused by one of them farming the land of an entire parish himself, who after declaring farmyard manure to be the sheet-anchor of farmers, turned to us with the question, "What is muriate of potash?" He was evidently impressed by Mr. Cook's success, and it is just possible he is a purchaser of considerable quantities of potash this season. The most remarkable effects of potash is, however, not always perceptible in the crop to which it is applied, but rather in those of the following year or two. But we must not wander from our subject, and will reserve some remarks bearing upon the results of the use of manures for another paper.

If proof were really required of the good work done by our Agricultural Societies we have only to turn to recent issue of the journals of two of them. The Journal of the Bath and West of England, in addition to sixteen lengthy reports and papers on as many important subjects connected with agriculture, has numerous short pithy papers on such subjects as "The Phenomena of Animal Life and Vegetation," "The Wheat Crop of 1887," "The Pig of the Future," "Seeds for Permanent Pasture," "Butter Making," "Management of Farm Horses, &c." The Journal of the Royal Horticultural Society has many important articles; but if it only contained the reports of chemical analyses of manures, seeds, and oil cake it would be invaluable, for there it undoubtedly exposes an evil that has done material harm to the confiding British farmer. It is solely owing to this great Society that we are now able to procure pure seeds. In the eighteenth volume, published in 1882, there appeared a paper by Mr. Faunce de Laune on "Laying Down Land to Permanent Grass," in which he said:—"I found, however careful I was in my orders, and from whatever seed merchant I ordered my seeds, the per-centage of Rye Grass, soft woolly grass, and other bad grasses and weeds, was beyond all belief. I found in a piece of land 8½ feet square about six plants of Cocksfoot, one Foxtail, two Meadow Fescue, five or six Crested Dogstail, and the rest Rye grass, soft woolly Grass, perennial Clovers, and weeds. I then got an introduction to Mr. Carruthers, and by means of his able help and valuable information, was enabled to make closer experiments. From these I learnt that good seed was most difficult to get; and to illustrate how difficult, I will give some of my experience. I had five acres of very valuable land I wished to sow with permanent grass for seed; the land was not only very good, but very highly manured and absolutely clean, having been a Hop garden. I divided this field into three parts, one to be sown with Cocksfoot, the second with Meadow Fescue, and the third with rough Meadow Grass I ordered, with special care, the three kinds of seed from one of the great seed merchants, and looked forward next year to a good crop of seed, not suspecting that when seed was especially ordered of a particular kind from a firm of repute it would be anything but good. But after a few weeks' growth, although I was satisfied that the Cocksfoot was true, my suspicions were aroused about the others, and I sent some of the seed that was left to be examined by Mr. Carruthers. To my great amazement I was told the Meadow Fescue was all Rye Grass, and the Rough Meadow Grass all Smooth Meadow Grass. There was nothing left for it but in the best way possible to destroy all the grass and resow it." He adds further on, "I have since these experiments never sown any seed except after the sample had been examined by Mr. Carruthers, and have, in consequence, obtained results most satisfactory to myself."

We might proceed to quote examples of an equal amount of good work done in the analyses of manures and oil cake, for the last number of the Journal contains no less than thirty pages of cases of adulteration, all which show clearly how heavily farmers have suffered from putting themselves in the hands of unscrupulous dealers. The fact is, however, sufficiently notorious, yet we fear even now that much so-called pure cake and special manures are comparatively worthless.

WORK ON THE HOME FARM.

As we write the weather is delightfully mild, and gentle rain has been falling for twelve hours or more. Nothing could possibly be more opportune than this change from cold dry weather, for the spring corn, Kohl Rabi, Mangolds, and Swedes were all ready for it, and the grass reserved for hay will also derive much benefit from it. It is true the rain prevents the finishing of corn-hoeing, but we do not mind this, for we have had an exceptionally favourable time for the destruction of weeds, and full advantage has been taken of it, so that we look forward confidently to full corn crops this year. It must not be forgotten that weeds among root crops will grow freely now, and we must resolve to get them under before haymaking begins. That important work will certainly be late in the season this year, and we shall have to push on briskly when we do begin in order to be ready for corn harvest. The grass mowers have already been sent in to the ironworks to be thoroughly overhauled and put in order, and we advise our readers to send in their machines if they are at all faulty, for every hour is precious when the haymaking begins, and all that is possible should now be done to prepare for it. To intending purchasers of new grass mowers we strongly advise preference to Hornsby's machines, simply because after a trial of several we have found none equal to them. These machines are compact and strong, and they have a very strong connecting rod which seldom if ever breaks. It is wise to have duplicate parts of the machine which are most subject to wear and tear and to risk of breakage. By attention to these simple matters of preparation and precaution we were able to mow from 200 to 300 acres of grass last season at the rate of 10 acres per machine daily. Stones have been picked, and fallen twigs and branches picked and raked up under timber trees, both for safety to the mowers and for the sake of the hay.

Food for sheep is now becoming abundant, and it has caused the price of store hoggets to have an upward tendency. Fat hoggets, too, have met with a brisk sale at good prices, and we have been selling some clipped ones at profitable rates. To do this advantageously so early there must be snug yards and sheds, with plenty of sound nourishing food. We are fortunate in having such shelter, and the food has consisted of coarse lamb food, chaff, and Mangolds.

BRITISH TOBACCO CULTURE.

IN the admirable report of the competition for the prizes offered by the London Chamber of Commerce for British grown Tobacco in your issue for May 16th, there is one point we would ask you to be good enough to allow us to explain. It reads as follows:—

"None of the samples submitted were in a merchantable condition, so that it would appear that English growers have still a great deal to learn, especially as regards curing."

We would state that Tobacco of the crop of 1887 could not possibly be in a merchantable condition on May 1st, 1888.

If it was intended to convey that the Tobacco should be in a merchantable condition, by which we understand in a condition to go into the hands of the manufacturer, or the broker, from the producer, the competition instead of taking place on May 1st, should have been delayed until September 1st, when the Tobacco would have passed through what is familiarly known in America as the "May sweat," and would ultimately have reached the mature stage it is supposed to attain before going into the hands of the broker or manufacturer.

This we feel sure you will recognise is an important point and sufficiently interesting to justify our asking you to insert this letter for the information of your readers.—JAMES CARTER & Co.

[Undoubtedly the point is important, and ready insertion is given to the explanatory communication.]

REMARKS.

13th.—A lovely summer day; the first with temperature above 70°.
 14th.—Bright early; generally cloudy after 10 A.M.
 15th.—Generally bazy, and frequently cloudy; but bright at times.
 16th.—Cloudy morning, wet afternoon, damp evening.
 17th.—Continuous rain till 3 P.M., then damp and showery.
 18th.—Dull and damp early, gradually cleared, and bright and hot after 11 A.M. Lunar halo at night.
 19th.—Close, hot, and frequently cloudy. Thunder heard in the neighbourhood in the afternoon.
 Although Wednesday and Thursday were wet and uncomfortable, the rest of the week was extremely pleasant, and Friday and Saturday were quite summerlike.—G. J. SYMONS.

STRAWBERRY RUNNERS AND FORCING.

CAREFUL watering, steady forcing, judicious ventilation, and other cultural requirements are unquestionably of great importance in the culture of forced Strawberries. But these are of but little avail if the grower has plants with small unripened crowns. Fine large fruit does not entirely depend upon the treatment the plants receive while they are in the forcing house, although this is essential to success; but it is dependent mainly on a good start, for without strong plants with well-ripened crowns fruit of first quality will not be produced.

Young plantations made early last August, and made firm in the ground directly signs of growth were visible, and the ground well mulched at the same time, will now be growing vigorously. The first runners are now showing, and the flower stems that are pushing up strongly from the centre of the plants should be removed. The past dry weather has been the reverse of favourable for rapid growth, and early mulchings have already proved beneficial. Plants could not have looked more promising even had they enjoyed showery weather. When the flower stems are removed the plants can devote all their energies to growth and the production of early runners. If the ground in which they are growing was in a good fertile condition at planting time a soaking of clear water will help them wonderfully. If the soil was not liberally supplied with manure before planting, or rendered sufficiently rich by that used for mulching, liquid manure in a weak state may with advantage be given now. Where liquid from the drainings of the manure heaps does not exist, a little artificial manure may be used, and even this will do no harm, but the reverse, if the land was in good condition at planting time. I have found this to be the quickest and most economical method of feeding the plants, or for exciting them into vigorous growth for producing strong runners early. When liquids have to be carted a distance and then diluted with water the labour soon amounts to more than the cost of artificials, that act equally well, if not better. The effect of suitable artificial manures acts almost magically upon the plants in producing strong early runners, which are so desirable for the purpose in question.

Those who have followed my previous writings are perfectly aware that liquid manure has not for years been applied to fruiting plants during forcing. When used it must be discontinued directly the fruit shows signs of colouring, just when the plants need most support. This can be given by artificials without fear of injury to the fruits, either as regards their flavour or appearance. If the plants have been well treated, and are given the last dose of artificials when the first fruits are colouring, hundreds of white roots will quickly appear on the surface to take in the food provided. Their appearance shows at a glance the healthful condition of the roots, and if they did not need the food they would not appear so freely and quickly on the surface for it. Roots of plants in pots, fed with liquid manure of any description do not so readily come to the surface; they have a tendency to leave it and make their way out through the drainage. If there is anything in which they can root they soon form a large quantity of fibres outside in comparison to what plants will if fed by artificials. Yet strong doses cannot be too much condemned. Most artificials if given in too large quantities do more harm than good. A little applied frequently is the secret of success. The first application

should be given directly the fruit is thinned, and then weekly until they reach the stage already stated.

Notions that should have been obsolete long ago about top-dressing are still thoroughly and firmly believed in. Those who have practised top-dressing with light rich material prior to starting the plants, and observed its effect upon them in their later stages of development, cannot well conceive that practitioners should still believe that such a course is liable to promote leaf growth at the expense of fruitfulness. If too much foliage is pushed up at the start the evil must be traced to other causes, and the most general ones are, either forcing them too quickly in their early stages or the unripened condition of the crowns in autumn. Some kinds, of which Sir Joseph Paxton may be noted, are very liable to do this, and therefore those who wish to have full crops of this variety must have good runners early, so as to insure the crowns being thoroughly matured. Top-dressing after the fruit is set does not do half the good as is the case when done early. When done at starting time the roots take possession directly the plants start growing, and these in consequence throw up stout healthy flower stems that stand well above the foliage.

All those who have grown Strawberries know the ruinous effect of allowing them to become dry when the fruit is swelling, and this has often led to the opposite evil of giving them too much water. When grown in small pots, say 5-inch, and arranged on shelves near the glass, we are told they must be watered two and three times a day. I cannot think such treatment good for any plant. When the sun has considerable power, and the fruit set, they swell better some distance from the glass, where, instead of the fruit being exposed unnaturally to full sunshine, they can be partially shaded by their own foliage. Where the shelves are close to the glass the only chance is to turn the fruit from it. I have said watering two or three times a day is not good for any plant—crippled fruit during the setting period, a sodden condition of the soil, and unsatisfactory root activity are the results. Good fruits are and have been produced by such methods, but there is some uncertainty about the system, as we have felt for years while practising it, and much, very much, of the success attained, or the reverse, is dependent upon the man in charge. Under a good reliable man all may go well, but under the care of a thoughtless careless person all may go wrong. Success should not be solely dependent on those entrusted with the application of water to the plants. How can this state of things be altered, and labour in watering saved, with a greater certainty of success? is only a natural question to ask. The difficulty has been solved, and a plan that has been found serviceable will be more largely practised another year if I still remain in charge of these gardens. The shelves, narrow ones, will all be so arranged by nailing a board on each side and at the ends, so that the pots can be plunged as far as practicable to the rim in ashes, cocoa-nut fibre refuse, or any similar material. Filling in between the pots as they are arranged is work that can be done quickly, and making the shelves so that they will hold the plunging material will not take much longer. This can all be done at the season of the year when work does not press so heavily as during the months of April, May, and later. This system will insure the roots of the plants from injury by the exposure of the pots to the sun, and what will be the watering compared with the present system of growing them with the pots exposed? Some plants plunged to the rim in January only needed watering twice up to the time they came in flower, while another lot of plants arranged for the purpose of testing the matter needed attention daily, and some days twice, from the time the flower spikes first made their appearance. Plunging the pots will insure the soil being in a uniform condition of moisture, which must prove beneficial to the plants, save labour, and insure success with half the care and responsibility to those in charge. Have glazed pots been tried for Strawberries?—W. BARDNEY.

BELGIAN WORK AND WAYS—DIGGING.

IN a previous communication reference was made to the circumstance of far more workers being visible on the land in Belgium than in England. It is quite within the limits of the strictest accuracy to say not that ten, but certainly more than twenty times the number of persons were seen working in fields between Antwerp and Ghent, on about forty-three miles, than between London and Harwich, which is, perhaps, half as far again. There are two lines of railway between the two Flemish cities—namely, the Pays de Waes route, before alluded to as starting from the Scheldt, opposite the landing place from the steamer, this being a private or “company” line; and the State railway, starting from the opposite side of the city, the station de l’Est, which is about a mile from the quay. This is a comparatively new and direct route, formerly travellers having to go *via* Malines and change there or somewhere else; but by what may be called the Boom route there is no change, and the second class fare is about 3s. 6d.

I had read that the old Pays de Waes line traversed the district of small holdings, where spade culture was supreme and every inch of land made to yield a reward for honest labour. No doubt the majority of the holdings are very small, plots of a few acres only, and tillers of the ground very numerous; but having travelled by one line to Ghent, and by the other back again, and forming an opinion from the not too quickly moving train, I thought the busiest scene and the best work was in the district through which the State line runs. A few years ago I passed through a district of “small culture” a little further south, between Brussels and Waterloo, and was greatly disappointed. The land was light, very sandy, and not by any means well worked. Potatoes were being taken up, miserably poor crops, women appearing to do nearly all the work, while vacant land was being scratched over with an apology for a plough, and horse to match, while the human workers showed to great disadvantage with English peasantry as a rule. I think possibly I saw “small culture” in its worst aspect there, and now I am inclined to surmise I have witnessed it in its best form, and at another period of the year—planting instead of reaping time, or the Potato setting period—and this might account for the number of persons employed, as for miles they appeared to be almost as thick as gleaners in an English Wheat field in the autumn.

I suppose any person who has gone through the mill of gardening in every phase, and who has learned to use the spade as deftly as the pruning knife or pen, knows in a moment as soon as he sees a man “handle” an implement whether he understands it or not. It is painful to see young men who have been brought up in the houses all their time, and become expert potters, plant trainers and table decorators, and whom fortune has not favoured with a continuation of such “light employment”—it is painful, I say, for an old hand to see their ungainliness when necessity compels them, as is often the case, to use the spade and other garden tools, which they may have thought were only fit for labourers. The work in such case is truly hard, whereas it would have been comparatively easy had they learned in the school of practice the right way of doing it. This every young gardener should do, and never rest contented till he can do every kind of work in a garden as well as an expert labourer can do it, and a little better if possible. He will then be provided for emergencies, and if he has never to dig or trench, and do ordinary outdoor work, the men under him who do it will respect him the more, and readily bow to his authority when they see, as they are quick to do, there is someone over them who “knows his business.” This is a digression, but not, after all, very foreign to the subject, even if that subject be digging in a foreign land, for if a lesson useful in its tendency cannot be derived from a narration, or a suggestion thrown out by the way that may be of possible service, it is small use narrating.

And now to the Belgian diggers. The first thing that strikes a stranger is to see women using the spade as well as men, not merely pottering about with it, as is the case in this country when they venture to “help in the garden,” but doing downright good work, and doing it as well, and as much of it, also apparently as easily, as the masculine workers. The implements, as they were driven boldly in the land and withdrawn with a clean turn over, glittered in the sunshine—clear evidence that their value was known, and that pride was taken in the digging. It is conceivable that there are kid-gloved dandies who cannot see what there is to be proud over in spades and spade work. Well, so much the worse for them if they hope to become gardeners. A gardener who cannot dig—and there are hundreds of probationers who appear to have no great desire to learn—is ignorant in the very elements of his calling. I have never seen a man who did not cherish his tools and keep them bright and clean who was a good workman. Digging can no more be well done with a rusty spade than pruning can with a dull knife. The Belgian diggers keep their spades bright and do the work the better and the more easily on that account. There are “lucky men” in the gardening world no doubt, men who have had friends to help them onwards, and it may be hoist them upwards, but no one should rely on patronage, which is a lottery of one prize to a thousand blanks. The safe course for a man to pursue is to strive for excellence in every kind of work, and never to rest contented so long as he sees a fellow worker surpass him. If he is earnest in that respect he will not only train his hand and his eye, but strengthen his brain, and become a good deal more than a mere delver—an intelligent worker. I have been reading with pleasure some articles in the *Journal* of late by Messrs. Dunkin and Coombe on artificial manures, and I dare venture to say that the writers of those articles are real workers. Their perseverance

in searching for knowledge, their watchfulness for the results of practice, and the absence of “showiness” in formulating their opinions, indicate to me at least that they are not mere surface scratchers; but when they dig do it with a will and keep their spades bright. If I had a good garden, and wanted a good gardener to manage it, I dare engage either of those men; but I do not, as my man can dig as well as a Belgian peasant, and he does not do his work the less well for knowing that I can “take a turn” without knowing it. The lesson I wish to impress on all young aspirants to fame in the world of gardening—a world of labour and delight, is to be earnest, to think of no kind of work as worth no thought and care; but if digging is to be done take a pride in it and do it well, and if anyone thinks the worse of them for that, depend on it his acquaintance is not worth cultivating, and he may be regarded as either a drone or a snob. Every man in the gardening ranks who has achieved a good position solely by his own endeavours was, so far as I know, an industrious worker in his earlier days, and did not allow anyone to excel him in whatever was in hand. His spade-work was as well finished as his table decorations, and as the plans he so carefully drew to scale for landscape work and buildings. Am I forgetting the Belgian diggers? No; only wandering from them for a few moments, but not from the subject, and now return for a few more moments to the men, women, children, dogs, and water barrows in the fields.

Water barrows in April, what can they be for? We do not see them dragged about on the land at home at that season of the year. They are for conveying liquid manure, sewage, slops, and refuse of every kind that can be collected for enriching the land. Nothing appears to be allowed to run to waste and to pollute watercourses; and it is observable the sewage is applied before the crops are growing. The wrong time, some may fancy; but if there were anything very wrong about it would it not have been found out long ago by the busy workers whose livelihood depends on what they put in the land, for obviously money must be placed in a bank before it is drawn out? Such applications do good at any time whenever the surface of the ground is dry enough to facilitate the transport of the fertilising medium, and it is far better to apply it then than to let it accumulate and poison the air and be wasted at the same time. A sturdy dog harnessed to the barrel on wheels drags it along as if he enjoyed the work, the man behind giving a helping hand. Those who have no dog help place their barrels in a barrow and trundle them along. Women seem to be as apt at barrow work as men, and spread manure in the trenches, children dropping in Potatoes, and the more able-bodied dragging the earth over them with a heavy-looking hoe. It may be added that the sewage from the cities is carted away nightly in railway engine-like vessels, it being drawn into these through hose with pumps. It is a curious process, and offensive enough in Ghent after midnight; but in Antwerp the appliances seem better, yet the same kind of nocturnal work goes on continually. But we must return to the digging.

In the district in question the workpeople were in trenches, about two spades wide, and appeared to be turning up the soil about the same depth—bastard trenching, perhaps, but when we particularly wanted the train to stop to enable a closer examination, it seemed to move the quicker. In the finish of beds good workmanship was particularly noticeable. Long stretches of them were passed here and there, but what was in them I know not. They were about 4 feet wide, as level as a floor, and not only were the edges lined off without kink or flaw, but the line appeared to have been set back about 4 inches, and that portion smoothed—a sort of beading being formed in the line course. The neatness was very remarkable, and although the crops would neither be better nor worse for the fancy indulged in, it clearly showed the difference between careful and slovenly work. It reminded of the exactitude of the rows of upspringing corn in the best agricultural districts of England, where prizes are given to drillmen for the excellence of their work. Practically no more time, and often not a minute more, is occupied in doing work well, and in such a way that the eye rests on with pleasure, than doing it in a slipshod and unworkmanlike manner that gives no satisfaction. The best workmen I have met were usually the quickest, or at least could get through as much as the “rough hands;” and the rule holds good both in the workshop and the garden. As regards work with the pen, perhaps I had better “sing small,” because some of my friends tell me they cannot read my writing; but the printers can, which seems to suggest that there is something to be learned by those readers who confess their failure.

We will now for a time link the spade with the plough. In the well tilled Belgian campagne through which we are passing some of the holdings comprise ten or twenty acres I was told, and it is the custom to turn a third or fourth of the land up deeply with the spade every year, the remainder being worked with the plough. This means that the whole is either very deeply dug or trenched every three or four years. There can be no question in my mind as to the value of this practice in two important respects—namely, in providing employment for men, and in enhancing the value of crops, thereby making the labour remunerative; and with otherwise good management the work is remunerative, but it is, or ought to be, clear to all cultivators that it is wealth wasted to improve the ground by labour or enrich it with manure if its virtues are abstracted by weeds. Thousands of acres of land in Britain have been rendered unprofitable through nothing else but growing weeds, and if all soil of good staple, so neglected, were well worked, fortified, and kept clean, the produce would be doubled, and landlords, tenants, and labourers benefited. If anyone should be

inclined to dispute the proposition let him declare the grounds of his assension, and somebody or other will probably endeavour to ascertain whether they are well founded or not. I venture to say those Belgian cultivators who work the land so well do not grow weeds. But if they are expert diggers they are a generation or two behind in ploughing. The implements are rude and animal power weak. The ploughs are dumpy and short-breasted, with one shaft nearly straight up and a cross piece sticking out of one side of it near the top, which the ploughman or woman takes hold of with one hand and drives the gaunt bullock or lean pony with the other; and as for harrowing, it is sometimes done by two men, while in one instance I saw a combination team—a woman, boy, and dog yoked to an implement and trailing it over the land.

A laborious life these Belgian peasants lead, and what their homes must be is not a pleasant thought to dwell on. Domestic comforts must be few according to our notions, but perhaps not to theirs. Let us hope the people are happy. In the London market gardens some of the hard-working Irish labourers think it a bad arrangement having to live in houses that want so much "claning," and have to pay 4s. or 5s. a week for doing it, instead of having shanties on the land and little or no "rent" to pay, and little or no scrubbing to do. Of course there is not a tinge of reproach in this, but it simply shows the force of habit; and as a balancing of national prejudices or preferences a Scotch and an English case may be cited. A Scottish nobleman had bedrooms built over some of his one-storey cottages. A few months after they were finished he took some friends to see how comfortable he had made his people, but was surprised and annoyed by finding the new rooms filled with Potatoes, wood, and general lumber. Protest was useless, as the occupants were firm in the conviction that they could not go upstairs to sleep. Not long ago an English gardener entered on a charge. He describes the place as a very good one, but his family are not comfortable because the cottage is so constructed that they have to go downstairs to bed. Thus do ideals of happiness differ, and it is easy to waste sympathy over persons because they are not as you wish them to be, while at the same time they may be as honest, as happy as yourself. We will hope this is so with the plodding Belgian peasantry. We leave them for the present, and arrive at Ghent, and jump into a cab. "Hotel de la Poste!" brings a responsive, "Jah, Mynheer!" and we rattle away over the stones, for there is no mistaking their presence in the streets of the Flemish city. A footsore carpet trotter described them as the hardest stones in the world, and all placed wrong side upwards.—A JUROR.

LATE-BEARING MUSHROOM BEDS.

I SEND some Mushrooms for your inspection, gathered from a bed which was made up in a cool shed and spawned early this year. We have been gathering fair quantities of Mushrooms for several weeks, and the bed is yet in good bearing. The bed is 8 feet long, 3 feet wide, and 1 foot deep, and 4 feet from the floor of the shed. The manure heated violently at first and then went quite cold after the spawn had been inserted. The bed was spawned when the temperature was about 75° and on the decline, but in two or three days after the heat had fallen very low. We were unable to prepare the manure in a proper manner owing to the frosty weather prevailing during the time it was in the open shed. It appeared to be in good condition when the bed was made up, but soon after the frost went, and the weather became mild, which caused the material to heat so violently. In future we shall not make up a bed during a frost if we can avoid doing so. If the manure had remained in the open shed and been turned over once or twice after the frost had gone, I think the heat in the bed would have been more steady and lasting, and not so much time lost. Instead of pulling the bed in pieces after the heat had declined we placed some long litter on it, and added a few barrowfuls of manure, which caused a gentle heat in the bed which lasted for several weeks, when all the material went cold again. My object was to get the spawn to run. The temporary manure was then removed and the bed covered with dry litter. About a month ago Mushrooms made their appearance, and the spawn shows no signs of exhaustion yet.—G. GARNER, *Amberwood Gardens, Hants.*

[The Mushrooms are very fresh and firm, also beautifully clean through each being wrapped in a piece of slightly damp tissue paper. Not a few are cut too old, and are the reverse of tempting after a long journey through want of care in packing.]

THE CULTURE OF THE PEACH AND NECTARINE UNDER GLASS.

[A paper read by Mr. Atkins, gardener to J. Kaye, Esq., J.P., Clayton, West Yorks., before the Wakefield Paxton Society.]

It is my intention in this paper to touch as briefly as possible upon the main points on the cultivation of these fruits under glass. There is no doubt whatever that good Peaches can be grown on open walls, but not without considerable expense, and when we have done all for them we can they are uncertain, and will not compare with fruit from trees under glass. It would be unwise to

waste time in giving every detail of a suitable structure for the culture of this fruit. Suffice it to say that preference should be given to large houses, as they are easier to manage. In fact it becomes necessary where early forcing is carried on, being less liable to extremes of temperature than small houses or narrow cases. Extremes of heat at any season are dangerous and must be strictly avoided.

The successful cultivation of these fruits greatly depends upon a good border. A suitable soil, for the Peach, like most other fruits, is one of a strong holding character. The borders must be kept firm at all times, especially near the roots of the trees. This will induce the trees to form a large mass of fibrous roots, and it is very desirable to keep these roots near the warm surface. The soil in the border should vary in depth from 2 to 3 feet, according to the bottom on which it rests. Gravelly or dry bottoms require the deepest borders. In the majority of cases one-third of suitable soil may be added to the natural soil of the site, and the whole trenched to the required depth, at the same time adding any other ingredients to enrich or keep it open, as may be thought necessary. Two things must be avoided, the one of using rank manures to enrich the soil—for these induce growth in young trees not easily ripened—and the other of making it too open. Should there be any fear of the border becoming saturated at the bottom with stagnant water, drainage must be provided to carry it away, but in most cases no further preparation in the shape of drainage is required than that which constitutes the remaining part of the garden. But as often suggested, laying cross and main drains, and from 6 to 9 inches of other materials, and form the border of light soil, is the first step to disappointment and failure. More trees suffer through want of water than from the other extreme, especially where confined to inside borders. Apart from that, one of the greatest objections to owners of private establishments, especially near large towns, is the costly outlay in forming borders.

Another important item is the selection of trees. Failures and disappointments frequently arise from the hard treatment trees have received during their nursery career, premature decay of some of the main branches being brought about by the severe cutting back annually to keep them within saleable size; and after all, the majority of specimens have all their strength in the centre, and are more adapted for horizontal training than the free and open fan, the most suitable to this class of fruit. Trees of this description are dear at a gift, and should be avoided. Last season I lost the limb of a Grosse Mignonne tree that had been planted about seven years, through the above treatment; this is very discouraging, and results in a disfigured tree in the future. I do not wish to underrate the work done by our nurserymen, in fact we are much indebted to some of them of late years, but seeing that we are expected to give an ample return from our fruit houses, and are held responsible for any failures that may occur in future, it is well to be on our guard.

I would strongly advise all who have to keep houses stocked with fruitful trees to have young trees in training, so that blanks can be filled up quickly. We cannot spare wall space for these, but the system followed by one of my late masters, who was an able and successful fruit grower, was to plant a line of trees on a border with a good aspect, and form a temporary trellis for each tree, with three strong stakes, one in the centre and one on each side, the side stakes to meet the centre one at the top, and driven in the ground at an angle of about 45°. If trees are intended for front trellises and upright for walls, a few maiden trees untrained that have made a season's growth from the bud or graft should be purchased and planted early in November and cut down the following February to within a foot of the ground, encouraging two shoots right and left to grow unchecked the first season, all the main branches in future to be taken from these shoots. Nothing is easier to train than the Peach if taken in hand at the commencement. My object with a young tree from this stage is to cover the space allotted to it as quickly as possible, and with a little forethought and care in disbudding and pinching, and laying in suitable wood, but little pruning is necessary until after the trees have clothed the trellis, looking well to the lower branches; then an evenly balanced and well formed tree will be the result that will in future furnish the bottom of the trellis equal to the top.

Since I have had the management on my own responsibility I carry out the old system of summer-pruning established trees. This consists in removing all useless and exhausted wood as soon as the crop is gathered. I am aware this system is not generally adopted, but why, I do not know. In my estimation it is one of the main points connected with the culture of this fruit, especially in these late and sunless districts. This naturally strengthens and encourages the proper ripening of the wood left. At the same time we shorten some of the branches to a healthy and younger

branch where necessary to insure a generally even growth. We have not only to prune for the present, but for the future, and by cutting back a few of these branches we induce the formation of young growth much nearer the stem that will furnish a supply of shoots to cover naked places and keep up a supply of bearing wood over the whole surface of the tree. If this is carried out when the trees are in full foliage a better judgment can be formed of the quantity of wood required to cover the trellis. Crowding in unnecessary wood that cannot get well ripened is one of the greatest evils connected with this fruit. From 4 to 6 inches is a rule with me, and at the winter's pruning I prefer to shorten these according to their strength, varying from 6 to 18 inches. In the majority of cases we only take one fruit from a shoot, and two at the most, sufficient fruit buds remaining to select from, and by shortening or reducing the number, those remaining are stronger in consequence, remembering the stronger the bloom and the more perfect set we obtain the finer will be the fruit; and further, it induces the shoots to break stronger at the base to give us a shoot to fruit the following season.

The trees should be taken down and tied in bundles, and the house thoroughly washed in every part with soap and water, and the trees thoroughly syringed with a mixture of soap, petroleum, and water. I never use, nor would I recommend, any of the mixtures used by some to paint their trees. This is waste of time, and in many cases the insects are only covered for the winter, coming out as soon as the trees start in spring and puncture the young leaves. The trees are returned to their proper places, the surface of the border being cleaned and pointed up with a fork, then given a light covering of fresh loam.

The house is ready for starting any time after the 1st of December, according to the time fruit is required. My earliest house is started on the 1st of January, and brought on gradually, applying fire heat about the middle of the month. Trees that are accustomed to start at this season are easily excited and will soon be on the move. The cultivator must keep one object in view, and that is, to bring out a strong healthy bloom whilst the wood buds make but little progress until setting is nearly completed. This is of far more importance than many imagine, but those who pay strict attention to trees at this stage obtain the best results. One of the greatest errors frequently committed during the earliest stages is exciting the wood buds at the expense of the flowers by a high temperature and an excess of moisture. The house should be started with a temperature of 45° at night, dull days 55°, and 60° with sun heat, a free circulation of air day and night at all seasons, avoiding cold draughts, especially when the trees are in bloom. I never use the evaporating troughs, nor do I practise syringing the trees, except on bright days, until after the crop is set and the petals falling freely; if the house is kept moist in every part it is sufficient during the earliest stages. When the flowers begin to open the temperature should rise 5° more all round, but no hard-and-fast rule can be laid down, we must be guided by the external atmosphere, as during a spell of mild weather and an atmosphere loaded with moisture a few degrees more are necessary to bring the pollen into a fit state for fertilisation, or, on the contrary, when hard firing is necessary during severe weather such as prevailed this spring from the 7th of February until far into April, with the thermometer outside standing at 30° during the day, with from 4° to 6° of frost at night, and very few hours' sunshine. Five degrees less during the day, and 10° at night, will give better results under such circumstances. A rather drier atmosphere should be maintained during this period, but avoid carrying it too far. The house should be damped on the afternoons of fine days, and I prefer to go over the trees on alternate days at noon with a camel-hair brush. With this aid I have never found any difficulty in obtaining an even set on such varieties as Barrington, Walburton Admirable, Noblesse, and Princess of Wales with the pollen carried from the smaller flowered varieties. After the fruit is set and swelling suitable temperatures are 55° at night, 65° on dull days, and 75° from sun heat. These figures must not be exceeded until stoning is completed.

Thinning the fruit must commence as soon as they can be pronounced safe, or before they reach the size of peas, and with a liberal hand at this stage, followed up at intervals as the fruit advances. When they attain the size of Hazel nuts the fruit will swell rapidly until the stones begin to harden, and the healthiest trees will feel the strain of any excess of fruit left on them. I like to leave 20 per cent. to be thinned finally after stoning is completed. If trees are allowed to be shaded with shelves used for Strawberries, Beans, &c., they are liable to cast their fruit at this period. As a rule trees do not shed their fruit under proper management. If they do this to any extent it is due to over-cropping, either in the current or preceding season. My rule is, a Peach to each square foot. This is a good annual crop, and

one fine fleshy Peach will give better satisfaction than three ill-flavoured small fruits, and we invariably find the stone as large in a small fruit as in a large one, hence the difference is made up in flesh.

Disbudding must be followed at intervals with care and judgment from an early stage, taking care not to give old or weakly trees a check by operating too early or removing too many shoots at one time, pinching those with fruit at their base or where spurs are required on permanent wood. A free and steady growth should be encouraged until the stoning period is past. After this time the trees will make rapid growth, and the future work of the season will consist of tying in sufficient suitable wood and stopping terminal growths if not required to extend when they have grown 8 inches or a foot. The syringe may be used freely every afternoon when the air is reduced to keep the trees free from insects. The maintenance of a moist atmosphere, a steady temperature from 60° at night, with a rise to 80° from sun heat, with plenty of air in the daytime, and the usual chinks left top and bottom on at night, will encourage a free and short-jointed growth.

When the fruit shows signs of ripening syringing must be discontinued, but the stems and surface of the border may be kept moist until on the point of finish, when a comparatively cool temperature, with abundance of air, is necessary to assist the perfect ripening of the fruit. Peaches or Nectarines must not be allowed to fall nor be gathered before they are ripe. Trees should be examined daily, and twice during hot weather, morning and evening, but morning should be preferred when the fruit is fresh and cool; nets may be put up to catch any that may fall, otherwise the fruits would be useless.

Careful root watering must be attended to. Peaches must never be allowed to feel the want of water at any time. Duties press hard on all sides and at all seasons; but our fruit trees under glass, after we have secured the crop, must not be neglected. The surface of the border, where hard, should be pointed up with a fork and receive a thorough soaking of water. Diluted liquid or any other artificial manure should be given to old or weak trees that have felt the strain of a crop. Root-action is brisk at this season, and any lack of food or moisture will lead to bud-dropping. Although this arises from immature wood through the roots having wandered away in unsuitable soil, rich borders, and over-cropping, still in the majority of cases it can be traced to dryness. Borders should be frequently examined and kept moist.

Trees should receive a good watering six weeks before they are started, and the final watering must be given a month at least before the fruit is ripe. Water given after this time might cause the fruit to fall. A certain amount of vigour in the trees must be kept up by applications of stable liquid, or Beeson's manure as a top-dressing, or mixed with water and applied during active growth. Whilst I am recommending stimulants to assist the trees in perfecting their crop of fruit, I would at the same time urge the cultivator to guard against overfeeding, as stone-splitting and bud-dropping, and in numberless instances barrenness, is the result of over-feeding. This tendency to cause an over-exuberant growth, especially in late districts, not favoured by sunshine, must be avoided.

Last but not least is root lifting, this being the keynote to all success. No work pays the fruit grower better than this when carefully carried out at the proper time—i.e., when trees have or should have completed their growth, and before the leaves fall. I have been accustomed to lift some portion of our trees every autumn. I have one tree of that well-known but shy-bearing variety Walburton Admirable, which owing to the limited space of trellis, has been subjected to this treatment every alternate season for the past six years, and has never failed to finish a crop of fine-fruit. Trees that have a disposition to rush off into growth as soon as the sap rises in spring, and continue to make strong sappy growth late in the autumn, are the kinds to be dealt with, shortening all strong roots and placing them in firm soil, free from manure, in a horizontal position near the surface, which they should never leave. This operation increases the number of feeding or fibrous roots and brings them within reach of food and warmth. In fact, trees that occupy limited spaces of trellis cannot be kept in a healthy fruitful condition for any length of time where root-lifting is neglected. Trees thus treated make clean and healthy wood, and are rendered less liable to become a prey to insects and diseases so prevalent amongst these fruit trees. With plenty of fibrous roots and good feeding when necessary annual crops of fine fruit will be the result. But it is useless to feed where there are no roots, or rather where they are out of the reach of food given to them, and the more we seek to make ourselves thoroughly acquainted with the condition and requirements of our trees the more successful we shall be.

DENDROBIUM DENSIFLORUM.

NOBLE specimens of this beautiful Orchid have frequently been seen at our leading exhibitions, and occasionally we find as fine specimens hidden away, as it were, in some of our old-fashioned gardens, where exhibition honours are never sought after or much thought of either. But rarely do we find in the average garden of to-day plants of this lovely Dendrobe worthy the name; when we do, however, the fact is worth chronicling.

Mr. Pinnington, the gardener at Blacklow House, Roby, Liverpool, has grown a very creditable plant, and flowers it well annually. Many larger plants have been grown, but I am sure our readers will agree that sixty-two flower spikes, with an aggregate of upwards of 1500 blooms on a plant in a 10-inch pot, is something not to be ashamed of; the plant produced the above last season, and made more than 100 new bulbs. The only drawback to the variety densiflorum is its short duration in bloom—at the end of one short week after expanding its glory has departed. It is hard to pass many other things in this establishment without a notice. *Daphne indica*, 4 feet through, covered, as we seldom see it, with foliage, dense from top to base; a picture, when laden with its rich and fragrant flowers, more easily imagined than described. *Tecoma jasminoides*, on roof of conservatory, is also fine, with capital Camellias underneath; and in an adjoining house grand specimen Ferns that come in for special favours. Again, adjoining is a fernery containing a rare Fern mentioned in the Journal about a year ago—*Angiopteris evecta*, which is deserving of a little consideration in the matter of raising the roof to afford it necessary head-room. *Bougainvillea glabra*, probably about thirty years of age, has a trunk that gives it the appearance of being an artificial prop to the house, affords an enviable wealth of bloom in this house.

Mr. Pinnington is not unknown as a fruit exhibitor at Liverpool, and a successful one also, particularly so in hardy fruit, a fact to be proud of under circumstances the reverse of favourable.—L. B. T.

MR. SMEE'S CATTLEYAS.

THE Hackbridge collection of *Cattleya Mossiæ* varieties is very choice, and the display is heightened in effect by the abundant foil of Ferns in the interesting house in which the Orchids are flowering. The following descriptions by Mr. Lewis Castle accurately represent the varieties, and these, with many others unnamed, but excellent, combine in producing a beautiful effect.

Cattleya Mossiæ Mrs. Smeæ.—Sepals and petals suffused with rosy mauve; petals 4 inches long by 3½ inches broad, slightly but evenly undulated towards the apex, gracefully curved or drooping. Lip open, 3 inches from the throat to the apical margin, 2½ inches in diameter, beautifully frilled and crisped, the base of the lip rich gold, running up to the side margins, intense magenta in the centre and veined with crimson in the throat. A very handsome variety. Two years ago this plant bore five pairs of flowers; last year it had sixteen blooms, and it now has ten spikes with twenty-six fine expanded blooms.

Cattleya Mossiæ Southgatei.—Sepals spreading, and petals slightly drooping, undulated, purplish mauve, splashed and streaked with a darker tint. Lip oblong, beautifully frilled, golden bronze in the throat, dark crimson centre and veining, light blush margin. An effective variety.

Cattleya Mossiæ Percivaliana.—Sepals and petals narrow, recurving, slightly undulated towards the apex. Lip narrow, but of rich colour, the centre crimson purple, with a fine white margin, broader at the apex; lateral lobes and throat veined with golden bronze on an orange ground, the base marked with crimson. There is very slight frilling, but the variety is a peculiarly beautiful one.

Cattleya Mossiæ Cummins' variety.—Distinct and pretty, the flower of good shape, with broad light mauve petals. The lip well proportioned, sharply cut into a fringe at the edge, but not so deep as most others; the margin is pale, with a rich crimson centre, running into the orange veins of the throat, and giving a peculiarly rich coppery hue.

Cattleya Mossiæ Lawrenceana.—A small flower with blush sepals and petals. Lip with a solid crimson purple centre, bronze-gold veining in the throat, and a narrow white even margin.

C. Schröderi, *C. Wagneri*, with several forms of *C. Mendelli* are also flowering, one of them being very distinct and beautiful.

CYPRIPEDIUM BELLATULUM.

MESSRS. H. LOW & Co., Clapton, have been fortunate enough to introduce a superbly beautiful *Cypridium* which may be popularly described as the finest variety of *C. Godefroyæ*, though there is more justification for ranking it as a distinct species than there is for some that have been so distinguished. The flowers on the plant shown at Westminster last week, when the Royal Horticultural Society awarded it a first-class certificate, had partly expanded upon the plant in the case as imported, and would therefore not be expected to be full sized; they were, however, 2½ to 3 inches in diameter, and dried flowers have been obtained 4 inches across.

FIG. 60.—CYPRIPEDIUM BELLATULUM.

The dorsal sepal and the petals are broad and well formed, creamy white with deep crimson maroon spots clearly defined, the lip having a few smaller dots. It appears to be free in growth and flowering, and we have seen several imported plants already showing flowers.

WOODHATCH LODGE, REIGATE.

SOME good spirit prompted Mr. T. B. Haywood to invite a party of the "Councillors" and Fellows of the Royal Horticultural Society to inspect his garden at Reigate last Thursday, and as the weather proved exceptionally favourable, it can be imagined that with such an admirable host and hostess as Mr. and Mrs. Haywood the guests most heartily enjoyed their visit, and departed reluctantly. The garden at Woodhatch Lodge is widely famed for its Roses, but Orchids are also a specialty, hardy plants are prized, and everything that is undertaken shows the same good results as the Roses. Every department found its admirers amongst the visitors. Mr. Harry J. Veitch, Mr. H. M. Pollett, and Mr. Dominy examined the Orchids with the keenest interest. Mr.

George Paul inspected the extensive collection of Roses as such an enthusiast might be expected to do. The Rev. W. Wilks discoursed upon hardy plants, and Mr. Pearson investigated the structure, heating, and ventilating of the glass houses as an expert; while a nameless individual had a full share of the enjoyment, and will endeavour to briefly chronicle something of what was seen during the afternoon.

Woodhatch Lodge is situated on a considerable elevation above and to the south of the town of Reigate, commanding some delightful views towards the Sussex Weald, and rejoicing in an atmosphere of exceptional purity. The garden itself comprises about 10 acres, but the major portion of the estate constitutes the Home Farm, which, with his choice breeds of cattle, receives much of Mr. Haywood's attention. Around the house the grounds are tastefully but unpretentiously laid out, winding walks, vigorous and varied shrubberies, and abundant trees constituting what may be termed the framework; beds and borders of hardy plants, and Roses by thousands in grand condition, filling up the picture. Some of the Roses are grown at the upper part of the garden near the houses, but the principal Rose garden is situated lower down, near the farm, and there are numberless beds of dwarf H.P. Roses cut hard back with Teas pegged down, all looking as promising as could be wished, and the Woodhatch record of exhibition victories, remarkable as it is, it may be hoped, is by no means completed.

The glass houses are, however, extensive, and we must direct a few minutes to them, for respecting the Roses something will probably be said later on. The first range entered is approached by a lean-to house 36 feet long, with lobby or porch entrance and double doors—a wise provision to avoid draughts in winter. At this time of year the porch, like the other part of the house, is filled with *Odontoglossums*, comprising wonderfully strong plants and several fine varieties of *O. crispum*. The plants are in excellent health, and have quite a forest of spikes either expanded or advancing, and the plants have afforded a succession of flowers since Christmas. *O. crispum*, *O. Pescatorei*, *O. Halli*, *O. Andersonianum*, *O. sceptrum*, *O. vexillarium*, including a good plant of the variety *rubellum*, *O. Rossi majus*, *O. Cervantesi*, and *O. cirrhosum* contribute to the effect. *O. vexillarium* is grown in slightly warmer quarters, but *O. cirrhosum* does well in the house, the temperature of which is not allowed to fall below 50° in winter, and it is kept as cool as possible now. Arranged with these *Masdevallias* have an extremely fine appearance, the contrast of their brilliantly coloured flowers with the delicacy of the *Odontoglossums* being very striking. *M. Veitchi* is represented by several fine specimens; one has had fifty flowers and a fine variety has nineteen large flowers; *M. ignea*, Paterson's variety, has fifty flowers, and several good varieties of *M. Lindeni* are grown with forty to sixty flowers each. Prominent at the end of the house is a specimen of *Dendrobium thysiflorum*, having twenty-two long racemes of white and golden-lipped flowers; but this is only one of many fine plants of this useful species which is made a specialty at Woodhatch Lodge, and to which we must refer presently.

At right angles to the *Odontoglossum* house is a lean-to range, 90 feet long, facing the south, the opposite side of the back wall being devoted to a range of lean-to houses for cool Orchids. It may be here remarked that throughout a capital material is employed for covering the stages—namely, a fine clean grit obtained from Eastbourne, which serves all the purposes of retaining moisture, and has a better appearance than small coal or coke. Beneath the stages are moveable zinc tanks filled with water, intervening spaces being planted with *Selaginella*. The first division of the long range is filled with *Aerides*, *Vandas*, *Cypripediums*, and a few other choice plants, such as *Dendrobium nobile* *Sanderianum*, a handsome variety of the nobilium type; the valuable hybrid, *Cattleya calummata*; then amongst *Cypripediums* are the choice hybrids, *leucorrhodum*, *Morgania*, and *candibulum*, with the recent introduction *C. bellatulum*, now showing flowers. *Saccolabium ampullaceum*, *præmorsum*, and *curvifolium*, the latter with two spikes of bright red flowers, are included in this house.

The *Dendrobiums* have the next division of the range, and there are the plants of *D. thysiflorum* already mentioned. Over twenty large bush-like specimens are grown, and these have had a total of 209 racemes out at once, the majority of them being still in fine condition at the time of our visit. The plants are remarkably strong, with stout growths 3 feet or more in length, bearing more and larger leaves than are usually seen. The gardener, Mr. Ridout, has been very successful with these as with other plants, and it may be useful to briefly record his practice. The minimum winter temperature is 60°, with 70° to 75° in the summer, and full exposure to sun in the autumn to ripen the growth. During the winter the plants are never allowed to become very dry, as the object is to preserve the foliage as much as possible, and this, with a thorough maturation of the growth, Mr. Ridout considers essential to success. The plants are potted in peat and sphagnum, and started into growth immediately after flowering, a little weak liquid manure being beneficial, but when the plants are well established, as some are in 10 or 12-inch pots, they do not require repotting every year, some of the finest in the collection not having been so treated for two years. Some of the largest spikes, including those of the variety *Walkerianum*, exceed a foot in length, and altogether these *Dendrobiums* are most satisfactory examples of good culture. In the same house a fine variety of *D. Dalhousieanum* has nine racemes; *D. chrysoxum*, fourteen racemes in a 24-size pot; *D. Wardianum*, *D. Jenkinsi*, and *D. suavissimum* are equally at home. The *Cattleya* house contains a number of fine *Lælias* and *Cattleyas*, with *Vanda cœrulea*, 242 flowers of the two former having been open at once, all good varieties. The houses at the north side of the range are filled with *Phalænopsis*, *Odontoglossum*

vexillarium, grown in a temperature ranging from 55° to 75°; *Odontoglossum* with *Masdevallia* in other divisions. *Masdevallia tovarensis* is a favourite, two dozen large plants being grown which have had from twenty to fifty spikes each. The old spikes are always allowed to remain on the plants, and it has been found that while young ones only bear two flowers each, the older ones have four and five each. Beautiful varieties of *M. Harryana* are grown, including the celebrated Bull's Blood, which has thirty flowers, a fine form of the hybrid *M. Chelsoni*, and innumerable others.

The plants under glass are not all Orchids, Ericas and hardwooded plants receive some attention, together with ordinary stove flowering and foliage plants, the majority of the latter being grown in a long range of houses, comprising four span-roof structures at right angles with the lean-to's and corridors which connect them. Covering the back wall of a stove in this range is a grand old *Combretum purpureum* which has been there for about twenty years, and annually bears a profusion of its flowers. In the same range Peaches and Vines have houses devoted to them, Cucumbers, Melons, and Tomatoes having pits elsewhere. The kitchen garden is in excellent condition and well furnished with healthy fruit trees, the different quarters being surrounded by horizontally trained trees. *Chrysanthemums* are a feature, and 600 or 700 of the best varieties are grown. *Dahlias* constitute another specialty, and prizes for these with Asters, Grapes, Peaches, Apples, and Strawberries have been repeatedly taken for produce from this garden. Woodhatch Lodge is, in fact, what is termed in gardening language "a good all-round place," and that was the unanimous verdict of the "Royal" visitors. A wish was also expressed that so pleasant an excursion might be repeated at some future date, and that wish is cordially endorsed by—THE RECORDER.

ARTIFICIAL MANURES.

BEFORE resuming the discussion on the above subject I would draw attention to the object I had in view in taking a retrospect in my previous article; it was to keep before your correspondent the points on which I took the liberty of differing from him, and as no controversy can come to a satisfactory issue unless the original views and the opposition to them are not kept well to the fore, I would again call his attention to a few facts in the previous articles. In the first place I took exception to the advice of applying nitrate of soda alone as a manure on account of its too evanescent and sometimes apparent ill effect on the soil, recommending it to be combined with some of the more substantial manures.

This point Mr. Dunkin has finally settled in my favour in his somewhat ingenious treatment of the question I asked in a previous article, "Does the constitution of a plant improve because its bulk is increasing?" The answer is, Yes. But he makes haste to add a prop to this bold assertion—viz., provided the plant has within its reach a sufficiency of the principal solidifying agent. Exactly so, but supposing the plant had not a sufficient supply within reach, what then? I leave the answer to Mr. Dunkin's careful consideration. Why he should consider this the rock on which my argument splits I am at a loss to understand, as I maintain that the theory of the application of the stimulating combined with the solidifying agents, a rock on which the whole practice of successful fertilisation will rest securely, and on these lines I have endeavoured to maintain my argument throughout the discussion. Or does he infer that my arguments have come to grief through my not taking into consideration the various stages of growth that the plants are in at the time the manures are applied? Now, if Mr. Dunkin had kept his memory refreshed with an occasional reference to what has been written in previous articles he would not have fallen into this error.

Again, your correspondent metaphorically cut the ground from under his feet when advising one kind of manure for some time to change to another as a course especially beneficial to plant life, and which I pointed out was theoretically and practically unnecessary, provided the manure used in the first instance was a properly proportioned combination of the elements needed for the plant's support. He now advances as the results of the latest scientific investigation that the true system of manuring is to supply to the soil phosphoric acid and potash, regulating the amount of growth by the supply of nitrogen. Evidently Mr. Dunkin is making rapid strides in the science of chemistry, as heretofore the haphazard change from one manure to another was deemed sufficient, but now he has apparently been brought to see the untenable nature of these views, thus his conversion to the "true system." If your correspondent had not unfortunately been in previous opposition he would have made a valuable alliance through his being in possession of the results before mentioned, and which I presume have come to hand since the commencement of this controversy. To reduce the theory of the "true system" to practice and to use practical terms, I must point out that the soluble nitrogen, phosphoric acid, and potash are merely old friends under new names, nitrate of soda being a valuable source of soluble nitrogen, superphosphate of lime that of phosphoric acid, and kainit of potash. Thus we see that by a skilful combination of these substances we are enabled to supply a plant with its means of support as derived from the soil. Of course, discretion must be used in regard to the quantity applied to a special subject, as none but the merest tyro would ever administer the same quantity to a seedling as to a full grown plant, or, again, to one in this stage to another maturing a heavy crop of fruit or flowers; and the mode of administering liquid manure as mentioned by your correspondent is only a simple illustration of what I should call common-sense practice.

While on the subject of liquid manure I would like to add a word or two on the case mentioned by "B." on page 384 in regard to the *Chrysanthemums* which he inferred had been fed with liquid manure until they were so surfeited with it as to be actually starving in the midst of plenty. I should from the fact of their quick recovery on the application of artificial manure be rather dubious in accepting the cause as set forth by "B," though as regards the theory it may on first sight look feasible enough, and the solution read very well to anyone holding peculiar views; but as the evidence is inconclusive it cannot be taken as a very striking example of applied science, the palpable weak point being in regard to the strength of the liquid manure, and the flushing of the soil with clear water loses weight as an operation, absolutely necessary on account of all being done alike. If only one-third had been thus treated another third had artificial manure applied without the flushing, and the remainder had their usual dose of liquid manure supplemented with artificial the results would have been conclusive as to the cause of starvation; as it is they are not. What makes me inclined to doubt the "starvation in the midst of plenty" theory is a case that occurred under my charge in much the same way, *Chrysanthemums* being also the subject. These, according to our usual practice, were potted in fresh chopped turfy loam without any of the usually considered indispensable admixtures, and from the commencement they were watered with liquid manure; a vigorous growth ensued, and as they were in a fully exposed position to get all the benefit from the sun the growth was of a fine solid nature. This continued up to about the middle of August, when they showed signs of starving. This I attributed to the disproportion of the spread of foliage to the limited root run; consequently I reasoned that as the soil at the command of the plant was ramified in all directions with its roots, any nutriment brought into the pot by the liquid manure was quickly assimilated, and no accumulation of a store was possible. I therefore supplemented the liquid manure with frequent surface dressings of artificial, and the renewed vigour that followed was astonishing, and the crop of flowers that followed gave satisfaction to all concerned.

The subject of water in conjunction with manuring is treated in a masterly style by "B.," and I cordially endorse what he says in respect to its application, and if its powerful agency in the cultivation of plants was better understood, and duly impressed on young beginners, their progress towards competency in gardening would be greatly accelerated. Given a plant, the best variety, potted into the most suitable of compost, and placed in the finest of modern built structures, but let a non-discerning individual armed with a waterpot come near it, and all the foregoing counts for absolutely nothing.

Turning, again, to Mr. Dunkin's article on page 408, in reference to the question, "Does nitrate of soda leave the soil in an exhausted state?" Can he not see that the quotation he gives directly supports what I advised at the commencement, that it should not be used alone, but combined with some other more substantial plant foods? and in the quotation referred to reasons are given why such a course is beneficial, though the figures, as they appear, are open to criticism, but as they are presumably given with merely the object of illustrating a great point in the science of artificial manuring I will not touch thereon. Nitrate of soda is there shown as an active agent that stimulates the plant and enables it to take up nourishing materials lying around, and thus arises the notion that nitrate impoverishes the soil, which it undoubtedly does, or rather causes the plant to do so, therefore the true science of manuring is absolutely indispensable to successfully transfer mineral substances into field produce; but, as I mentioned previously, if the phosphoric acid and potash should unfortunately not be present—say, for instance, repeated applications of nitrate had caused the absorption of all the elements—would not the nitrate soon come into disrepute with the unscientific user, as it has done in many instances when used alone? but if applied as "B." recommends sulphate of ammonia and superphosphate to be, we should soon cease to hear so much of these objections.

If instead of indulging in unfounded charges of inconsistency and misrepresentation in reference to the arguments I have brought to bear against the change of food system, and also on the need of an elementary knowledge of chemistry as essential to every cultivator, Mr. Dunkin had applied himself to scientific research somewhat earlier in the debate, he would not have placed himself in the anomalous position he now holds. For instance, if he had looked into the case of applying the different manurial agents to a pasture he would have found plenty of scope for criticism if he had not beforehand depreciated a slight knowledge of chemistry, relying rather on the experience he holds so dear. There we see experimental trials made with various substances to see what effect they would have on vegetation, both the experience your correspondent holds in so much esteem, and also the rudimentary knowledge of chemistry, on which he considers I place a too high value on, was conspicuous by their absence, and possibly if careful reflection and reasoning had not been followed the conclusion arrived at would have been grossly erroneous. Had chemical knowledge been brought to bear on the experiments the nitrate of soda, superphosphate, and muriate of potash would have been combined together for obvious reasons. Provided Mr. Dunkin had a supply of artificial manure of this description on hand, would he consider a recourse to the "change" had beneficial? I venture to think not, as by his own showing he would have a perfect plant food, which idea he previously opposed as impossible, containing the essentials necessary for a plant's support—viz., soluble nitrogen, phosphoric acid, and potash, and if he had the ingredients separately he could combine and administer them to the plant in

such quantities and proportions as, after considering the nature of the plant and its state of growth, his judgment tells him is necessary.—*M. COOMBE, Ashton Court, Bristol.*

EVENTS OF THE WEEK.—Messrs. Protheroe & Morris announce a sale of Orchids at their rooms in Cheapside, on Friday next, June 1st; and on Tuesday, June 5th, the first portion of the choice collection of Orchids formed by Dr. Duke at The Glen, Lewisham, of which several accounts have appeared in the Journal, will be disposed of at the same rooms. On Wednesday, June 6th, the Covent Garden Fête in connection with the Gardeners' Orphan Fund, will be held in the Flower Market, from 9 to 12 P.M. On the same day the Bath and West of England Society's Show at Newport (Monmouth) will be opened and continue until June 11th. At this Show a cup, or money, value £10, will be given for the best group of Orchids, and two classes are provided for Roses, for amateurs and nurserymen respectively, the prize in each case being a cup or £5, for eighteen varieties (single blooms) of Tea and Noisette Roses.

— **THE WEATHER.**—Our Perthshire correspondent writes:—"The week ending May 28th has been throughout one of brilliant sunshine with the exception of Sunday. In the afternoons and evenings cold easterly winds have prevailed." Towards the close of last week bitterly cold winds prevailed in the south, and tender plants put out too soon suffered accordingly.

— **WE** learn that SIR ROBERT LODER, BART., died somewhat suddenly on Sunday evening at his marine residence, Beach House, Worthing, from a stroke of paralysis. He had been in indifferent health for some months. The deceased baronet was the only surviving son of the late Mr. Giles Loder, of Wilsford House, Salisbury, and is succeeded in his baronetcy by his eldest son, the present High Sheriff of Northamptonshire, Mr. Edmund Giles Loder, who is a member of the Council of the Royal Horticultural Society.

— **ORCHIDS IN PARIS.**—We are informed that President Carnot's prize, offered for a collection of Orchids at the Paris Exhibition, was awarded to Messrs. F. Sander & Co., St. Albans, for a group including several that were shown in the Temple Gardens recently.

— **MR. H. CANNELL**, in sending a magnificent bloom of *CEREUS SPECIOSISSIMUS* for our inspection, observes:—"The largest plant of *Cereus speciosissimus* in England was at the seat of Richard Gurney, Esq., Thickthorn Hall, Hetherset, Norfolk, forty years ago. It was planted out in the centre of a lean-to 40 feet house against the wall, and after covering the wall it was allowed to extend round to the front door on the opposite side, and it became so attractive that it was allowed to occupy the whole house, and it was the talk of the nation. It had as many as 300 flowers open in a day. Can anyone say what became of the plant?" There are two varieties of this handsome Cactus, one having much larger flowers and more purple in them than the other. The one sent by Mr. Cannell is the better. We have lately seen some blooms of seedling *Caeti* raised by Mr. C. M. Major of Croydon. They belong to the section of *Phyllocactus*, the plants having flat stems. The flowers are large and brilliant in colour, one, a deep crimson scarlet, especially so, and are more or less deeply tinted with purple, suggestive of the beautiful *Cereus* referred to.

— **MR. T. S. WARE**, Tottenham, recently sent us a box of *PEONIES* AND OTHER FLOWERS, of which the following are noteworthy:—*Peonies*, *Souvenir de Madame Knorr*, large semi-double, pale crimson, darker at the base, very light at upper part, delicate and pretty; *Louise Mouchelet*, double, full, rosy crimson, handsome; *Lambertiana*, pale blush, nearly white, double; *Souvenir de Chinonceaux*, purple, semi-double, bold; and *Cerenie*, deep purple, semi-double, distinct, and rich; and double varieties of *Paeonia officinalis*; *La Nègresse*, very dark rich crimson; *Alba*, double white; and *Chamois*, blush streaked rose and crimson. The double white *Narcissus poeticus* and the white Pink, Mrs.

Welch. were also included, together with some fine varieties of Corn-flowers—crimson, blue, and white.

— "B. C." writes:—"The extensive ranges of glass at HEATHFIELD, LOW FELL, GATESHEAD, the seat of Theodore Lange, Esq., is well known to the readers of this Journal, containing as they do many rare examples of plant culture, especially Orchids. It was my pleasure to see them the other day, and in the stove were about thirty plants of *Cattleya Mossiæ* and *Mendeli* all in flower, the former predominating, the labellums of which are very richly marked. The plants are effectively arranged amongst Ferns, giving them a highly pleasing appearance. The *Cattleyas* are in small pots and flowering vigorously. I observed a number of *Odontoglossum Alexandræ* in bloom. Many interesting crosses of Orchids have taken place at Heathfield lately, so the Orchid-loving public may expect something good and distinct under the care of the experimental cultivator, Mr. Methven."

— THE second annual Summer Show of the ENFIELD HORTICULTURAL SOCIETY is announced to be held in the grounds at Chase Side House on July 4th next, eighty-six classes being provided, and the Autumn Show will take in the Bycullah Athenæum, November 7th and 8th. The result of the two shows held last year is a satisfactory balance of £16 16s. 7d., which is encouraging.

— UNDER the title of the KENT COUNTY CHRYSANTHEMUM SOCIETY a new Society has been formed in the Lewisham and Blackheath district that is likely to have a prosperous career. The President is F. W. Prior, Esq., Gordon House, Blackheath Park, and amongst the Vice-Presidents are Sir John Lubbock, Bart., the Very Rev. S. Reynolds Hole, Colonel J. T. North, Major H. M. Wood, Harrison Weir, and H. M. Pollett. The Committee include Messrs. N. Davis, H. J. Jones, J. H. Laing, T. W. Sanders, and E. Trollope, the Hon. Secretary being Mr. H. A. Needs, 35, Ringstead Road, Catford Bridge, S.E. The schedule of the Show to be held on November 14th and 15th this year in the rink at Blackheath, enumerates fifty-six classes for cut blooms and plants, special prizes being contributed by several of the Society's supporters.

— GLAZED FLOWER POTS.—"A. L. B." writes:—"I was very much interested in reading the article at page 355 on glazed flower pots. It is surprising what good things are sometimes either ignored, neglected, or not taken advantage of when made visible to the greatest as well as the meanest observers. I remember fifty years ago specimens of Roses, Pelargoniums, &c., being grown in glazed pots, such as old bowls, crocks, and old teapots, even in crystal dishes; nearly every house had its favourite flower, and very often in an old teapot."

— THE RUGBY AND DISTRICT CHRYSANTHEMUM SOCIETY will hold their second annual Exhibition in the Town Hall, Rugby, on Wednesday and Thursday, November 21st and 22nd, this year, when prizes will be offered in forty-six classes, besides several special classes. The chief class for plants is that for a group arranged in a space of 80 square feet, the prizes being £2 10s., £2, and £1 10s. For cut blooms the principal is for thirty-six, eighteen incurved and eighteen Japanese, the prizes of the same amount as for the groups, but to the winner of the first prize will be presented a silver cream jug and sugar bowl, value £2 10s., given by Mr. W. Bryant, seedsman, 23, North Street, Rugby, who is Secretary to the Society.

— THE HIGHGATE HORTICULTURAL SOCIETY'S Summer Show will be held at the Priory, Highgate, on July 19th, this year, when in addition to the eighty-eight classes provided by the Society for plants, flowers, fruits, and vegetables, the President, Colonel Stedall, offers eighteen prizes in six classes; the Baroness Burdett-Coutts offers six prizes in six classes, and other friends provide prizes in twenty-five classes, in addition to those contributed by the Baroness Burdett-Coutts for cottage and allotment gardens.

— THE GARDENERS' ORPHAN FUND.—The usual monthly meeting of the Committee took place at the "Caledonian Hotel," Adelphi, W.C., on the 25th inst., Mr. Geo. Deal presiding. The minutes of the last meeting having been read and signed, a letter was read from the widow of the late Mr. John Woodbridge, acknowledging the letter of condolence and sympathy with her on the death of her husband, who was an active member of the Committee of the Fund. The Hon. Secretary, Mr. A. F. Barron, reported that a sum of £772 16s. 5d. stood

to the credit of the Fund at their bankers; that the total sum of donations promised to date was £1195 8s., of which sum £1093 5s. had been received, and subscriptions, £398 12s., of which sum £244 2s. had been paid. Those who have promised subscriptions need to be reminded that the first election takes place on July 13th, and that no one will be entitled to vote whose subscription remains unpaid. Since the last meeting of the Committee the names of twenty-two new donors and subscribers had been received; donations amounting to £26 13s.; and subscriptions 11s. Mr. Smith, of Mentmore Gardens, handed in the sum of £7, the proceeds of a concert given at Mentmore on behalf of the Fund. The sum of £7 16s. was sent in by Mr. W. Howard, of Southgate, collected by him at the Temple Show. Votes of thanks were passed to Messrs. Smith and Howard for their valued services. It was resolved that a further sum of £500 be invested in consols, making £1000 in all. The Sub-Committee appointed to prepare the voting papers for the election on July 13th, reported the completion of the same, which was cordially approved. A letter was read from the nominators of Albert Edward Best, the youngest of a family of four children, stating that since his nomination the mother also had died, and that he is destitute. The Hon. Secretary laid upon the table a list of subscribers of the Fund to date, and persons desirous of obtaining a copy for the purposes of the election can have it by applying to Mr. A. F. Barron. A form of invitation to dinner on the evening of the day of the election to be sent out with the voting paper was approved. The Committee appointed to consider the details of the promenade and floral fête in the wholesale flower market, Covent Garden, for the benefit of the Fund, reported that it had been fixed for the evening of June 6th, from 9 P.M. to 12 P.M., and that Princess Mary, Duchess of Teck, had announced her patronage of the fête. The arrangements for the dinner for the evening of July 13th were also considered, and a letter was read from Mr. E. Roger Cutler, stating that his daughter, Miss Marie Belval, had kindly promised her assistance as a vocalist gratuitously, and the Hon. Secretary was instructed to acknowledge Mr. Cutler's letter with thanks and the acceptance by the Committee of Miss Belval's kind offer. Some further details were considered. A hearty vote of thanks to the Chairman closing the proceedings.

— THE SCOTTISH AURICULA SHOW.—In the prize list of this Show sent to us for publication last week, we are informed that the words "Blair Adam" and "Douce" should have been Blair Drummond in both cases, this being the address of Mr. Wm. Kilgour, the winner of the prizes indicated. We are also requested to state that the variety named "Cathedral (Browning)" should have been Downing's Catherine. We assumed the name had been copied from a label, and for aught we know to the contrary, might have represented a local variety.

ROYAL HORTICULTURAL SOCIETY.

MAY 22ND.

SCIENTIFIC COMMITTEE.—Present: D. Morris Esq., in the chair; and Messrs. G. Murray, G. F. Wilson, F.R.S., J. O'Brien, W. G. Smith, Boulger, A. D. Michael, A. McLachlan, F.R.S., Professor Church, Dr. Lowe, and Dr. Masters, F.R.S.

Lily Disease.—Mr. George Murray reported that the specimens sent were too much decayed to examine satisfactorily. Probably the appearance was due to fungus, *Peronospora* or *Ovularia*, or both.

Monstrous Cattleya.—Mr. Ridley sent a report on the *Cattleya* exhibited by Mr. Smee at the last meeting:—"This *Cattleya* is a good example of petalody. The bract subtending the flower is replaced by a petal. The dorsal sepal is lip-coloured, as are the laterals, but in a less degree. The left petal is also lip-coloured, and has the same shape as the lip. The right petal is adnate to the column, and lip-coloured; at about three-quarters of its length from the base it bears an anther cap on its edge—of course, abnormal and abortive. The lip is tolerably normal, but not lobed. The column seems to have entirely lost the staminal whorl; elinandrum, anther, and all traces gone. The rostellum and stigma are present."

Jaborandi.—Mr. Morris reported that the specimen exhibited by Mr. Lynch at the last meeting was the true plant, *Pilocarpus pennatifolius*, which yields the medicinal substance above-named.

Fertilisation of the Scarlet Runner Bean.—With regard to Mr. Burbidge's remark at the last meeting, that "the Scarlet Runner does not set its fruit in South America, but in this country it fruits freely, owing to the bees, which bore through the base of the flower," Mr. Henslow observed that this was an error, as no flower is benefited by the perforations made by insects from without. The bees fertilise them, however, in the legitimate way; but in their absence the Scarlet Runner can scarcely

fertilise itself. The French Bean, on the other hand, is quite self-fertile, as horticulturists can force it in winter.

Shoots of Spruce Fir Injured, &c.—Referring to the specimens exhibited on the last occasion Professor Boulger suggested that the injury might have been occasioned by hail. The general consensus of opinion, however, was that the damage was, as previously stated, effected by squirrels. Mr. McLachlan alluded to the death of Hollies in consequence of the "ringing" of the bark by rabbits. Similar injuries were detailed as caused by deer.

Self-coloured Tulip.—A pale primrose-coloured Tulip, shown by Mr. Walker, was referred to Mr. Baker for report. It had occurred among a bed of *T. Gesneriana*, of which it is only a seedling form.

Castaseum.—A specimen was referred for name, and considered to be *C. viride* (*Monacanthus*).

Scilla Bulbs, &c.—Dr. Lowe showed elongated bulbs of this species, which were referred to Dr. Masters for examination and report.

Iris.—Dr. Lowe also showed a yellow flowered Iris he had originally received from the late Rev. Harpur-Crewe, and which was referred to Mr. Baker for report. Mr. Baker reports it to be *I. lutescens*.

Tetramerous Pear.—Professor Boulger showed flowers of a Pear in which the parts were in fours.

Notched Lilac Leaves.—Mr. Boulger also showed some leaves of Lilac which, owing to close adhesion one to the other, had developed a little notch or rather lobe, on one side of the obstruction.

Sphinx ocellata.—Mr. Roupell sent a specimen of this moth in illustration of "mimicry," the dull colour of the upper wings approximating to that of the dead leaves of the Apple, on whose branches it rested. This view did not find favour with the entomologists present.

Beetle Attacking Mangolds.—Hon. and Rev. J. T. Boseawen sent specimens of a beetle which attacks Mangolds. Referred to Mr. McLachlan.

Himalayan Primula.—Rev. C. Wolley Dod sent a specimen with the following communication:—"In the winter (January, 1886) I received amongst many others from Dr. King a packet marked *Primula reticulata*. This produced in April, 1886, a fine crop of *P. sikkimensis*. When these were removed, there came up in spring, 1887, a small crop of very delicate seedlings, all with distinctly cordate leaves, and very different from *sikkimensis*. I sent a few away. Those I kept have nearly all been cleared off by the 'leather jackets.' I enclose the largest left. I cannot make it fit any species described in 'Flora of British India,' Hooker. The calyx does not seem to fit *reticulata*. It is three weeks earlier than *sikkimensis* under the same conditions.—C. WOLLEY DOD, *Edge Hall*, May 21st." The specimen was referred to Kew for comparison, and has been determined as *P. glabra*.

Cynomorium coccineum.—Mr. Morris showed a fine specimen of this curious parasitic plant from Gogo, whence it had been received from the Governor of Malta, Sir Lintorn Simmons. This is the fungus *Melitensis* of old writers, and was formerly valued as an astringent; so highly was it valued that the plant was placed under the protection of a special guard.

Canker of Maréchal Niel Rose.—Mr. Froud, gardener to G. N. Marten, Esq., sent a portion of the stem of this Rose cut 6 inches below the soil. The plant was covered with buds which failed to open, and on examination the stem was found cankered. The specimen revealed traces of old injury rather than of present mischief, the appearances being possibly due to the attacks of fungus. Mr. Morris remarked that *Maréchal Niel* was the best Rose for the tropics, where it is not subject to canker.

Double-spathed Richardia.—Mr. H. Tull exhibited a specimen of *Richardia ethiopica* with a double spathe.

Dendrobium Flower on the New Growths.—The same exhibitor sent a specimen of this not very uncommon occurrence, which is analogous to the midsummer shoots of the Apple.

Conifers.—Dr. Masters showed specimens of *Juniperus flaccida*, a very elegant species from the highlands of Mexico; also fine cones of *Araucaria Bidwilli* and *Pinus Pinea*, received from M. Naudin, Villa Thuret, Antibes.

Specimens were exhibited of the following from Kew:—

Iris Korolkowi.—A species received from Herr Max Leichtlin in 1885, and now flowering for the first time at Kew. It seems to be a variable plant, as the figure in the "Gartenflora" differs in colour from the one exhibited, in which the falls were of a pale lilac or grey-coloured, with narrow lines of purple, and with a deep purple-fringed blotch at the base. The grey standards are also lined with purple veins.

Ferula (Narther) asafetida.—A handsome, but atrociously smelling Umbellifer, with boldly cut glabrous foliage and umbels of yellow flowers like those of the Parsnip. It is interesting as being the source of the drug *asafetida*.

Saxifraga Kolenatiana.—A Siberian species of dwarf habit, with leaves like those of the Aizoon section and flowers not unlike those of "London Pride."

Allium Suwarrowi.—A species of globose many-flowered umbels; flowers about half an inch across, segments spreading, narrow oblong, rich violet; stamens of the same length and colour.

A. Jesdianum.—A species with globose, many-flowered umbels, individual flowers nearly three-quarters of an inch in diameter; segments linear-oblong, spreading, ultimately bent downwards, pale lilac; stamens erect, whitish, longer than the perianth segments.

SUCCESSFUL ROSE CULTURE.

IN one of the houses connected with the gardens at Haysford House, near Frome, the residence of A. G. Hayman, Esq., there is a fine healthy plant of Tea Rose Adam, which has this season perfected upwards of two hundred blooms. This is worthy of note, owing to the fact of its being rooted in an 11-inch pot only, and also on account of the great size and good colour of the blooms, many of which were equal to any I have seen at exhibitions. The plant is trained on a trellis near the glass, an intermediate temperature is maintained, and no cold currents of air reach the foliage. It is almost needless to add that this Rose is well attended to by Mr. S. Andrews, and gets a fair share of farmyard and other liquid manure.—I.

FORCED ROSES.

HYBRID PERPETUALS that flowered early in the season may now be placed outside if they have been properly hardened; if not in this condition prepare them by exposure to the sun in a cool airy structure. If removed from a close atmosphere their foliage is certain to be seriously injured by sudden exposure. At first place them in a sheltered position, and finally plunge them in their summer quarters. Plants that have made vigorous growth in 7 and 8-inch pots may with advantage be placed into others 2 or 3 inches larger. By this treatment, if carefully watered and the foliage kept free from insects, they will without further trouble in potting be in the best possible condition for forcing another year. The general stock that may require at potting time the reduction of the soil should not be done before the end of July. For H.P.'s good fibry loam, one-seventh of decayed manure, and a little sand should be used. In some loams sand is not necessary, while in those of a heavy nature it should be liberally used. Clay reduced to a powder by drying should be added to light loams at about the same rate as the sand to those of a heavier nature. Soot and bone meal may with advantage be added; a 6-inch potful of each will be plenty to a barrowful of soil.

MINIATURE ROSES.

Such kinds as The Pet are invaluable for conservatory decoration, and few flowering plants in from 5 to 7-inch pots surpass them in usefulness and beauty for a variety of purposes. Cuttings of not quite half-ripened wood strike freely at this season of the year. The cuttings need not be more than 2 inches in length, and will be found to root quickly in sand, if well watered, covered with bellglasses, shaded from the sun, and placed in a temperature of 65° to 70°.

WINTER-FLOWERING ROSES.

Such varieties as Safrano and Isabella Sprunt, that are so invaluable at Christmas and during the early months of the year, are not of great value at this season unless they are cut when the buds are very small indeed. In any other state they are useless for travelling. The flowers of these are so thin and composed of so few petals that they open fully a few hours after they are cut. Other varieties should be plentiful, and in order to give these every chance of doing well during the worst months of the year the buds should be removed as they appear. All the weak growths can be cut away, so that the whole energies of the plants will be devoted to the production of strong wood. By thinning the plants now air and light is freely admitted to the strong growths, and others will be induced to push from the base. The object must be to secure strong well-ripened growth, as weak wood produces small buds. Plants that have been brought forward gradually of Rubens, Innocente Pirola, President, Abricoté, Niphotos, Catherine Mermet, and others will continue yielding their large and delicate buds, that will last a considerable time after they cut, provided they are cut before they expand too much. These plants will be pushing up strongly from the base, and it is frequently from these shoots that the finest flowers are produced. They will stand liberal feeding, whether they are in pots or planted out; if the latter, the surface may be mulched with manure. Apply water carefully, syringe freely, and admit air liberally during bright warm days.—N. G.

REVIEW OF BOOK.

A Manual of Orchidaceous Plants, Part 3, Dendrobium, Bulbophyllum, and Cirrhopetalum. James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea.

THE third part of Messrs. J. Veitch & Sons' important and exhaustive work on Orchids is just to hand, and is devoted mainly to the genus *Dendrobium*, with a brief consideration of the less important horticultural genera *Bulbophyllum* and *Cirrhopetalum*, which are, however, included in the sub-tribe *Dendrobieae*. The cultivated *Dendrobiums* are numerous, but there are also many of such little value for garden purposes that they are necessarily excluded from a work of this character which does not deal with plants of botanical interest only. Ninety-two pages are devoted to particulars of structure and culture, with descriptions of the best species, varieties, or hybrids, 123 distinct type.

being fully considered in the work, besides incidental reference to and short notes respecting other species.

As in the preceding parts this one commences with the leading characters of the genus, and the groups in which the known *Dendrobiums* are classed. Then follows an interesting and useful account of their geographical distribution and the climate of the districts where they abound. Two excellent maps accompany this portion of the book and serve to illustrate the subject admirably. In the first South-East Asia, comprising India, Burma, the Malayan Archipelago, and the Philippine Islands; the second dealing with the Australian region. Some difficulty has been experienced in the first map—the South-eastern Asia region—in indicating the precise districts where the plants have been found, because in Burma, and Moulmein especially, large numbers came from a limited area, and the names in consequence could not all be printed on the maps. This has been overcome with regard to the Moulmein district by a marginal list of forty-three species, including such well-known garden plants as *D. Bensoniæ*, *D. chrysotoxum*, *D. Dalhousieanum*, *D. fimbriatum oculatum*, and *D. thyrsoflorum*, though some of these are by no means confined to that region. One of the most widely distributed *Dendrobiums* is *D. crumenatum*, which is found in the Andaman Islands, Sumatra, Java, Borneo, and the Philippine Islands; *D. secundum* also has a wide range. In Java over sixty species have been discovered, but as these are mostly of little horticultural value, they are, with the exception of six, omitted from the book. Upon the western side of the Indian Peninsula, in Nepal, Bhotan, Western Burma, and Moulmein, are found the chief homes of the genus in this portion of the world. The Australian forms are not very abundant, a few coming from the eastern side, but these, except *D. speciosum* and its variety Hilli, are mostly more curious than beautiful. The more northern and New Guinean *Dendrobiums*, *D. superbiens*, *D. bigibbum*, *D. Phalaenopsis*, and *D. Macfarlanei*, are, however, amongst the most handsome members of the genus.

The cultural instructions are most valuable, and full details are given respecting the peculiarities of the different species, as though these are nearly all tropical they vary considerably in their requirements, a few, like *D. infundibulum* and *D. Jamesianum*, now classed as a variety of the preceding, which come from a higher altitude, requiring cooler treatment than the others. The descriptions, historical information, and illustrations are all that could be desired, and the book will be welcomed, not only by admirers of *Dendrobiums*, but by Orchid growers generally, as a useful and reliable addition to Orchid literature.

BARREN STRAWBERRIES.

At pages 405 and 406 "F. J." records his failure to induce Strawberries to fruit, and the Editor invites correspondence on the subject. I do not think I can solve the "puzzle," but at page 414 of the same number the answer to "F. G." goes far to solve the problem. I will therefore, as one that made Strawberry-growing a speciality, give my mode of selecting plants and cultivation.

My mode of securing fertile and strong plants was to plant strong runners in July in rich soil. These along with the main plantations grew into large plants by October, no runners being allowed to issue from them, and they were kept free from weeds. Whenever the flower blossoms appeared in the crown of the plants a careful examination was made, and if any showed signs of barrenness they were instantly taken out. Then, as soon as the blossoms were well up, they were cut from the plant and allowed to throw out runners for again planting in July if possible. If any of the runners showed an inclination to shoot out far before a plant was formed it was pinched, and the shorter ones allowed to root, as being more to be relied upon than the grosser ones. In fact the shorter the runner the better I found the plants to be. After I had secured my plants I dressed the ground, and some varieties rewarded me with a late crop of Strawberries, particularly Garibaldi, not Vicomtesse Hericart de Thury.

When runners could be had from young plants I never depended upon taking them from old ones, believing it to be a cause of producing blind or barren plants. A case in point. My garden has been neglected for eight years; a bed of Dr. Livingstone Strawberry previous to that time never had a blind plant, now many of them are blind.—A. L. B.

WISLEY.

HORTICULTURISTS, whether amateurs or professionals, who visit many gardens are often made almost painfully conscious of the formality of design, want of originality, or what may be termed unnaturalness of the majority. Too frequently the larger establishments are the worst in this respect. A pretentious striving after effect results in glaring incongruities or a most tiresome monotony utterly defeating all the objects of a true garden. Many a quiet little country retreat unknown to the horticultural world generally displays more real taste in its arrangement than the "show places;" and satisfactory as it always is to see good examples of cultural skill in plants, fruit, or vegetables, it is a pleasant relief at times to leave the glass houses and wander in a charming garden free from the restraints of the all-prevailing conventionalism. I have had the good fortune to visit some of the best gardens in all parts of the kingdom, and last year when penetrating the wilds of Northumberland I included in my tour Lord Armstrong's celebrated garden, Craggside, Rothbury. Favoured by exceptional natural advantages this has been treated boldly and must be ranked as one of the most remarkable of natural gardens in this country. On

Monday last I visited Mr. G. F. Wilson's garden at Wisley, and though totally different in surroundings and scenery, yet for natural treatment and freedom from artificiality it is equally as remarkable as Craggside, but for its collection of hardy plants it is unique. It is an extraordinary garden, and with its owner, designer, and superintendent as conductor, it is one of the most interesting a plant lover could visit. It is not one that can be dispatched with a cursory survey, and a day is far too short to enable a stranger to realise its character and contents. I cannot attempt in the present notes to give anything more than a resumé of its features, in another letter I may have something to say of its occupants in detail.

Wisley has been repeatedly described before, but I will attempt to convey my own impressions of the place and the work, as it contains much that is suggestive. The garden is about five miles from Weybridge, being reached by a pleasant drive along the Guildford road through plantations of Conifers and across wild heaths of Furze now rich with its golden flowers, and is situated at a much lower level than Heatherbank. Some seven or eight acres of level woodland and fields on irregular hill slopes have been there taken in hand by Mr. Wilson, the variety of soils and aspects afforded having induced him to select it as a fitting site for "an experimental garden." The diversity of aspect has been greatly increased, but only gradually; it was not a garden to plan by rule and compass, anything of that character was far from its owner's intention, and he wisely preferred to let it develop slowly, and as the result of experience, than to map it out all at once. Besides, as he rightly observes, very much of the pleasure of gardening is lost when it is drawn up to scale and furnished like a house prepared in haste for a new tenant. So Wisley, as we see it now, is the result of ten years' pleasurable work. "The first season or two," says Mr. Wilson, "we committed many blunders, which it took us several years to correct, and even now we have much more to do, but we have learnt much and are still learning."

The garden is devoted exclusively to hardy plants, shrubs, or trees; there is not a glass house on the place, and even frames are dispensed with, for many thousands of seedlings are raised out of doors in special beds. Digging in banks and mounds occupied with valued plants is tabooed, and the result is that seedlings are springing up in all directions, and one is almost afraid to step lest some precious gem that is being daily watched may be crushed. Conventional paths and edgings are carefully avoided, the ground rises into innumerable mounds of varying height, or sinks into little dells and rivulets in the woodland portion, while in the more open part is a small lake filled with the fragrant Cape Pondweed, *Aponogeton distachyon*, and other choice aquatics, with higher mounds of a miniature alpine character, and a steeper slope behind these occupied with choice shrubs and trees, or devoted to Lilies.

Amongst the shrubs just now the handsome *Exochorda grandiflora* (fig. 61) is flowering profusely, and it is one of the features of the garden. This remarkably handsome shrub is one of the numerous valuable additions to our garden plants for which we are indebted to the assiduous collector Mr. Fortune. He first discovered it in the northern part of China in the year 1845, and some short time afterwards he found it in the Che-kiang Hills, and the specimens collected were despatched to Messrs. Standish & Noble of the Bagshot Nurseries under the name of *Amelanchier racemosa*. It flowered at Bagshot in 1854, and then attracted considerable attention owing to the profuseness with which the flowers were produced and the length of time that they continued in beauty. From examinations then made the name *Amelanchier racemosa* was found to be inaccurate, and the plant was referred to the genus *Spiræa* under the name of *S. grandiflora*, but from certain characters of the fruit the present generic title was finally adopted. The name being definitely determined general interest in the plant seemed to subside, and so we find that although more than thirty years have elapsed since its introduction it still remains comparatively unknown in gardens. This is the more unaccountable, as the merits of the shrub are of no ordinary character. When we have hardiness of habit combined with beautiful flowers and a lengthened period of blooming it is a little surprising that such valuable qualities should remain generally unobserved or neglected; still this is only one of the many instances which are constantly occurring of useful and attractive plants being gradually lost in cultivation. The *Exochorda* is diffuse in habit, and occasionally requires a little pruning to keep it in form; and it can scarcely be surpassed for planting in shrubberies, as it rarely exceeds 9 feet in height and flowers freely during April and May. Mr. Wilson cuts the shoots in freely, and he finds this is the only way to ensure its annual free flowering. The same practice is adopted at Stillyans, the residence of Lady Dorothy Nevill in Sussex, with equally satisfactory results.

Lilies are a specialty at Wisley, and though grown in several different soils, under varying conditions, and in distinct aspects, all alike seem to thrive most luxuriantly. At Weybridge, upon a hill of sand said to be 70 feet in depth, beds have been formed 5 deep, filled with loam and peat, in which *Lilium lancifolium*, *auratum*, *Krameri*, and *tigrinum* flourish splendidly; but the soil has been excavated for several feet all round to form a kind of dell, and shelter is afforded by trees. At Wisley two other situations have been tried, one in the natural black vegetable soil, and damp shaded woodland portion, and the other on a steep northern slope of loam fully exposed. In the woodland the Lilies are the most satisfactory in a dry season, and on the slope in a dry one, but at the present time it would be difficult to say which are the stronger and better. *L. Hansoni*, *L. Krameri*, *L. Browni*, *L. giganteum*, *L. lancifolium* varieties, and many others make up a

wonderful collection, not in single plants or pairs, but in fine clumps and beds of dozens or scores, and the stock of Lilies is estimated at 100,000.

Exceedingly beautiful at the present time is a mound covered with

also surmounts a mound, and with the lighter yellow but bright *Genista hispanica* furnishes a welcome mass of colour. A solitary but well developed plant of moderate size of a deep red Japanese Maple lights up another portion of the open garden, while in the woodland we

FIG. 61.—EXOCHORDA GRANDIFLORA.

Phlox setacea varieties, purple, pink, and white, from the late Mr. Nelson's Aldborough collection, large patches densely covered with flowers, looking at a distance as if clear well defined colours had been laid on liberally from an artist's brush. A grand bush of double Furze

have delightful glimpses of brilliant Azaleas of the Mollis type and rich Rhododendrons. Numbers of the finest named Rhododendrons have been planted, all with too close a resemblance to *caucasicum* being rigidly excluded, or if found are destroyed. They were originally

planted for protection, but were found to succeed so well and to form so pleasing a feature that the collection was wisely extended, and with the seedlings obtained the varieties include some of the best and most distinct.

For protecting delicate plants or beds of seedlings several methods have been tried, that found the cheapest and most convenient now being iron hurdles covered with green scrim, which breaks the force of the wind, yet permits a free circulation of air. Split bamboos secured to hurdles in a perpendicular position have proved similarly useful, but rather expensive; split wood of various kinds has been tried in a similar way, and dried Furze tied to hurdles makes a very effective hedge. This is employed for the larger divisions as protection for hedges of *Rosa rugosa*, of which there are thousands of seedlings, and in some cases Clematises have been planted to cover the Furze. Still, speaking of hedges, it may be added that Mr. Wilson commends the Cherry Plum for this purpose, but to utilise it he takes up stems at intervals, and these are worked with choice varieties of Plums, a combination of the useful with the ornamental that many could appreciate. At one spot, what is termed the "hot bulb" bed, where the most delicate and choice bulbous and similar plants are grown, protection is afforded at the back by ground glass with Furze hedges at the side and open to the south, but this is an extreme case, and the only one in which glass is used.

It is really a philosopher's garden, and is aptly designated "experimental," for when plants are being tried for the first time, two or three different kinds of soil are prepared in the same situation, and it is soon found which is preferable. Seeds are sown in different positions with the same object in view, and several instances are noticeable of the ready way in which the seedlings thrive in some places. *Primula japonica*, for example, sown on the bank of a small rivulet is flourishing low down near the water, yet on the top of the bank plants of exactly the same age are not one-fourth the size, with comparatively puny flower stems. As Mr. Wilson observes, you never know the capacity of a plant until you have tested it in a variety of situations, and in illustration of this he points to the beautiful glaucous-leaved and bright blue *Omphalodes Luciliae*. Upon a mound in the woodland is a fine healthy plant such as is seldom seen, and which many would be well contented with, but on a bank in a more exposed situation another plant is so much more vigorous that it might be taken for a stronger variety.

A word or two about the Gentians must conclude this week's notes. At Wisley *Gentiana acaulis* seems to have found a congenial home, for it both grows and flowers in the most satisfactory manner. By the lake is a beautiful bed of it, about 2 square yards of vigorous plants in one bright green mass, and upon this 600 large deep blue flowers have been counted, a good proportion of which are still fresh. Near this, too, are some highly valued gems, varieties of *G. acaulis* collected in the Swiss Alps by Mr. Scott Wilson, our courteous conductor's son. Flowers of these were recently submitted to the attention of the Royal Horticultural Society's Floral Committee, when they were much admired for the interesting variations and delicate tints they displayed. There are four well marked forms, one very pale, nearly white; another a clear bright pale blue, very beautiful; a third of a rather deeper blue, and approaching a double form; the fourth, the most remarkable of all, being a distinct pink hue, all the blue tint having disappeared. The plants are small and require careful watching, but the characters of the varieties have been admirably fixed on paper by an accomplished artist, Miss Florence H. Woolward, who evidently possesses a happy facility of combining in her numerous drawings of plants strict botanical accuracy with artistic effect. The lovely *Gentiana verna* shows its brilliant little blue flowers in several places; the rather fastidious *G. ornata* and many others are equally suited with comfortable quarters in the Wisley garden. But I must stop for the present, and reserve some further observations for another contribution.—L. CASTLE.

COCHIN CHINA VINE—*VITIS MARTINI*.

AN apparently new species of Vine has been received at Kew from the Botanic Gardens, Hong Kong. It was sent by Mr. Ford as *Vitis Martini*, *Planch.* From botanical specimens also contributed by Mr. Ford to the Kew Herbarium, Professor Oliver has identified the plant as *Vitis* (*Ampelocissus*) *Martini* of Planchon, but he is doubtful whether it is specifically distinct from *Vitis barbata*, *Wall.*, of Bengal and Burma. As plants of this Vine have been distributed from Kew to correspondents in the colonies it is desirable to place on record all the available information respecting it. In the report of the Superintendent of the Botanical and Afforestation Department, Hong Kong, for the year 1885, the following interesting account is given of the Cochin China Vine:—

"Another plant of considerable interest is a new tuberous-rooted Vine, *Vitis Martini*, *Planch.*, from Cochin China. It fruited this year in Hong Kong for the first time. The seeds were procured from the Botanic Gardens, Saigon, in 1883. The seedlings were planted out the same summer and made several shoots, each of which died down in the winter. They began to make fresh shoots about the middle of April, 1884, and grew well during the summer, but showed no inclination to flower; and again died down in the winter. Last summer they started vigorously and showed flower about the end of May. Many of the bunches, however, failed to develop fruit, owing, apparently, to imperfect fertilisation; but there was a good average crop of bunches on the canes irrespective of the failures. The fruit was ripe in October, many of the bunches weighing a pound each. The berries, when ripe, are jet black, and rather under the average size of ordinary Grapes. The seeds

are large in proportion to the size of the berry. The flavour is a peculiar blending of sweetness and acidity; very pleasant, but tending, in my case, to leave a curious smarting sensation on the tongue; others might not find this peculiarity at all objectionable. The flavour might be altered, as is well known, by varying the mode of cultivation; but the size of the seeds is likely to prevent the Grape becoming popular as a table fruit; it may, however, be very well adapted for a wine-producer.

"A number of seedlings of this Vine were distributed amongst residents of the colony, but I learn that none of these plants have fruited. A few remarks as to the mode of cultivation may therefore be useful. The tubers should be planted at a distance of 12 feet apart in well manured soil, taking care to keep the manure near the surface, as the tubers take a horizontal direction and do not penetrate the soil to any great depth. When the shoots appear in the spring it is well to cut off all the weak ones, leaving only four strong canes; these should be trained along a trellis or wall, as the case might be, leaving a width of 3 feet between the canes. All the lateral branches should be pruned back to within one bud of the main rod, except those laterals that show bunches; but it will be found that very few bunches will be developed on the lateral shoots, most of the bunches springing directly from the main rods; but in the case of a bunch springing from a lateral branch the branch should be stopped at the second bud above the bunch. The laterals might be allowed to grow till they are 2 feet long. It will then be seen if they are likely to throw out bunches or not. If not, prune them back as described, and also pinch back all subsequent growth as it appears. It may be found necessary to thin out the leaves to allow the sun to get at the branches, but in doing this great care should be taken not to break or otherwise injure the leaf directly above the bunch. If this happen to be accidentally removed the bunch below it will ripen immaturely and soon shrivel up. It is an advantage to thin out the bunches, leaving a space of 15 or 18 inches between them. It is also advantageous to thin the berries, leaving hardly one-half of the original quantity on each bunch; but I am afraid this process would prove impracticable if the Vine were extensively grown, owing to the labour it would entail. After the fruit is gathered the Vines require no farther attention till spring. By way of experiment one lot of plants were allowed to grow at will. Some of them threw up as many as a dozen suckers and produced laterals in profusion, but they all failed to flower. Another lot was transplanted into well-manured ground just as the crowns began to push in the spring; they, too, failed to flower, and presented rather a sickly appearance during the summer.

"The Horticultural Press has already suggested that this Vine should receive the attention of Vine growers in the wine-producing countries of Europe where the phylloxera has denuded the vineyards of the old class of Vines. There being no phylloxera in Hong Kong, I cannot say whether the dreaded insect would spare this Vine, but in view of the wonderful improvements that have been and can be brought about by skilful and persistent cultivation, it is not unreasonable to surmise that this new Vine may ultimately become a wine-producer. It is easily cultivated, and seems to be well adapted for a tropical climate, or a climate in which the resting season is comparatively cold and the growing season hot."—(*Kew Bulletin*.)

THE LINNEAN SOCIETY.

ON Thursday last the centenary anniversary meeting of the Linnean Society was held at the Society's rooms, Burlington House; and in celebration of the Society's centenary there was a considerable addition to the programme of an ordinary annual meeting. The chair was occupied by Mr. W. Carruthers, the President, and there was a large attendance of Fellows and Associates. On the right of the chair was seated Sir R. Owen, Sir Joseph Hooker, Professor Flower, and Professor Thiselton Dyer, who had been specially selected to take prominent parts in the proceedings of the day. There were also present Sir J. Lubbock, M.P., and Professor J. G. Allman, former Presidents of the Society; Dr. H. Woodward, Professor Stewart, Professor G. B. Howse, Mr. J. Colebrooke, Dr. M. T. Masters, Professor St. George Mivart, Dr. A. Günther, Sir Walter Buller, Dr. A. C. Prior, Dr. R. Hogg, Professor M. Duncan, Mr. J. G. Romanes, Colonel Grant (companion of Speke), Mr. Bate-man, and Mr. Olsen of Sweden.

The Council having decided to make an exception to the general rule by admitting a few ladies to be present, seats were reserved for those whose relatives were officially connected with the proceedings, as President, former President, Members of Council, Speakers, Treasurer, and Secretaries. The following were invited, and were received by Mrs. Harting in the drawing-room of the librarian's apartments:—Mrs. Carruthers, Lady Lubbock, Lady Hooker, Mrs. Allman, Mrs. Lyell, Mrs. Busk, Mrs. and Miss Flower, Mrs. Thiselton Dyer, Mrs. Anderson, Mrs. Albert Michael, Mrs. Howes, Mrs. Seebohm, Mrs. Scott, Mrs. Maxwell Masters, Mrs. Crisp, Mrs. Daydon Jackson, Miss Flower, and Miss Harting.

The first business was the election of the King of Sweden as an honorary member of the Society.

The President said that His Majesty took great interest in the development of science, and, considering that this was an important meeting of the Society, whose history was of interest in Scandinavia as well as in England, it seemed to the Council that it would be appropriate to elect the King of Sweden an honorary member.

The election having been carried by a show of hands, and cheers, M. Olsen acknowledged the compliment on behalf of the King of

Sweden, who, he had no doubt, would be pleased to accept the honour which had been conferred upon him. His Majesty, he knew, took great interest in scientific subjects, and if he had been in England he would have attended that meeting, not only to show his attachment to science, but also to do what he could to unite more closely this Society with the corresponding Society in Sweden. (Cheers.)

The Treasurer submitted a financial statement, which showed a total income for the past year of £3246, beginning with a balance of £321, and leaving one of £302. The sum of £1405 had been spent upon publications.

Mr. D. Jackson, Botanical Secretary, read part of a paper giving a history of the Linnean books, herbarium, and other collections. In the course of the paper it was stated that Sir J. E. Smith, on the recommendation of Sir J. Banks, bought the entire collection and library of Linnæus in 1784, and six years later founded the Linnean Society. He remained President till his death in 1828, when the Society bought the entire collections (except the minerals, which were sold in 1794), and have carefully preserved them in their original state to the present day. The story that the vessel that brought the collections to England was closely chased by the man-of-war sent to intercept it was not accepted by the author.

The President, in his annual address, said that in no previous year had the Society to mourn the loss of so many members and co-workers at home and abroad. They had just received the sad news of the sudden termination of a young and promising life. William Threlfall a few months ago was enrolled a Fellow. He set out for the East to explore the flora of some districts in the Ottoman Empire in Asia. The Council had taken steps to help him in his work, and they were all looking forward to important results from his travels, when they were startled to learn that by a distressing accident he had lost his life. The work of the Society was being carried on more actively than ever; young, earnest, and able men were stepping to the front. That day they had to survey a century rather than a year. The acquisition by Dr. J. E. Smith of everything which Linnæus possessed relating to natural history or medicine, with his entire library, manuscripts, and correspondence, raised him at once to a position of high eminence among the students of natural history in England. The transference of the collections to England created a second centre for naturalists in London. Sir J. Banks had opened his house and given free access to his collections and library to scientific inquirers; and he rendered an unselfish and important service to science by exerting his influence to induce Smith to secure a rival and finer collection. The system of Linnæus had then completely displaced all others. The happy invention and careful definition by Linnæus of the words he employed, the precision of his descriptive characters, his terminal nomenclature, and above all the clear and certain divisions of his sexual system, presented such favourable contrasts to the systematic works of earlier authors that he had secured absolute sway over English naturalists. There existed at the time a small Society in London devoted to the study of natural history. It seemed to have been a kind of mutual improvement society which did not publish memoirs. The Natural History Society continued to hold its meetings for several years after the beginning of this century, and when the meetings could not be kept up, and the Society was dissolved, the books and other property were handed over to the Linnean Society, including the ivory hammer still used by the President. The new impetus given to natural history by the arrival of the Linnean collections showed the urgent need of a society which did not limit its operations to the mutual benefit of its members, and this led to the formation of the Linnean Society, whose first year's income was £65 17s. 6d. For the first fifty years the members were satisfied with annual parts of Transactions, two, three, or four years being required to make up a volume. In 1855 a quarterly journal had become necessary. The distinguished position of the Society was due less to its age than to the remarkable activity of its Fellows, the importance of their work, and the speedy and efficient manner in which the communications were put before the world. (Cheers.) During the past year the Society had published seven parts of Transactions, four devoted to botany and three to zoology, containing 429 pages, eighty-nine plates, and two maps. During the same period there had been issued twenty numbers of the Journal, nine being botanical and eleven zoological, containing 1151 pages, fifty-six plates, and fifty-four woodcuts, together with the proceedings for the year, requiring sixty-five pages of letterpress. These publications contained papers of the highest importance in all departments of science. Not everything submitted to the Society found a place in its publications. Every communication was reported upon by one or more experts, and was afterwards carefully considered by the Council, and only real contributions to knowledge, expressed in fitting language, were published. Fellowship was not limited to men of science, but it was extended to lovers and patrons of science, who often rendered valuable services. At one time the reading of papers at the Society's meetings was not followed by discussion, and the proposal to allow discussion was at first opposed as an innovation "that would turn the meeting room into an arena for gladiatorial combats of rival intellects and lead to the ruin of the Society." (Laughter.) The President also gave some account of the Society's collections.

On the motion of Sir J. Lubbock, M.P., a cordial vote of thanks was given to the President for his address.

The next item on the programme was the pronouncing of eulogia on Linnæus, Robert Brown, Charles Darwin, and George Bentham.

The eulogium on Linnæus had been prepared by Professor Thöre Fries, the present occupant of the chair of botany at Upsala. In the

unavoidable absence of the author, a translation of the eulogium was read by the President. Professor Fries began by referring to the profound sleep of the natural sciences through the Middle Ages, to the hard battles that had been fought before men of science could liberate themselves from the fetters of a narrow orthodoxy, and to the restraining hands men of science had forged for themselves by attaching infallibility to Greek and Roman authors rather than to the works of Nature. They worked slowly forward to a truer conception through the sixteenth and seventeenth centuries, longing for one who should bring order and quickening life. At last came Linnæus, to whom, although a poor and unknown youth, the world almost immediately paid homage as a master of the extensive dominion of natural history. And to-day his name was mentioned with the highest respect in all lands upon which culture had shed its benign rays. Passing over the story of his eventful life the eulogist surveyed the part taken by Linnæus in the development of the science to which his penetrating activity extended itself. Upon botany his systematic mind stamped its impress for all time. Industrious naturalists had described as well as they could plants brought from all parts of the world, but their descriptions were a shapeless mass of material. There was no lack of system, but none satisfied even the unassuming demands of those times. The Upsala student, aged 22, exhibited to his teacher some outlines of a system which, when published under the name of the sexual system, rapidly supplanted all predecessors. It was so simple that a child could grasp it. Contemporaries and successors rejoiced at the discovery of the thread of the labyrinth which for centuries had been sought in vain. Linnæus, with clear insight, had openly suggested the weakness of the system and put forward the establishment of a natural system which he laboured to find. Down to our days botanists had tried to raise the edifice of a natural system of plants without getting it complete or even being able to agree on a ground plan. But all agreed that Linnæus, over against an artificial system, set forth in a clear light the character and form of the natural one, marked out the way for its development, and secured its supremacy. By successive works Linnæus reconstructed descriptive botany in almost every detail, and that in such a manner that the opinions he expressed and the laws he established are even to this day approved of as in all essentials correct. From botanical language he swept away its inrooted barbarism, and gave the proper stability by accurately limiting every botanical idea and furnishing it with definite appropriate nomenclature. For describing plants and naming them he set up simple practical rules based on a careful analytical examination of the structure of many thousand species, especially their flowers and fruits. In opposition to all his predecessors he drew a sharp line between species and variations. To the then known 8000 species he gave not only new and appropriate names, but also new definitions, and he added critically tested statements of their nomenclature by prior authors, together with an account of their native country, manner of appearing, properties, uses, and so forth, and all this in a way easily apprehended in accordance with the simple laws he himself had established. All his work he endeavoured to arrange on the most natural and easily comprehended plan. In small as well as large things he proved himself a master yet unsurpassed in producing regularity and order where previously ignorance, carelessness, or arbitrariness had generated obscurity and confusion. (Cheers.)

It was sometimes said he was not qualified for the study of vegetable anatomy, and revealed a one-sided love for descriptive botany; but the reproach usually came from one-sided anatomists. The amount of what he did bordered on the miraculous. He himself admitted that the naming, describing, and classifying of plants was not the only or the highest function of the science, but only a necessary condition for a successful study of the more important parts. It was almost impossible to point to an investigator in botany who had studied the world of plants from so many sides, and who pointed out so many new aspects from which it ought to be examined. Much that had been said about botany applied also in the department of zoology. By establishing new, easily understood laws, he made scientific descriptive zoology, and he laid the first groundwork of a real system. In the history of mineralogy he occupied a by no means unimportant position, chiefly through his rearrangement of the mineral kingdom. More conspicuous was his energetic zeal in the field of medicine. He attempted to arrange scientifically the different forms of diseases. It was easy now, compared with what it was in the time of Linnæus, to bring together collections from widely distant places. Untiring was his zeal and unparalleled his power of stimulating persons of the most varied positions in life—monarchs and students, lords and poor seaman, bishops and ignorant tradesmen—all to work to one end. Devoted scholars, young and old, surrounded his chair. His disciples went to unknown regions to collect for him the treasures of nature, and many of them perished in foreign lands as the martyrs of natural science. Nowhere, next to his own native land, had his name been so revered as in England. The botanist, Dillenius, pressed him to remain at Oxford "to live and die with him." He was in active correspondence with nearly all England's naturalists, several of whom had enjoyed his instruction at Upsala. England, unluckily for Sweden, finally became his heir. In conclusion, Professor Fries said:—Many are consequently the ties by which the memory of Linnæus is united with England, the strongest, however, is the Linnean spirit—the genuine spirit of freshness and enterprise in which scientific research has continued, and still continues, in England. Is it not probable that this fact is due, in some measure at least, to the transfer of the Linnean collections here? At any rate it was that which gave the primary incentive to the formation of this Society, which has now, for a hundred

years, uninterruptedly manifested its vigorous life, extending its useful activity more and more over the whole globe. The precious gift of Sir James Edward Smith was indeed a noble seed, since grown up into a strong plant, which has borne flowers and fruits from year to year in abundance. Its vitality is a guarantee that it will thrive and flourish, so long as the *Linnæa borealis*, ever green, spreads its fragrance over young and old, high and low, rich and poor, in the mighty forests of the north. (Cheers.)

Sir Joseph Hooker pronounced the eulogium on Robert Brown, who was recognised as the greatest botanist of his age. Passing over the life, history, and personality of Robert Brown, the eulogist gave some account of his investigations and discoveries relating to the morphology, classification, and distribution of plants, and especially to their reproductive organs, their structure and economy—investigations which display an untiring industry, an accuracy of observation and exposition, a keenness of perception, together with sagacity, caution, and soundness of judgment, in which he has not been surpassed by any botanical writer. Where others have advanced beyond the goal he attained to, it has been by working on the foundations he laid, by the light and aids of correlative advances in chemistry and physics, and by the use of optical instruments unknown in his day. His collection of about 4000 species of plants belonging to all orders, and three-fourths of them new to science, in nine years, was a feat unexampled in the history of botanical science. In the course of a detailed review of his works the Professor gave some personal reminiscences, including these:—"His appetite for acquiring botanical knowledge amounted, I believe, to voracity, while his wonderful memory enabled him to retain, and his methodical faculties to classify all he had acquired. Of that memory and of his readiness in utilising it I had, thanks to his kindness, much experience. He seemed to me never to forget a plant that presented any feature of interest if he had but once seen it, and he could single out the specimen that he had examined from a sheet full of duplicates. It was the same with books; those of the old authors especially, as Ray, Linnæus, Rumph, and Rheede, they were all familiar to him, and he could often turn to a volume, and sometimes to a page, for a statement or figure without the aid of a reference. Thus, at the age of twenty-eight, when he sailed for Australia, it was as an accomplished botanist."

Professor Flower pronounced the eulogy on Charles Darwin, who, he said, had special claims on their consideration, inasmuch as a large and very important portion of his work was first communicated to the world by means of papers read at their meetings and published in their journal. His life and work, however, were so familiar and had been exhaustively treated so recently, that the task assigned him could be discharged with a brevity which would be by no means the measure of their appreciation. They were concerned chiefly with those great characteristics of Darwin which dominated all others and made him what he was—the consuming, irrepressible longing to unravel the mysteries of living nature, to penetrate the shroud which conceals the causes and methods by which all the wonders and all the diversity, all the beauty, yea, and all the deformity too, which we see around us in the life of animals and plants, have been brought about. Against our ignorance on those subjects his life was one long battle; the work of others, by comparison, was irregular guerilla warfare. His main victory was the destruction of the conception of species as being beyond certain narrow limits fixed and unchangeable—a conviction which prevailed almost universally before his time. It might be admitted that others had prepared the way, and that the work was carried on simultaneously by others who might have attained to the same conclusion; but the fact remained that he was the main agent in the conversion of almost the whole scientific world from one conception to a totally opposite conception of one of the most important operations of Nature. Such a revolution, with its momentous consequences to the study of zoology and botany, was without a parallel in the history of science. This rapid conversion was much facilitated by the fascinating nature of the theory of the operation of natural selection in intensifying and fixing variation as originally propounded in the rooms of the Society independently and simultaneously by Darwin and by Wallace. The theory had been subjected to keen criticism, and difficulties had undoubtedly been shown in accepting it as the complete explanation of many of the phenomena of evolution. That other factors had been at work besides natural selection in bringing about the present condition of the organic world probably everyone would now admit, as as indeed Darwin did himself. That, however, was not the occasion to examine so complex a subject, and indeed the time seemed scarcely yet to have come when it could be done with the necessary calmness and impartiality. But Darwin's work and the controversies that had gathered round it had proved a marvellous stimulus to research. Though he did not, as it had been too rashly said, tear down the curtain which obscured our gaze and lay bare the birth of life, he had lifted the veil here and there and given us glimpses which would light the path of those who followed in his steps, and, more than this, he showed by his life and by his work the true methods by which alone the secrets of Nature may be won. (Cheers.)

Professor Thiselton Dyer delivered the eulogy on George Bentham, whose friendship he had enjoyed. A nephew of Jeremy Bentham, he was early imbued with a taste for methodising and analysing, and through his mother's fondness for plants and the attraction which their classification had for him he was led to study them with marvellous results. He was President of the Linnean Society from 1863 to 1874, and his devotion to its interests knew no bounds. He shrank from no labour; he indeed the first twenty-five volumes of the Society's Transactions; and he delivered a valuable series of addresses. He stood

in the footsteps of Linnæus; and, although the descent was oblique, he inherited the mantle of the master whose memory was that day commemorated. (Cheers.)

On the motion of Professor St. George Mivart, seconded by Mr Grant Duff, thanks were voted to the authors of these eulogies.

Then followed the presentation of Linnean gold medals to Sir R. Owen as a zoologist, and Sir J. Hooker as a botanist.

The President explained that it had been determined to establish a Linnean gold medal to be presented in subsequent years alternately to a botanist and a zoologist; but on this occasion two were to be presented, and there had not been any question in the Council as to who the first recipients were to be. The medal had on one side a portrait of Linnæus, taken from the bust in the room, and on the reverse the arms of the Society surrounded by the *Linnæa borealis*. The President first made the presentation to Professor Owen, recounting his distinctions and scientific services, and handed him the medal amid loud cheers.

Professor Owen, who was much affected, expressed his high sense of the honour conferred upon him, and thanked the Fellows for their cordial reception.

The President then made the presentation to Sir J. Hooker, recapitulating his services to science.

Sir J. Hooker, who was warmly cheered, returned his cordial thanks to the Council and the Society.

This terminated the proceedings.

In the evening the annual dinner was held at the "Hotel Victoria," the President being supported by Sir John Lubbock, Sir Joseph Hooker, Professor Flower, Professor P. M. Duncan, and Mr. St. George Mivart. The toasts of "The Queen" as patron of the Society, "The memory of Linnæus," and "The Linnean Society" having been duly honoured, Professor Duncan proposed "The health of the Linnean Medallists," Sir Richard Owen and Sir Joseph Hooker. He recalled the time more than forty years ago when, as one of a band of noisy medical students, he sat upon the gallery of the Royal College of Surgeons and saw a wonderful company of men, including judges, bishops, lawyers, and medical men, assembled to hear the marvellous lectures of Professor Owen in his prime, characterised by fine delivery, wonderful powers of description, and grand generalisation. To him he owed his love of natural history. For long his name had been synonymous with British science to vast numbers of people wherever science was esteemed. To him the medical profession owed much of its modern development through its greatly increased interest in physiological science. As regarded Sir Joseph Hooker, he could not refrain from mentioning his exquisite Himalayan journals as among the two or three most charming books of travel and science in the language. Sir Joseph Hooker, in responding, said the reception of the medal had given him a gratification of a peculiar kind, which no other society could have afforded, inasmuch as his father, grandfather, father-in-law, and uncle had been Fellows, he had personally known eight of its Presidents, and many of his own papers had owed their publication to the Society. Moreover, it was Sir J. E. Smith, the founder, who had induced his father to take up the study of botany. He was grateful also to the memory of Linnæus for his own early studies in botany, which were made with a pin and flowers, making out their parts and names according to the Linnean system; and that he believed to be the most valuable way of beginning. Sir John Lubbock proposed "The Health of the President, Officers, and Council of the Society," to which Mr. Crisp, the Treasurer, replied, and the proceedings closed.

CONVERSAZIONE.

The President and officers of the Linnean Society gave a conversazione on Friday night at their rooms in Burlington House. All the memorials of Linnæus in the possession of the Society were exhibited, together with many other interesting objects.

Among the more interesting exhibits were the personal relics of Linnæus, including a small interleaved almanack for the year 1735, the year of Linnæus's betrothal to Sara Lisa Morea, his journey to the Netherlands, his doctorate, and the issue of the first edition of the "Systema Naturæ." Linnæus's walking-stick, presented by Professor Hartman in 1849, is said to have been cut and carved by himself during his journey through Lapland in 1732. The carved rhinoceros horn, of Chinese workmanship, is an excellent specimen of Oriental sculpture, the whole inverted base of the horn being carved into an elegant leaf of *Nelumbium*, the Indian Lotus; surrounding it are smaller Peach, Medlar, and other flowers and fruits, and some fantastic Lizards, with bunches of Grapes and the Li-tchi fruit in their mouths, are crawling over the whole. This was presented to the Society by Lady Smith in 1869.

Very many of Linnæus's manuscripts were also on view, including the earliest extant, the "Hortus Uplandicus," or list of plants in the botanical garden of Upsala and others in its neighbourhood, dating from 1730, and containing the first hint of the sexual system.

The vast collection of letters written to Linnæus (about 3000) was not on exhibition, but the few written by him which the Society possesses are of much interest, being addressed to G. D. Ehret, F.R.S., a German botanical artist of celebrity in the last century, who co-operated with Linnæus in producing the "Hortus Cliffortianus" at Haarlem in 1737, and who afterwards lived in London for many years. One of the letters (a translation), dated October 19th, 1756, is addressed to Dr. Patrick Brown, author of the "History of Jamaica," the beautiful plates of which were by Ehret. It is a very characteristic letter, and shows the great naturalist's enthusiasm and scientific temper so clearly that we reproduce a part of it:—

"I never coveted any book, I know not by what instinct, with more

ardent desire than yours. At length I understood that an English gentleman residing at Stockholm had got it; I entreated him to lend it me for a fortnight, and obtained it. I spent day and night in reading it through; I read it over, but never enough, and returned it. Two things I particularly observed therein, which I had not met with in other authors. The first was the author's most honest candour and humane disposition, who is not sharp upon any, severe to none, nor inveighs against others, as now is the custom among the vulgar herd of authors, but candidly inculcates his own observations without taxing others, because they could not see these things they wished to inspect, but not in their power. The other thing I noted was the writer's perspicuity, who has set forth his plants so correctly, and so exactly to the life, that I could see as it were the very plants themselves before me."

In connection with these an exhibit by Dr. Muric, lately the librarian of the Society, was of interest, being a series of impressions of seals used by Linnæus.

The Linnæan medals shown were also very interesting, including the silver medal struck for Count Tessin in 1746, and the gold medal struck for the Count in 1758. Both have a bust of Linnæus on the obverse, while the second has three crowns, representing the three kingdoms of Nature. To Count Tessin Linnæus dedicated in 1758 the first volume of the tenth edition of the "Systema Naturæ." The silver medal by Linnberger, struck by command of Gustavus III. of Sweden after the death of Linnæus, has the usual bust on the obverse, and on the reverse Cybele bewailing her loss; she has a key in her left hand, and a lion and various animals and plants lie at her feet. The motto is, "Deam luctus angit amissi." These medals were the gift of Mrs. J. J. Bennett, in 1876, her husband, long the Secretary of the Society, having received them as a gift from Robert Brown, formerly Librarian and President.

The busts, portraits, and engravings in the Society's rooms of course received much attention, and from them no one could fail to derive an accurate impression of the great Swede's countenance. They included the bust cast from Thorwaldsen's statue of Linnæus at Copenhagen, and that from the original in the Stockholm Royal Academy of Sciences; the alabaster medallion given by the same Society; the Wedgwood medallion lent by Sir Joseph Hooker, which Dr. Solander, who knew Linnæus well, said was a better likeness than any of the paintings; the oil painting on parchment by Hallman, presented by Sir John Lubbock; and that copied by Pasch from Roslin, and a large number of engravings. Among these the most interesting is a mezzotint of Linnæus, full-length, in picturesque Lapland dress. It was painted by Hoffman and engraved by H. Kingsbury in 1795. A collection of photographs from the series by E. M. Fries included views of Linnæus's old dwelling-house at Upsala, his country seat at Hammasby, where he spent his summers and wrote his most important works, his museum, the last letter he wrote with his own hand, and several interesting relics. A few of the rare books from Linnæus's library were also exhibited, including Rudbeck's "Campi Elysii Liber Secundus," 1701, folio, of which only a few copies exist, the greater part of the copies of both volumes having been burnt in the great fire at Upsala in 1702, which destroyed the cathedral, in which the stock, manuscript, and wood-blocks for ten more volumes were lodged. The elder Rudbeck never rallied from the shock, but died in the following December. The set of proofs from engravings from a manuscript copy of Dioscorides, in the Imperial Library at Vienna, is still more rare. Only two copies of the 142 plates were made, one being sent to Linnæus, the other being now in the library of the Botanic Garden at Oxford.

The collection of medals, medallions, and portraits of eminent scientific men lent by Sir Joseph Hooker was specially noteworthy. The Wedgwood medallions included those of Captain Cook and his companions, Sir Joseph Banks, Dr. Solander, and Dr. Reinhold Forster; also of Sir Isaac Newton, Sir Christopher Wren, Dr. Priestley, and Sir W. J. Hooker; also a Sèvres medallion of Cuvier. With the memorials of George Bentham was shown an antique silver watch formerly belonging to Jeremy Bentham, his uncle. Sir Joseph Hooker also lent a large series of silver medals struck for the Royal Academy of Sciences at Stockholm, and several bronze medals.—(*Times.*)

KITCHEN GARDEN.

MUSHROOM BEDS.—Where numbers of beds are made up in winter some of them are almost sure to miss bearing at the proper time, but this is not always a misfortune. In October last we formed three beds; one produced a supply at Christmas, another commenced bearing in February, and the third appeared to be a failure. Knowing from past experience, however, that some which appeared to be failures only required time and favourable circumstances to develop, we did not destroy the bed in question, but left it, and at the present time this bed is producing a daily supply of fine Mushrooms. These beds were all formed in a cool unheated structure, and we would advise those who contemplate destroying beds at the end of three months or so after

being made up, because they do not bear, to keep them on for six months at least. We have done this many times, and benefited by it. If dry, give the beds a thorough soaking with water heated to 90°, previously sprinkling a very little salt on them before watering, to destroy maggots, and cover with a thin coating of hay afterwards. Cease fire heat for Mushroom houses, and make up a bed or two in the open air to bear in July. This bed will precede the supply of Mushrooms in the fields. We prefer a cool position for the beds at this season, and the manure should be made very firm.

WEEDS.—These are now growing rapidly, and on the action of cultivators now depends the condition of the garden for the whole year. If they are allowed to seed, after trouble is inevitable, but if they are carefully hoed out by the roots now in every part the hoe can reach, and pulled up by the hand where they cannot be hoed, a clean garden through the season will be the easily accomplished result.

EARTHING UP CROPS.—We have heard some growers say they did not believe in earthing up; we have practised it for thirty years and regard it as good practice. Potatoes are greatly benefited by it, as it keeps the stems firm and prevents the tubers near the surface from becoming green and unfit for the table by exposure to the light. All Potatoes should be earthed up when the stems are about 8 inches high, and many of them require this attention now. Cabbage, Cauliflower, Brussels Sprouts, Broad Beans, Kidney Beans, and in short everything in this way, should also be earthed up to steady the stems and prevent the roots being exposed to the sun. Where the surface of the ground is very hard a fork may be used, but where the ground is friable earthing up may be done with a drag hoe.

CUTTING ASPARAGUS.—Of late Asparagus has been growing freely, and many good dishes have been secured. Growers, particularly amateurs, are often afraid to overcut it. There is little danger of this during the first stage of its growth. Let us take forced Asparagus as an example. The heads of this are cut as soon as they are high enough for us to use, and every one that follows is cut also, and this induces the whole of the crowns to push until there are from two to three dozen cut from each root, but it is very seldom that so many are cut from roots in the open ground. It may be that only two heads are seen growing from a root. These are looked upon as the only growths that will come, and one is cut and the other allowed to remain. All may be cut until the 1st of June at least, and after that more growths will appear that will mature during the season; but plants under three years old should not be cut, and weakly ones ought to be avoided, as by missing cutting for a season the plants will gain strength and the beds bear more heavily afterwards.

LETTUCE AND ENDIVE.—Paris Market is still our earliest Lettuce. Spring-raised plants are now in fine order for cutting. The supply of Lettuce should now be constant by successional sowings. From now onwards for three months we sow a pinch of seed every fortnight, and plant out a few dozens from each, which give us a constant supply. It is too early to sow the main crop of Endive, but as a few plants are often required about the end of July or in August a pinch of seed of the green Moss-curler may be sown at once.

SALSIFY AND SCORZONERA.—These are two most useful winter vegetables, generally cultivated in large gardens, but not so much grown in small ones as they should be. They are both perfectly hardy, and may remain in the ground all the winter. We use them largely from November until April, and dig them up as required. The roots penetrate like a Carrot, and will grow in any deep fertile soil. Grubs never trouble them, and as they may be grown in rows 10 inches or 1 foot apart and 4 inches from plant to plant, a large quantity may be secured from a small space. The present is the best time to sow the seed, as the roots will develop fully by October, and there is no danger of the plants "bolting," which is apt to occur from early sowings.

FRUIT FORCING.

VINES.—*Early Houses.*—Where houses have been cleared of ripe fruit the foliage of the Vines should be cleansed of dust and red spider, employing tepid water, and, if necessary, an insecticide. On no account allow the borders to become dry, but afford water to the inside borders as necessary to maintain the soil is a moist condition, keeping the foliage clean and healthy to the last, that it may aid in the proper development of the fruit buds for next season. The leaves being fresh and clean keep the laterals in check by pinching, yet if there be anything defective with the principal foliage a little more freedom may be allowed to the laterals.

Houses with Fruit Swelling.—Maintain a warm atmosphere, damping the floors and borders two or three times a day at closing time and again before nightfall. Although fires cannot be dispensed with at night, much may be done in economising fuel by closing early on fine afternoons, but it must be accompanied with plenty of atmospheric moisture. Do not allow the laterals to grow so as to crowd the principal leaves, but keep them well in hand, although where there is plenty of space they may be allowed to extend, yet not so as to necessitate their removal in great quantity later on.

Houses with the Fruit Ripening.—Allow a constant and liberal supply of warm rather dry air, and do not neglect to afford a good watering, and if a mulching of short litter be applied it will tend to a more equable moisture at the roots. A moderate amount of moisture must be accorded for the benefit of the foliage, but it must not be stagnant or it will prejudice the ripening, and without a good heat it is not possible to insure the highest quality; indeed there is no comparison

between Grapes that are ripened in good heat and those finished in a low temperature.

Grapes Scalding.—Muscats and Lady Downe's completing the stoning must be watched in hot bright weather, and in case of scalding air must be admitted more freely for a fortnight or until colouring commences, when all danger will be over. Even Hamburgs are being scalded this season, which can mostly be avoided in their case by a good spread of foliage, and remedied by a bountiful supply of air by day and a little ventilation left on constantly at the upper part of the house, and a genial warmth in the hot-water pipes.

Late Houses.—Late varieties of Grapes in flower must have a constant circulation of dry warm air, and a temperature of 70° to 75° at night, rising to 85° or 90° with sun heat, or without this the thick-skinned varieties do not set well. Thin the berries freely as soon as they are set, but this in the case of the shy setters must be confined to the removal of the smallest and imperfect berries in the first instance, deferring the general thinning until the properly fertilised berries can be determined by their free swelling. There must not be any deficiency of moisture at the roots, therefore afford liquid manure copiously after the Grapes are thinned and swelling, or a top-dressing may be given of some approved artificial manure, distributing it evenly over the surface, and work it in with tepid water. Outside borders, if the weather be dry and the soil light, should be well watered, employing liquid manure at a temperature of 85° to 90° if the Vines are carrying a full crop and are not very strong.

Vines in pots for next year's fruiting should have the leading shoot or cane stopped at 8 to 9 feet, and the laterals or sub-laterals stopped at one leaf as produced. Supernumeraries in recently planted houses should also have the leading shoots pinched at the length indicated for pot Vines—that is, those intended to fruit next season, the laterals and sub-laterals being closely stopped, but the permanent canes may be allowed to make all the growth possible, as well as pot Vines not intended to fruit next season. Young Vines after they become established should be encouraged with plenty of water at the roots and abundant atmospheric moisture, closing the house early on sunny afternoons so as to husband sun heat and save fuel.

Figs.—Ripening.—To have fruit in perfection it is necessary to keep it free from damp throughout the ripening process, affording a free circulation of dry warm air. Maintain the night temperature at 65° to 70°, by day at 75° to 80°, and with sun heat 80° to 90°. There is no comparison between Figs ripened in a close moist atmosphere and in shade and those enjoying full exposure and a favourable atmosphere. It is necessary to afford a circulation of air constantly. If red spider become troublesome during the ripening it is a good plan to gather all the fruit about ripe or sufficiently so for its being effected with the fruit in an airy fruit room, and then give the trees a forcible syringing, directing the water against the under side of the leaves so as to dislodge the pest, and clear water being used and air admitted rather freely it will not interfere with the ripening of the fruit remaining, and by pursuing this process the pest may be kept from increasing very much until the fruit is gathered, when it may be destroyed by sponging or otherwise applying an insecticide.

Second Crops.—Generous treatment will be necessary to enable the trees to swell the second crop, syringing twice a day to keep red spider in check, and affording liquid manure when watering is necessary, trees in pots requiring it daily, and those in borders once or twice a week according to the vigour of the trees and extent of the rooting area, those with borders of limited extent requiring it more frequently than those with the roots less restricted. The second crop must be thinned where thickly set before the Figs are the size of Walnuts, and in thinning reserve the largest fruits at the base of the shoots.

Young Trees for Next Season's Forcing in Pots.—Those coming on for early forcing must not on any account be neglected, or they will disappoint the grower. They must have all the light possible, and not be at a greater distance from the glass than is necessary for their growth, keeping them well syringed and supplied with liquid manure, so as to secure a sturdy growth, and when the growth is complete they may be placed outdoors in a sunny corner to induce rest, but they must have the wood thoroughly ripened, as all fruit trees, especially those for very early forcing, require to have the wood matured early.

CHERRY HOUSE.—When the whole crop is perfectly ripe the chief consideration will be to prolong the season to preserve them fresh. Shading will do so, but it is only desirable when the fruit is exposed directly to the sun owing to the limited foliage. Free ventilation must be attended to, and in hot weather a sprinkling of the surface of the border in the hottest part of the day will assist in keeping the fruit plump. The roots must not be neglected in the supply of water, for dryness is inimical to the development of the buds for the ensuing crop of fruit.

FLOWER GARDEN.

Bedding-out.—In many districts a considerable number of plants have been put out, but on the whole not much is gained by very early planting. Bright sunshine, easterly winds, and cold nights are anything but beneficial. In most localities, the bulk of the Pelargoniums, Calceolarias, Violas, Verbenas, Pyrethrums, Lobelias, Marguerites, and other comparatively hardy plants may well be planted during the first week in June; but a week later is quite soon enough to put out Iresines, Heliotropes, Begonias, Ageratums, Petunias, and other more delicate plants. Coleuses, Cannas, Acaeias, Grevilleas, Abutilons, Centaureas,

and the commoner Palms may be planted early in June; but the large-leaved Solanums, Wigandias, Ricinuses, Amaranthuses, and Tobacco are injured by a very slight frost, and ought, therefore, to be kept where they can be protected till the second week in June, and even later in cold districts. Dahlias are rather delicate, as also are the African and French Marigolds; while Stocks, Asters, Zinnias, Gail-lardias, Godetias, Antirrhinums, Pentstemons, Cornflowers, and Sun-flowers may well be planted as soon as strong enough to move.

Hints on Planting.—Each bed or border should, prior to being filled, be well forked over, and made fairly firm and level. If of a rather heavy nature it is unwise to bring any bad working soil to the surface, and it would be further improved by having plenty of good leaf soil forked in. The winter occupants of the beds, such as Forget-me-nots, Wallflowers, Silenes, Saponaria, and Limnanthes, were very late in flowering, and when cleared off they leave the ground in a dry and impoverished state. Such beds should have a dressing of either short manure or decayed garden refuse, and be well watered the evening before planting. This will be found a better plan than planting first and then watering. Verbenas, Violas, Begonias, Calceolarias, and Dahlias are all moisture-loving plants, and should, therefore, be given the coolest sites, and plenty of manure or vegetable matter in the soil. Zonal Pelargoniums, notably the doubles, Petunias, Marguerites, Antirrhinums, and Tropæolums, thrive and flower surprisingly well when planted in rather hot and dry positions, and the majority of the Zonal Pelargoniums flower most freely when growing in only moderately good soil. As a rule, it is the best plan to commence with the edging plants, finishing in the centre. Where places have to be left for the less hardy kinds, these should be duly lined out, and lines formed with the back of a rake, or any other means, are of great assistance to the novice in planting. Mixed beds, if well done, have a pleasing effect. If it is intended to peg plants down so as to form a flat even surface, the stiff-growing Pelargoniums and Calceolarias especially ought to be planted in a sloping direction, or otherwise they easily snap off.

Watering and Shading.—The roots and soil ought always to be in a moist state when placed in the ground, as it is a difficult matter to moisten them subsequently. The soil should be firmly pressed about them, and a gentle watering given. If the nights are warm sprinklings given in the evening are beneficial, but on no account should deluges of cold water be given nightly, these rendering the ground very cold. Should the weather keep clear and hot temporary shade prevents the loss of much moisture, and also helps plants that are not strongly rooted. Especially is shading necessary for the Sedums, Herniarias, Mentha, and Antennaria used for filling-in the groundwork of designs in carpet beds. These have to be pulled in pieces and thickly dibbled over the ground to be covered, and if this is unavoidably done in hot weather only shade and frequent waterings will insure even and quick growth.

Late-struck Cuttings.—If there is any likelihood of Iresines, Coleuses, and Alternantheras being scarce, it is not yet too late to strike a number of strong tops. Towards the end of May or the first week in June thousands of Alternanthera cuttings may be taken off the old plants and dibbled-in without any trimming about 2 inches apart in a frame over a very slight hotbed. Coleuses, Iresines, and soft Verbena tops may be similarly treated, and if kept close, shaded from bright sunshine, and duly watered all will strike root very quickly, and grow into useful plants by the middle of June. Small plants raised in this way are the best for carpet beds.

Seeds to be Sown.—If seeds of Carnations, Pinks, and Picotees are sown now in pans of fine soil, set in a handlight or frame, and properly shaded, they will soon germinate, and capital plants for the borders eventually result. It is necessary to raise a batch every year, especially of Carnations and Picotees, as seedlings invariably exhaust themselves in flowering the first season after they are raised. Campanula medium may yet be sown similarly to the Carnations, the plants resulting being suitable for either borders or pots. Campanula pyramidalis sown now will not grow to a flowering size under two seasons. Sweet Williams, both double and single, ought to be sown now, as well as Polyanthuses, Wallflowers, Stocks, and Myosotises in the open border. Sow also Sweet Peas for late flowering, and it is not yet too late to sow Poppies, Ornamental Grasses, Mignonette, Godetias, and other showy annuals.

THE BEE-KEEPER.

THE MANAGEMENT OF SWARMS.—No. 2.

THE object of every bee-keeper who depends rather upon the production of honey than upon the sale of swarms for his profit is to get the newly hived swarm to work in surplus chambers with all possible speed. Swarms hived and treated in the manner pointed out in our last article will soon be ready to store honey in sections or other surplus chambers, but this is only to be expected in the case of strong swarms. Whatever else a bee-keeper may do, keeping the attainment of the greatest possible amount of surplus honey in view as the goal and object of all his manipulations, we

must once more emphatically warn him against taking measures to compel the bees to work in supers before they are really strong enough to do so, having regard to the fact that swarms of this year will form the stocks of next. A swarm may be forced into supers by contracting the brood nest, but the result of such an injudicious manipulation is that the queen has not sufficient cells to hold the eggs which she should deposit, and as a consequence there are not sufficient young bees hatching out from time to time to take the place of those which issued from the stock and formed the swarm when it was first hived. No brood chamber should ever consist of less than ten standard frames, and in many instances—in fact in almost every case, and under nearly all circumstances—a hive of double that size will in the end be more profitable.

We grant that if the old stock from which the newly hived swarm has issued has been confined to a small brood chamber, that the swarm will be comparatively small, and that therefore the bees will be less able to raise all the brood which they would have the power to rear if the swarm was of proper strength; but we maintain that to hive a swarm which has issued from a stock located in a hive of the capacity of fifteen or twenty standard frames in a brood chamber containing eight or ten frames of that size only, is a suicidal policy, and against the weight of reason. A swarm should be hived on never less than ten standard frames, and when the swarm is a large one such a confined brood chamber is far too small.

Early swarms hived in large hives give, in our experience, greater results than the same swarms hived in hives of small capacity. It may be that swarms hived in small brood boxes are ready to work in supers before swarms which have a larger space to occupy, but in the former case there are fewer bees to go to the fields, and fewer bees hatching out to take the place of those dying or getting lost than in the latter. With small swarms and with late swarms the same line of argument hardly applies, because in the one case it will be as much as a small swarm can do in the course of the honey season to occupy fully the space given to it; and in the other, because no sooner has a late swarm filled the space already given to it than the season is at an end, and consequently the constantly hatching bees will never have a chance of going to the fields and bringing in their loads of honey.

The moral to be drawn is clear. Large swarms hived in capacious hives are the most profitable. Small swarms are, for honey gathering in the current season, practically worthless, but are excellent for forming stocks for another year, while late swarms are neither valuable for honey gathering purposes nor for the purpose of forming another season's stocks, unless special attention is devoted to their management. By uniting small swarms and late swarms, and thus forming from say every two or three swarms one strong swarm, the evil may be partially remedied, but happy is the man who has early swarms from stocks in large hives. Bee-keepers cannot nowadays afford to expend as much time on the care of individual stocks as was the case when honey was saleable at high prices; the object must now be to produce the largest possible quantity at the smallest possible cost. In a question of profit and loss the bee-keeper must watch small matters in order to gain his end, and if there is one thing more important than another to a practical bee-keeper, it is to either prevent swarming altogether, or else to take measures to insure that his swarms shall be both early and strong in numbers, and headed by prolific queens, and not by worn-out dowagers who are compelled to lead off a swarm by the importunate demands of their children, who desire the population of the colony to increase at a greater rate than the powers of the queen enable her to give them the means of accomplishing.—FELIX.

NOTES ON BEES.

On the 18th of May the day temperature had risen in a week's time to a mean of 50° Fahr. from one of 40° Fahr., and on the next day the temperature rose to 80°, culminating in a severe

thunderstorm with heavy rain, and it continued thundering for twenty-four hours. Owing to the sudden but welcome rise in temperature the bees for the first time this year could venture out without being chilled, as they have been so much subjected to the entire spring throughout, and they took advantage of it, working in fine style for the first time, and enabled us to form a proper estimate of their forwardness. Some of them are in readiness for swarming, and we hear of many hives expected to swarm daily, which have received no feeding whatever; this is sufficient to warrant us in condemning the manipulating and meddling system.

Apropos of the question of introducing queens, I may state that before introducing a valuable queen I give the queenless bees a piece of comb containing eggs and larvæ. If the bees start queen or royal cells I give them the queen at once; if they refuse to raise royal cells I decline introducing her, as there is not only a risk but a great likelihood that the queen will be killed. In all cases of hives having young unfertilised queens, I provide them with a piece of comb containing eggs and larvæ, in case the queen may be lost during her wedding tour.

The simplest plan of doing so, and to see at a glance without opening the hive, is to put the comb containing the eggs inside a clear tumbler on the top of the hive over the centre of the cluster of bees.

Swarming will soon be general, and the eye should never be long absent from the bees, as owing to the nature of the year many hives will make an effort to raise queens which will swarm in spite of every care taken, and every system supposed to prevent it. The loss of a swarm means the entire loss of a honey harvest, and nothing said to prevent it or assurance that they will not swarm should cause the owner to relinquish watch over his favourites until the honey season is past, when young fertile queens should be given to every stock.—A LANARKSHIRE BEE-KEEPER.

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Hyacinth Bulbs (*Spalding*).—We have received some Hyacinth bulbs, but no letter pertaining to them.

Insects in Peach House (*J. P.*).—The insects sent belong to the aphid tribe, a hand magnifier revealing the honey tubes, which may indeed be perceived by the naked eye, and which serve as a "bond of union" between ants and aphides. The particular species appears to be that called *A. ulmaria*, and occurs on various plants in and out of houses. It has been conjectured that in the winter months this and some other aphides that infest fruit trees retire to the low plants of fields or gardens which are green during the winter, and come back to the trees in spring. This suggests the application of some such preparation as the wash of soap and petroleum often recommended, which would render the branches distasteful to the aphides returning; also, they would doubtless be kept off or destroyed by tobacco water.

Profitable Use of Light soil (*A Thirty-years Reader*).—Flowers are grown in such abundance by expert cultivators and in private gardens that an inexperienced person could scarcely expect to compete successfully with them in the market supply, and you would perhaps do better by growing early Potatoes, Peas, Kidney Beans, Strawberries, Cos Lettuces, &c., taking cognizance of the markets, and growing those for which there is a demand and most likely to yield remunerative prices. The dryness of the soil may, to a great extent, be overcome by mulching; indeed it would be better to use the manure as a mulch than apply great quantities to the soil. Early flowers would be most likely to pay, and those you name would grow very well, but whether, having bulbs to purchase, you would find the culture profitable or not, is an open question. We neither advise you to make a change nor dissuade you from doing so.

Conserving Moisture in Soil (W. R. R.).—We have not a doubt you act rightly in keeping the surface of your light soil, on gravel, as loose and dry as possible for conserving moisture for your Roses, for an inch or two of dust is an excellent preventive of evaporation. But all the same, loosening the soil facilitates the drying of the surface in spring, and often beneficially. It is the water "hanging about" the surface of land planted with winter Lettuces that causes the loss of many in the spring if relief is not afforded through hoeing the ground and ridding it of some of the moisture by evaporation; that is often the chief object of the first hoeings, and subsequently as growth progresses heat increases, and more moisture is required by the plants, it is conserved for them by the dusty surface. But if you were to observe the men at work with their hoes you would find the portion immediately done early in the season damper than that to be done, and in an hour or two it dries on a fine day. The sun-warmed surface soil turned in and the colder layer brought up to be warmed and dried in turn makes the plants grow at that season. Later on the moist soil below is not brought up in hoeing, because the moisture is then wanted in the earth for the crops. A loose surface is equally good for conserving moisture in heavy soil in summer when it is wanted there, for if not loose the ground cracks and the moisture escapes through the fissures. We think you quite competent to discuss the whole matter, even with the author of the sentence that is not quite in accord with your views, but have no wish to influence you in the least in that direction.

Intermediate Stocks (Aberystwith).—As we gave you instructions a short time ago on East Lothian Stocks, we presume you now refer to the London Intermediate kind, which is quite different—quicker in growth and less hardy. Nowhere are these Stocks seen finer than in Covent Garden Market, where they are sold by thousands for the decoration of metropolitan homes. The scarlet, or rather crimson, variety is the best. Sow very thinly in rich light soil in the open garden at the end of July. If the soil of the garden is naturally heavy prepare a compost of light loam and very much decayed manure or leaf soil in equal parts, and make a bed of this about 3 inches thick in which to sow the seed. If the seed bed can be so formed as to be covered with handlights or other glass protectors so much the better, as if drenching rains occur when the seedlings are in a small state much injury may be done; still the young plants must not be coddled, but should be encouraged to assume a sturdy habit of growth from the very beginning of their career. When they are large enough to be handled, and before they are in the slightest degree crowded in the seed beds, pot them singly in 3½-inch pots, place them in a frame and keep them close for a week, and shaded if the weather is sunny, but the moment they can endure the sun they enjoy it, also all the air possible, even to the extent of removing the lights entirely night and day during settled weather, and dwarf vigorous plants will be produced before winter. They must be wintered close to the glass in very light frames, and must have protection in severe weather. They will require little water during the dull days, yet must have sufficient to keep them in a fresh growing state, but decay of the foliage must be specially guarded against. If very dwarf plants are required, they may remain in these pots until they produce flower buds, and the moment it can be ascertained which will be double and which single, either shift the former into larger pots, using very rich turfy soil, or plant them out if the weather is favourable.

Young Vines (J. E.).—You are doing right in allowing the Vines to break steadily, but if you allow the night temperature to fall below 60° after the leaves commence expanding neither Mrs. Pince, White Tokay, nor the Muscat of Alexandria will ripen. When the fruit is set the temperature may be 5° higher, with the usual increase in the daytime from sun. The top lights should not be entirely closed at night, and must be further opened as soon as the temperature rises in the morning. It should never be allowed to reach 80° or 90° before the sashes are opened, and then have to give air to reduce it, for that practice is injurious; so is a great and needless inrush of cold or dry air through doors or front ventilators. The maximum day temperature, with air, may be about 85°, as registered by a shaded thermometer, and this need not be exceeded with top ventilation alone, rightly conducted, except in very hot weather indeed. A good deal of injury is done by reckless front ventilation in the early stages of growth, but during the ripening process the danger is lessened. A genial buoyant atmosphere should be maintained by damping the house proportionate with the increasing heat; and when closing early in the afternoon, or when the temperature will not exceed 90° afterwards, every part of the house should be heavily syringed, except when the Vines are flowering. Those in pots must be judiciously watered, always giving copious supplies before the leaves droop, yet withholding water when the soil is wet. Top-dressing may be needed as the fruit swells. The weight of the crop must be governed by the strength of the Vines. If good and well managed they should bear 8 lbs. or 10 lbs. each, though all do not do so. The permanent Vines, if the canes reach some distance up the roof, should be denuded of buds to near the base of the rafters, taking a leading growth from these, with one lateral, if the Vines are strong, from each side below the origin of the leader, letting these side laterals grow 2 or 3 feet. The buds, if any, lower down the main stem in the house we should not rub off, but pinch the shoots at two or three leaves, these strengthening the stem. You may find many details in past and future columns of *Work for the Week*. Your chief object should be to produce a strong leading cane by concentrating the resources of the Vine on few growths, while if you shorten the canes now they will bleed. The portion from which the buds are removed can be cut back in the autumn.

Fumigating—How not to do it (N. S. R.).—We print your letter as a warning in case there should happen to be other readers who have overlooked what has been published time after time on the danger of burning sulphur in plant houses and vinerics. We have seen Vines ruined by it, also Cucumbers and Melons, and now we record this wreck amongst plants. You ask our advice under the following circumstances—"I have a span-roofed house containing a general collection of greenhouse plants, young stuff waiting to be bedded out, and two climbing Roses. Finding the latter troubled with green fly I closed the lights and burnt two small sulphur pastiles, used for disinfecting sick rooms. The house was only shut up for a quarter of an hour, and I then gave everything a thorough syringing with clear water. The next morning the effects, I presume of the sulphur, appear disastrous, though the effect on different plants is very striking. Large and small plants of Heliotrope and Dahlias have turned nearly black, but do not droop. Young Asters, Geraniums, and the leaves of the Roses droop and look withered as if in want of water. Young Stocks and Verbenas have become blanched. Mignonette, large plants just coming into bloom, have turned a red brown and withered as if they had finished blooming. Ferns seem all right, and Tomatoes slightly droop. A sickly smell pervades the house and all the plants. I have now the door and all lights wide open. Please tell me if I can do any more. I suppose these effects are from the sulphur. The only thing not affected is the green fly." Undoubtedly the disastrous effects are from the sulphur, and unless you are a very new reader of the Journal you have overlooked safe methods of destroying insects and adopted a course that has been many times alluded to as positively dangerous. Some of the plants will be of no further use, others may be cut back more or less, according to the extent of the injury—the Roses and Pelargoniums, for instance; then by syringing freely morning and evening, and maintaining a moist genial atmosphere by damping the floors and stages as they dry, giving water to the roots of the plants judiciously, and freely yet carefully ventilating, healthy growth may follow. Those intended for planting out may be stood in a shaded position outdoors till they show signs of recovery from the injury they have sustained, and which might have been averted. Tobacco smoke will destroy aphides without injuring plants, and solutions of the advertised insecticides are also safe and good for the purpose for which they are prepared.

Peach Trees Unsatisfactory (J. H.).—The leaves are very badly scorched. They have every appearance of having been subjected whilst damp or wet to tobacco smoke or fumes of an injurious character. As you state it is not caused by tobacco smoke, we can only conclude that the structure has been kept much too close and too moist, which in a dull period favoured the formation of thin foliage and soft long-jointed wood. Upon a return of bright weather and the consequently increased evaporation, the foliage would part with more moisture than the roots from their having such a depth (4 feet) of light porous material, would be able to maintain, and as a consequence the tissues of the leaves would shrink, especially the edges and softer parts of the leaves most distant from the midrib and veins or sources of supply. In that way only can the present appearance of the leaves be accounted for, unless we assume that the scorching is due to want of air in the early part of the day, the sun being allowed to act powerfully upon them whilst wet, not necessarily from syringing, but from the deposition of moisture through the night, and a large influx of air, rapid evaporation taking place, with the resulting scorching. Though the scorching might have been lessened, if not prevented, by judicious treatment, nothing but a radical change in the soil will cause the trees to make healthy and fruitful wood. The remedy is to lift the trees in autumn as soon as the leaves are showing the first indications of ripening, doing it carefully, so as to preserve all the roots practicable, and particularly those near the stem, keeping them from the drying influences of the atmosphere as much as possible. If you cannot obtain fresh soil mix about a fourth of clay marl with the present light soil, breaking it up small, and incorporating evenly with the soil to a depth of 2 feet. It would be an advantage if you could take out the soil to a depth of 3 feet, and put in a foot depth of old mortar rubbish from an old building, roughest at bottom and finest at top, and then the soil mixed as advised with the clayey marl, making it firm by treading, it being in such condition that it will not clog, yet having sufficient moisture to favour the spread of the roots. Lay the roots in the border so made, the uppermost not being more than 3 or 4 inches from the surface, and the others disposed in layers with a similar thickness of soil between. Make the soil very firm, afford a good watering to settle it about the roots, and mulch as far as the roots extend with 2 or 3 inches thickness of short fresh stable manure, the straw being shaken out. If the weather be bright syringe and shade whilst the work is being done and for a few days afterwards. The trees will push fresh roots quickly, and they will set and stone the fruit in a satisfactory manner next year.

Strawberries Failing (J. M. G.).—Yours is a misfortune rather than a fault, that has happened with many a good gardener. On some soils large-growing varieties, such as President, Sir Joseph Paxton, Eleanor, Dr. Hogg, British Queen, and others, "run out" or produce nothing but leaves, with the exception of a few small flowers. In our garden the first and second named, three-year-old plants, are practically barren, while young plantations, one and two years old, are flowering abundantly. We visited a garden recently, and every plant of President was barren, as was the case last year; runners from these have also failed, not one in a hundred showing, while others, planted at the same time, of Vicomtesse Hericart de Thury, obtained from a distance, were all flowering well. If you have not tried this Strawberry we advise you to do so, for it is

one of the most fruitful; it never fails with us, though others do occasionally. You will do well to obtain fresh runners of such varieties as you desire to grow for a new plantation, and before planting give the ground a good dressing of wood ashes, for your soil may be deficient in potash. Plant them on ground that has not been occupied with Strawberries at least for some years, say after early Potatoes have been cleared from the ground. Do not trench it, for the plants would do better on your soil without. If it has been liberally manured for the present crop, plant without the addition of fresh manure. If the ground is not fertile, spread a liberal dressing of manure on the surface, as if you were preparing for a crop of Potatoes, only forking the manure into the surface so that the roots of the Strawberry plants can quickly take possession of it. The autumn and winter rains will carry its virtues down as deeply as the roots descend. Good Strawberries are grown without mulching, and if manure on the surface is objectionable you should work on the two-year principle. To do this you would have to make a plantation every year, and destroy a corresponding number of rows as soon as the fruit is gathered. For this purpose you can place the plants closer together, say 18 inches from row to row, and 1 foot or 14 inches from plant to plant. The plants would cover the ground the second year, and bear heavily. As you want fruit as soon as possible, however, you may place the plants in the row only 9 inches apart, and after the crop is gathered the first year cut out every alternate plant for the others to develop and afford the principal crop. Vicomtesse Hericart de Thury and Sir Joseph Paxton are good and free varieties, Eleanor succeeding. Some of the best Kentish Strawberry growers have fruitless plants this year, through the heat and drought of last season checking growth at the proper time, the result being late, small, and immature crowns, especially where mulching was not resorted to.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*J. M.*)—All the specimens are inferior, not one having spores. No. 1 is, perhaps, *Phlebodium aureum*, but no one could be positive from such an imperfect scrap. 2, Resembles *Cyrtomium falcatum*, and 3, *Pteris tremula*. (*M. N. O.*)—1, *Epimedium alpinum*; 2, *Cerasus Padus*; 3, *Exochorda grandiflora*. (*J. M.*)—*Polygala Chamæbuxus*. (*Inquirer*).—1, *Leptospermum bullatum*; 2, *Brachysema lanceolata*. (*Senex*).—Specimens sent packed loosely in brown paper never arrive in a satisfactory condition for naming, and this is the case with yours. Send them in a tin box or carefully packed, and we will name them with pleasure. (*M. R.*)—1, *Gentiana verna*; 2, *Gentiana acaulis*; 3, *Myosotis dissitiflora*. (*E. M.*)—1, *Pyrus Malus floribunda*; 2, It is not easy to recognise a plaut from a damaged leaf and a single petal, and we can only guess that your *Geranium* is *pyrenaicum*.

COVENT GARDEN MARKET.—MAY 30TH.

MARKET quiet owing to the holidays, with prices lower.

THE COMPARATIVE VALUE OF MANURES.

FOR economy to have its right place among remedial measures for agricultural depression it must be sufficiently comprehensive to embrace every possible detail of farming. We must not only avoid waste in the ordinary sense of the term, but in all we do there must be strict economy of time, labour, money. To insure this there must be no speculative work in general farm practice; our end and aim must be clearly defined, and the means for the attainment of success be as simple, sure, and inexpensive as possible. It is true enough that exact precision is hardly possible in regard to the quantity of seed or fertilisers used in our work, but it may be approached sufficiently near to avoid waste, and so sensible have intelligent farmers become of this fact that increasing attention is given to the careful selection of manures. To them it is quite clear that the use of muck or farmyard manure for crops generally will eventually come to an end, because it has been proved to demonstration that we can impart fertility to the soil at much less expense by the use of chemical manures.

This fact has been brought before our readers so often that they certainly must by this time regard it as no new thing. But it is only by persistent effort that we can hope to drive the muck cart from the land, and to induce farmers to avoid the serious loss involved in the needless manufacture of farmyard manure. Change from an old-established custom is always slow, and in this particular matter it is especially so, because of the lamentable ignorance of the real value of chemical manures. No doubt dealer's mixtures are a hindrance here, owing to the poverty of results and the consequent losses which have gone on for so many years, and the only way to overcome this difficulty is to show what is being done by the use of pure manures specially adapted to the requirements of the crop for which they are used.

In the new number of the Journal of the Royal Agricultural Society of England we have a valuable contribution to this work in the article on "The Practical Value of Dung as Compared with Artificial Manures," by Mr. R. Vallentine of Burecott, Leighton Buzzard. "Dung," says he, "is merely what is added to the straw. If one waters 1 ton of straw, and does nothing else but let it lie about for a time, something like 4 tons of mere wet straw-dung may be obtained. The manurial value of a ton of straw is estimated at about 10s., therefore 4 tons of merely wetted straw is only worth 2s. 6d. a ton as dung. On the other hand, if a ton of straw be used as litter for twenty weeks for a fattening bullock, receiving about 17 lbs. per day of cake—say of cotton and linseed

cake—besides Clover, hay, and roots, the original ton of straw has most costly additions made to it. Is the manure worth the extra cost and additions? Most people would answer, No. As few farmers have either boxes or covered yards to preserve any kind of manure, what part of the original value of the manure in the food would remain after repeated washings? Just in proportion to the number and thoroughness of the washings we may suppose; and these are frequent enough in all ordinary seasons. Again, when dung does contain a good per-centage of nitrogen, it seldom shows such favourable results in the crops as artificial manures, containing much less in quantity, but in a more readily available form.

"The cost of oilcake dung is apparently very great. The notion that the land will get richer is true; but will the ordinary farmer who makes it get richer or poorer? Artificial manures have hitherto produced crops of both corn and roots fully better than dung. If dunging is partially or wholly left off the crops fall off. Then where is the permanency of dung? If artificial manures containing both phosphates and nitrogen are used it is known on the best possible authority—that of Sir John Lawes—that after more than forty years' trial neither does the soil get poorer nor the crops get worse. Further, dung may be applied in very large quantities to all kinds of crops, and although the soil becomes richer and richer the crops never increase in proportion, nor yet at all in fact, as the yield of corn on dunged land—dunged heavily for forty years—does not increase.

"People who know least about artificial manures condemn them. Many say nitrate of soda is the great criminal charged with scourging, wearing out the land, and doing all the evil possible in every respect to the land. Can an authentic account be really obtained of any farm that has been really injured by the judicious use of artificials? What farmer who knows anything much about artificials would use nitrate of soda or ammonia salts year after year alone without phosphates? No one could continue to do so without loss.

"Cattle foods of various kinds no doubt contain the amounts of manurial ingredients which chemists assign to them, and the loss by consumption may also be fairly enough estimated. For all this, in real practice, by making dung from dear food and applying it to the land, there is usually a considerable loss when the crops are produced. Dung does not act so quickly as artificials, a small per-centage only coming into immediate use. The residue of the dung left often assisting one crop is subjected to continual loss by the usual rainfall in winter, and this for the four or five years that elapse before the dung is again applied.

"In very wet seasons even dung produces no very visible effect on crops. The soluble ingredients of value may be washed away as soon as produced. Whatever theory there may be on the matter of loss, every farmer found that in the unusually wet season of 1879 the dunged crops appeared to suffer as much as where artificials were used. Nor were the crops much better after any kind of manuring than when nothing was applied. Practically, however, there is an enormous loss of manurial matter from dung before it reaches the field. In too many instances I have not the slightest doubt that much more than half of the most valuable ingredients of the dung are washed away and utterly lost, so far at least as the producer is concerned.

"My present system of farming is to aim at keeping up the manurial condition of the land, so that it may produce good crops at the smallest cost of manure. For years past my main reliance has been placed on artificial manures. Some dung is made and some bought, but it is found to answer best, as a rule, to sell hay and straw and purchase manures. The land is barely second class, but for all this in suitable seasons the crops have certainly been better than the crops of those average farmers who mainly depend upon dung. Profits on an average over thirty-three years would be considered fairly good by most people. In parts of half a dozen fields no dung has been applied for about forty years. On the parts

entirely manured by artificials the crops, save on one part of light sandy soil, are quite as good as on the parts dressed with dung. The yield of Wheat averaged fully four quarters over twenty years. Every kind of crop, excepting the seeds, is annually manured with either nitrate of soda, dissolved bone superphosphate, mineral superphosphate, or a mixture of all. The land was never rich, nor is it rich now, as when any portions are left (as some are every year) without any manure, the yield of corn is a good deal under what is manured."

The article contains much more valuable matter, and statistics are given in support of his facts and reasoning, but the quotations we give possess an especial degree of importance, tending as they do to support the views we have so frequently laid before our readers, and which we profitably embody in our own practice. Invaluable is the advice to keep the fertility of the soil fully sustained, and the outcome of forty years' practice goes to show that the soil is simply a medium for the conveyance of food to plants; be it our aim to see that such sustenance is given in due and timely measure.

WORK ON THE HOME FARM.

By the time this note is printed corn-hoeing will be finished, but as we write horse and hand hoes are still in full activity, and the weather is certainly most favourable for such work. Bright sunshine and winds soon destroy the weeds, and our expenditure upon this important work is proportionately higher than usual. We believe in turning such seasonable opportunities to full account, for clean land may be rendered profitable, but foul land never can be under present prices. Men working horse hoes have had to be looked closely after, for a little inattention may cause the corn itself to be destroyed or buried beneath the soil. With due care, however, horse corn hoes are a great help in turning a spell of fine weather to full account. Mangolds are nicely visible along the rows. Weeds are coming plentifully among them too, so that hoeing will have to be done among them now, for we much object to leaving such work till weeds get strong hold of the soil. The growth of grass left for hay is so backward that there will be ample time to get the root crops weeded and the plant thinned before haymaking begins.

Much carting of hay and Wheat straw has been done as horses could be spared for it. With our large supplies of both these articles we are able to supply a variety of markets and private customers, some at a distance of twenty miles, such long journeys being done on a Saturday, so that the horses may have the benefit of Sunday's rest. The demand for both hay and straw has been so good that we could have disposed of much more than we had to spare, but the price of hay has not risen with the demand owing to the low price of imported Oats.

Rye over which sheep and lambs were folded is now in full growth again, and would be available for a second folding did we require it, but we do not. The Rye will be left now for harvest, and we have reason to expect a full crop of both corn and straw, for both which there is a ready sale. The folding upon new permanent pasture is finished for the first time, and stone-picking is being done upon it now. The plant is strong and abundant, and we hope to see good progress made by next autumn. A piece of Rye Grass of last year's sowing on some heavy land is a full plant, but the application of a hundredweight per acre of nitrate of soda has not told as it ought, which is a clear indication of a want of drainage.

REMARKS.

27th.—Fresh, and generally bright.
 21st.—Bright pleasant day, with slight shower at 9 P.M.; moonlight night.
 22nd.—Cloudy all day
 23rd.—Almost cloudless throughout.
 24th.—Cloudy till about 11 A.M., then bright and warm.
 25th.—Fine and bright.
 26th.—Overcast morning; fine afternoon and evening.
 A fine week; temperature variable, but on the whole near the average.—G. J. SYMONS.

TULIP NOTES.

TULIPS have not been favoured with the most suitable weather this season, but the early bedding varieties proved much better than could have been expected, and produced some brilliant but brief displays in the metropolitan parks and public gardens, where they are now extensively planted every season. Hyacinths are employed for a few beds, but they are not nearly so popular for this purpose as the Tulips, which combine with rich, bright, or soft clear colours a more graceful form, and present a more pleasing general effect, either massed in beds of one variety each, or mixed. Both systems have their advocates, and good results can be obtained in either case by judicious planting if due attention be paid to the average height of the varieties, and contrasting or harmonising the colours. For situations where the beds can be seen from a distance the massing mode of planting is the more telling, but for closer inspection mixed beds afford an agreeable variety.

The most extensive display of early Tulips in London has been provided in Hyde Park, where the numerous large beds near Park Lane were almost exclusively devoted to these plants this season, and many thousands of bulbs of the best varieties have been there yielding some glowing colour effects. Though on a less elaborate scale, the beds at Kew in the long walk leading from the Wood Museum towards the Palm house have been excellent, and were amongst the most pleasing we have seen this year. Particularly fine was one bed planted with Proserpine margined by two rows of Queen Victoria, a useful pure white variety, about 2 inches shorter than Proserpine, thus giving a less formal outline than when the varieties are of similar height. An example of the flatness resulting from the latter mode of planting was noticed in a neighbouring bed to the preceding one, the variety Potter (rosy crimson) having a margin of the clear yellow Chrysolora, but though the colour effect was good, the varieties were so nearly the same height that they were not seen to such advantage. In another bed, L'Immaculé (white) was edged with La Précieuse, flamed with rose, very pretty; extremely handsome also was Duchesse de Parma with rich orange scarlet well-formed flowers, margined with two rows of Queen Victoria, forming one of the grandest beds in the garden.

All those named were oblong beds, but there was a bold crescent-shaped bed having the orange-tinted Thomas Moore for a centre, then rows of Potter and Chrysolora in that order for a margin, a capitally effective combination. Very simple but extremely telling also was a large circle of Tulipa elegans, which is about 15 inches high, with long tapering brilliant scarlet petals and a yellow centre, the bed having a neat margin of Euonymus radicans variegata. Several of the distinct Tulips regarded as species might be advantageously employed in a similar way, such as the tall yellow *T. retroflexa*, the dwarf white *T. stellata*, or the graceful equally dwarf yellow *T. australis*, the crimson and white *T. suaveolens*, the spreading *T. sylvestris*, or the very distinct *T. Greigi*. At the top of the walk mentioned is a narrow circular border surrounding a vase, and the "mixed method" there adopted was so charming that it merits a word or two of description. The edge was formed of red and white double Daisies alternately, then a band of purple Aubrietias, followed by Tulips Queen Victoria, Duchesse de Parma, and Proserpine not too closely placed, the centre being yellow Wallflowers, and the ground beneath was covered with Forget-me-nots and the white Arabis. Such a

diversity of tints without any discordant results, and such a freedom of design, secured many admirers, for what one critical gardening friend unhesitatingly pronounced to be the best border of spring flowers he had seen.

The season has also been unfavourable to the later or florists' Tulips, and those who are looking forward to the annual gathering of the National Tulip Society in the Manchester Botanic Gardens next Saturday do not anticipate one of the best representative displays. Dwellers in the south whose gardening careers do not date back to the time when these Tulips were such general favourites have but little idea of their diversity and beauty. It is doubtful if one collection could be found round the metropolis now, and in the whole of the southern counties there are but few who still find space in their gardens for their old favourites. Even in the north cultivators are not by any means numerous, and the collections of Mr. S. Barlow and the Rev. F. D. Horner are probably unrivalled. Why Tulips have declined in popularity is not very clear, for their marvellous varied and richly coloured flowers, if only studied in the most cursory manner, cannot fail to awaken admiration and interest in the minds of any plant lover. Perhaps the short duration and somewhat tantalising uncertainty of the flowers in our equally uncertain climate may have had something to do with the neglect; but whatever be the cause many still hope to see a revival of public interest in such a fine group of plants.

Several years ago I had an opportunity of visiting the Manchester Tulip Show for the first time, and plunged immediately into all the mysteries of Bizarres, Bybloemens, Roses, and Breeders—which until then had been to me words that conveyed a very imperfect idea of the characters they represent. Fortunately the improvement of my neglected education was undertaken by an excellent tutor, the Rev. F. D. Horner, who, in a few brief lessons and demonstrations, quickly cleared away the difficulties. Perhaps if I repeat the substance of his instruction respecting the different types of Tulips it may help others who have not mastered the distinctions, though their titles are so familiar. First on the list is the class termed Bizarres, which comprise a series of varieties with flowers having a ground colour of yellow, marked with red, brown, or even black, and present a strange combination of tints comparable perhaps to some extent to the peculiar Spanish Irises in another family of plants. Next follow the Bybloemens which have a pure white ground colour marked with purple, lilac, mauve, and similar tints, ranging in the darkest almost to black. The third class comprises the Rose Tulips, also with a white ground colour upon which the rose, red, or scarlet markings in many shades show in fine relief. The first includes many grand varieties, but the last two contain those that would be considered most beautiful by the majority. Each of these is divided into two sections according to the form the markings take upon the petals of the flower. When its colour is confined to a narrow marginal band it is said to be "feathered;" when, however, it runs up the centre bursting out on each side and expanding towards the apex it is "flamed," and such flowers are usually feathered also. At exhibitions, therefore, classes are provided for feathered Bizarres, flamed Bizarres, feathered Bybloemens, and so on, making six divisions in all.

But another important and highly interesting class calls for consideration—namely, the "breeder" or "mother" Tulips, which have a remarkable history. When florists' Tulips are raised from seed four to six years elapse before flowers are produced, and then in a large majority of cases the flowers are all self-coloured, showing none of the peculiar and beautiful markings of the parents, though individuals can be found in every recognised Tulip tint, and the class to which they will be ultimately assigned, except in a few mixed cases, can commonly be determined by the ground and body colours respectively in accordance with the rules already mentioned. The "breeders" have to be grown until they "break," or "rectify" as it is termed, that assume the feathered or flamed characters as Bizarres, Bybloemens, or Roses, and this is a very interesting period

for the cultivator, as it appears there is no certainty when it will take place, or what form it will take. Offsets from "breeders" have been known to produce both flamed and feathered flowers, but when once the "rectification" has occurred the characters are fixed with extremely few exceptions, and all offsets produced are true to the parent that yielded them. There is something extremely strange in this alteration of character in seedlings after the lapse of perhaps six or eight years from the time the seed was sown, and so far the determining causes have not been ascertained, though change of soil has been thought to have an influence in the matter.

This peculiarity has a bearing, however, upon another subject, which is worth a few moments' consideration, though the ideas here stated must be regarded more as queries than any attempt to settle a difficult point. Many so-called wild Tulips have been introduced in recent years and received names as distinct species, probably from a botanical point of view upon adequate grounds, but I have seen several of these that possess a remarkably close resemblance to the "Breeder" Tulip of the florist. Has it ever occurred to those who collect and describe "wild" Tulips, that it is possible the phenomenon of "breaking" might also occur in a state of nature, and have the newly found species been sufficiently proved as fixed types? This was brought rather forcibly to mind recently by a comparison of some "Breeders" received from Holland with the Tulips at Kew, one of the latter named *T. platystigma* being exactly like one of the Dutch Breeder forms in all characters. The subject is well worth investigation, and is only one of numberless points which render Tulips such interesting garden plants.—RECORDER.

A CHAPTER ON WATERING.

I DO not intend dealing with increasing the water supply in cases where it is deficient. As to whether this can be done or not depends entirely on circumstances of which I have no knowledge, but as to the application of water in times of drought much may be said. It is not always where the water is most plentiful that the plants are best watered; indeed it is not a question of mere quantity, but the secret of successful watering lies in doing it well and at the proper time. It is almost impossible to make a mistake in watering a plant that has so many roots as to fill the soil and pot in which it is growing. If too much is given it will simply run through the pot and do no harm to the roots, but such plants suffer terribly from neglect in watering. It is ruin to Heaths, Azaleas, and other hardwooded plants, and all others suffer. One may be very careful in watering for a week or a month, but let them become dry once so much as to cause the foliage to fall, the evil is done, and all previous benefits from careful watering are lost. Amateurs, especially, who may water their plants in the morning before going to business, and not see them again until the next morning, should place saucers beneath every one of such plants, and fill them with water every morning, when all danger of their suffering will be obviated. In gardens where young men are daily employed to water the plants this plan may be superfluous, as no plant should suffer that is examined twice a day, but where hands are short in large gardens the saucer plan will save much labour.

Now we come to another class of plants—namely, those that have plenty of soil and root room but few roots, which very quickly test the ability of the attendant, as over-watering soon causes the soil to become boggy, and then the plants will fail. Many are killed or kept in permanent bad health from this cause, and I find it a most difficult matter to get young gardeners or amateurs to understand that a plant with few roots does not require so much water as those with abundance of roots. The system of general watering is a bad one—that is, going into a house and watering every plant, whether it is needed or not. This is often done in the morning under the impression that if some of the plants do not require water then they may do so before the day is over, but this indiscriminate watering will soon lead to many of them becoming unwell, and if I found a man acting thus he would not fail to be corrected. Sometimes soil appears dry on the surface when it is really damp beneath. Where there are any doubts watering should not be done by sight only. If each pot is rapped sharply with the knuckles those in which the soil is dry will give a hollow sound, while those in which the soil is sufficiently moist will have a dead sound. By giving a little attention to this it is astonishing how expert anyone may become at watering plants in pots.

One of the best methods of preventing plants in pots suffering

from drought is to plunge them. In good plant-growing establishments plunging, both under glass and in the open air, is largely resorted to. It saves labour in watering, as plunged plants do not require water so often as those with the pots exposed to the sun and air, and while the pots may become so hot and dry in the latter case as to injure the roots which come in contact with them, this never occurs with plunged plants. As a rule we plunge all our Chrysanthemums. Last year for some reason we did not do so, and the result was the poorest we ever had. Few plants suffer more from having their pots exposed than Azaleas, but when plunged they may be kept healthy without any difficulty. It is not always possible to plunge pots in greenhouses and on shelves in houses, but if a board or some screen is put up to shade the pots from the sun it will prove a great advantage.

When once the soil becomes thoroughly dry no ordinary watering will rectify the mistake, as three or four applications of water will pass through the pot without wetting the soil in the centre. The only perfect mode of watering over-dry plants is to plunge the pots over the top in a bucket or tank of water, and allow them to remain there for an hour or more. The water then penetrates the whole of the soil, and there is no difficulty in watering them in the ordinary way afterwards. In syringing it is generally the foliage only that is moistened, but it is an excellent plan to syringe the pots once or twice a day in hot dry weather, as they absorb much of the moisture and are cool for the roots. The soil in pots that are syringed does not dry quickly.

In dealing with Vine, Peach, and other borders under glass surface dribblings must be rigidly avoided. Nothing short of a thorough soaking will prove beneficial, and where the drainage is good a copious supply must be given. We hear much of Peach flowers and fruits falling. In many cases it is caused by a too dry subsoil and nothing else. I never knew a Peach tree that was properly watered behave very badly. A painful or two of water is a delusion, but a deluge "sets them up" for the season. Some say "We will not water until we see how they are going on." This is a mistake. By the time that fruit trees show, whether they want water or not, the mischief has been done, as a check will have been given from which they will not quite recover for that season. The better way is to judge by the state of the weather and the soil if they are likely to require water. Anticipate it, and apply water thoroughly before the condition of the tree indicates want. Strawberries will take any amount of water in May and June, but many of them do not receive any until the fruit begins ripening, then it is seen they are small, and all of a hurry water is applied; but it is labour in vain, as unless they are quite wet at the roots when the fruit is forming after attentions are useless.

Vegetables are sometimes watered, but it is generally applied with the object of "finishing them off," whereas if it were given to them during the early stages of their growth to make them develop the "finishing off" would follow as a natural certainty. We have watered Peas in flower, and also long before they came in bloom, and the latter invariably proved superior. This applies to all vegetables. Timely application is the secret of successful watering. All trees planted during the last twelve months will be apt to droop should warm dry weather occur, and their chances of existing will be greatly increased if they receive a thorough watering at the roots before they suffer. Grass seed sown during April or May, or turf placed down in the spring, would grow better and form a finer lawn if watered so as to prevent the drought checking the growth of the grass. Extensive lawns might not easily be watered, but small ones could readily be attended to, and it is always important that they should be in good order.—A KITCHEN GARDENER.

THE PEAR-GNAT OR MIDGES.

WE learn from the "Entomologist" that this tiny insect, the identification of which has presented some difficulty to naturalists, has been verified by Dr. Riley, the American State Entomologist. The species appears to have been first observed in Connecticut about seven years ago. Dr. Riley infers that it was imported from France with some Pear stocks. It has been known in England for a longer period, but owing to its occurring only sparsely, and confining itself to a few varieties of the Pear, little notice has been taken of its habits hitherto. Previous names being doubtful, Dr. Riley has now called the species *Diplosis pyrivora*. It is probably the same as that to which some naturalists gave the name of *Cecidomyia nigra*. That the insect is widely diffused is shown by Miss Ormerod's letter from a gentleman in Wales, who says, "I have sent some specimens of Marie Louise Pears, of which there was a splendid promise of a crop, but they are all attacked by grubs within. The same thing happened last year, causing the destruction of a crop, as well as in addition having destroyed a fine crop of Beurré Bachelier. I observe that the winter Pears have entirely escaped."

So far as the observations have proceeded, they prove that, though this midge visits several varieties of the Pear, its favourite food is the Marie Louise, a Pear known to cultivators for at least fifty years; brought from France or Belgium, and which may have been more or less infested by this insect ever since it has been grown in England. At present no complaints concerning it have reached entomologists from what are the great districts of the Pear, as in those counties where perry is made, or those where the fruit is grown for the London market. It is to be earnestly hoped the insect will not become abundant in our orchards, for its minute size renders it difficult to deal with. Under a magnifier we see it is furnished with long antennæ, the wings are dusky, and the body black and grey studded with yellow hairs. The grub or larva is whitish yellow, having a pink projection on the under side near the head, used for holding or grasping doubtless, it being minus legs, as is customary in the Dipterous or fly order.

Mr. R. H. Meade thus outlines the history of the species:—
 "Its eggs are laid by the females, which possess a long and slender oviduct, in the interior of the blossom buds of the Pear tree before they expand. They are said to deposit the eggs upon the anthers of the flowers, sometimes piercing through the unopened petals to reach them. The eggs soon hatch, and the little maggots bore into the core of the young Pear, where they quickly increase in size, and spread and eat in various directions. The vitality of the fruit is not destroyed at once, but it continues to grow, sometimes, however, becoming distorted and lumpy in shape. By the time these young Pears have become an inch or two long the larvæ will have attained their full growth, and the fruit has become partly rotten and disorganised in its interior. If now cut open the core will be found partly hollow, the fruit fissured in various directions, and surrounded by excrement and *débris*, from ten to thirty maggots may be seen. Next, the Pears fall off or crack, when the larvæ leave the fruit, which they seem especially inclined to do in wet weather, as the rain either makes the fruit crack or it penetrates into the fissures, and they spring to the ground, for they possess, like some others of the genus, the power of skipping or jumping. Having reached the earth they bury themselves and remain hidden until the following spring." Besides the removal of all infected Pears seen during the season of growth it might be well to ward off attack by the application of some liquor to the buds which would be distasteful to the flies.—J. R. S. C.

TABLE PLANTS.

WHERE large numbers of plants are needed for table or room decoration, and the pots are placed in vases, much may be done to improve their appearance by surfacing the soil with low-growing plants, which will form agreeable contrasts with the foliage of the larger plants. This applies to foliage plants only, which are more often grown in a light manner, as Crotons with a single stem, *Aralias*, and *Dracænas*. Flowering plants, as a rule, are more bushy in character, and generally so grown as to partially, if not wholly, hide the pots or vases in which they are placed. Beyond the improved appearance gained by using living plants to hide the soil in the pots, and frequently several inches of bare stems, much time is gained in changing them, as when properly grown all that is required is to simply place a fresh one in the vase instead of having to cover the soil with moss or Ivy leaves. In some places, near towns especially, fresh green moss cannot be had, and artificially coloured moss has then to be employed, which at its best is but a poor substitute for the real article. I propose to name those low-growing plants which I have found suitable for the purpose, the method adopted in their preparation, and a few examples by way of contrast. The advantage of some of the plants is that they are hardy, and many need only greenhouse treatment, so that several classes of cultivators can be accommodated.

Selaginella Kraussiana is the most useful of all. It forms a dense green covering, lasting a long time in perfection, is not particular as to temperature, and may be made to contrast with any kind of plant, as for instance, when it covers the soil in which *Cocos Weddelliana* is growing, by adding a few pieces of *Panicum variegatum* the effect is much improved. The spring is the best time to increase the stock by pulling it in small pieces, dibbling them into sandy soil placed in heat and shade—a viney answers well. *Tradescantia zebrina*, *Fittonia argyroneura* and *F. Verschaffelti* are easily increased by inserting short cuttings in bottom heat in sandy soil. *Pilea muscosa* is well adapted for this purpose, being dwarf in habit, deep green when in growth and when in bud deep pink, changing to a greyish white when in bloom. Cuttings strike freely at any time. *Ficus repens*, where low drooping growth is required, is capital; *Vitis heterophylla* and *Peperomia argyræa* are also suitable plants, *Sedums Lydium* and *glaucum* are useful hardy plants suitable to associate with those

requiring greenhouse temperature only, and Harrison's Musk is sometimes used for this purpose.

One month before the plants are required is soon enough to surface the soil if the plants are suitably prepared and placed in sufficiently thick for immediate effect; or should the plants need potting a few weeks earlier than this the surfacing may be put on at that time. Drooping plants, such as *Panicum* and *Tradescantia*, are placed around the pot. These droop over the sides of the vase when grown into form; by pinching out the points a thicker growth is obtained. Those of upright growth should be placed in the centre. An example of arrangement in this form may be, for instance, red-leaved *Croton* with a base of *Selaginella* and *Panicum*, *Tradescantia*, or white *Fittonia*, while yellow-leaved *Crotons* may have red *Fittonia*, *Pilea*, and *Panicum*. After planting shade should be given for a few days.—E. M.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 336.)

THE Romans are often spoken of as an iron race, a people hardy and fierce, but during their later history their love of gardening brings out their character in a milder phase. We do not, perhaps, allow sufficiently for their influence upon English horticulture, when we look at the unsettled and warlike times which followed, for long centuries, the Roman occupancy. It is true that the gardens attached to their town and country villas fell into neglect, still we may trace a descent of horticultural traditions from the Romans to the monks, in whose gardens flowers bloomed and fruits and vegetables were reared when other pursuits occupied all the attention of nobles and citizens. And moreover, of the large number of plants introduced by the Romans only a part became extinct; others propagated and gradually spread themselves, so as to make it a doubtful point with many species whether they are true natives or early introductions. People show us even now, for instance, a Plum growing apparently wild in Stone Wood, Kent, which is presumed to have been planted by one of the Roman residents in the town which grew up at the extremity of the valley below Southfleet, and on the border of the ancient road from Dover to London and the north—viz., Watling Street.

Still we discover, or surmise, that some species, once thought to be foreign, are really of English descent. Thus the Yew, which for centuries writers referred to as an imported tree, has of late been found in such abundance amongst other trees of forests long submerged, that we are assured it grew here when Cæsar landed, and before. That bald-headed and vain-glorious general was a successful soldier, but not always a good observer. He thought the Beech or *Fagus* did not occur in Britain because he did not find it along the line of his march, unless by *Fagus* he meant the Sweet Chestnut, which is not a plausible explanation. But the Abies which Cæsar also said he missed was not the Scotch Pine, sometimes erroneously called a Fir, but the Silver Fir, certainly not British. If afterwards brought in by the Romans, it died out later on, for it was not known to horticulturists of the Middle Ages.

Although we possess a meagre fragmentary account of Roman everyday life in Britain while the island owned the supremacy of that empire, we can picture to ourselves what the gardens of the resident gentlemen were by the accounts we have of Italian villas, which would be doubtless imitated on English shores as nearly as possible. Being conquerors of the world the Romans acquired a knowledge of trees growing in Europe, Asia, and Africa, but on the whole they were most indebted to Persia and Greece. Few things are new under the sun, and on a survey of the Roman gardens lying round London—let us say about the third century—we should see the two styles described in modern works on gardens—viz., natural and artificial. That the Romans took the hint of the irregular or natural one (in fact our Laureate's "careless ordered garden") from the pleasure grounds or paradise of Eastern kings seems likely. And the delineation of garden spaces or courts on some of the ancient Egyptian monuments by their formality suggest that the formal manner of laying out originated in that land, but the Romans probably learnt it from the Greeks. We should perceive that the larger gardens, as might be expected, were chiefly laid out in the natural mode, and the smaller in an artificial or geometric fashion. If of any extent, the gardens were always well shaded with lines of trees, and shrubberies or clumps interspersed. Seats were numerous, and the Romans added the additional luxury of low couches, so that persons could lie if they chose without the risk of resting upon the ground. As a rule they liked to introduce water, preferring to a pond or lake some streamlet, so contrived that its turns and changes of level made it flow with a murmuring sound

agreeable to the ear. A favourite practical joke, however, was to have a concealed fountain, and as the by-passer went along, by stepping on a lever he set it in motion, unawares, perhaps to receive its stream upon his person. It was very usual to place plants in pots or in boxes along the sides of garden paths. It may be inferred that these were removed for the winter, especially in our colder climate, and protected by some means. One favourite style of setting out gardens was in squares, four, eight, or even more, each square separated from its neighbours by trelliswork, upon which climbers or creepers were placed. On the outside of gardens there were often hedges of some thorny species. It is supposed the Romans occasionally formed those of the Broom (*Cytisus scoparius*).

I think it is quite possible we might learn, even now, from the Roman lords of Britain, as did our ancestors, for there rose up a class amongst the Britons who copied Roman ways and methods, in gardens amongst other things. The Roman horticulturists thought it of importance to study not only the senses of sight and touch, but that of smell, when planning gardens or shrubberies. As a matter of course they excluded all species, even if beautiful, when the odour of leaves or flowers was offensive, and they made a study of the various aromas given off by fragrant plants and trees, taking care to place together such as would assimilate. Certainly they would have much admired the Eucalyptus tree and other exotics we possess, but unknown to them; they, however, much encouraged the Pine, on account of its refreshing odour, and the Cedar, deemed a health-giving tree. The Bay was a favourite because of its beauty and its use in furnishing crowns of honour. The Eastern Plane, popular with us, was also popular with the Romans, but we cannot see clearly why they had a partiality for the Cypress. Even, as in later times, certain plants came to be dedicated to particular individuals—the Violet, for instance, to Napoleon, and the Primrose to Beaconsfield—so the Romans assigned trees to imaginary personages; thus the Olive to the Queen of Wisdom, the Poplar to Hercules, and the Myrtle to Venus. Very probably they planted in the groves about their English villas both the trees of the warmer countries of South Europe or Asia, and species obtained from northern regions colder than Britain.

The fanciful mode of cutting trees or shrubs into imitations of the shapes of human beings and animals, or forming letters of names from them, was an old device of the Romans, though re-introduced to us by the Dutch after William III. became monarch of these islands. In forming vineyards or Vine plantations the Romans made an artificial slope, if they had not a natural hill available, and it was a notion of theirs to have the ground above the Vines set with low shrubs, growing thickly. One of their fads was to plant the walks around some of the gardens with a plant they call *Acanthus*, presumed to be a species of moss, but we do not know; of course it was kept short and even, being soft to the tread, silent also, but probably at times slippery. The practice of forcing plants was introduced to Britain by the Romans; this they managed on an original plan by means of *specularia*—i.e., plates of talc, with which they covered boxes or baskets, also using manure to heat; for they were well aware of the importance of manuring or enriching the soil, and even with this object sowed crops and then buried them while green. But as to their *specularia* it remains a wonder how they got talc plates of 4 or 5 feet long (so it is asserted), for none such can be split now. Though some have argued, from the Roman custom of warming dwelling houses by subterranean stoves, that in a similar way they probably applied heat to houses containing vegetables and fruit, the silence on this point of all writers on gardening and rural affairs leads rather to the negative conclusion. They understood grafting and inoculation, layering also, but frequently propagated fruit trees by seeds or suckers; and the Romans had their florists, too. Some in London doubtless, if not at other British stations, would ply their trade, which was to sell chaplets or wreaths made up both of wild and garden flowers. These were used for various purposes, the flowers in them being chosen not only for their beauty and perfume, but arranged to represent symbolical or mythological ideas.—J. R. S. C.

IVY-LEAF PELARGONIUMS.

IVY-LEAVED Pelargoniums are becoming very popular, and we cannot feel surprised, for they are of easy culture, and can be trained to almost any shape, pyramidal plants being very ornamental. They are also quite as useful to cover spaces on walls or pillars in the greenhouse or conservatory, and afford abundance of flowers for a long time. The semi-doubles are especially to be recommended for the latter purpose. In one of the Pelargonium houses at Chilwell these may be seen to perfection trained up pillars on each side of the pathway, so as to form arches over the pathway. These arches are from 8 to 10 feet apart, and form a

very interesting feature, being at the present time covered with flowers.

Amongst the most notable varieties may be mentioned Anna Pfitzer, Comte de Choiseul, Emile Lemoine, Furstin Josephine von Hohenzollern, Jeanne d'Arc, Le Printemps, Louis Thibaut, Madeline Reiterhart, and L'Elegante, the old variegated form, a mass of flowers. This variety is also much prized for bedding. Many others may be mentioned, which appear mostly to be closer growing, more fit for specimens or for bedding, such as A. Carrière, Congo, Isidore-Feral, M. de Borringe, Madame Thibaut, and Souvenir de Charles-Turner, which are flowering from nearly every joint. Of newer varieties, notable are Galilee, a charming pink double, and Lavosier, a very fine type of the rose-coloured section; this is also a double variety. Many others could be mentioned, but the above are sufficient to form an idea of what are good. In another house may be seen the old, but yet useful, *Solanum jasminoides*, trained as mentioned above, and it has a charming appearance, producing its pretty white clusters of flowers in profusion. This is very useful for wreaths.—S.

HARDY PLANTS AT WISLEY.

A SLIGHT acquaintance with poor collections, indifferently grown, has induced some individuals to indulge in a general condemnation of hardy plants, and to stigmatise them as "weedy;" but however this may be deserved in particular instances, it is unquestionably an error very easily dissipated by the inspection of such a garden as Mr. G. F. Wilson's. The best of plants amply repay for good cultivation, and some that under less watchful care seem scarcely worth the space they occupy are greatly improved with suitable attention. Successful culture with many of the choicer hardy herbaceous and alpine plants means finding them the right soil and situation, and then leaving them to take natural possession of it, merely protecting them from their enemies and preventing stronger coarse plants encroaching upon them. It is a common mistake when a plant is seen to be thriving to instantly start cutting and dividing it, and many choice occupants of borders and rockeries have been lost by this species of greed. It is always well to strengthen one's resources, but in this, as in other matters, "hasten slowly" is a good motto. One enthusiastic amateur always recommended his friends (and I believe consistently practised it himself) to distribute portions of any rare or difficult plant with which they had succeeded, as in case any accident befel the original plant there would always be a reserve to fall back upon, as it was unlikely that all would be lost. This also is an idea worth remembering, but if it is carried out too hurriedly or injudiciously it will simply bring the result that it is wished to avoid—namely, the destruction of the parent. There are certain to be many losses and failures before the right conditions are ascertained, but when once the plants are established they seem fully capable of taking care of themselves, and one of the charms of the garden at Wisley is the number of its occupants that are seen to be prospering as they might do in a wild state under the most favourable of natural conditions.

A few instances of this may be given in the following notes. Of Irises a great favourite is *I. Kämpferi* with its varieties, so distinct in the shades of its large Clematis-like flowers. This thrives in several different aspects, but on sloping sandy banks near the water, and though the plants are at different elevations, from quite close to the water's edge up to several feet, yet in all cases the requisite condition seems to be that their roots should be cool, with a constant moisture rising from below. In the Cambridge Botanic Gardens, where this fine Iris also succeeds, it has a similar position, but it is seldom seen luxuriating as it does at Wisley. The Japanese Iris is, of course, not yet in flower, but another beautiful species that thrives well on banks near the water is *I. longipetala*, of which there are some handsome clumps now bearing abundance of its delicate lilac-veined flowers. The dwarf early Irises have also afforded plenty of their deep purple or parti-coloured flowers in compact clusters, though now past their best.

Two comparatively diminutive plants deserve a special note, as they are rarely seen happy in gardens, and though both are natives of this country they cannot be despised except by those who think that all floral beauty is confined to exotics. One of these is the Chickweed Winter Green, or, as it is more euphoniously named, the Star Flower, *Trientalis europæa*, which, amongst its bronzy green leaves, bears numbers of pure white small starry flowers. It is growing capitally in a somewhat damp position in "poor hungry peat," and is evidently thoroughly at home. The other is the Mountain Avens, *Dryas octopetala*, one of the smaller members of the Rose family, and which grows vigorously, and bears its white flowers freely on a bank in the garden with the golden North American species, *D. Drummondii*, though the latter has not made quite such good progress. Other trailing plants that succeed admirably in the woodland garden are the interesting little *Linnaea borealis* in two varieties, *Mitchella repens*, and *Epigæa repens*, which scramble about covering the ground with a dense carpet of greenery. With them are associated hardy Heaths by hundreds, *Ledums*, and similar plants that like a peaty soil and shade. The Heaths are treated in the same manner as some of the softwooded *Ericas* grown for indoor decoration—namely, they are cut in closely with the shears about this time of year, and then make strong fresh growth, also keeping them within moderate limits.

Several mounds are devoted to *Saxifragas*, *Sempervivums*, and

Sedums, of which good selections of the most distinct are grown, and as a preservative of moisture and to afford protection to the plants stones are freely employed around the plants on the banks, and evidently with beneficial effects. One mound of *Verhaseum phœniceum* is now very beautiful, the plants 3 or 4 feet high, with graceful spires of flowers half their height. The variety is one with flowers of a peculiarly rich purple hue, and established upon the tops and slopes of the mound the plants shed their seeds and a constant succession of seedlings is thus secured.

Still keeping to the woodland, *Seilla nutans* and its varieties were flowering beautifully at the time of my visit, and greatly prized are the varieties received from the late Miss Hope of Wardie Lodge. These are pure white, blush, pink, bright rose, and blue, all with fine spikes and bells, a delightful contrast of tints. Lilies of the Valley are found thriving in several shady situations, and they will be greatly extended. Ferns also are at home, particularly in one retreat, which, while shaded from sun at mid-day, yet admits some broken rays early in the day, and there the Holly, the Oak, and the Parsley Ferns are most luxuriant, while a graceful New Zealand Fern, *Hypolepis millefolium*, introduced some years ago, has taken possession of the ground, and is spreading like Braeken. Along the margins of the dells and rivulets, and wherever a fresh cutting is made in the soil, the common *Blechnum spicant* springs up in abundance, forming a pretty fringe to the banks.

In the open again, the lake has already been incidentally mentioned together with that charming little Cape of Good Hope aquatic *Aponogeton distachyon*, or Water Hawthorn as it is so fittingly designated in popular language. This has taken full possession of the lake and covers its surface with its pale green leaves and white fragrant flowers, being perfectly hardy, a fact that is not sufficiently realised, as there are many similarly sheltered situations where it would be equally satisfactory. Some years ago I remember making its acquaintance in Mr. Parker's nursery at Tooting, where in small watercourses, that were little more than ditches, it had become established, and year by year increased rapidly and flowered as freely. At Merton also, near the river Wandale, a piece of water is filled with the plant equally as vigorous, floriferous and uninjured. Water Lilies of various kinds are included in the Wisley lake, while its margin is clothed with a selection of the most effective of water-loving plants, a variegated *Carex* showing up well in contrast with the prevailing green tints.

The shrubbery, in addition to those noted last week, contains numerous fine plants of *Rubus odoratus*, *R. nootkaensis*, and the handsome white *R. deliciosus*. The last is of smaller growth than the others but seldom seen flowering so well, though they have been successful with it at Kew and Regent's Park, but Messrs. C. Lee & Sons exhibited specimens a few years ago at South Kensington in fine condition from a plant in the private garden of one of the members of the firm at Hounslow. Upon the higher ground near the Lily beds is a row of seedling plants of *Chimonanthus fragrans* which are fast developing into a little hedge, and possess considerable interest. Mr. Wilson says that when visiting Dangstein some years ago in the company of Dr. R. Hogg and the Rev. M. J. Berkeley, a plant of *Chimonanthus* was noticed that was bearing a quantity of seed, which at once attracted attention, as it had been declared by scientific authority that seeds could not be formed without the fertilisation was assisted by insects, and the early period at which the flowers are produced rendered it very improbable that such assistance could be afforded. However, the seeds proved fertile, as both Dr. Hogg and Mr. Wilson succeeded in raising plants, and, as already remarked, the latter now has a long row of healthy specimens. The increase of the *Chimonanthus* has always been a subject of interest, and there is a well-worn story to the effect that Dr. Lindley once offered a guinea for every plant that was raised from a cutting, but the prize was never claimed. Mr. F. Bause, when propagating in the Chiswick Gardens, however, succeeded in accomplishing this so far as the formation of roots is concerned, but I believe that they never grew and ultimately died. Some time ago it was claimed that plants had been raised by means of cuttings taken when the leaves were fully developed well rooted in a vinery, and an experienced friend assures me he has succeeded in a similar way.

Roses are favourites at Wisley, not formal standards or bushes, to afford exhibition blooms, but all climbers and trailing Roses that cover walls or hedges with growth and flowers. Two sides of the cottage facing full east and north are clothed with plants of *Rêve d'Or*, which are promising a delightful display of flowers. The golden bronze William Allen Richardson is planted to cover hedges and trellises, while the fresh green foliage and large red and white flowers of *R. rugosa* succeeded by plentiful crops of fine fruits make superb hedges. For a similar purpose the American Blackberries are extensively employed, and plentiful gatherings of fine fruits are obtained during the season.

Such in brief are some of the characters and features of Wisley, imperfectly portrayed, but an hour or two spent amidst such a diversity of interesting objects admits of little more than generalisation.—L. C.

APRICOT BRANCHES DYING.

In an article on Apricots on page 434, it is stated that old trees are constantly losing branches as well as numerous spurs on the live wood. This can be prevented in a very simple way—namely, by leaving the ground undug, and weeded only by hand for 3 feet from the stem of the tree. As sure as the roots are injured by the fork or spade so sure is a branch or spur to suffer in consequence. If in the height of summer the ground near a tree is dug and a strong root cut off, in a few days a branch perhaps laden with half-ripened fruit will wither and die, or if the

small fibrous roots near the surface are damaged, the spurs will die just in proportion to the mischief done to the roots. Instead of bringing on young trees to take the place of the old ones, I advise your readers to avoid injuring the roots of the old trees, but protect and manure them well, and thus insure a constant large crop of any and all wall fruit.—Y. Z.

HABERLEA RHODOPENSIS.

At the meeting of the Royal Horticultural Society, on May 22nd last, a plant of *Haberlea rhodopensis* was exhibited from the Royal Gardens, Kew, and a first-class certificate was awarded, as, though by no means a novelty, it is seldom seen. It is dwarf, resembling a *Ramondia* in habit, but with somewhat funnel-shaped flowers, 1 inch long, like a small *Streptocarpus*, the tube purple, and five white lobes.

FIG. 62.—HABERLEA RHODOPENSIS.

They are borne in trusses of three or four flowers each, arising from amongst the foliage. *Haberlea rhodopensis* is a native of Macedonia, and is closely related to the two genera mentioned above. In DeCandolle's "Prodromus" it is placed in the family *Cyrtandraceæ*, between *Ramondia* and *Conandron*, both monotypic genera, *R. pyrenaica* and *C. ramondioides* being well-known garden plants.

GREENHOUSE RHODODENDRONS.

I AM not surprised that some of your readers should have recently inquired about these. In my opinion they are amongst the finest of all greenhouse plants. Some also possess a delightful fragrance like *Rhododendron fragrantissimum*. I was telling a friend the other day what grand flowers they were. His reply was, "I know, but I have no room to grow them." Now this seems to be the impression of many who own comparatively small greenhouses and conservatories, and it is a mistake. They do not require any more space than *Azaleas* and ordinary greenhouse plants.

Of late we have had some plants of *R. fragrantissimum* masses of flowers. These are in 9-inch pots, and the plants are not more than

3 feet high and about the same in diameter. They flowered with the greatest freedom when not more than half this size. R. Countess of Haddington is more compact still, and if anything more profuse in flowering, but the flowers droop more, and are not so fragrant. It is, however, a grand variety. R. balsaminæflorum album is one of the best of the new varieties, but it is rather expensive as yet. In the general class I can speak most favourably of R. Duchess of Teck, R. javanicum, R. Maiden's Blush, R. Searlet Crown, R. Countess of Dalhousie, R. Lady Fitzwilliam, R. Princess Alice, and R. Veitchianum.

Anyone beginning with two, three, or half a dozen plants will soon add more to their collection, and their culture is easily mastered. The proper time for them to make their growth is immediately after they have flowered. New shoots will appear then, and ought to be encouraged. If the soil is not in good condition at the roots turn them out and repot. If they require a larger sized pot let them have it, but being a little root-bound induces them to flower more freely. Fine plants may be grown in 10-inch pots. They grow well in a soil consisting of three parts peat, one of loam, and a liberal dash of silver sand. The drainage must be perfect, and placed in so that it may remain of use for two or three years, as this is often enough to repot them. Repotted or not, they may be placed in a warm house or pit until they make their growth, and during that time syringe them daily. As soon as the growths are well developed remove them from their hot quarters, and gradually harden them until by July or August they may be placed in the open air. There they may remain until the autumn, when they can be placed in a frame or house, well watered at the roots, and frequently syringed to keep the foliage clean. When frost comes protect them, but do not attempt to keep them in a strong heat.—J. MUIR, *Margam*.

GLADIOLI NOTES.

I TAKE an opportunity to write a few more notes. Mr. Kelway finds the Gladiolus almost as easy of culture as the Narcissus and Snowdrop. I have no doubt that is so under conditions which suit it. But were Mr. Kelway located 5° further to the north, and instead of soft western breezes he had to put up with dry easterly winds for weeks together, he would find the Gladiolus not amongst the most easily managed of bulbous plants. However, Mr. Kelway hardly does the Snowdrop justice when he concludes the second paragraph of the article on page 402 with the remark (referring to the Gladiolus) that "After all, without care and skilful knowledge failures are certain." Surely there is not much care or skilful knowledge required to grow the simple flowers he names. They make themselves at home here along with Tulips, Scillas, and other bulbs, and are cut down with the scythe after flowering, and fail neither to increase nor flower under such rough treatment. Facts do not bear out Mr. Kelway's theory taking the country in general. Taking writers in this Journal, "D., Deal," has been troubled about the Gladiolus for many years. "A Northern Amateur," who is a most skilful grower, plainly says there are some which he cannot keep. Out of a large number of varieties of Mr. Kelway's raising which I bought eight years ago I have only one left. Some have increased here in the course of a dozen or so years a hundred fold. What is the reason for the difference? "D., Deal," considers disease the sole root of the mischief, but although I lose a few with disease that is not the reason. Mr. Kelway says, and has said so for many years, that "exhaustion" is the cause. That is to say, as I take it, that flowering the plant has exhausted the energies of the young corm. But the fatal objection to that theory is that the varieties which disappear are not those which flower freely and early in the season, but those which in cold seasons have no opportunity of flowering on account of winter overtaking them before that stage is reached. If my experience in the north teaches anything, it goes in the line of showing that many of our seasons are too short to enable the later varieties to be grown, unless some method of lengthening the season of growth is followed. I believe starting the corms under glass will prove the best way of doing this, and I hope another season to again try Duchess of Edinburgh under such conditions. I have just been dibbling out little plants from spawn which were started in boxes. Mr. Kelway, and doubtless many others, find these do well enough in shallow drills out of doors, but they do not succeed well here in that way. So far Gladiolus are looking very well, not quite so strong as last season, but if we only had a few genial showers instead of hard drying winds the strength would soon be increased.

I am sorry if I incautiously misrepresented Messrs. Kelway's position as exhibitors. I was under the belief that the firm I named had beaten them at London a dozen years ago. Certainly the spikes as seen at home were splendid, and the papers gave no stinted praise to their excellence, but, though under the impression that they had Messrs. Kelway as antagonists, I may, of course, be wrong.

Just a few words as to varieties. Tastes differ so much, especially when any standard is set up to test by, that what "D., Deal," condemns others would at once select as fine. I always find, whether in Gladiolus, Carnations, or Auriculas, and perhaps less so in other flowers, that the untutored eye selects that which the florist considers poor. A florist looks at a flower as it is, and as it should be from his point of view, and the nearer it approaches his ideal, apart altogether from its intrinsic merit, the better pleased is he. Ordinary people, of whom the world is composed, see simply the flower as it is, and are delighted with its colour, its form, its odour, without needing to look any further as to whether it may be offending against the law of the florist. Just so with some of the Gladiolus, which I like altogether apart from their pro-

perties as florist flowers. Diamant, though flimsy as a piece of tissue paper, is nevertheless a lovely flower. Le Phare is a most brilliant colour. Penelope I also like for its colour; and to sum up, I must confess to more than a weakness for the old *gandavensis* itself.—B.

ORCHIDS AT CROYDON LODGE.

A GRAND variety of *Cattleya Mossiæ* is now in bloom at Croydon Lodge. The plant has fifteen flowers, the sepals and petals are very pale, the lip is of great size and richly coloured with a pure white margin. Of *Dendrobium densiflorum* there are some fine specimens; one plant is 4 feet across, bearing three dozen spikes of bloom. *D. thyrsoflorum*, similar in habit to the above, is also well flowered in 32's; the best, a large form, has six spikes with about sixty blooms each. The flowering house is attractive at the present time with these and many other Orchids. Another cool house has recently been erected against a wall having a north-west aspect. On the front stage *Masdevallias* and *Odontoglossums* are growing, and the back wall is artistically made to represent a rockery from the roof to the ground. Pockets have been made in it for the reception of Ferns and Orchids; a few of the latter have been planted and some are in bloom, and no doubt when well furnished it will be a most interesting place.

The *Phalænopses* are grown in the plant stove. They are few in number, but the plants are large, and one piece of *P. Schilleriana* is said to be the largest in the country. They are in baskets, and the rule observed here is to water them from the spout of the can, and syringe the long roots occasionally, a system to be recommended where it can be carried out without interfering with plants beneath. *Epidendrum bicornutum* has been in bloom for a long time. It is grown successfully near the glass in the stove, and while growing syringed every day along with the *Crotons*, &c., but while at rest it receives no water. *Peristeria elata* in the same house is well grown; one plant is in a 14-inch pot, and has enormous pseudo-bulbs and four strong growths; they all flower annually, sending up thick spikes. The collection belongs to Stephenson Clarke, Esq., and the compost used by his gardener, Mr. Carr, is good yellow fibrous loam with a little peat and moss, and charcoal is used very liberally.

CATTELEYA SKINNERI AT ELMER'S END, BECKENHAM.

Mr. Goddard's plants have again been a magnificent sight. When I saw them a fortnight since they were arranged in a high lean-to house 24 feet long by 15 feet wide, forming an immense bank of rose purple coloured blossoms. There were over a hundred spikes averaging nine blooms each. A few Ferns and foliage plants were tastefully arranged amongst them and along the front. Racemes of *Oncidium ampliatum majus*, *Odontoglossum vexillarium*, and well bloomed *Lælia purpurata*, including the beautiful delicate coloured variety *Russelliana*, the bright *Epidendrum rhizophorum*, with *Cattleya Mendeli* and *C. Mossiæ*, helped to give variety in colour, and also to break up the straight lines of *C. Skinneri*.

PHALÆNOPSES AT OLDFIELD, BICKLEY.

These continue to increase in size. They are grown in baskets suspended from the roof, and the long healthy roots hanging down denote the care bestowed on them in watering. Each plant as it requires water is taken down and carefully steeped, and then hung up again in its place. This is a simple lesson which young men would do well to remember. I have frequently seen choice Orchids in baskets thrust into a vessel of water too small for the purpose, and the roots broken or damaged. So long as this occurs the plants cannot possibly compare with those of Mr. Philbrick or give the grower satisfaction. There is a fine display of flowers now in the other Orchid houses at Oldfield.—G. W. C.

DENDROBIUM CLAVATUM.

A CAPITAL coloured illustration of this *Dendrobium* is given in the *Botanical Magazine* (t. 6993), with the following remarks:—"This magnificent species has never been described or figured in all its beauty as here represented, and yet it is one of the earliest discovered of the golden *Dendrobes* of India, having been found by Wallich in Nepal in 1821, and subsequently by his collectors in Silhet. Unfortunately the specimens he distributed were not in flower, and the species was hence passed over by Lindley in his 'Genera et Species Orchidearum.' It was for some time supposed to be a variety of *D. moschatum*. The first description of it is that

in Lindley and Paxton's 'Flower Garden, drawn up from Assam specimens that flowered in England ;' it is accompanied by a wood-cut of the flower. Though having a wide range in distribution it must be a rare species ; Strachey and Winterbottom found it in the North-West Himalaya in the province Kumaon, west of Nepal, which is perhaps the westernmost limit reached by the vast genus to which it belongs, but it has not been recorded from Sikkim or Bhotan, and very few collectors have met with it in Silhet or Assam. It must not be confounded with the *D. clavatum* of Roxburgh (*D. sulcatum*, *Lindl., Bot. Mag.* 6962), a much more common species, and to which, from its club-shaped stem, the specific name of *clavatum* far better applies. The specimen here figured flowered in the Royal Gardens in September of last year ; the plant was sent from the Khasia hills by Mr. Gustav Mann in 1885, and flowers in September." The flowers are borne in racemes, and have broad rounded petals and sepals deep orange yellow, the lip having a bright crimson centre and a golden yellow margin.

ORCHIDS AT HOLLOWAY.

MR. B. S. WILLIAMS'S nursery at Upper Holloway is full of interest at the present time, and contains an excellent display of flowering Orchids. During several years the large Palm house near the office has been specially appropriated to the Orchid exhibition, but shifting the plants from their various quarters to this house was not found beneficial, and they are therefore more suitably grouped in their respective houses. The extent of Mr. Williams's collection is well known to Orchid growers, and it is not surprising that the home stock suffices to form a display of varied interest over such a long period in the year, though during May and June the greatest number is in flower. In another important respect the Holloway Orchids are interesting—*i.e.*, they are well grown, sturdy finely developed foliage and pseudo-bulbs or stems result in proportionately fine durable flowers. To this must be added the fact that the formation of the collection has been the life-work and study, the selection of species and varieties having been conducted with the keenest critical knowledge of their merits. Consequently in all the leading genera the best types only are represented, and it is for these that amateurs now look to nurserymen specialists when tiring of the numerous indifferent varieties that are unavoidably introduced with imported plants.

Lælia purpurata has been made a special feature, both plants and varieties being extremely good ; and a pretty group is formed at the entrance of one of the houses with these ; *Cattleya Mossiæ* varieties, *Masdevallia Veitchi grandiflora*, bearing twenty flowers ; *M. Harryana*, *M. Lindenii*, *Dendrobium thyrsoiflorum* and *chryso-toxum*, *Odontoglossum vexillarium*, capitally grown ; the graceful *Oncidium sarcodes* at the back, the greenish white *Cyrtocilium stellatum*, *Maxillaria grandiflora*, *Aerides Warneri*, *Cœlogyne Massangeana*, and *Scuticaria Hadwenii*. In another house we find a group comprising several similar plants, with *Cymbidium Lowianum* bearing five long racemes ; *Cypripedium barbatum superbum*, having eleven fine rich flowers ; and *C. b. nigrum*, with nine dark flowers ; *Lælia cinnabarina*, *Dendrobium suavissimum* the sweetly scented *Burlingtonia fragrans*, *Anguloa Clowesi* and *A. Ruckeri*, *Dendrobium Dalhousieanum*, with seven racemes of large flowers ; *Brassia verrucosa*, with eleven racemes ; *Brassia Keiliana tristis*, a dark form ; *Brassavola lineata*, and the wonderful *Lælia elegans prasiata*, which is one of many grand forms of *L. elegans* that enrich the Holloway collection. In a third house *Vandas* predominate, *suavis Hrubyana*, *tricolor Patersonii*, *insignis*, and the *Glen* variety being fine. *Calanthes veratrifolia Dominiana*, *Textori*, and *Masuca grandiflora* are represented by good plants, together with numbers of choice *Cypripediums*, *Phalænopses*, *Thunias*, *Saccolabiums*, *Dendrobiums*, &c. In the cool house *Odontoglossums* of the best varieties afford some bunches of spikes, beautifully contrasted with the richly tinted *Masdevallias*, while in one house is a valuable group of all the principal hybrid *Cypripediums* and rare species in the best of health and flowering well, *C. selligerum majus* being uncommonly good. Ferns, stove and greenhouse flowering and foliage plants, are in excellent condition, and the nursery altogether is well worth a visit.—Z.

THE EFFECT OF VEGETATION ON RAINFALL.

An interesting pamphlet, entitled "The Natural Law of Relation Between Rainfall and Vegetable Life, and its Application to Australia," has just been produced by Franz A. Velschow, C.E., of Copenhagen (Stanford, Charing Cross), in which, in the course of some forty pages, the peculiarities of the Australian climate are fully discussed. By comparing the recorded rainfall in different districts the author shows that as the moist air flowing in to land from the ocean rises at a short distance inland above what he terms a "dry air cushion," through which rain can only penetrate by the greatest difficulty—namely, after the air has become partially saturated. He contends that a gradual extension of

the moist boundary could be effected by planting trees largely, as a circulation would then be established that would result in more regular and frequent rains. The subject is summarised in the following remarks :—

"Over the dry and warm tracts of Australia the general Heath-like vegetation is marked by a pervading blue-green colour, with dull leaves so arranged upon the plants as to afford but little shade. The Eucalyptus, or Gum Tree, and other trees and shrubs bearing bright honeyed flowers, together with thickets of Acacia and Marsh Oaks, give a peculiar character to the forest lands. As the foliage of these trees generally consists of heavy leathery leaves covered by a thick cuticular coating, the evaporation from them is exceedingly small, and it is therefore strange that the Gum Tree has been thought to possess the quality of removing the moisture from marshy places by being planted there. This is evidently owing to the circumstance that Gum Trees, when felled, are generally found filled with water in abundance ; but this is always the case with the vegetation found in deserts or very arid zones, more especially with the Cactus plant, which has been proved to give no evaporation at all, so to speak ; and they thereby become prepared to withstand excess of dry weather. As the camel before entering on his journey across the desert stows away a large quantity of water, so these trees of the desert prepare themselves for the dry season by taking in water ; but, like the camel, they economise this supply, being protected against a too rapid evaporation by their cuticular coating.

"It is to the small degree of evaporating power of the Australian vegetation generally that the irregularity of the rainfall may be considered due, and the rainfall could therefore be highly improved if by some means or other we could substitute for the present vegetation another possessing a high degree of evaporating power.

"Looking upon the subject at large the question before us may be defined thus : Is the want of trees exhaling much moisture in Australia due to the impossibility of their growth there, or is it due to accident ? It is well in this respect to notice how the earth's surface has been divided into six distinct regions, each with its own particular flora and fauna, more or less independent of latitude and temperature, but principally caused by the insurmountable barriers formed against their further spread by mountain ranges, deserts, and oceans ; and that it has been found that trees transplanted from one of these regions into another grow there equally well, or even better, than in their aboriginal home. Among these regions Australia, with the surrounding islands, forms one, and it seems therefore highly probable that European deciduous trees, or any other kind of trees of high evaporating power, would thrive equally well in the south-eastern temperate part of Australia, as in Europe. The desert theory now put forward serves to prove that the climate would be changed if we could manage to establish forest belts of deciduous trees over this south-eastern part of Australia. Along the east deciduous trees, grow exceedingly well, as can be seen in the botanical and private gardens, and there can be no doubt that they will grow equally well wheresoever the ground is sufficiently moist. It might, therefore, be a practicable undertaking to commence plantations at the coast, stretching thence further and further inland, the effect being that of breaking up the border of the air-cushion, so as to permit the rainfall along the coast to reach further inland.

"The difficulty would evidently at first be where to find enough of moist soil to start the plantations. But the various colonies have voted considerable sums of money for the conservation of water in general, and particularly for the irrigation of the Murray-Darling River. The evaporation from the country hereby brought into cultivation would in itself be very considerable, and could be highly augmented by plantations along this line of irrigated country. In this manner the air-cushion, too, would be likely to be broken along this line, the ultimate effect of works of plantation on both sides of the district being the entire change of climate in south-eastern Australia.

"To find out the most suitable trees for planting, it would be necessary to carry out careful measurements of the evaporation from different kinds of deciduous and other trees by planting them in large covered boxes constructed for this purpose. Among those which hereby show the highest amount of evaporation such must be chosen for plantation as will grow most easily in the colonies, besides being useful as timber trees.

"It might then even be found that the project of establishing the growth of these trees in Australia would be materially assisted by Nature, according to Darwin's theory of the survival of the fittest, as it of late years has been found that in northern Europe the Beech is gradually superseding the Oak, which was formerly the dominant tree. Likewise in Australia, if trees of a more vigorous growth than the native trees are introduced the ultimate extermination of the latter may be anticipated.

"From a geological point of view Australia is recognised as the remnant of some former extensive continent. By being situated in the central most elevated region of this continent Australia would in all probability have formed a desert exactly similar in position to the desert of Gobi in Central Asia. When afterwards the surrounding country became submerged this central part preserved the once-attained characteristic features of a desert—namely, a non-evaporating vegetation covered by an air-cushion, in spite of the oceans which have gradually approached the borders of this desert. In this way it is to be explained how it has been brought about that we nowadays find ourselves opposite this phenomenon, so extraordinary to all scientific minds, of a large desert island placed in the centre of the largest expanse of tropical seas. But the greater this absurdity appears the

greater is also the probability that the work of restoring this country to cultivation will prove to be an easy and delightful one, so that if the work is taken energetically in hand at once there can be little doubt that Australia, perhaps even before another generation has passed away, will have shown some marked signs of ultimately becoming one of the most fertile countries on earth.

This geological explanation is, however, a suggestion which ought to be kept quite distinct from the other parts of my argument, which possess all but mathematical exactitude, being based as they are on the number of gallons of water exhaled by an ordinary tree during twenty-four hours, and the proved effect of this evaporation on the specific gravity of the atmosphere that absorbs it."

EVENTS OF THE WEEK.—The Royal Horticultural Society will hold a meeting in the Drill Hall, Westminster, on Tuesday next, June 12th, and the York Gala will open on Wednesday, the 13th inst., which, with the usual sales, will be the principal horticultural occurrences of the week.

— **ROYAL HORTICULTURAL SOCIETY.**—We are informed that efforts are being made to render the next four meetings in the Drill Hall at Westminster specially interesting and attractive. The Assistant Secretary has written to several leading nurserymen and flower growers, calling their special attention to them, and asking their support during these two months, the height of the London season. The meetings and their special features are as follow:—June 12th, cut Rhododendrons, Hardy Azaleas, flowering shrubs, Ranunculus, Anemones, and Iris. June 26th, Begonias, Gloxinias, Pelargoniums, cut Clematis, Paeonies, Roses, Pinks. July 10th, Roses, Lilies, Strawberries. July 24th, show of the Carnation and Picotee Society, also Ferns, Ivy and Zonal Pelargoniums.

— **THE WEATHER.**—"B. D." writes—"May has closed and June begun with very unseasonable weather. In the middle of last week many of the hills in W. Perthshire were covered with snow. An intense frost is reported from the north that has made complete havoc of vegetables and flowers in gardens, and done much damage amongst forest trees. In S. Perthshire the 2nd and 3rd inst. were extremely wet with a bitter N.E. wind. Hawthorn is beginning to show blossom. The *Scotsman* of the 4th inst. contains reports from the north rather startling for the beginning of June. I therefore quote—"Snow fell over north of Scotland last Saturday. In Strathspey the hills were covered to their base, and water was coated with ice a quarter of an inch thick. At Balmoral snow fell for twenty-five hours, and last night it was lying several inches deep." More genial conditions have prevailed in the south, Saturday, Sunday, and Monday being extremely hot days. Tuesday was dull with very cold wind.

— We are desired to announce that the **COLCHESTER AND EAST ESSEX HORTICULTURAL SOCIETY** will hold a Rose Show on June 30th, at which liberal prizes are offered for amateurs. The Hon. Secretary is Mr. J. C. Quilter, Head Street, Colchester.

— "G." writes: "Two **USEFUL FUCHSIAS** for decorative purposes are Starlight and Prince Imperial, which are employed extensively by Mr. W. Holmes, Frampton Park Nursery, Hackney, in conjunction with other decorative plants, such as Pelargoniums, Rhododendrons, Hydrangeas, Ferns, and Palms. Starlight is a free flowering variety of compact habit, the sepals and tube white, and the corolla of a bright rosy tint and good size; it is regarded as a great improvement upon Mrs. Marshall, and is much appreciated in the market. Prince Imperial is a dark variety, with scarlet sepals and tube and deep purple corolla, of similarly free habit. They afford a pleasing contrast when together, and are very effective in windows or recesses."

— **MESSRS. E. H. KRELAGE & SON**, Haarlem, send us a **COLLECTION OF BREEDER TULIPS**, which they intend offering for sale next autumn, without waiting until they have "rectified." The flowers are large, of good form, and most varied in colours, purple, mauve, crimson

rose, and vermilion shades being very abundant, and a number could be selected that, judged by a florist's standard, would be considered most promising when "broken."

— In recognition of the assistance rendered by **MR. J. NEWTON** on the occasion of the recent Show in the Inner Temple Gardens, he has been elected a Fellow of the Royal Horticultural Society without payment of the usual fees.

— "M. C., *Ashton*," writes—"A decided acquisition to the select list of spring bedding plants will be found in **MYOSOTIS GRANDIFLORA**, a really grand improvement on the old form of *M. dissitiflora*, both in the size of the flowers and also in the profuse way they are produced from free growing yet compact little plants. As grown by Mr. H. Virgo at Portishead, the plant has a charming appearance, its large deep blue flowers and general habit giving one the impression of a blue *Silene compacta*. To judge from the great demand for its sprays in Clifton and Bristol the plant in question will undoubtedly become the most popular form of the poetical Forget-me-not. The enclosed flowers hardly do it justice, the hot weather has reduced their size and colour." The variety is a good one, as our correspondent represents, the flowers being much larger than those of the ordinary *M. dissitiflora*, but we have seen a variety shown by Mr. Virgo with much more deeply coloured flowers.

— **MR. H. CANNELL** sends us a box of blooms of **HOSE-IN-HOSE MIMULUS**, and most effective a bed of these richly coloured flowers must be. They are represented in several brilliant varieties, every one possessing the duplex character in a marked degree.

— **LEEDS PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY.**—"J. L. B." writes—"In the Journal, May 24th, there is an account of a very interesting presentation to the Secretary of this Society, and I thought I should like to encourage young gardeners to join such a Society in preference to mixed clubs which have all classes in them, whether they follow a healthy or an unhealthy calling. Gardening is considered a healthy occupation, and I find, as a rule, gardeners do not go on the club for a slight illness. I have often wished I knew of the existence of gardeners' clubs when I was a young man, and I should not have joined a mixed club. In the above mentioned gardeners' Club by paying only 1s. per month 10s. per week may be had during sickness, £10 at death, and £6 at death of a wife, and it does not matter what part of the country a gardener may reside, he can join and pay his money without ever going to Leeds."

— **MR. G. ASLETT**, Warren Wood Gardens, Hatfield, Herts, sends us flower trusses of **RHODODENDRON FORTUNEI**, variety **MRS. C. BUTLER**, which is notable for its powerful fragrance. The flowers are large and expanded, of a soft pale pink hue, in loose clusters, very delicate and charming.

— The following plants are figured in the *Botanical Magazine* for May:—T. 6993, *D. clavatum*, noted fully on another page. T. 6994, *Allium Suworowi*, a native of the Kerghis Desert and the vicinity of Bokhara, introduced by Dr. Albert Regel, and named in honour of Herr J. P. Von Suworow, Medical Inspector of the Province of Turkestan. It has scapes 2 feet high, and dense globular heads of mauve purple flowers. T. 6995, *Alpinia officinarum*, a native of South China, and formerly "in great repute as an aromatic stimulant amongst the Arabs and Greeks and in Western Europe. The flowers are white, veined with red, the long narrow leaves arising from a thickened tuber-like rootstock." T. 6996, *Douglasia levigata*, a primulaceous plant from the Alps of Oregon, of similar habit to the *Androsaces*, to which it is nearly related, and bearing bright rosy pink flowers on short stalks. T. 6997, *Passiflora violacea*, a Brazilian species related to *P. cornuta* and *P. Mooreana*, introduced from Rio Janeiro to Kew by M. Glaziou; the flowers are purple in the centre, with white and purple rays and pinkish petals.

— **GARDENING APPOINTMENTS.**—Mr. J. Rogers, late gardener to B. R. Langton, Esq., Langton Hall, Spilsby, has been appointed head gardener to R. Phipps, Esq., Buckenhill, Bromyard, Worcester. Mr. W. Strugnell, recently of Benham Court Gardens, Kingsclere, Newbury, has been appointed gardener to A. R. Baily, Esq., Willow Vale, Frome; and Mr. George Smith, who has been principal foreman at Mentmore for the last five years, has been appointed gardener to E. L. Rowcliffe, Esq., Hall Place, Cranleigh, Surrey.

— "A PERTSHIRE GARDENER" communicates the following:—"Some of the members of my employer's family, having had the pleasure of inspecting the famous DRUMLANRIG GARDENS lately, they saw much to interest and instruct them. Splendid crops of Grapes, Figs, Pines, and Peaches. In one of the vineries inarching was being done, the scions supported by bottles of water till the junction is completed. In other houses they saw plenty of the glazed pots described as extremely smart looking, and contained many fine healthy plants, a good number being Orchids. I hope we may also have a trial of them soon, as a good-sized conservatory is in course of construction at present. Another plant they saw was described as being tall, carrying large red flowers; it was very much admired. They were told what it was, but cannot remember. Could Mr. Thomson kindly tell us anything of this plant?"

— MR. JOSEPH MALLENDER sends his monthly SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR MAY.—Mean temperature of month, 51.5°. Maximum on the 19th, 78.3°; minimum on the 10th, 28.2°. Maximum in the sun on the 6th, 130.5°; minimum on the grass on the 10th, 22.3°. Mean temperature of the air at 9 A.M., 53.9°. Mean temperature of the soil 1 foot deep, 50.9°. Nights below 32°, in shade three, on grass thirteen. Sunshine total duration in month 201 hours, or 41 per cent. of possible duration. We had two sunless days. Rainfall—Total 0.74 inch; maximum fall in twenty-four hours, on the 29th, 0.27 inch; rain fell on seven days. Wind—Average velocity 12.0 miles per hour; velocity exceeded 400 miles on five days, and fell short of 100 miles on three days. Approximate averages for May—Mean temperature, 50.6°; sunshine, 174 hours; rainfall, 1.93 inch. The driest May since 1876, and the brightest since 1882. As is usual with such conditions, the days have been warmer and the nights cold. Vegetation very late.

— THE BROWN WEEVIL.—Mr. George Bunyard, the Old Nurseries, Maidstone, writes:—"Will you allow me to call the attention of fruit growers and gardeners to this enemy, which has hitherto been overlooked by cultivators? It is a small earth-brown beetle, which being nocturnal in its habits, is not often detected. Its habit is to climb up the trees and bushes in the twilight and to devour the young buds as they appear. In May, until the buds sprout, the weevils will eat away the bark from the ends of the shoots, more especially from the sharp angles left in pruning, leaving the ends bare. Its attentions are not confined to one kind of tree, as it may be found upon all fruit, nut, and many ornamental trees, which, in isolated specimens, it will denude of its buds, so that the trees appear dead. It also affects Roses, and can be found on Rhododendrons, Laurels, and such large-leaved evergreens, where it confines its attention to young tender leaves, which afterwards assume a jagged appearance. It is not a new insect, but has always been a native, and is spread over the whole country, and my object in calling attention to it is to state that tar and similar substances placed on the bark will not arrest its progress, and the only effective remedies are: First, to catch them by night. One man carries a lantern, and another holds under the trees a net or white cloth, and the other throws the lantern on the tree, when they at once fall. The remainder (in the shady parts) will fall on a smart tap being given with the hand. The insects can then be collected and killed with hot water. They are so tenacious of life that none of the usual remedies will kill them. In fact, by accident, some were shut up in a tin box for twelve months and then came forth lively. Second, they may be killed in the earlier stages by ramming the soil tightly round the stem of the tree or bush, and thus smashing them, but as they become perfect insects they are tough and will stand a great deal without injury. Third, the soil round the trees may be made smooth with the foot and a few flat stones or clods of earth may be laid on it. The insects will crawl under this in the daytime, and can be caught by lifting the clods and watching the soil. At first none may be seen, as they are so near the colour of the soil, but they will soon move to get away from the light, and then can be detected and caught. In my opinion the orchards suffer most when a plantation of Raspberries, Currants, or berries have been removed, as the insects then concentrate their efforts on the remaining trees. As a rule they are not so abundant in grass orchards. Cleanliness is very important, as they winter in tufts of grass, &c. It only remains for me to say that its Latin name is *Otiorhynchus tenebricosus*, and its allies, *O. picipes* and *O. sulcatus*, are also found on the same deadly work in its company. The latter is occasionally troublesome in vineries. As the insect is now at work prompt measures should be

taken, as they will soon pair and lay eggs. Like other insects it passes through an egg state; a larva or grub state; a chrysalis; and emerges as a perfect insect or imago in April or May according to the weather. In the grub state it also does much damage to the roots of trees and plants. Figured plates and further information can be found in Miss Ormerod's work on noxious farm and garden insects."

THE LATE CANON HODGSON.

DEATH, at the advanced age of seventy-six years, has taken a great lover of flowers and a true patron of horticulture; this village has lost a kind-hearted pastor, and a wide circle of friends a genial gentleman. He was a born florist, cultivating Carnations, Pansies, and Dahlias which quite a young man, and later on Gladioli; but of late years his special favourites were Roses, Chrysanthemums, Gloxinias, Zonal Pelargoniums, Azaleas, Begonias, and he knew their properties. Substance, size, colour, refinement, were the qualities he sought; and a flower without more than one of these he wished to be put out of his sight. He not only cherished flowers with an intense fondness, but was keen in the cultivation of Strawberries, Grapes, Pears, Apples, and also interested himself in the growth of Peas, Asparagus, Potatoes, and other vegetables.

It was our duty and pleasure to minister to his ruling passion in his declining years, and among many things to remind us of him are several volumes of this Journal with marginal marks, which will remain to us an index to his gardening tastes. Knowing a gardener's difficulties, he was equally ready to excuse failures and to applaud successes. A florist of years ago wrote of Carnations words which we will adopt for the deceased gentleman of flowers generally, "They were the marvel of my childhood, the admiration of my youth; in maturer years they lent a charm to many a rugged pathway on the journey of life: in old age they have been my familiar companions, and I shall continue to cherish them until my dying day."

His last utterance was of flowers. On Wednesday last his coffin, literally covered with wreaths, was borne to the grave very near the garden, which was to him a source of so much happiness. He was mourned by the assembled villagers, who will sadly miss one who had learned the luxury of doing good. We have lost a master whom, living, we regarded with the most profound respect: dead, we pay this tribute to his memory.—H. S., *Saltwood, Hythe*.

TRING PARK.

ADJOINING the quiet old Hertfordshire town of Tring, and about two miles from the station of that name on the London and North-Western line, is Lord Rothschild's estate known as Tring Park, which is unquestionably one of the best kept establishments in England. Some three or four hundred acres are occupied, the chief portion constituting a beautifully varied and well wooded park. The tastefully designed gardens and pleasure grounds are adequately furnished with shrubs and trees, while the extensive glass ranges are remarkable for the collections of admirably grown plants they contain. It is evidently an establishment where good gardening is thoroughly appreciated, and the gardener, Mr. E. Hill, meets the requirements of his employer with all the energy and skill which should be the result of liberal encouragement.

Time only admitted of a hurried glance at the park and grounds, but in the latter one dell or shrubbery retreat calls for special mention. It is an open space devoted to flower beds surrounded by steep banks, upon which Conifers and other trees with shrubs and the bolder herbaceous plants or bulbs are planted. Very notable are some hundreds of plants of *Abies excelsa pumila*, dwarf, compact, little specimens, about 2 feet high, which, placed on the lower part of the slopes all round the dell, have a striking effect. This is a good variety for the purpose, but there are several other similar dwarf forms that also present a remarkable contrast with the typical *Abies excelsa*, which received its name as the tallest of European trees, while these variations are strangely enough some of the dwarfest. They have mostly originated under cultivation, a well-known variety, *A. excelsa Clanbrasiliana*, having been found at Moira, Lord Cranbrasil's estate near Belfast. *A. excelsa Gregoryana* is from Cirencester, and then there are *pumila* mentioned above, and *pygmæa*, the origin of which I have not seen recorded. A finely developed specimen of *Abies Hookeri* arrests attention in this part of the garden, and the handsome *Cupressus Lawsoniana lutea* succeeds equally well, and one plant 16 feet high is now assuming its bright yellow colour. *Retinospora obtusa aurea*, 16 feet high, is an uncommonly good example of this bright graceful variety, numerous other Conifers of similar interest abounding on the slopes and lawn. For spring effect a score or more of large beds are planted with *Myosotis dissitiflora* surrounding a central one filled with Veitch's Dwarf Yellow Wallflower, affording a fine contrast. The Forget-me-nots last week were extremely beautiful, as the plants are placed closely together, forming dense masses of lovely clear blue flowers.

ASPARAGUS.

Returning to the trimmest of kitchen gardens, one of the Tring specialties is at once observed—namely, Giant French Asparagus, and the results of the system adopted are sufficiently satisfactory to convert many doubters respecting the merits of the variety and its produce. Prejudice has been created against the Asparagus in some cases by estimating its qualities from samples sold in English shops, which, at the least, have

probably been cut for two or three days, and sometimes much longer, but when served at table as it should be, within a few hours of being cut, it would satisfy the most exacting connoisseur. The variety grown at Tring is the Giant Argenteuil Asparagus, which produces succulent stems frequently an inch in diameter at the base, and it is cut in beautifully blanched lengths of 8 inches, the whole of which when young and fresh can be eaten. Strong roots are obtained and planted on the level just beneath the surface of well prepared soil, and 3 feet apart; over each root is placed a mound of fine soil, and this again, if greater depth is needed, is covered with cocoa-nut fibre refuse. The shoots come through this strong and clean, and they are readily cut without damaging others not sufficiently advanced. One bed has been cut from for four years, but sufficient stems are allowed to remain to each root to allow it to strengthen itself, and liberal top-dressings of old manure are applied. The usual way, however, is to cut the beds in alternate years, and one this season undergoing the renovating will be ready for next year, and the bed yielding this season's supply will then be rested.

FRUIT HOUSES.

The fruit houses comprise a remarkable Peach case, 360 feet long and 6 feet wide, the perpendicular front lights and the comparatively flat roof affording a convenient space that is utilised for a low stage for Strawberries, &c., without shading the principal occupants of the case. The back wall is covered with extremely healthy fruitful Peaches and Nectarine trees, with upright cordon Pears on the wall piers at intervals. The early Peaches are Grosse Mignonne and Royal George, the favourite Nectarines being Elruge and Lord Napier, the trees giving ample indication of the good treatment they receive in their well developed but not rank growth and foliage, which is as clean and free from that special Peach pest, the red spider, as anyone could desire. The chief midseason and late varieties of Peaches are Royal George, Violette Hâtive, Lord Palmerston, and Walburton Admirable; and of Nectarines Lord Byron, Pine Apple, and Victoria.

One point that Mr. Hill rightly considers of great importance in successful Peach culture is a liberal supply of water, and this is effected by means of a hose screwed into the hot-water pipes when required, and the water is allowed to run into the border until it is thoroughly saturated, partial supplies being carefully avoided. In the earlier stages when the heat of the water has sufficiently declined, the border can have a soaking at a temperature that will not give such a check to the roots as the icy-cold water often poured into the soil. The foliage is freely and frequently syringed by hand. A border 6 feet wide in front of the Peach case is also well utilised without shading that structure, two rows of horizontal Pears on the Quince being there planted with Strawberries between them, and crops of fine fruits are obtained. A range of vineries in four divisions, each 27 feet long and 17 wide ($\frac{2}{3}$ span) is devoted to early midseason and late Grapes, of which there is a capital show of bunches in all stages. Muscat of Alexandria is first favourite, and is capitally grown. Madresfield Court is also successfully managed, Foster's Seedling and Black Hamburgh affording the ordinary early supplies. Alwick Seedling has been found to be greatly improved in flavour by working it on the Royal Muscadine, a hint that is worth the consideration of those who grow the variety for late use, but find it only second rate in quality. Two varieties that are valued at Tring for their flavour are Dr. Hogg and Grizzly Frontignan, the first of which is more frequently seen in modern gardens than the latter, which is one of the oldest Grapes grown in England, as it is said to have been introduced by Sir William Temple in 1654. Both, however, are finely flavoured Grapes, but Dr. Hogg has the advantage in point of constitution, and as Mr. Barron tells us, "the great fault of Grizzly Frontignan is its tendency to shank. It grows freely, fruits and sets freely, and promises well till it approaches maturity, when it almost invariably shanks." The end division of the range is occupied with Figs, Brown Turkey chiefly, but Negro Largo, which when planted out was too gross in growth to fruit well, in pots is most prolific, and perfects ample crops of fine fruits.

CARNATIONS.

Plant culture under glass is conducted on an extensive scale and with marked success, especially as regards Carnations and Orchids, the leading favourites at Tring Park. The Carnations are simply wonderful, and in numbers and culture are probably unequalled in Great Britain. They are extraordinary in all respects, and would alone render the garden a remarkable one. Two varieties constitute the bulk of the stock under glass—namely, the blush white Souvenir de la Malmaison and the pink variety of the same type, which is usually designated Princess of Wales, though it was shown by Mr. Turner and certificated last year (R.H.S., July 12th) as the Pink Souvenir de la Malmaison. They are both of strong Clove-like habit, with broad leaves, massive fragrant flowers, and form vigorous bashy specimens that have a very imposing appearance. Several span-roof houses are devoted to the 1800 plants grown of these two varieties, and a grand appearance they have, the majority in 8-inch pots, the plants 18 inches in diameter, and bearing from eight to twelve magnificent flowers each, some of which are 6 inches in diameter. Most of the flowering plants are two years old, the limit of their existence, as it is found preferable to obtain a fresh stock of young plants every year than to grow the old plants for a longer period. Good sandy loam only is employed as soil without the admixture of manure, but a little assistance is afforded when the flowers are advancing, and nothing more is required beyond promoting sturdy clean growth by close attention to watering and

ventilation. They afford flowers from May to the end of July, and the value of such plants in any establishment could not be overrated.

Other tree Carnations for winter flowering are also accorded some space, notably Empress of Germany, a large white-flowered variety, but La Belle is considered the best of the smaller white varieties for general utility. Irma is a good pink form; Lucifer, scarlet; and Andalusia, yellow, the last being found much better for winter flowering than Pride of Penhurst. Out of doors also large beds are devoted to such Carnations as Sir Beauchamp Seymour, W. P. Milner, Thomas Moore, and Florence, which are most valuable for cutting.

ORCHIDS.

Turning to the Orchids we again find much to admire, and a pleasure is apparently taken in proving that plants reputedly difficult to grow can be made to flourish like weeds. Phalænopses, for instance, which puzzle many able cultivators, are represented by 200 uncommonly vigorous plants of the best forms, which are grown in a small lean-to house facing the south, shading being afforded by means of a wash applied to the glass and roller blinds. Most of the plants are in upright teak cylinders filled with potsherds, the roots being allowed to ramble freely outside, as also they do in the case of some plants in baskets suspended from the roof. Abundant moisture and heat are supplied, and $1\frac{1}{2}$ -inch pipes connected with the ordinary hot-water pipes below are taken along the roof, one in front and one at the back, a system adopted with evident advantage in all of the plant houses at Tring Park. Theoretically, it might be thought that these roof pipes would be less useful for Orchid houses than in those devoted to Pelargoniums or similar plants that require a drier atmosphere, but practically they seem to possess a double use—*i.e.*, assisting in the dissipation of moisture accumulating on the glass or woodwork, and in the preservation of a more uniform temperature. This, no doubt, is only one of the many small matters that conduce to success, but it is worth consideration, and combined with a healthful cleanliness and most careful avoidance of check at any time, it has something to do with the unusual fine condition of the Tring Phalænopses. Numbers of plants of *P. amabilis* have seven to ten leaves each, *P. Stuartiana* six leaves, *P. intermedia* Portei seven leaves, a grand specimen; *P. Schilleriana* with two growths and eight leaves each is a wonderful plant, the leaves 18 inches long by 4 and 5 inches in width. *P. Sanderiana* and several others are similarly remarkable.

The Vanda house is also a lean-to facing south, and contains one of the finest collections of plants of *V. teres* and *V. Hookeri* in the country. Over 400 plants are grown, which are placed in beds of sphagnum at the back and front of the house above layers of potsherds for drainage. The house is never shaded except when the plants are flowering, as a free exposure to the sun is one of the requirements of these Vandas, and perhaps the most important. They evidently like their treatment, both growing and flowering admirably. Of Cattleyas and *Lælias* there is a fine stock, *C. Mendeli*, *C. Mossiæ*, *C. gigas*, *C. Dowiana*, and *C. Trianae* being strongly represented by excellent varieties. A large and healthy example of the beautiful *C. exoniensis*, and one of the true autumn-flowering *C. labiata* are noteworthy, as also are the plants of *Lælia purpurata*. Other houses are devoted to choice *Odontoglossums*, *Cypripediums*, *Epidendrums*, *Calanthes*, and various useful Orchids, and a new range is just being completed that will be mainly appropriated to similar plants. A newly furnished conservatory, and numerous pits for ordinary decorative plants, with a large supply of *Nerine Fothergilli* major complete the principal portion of the attractions of this exceedingly well kept garden.—L. CASTLE.

AUBRIETIAS AND DWARF IRISES.

IN the notes of spring-flowering at Belvoir (page 428) reference was made to Aubrietias, and especially to the glowing effect produced by the distinct *A. Leichtlini*. In one of the beds a small colony of dwarf Irises, *I. pumila* bicolor, had a charming effect. A little more may not inappropriately be said about the spring-flowering plants in question. Taking the Aubrietias first, there are scarcely any other spring-flowering plants capable of succeeding in such a variety of ways. It matters not whether they be planted on the well made rockery or the flat surface of a bed, for any of the species will quickly be at home in either place, and equally so if overhanging some projecting ledge of rock, or rambling over ruins; down sloping banks they form sheets of colour that remain fresh for weeks, if not for months, while they appear to thrive nearly as well in town as in country gardens.

Turning to the best of well-known kinds mention may be made of *A. deltoidea* and *A. purpurea*. The last named is from Asia Minor, and is noteworthy on account of its having given rise to the now more important forms, such as *grandiflora*, *græca*, *Campbelli*, and so on, though upon this point there seems a wide difference among botanists. Before me I have living specimens of *purpurea* type, also *Hendersoni*, *Eyrei*, *Bougaiuvilla*, and *græca*, all agreeing generally with *purpurea*. In Wooster's "Alpine Plants," the first three named are given as forms of *A. deltoidea*, though in no plants of my acquaintance do I remember the deltoid leaf characteristic displayed. The kinds named, however, rank among the showiest of this group, or at least that portion generally in

commerce. *Hendersoni* has bright purple flowers with a dark centre; *græca* has bright lavender flowers; *Bougainvillea* light blue; *Eyrei* deep lavender shaded mauve, very pleasing. Beyond these are several very distinct, particularly *A. violacea*, having violet purple blossoms, and *A. Leichtlini*. It is this last named which may be seen nestling around the base of the Iris in the illustration. A more delightful plant it is next to impossible to conceive, both as regards its colour and freedom of flowering. In colour it is quite a departure from all else. Speaking from the masses as seen at Belvoir, the colour is lively rose, still deeper when in bud. This is the most effective of all, the plants representing such a carpet of flowers in spring time that are not excelled, if equalled, by any others so easily raised and grown.

Now a word or two respecting the dwarf Irises. The dwarf

cœrulea, *cœrulescens*, and *bicolor*, the last-named being faithfully represented in the engraving. The variety *cœrulescens* is of that clear almost transparent sky blue which renders it conspicuous at a glance, consequently a general favourite. The same remarks apply equally to the variety figured, in which the clear white of the standards shows to good advantage. These dwarf Irises have appeared to advantage in the Chiswick collection this spring, and with the glowing *Aubrietia Leichtlini* should find their way into many gardens.—A LONDONER.

MY GREENHOUSE IN 1887.

I SHALL not be in the least surprised or offended if many of the readers of the Journal will say to themselves, "What do we care about

FIG. 63.—AUBRIETIA LEICHTLINI AND IRIS PUMILA BICOLOR.

Iris, *I. pumila* or the Crimean Iris, has during the past week or two attracted more than usual attention. Several of the most distinct varieties were well represented among the groups of hardy plants at the Royal Botanic and Inner Temple Shows, notably among those shown being *I. pumila lutea* and *I. pumila cœrulea*. *I. nudicaulis* was also well shown. This is a native of Southern Europe, and though a very dwarf Iris does not appear to belong to *I. pumila*, but is regarded as a distinct species. Few plants are more effective, however, than the deep violet purple flower of this. In some positions it is a day or two earlier to flower than *I. pumila* varieties, and the last-named precede the section known as *I. olbiensis*, thus bringing the successional flowering well into June. In both the *pumila* and *olbiensis* sections almost the same variation of colour may be found. The latter is, however, somewhat taller and a little later in blooming. Of the *pumila* section, the best are *lutea*,

your trumpery greenhouse? You make as much fuss about it as if it were a whole range of elaborately arranged plant houses." It may be so, but I am assured on the other hand that my small experiences have been helpful to many; and this I am convinced of, that no owner of his ranges of greenhouses has more enjoyment out of them than I have out of my single house, and although it requires some generalship to get all I do out of it, I am amply repaid for all my trouble: from early spring indeed, from Christmas to the end of October my house is never without its interest to me, and whether I succeed or fail in my culture there are lessons to me for the future.

I made one alteration last year which cost me some pangs of conscience, but which I do not regret having made. I gave up after some twenty-five years or more the Camellias, in which I used to take much pleasure. I thought, however, that there was more to be had out of pot Roses. The Camellias took up a good piece of the house and somewhat darkened it, whereas the Roses had light foliage, and at the time of the

year when light was most wanted for the house have made but little growth, and consequently are not so much in the way. Then the Camellias required a great deal of looking after, the leaves were apt to get dirty, and had to be kept clean by frequent washings, so at last I gave them up. I have now some nice plants of Tea Roses, including such kinds as Niphotos, Anna Olliver, Innocente Pirola, Jean Ducher, Miss Ethel Brownlow, The Bride, and Catherine Mermet. The plants of Niphotos have already become too large, and I must exchange them for smaller ones. I had much pleasure in these last year. Unlike the Camellia one can always cut them, and they give a succession of blooms, giving, too, a foretaste of the harvest which we hope to reap out of doors by-and-by. The Bride has fairly established itself as a most decided acquisition.

I was rather fearful last year that I should have but little bloom from my Lapagerias, which are trained up at the east end of the house. I had taken them down in the previous autumn and repotted them, if the term is applicable when the plants are grown in a box. This apparently checked the growth, which it would not probably have done had there been more heat in the house, but as mine is essentially a cold house they had not so much chance. However, be that as it may, *rosea* made no growths from the bottom, while two made by *alba* were cruelly eaten off by slugs, so that there were no root growths, while none of the buds on the branches pushed at all. To my surprise, however, both plants were covered with bloom, which came out from the old wood. These blooms were very fine both in size and colour, and so I was agreeably disappointed, and this notwithstanding the hot summer, which must have been bad for the Lapageria which likes shade and moisture.

Disa grandiflora, which I have grown so successfully for many years, was not a success in 1887. I had read that it liked being pulled about and divided, and so as some friends were anxious to have bulbs I did this with the result that where in 1886 I had had some twenty spikes of blooms, I had only one last year. The plants did not seem to recover the shock; but although I was thus disappointed, I am glad to say that as I this year did not shake them out they have quite recovered, and look as if they were preparing for a good bloom. I fancy that not only in this, but in many other cases, we are too fond of repotting. There is, however, a more robust variety of *Disa*, with inferior flowers, to which this process is applicable, but I shall certainly not subject my plants to a similar course again, giving them, however, fresh peat, and when running removing them bodily into a larger pan, for I find that pans suit them better than pots.

My Cyclamens were not a success in 1887, although I have always before done them well, but they made poor growth, and on examining the pots I found that they had made but few roots; I, therefore, concluded that we had put something into the soil that they did not like, and I am sure now that this was the case, for this year the same corms have flowered to perfection. They were completely shaken out and repotted in thoroughly sweet soil in which there was a good portion of charcoal. Thus failure has led one to be more careful for the future. I may say that I tried two different methods with them after flowering; some were laid on their sides and thus dried off, while others were kept in a cold frame and never thoroughly dried, and I did not see any difference in the corms or in the flowering.

Bulbs form rather an important feature in my little greenhouse. They come in early in the year when flowers are so much valued, and they are easily put on one side after flowering. Leaving them out of the question, Roman Hyacinths, Roman and Paper White Narcissi, and Hyacinths, which are really to be regarded as annuals, I may mention some that I have found particularly useful, ornamental, and easily managed. Everyone knows the Neapolitan Allium, which has been largely used of late years, but there is a much better variety, which I received from Ant. Roozen & Son, called *Hermetti grandiflorum*. The former has a curious way of hanging down its flower stems, which gradually twist back and assume the upright position, but they are always somewhat slight in the flowering stem, and so either hang about or require stakes; but the variety of which I write throws up its stems straight at once, is much more stout, and thus the umbels of flowers are held boldly up. The flowers are a little larger than those of the Neapolitan sort, and altogether it is a very desirable variety. *Tropæolum tricolor* is another very great favourite. I have three pots of it, and nothing can be more attractive than these plants were. They are trained on a wire trellis, which they cover from top to bottom with their little bird-like beautifully coloured blossoms. I wonder that these bulbs are so little grown. I go into many greenhouses at this time of the year, but rarely do I find them, and yet all who come to see mine are especially delighted with them. They are very easy of cultivation, and require but little looking after in the matter of training them on the trellis. The shoots at first require a little regulating, but afterwards they may be left to themselves.

With Freesias I was very successful. One often hears complaints as to persons not being able to grow these most charming bulbs successfully. I have of late years had no difficulty with them, have raised a number of seedlings, and greatly increased my stock, so as to be able to give quantities away to friends, and I am inclined to think that the secret of success was in the thoroughly maturing the bulbs. After mine have flowered I place them on a shelf near the glass where the pots are fully exposed to the sun's rays, and there they are left until the foliage is completely dried up. They are then, but not until then, taken down and laid under the stage, there to remain until potting time comes round again. As I have already said, a good deal of fine charcoal is used in

the compost, as I am sure bulbs rejoice in this. Another class of bulbs were very good with me—the early-flowering *Gladioli* of the nanus and ramosus section. These I planted in a 6-inch pot in the usual bulb compost, and they came in very well about the same time as the *Pelargoniums*. Of course *The Bride* or *Colvilli alba* is well known, but there are others in both sections well worthy of a place in any greenhouse; they are, moreover, delightful for cutting. Of the ramosus section, besides the type, *La Ville de Versailles*, lilac, red, and purple; *Ne Plus Ultra*, deep red flaked with white; and *Rosa Mundi*, deep rose with large white flakes are well worth growing; while in the nanus section there are *Fire King* or *Ardens*, fiery scarlet; *Blushing Bride*, rose with deep markings; *Delicatum*, rose flaked white; and *Rosy Gem*, rose flaked pink. These all did well, and were very effective.

Ixias I have had to treat as annuals, for I have never been able to flower them a second year, and yet with the allied genera of *Sparaxis* and *Babiana* I have had no difficulty. There are no more beautiful flowers for the greenhouse than the *Ixias*, and the colour of *viridiflora* is unique amongst flowers. I, however, last year subjected them to the same baking process that I have done the *Freesias*, and am curious to see what the result will be. *Azaleas* were a great success, for although I have no heated structure in which to place them after they have flowered to enable them to complete their growth, they made excellent growth and formed nice bushy plants with plenty of buds for the following year. I never place them completely out of doors, but after they have completed their growth put them under a glass shed fully exposed to the air. I do not pretend to say that this is the best plan, only that it suits me best, and that the plants are good and covered with flowers.

I have already said in a former paper something on the subject of *Lilics*, and a correspondent to whom I owe many apologies asked in reference thereto a question with regard to *L. punctatum* and the colour of its anthers. I could not have given him any information, for I had not noticed, but will promise him carefully to note this year. I had a fine lot of *Lilics*, the only fault I found with them being that they were rather tall for my house. However, they are so lovely that I must forgive them that, for they come in so usefully in the autumn that I cannot dispense with them.

And what shall I say of the glories of my *Maréchal Niel*, which I have in the small lean-to annex attached to my greenhouse? It is still in the pot, and, I am happy to say, now in its seventh year shows no sign of decay. It has filled all the back of the annexe, and would fill the whole of it if I allowed it to do so. The foliage is most abundant and luxuriant, while I gathered from it last year upwards of 350 flowers. Where the roots have gone to I have no conception. They have, of course, worked through the hole at the bottom of the pot and travelled off somewhere, but people who see only the pot, and know nothing of its history, are very much nonplussed when they see such luxuriant growth. The flowers were not large, but they were exquisitely formed, nor were they of that deep rich colour which we mostly associate with the *Maréchal*, but they were very beautiful, and I shall be indeed sorry when the symptoms of decay set in. When they do I believe there is nothing for it but to take the plant away altogether and substitute another.

These are some of the things which did best with me in my small house in 1887. Other things I had, but I have simply written of those which I consider most worthy of note, and some of which are not always, even in much larger places and houses, not so well grown as in my small house.—D., *Deal*.

A DAY OUT.

NEWTON'S DRY GLAZING.

THOUGH a day was spent agreeably in driving through a fertile district and resting in a beautiful garden, half an hour must suffice for describing something of what was seen during the spurt from town. Finding myself at Hitchin, a much more agreeable place than appears from the station, I called on Mr. Edgar Newton and inspected his system of dry glazing. When a gentleman so scientific and practical as Mr. A. H. Smec, and so solicitous for his Orchids, finds the Newton system highly satisfactory, and when a gardener so experienced and, I may say, so jealous of innovations as Mr. Allis of Old Warden, was after a close inspection enabled to speak of the plan with approval, I thought there must be something in it. It has been advertised, but is not, perhaps, yet by any means well understood, yet it is simple enough. There is nothing whatever complex about it. Instead of the glass resting on wooden sashbars and unbedded in putty, the bars are of T-shaped galvanised iron, and no putty is used in glazing. The squares of glass are held secure by small copper springs, while the yielding nature of these allows of expansion and contraction by heat and cold, so breakage cannot occur through rigidity. Grooves in the bars also collect moisture that forms on the glass by condensation, and thus there is no drip. The squares are "lapped" in the usual way of putty glazing, and the thin edge of the bars rising an inch or so above the glass not only forms a convenient rest for blind rollers, but a current of air can circulate under the blinds; thus shade may be afforded without air being excluded, and a little filters through the roof—a great advantage in hot weather.

A roof glazed on this system bears a resemblance to the old style, but is lighter and necessarily more durable, while periodical paintings are obviated. A square of glass can be slipped up and taken out in a moment from any part of the roof in case of accidental breakage. The

cost of these roofs, in which lightness, strength, and durability are combined, is now the same as a rule as when good wood is used instead of iron. Many practical gardeners have inspected the Newton glazing, and all, without exception, pronounce it good, while it has further secured the approval of the engineer of the Great Northern Railway.

Mr. Newton is growing Tomatoes in some small houses, and it is not easy to imagine any roofs better adapted for ripening and colouring this and other fruits that require a maximum amount of light for perfecting it; while this, with freedom from drip, is equally favourable for plant culture. This is without doubt a good system of glazing, and as it becomes better known can scarcely fail to commend itself to many trade and private growers of plants and fruits. A house glazed on this plan would be excellent for Roses in summer and Chrysanthemums in the autumn, for the greater the amount of light the greater the substance and better the colour of the blooms. One side of a small span-roofed house at Hitchin is formed of corrugated iron sheeting and is found cheaper than boards, and is at least equal in appearance. The ventilators in it are quite new in idea and effectual. There are other features, such as strengthening span-roofs without cross-bars, and fixing wires for training purposes, worthy of notice, but these require to be seen to be fully comprehended. A quarter of an hour is gone, and the remaining time must be devoted to the garden above referred to and some wayside features of the fertile district of Bedfordshire in which it is situated.

OLD WARDEN.

As was stated in the Journal a few years ago the fine estate of Old Warden was purchased by the late Mr. Joseph Shuttleworth of Lincoln, from Lord Ongley. It is grandly timbered and the soil of the best character. The place, moreover, possesses historical interest. It is the home of the Warden Pears on which the "Friars of Orders Gray," after feasting on pullets and cream, themselves "by denial did mortify with a dainty bit of a Warden pie." But nothing remains of the old Abbey beyond some relics in the beautiful Swiss garden. The old hall was taken down by Mr. Shuttleworth, and a handsome Tudor mansion erected, with a clock tower and chimes similar to those at Westminster. It is an imposing pile. The village, which is a model one, was rejuvenated and made to form an ornamental approach to the park. On one side is a Pine-clad hill; on the other, at this season, such a wealth of Lilac as is perhaps not to be seen in any other village; and the cottages, many of them with dormer windows and thatched roofs, have a picturesque effect amongst and behind the flowering and evergreen shrubs. The village is kept in pleasure ground order by Mr. Allis the gardener, and his pretty cottage on the hillside, with terraced lawn in front, is admired by the many sightseers who visit this Arcadian village, especially during Lilac-tide.

A drive of nearly a mile conducts through the park to the mansion. Near the entrance gates Conifers have been planted and are forming fine specimens, notably *Abies nobilis*, which bristles with its conspicuous upright cones. The pleasure grounds are very extensive; admirably kept and enjoyable. Embowered walks and glades afford cool promenades in summer, and conduct to one of the most charming gardens to be found in the kingdom. This is the Swiss garden, so called because a most picturesque cottage or tea room stands on a prominent mound, the rustic balcony on one side, under the wide eaves, overlooking a dell. This garden has been entirely remodelled by Mr. Milner and Mr. Allis, and by its hill and dale of smooth lawn, its twisting streams meandering among the trees; its islands, bridges, rockeries, and charming vistas, with its underground conservatory as a surprise, reached through a grotto, with rich stained glass windows here and there, form a combination of nature and art so balanced and blended as almost to disarm criticism, and the only suggestion that arises is the removal of a few trees here and there that possibly obscure something more beautiful than themselves, and which appear to contract somewhat one of the most delightful enclosures that has been created by the art of man. There are few flowers, and few are wanted in this sylvan scene. That it is a cherished garden is evident; indeed Major Shuttleworth has happily both the means and the will to keep his splendid estate in high order, and this, too, is a boon to the working tenantry he so largely employs.

The walled kitchen garden is not large, and it seems difficult how it, with the glass structures, can be made to meet the demands of the establishment; but Mr. Allis is a gardener of great experience, a thinking as well as a working man, and knows how to turn every inch to advantage. Peaches on the south wall bear abundantly, and the Vines in a good range yield wonderful crops of Grapes year after year. For nine or ten years they have been spurred, and the "snags" are only about an inch long, many less, and even Gros Guillaume bears on every lateral by this close pruning. Laterals have been encouraged to the ground, with the result that the rods are thickest at the base, tapering upwards as Vine rods should, as the sap has then free transit, and the roots being in a good medium, free growth follows. Growth is started slowly, and fire heat, with air, supplied after the roots are active and right through the autumn for ripening the wood. To this is attributed mainly the continued fruitfulness of these good Vines. Melons in a pit are bearing a good second crop nearly ripe, the first having been cut early in May. Mushrooms in a very cool shed are as fine as they can be produced at any season, and a ridge under trees in the open air has been bearing for four years, and we could have cut most of half a peck last Saturday from a square yard. They keep coming up unexpectedly in great clusters, and the ridge will remain undisturbed for this season at any rate. Has anyone known of a Mushroom bed to remain productive for a greater length of time than this outdoor ridge? Old Warden is

within two miles of Southill station on the Midland line between Bedford and Hitchin.

PROFITABLE LAND CULTURE.

The half hour is expired, so there is only time to mention the splendid Wheat culture in the district, the high farming, market gardening, and seed growing, which enables the cultivators to pay from £3 to £5 an acre rent. It is one more example of what appears to be a simple lesson slowly learned—namely, that when a man's capital is equal to his acreage, and his skill equal to his capital, that a living can yet be made from the land and a substantial and fair rent paid out of the profits of cultivation. It is bad culture, the result of lack of capital or knowledge, or both, that is ruining the land. Acres of "ridge" Cucumbers are grown on the level by sowing the seed in rows in rich ground between strips of Rye sown a few yards apart in the autumn, and which soon grows into shelter. Early Potatoes are also grown between these sheltering lines.—EXPERIENTIA DOGET.

ROSE SHOWS IN 1888.

- June 26th.—Boston.
- „ 28th.—Broekham and Ryde.
- „ 30th.—Eltham and Reigate.
- July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
- „ 4th.—Croydon, Dursley, Farnham, Hitchin, and Richmond (Surrey).
- „ 5th.—Bath, Farningham, and Norwich.
- „ 6th.—Sutton.
- „ 7th.—Crystal Palace (National Rose Society).
- „ 10th.—Gloucester, Ipswich and Oxford.
- „ 11th.—Ealing and Tunbridge Wells.
- „ 12th.—Birmingham, Carlton-in-Lindrick, and Winchester.
- „ 14th.—New Brighton.
- „ 16th.—Newcastle-under-Lyne.
- „ 17th.—Leek and Ulverstone.
- „ 18th.—Birkenhead.
- „ 19th.—Helensburgh.
- „ 20th.—Darlington (National Rose Society).
- „ 21st.—Manchester.
- „ 24th.—Tibshelf.

In the above list the only exhibitions not held by the National Rose Society, or by Societies in affiliation with it, are those at Birmingham, Boston, Carlton-in-Lindrick, Dursley, Manchester, Newcastle-under-Lyne, and Richmond. In the case of Birmingham and Boston, where the shows extend over two days, the date of the first day's exhibition only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

NEW PEDIGREE TEA ROSES—HARDY.

I SEE Messrs. Dickson, Newtownards, have announced in your columns two new Pedigree Roses—Caroline D'Arden (H.P.), and Lady Castlereagh (Tea). The question of the hardihood against frost, if I may so put it, was raised some time ago in the Journal, of those Tea Roses, so I resolved to try Dickson's Miss Ethel Brownlow (Pedigree new Tea) planted out in the flower border. Though it was killed to within a few inches of the soil, strong shoots have started from the base and promise splendid blooms—much finer than those grown in pots in greenhouses, though not so early. Any reader, therefore, anxious to try those delightful new Roses will be perfectly safe in planting them out. They will do better if the soil is not made unduly rich.—W. J. MURPHY, *Clonmel.*

REINE OLGA DE WURTEMBERG.

PLEASE note the vigour by the sample of foliage I send you of what I believe to be the best evergreen climbing Rose—namely, Reine Olga de Wurtemberg. It is wonderfully vigorous with me, and the flower, though thin, is of a delightful colour.—J. A. W., *Alderminster.*

[The terminal leaflet exceeds 3½ inches in diameter and 4½ inches in length; the others are longer, but not quite so wide. The sample represents clean, vigorous, healthy growth.]

ROSES IN WINTER.

THE time for starting the young Roses planted out or repotted in September depends upon the completion of the last growths they pushed from the base. If the plants in the first division have enjoyed a few weeks' rest by the middle of January they should be started gently into growth; the object being to induce Safrano, Isabella Sprunt, and those on the roof to make a strong vigorous growth that will be matured early in the season, for without this is accomplished the plants will not be in the best condition for producing early flowers the season following. Those in the other divisions may with advantage be allowed a longer season of rest. Those in the third house may advance gradually, and may be encouraged to grow under warmer and more genial conditions. The second division may be started a month after the first. H.P.s that

may be forced must for the present be left until I have further considered Tea varieties for the purpose we have in view.

Beginners in the culture of Roses for winter will be anxious about the vexed question of pruning prior to starting the plants into growth, but at the present time this matter will only have passing notice, and will be fully dealt with, because pruning should be conducted on two different principles according to the object in view. The use of the knife to the plants in their present stage and condition does no good, but rather the reverse, as it has a tendency to check the plants. Their roots are still active, and this quickly induces growth to start from the weak shoots, encouraging greater activity at the roots and eventually stronger shoots from the base. These will be stronger and earlier than would be the case if the plants were well pruned. Some may be inclined to doubt this who are firm believers that hard pruning is followed by greater luxuriance, but, however sound such practice may be in cases where the plants have thoroughly matured wood and are well established, it does not hold good with the plants in the partially ripened condition. Early worked or early rooted cuttings of Gloire de Dijon will be strong with shoots 10 to 15 feet in length, more or less according to the quantity of side shoots they produced, provided they were trained upright. Plants in this condition may have the unripe ends of the shoots removed, for they will produce a number of small but useful buds, which if they are allowed to expand will do them no real harm. To flower them that are planted out, however, is a loss of time, especially if they have been thinly planted with the object of increasing the number of shoots under the roof the second season. In this case they may be cut back to the eaves of the house. As many shoots as are required may be trained at the base horizontally until they reach the place where they are intended to be trained, and then they can extend up the roof. Another plan is to lay the plant, or as much of it as may be required to fill a given space, along the base of the house, and then train shoots upright from it. Either plan is good, and the results are much about the same. The remarks on pruning apply equally to the plants in the centre beds or those trained upon the roof.

Whether the Roses generally should be allowed to flower the first season after they are planted out is another matter of importance. This to a large extent must be decided by each cultivator. But it will be as well to point out that the more the plants are flowered in their early stages the greater will be the length of time before they attain the object the grower must keep in view—namely, strong growth that can be matured early. Year-old plants of *Maréchal Niel*, if they have been well grown, will yield on an average thirty blooms. I have cut forty-five from plants rooted in February, and it may seem hard to cut away these; but if the future well-being of the plants is considered it must be done. The constitution of this variety I firmly believe is sadly injured by overflowering it in the early stages of its existence. The short life of this favourite variety before it cankers and finally dies must be taken fully into consideration, so that the method of culture to be pursued should be of such a nature as far as possible to prolong its life in robust health. The plant will certainly linger for a long time after it is badly cankered, but the blooms are small, colourless, and practically of no market value.

Not only is overflowering injurious, but a too robust growth in its early stages is also detrimental. This Rose strongly grown often in the richest of soil resembles in no small degree an overgrown Vine, which to all outward appearance should fruit well and freely, and perhaps does for a few years, eventually to collapse. From the first its constitution is impaired by being built up too quickly—not half ripened, and therefore the strain of fruit-bearing after a few years proves too much. I firmly believe the *Maréchal* can be overgrown in its early stages, and as growth continues until late in the season the wood in the first years of its life is never well ripened, and thus the seeds of destruction are sown. Moderate growth the first season, produced without those uphill systems of forcing that are practised to turn out luxuriant plants with firm and well matured wood should be the aim of cultivators who desire to so build up the plant that the ordinary span of life allotted to this variety may be considerably exceeded. If this variety then is of moderate growth the first season and established in the soil before winter, cut well back instead of flowered, say early in February, strong growths that will have a chance of ripening before the close of the season will be produced that are certain to bear good flowers. When they are allowed to flower much time is lost, and the plant is growing when it should be maturing its wood. If our borders were made of such materials that would produce moderately strong firm woody shoots that can be well ripened, instead of those strong soft ones generally seen that have no solidity, I am of opinion that the plant would live longer and yield better coloured flowers.—WM. BARDNEY.

(To be continued.)

FRUIT FARMING IN FLORIDA.

A SCOTCH gentleman now on a visit from Florida, whose business brings him in contact with traders of all classes, and to whom the deplorable condition of our agricultural industries generally, on this side, is perfectly well known, communicates to the Anglo-American Live Stock News Agency the following remarks upon Florida as a field for farmers, fruit growers, kitchen gardeners, or other small capitalists. Those desirous of obtaining further information can communicate with Mr. Stewart, 16, Thurnham Street, West Derby Road, Liverpool.

During the short time I have been here my attention has been attracted largely towards the various measures promoted, both publicly

and privately, for improving the condition of agricultural matters. Considerable reliance seems to be placed on the efforts of Government, and particularly those efforts which are being directed towards establishing a higher educational standard. While quite in sympathy with this latter movement, and appreciating fully the value of a scientific training, I cannot see how any immediate relief or benefit will accrue to those now suffering so severely from the existing depression. Generations hence will, it is to be hoped, reap the full reward of the present agitation, but this bright future will not relieve the present burdens. What, then, is to be done for those who, having lost nearly all their capital, find themselves about to be handicapped in the race for life against younger and better educated competitors? My answer is simply emigration. But where? Not to the blizzard-blighted regions of Western America! Not to the ice-bound Manitoban prairies! Not to the tropical plains of the Argentine! Not to the far-off New Zealand or Australian Colonies, where success is so difficult of achievement! Where then? To Florida, the most fertile of the Southern States of America, where the greater portion of the soil is of the richest description, and available for the production of every species of crop, fruit, cereal, or vegetable.

That this wonderful country has so long been allowed to remain undeveloped is probably due to the ignorance displayed as to its position, climate, and agricultural resources. Misconceptions of the most serious character have been allowed to go on unchecked, increased indeed until recently by the operations of unscrupulous speculators, who, in order to get rid of certain poor lands—for there is such a thing even in Florida—grossly deceived their clients, who not unnaturally formed their opinion of the country from what they saw and experienced. A few plain facts may be given, which I hope will clear up many of the erroneous impressions current on this side, and considerably enlighten anyone anxious to found a home and make an independent living in a land where overcrowded competition and other difficulties are unknown. Florida has a history covering nearly 400 years, and yet in spite of her unequalled natural advantages, she has to-day a smaller population, in proportion to her size, than any State in the Union, excepting perhaps Nevada or Colorado. Florida now is no longer an unknown country, a constantly rising tide of immigration is flowing in from all parts. True, many of the visitors are only flocking there for health, but once having breathed its balmy airs, not a few of them remain permanently.

So recently has the attention of land operators, fruit growers, agriculturists, and others, been directed to Florida, that it will be many years before the entire State will be in private occupation. The class of emigrants, however, who could best take advantage of the opportunities presented in Florida for making a competency are farmers, market gardeners, fruit growers, or others, possessed of a moderate capital. Alachua County, where I come from, is reckoned the fertile centre of Florida, and lots of ten, twenty, and forty acres of cleared and uncleared lands can be had on reasonable terms. A ten-acre lot is generally considered sufficient for one man to work—that is, easily, and without any great expenditure for occasional hired labour. Too much importance cannot be given to the fact that fruit and market gardening form the staple industry of this section of Florida. In the neighbourhood of Gainesville, Strawberries, Peaches, Le Conte Pears, Japan Persimmons, Figs, Grapes, Plums, and Pomegranates, are cultivated in perfection, and find a ready market in all the great cities of the Northern, Eastern, and Western States. Numerous wild fruits and Nuts of various kinds also grow in luxurious profusion. During the early shipping season Strawberries realise fabulous prices, ranging from 10s. to 15s. per quart. The Strawberry season lasts from February till June, values falling gradually as the season advances and supplies increase. The very remunerative character of the Strawberry crop may be realised when I state that from £120 to £150 per acre are frequently made, a very moderate estimate indeed being £100. The yield during the season per acre varies from 2000 to 3000 quarts. Prices for other fruits are proportionately high during the earlier months and equally as profitable.

For kitchen garden produce the returns are almost beyond belief—Irish Potatoes, Sweet Potatoes, Cabbages, Onions, Turnips, Radishes, Parsnips, and field Peas, commanding the best prices to be obtained in the North from January to May, no other produce being on the markets during this period of nearly six months. With respect to the other crops with which home farmers are more intimately acquainted, such as corn, oats, and hay, there are plenty of facilities for cultivating and disposing of the same, and also for the cultivation of Cotton, Sugar, and Tobacco. For the three last-named products Florida already enjoys a high commercial reputation.

I do not make any special reference to the great Orange-growing industry of Florida, because, to do it justice, it would require a whole paper, but wherever the Orange business has been carried on with capital, energy, and intelligence, it has proved an investment of the richest kind. The Orange groves of Alachua County are reckoned among the finest in the State. In this county, which, it must be borne in mind, I have had specially in view throughout, it being my home county, the climate is simply magnificent, a cool breeze prevailing night and day during the summer months, enabling even the most delicate to enjoy sound refreshing sleep. Water of the purest mineral kind is abundant, in fact the natural supply is practically inexhaustible. A perfect network of railway systems are rapidly converging at Gainesville, which, from its central situation, will shortly be the business capital of Florida. Already the State Military Academy and U.S. Land Offices are established there, and it is likewise proposed to locate in it the State Agricultural College, simply because it is the centre of a great agricultural region.

From the foregoing facts, which have been set down in real, sober honest truth, I think it will be patent to everyone that Florida, as an outlet for agriculturists, cannot be surpassed. The acquisition of land is offered them in perpetuity for a sum actually less than ordinary annual rent charges on this side, and within twelve months after settling on cleared lands, sufficient money can frequently be earned to cover the cost of purchase. To any intelligent, industrious man with a very moderate capital, an honourable, independent position is at once assured.

BELGIAN WORK AND WAYS.

LET no one suppose I am going to describe the Belgian nurseries and the work that is done in them. It is sufficient to say there are between two and three hundred horticultural establishments large and small, chiefly small, in Ghent alone to render any such idea impracticable. It will be readily understood that much more than a local and even a national trade is essential for keeping all these plant manufactories in brisk working order. The trade is international, the chief establishments having business relations with every State in Europe, and far beyond the borders of the Old World. The past generation of Ghent horticulturists, the Van Geerts, Verschaffelts, Van Houttes, De Smets, and others, must have been observant, far-seeing, enterprising men. They perceived the national advantages of the situation—free soil, abundance of water, cheap labour, and direct lines of communication by land and sea for conducting a trade world-wide in its ramifications. Energy, industry, with keen business aptitude did the rest, and they lived to see the old capital of Flanders occupy a central position in the universe of horticulture. All the qualities that created the plant industry that has become so great appear to have been inherited by those who have succeeded the old masters, and the present representatives are not likely to allow the trade and the fame of the city to suffer in their keeping. Competition becomes brisker and brisker. New businesses spring up in every country, but Ghent appears to hold its own as a chief source of supply of plants for the demands of nations. The people are a social community, and know the value of combination for a common object, while individual zeal is stimulated. They are excellent organisers and splendid entertainers. They prepare to economise for great efforts. For these they labour, and when the time comes for displaying their strength, issue invitations and provide attractions that are irresistible. They secure friends from all lands, spare for nothing in satisfying them, and send them home with something to talk about. This may be called showy, theatrical, sensational, or what not; but no matter how described, the great gatherings mean business and develop trade, as they ought. They are means to an end, and this is attained, congratulations being fairly due to the promoters on the success of their enterprise, and no one can begrudge them the reward they may win by their labours.

The local trade in plants in Belgium is trifling in comparison with the trade in England, relatively considered; or, in other words, in a given radius round Ghent, the city of nurseries, there can be no approach to the amount invested in gardens to that expended in an equal area round the chief towns in Britain. Though the well-to-do Belgians attend flower shows very well, there is no great crush, and it would probably be less if the shows were much more frequent and correlatively of reduced dimensions and impaired novelty, the consequence of familiarity. Nor is there an apparent great demand for well-grown flowers by the general community if we may judge by the presence of plants in windows and dwellings; or better, perhaps, by the supply in the markets. The large open space of the Plas d'Armes, Ghent, a parallelogram, perhaps 200 yards long and 50 or 60 wide, margined with trees, is converted into a flower market on Sunday mornings. The plants are arranged in semicircular groups, about as many in each as could be arranged in a handcart or Belgian dogcart, these differing very widely from dogcarts in England, for in Belgium the dogs draw the carts, in England the carts carry the dogs. There were eighty or ninety of the groups referred to, the plants being worth little from our point of view, the majority being in 3 and 4-inch pots, and appeared to represent the contents, very much mixed, of workmen's greenhouses, and might bring in a few francs to the possessors. They had nothing in common with the "market plants" in England that display such splendid culture and are correspondingly valuable. Ornamental foliaged plants, such as Palms, Aspidistras, Ficuses, and the like, appear to find more favour than flowering plants do for home adornment, and beyond question the former last longer and are cheaper in the end. Nor do flowers appear to be grown to any noticeable extent in gardens attached to dwellings either in the suburbs of towns or in the country. There is a marked absence of the trim little gardens that form pleasant appendages of the houses of the masses, where plots can be had, to which we are accustomed; indeed, people who might do so do not grow their own vegetables in anything like the variety and to the same extent as is common in Britain. The Belgian workers are not gardeners from our point of view, and they seem to avoid indulgence in what may be termed the luxuries of the earth, devoting their time and strength to the production of necessities. Possibly it has been found that in the supply of vegetables for market the small cultivators of necessarily limited quantities cannot successfully compete with expert market gardeners who produce them in larger bulk for the demands of towns. Nor do we find lush fruits, such as Strawberries, Currants, and Raspberries, anything like so freely grown in Belgium as in England, while the Belgians do not grow Rhubarb, nor, as a community, do they care for Cucumbers.

To return to the Ghent nurseries. If these cannot be described they

cannot be ignored, and, presumably, few readers of these notes who may visit the Brussels Exhibition this year would think of returning without a day in those nurseries. They are easily reached by tram or otherwise from the Plas d'Armes, the two hotels there, the Royal and Poste, being the favourite houses of Britishers. In order to see the most nurseries in the least time a tram may be taken to the Porte de Bruxelles, which is not much more than a mile, and you land at M. Pynaert Van Geert's. There you find an accomplished horticulturist and most genial man, who converses in English very well, while his better half speaks our language like a native. It is a well arranged, well furnished nursery. Orchids, Clivias, Palms, Begonias, and most other plants being represented in the best established and many new varieties. An easy walk brings to M. de Smet's, where splendid Bays are to be seen outside, and the finest collection of Caeti and other curious within, besides a general stock of miscellaneous plants. Almost within stone's throw is the old nursery of the late Jean Verschaffelt, now De Smet Frères. Here are avenues of standard Bays outside, the other great feature being the Kentia house, consisting of a series of span-roofs supported on iron pillars, covering a space in which 15,000 or 20,000 Kentias are planted, on what may be described as slate stages, in beds 5 or 6 inches deep, paths running between along the centre of each division. From a saddle boiler exposed in the house flow pipes are conducted overhead—that is, under the purline, where the roofs rest on the pillars, the returns dipping and conducted to the boiler just under the slate stages, so that gentle heat is imparted to the soil in which the Palms are growing, while heat is also diffused in the atmosphere. It is an excellent arrangement, and the forest of young Palms is sufficient to "strike a stranger." Almost adjoining is M. D'Haene's well stocked, clean, and interesting establishment. As in other Belgian nurseries a great increase in Orchids is noticeable here, while Palms and various other plants are admirably represented. Opposite is the establishment of M. Dallièrè, but there was no time for calling, but various plants in the great Show demonstrated that good work is done in the establishment. A walk of five or ten minutes and we are at the greatest of the plant emporiums of Belgium—the world-famed Van Houtte's. If I had to tell in a word what is to be seen there I should say everything in the plant line, hardy and tender, outdoors and in, that is in demand by cultivators in all countries. It is a great universal supply establishment, and was never in more thorough working order than now. The linguistic accomplishments of M. Van Houtte are remarkable. He appears to be at home with all nationalities, and speaks English like—well, exactly like a fluent American; and as an entertainer is not soon to be forgotten. On the opposite side of the city there is, among others, the extensive and complete nursery of M. Auguste Van Geert, and here, again, we find an admirable English-speaking proprietor and most agreeable man; but all the Belgian nurserymen accord a pleasant reception to visitors of kindred tastes with themselves—the De Cocks, Vervaets, Vervaeens, Vuylsteke, with others whose names are familiar to readers of garden literature. They are too numerous to be even mentioned, but the scenes of their labours are easily reached by all who have a day or two at their disposal in Ghent.

We now leave the city of nurseries, but before doing so will try and settle a dispute respecting the pronunciation of its name. The question propounded is this—"Is Ghent sounded like 'Gent,' the abbreviation of gentleman, or is the 'h' mute and the 'g' sounded as in 'get'?" "I hope the latter is the case," writes an interested gardener, "or I shall have to pay." Our friend may compose himself, he will not have to "pay," unless in his gratitude he is constrained to send me a guinea for the Gardeners' Orphan Fund, which shall be entered, if he likes, under the signature of "John of Gaunt," that celebrated historical personage having been so named because he was born in Ghent, or Gand, according to the original French appellation. And now, awaiting the fee for the advice solicited, we return to Antwerp, and pass on the way a substantial building bearing in large letters the sign "Ecole d'Horticulture."

A good deal has been heard from time to time about schools of horticulture, and their establishment has been advocated in England for making better gardeners. There is or was a "school" for this object at the Crystal Palace, and Chiswick has been proposed as a "seat of learning," where students may "graduate" as certified cultivators. It is something to talk about and write about certainly, and the subject will perhaps be written about and talked about till Chiswick as a garden is talked out of existence, and that will settle the matter. The best schools of horticulture in Britain are the well managed gardens of the aristocracy and affluent, and the best gardeners in the world have been trained in them; then after the multitudinous details of practice learnt there is the splendid establishment of Kew as a finishing school, where lectures of great value are delivered; but the resources of Kew are obviously inadequate for teaching men the duties they have to perform in maintaining unbroken supplies of vegetables and fruit for the demands of families, while the important branch of forcing early crops is not practised at Chiswick, nor is it likely to be. There will always be plenty of gardeners equal to all the duties required of them, trained in the best of existing schools, with plenty to weed out. But to this Belgian School of Horticulture. It is a substantial building, with a garden containing fruit trees. The students learn to draw plans inside and prune trees outside. I saw no glass structures. On inquiry of persons competent to speak on the subject, and who are well acquainted with British gardens, I was informed distinctly that the schools possessed no means of teaching practical horticulture equal to our best private gardens, and that the students could not take the management of such

gardens and maintain regular supplies of the different kinds of produce required by their owners. The scholars after their training find employment as best they can as landscape gardeners, not as cultivators; and as affording slight testimony of the value of our "rude" system of training men without technical schools, the fact may be recorded that of the two best managed private gardens I have seen in Belgium, one is in charge of a Britisher, and the other of a native, who was taught English in order that he might read the *Journal of Horticulture*, for learning English work and ways, which he represents very well on Belgian soil. So here against the theory of some of our "school" advocates, and most excellent men, we have the practice of King Leopold and his loyal subject, and great amateur horticulturist, Mr. J. Everaerts, who did not go to a "school of horticulture" for their gardeners.—
A JUROR.

PLUNGING PLANTS.

[A paper read by Mr. Wm. Bardney, Norris Green Gardens, before the members of the Liverpool Horticultural Association.]

WE have to consider whether plants can be grown better with their pots protected from atmospheric conditions by plunging them in tan, cocoa-nut fibre refuse, sawdust, ashes, soil, or any other material, or by growing them with their pots fully exposed. What are the advantages to be gained by a general system of plunging? and what are the disadvantages that can reasonably be urged against it? I shall contend, then, that it should be practised for the economical advantages it offers. If gardening is to prosper in the future the cost of production must be duly considered, so that the returns will justify the outlay. If labour can be saved by plunging, why persist in growing plants with their pots exposed? Appearance will always have to be considered in gardens as well as economy, whether in private or trade establishments. What renders plant houses more disagreeable and unsightly than dirty stages and pots? The work of keeping the pots clean is considerable, which by plunging would be entirely dispensed with. There would be no stage-washing, for open trellis staging is not yet obsolete, but it should be. If gravel is used it soon becomes green, and entails as much labour in washing or renewing as the plunging material would cost. The labour of pot-washing is saved, practically so, for what will have to be done is reduced to a minimum. When the pots are constantly exposed they soon present an unsightly appearance, and they are no sooner washed than they are green again. Use ordinary pots, follow a system of plunging them, and this laborious system of pot-washing will be dispensed with.

But the labour saved in this matter so far, is not to be compared with that saved in watering. Watering, to do it well, is, perhaps, the most expensive item in the production of plants when grown on the ordinary methods with their pots exposed. The labour can scarcely be estimated, for so much depends upon the supply, and whether it is close at hand or the reverse. By plunging the pots evaporation is arrested, and very little moisture is drawn from the soil in which the plants are growing. When the surface of the soil and pot is covered very little moisture escapes, only what is naturally evaporated from the leaves and stems of the plant. Evaporation will go from the surface of the plunging material, but if a judicious system of syringing is followed daily as the state of the atmosphere and the requirements of plants demand it is replaced. To do this does not require one-tenth the labour entailed in watering when plants are grown on the usual principle. Not only can plunging be proved to be economical, because it saves labour in pot-washing and in watering, but because there is a corresponding saving of food provided for the plant within the limit of the pot. I think it cannot be disproved, or even doubted, that rain will wash down into the earth, and often below the reach of the roots of plants, to be carried away in the drains, much of the essence of manure when applied in autumn, even if placed on the surface of the soil. Of course considerably more will be lost, if I may use the term, on light than heavy soils. What is the rainfall of our climate in comparison with the amount of water poured into the soil of plants when they are grown with their pots exposed? I contend, then, that growing plants with their pots exposed to the atmosphere results in the waste of more food from the soil than is taken up and utilised by the plant, in fact more than is really needed to carry out its proper functions to sustain health and vigour. It may be argued that the requisite food can be supplied to the surface, as I readily admit, but it strengthens my argument that a system of culture should be adopted by which the food supplied to the plant when it is potted can be retained for the plant's use, and not washed away. This can be accomplished by plunging, evaporation is thereby arrested to a large extent, and it is not necessary to pour one-tenth the quantity of water into the pot. The food placed within the pot at first is sufficient, then, for the plants for a much longer period than would be the case if watered as many times as becomes necessary when they are grown with their pots exposed to the atmosphere.

In further considering the benefits that result from plunging, it is evident the system provides the most uniform condition about the roots both as regards moisture and temperature. By the ordinary method of watering this cannot be done, for the soil is seldom in that satisfactory condition; it is either wet or dry, and they need water during dry weather two and three times a day, more or less according to external conditions.

I have said that by plunging a more uniform temperature about the roots is maintained. Some may deny this, and point to the genial warmth that encircles the pots in our glass structures. But we must not

overlook the fact that they cool in a corresponding manner. The variations of temperature to which the roots are subjected are greater than than can possibly be the case when the pots are buried beneath the surface. The roots beneath the surface may not become so warm by day as those fully exposed, but they are warmer at night. To be understood I will put it in simple form. A pot exposed will become frozen all round it, not only on the surface, while the one plunged would only freeze on the surface, this is supposing they are exposed to a moderate frost only. By plunging the pots are protected from extreme heat and cold, more in accordance with the conditions provided for plants in a natural state.

If we turn to plants grown in glass houses and plunged, it may be pointed out that those in large pots would be much cooler at their base than they would on the surface. There would unquestionably be a difference, as great as exists when plants are growing in a state of nature. If they are cooler by day they have the advantage by night—that is in a natural state; but under our artificial system they would be cooler at all times below than on the surface unless bottom heat was employed. The use of bottom heat and plunging would appear by the statements of some cultivators to be inseparable. I intend to separate them, for bottom heat need form no connection with the system of plunging I am bringing before you. I do not advocate the employment of deep brick beds in the centre and sides of houses for the purpose of carrying into effect a system of plunging. I object to these brick beds, in the first place because they prevent providing for the roots of plants the uniform temperature desirable; secondly because the two outer beds, part of them at least, are exposed to the cooling condition of the external air. Plants near the outer wall would, during cold weather, be many degrees cooler than those nearer the path; in fact, they would be too cold to insure their doing well. Thirdly, because it obstructs the means of evenly distributing the hot-water pipes. These objections alone are sufficient to guide us to consider whether arrangements cannot be provided by which these objections can be overcome without adding to the expenses of construction and production.

The beds for plunging should be provided on the same principle as the side stages of our houses when erected with legs of iron connected with angle irons secured to them at the back and front, leaving a clear space at the back so that the heat from the pipes can pass up. The central bed would be constructed on the same principle, with the pipes distributed below it. I need not enter into details how large pots could be plunged on this principle without the front edges looking untidy, by a thick layer of plunging material, or a deep edge that could be furnished in a more striking manner than is the case at present if the structures were required for ornamental purposes instead of for growing on. This plan would provide for the roots being as warm at the base as at the top, because slates absorb heat to such an extent that they quickly become thoroughly warm. It is radiated under certain circumstances equally as quick, and slates are therefore the most objectionable base that can be employed for plants if the pots are stood upon them in cool structures without gravel or some other material. The last is no part of our subject, and is only alluded to in passing because such objectionable practices are persisted in, and the gardener often blamed because plants fail to do well on them. The new Vine house at the Aigburth Nurseries is exactly to my fancy as far as the distribution of the heat is concerned, and the method of plunging that was adopted with the Vines early in the season. The arrangements are worthy of special note, because they have been the result of careful thought and consideration.

Plunging the pots is advocated because it protects the roots from injury. How quickly are the silk-like roots of many plants injured when the pots are exposed to the sun and the drying conditions of the atmosphere! Even when the sun has but little power, moisture from the pot and soil is evaporated at such an enormous rate that injury to the roots in a greater or less degree can scarcely be prevented. Who has not protected the pots of Heaths, Azaleas, and other hardwood plants on the sunny side to prevent the roots being ruined by the heat the pot naturally absorbs? Why is this done? Such practices strengthen my argument that the protection of the pots insures the roots of the plant against injury. If we consider the roots as "absorbent organs," every precaution should be taken to preserve them. Injury to the roots means a check to the plant, the evils of which may not be perceptible for some time. I believe that the foliage of more Heaths is browned, and eventually falls, while Azaleas lose before flowering a greater percentage of their leaves by injury to the roots through the exposure of their pots than from any other cause.

By plunging plants earlier, quicker and increased root activity is ensured, and in consequence a better and more luxuriant growth follows. To prove this take two cuttings equal as far as the wood is concerned, make them of equal weight, and put them into the propagating box to root, say two Crotons. Treat them to the same heat and atmospheric conditions, only one must be plunged, covering the rim and surface of the soil. When rooted place them in 5 or 6-inch pots, plunge the one again and grow the other without for a time. Now, turn the two out of their pots, wash the soil from their roots, and when thoroughly drained weigh them, and it will be found that the one that has been plunged has not only the most roots, but will be the heaviest. The one may be watered and the other given none after it is rooted, provided the soil is in an intermediate state of moisture when potted and the plunging material is kept moist. An example may be given to show the difference in the supply of water needed when they are plunged and when they are not. I have rooted Crotons in 2-inch pots, and they have been repotted until they were placed in 10-inch pots, and filled

them with roots before water was poured into the pots. They were well syringed, and the plunging material kept moist. Lift two Rosas, pot them, and plunge one outside in ashes below the surface, and stand the other on the walk. Water one when it needs it, and give the other none, if the soil is in a proper state of moisture when potted. Examine when frost compels their removal to frames, and it will be found that the plunged one has double the roots of the other, and the soil in a much sweeter and better condition. Plunge Lilacs, Guelder Roses, or any similar plant after potting or pruning in autumn in ordinary garden soil for the next season's forcing, and the season must prove exceptionally dry if they need a supply of water. I need not enumerate examples of the advantages gained by plunging, because they can be tested by all who will put the system into practice. From a general system of plunging Orchids must, however, be excepted.

I said it was necessary to consider the disadvantages that could be urged against plunging. The only one of weight that can be brought forward is that of over-watering. Now, this when carefully considered is a difficulty that bears no comparison with the mistakes that are made, often unavoidably, in watering plants when their pots are exposed. Watering properly when the pots are plunged is a mere matter of training. If they are over-watered it arises from either lack of proper training, ignorance, or generally from carelessness. To water plants properly when they are plunged only needs observation and thought. This seeming difficulty in a method of procedure that offers advantages, the importance of which cannot well be over-estimated, is readily overcome.

THE DISPERSION OF SEEDS AND PLANTS.

IT may seem strange, at first sight, to assert that cattle have been the means of distributing the seeds of certain plants from one country to another, but a statement is made by Grisebach respecting *Pithecolobium Saman*, a large tree native of Tropical America, now naturalised in Jamaica, that the "seeds were formerly brought over from the Continent [of America] by cattle." This statement has been carefully examined, and it is fully borne out by facts. Formerly, Jamaica, like Trinidad at present, was dependent for cattle on Venezuela. The food of the animals during their voyage consisted amongst other things of the pulpy legumes of *Pithecolobium Saman*. The seeds being very hard were uninjured by the process of mastication and digestion, and they were deposited in the pastures, where they germinated and grew up into large trees. In this instance the seeds were carried across the sea a distance of about a thousand miles, and there is no doubt that the cattle were directly concerned in their introduction. Indeed, without them the seeds, even if accidentally introduced amongst the fodder, would not have been placed under such circumstances as would have enabled them to give rise to plants. In the first place, by being passed through the animals the seeds were softened and the period of germination hastened. In the second place the seeds had a suitable medium to promote germination, and this enabled the young plants to withstand the season of drought which is incidental to almost every tropical country. In this instance we have cattle not only the means of introducing the seeds of a valuable tree, but also involuntarily instrumental in establishing the tree in a new country, and providing shelter, shade, and food for their progeny. Those acquainted with the Guango or Rain Tree, as this *Pithecolobium* is locally called, will fully realise its value as a shade and food tree for cattle, and they will also appreciate the singular concurrence of circumstances by means of which such a tree was introduced to a new country by the very animals which required it most.

It is possible there may be some who will doubt the possibility of seeds retaining the power of germination after undergoing the processes of mastication and digestion, and especially in the special case of ruminating animals. There is, however, very clear evidence on the subject. It is a common occurrence in India to utilise the services of goats to hasten the germination of the seeds of the common *Acacia arabica*, known as the Babul. This tree belongs to the same natural order as the *Pithecolobium*, and grows in the poorest and driest soils of India. The Babul seeds will not germinate readily in the hot weather, and it is the regular habit, in order to save a season, for a person desirous of a crop of seedlings to make a bargain with a herdsman or a neighbour who possesses a flock of goats to quarter them for some days in a small enclosure in which they are fed on Babul leaves and pods. The droppings of the animals contain a certain number of seeds which are uninjured, and these now readily germinate, and give rise to plants the same season. I am informed by Dr. Watt that in India "several other plants are treated in the same way." The seeds of the several species of cultivated Guava are hard and do not easily germinate. These, however, are said to germinate more freely and readily when they are picked up in night soil.

While on this subject I would mention that when at St. Helena in 1883 I expressed some surprise that no attempt was made to utilise "urban" manure in the neighbourhood of Jamestown, when the land was so impoverished and yielded such poor crops. I was met by the fact that if such manure was largely used the land would become overrun with plants of the Prickly Pear (*Opuntia Ficus-indica*), the fruit of which is largely consumed by the inhabitants. There is little doubt that the seeds of this plant, like those of the Guava, and I suspect also species of *Passiflora*, which are swallowed whole, are capable of germination after they have passed through the human body. Another instance occurs to me where the use of manure has been the means of

distributing an undesirable plant on cultivated lands. In many tropical countries a Grass known as Para, Mauritius, or Scotch Grass, and sometimes as Water Grass (*Panicum barbinode*), has been introduced from Brazil, and highly esteemed for its rapid growth and nourishing properties. It grows well in moist situations, on the banks of streams, and even in soils so swampy as to be suitable for nothing else. In such situations it spreads rapidly and yields abundant food for cattle and horses. Nothing, however, could be worse than this Grass for cultivated areas, where the land is required to be kept free from weeds, and where crops of Sugar Cane, Coffee, Tea, and Cacao are raised. It has been found that where animals are fed on this Grass the joints even after passing through the animals have been known to grow. Hence the manure, if freshly used, has been the means of establishing the plant over wide areas.

In a recent work Mr. Ball has drawn attention to numerous introduced plants which are met with in South America. He naturally mentions the Cardoon, the wild state of the common Artichoke, which is now more common in temperate South America than it is anywhere in its native home in the Mediterranean region. Darwin doubted whether any case exists on record of an invasion on so grand a scale. Several hundred square miles are covered with this introduced plant, which has overrun all members of the aboriginal flora. The introduction of the Cardoon appears to have been effected directly by man for the purpose of contributing to the food supply of cattle; but as regards another widely spread plant the mode of its introduction is not clearly known.

Mr. Ball states:—"As to many of these [introduced South American plants] it appears to me probable that their diffusion is due more to the aid of animals than the direct intervention of man. This is specially true of the little immigrant which has gone farthest in colonising this part of the earth—the common Stork's-bill (*Erodium cicutarium*), which has made itself equally at home in the upper zone of the Peruvian Andes, in the low country of Central Chili, and in the plains of North Patagonia. Its extension seems to keep pace with the spread of domestic animals, and as far as I have been able to ascertain it is nowhere common except in districts now or formerly pastured by horned cattle. It is singular that the same plant should have failed to extend itself in North America, being apparently confined to a few localities. It is now common in the Northern Island of New Zealand, but has not extended to South Africa, where two other European species of the same genus are established."

Erodium as a genus is separated from the true Geraniums amongst other reasons on account of the tails of the carpels being bearded and spirally twisted on the inside. It is possible that these characteristics have enabled the seeds to attach themselves to the legs and bodies of cattle, and so effected their distribution over wide areas in such situations as are favourable to their growth.

In the Island of Jamaica we have a remarkable instance of the naturalisation and wide distribution of an introduced plant in the case of the Indian Mango. In an official report, published in 1885, I stated that to the Mango, possibly more than any tree in the island, is due the reforestation of the denuded areas in the lower hills; and as in consequence of the changes taking place in the climate members of the indigenous flora are unable to maintain their ground, it is fortunate the island possesses in a vigorous and hardy exotic like the Mango the means of counteracting the baneful effects of deforestation. It specially affects land thrown out of cultivation, and the sides of roads and streams where its seeds are cast aside by man and animals. It practically re-clothes the hills and lower slopes with forest, and it enables the land to recuperate its powers under its abundant shade-giving foliage. It is strange that in Ceylon, which is so much nearer the home of the species, the Mango does not spread by self-sown seedlings. This corroborates Mr. Ball's statement with regard to *Erodium cicutarium*. The latter is widely spread in South America, but only sparingly found in other countries under apparently exactly corresponding conditions. We cannot say why such anomalies exist. They do exist, however, and offer problems which can only be solved by a closer study of the conditions of plant life, and the interdependence of plants and animals acting and reacting one upon the other.—D. MORRIS (in *Nature*).

HARDY FRUIT GARDEN.

PEACHES AND NECTARINES.—These flowered very freely, and the fruit has set thickly, but unfortunately the foliage is much crippled and dirty. We kept the blinds and fish nets over the trees longer than usual in order to screen them somewhat from the cold easterly winds, though this does not appear to have done much good. There are many more swollen and curled leaves than usual, and these ought to be at once picked, as if left on the trees they do more harm than good. A considerable number of the worst placed and all deformed fruits should be removed at the same time, and where there are plenty of shoots these also may well be thinned. What is wanted is one good shoot at the extremity of each piece of young wood, and another as near the base as

possible, and on the upper side. The intermediate shoots to be thinned, reserving any near a good fruit, and if these are duly stopped at the third or fourth joint there will be sufficient leaves to nurse the fruit. Near the centre and stem of the trees especially as many young shoots should be laid in as there is room for, these eventually taking the places of worn out older branches. Very healthy trees are apt to form extra gross shoots, which, if preserved, rarely ripen properly, and in fact are very liable to spoil the trees. Pinch these back, or, better still, disbud or pull them out of their sockets, and if this is done early better shoots will start from the same bud-rank growth usually proceeding from triple wood buds. Green fly is plentiful, and this must be washed off either with the syringe or engine, using soapy water.

PEARS.—Where moderate numbers of flower trusses were formed on the trees a good set has resulted, but those very freely flowered have not done so well, the greater portion of the bloom having fallen and left but few fruit behind. The worst offenders in this respect are Duchesse d'Angoulême, Josephine de Malines, Glou Morceau, Marie Louise, and Winter Nelis. Trees much exhausted last season in very many instances are only lightly set with fruit, and this ought to be a warning not to overcrop any that are well furnished with fruits this summer. The thinning ought to be timely and unstintingly carried out, all being sufficiently advanced to render it an easy matter to distinguish which are the best-formed. No clusters should be left, more especially in the case of such large varieties as Williams' Bon Chrétien, Jargonelle, Marie Louise, Beurré Superfin, Pitmaston Duchess, Beurré Diel, Beurré Clairgeau, Louise Bonne of Jersey, Maréchal de Cour, Van Mons Leon Leclerc, Beurré Bachelier, General Todleben, Easter Beurré, Ne Plus Meuris, Glou Morceau, and Beurré de Rance, all of which should be grown to their full size, or otherwise the quality is not so good. The medium-sized and smaller varieties, notably Winter Nelis, Bergamotte Esperen, Josephine de Malines, Beurré d'Arenberg, and Ollivier de Serres, are, as a rule, heavy croppers, but unless freely thinned the fruit is small and flavourless, and it is much the same with numerous other Pears that could be named. In the case of the larger varieties, including those first mentioned, each cluster should, unless they are few and far between, be reduced to a single fruit, and where very thick they ought eventually to be still further thinned. As a rule the trees are not forming so much strong growth as usual, and it is advisable to prevent their wasting any of their apparently already impaired vigour. The lateral growths should therefore be freely thinned where at all thick, and that reserved stopped at the fifth or sixth joint. Closer stopping must not be resorted to, as this most probably would force fresh growth from buds that it is desirable should be converted into fruit buds, while if the growth is left unstopped till after midsummer this will necessitate the use of a pruning knife. Early stopping, in addition to favouring the fruit, also encourages the strong growth of the leaders where space has yet to be filled. Pyramids of medium or small size to be treated similarly to the wall trees, but large trees need not be touched at present.

MULCHING STRAWBERRIES.—Gentle rains have much benefited the Strawberries, and those mulched with strawy manure will not be dry at the roots for some time to come. Any not mulched ought to be attended to at once, this being necessary to enclose moisture, and also because it cannot be done so cleanly after the fruits are heavy and falling clear of the foliage. Before this is applied a good soaking of liquid manure should be given if possible, and the ground being already in a moist state will be in just the right condition to absorb the greater portion of the manure. Guano, soot, or other manures as previously advised may also be washed in with advantage, something of the sort being necessary where the plants have been on the ground more than one or two seasons. Directly after the watering has been given apply the mulching. Clean strawy manure is perhaps most generally used, and this, if not washed sufficiently clean before the fruit is ripe, may be further faced over with a thin layer of straw cut into 1-foot lengths. The latter alone is sometimes used; but though it keeps the fruit clear of the ground it does not sufficiently prevent the loss of moisture; and for this reason it is a good plan, failing strawy manure, to freely use short lawn grass by way of a mulch. This may be put on as fast as it is cut by the mowing machine, or better still a quantity may be cut with scythes from banks and other spots not mown very often; and the grass being duly dried or converted into hay is fit to use among Strawberries without a surfacing of straw.

STRAWBERRY SUPPORTS.—During a dull wet summer especially the wire supports as advertised and sold cheaply by different makers are simply invaluable, and they are of good service even in a season favourable to the proper ripening of the fruit. They prop up and expose the fruit to what sunshine there may be; they preserve it from the slugs, and admit of liquid manure being freely used about the plants without touching the fruit. For reasons just given, and also for preventing soil being splashed over the fruit, some kind of mulching must be given in conjunction with these supports. Those who may have a plentiful supply of strong old fencing wire may easily make a number of Strawberry supports. If wanted for fairly strong plants cut the wire into 3 feet lengths, turn down about 9 inches of each end, and form the centre into a half-circle, this being easily done with the aid of a strong hammer and circular block of wood. Two of these are required for each plant, one person holding up the leaves and fruit while the other thrusts the uprights or legs into the ground to a sufficient depth. A strong collar is thus formed round them quite capable of supporting the heaviest crops that may be produced.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest House.*—When the fruit is all gathered, or from individual trees, the wood upon which it has been produced should be cut away to the shoot at its base, which is to afford the bearing wood of next season, except if the fruit has been produced on wood that it is necessary to retain for the extension of the trees. All growths not absolutely necessary for bearing next season or the extension of the trees should be cut away, as it is important that the foliage be fully exposed to the influence of light and air, and it is equally important that it be kept healthful and die naturally. Employ the syringe freely, keeping the inside borders well watered, and the outside border must not be neglected if the weather be dry. All the air possible should be admitted, and when the buds are plumped, and the wood thoroughly ripened, the roof lights where moveable may be taken off.

Second Early House.—In gathering the fruit great care is necessary in handling it, as slight pressure is sufficient to spoil the appearance. Fruit for packing should be gathered before it is quite ripe, and all is better taken from the trees rather under than over ripe. Some netting suspended beneath the trees is useful to prevent fruits that fall from being bruised. Ventilate freely, leaving a little on constantly, and to ensure the necessary moisture so essential for the preservation of the foliage in health sprinkle the paths and borders in the morning and afternoon, not allowing the soil to become dry, but giving water as required to maintain it in a moist healthy state. A mulching of short spent material is very useful in preventing the surface cracking and the roots going down in quest of moisture. Syringing must cease directly the fruit commences to soften for ripening, or the moisture will cause the skin to crack and leave an unpleasant musty flavour.

Trees Started in January.—There is a great difference in the fruit ripening, not only as regards varieties, but in the treatment they receive. Sharp work is seldom good work. We have trees now that under ordinary forcing would have ripened the fruit early in the current month. The varieties are Early York and Royal George, with Elruge Nectarine. They have been brought on very gently and in accordance with the weather, which is later than usual in forwarding the crops, and as a consequence the fruit will be later by fully a month. This is as regards the size and quality of the fruit a matter of great importance. The fruit will when ripe be heavier, and its juices being more fully elaborated, be very much higher in quality. This we mention, as those that want quality must allow time for it. Mere size and even appearance—*i.e.*, colour, can be had, but there is no comparison of the fruit ripened in a high and moist, somewhat close atmosphere, and that finished in a well ventilated and naturally aided structure, no more artificial heat being employed than is necessary for the safety and gradual progress of the crop. There is the still further difference that the fruits in the stage of swelling prior to stoning attain to a much larger size, and they make more rapid progress after that process is completed, than those having more heat during the early stages. Then there is a difference again as to the time of month the trees are started, also as to the treatment of the trees during the resting period. Those that have fixed roof lights may, if the weather have been mild, have the buds advanced in swelling when the house is closed, whilst those that have been exposed will be fully a fortnight behind, assuming them to be started at the same time. Those are matters requiring notice in calculating the time the fruit is to be ripe. After stoning the fruits assume colour and flesh quickly; every attention should therefore be given the trees in watering either with liquid manure, or affording water through a good mulch of rather fresh short material. The shoots should be allowed to extend, not pinching the laterals in too closely, but they must be kept from shading the fruit, which must be raised with its apex to the fullest light. This can be effected by laths placed across and secured to the wires of the trellis. Continue forcible syringing morning and afternoon until the fruit begins ripening, then cease syringing, but do not allow the border and other surfaces to become parchingly dry, as moderate air moisture, provided the ventilation is liberal, will not injure the fruit, and it is absolutely necessary for the benefit of the foliage.

Trees Started in February.—The fruit of these is stoning. It has made very satisfactory progress, attaining to a good size, and to continue this there must not be any deficiency of moisture at the roots, and the foliage must be kept clean by daily syringings, and if necessary the prompt application of an insecticide. The temperature should be continued at 60° to 65° artificially, and a free circulation of air allowed between 70° and 75°, having it full when the latter is reached, and close at 75° with plenty of atmospheric moisture. If the temperature rise to 80° or 85° it will not do any harm, but admit a little air before night-fall, so as to allow the pent-up moisture to escape and the temperature to gradually cool through the night. Commence increasing the ventilation with the advancing heat from 65°.

Later Houses.—The failure of Peaches and Nectarines outdoors in many places this season owing to the frosts and prolonged cold will render those under glass particularly desirable, and it may be desirable to retard trees that under ordinary circumstances would afford a supply of fruit in advance of that from trees on walls, so as to prolong the season of supply. This is readily effected by a freer and lengthened ventilation during the day. There is only need to ventilate day and night to keep back the crop so as to ripen about the same time as that usually occurs with trees against walls, and by judicious ventilation the fruit may be had over a prolonged period. The crops under glass are abundant, but they are not stoning so well as could be wished, which is probably a consequence of the wood not being so well matured as would have been the

case had the preceding season been more favourable to the storing of aliment. It is necessary not to overburden the trees with more fruit in the early stages of growth than is necessary to remain for the crop, and a moderate crop is always better than a heavy one; therefore thin well in the early stages, leaving a few more only to meet casualties than will be required ultimately. Keep them well syringed, and mulch so as to keep the surface moist, thereby encouraging the roots to the surface, giving applications of water, and if necessary liquid manure.

PLANT HOUSES.

Kalosanthes.—Plants that have been kept moderately close for the past two months will be in full flower. Retard later plants by giving abundance of air; those not yet showing colour may be stood in a sheltered but northern aspect. It is surprising with a little management how long they can be kept back. There is no difficulty in having these effective plants in flower over a period of three months. They must have one clear season's growth, which, if well ripened, will be certain to produce flowers on every shoot. Those that flowered last year or were raised from cuttings should be in the pots in which they are intended to flower. They will do well in a compost of good loam, one-seventh of manure and sand. Press the soil into the pots firmly, and water carefully until they are rooting into it freely, when liberal supplies may be given. The plants must be exposed to full sunshine, and for a few weeks longer only need they be protected in cold frames. On fine days the lights may be thrown off and eventually the plants put outside. This treatment will insure dwarf firm growth that is certain to flower. If there are any growths on the plants now in flower or likely to flower that have missed, they should be taken off and rooted at once. They can be rooted singly in 3-inch pots, or four or five may be rooted in 5 and 6-inch pots and grown together. Much, however, depends upon whether the plants are wanted for flowering next year or the year following. If rooted at once, gradually hardened, and then grown with next year's stock, they will all flower; but if they are not wanted root them singly, and pinch out the points, which will induce them to branch, and four to half a dozen shoots will be produced for flowering the following season.

French and Fancy Pelargoniums.—Cuttings for flowering early next year should be inserted as rapidly as possible. Failure often results from striking hard flower stems late in the season instead of doing the work when good cuttings can be had in plenty. If firm sturdy shoots are selected they will root freely in any structure where a temperature of 60° can be maintained, provided the atmosphere is not too moist. When the earliest plants have flowered place them outside in a sunny position to thoroughly harden and ripen their wood. Those who want white flowers for cutting either for vases, bouquets, or sprays should grow a number of *Volonté Nationale* album, as its flowers are pure white, travel well, while the plant is of dwarf sturdy habit and one of the most profuse flowerers in this section. It will not strike so freely as some varieties unless the cuttings are moderately firm before they are inserted. Those intended for flowering late should be kept cool, but fully exposed to the sun. Do not pinch them after this date, or growths instead of flowers only may be the result. Those that are already showing their flower stems will bear liberal feeding, in fact in this stage they are much benefited by artificial manures.

Zonal Pelargoniums.—Pelargoniums intended for flowering during September and October are well established in their largest pots, and they can now be placed in a sunny position outside. Pinch their shoots as they need it, and remove all flowers as they appear for the next six weeks. Those intended to succeed them should be placed in their largest pots as rapidly as possible, or as they become ready. Place them in cold frames and keep them close for ten days, then gradually harden them and stand them outside. The same remarks apply to Ivy-leaf varieties. All for winter flowering must be potted firmly in 5 and 6-inch pots, which is the most suitable size. Use for a compost, loam one-seventh of manure and sand. With this treatment the plants will make firm sturdy growth that will ripen and flower well when required. Zonals may still be rooted, but these should be inserted in 3-inch pots and flowered in them. After they are rooted they must be prepared by placing them outside, the same as those in larger pots.

Celosias.—Seedlings may be placed in small pots and grown gently. Be careful not to keep them too close, or they will run up tall and soft, and plants produced by such means are very liable to damp off during dull weather in November. Seed may be sown in gentle heat for the same purpose and grown on gradually afterwards in cold frames. Be careful not to allow them to become root-bound before they are placed in 5 and 6-inch pots. Celosias are amongst the most useful plants for furnishing purposes during the autumn and winter months.

35°, and the day temperature for four days rose to 70° Fahr.; the two following the day temperature was 45°, and has continued about other six days, with a night temperature of 38°. During these last-named six days the wind was high, accompanied by heavy showers of rain; altogether the severest weather of the kind I ever experienced at this season.

Some trees are almost denuded of their leaves, and more bees were lost in these few days than at any time during the whole year.

SWARMING.

Before the weather became so tempestuous some hives had swarmed, and many appeared to be on the eve of it, but they have cooled down now, and will have the loss to make up again before attempting to swarm. During the four fine days we had, and the only honey ones this season, strong stocks gained greatly in weight, but owing to greater consumption of honey in these strong hives, those that were nuclei at the end of September are as good, while the queens must be in a better state for keeping up egg-laying throughout the height of honey season, and will not be so liable to swarm at a time most undesirable.

While speaking of swarms, it may be well to mention a little thing which tends to insure the safety of a swarm having a few combs when sent by rail to a distance with no one in charge. The plan has always been adopted by me when in charge of the bees, but it was the late Mr. T. W. Woodbury who first put it into practice. When that gentleman sent out Ligurian stocks he gummed a printed label across the frames reading, "Please let this line run across the rails." When honey and bees are otherwise properly packed, and having the ends of the combs towards the engine, and the line placed across the combs, any jar they may receive will not injure them so readily as if they ran in the opposite direction. When upon a spring vehicle the position ought to be changed. I observe that an American has hit upon the same plan.

FERTILE WORKERS AND QUEEN-REARING.

During the fall of 1887 I put right for the winter a hive having a Carniolian queen about four years old, not with the intention that it would survive and come out strong in the summer, but for the purpose of raising queens from it to join the hives that had swarmed. Like my other stocks, this one commenced breeding in December, and from the appearance of the queen, which I found dead in March, she must have died in February. One queen cell was visible where a queen had been hatched, but was also lost. The bees, however, wrought well, their mournful hum only betraying the absence of a queen. During the month of April I gave a piece of brood comb containing eggs and larvæ, so that a queen or more might be raised therefrom. This was done after I satisfied myself that there was no queen, and I could not detect any signs that a fertile worker was present. The bees, however, refused to raise a queen. About the middle of May I observed some eggs, which the bees immediately began to raise royal cells round. These were destroyed and fresh worker brood added, but to no purpose. Royal cells were continually being raised containing the eggs of a fertile worker, while the worker eggs were simply taken care of and nursed towards maturity. This state of matters continued for about three weeks, when I removed the combs containing the eggs of the fertile worker to another part of the hive and added still more worker brood. After this a rather remarkable thing occurred. The bees commenced and enlarged a cell which had neither the appearance of being a queen, worker, nor yet the cell of a drone. Of the three, however, it most resembled in colour that of a queen cell. The larva which I could see distinctly through the tumbler, and which was now approaching the pupa state, had the appearance of a queen more than that of a worker or drone, but its body seemed extra long. This cell, after it was sealed some days, was destroyed by the bees, and a royal cell proper has been raised containing a queen.

There is something yet to be learned about these fertile workers,

NOTES ON BEES.

SINCE my last notes were written we have had variable weather in the North. Six days in succession the night temperature was

and the obstinacy of the bees to accept a queen or to raise a queen from worker eggs when a fertile worker is present amongst them. Although we cannot solve all these mysterious phenomena, I think it may be safely said that bees do not think, or they would act differently from what they do in many ways. Their virtues and good qualities must be attributed to instinct.

STOCKS FOR NEXT SEASON.

During the next six weeks attention should be given to selecting queens and forming nuclei for next year's stocks. There is no rule to guide bee-keepers how to select the best queens. So far as man knows he is at fault here if he pretends to know either a cell or queen that will surpass normal ones that have gone before or to fall short of them. Much has been written on this subject, both on the selecting of the cells and queens, which would have been as well left unsaid. My advice is, if a queen is undersized, or if a royal cell is smooth having little wax expended on it, destroy it, and if you have a choice of a thin but longish queen or a short thickish one, select the latter.—A LANARKSHIRE BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Laburnum (W. S.).—We have received the branch bearing yellow and reddish purple flowers, and have seen hundreds similar. The tree is *Cytisus Adami*, which originated from a bud of *C. purpureus* inserted in *C. alpinus* by C. Adam, a nurseryman at Vitry, near Paris, in 1825. The yellow flower on the branch is *C. alpinus*.

Luxuriant Peach Trees (R. W.).—We only received your letter just as we are going to press. The specks are not caused by insects. The growth is so exuberant that the leaves cannot elaborate the sap. Admit all the air practicable, and employ no more moisture than absolutely necessary for cleanliness. In the autumn carry out your proposition, which is practically in accordance with the advice given to a correspondent on page 456 last week.

Plunging Chrysanthemums (T. B.).—A categorical reply cannot be given to your question. We know of so-called Vine borders in which Chrysanthemum pots might be plunged a few inches deep without injuring the Vines, because practically all the fibrous or food-imbibing roots are outside the space originally provided for them; but we should not like to plunge "Chrysanthemum pots all over a border" that is filled with the fibrous roots of Vines.

Narcissus Buds Withering (C. B. M.).—It is not uncommon for some of the buds of the Poet's Narciss, and especially of the beautiful double variety, to shrivel. Whether those from the stronger bulbs open in your case, and those from the weaker fail, we have no means of knowing, but that is so in some cases. It will probably be a good plan to dig up the bulbs when the leaves have turned quite yellow, sort them into sizes, and plant them in rows or groups in deeply dug and enriched ground as soon as convenient afterwards. It is not desirable to keep them out of the ground very long, nor to dry them in the sun.

Tobacco Cloth (C. W.).—This varies in quality, and we have found some more effectual in destroying insects and less deleterious to vegetation than others. As we cannot undertake to subject articles that are sent to us to analysis, and as an inspection is insufficient for determining the quality of tobacco cloth, your experience must have greater weight than the expression of an opinion under those circumstances. Tobacco cloth and paper should only be purchased from vendors of repute, who guarantee it safe when properly used.

Hyacinths Failing (G. F. B.).—You omit to state one important matter in your letter—namely, the time when the bulbs were planted, and possibly this may have had something to do with the result. We have seen whole beds fail from late planting if the bulbs had not been kept in a suitable place. Old bulbs will often prove unsatisfactory in the same way, and sharp frosts or keen winds when the leaves or flowers are showing cause similar injury. We have examined the bulbs sent, but can find nothing in their condition to account for their failure.

Narcissi not Flowering (Cambridge).—When the flowers are cut immediately they open, or almost before, for they expand readily in water, the leaf growth is stronger and the bulbs much better supported than can possibly be the case when the flowers remain to form seed pods, and these left till the growth withers. This is common in many gardens, though possibly not in yours, and expert growers take care not to make such a mistake. You had better take up the bulbs, sort and replant them as is advised in a reply to another correspondent.

Moss in Watercress Beds (C. M. B.).—An extensive Watercress grower who has been consulted on the subject says he is sometimes bothered with the same kind of moss, especially in newly dug beds. He attributes this to the poverty of the soil, and the only remedy he has for destroying it is to clean all out and start afresh, using plenty of good rich soil to plant in. You can check the progress of the moss now by occasionally drawing a birchbroom lightly through the water, and by following the above example you will have better results next time.

Thinning Victoria Plums (F. J.).—The fruit should be thinned in proportion to the vigour of the tree. If very vigorous it will bring to perfection more fruit than were it only moderately so, and more if moderately vigorous than weak. Two or three fruit would be sufficient to leave on each cluster, in order to have them a good size and to finish satisfactorily, and about two such, or half a dozen fruit to each square foot, would be an ample crop. We should not, however, thin too severely at first, but allow the fruit to swell freely before reducing it to the quantity required for the crop, and it is best done gradually, a few at a time or each day in preference to removing a large quantity at once, leaving a few more than will be required to meet casualties.

Grass Edging (Idem).—We do not know of anything you could plant along the grass edging that would keep it from crumbling down, unless it be Yarrow, which succeeds admirably on a light soil, and keeps green in the driest weather. Lotus corniculatus minor is also excellent. We fear they would be difficult to establish on the edge of the turf, but the seed might be inserted on the top, and growing plants would soon spread so as to give a good edging, especially the Yarrow.

Tree Carnations (Shenley).—These Carnations do not "damp off and the leaves become brown before the plants attain any size" if properly managed. If you had described the treatment of your plants or cuttings we could perhaps have indicated where you erred. Stout healthy cuttings are essential to begin with, and these strike in sandy soil in a close case or frame, or under bellglasses, but the moment they are rooted, and fresh leaves show signs of growth, they must have full exposure, and all the light and air possible for insuring sturdy growth. It is well to strike them in separate 2-inch pots, as then they can be transferred to larger without breaking the roots, shifting them when roots are seen through the drainage, and using turfy loam with a sixth part of decayed manure and a little bruised charcoal, potting firmly. A cold frame is suitable for them at this season, with the sash drawn off day and night in fine weather when the plants are in free growth. They are often drawn and spoiled in greenhouses during the summer, and damp off if kept too close when young. Light greenhouses are suitable for them in the winter. There is no pamphlet such as you appear to desire, but a practical work on florists' flowers can, we think, be obtained from Mr. James Douglas, Great Gearies, Ilford. The spray you send is of *Cerasus Padus*, the Bird Cherry.

Plants for the Conservatory (W. S. S.).—You could have Achimenes in good condition throughout the months of September and October. To do this you should keep a few old plants, and take cuttings from them. The old plants could be grown in your vineries. The cuttings should be inserted in 5 and 6-inch pots, and would root quickly in the stove, and could then be grown in the lean-to house. Gloxinias would be useful raised from seed sown in February or even in March; also Begonia Knowsleyana, B. Ingrami, B. Carrieri, and the whole of the B. semperflorens section. The tuberous kinds would also do service then if the tubers were started late. For the last month Bouvardias could be had, Salvia splendens, Heliotropes, Mignonette, and Rhodanthes, which take about three months to come into flower from the time the seed is sown. Early flowering Chrysanthemums in variety could be had in quantity—for instance, Madame Desgrange and its golden form G. Wermig, La Vierge, as well as several others that flower earlier than these. Zonal Pelargoniums, single and double, as well as Ivyleaf varieties, are invaluable for flowering during those months. Abutilons, Pectunias single and double, Fuchsias, Liliun lancifolium rubrum and album can be had then; so can Primulas in quantity, both the varieties of sinensis and P. obeonica. Cyclamens may be had in flower in October, and Roman Hyacinths after the middle of the latter month.

Banana Culture (A Subscriber).—The chief essentials for growing Bananas are light, lofty, well heated houses, rough rich soil, and abundance of water. The plants may be fruited in large tubs, but they

do not grow nearly so vigorously as when planted out, nor produce such large clusters of fruit. We have not seen *Musa Cavendishi* better grown than by Mr. J. Ollerhead in Sir Henry Peck's garden at Wimbledon House. Stout young plants, or rooted suckers about 2 feet high, were planted in the spring, and huge clusters of fruit were cut from them about Christmas. One of these, we think, weighed upwards of 90 lbs. They were grown in very rough, rich, turfy loam, and we think had the advantage of slight bottom heat, while enormous quantities of tepid water were given during their growth. In August the stems were considerably more than 2 feet in circumference, the leaves magnificent, and the fruit clusters showing. The temperature of the house ranged from 75° at night to 90° in the day with sun in summer, and a moist genial atmosphere maintained. We have cut a cluster of fruit weighing 30 lbs. from a plant in a tub 3 feet in diameter, sunk in a bed of leaves, in a temperature ranging from 65° at night to 85° with sun. In the winter, when the plants are resting, a temperature of 60° to 70° suffices. If you mix one part of decayed manure and the same of leaf mould with five parts of good and very turfy loam, *Musas* will grow freely in it if afforded adequate supplies of water and a temperature between 70° and 90° is maintained.

Stopping Fig Shoots (*A Subscriber*).—Very vigorous growth is not a good indication of fruitfulness. Either the border is too large or it is composed of too light, rich, and open material. Fig trees are best with the roots confined to a somewhat small border composed of good loam with a free admixture of calcareous and siliceous matter, such as old mortar rubbish and road scrapings, any manure that may be needed being applied to the surface or in liquid form. Shoots that have reached the top of the house or trellis should be pinched 9 inches from the extremity, which will cause them to push fruit from the joints below, also on the young growths resulting, these latter to be pinched at the fifth or sixth leaf. These extremity growths require to be cut out after they have fruited, or, if not fruited, they should be cut out so as to give place to those succeeding, thereby keeping up a succession of bearing wood throughout the trees. Side shoots not required for laying in should be pinched at the fifth or sixth leaf so as to form spurs, which usually fruit freely, but they must not be trained in too abundantly, as it is very important that the wood be thoroughly exposed to light and air for its solidification, for on which its fruitfulness depends. With the trees in full leaf, the temperature should be kept at 60° to 65° at night, 70° to 75° by day, ventilating from 70°, and maintaining a temperature through the day from sun heat of 80° to 85°, closing between those degrees so as to raise it to 85° or 90°, having plenty of moisture in the house, which will be obtained by forcible syringing, so as to keep the leaves free from red spider. The top ventilators should be slightly opened before nightfall, so as to allow of the pent-up moisture escaping.

Infested Apple Trees (*Thorn Hays*).—The leaves arrived much dried and shrivelled and no insects could be detected. Have not some of the leaves been injured by petroleum? This, when used, should always be applied in the evening, soon enough for the trees to dry before night; applied in the morning and hot sun following, the leaves are almost sure to be scorched. We suspect your trees have been attacked by the small Ermine moth, the caterpillars of which are highly destructive to the leafage and blossom of Apple trees. Miss Ormerod, in her manual on injurious insects, says:—"The female lays her eggs in roundish patches on the small twigs, and covers these patches with a kind of strong gum, which is yellow at first, but gradually changes to a dark brown, so as not to be easily distinguishable from the brown twigs. The eggs may be found hatched by the beginning of October, but the caterpillars (which are then little yellow creatures with black heads, and only about half a line long) remain sheltered under the patch of gum during the winter, and do not come out till the leaves begin to unfold in spring. They then burrow into the young leaves and feed on the soft matter within, until they are strong enough, when they come out from their minings and thus make their appearance suddenly in large numbers where none have been noticeable before. When full fed each caterpillar spins a light cocoon in which it changes to the chrysalis inside the general web. The moths, which comes out towards the end of June, are about three-quarters of an inch in expanse. The fore wings are usually livid or whitish, dotted with black; the hind wings livid or lead-colour. It has been observed that the whole brood of moths usually hatch from the chrysalis at the same time, when their light colour makes them easily seen, and they are sluggish by day; it has therefore been found useful to spread a sheet under the tree, and by beating or shaking the boughs make the moths fall into the sheet and destroy them. Fish oil, or petroleum and softsoap, is an application that can be used, and good drenchings are of service in clearing the trees of moths when they are hatching out of the chrysalids, and in dispersing the caterpillars." You did not commence action soon enough. A solution of hellebore made by dissolving 2 ozs. of powder in a gallon of water also destroys the caterpillars. The mildew is the consequence of vitiated sap, the result of injury to the leaves.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*A. B.*).—Since we state that "flowering specimens are necessary for naming flowering plants," is it not strange that you should have waited just till the trees from which you send sprays ceased flowering? It is possibly an *Amelanchier*; but you had better send flowering specimens

next year. (*H. A.*).—*Philadelphus mexicanus*. (*M. R. S.*).—1, *Arenaria balearica*; 2, *Erinus alpinus*; 3, *Sempervivum arachnoideum*. (*P. T.*).—1, *Oncidium Jonesianum*; 3, *Scuticaria Hadweni*; 3, *Maxillaria grandiflora*; 4, *Masdevallia Harryana*. (*R. P. & Sons*).—We think your plant is a very distinct variety of *Cattleya Mossiae*, the sepals and petals highly coloured, and the lip beautifully veined with gold; but the flower is not of such good shape as some we have seen.

COVENT GARDEN MARKET.—JUNE 6TH.

SUPPLIES good, with business much improved, and prices firm.

THE BRITISH DAIRY FARMERS ASSOCIATION.

EXCURSIONS AND CONFERENCES IN EAST ANGLIA.

It was at a general meeting held in March, 1886, that the members of this Society resolved to hold an annual conference at some place or places in the provinces. In the following June the first gathering took place in Cheshire, which, as the leading

dairy county, did well to set so good an example. This was followed by visits to Derbyshire and Ireland, the latter being especially successful; and this year, in the fourth week of May, came a visit of the Association, extending over four days, to the great corn-growing district of East Anglia.

On the first day there was a butter-making contest in the Drill Hall at Ipswich, with both local and open classes, of which it is worthy of remark that all the prizes were awarded to butter made in end-over-end churns. Cream for the contest was supplied from local dairies, so that the competitors were upon a footing of equality as to quality of cream, and though prizes were awarded for skilful manipulation of the butter, yet Professor Long, the Judge, remarked subsequently of this Suffolk butter that it was as poor as could be, while at Norwich he found as good butter as anyone could desire.

During this contest Mr. W. H. Lynch of Ontario, Canada, gave an address on butter making, in which especial stress was laid upon four essential points:—1, The removal of all the butter milk. 2, The preservation of the grain, injury to which affected the flavour. 3, Even and properly salting. 4, Uniformity in quality. Then came a conference in the Council Chamber of the Town Hall, at which Mr. H. A. Howman of Tame Hurst, Kingsbury, Tamworth, read an appropriate paper on Dairy Farming in Arable Districts, and the remainder of the day was devoted to an excursion by water to Woolverstone Park Dairy.

On each of the following days the programmes were full—in point of fact they were too full, and on the last day there was such a multiplicity of engagements that the short intervals allowed at each halting place detracted from the pleasure of the meeting very much. Without giving the whole itinerary, we may mention visits to some of the best herds of Red Polls, to the Duchess of Hamilton's Pound Farm Dairy at Glenham with its herd of some fifty choice cows, its model cowhouse, and elaborate steam apparatus for driving the Laval Separator, the churn, as well as machinery for the preparation of the cows' food. Then to Easton Hall, then to Albert College, Framlingham, where a paper was read by Dr. W. A. Elleston of Ipswich on "Milk." Next to Bury St. Edmunds, where, in the Constitutional Hall, Professor J. Wortley Axe read an important paper on "Parturient Apoplexy," which though highly technical was much appreciated, and was followed by a practical discussion calculated to do much good. This paper was certainly the most valuable of all. Then came excursions to Ickworth Park, Carrow Abbey, the Whittingham Herd and Dairy, followed by a conference in the Agricultural Hall, Norwich, where Professor James Long read a paper on "Profitable Summer Farming." This, too, was a valuable paper, wherein Professor Long endeavoured to show that forage cropping and stall feeding produce a better result than grazing. He gave tables illustrating how much of each crop would keep a cow for six months, the result being that 100 acres of good grazing, and the same area of Clover or Tares, would keep 100 head of stock, while the powers of maintenance of other crops on the 100 acres were Trifolium, eighty head; Lucerne, 200; Sainfoin, 117; Rye Grass, 188; Rye, 117; Maize, 163; Sorghum, 160; and Cabbage, 133. The farther advantage claimed for such temporary crops over pasture was the inestimable value that they could be removed and succeeded by others. For this reason their value was almost double that shown in the figures.

The excursions throughout East Anglia culminated in a visit to Sandringham, where a pleasant surprise awaited the visitors in the presence of the Princess of Wales and the Princesses Louise, Victoria, and Maud. Many of the visitors went round the cow stalls with the Princess, who pointed out some of her favourites, and luncheon was subsequently served to some 200 guests in a spacious marquee near the dairy, the chair being taken by Sir Dighton Probyn.

Of the value of such meetings we can bear pleasant testimony, for we took some part in them, and derived much pleasure from the

keen discussions of points of interest in matters affecting dairy farming, which were constantly taking place. Men of mark, leaders in dairy farming were there from all parts of the country, and many of them were frank and outspoken with words of encouragement and advice. "Do not despair if you have a few failures," said one of them in a genial after-dinner speech, "I turn out upwards of 10,000 Stilton cheeses from my dairy every year, yet when we began neither I nor my wife had ever made a cheese." Suffolk cheese, though very much a thing of the past, was so bad that it is still a byword. "Why!" said Alderman Ridley at the dinner at Bury St. Edmunds, "the very dogs used to bark at it, but"—with a chuckle—"they could not bite it!" It was with regret that we heard the worthy Alderman go on to remark that very much of the butter sent into Bury now by farmers was not worth more than from 7d. to 9d. per pound. Can we wonder that such farmers declare that dairy farming, even in their small way, does not answer?

WORK ON THE HOME FARM.

Complaints of drought and cold are frequent; every change of wind is followed with anxiety, for upon the weather of the next few weeks depends the success or partial failure of many of the crops. A warm, dripping June would indeed prove a blessing, as in point of fact will the dry cold weather of the end of May, for has it not enabled us to grapple with our foul land as only such weather could do? Plough, harrows, rollers, have indeed done good work, because they have been freely used throughout the spring onwards to the present time. They must, however, be used with judgment, even under such favourable conditions, for when land is very foul with couch grass it requires to be left sufficiently long after each ploughing and stirring for the small pieces of grass root to die. For example, a farm which came upon our hands last Michaelmas had thirty acres which had been under a long fallow, and which was therefore presumably clean. We decided to sow it with Wheat, and after the drill and harrows had been used for that purpose we found many grass roots brought to the surface still alive. Now, we had in the valuation of this farm paid for a given number of ploughings upon the understanding that they had been done at proper intervals of time during the past summer; but we found that three of the ploughings had been done quickly without such intervals, and consequently the land was not left in as clean "summerland" ought to be. The reason of such hurried, improper ploughing was a want of horses to use for it at the proper time, and as the tenant was leaving the farm he would not be a sufferer from such bad practice.

Both Mangolds and Swede plants are now well above the surface, and the horse hoc has already been used to stir the soil well between the rows. The Swedes are wonderfully free from insects, and with some rain we hope for a full crop. Of white Turnips we do not require early roots, but the land is almost ready for sowing, which will be done in due course in favourable weather. Maize should now be sown in sufficient quantity both for use in autumn and for silage. The land should be rich in fertility in order to have a full crop, and care must be taken to keep off rooks, or they will uproot the whole of the seed. There is nothing for it but to have a boy in each field to keep them off, and it is surely worth while doing this to save so valuable a crop, which, if well planted, absolutely revels in a hot, dry summer, and gives us twenty times the bulk per acre of any other green crop.

REMARKS.

27th.—Rather misty all day.
 28th.—Hazy morning, cloudy afternoon, spots of rain in evening and night.
 29th.—Frequently cloudy, but with a good deal of sun in the middle of the day; solar halo in afternoon; rain at night.
 30th.—Variable morning, with a slight shower at noon; bright afternoon.
 31st.—Generally cloudy in the morning; bright afternoon and evening.
 1st.—Bright and fine morning; afternoon generally cloudy.
 2nd.—Cloudy till 11 A.M.; bright afternoon.
 Temperature gradually rising throughout the week. A frost on grass on Sunday morning, and on the following Saturday 79° in the shade and 126° in the sun. Very little rain except during the night between Tuesday and Wednesday.—G. J. SYMONS.

SOME weeks ago it was proposed by Mr. Howard, of Southgate, that an evening Fête should be held in the Covent Garden Flower Market for the benefit of the Gardeners' Orphan Fund, and as the idea at once received the hearty support of the Committee, the market authorities, and the growers, the project speedily developed into one of considerable importance. By arranging the Fête for Wednesday evening, the 6th inst., it was only necessary for the market growers who occupy the 370 stands for plants and flowers to bring in their wares an hour or two earlier than usual, the following being a market morning. This they readily agreed to do, and they entered into the spirit of the idea with most commendable energy, arranging their plants as effectively as possible upon the formal stages devoted to that purpose. No charge was made for admission, but large numbers of tickets were distributed free, and collecting boxes were placed at intervals throughout the building, to which the visitors voluntarily contributed, and it is highly satisfactory to learn that a sum of £227 was thus collected, including a handsome gift of £100 from the Duke of Bedford.

When the Market was opened to the visitors at 9 P.M. it presented a novel and brilliant spectacle, and never has this portion of Covent Garden been seen under such favourable circumstances. Every available space was filled with flowering plants of the richest and most varied colours, with groups of Ferns at intervals to relieve the preponderating brightness, and if it had been possible to obtain a general view of the whole market at once it would have had a wonderful effect. There were six avenues between the stands besides the end avenues, and each of these was a floral exhibition of a remarkable character, for the growers had not only brought freely from their stores, but they had also brought some of the best examples of their cultural skill. Beautiful and interesting as this Market always is, its appearance on ordinary occasions was far surpassed at the Orphan Fête, and it was estimated that the total value of the produce was something like £10,000, which must be considerably above the average. Buyers, no doubt, recognised their chances, and a most successful sale was held the following morning, nearly the whole of the enormous quantity of plants and flowers being cleared out before 9 A.M. on Thursday.

The Fête was visited by some thousands of persons, including many of the nobility, and the avenues were so densely crowded for two hours that locomotion was exceedingly difficult, and it was impossible until after that time to take a leisurely survey of the Market. The discomfort was partly caused by having two entrances near together, the streams of people converging into a third avenue a short distance from the doors, which for some time occasioned a rather serious block. In other respects the arrangements had been carefully made, the Market was well lighted, and an excellent band was provided, so that, with the exception of the crowding, the visitors could spend a pleasant hour in traversing the half dozen alleys or avenues through banks of plants and flowers.

The stands are upright wooden erections with three broad shelves, and all these, including the ground space in front, were closely packed with the specialties of the various growers; masses of the brightest scarlet Pelargonium alternating with golden Calceolarias, graceful Fuchsias, and the bluest of Lobelias, from which the eye turned with relief to cool fresh banks of Ferns or

Palms, the elegant fragrant *Lilium candidum*, or what was clearly in the majority, the Marguerites, or varieties of the *Chrysanthemum frutescens*. The latter constituted the most conspicuous plants in the Market, and it was surprising to see such fine healthy bushes covered with their white flowers in 48-size pots, while some specimens in a somewhat larger size assumed quite arboreal proportions. There is no question about the popularity of the Marguerites, and an enormous number must be grown, smaller plants than those named being employed in thousands for the window boxes of houses in the West End of London.

Pelargoniums of the Zonal, Show, and Decorative varieties were magnificent, and very rarely can these plants, especially of the last-named type, be seen so well grown as those brought into Covent Garden for sale at this time of year. They are grown on the rapid principle, for no time can be lost in market gardens, the space and labour are too costly, but the plants are sturdy, compact, vigorous examples, with dense heads of large richly or delicately coloured flowers, such as will endure the conveyance to market and some rough usage in the house decoration for which they are mostly purchased. Few varieties are grown, but these are selected for their combination of good qualities. Clear well marked colours, substantial durable flowers, and compact habit, are the points looked after, the finer qualities that commend themselves to the florists cannot be regarded.

Hydrangeas afforded another feature, the plants having huge heads of pink or blue flowers, over a foot in diameter, in small pots like the Marguerites, most telling in groups of foliage plants, and useful for the decoration of recesses in rooms. In marked contrast to these were the graceful specimens of *Saxifraga pyramidalis*, which were admirably represented on the Fête night, and this plant has evidently become a great favourite within recent years. The majority of those sent to the Market had many branched conical panicles of small white flowers, 2 feet or more high, arising from a neat rosette of leaves, 60 and 48-pots being the sizes employed. A year or two since much attention was called to these plants by the groups sent from the Royal Horticultural Society's gardens at Chiswick to the South Kensington meetings, and under the name of *S. nepalensis* it is also occasionally seen in gardens. As an easily grown plant of exceptional beauty at this time of year it is worth the attention of all who have large conservatories to fill, and it is abundant in nurseries now.

Charming little bush Heaths of the *Erica ventricosa* varieties were numerous, Roses in pots, Pansies of surprising size, Spiræas and Petunias, all occupied considerable space. Rhodanthes in thousands and Lilies comprised the chief of the plants in pots, but there were a few groups of a choicer character, consisting of Ferns and Orchids, for some of the latter plants have now become recognised as possessing "market value" amongst some purveyors.

One of the characters of market plants that strikes a horticulturist who seldom visits Covent Garden is the uniformity of quality prevailing. Inferior produce has no chance of commanding a sale, and growers soon find that out. The most successful are those who have taken up the culture of any class of plants coming into popularity, and giving them their best care, have made them specialties, at once commanding the attention of buyers. The selection or raising of improved varieties has also helped some men considerably, while throughout good culture is essential. There is no room for the laggards and the lazy, it is a smart contest between wits and energy in market work.

The cut flowers included hundreds of boxes of Roses, Irises, Forget-me-nots, Pelargoniums, &c., but as might be imagined the effective portion of the display depended mainly upon the plants in pots. The cross avenues, which are open on ordinary market days, were closed with groups of large Palms and Ferns, and in the recesses so formed were the collecting boxes, presided over by twenty-eight young ladies who had volunteered their services in

the cause of the Fund. Altogether the Fête was novel in character; so interesting, so brilliant, and so successful, that many have expressed a wish that it may become an annual event.

DIGGING AND STIRRING THE SOIL.

THE due performance of these well-known cultural operations demands no great mental capacity, yet they require a certain amount of knowledge and the exercise of judgment. Digging is not learned all at once, neither is hoeing, but "practice makes perfect," and that is the reason why the gardener's apprentice serves the kitchen, weeds, learns to hoe and rake, and takes a turn at digging and trenching, which gives him an idea of the requirements of an establishment and the means by which they are met. Initiation into work of this description is of primary importance, and instead of being derogatory to the gardener it is of great value, in fact, indispensable.

DIGGING.—According to the dictionaries—viz., Johnson's—this is "a loosening of the soil so as to render it more fit for the reception of seeds or plants," and the Imperial Lexicon defines it as "opening or turning the earth with a spade." Some soils can be worked very well with a spade, particularly when the intention is not to stir them deeper than the ameliorated surface. But everything depends on circumstances. If the soil will admit of a couple or more spade-depths being readily turned then I make no objection, but there are few soils except alluvial that will admit of such easy manipulation, most requiring if they are to produce full crops in continuity to have something more than a mere turning or loosening of the ameliorated surface soil. Turning the surface 4 to 6 inches deep with the plough, and 10 to 12 inches with the spade, gives rise to the difference in the resultant crops. Subsoil ploughing and trenching are still further characterised by values of produce in a ratio to the depth of soil available as a source of aliment. Soils differ very much in depth. All have a certain amount of ameliorated soil resulting of the disintegrating action of the atmosphere, rain, and the product of prior or existent vegetable and animal life, the combination effecting changes of a character essential to a continuous course of vegetation through the constant assimilation of nutriment in the soil. It is not enough to get a good result by ploughing when a better can be obtained by subsoiling, and if we can increase the products of the soil by trenching there is absolute necessity for its displacing digging. I am no great advocate, however, of subsoiling or of trenching, particularly under all circumstances, but the best results, so far as I have had opportunity of observing, have been on soils that admit of their performance. They, however, are not available for all soils or for all cultivators. Some soils have only a few inches depth of good soil over a subsoil of sand, gravel, or clay, or an admixture that is not of a nature favourable to a good tilth or to cultural operations. To put good ameliorated soil beneath 10 or more inches of sand, gravel, clay, or an admixture of stubborn material is subsoiling or trenching to the present injury of the crops, and is neither advisable nor justifiable in any sense as a cultural practice. Much in such a case may be effected through pulverisation, aëration, manuring, and working the soil, but some time must elapse ere it can be brought into a condition favourable to the germination of seeds or the speedy establishment of plants, and the increased labour entailed may render the whole transaction unremunerative.

In trenching, therefore, the nature of the soil must be considered. When the soil is good enough to allow of the bottom spit being brought to take the place of the top, and the bottom underneath broken up if necessary by a pick and left, we deepen and improve for all time the land for garden crops. Practised in autumn, the surface thrown up roughly for exposure, and manure being added, it becomes thoroughly incorporated with the soil, or sufficiently so by the forking over, which should follow trenching during the first dry weather that prevails in spring for cultural requirements. It is not always advisable to bring up the bottom soil at first, as that when of a stubborn nature is positively injurious to crops; consequently the soil ought not to be trenched deeper than the good soil extends, that is the better for being turned top to bottom. The bottom soil may be loosened with a fork, or, if necessary, with a pick, with manifest advantage, especially if it have some light manure, leaf soil, or the most reduced part of the rubbish heap, the woody portion being charred and mixed with it. The change effected in course of time will improve the whole soil by making it deeper. Its value will appear in the current crops, inasmuch as the rain will pass more freely through, and it will take in air and nutriment which follow the passage of water, enhancing the assimilation of food in the soil by the increase of air, warmth, and decomposition of matter.

There are other considerations that favour trenching. Cultivation has something more to effect than maintaining the soil in

fertility. The soil may be everything as regards tilth, yet the crops are not commensurate with its condition and the cultivation. The soil becomes rich in certain elements—decomposing matter, the result of preceding crops, and manurial applications, and filled with fungoid, insect, and other pests. Those detriments to successful practice are not to be trifled with, destructive agents must be used, or we must bury them well down in autumn to prevent their seeing daylight again. Inorganic substances, such as lime, have a tendency to descend, and the surface becomes a mass of organic matter, an intermixture becoming necessary for the formation of bases and plant food. Lime and potash may be present, but what good are they if beyond the reach of the roots?

Digging is only a primitive form of trenching; in fact trenching is often termed double-digging. Ploughing can only be characterised as an apology for digging, as demonstrated by observing the difference in the crops obtained by the two processes. By digging we stir the soil double the depth of the plough; the soil is more broken and intermingled; it is left more accessible to the atmosphere. But there is an advantage which dug land does not get in the dragging and the harrowing essential to the formation of a good tilth. These operations tend to loosen the soil in the spring, letting out water, and the warmth of the atmosphere is absorbed, which promote early growth, whilst the pulverisation forms a surface through which rain will pass freely, and also prevent subsequent evaporation. Autumn digging is all-important for pulverisation and the mixing in of manures. In such cases the surface should be left rough, for if left smooth and even it will, by the action of frost, have a surface of fine soil, and will not be nearly so warm, because there is more water in it than that which has been left through the winter in a rough state and turned over in early spring with a fork. This I have proof of in some land, part of which was dug in autumn level, and part by press of work had to stand over until early spring and was then dug even. Both were planted with Snowflake Potatoes in April, and now (June 2nd) those on the early winter dug part are 3 inches high, whilst those on spring dug are 6 inches high. The evaporation was greatest from the spring dug part because it was more open, and it consequently parted with water and took in air proportionately, and was more quickly warmed by the sun. This would infer that I advocate spring digging in preference to autumn or early winter; but, on the contrary, I advise, for all but very light soil, autumn digging, not breaking the soil with the spade, but throwing it up roughly. By that means there is a quantity of aërated and pulverised soil, and by turning it under we bring other less pulverised soil to the surface, which, if done early in spring, is sufficiently pulverised by the spring frosts to double the depth of the fine soil, forming a good tilth, and this is not only a good rooting medium, but admits of the free passage of rain, and is the best of all means of retaining the moisture for the benefit of the crops through the growing season, not being liable to crack, and admitting of expeditious cleanly culture.

That is no doubt the best way to treat heavy soils, but light soils I do not consider are improved by autumn digging or manuring. Such are fine enough and poor enough to begin with. They are best left alone during the winter, or if necessity prompt then by all means break the soil, but do not throw it up roughly, and if manure is used let it be fresh or rough. The strength of the manure will be incorporated with the soil by spring, and the land will be sufficiently loose for ordinary crops without further need of stirring it with the spade. Medium soils are best thoroughly dug in autumn, adding the needful manure, but light soils I would never trouble about digging until a short time before it is necessary to do so for putting in the crops or for cleanly culture, for to turn weeds under not being of a perennial character is a source of fertility and far too little practised.

Double digging is only another term for trenching, unless it be that the soil is only turned a spit deep, the top soil being left where it was but turned on the bottom spit, which is also turned and allowed to remain. It is a capital plan where the subsoil is poor. A better plan is to mix altogether as in turning a manure heap, keeping enough good soil on the top to secure ready tillage, and the best of all is to trench soils that admit of it every third or fourth year, and those that are not available for trenching should be stirred as deeply as possible.—G. ABBEY.

(To be continued.)

MY AURICULAS IN 1887.

As I have never been much of an exhibitor, and have long since given it up altogether, I have the pleasure of growing my small collection for my own gratification, and that of those friends who may kindly visit my garden. I am sorry to say that those who do so and can appreciate the refined beauty of the Auricula are

very few, and this is one great disadvantage of living so far away from the "busy haunts of men." Were I residing on the outskirts of London, for example, I could have many an opportunity of seeing other people's collections, and of having them to visit my own garden, but this is denied me, and I must take it as one of the "cons" against the many "pros" of a country life. However, one has the advantage of not being in the feverish state which seems inseparable from the very calmest exhibitor. I am in no worry as to whether this or that plant may be in bloom by the show day, or whether this other will be over, or whether I should put this one under a cap glass, as used to be sometimes done to open it better. Still there are undeniable pleasures in exhibiting, and were it nothing else, it brings one into close contact with those of a kindred spirit. I have, unfortunately, neither the patience nor the neat-handedness necessary for the hybridiser, and consequently I miss the pleasure of seedling raising. Besides, when one has reached the allotted span, seedling raising is, I fear, a vain dream, reminding me of a sturdy baronet in my neighbourhood who met with an accident in breaking in a horse for his own use when he was verging upon eighty. However, Auriculas have for fifty years given me many an hour of pleasant enjoyment, and I am quite as fond of them as I have ever been. My own collection is not a large one, but it contains, owing to the kindness of friends, most of the good sorts which I should not otherwise have had, for I do not care to pay highly; and while there are some of the old ones that I may perhaps discard if my stock of the better sorts increases, I cannot but feel how problematical it is that this will ever be in the few years which at best I can hope to see.

A dead set seems to have been made on the "friends of our youth," but I should be wanting in gratitude if I did not lift up my voice for some of them, and of those, too, whose acquaintance I made in middle age. I hope that I am not prejudiced, and I fully recognise the very great beauty of many (although not by any means all) of the flowers which have been raised of late years, and which have received honours. There may be, perhaps, some of the "sour grape" feeling, but withal that I, being obliged to grow many of the older varieties, still find beauty in them. There is no reason why the rate of progress should not hold good with the Auricula as with other flowers. It presents, it is true, greater difficulties, but that only requires greater patience. We have seen (at least I have) the beautifully round and brilliant coloured flowers of the Pelargonium, and can recollect such flowers as Garth's Joan of Arc, which created a furore in its day, a flower we should now stigmatise as starry and ill-shaped. We have seen the small Tuberosus Begonia so improved as to become almost too large for our requirements, and so on; but then there is this difference, we may soon expect, when we hear of anything remarkable in such plants, to get them for ourselves. Now those who raise seedling Auriculas are few in number, and I do not see why they, setting before themselves a high standard, should not be able to reach the same height of success as some have already attained; but we look on and admire, but do not expect to add them to our collections. Auriculas cannot be propagated as other plants. There may be some which by nature are prolific in giving offsets, such as Acme, Conservative, Traill's Beauty, and many of the selfs; there are others which will hardly give one in a year, and I fancy few care to cut the head off a fine plant in the hope of its yielding offsets, and hence the high price which many still maintain, even although they may have been in commerce for twenty years or more.

I have ceased to have any anxiety about the woolly aphid which some years ago so bothered me, not that I am free from it, for on turning out my plants I found it still with me, but I am doubtful as to its injurious effects if ordinary care is given to the plants. If they are not potted too low, and the collar well kept above the soil so that it can be watched, the effects of the aphid on the roots is not injurious. Doubtless if they were not disturbed, but allowed to work their own sweet will, it would be otherwise. Not only does the Auricula afford them a home, but I have found them on the plants of many species of Primula which I obtained from a well-known nursery in the North, and I have found them on Lettuce roots, and even on weeds in my garden, so that I do not see much prospect of getting rid of it, and as the general character of my collection last year was healthy, I must submit to what, I fear, is the inevitable.

I lost a few of my larger plants by rot or canker, which seems to attack them for no reason whatever that I can see, and I have often wondered whether it may not be a constitutional defect belonging to the Primulas, or at least to some of them—*i.e.*, whether they are not really more shortlived than we imagine. There are many species which are used in the rock garden which, although described as perennial, are little better than biennials, and of which it is necessary to keep up the stock by continual sowing of the seed. On wild Primroses it is very difficult to speak, they are

continually seeding, and seedling plants spring up around the habitat of the parent, but whether it dies or not I do not know, but *P. rosea*, for example, becomes, with me at any rate, very inferior after a couple of years or so, and apparently requires to be treated almost as a biennial, although it does not absolutely die after the second year of flowering. I had some fine but oldish plants of Richard Headly, which for some reason or other last year dwindled away. They did not die, but neither did they live; at least did not show much signs of life, and did not flower this spring, and as they were treated in the same manner as the others, I can only conclude that it is something of this kind of constitutional old age which has weakened them; at least I can discover no other cause than this. I will next refer to varieties.—D., Deal.

(To be continued.)

VEGETABLES FOR EXHIBITION.

CUCUMBERS.

FOR exhibition purposes Cucumbers must be quickly grown, straight, even sized, short necked, dark green in colour, and carrying a good bloom. Very rarely can old plants be made to produce fruit meeting nearly or quite all these requirements, and in most instances it is advisable to raise a few plants especially for the production of exhibition fruit. The majority of provincial or local shows are held late in July and early in August, and long before that time the plants started in the winter or spring months are in an exhausted state, and most probably infested with red spider. Instead, therefore, of relying upon these to yield presentable fruit, it will be found far better to sow seed about nine weeks before the date of the show, singly in 3½-inch pots, and set in gentle heat to germinate. They should be raised and kept growing well clear of any other plants likely to be infested with any kind of insect pest, and if the site is not ready for them by the time the pots are becoming filled with roots give them a shift into 6-inch or larger pots, using a fairly rich loamy soil. These precautions are necessary, as to start with either dirty or badly rootbound plants is to court failure from the first.

Whether the plants are eventually grown in houses, frames, or pits, must depend upon circumstances. They are certainly more under control, and produce the cleanest and straightest fruit in a house, but capital produce can also be had from plants in pits and frames. They succeed admirably on the north or shadiest side of a span-roofed house, or on the back portion of a three-quarter span-roofed house, Melons being grown if need be on the front or sunniest side of the structure. If a slight hotbed is formed this will give the plants a strong start, and the roots will soon take possession of the heating material. With good attendance they will thrive for a time quite as well in mounds of soil only, placed on a slate or trellised bench. A heavy clayey loam is altogether unsuitable for them, this better suiting Melons; but if it must be used let it be as rough and turfy as possible, and add plenty of burnt soil, charcoal, and leaf soil. If light turfy loam is available little else need be used, and in any case no partially decayed manure should be added, this soon clogging the soil, and also is a frequent means of introducing the tiny worms which cripple the roots so badly as to cause a complete failure. The plants may be placed out about 4 feet apart, and mounds equal to about two bushels of compost is ample for each at the outset. Plant as soon as this is warmed through. Rub out side shoots until the trellis is reached, when the plants may be stopped and encouraged to form two or three strong shoots, which, in their turn, may be stopped at the third or fourth joint, the breaks following upon this stopping being sufficient to lay the foundation of a profitable plant. Do not let the plants bear heavily, if at all, long before the date of the first show, and about ten days before they are wanted select four or five of the best formed young fruits, and after these have flowered and made sufficient progress to guide the cultivator in his selection, reduce the number to two or three fruits on each plant. Stop the branches at the second joint beyond the fruit before the use of a knife is necessitated, and also thin out superfluous growths so as to avoid unduly crowding the foliage. This treatment being persevered in, the plants will continue to produce handsome fruits suitable for any purpose. The roots ought not to be confined to the small heaps of soil, and should receive occasional light surfacings of turfy loam or as fast as the old compost is filled with them.

If only a few fruits are wanted, and that quickly, they may be either planted in tubs, large pots, or in mounds of soil about 3 feet apart, and taken up the roof without stopping, or much as Melons are trained. The laterals will be thrown out at each joint, and in most instances will form a cluster of fruit at the first and second joints. Stop at the leaf beyond these, and also freely thin out the young fruits, not leaving more than two or three of one age to

mature. The leader need not be stopped till the limit of roof trellis is reached, and a good succession of handsome fruit ought to be produced throughout the whole length. As a rule plants thus trained and closely cropped are scarcely worth keeping after the uppermost fruits have been cut, but if they are in good health the sub-laterals should be frequently thinned and stopped at the second joint, and many more fruit obtained. Cucumbers have been cut in about six weeks from the time of sowing the seed, but in this case they were grown at an express rate, and not less than eight weeks had better be allowed.

Old house-grown plants, or those that have done good service for several weeks or months past, can sometimes be brought into a vigorous condition again and capable of producing fairly good fruit. It is useless to make the attempt with plants badly overrun by red spider, mealy bug, or other pests, as none of these can be got rid of short of destroying the foliage. The first proceeding should be to freely thin out the haulm, removing as much of the old growth as possible, and also the greater portion of any fruit that may be hanging. Next loosen the surface soil, removing any that is sour, or which is not occupied by roots. Give a good watering if need be, and top-dress with roughly chopped turves, or a compost such as I have previously described. Then if a brisk "growing" temperature is constantly maintained, the plants being frequently syringed and plenty of moisture distributed about the house, fresh growth will soon be formed. This should be allowed to ramble to a good length before the points are taken out, and the subsequent breaks will produce fruit in abundance. A heavy crop ought never to be left on plants that are to produce exhibition fruit; in fact it is very necessary that Cucumbers for all purposes, if they are to be continuous cropping, must be prevented from bearing as they please, or otherwise gluts will result at one time and scarcity at another.—EXHIBITOR.

(To be continued.)

GARDEN FARMING.

It is somewhat late, but better late than never, to direct attention to an exhaustive article under the above heading in the *Quarterly Review** for April. The volume did not reach us till a considerable time after its publication, and then the pressure on our space was great. The subject, however, is not of an evanescent nature, but of permanent interest, and never out of date. The writer of the article appears to have a good grasp of his subject, and seems to have spared no effort in acquiring information, statistical and otherwise, to render his deductions reliable and his work of substantial value. The extent of nurseries, market gardens, and orchards are tabulated, and their areas compared with former years. We next find statistics given on Potato culture, with the extent and value of importations from the Continent and Channel Islands, these being mainly of early produce. As regards late Potatoes for winter use, which those who do not know how to grow them say they cannot be grown profitably, we find an enormous increase in their culture in the chief English Potato-growing counties, but a comparatively slight decrease in the less favourable climate of Scotland. Full crops of late Potatoes are still remunerative, if we may judge by the evidence of the best growers, and a considerable export trade was opened last year with America, the extreme severity of the winter there preventing the produce of the Northern States reaching the great centres of consumption.

The sources of supply of different kinds of vegetables and fruits, with indications of the bulk and value of the produce, are brought under review—Asparagus, Broccoli, Beans, Seakale, Onions, Mushrooms, amongst the former; and in respect to oversupply and loss in culture that occasionally occurs, the author points out two evils—faulty distribution and high railway charges—on this twin question observing:—

"Mr. Whitehead and others contend, not only that the home supply would not be too large, if we had a better system of distribution, but that it might well be increased to a great extent. The fact that rail charges and the salesman's commission often balance, and sometimes exceed, the amount realised by vegetables sent to market, is alone a strong indictment against the existing system. It is to be observed, moreover, that in seasons of the greatest plenty, when the markets are supposed to be glutted, and growers get extremely small prices, millions of the population are short of vegetables on their dinner-tables. The poor can buy vegetables more cheaply in the markets of the East of London and in such great centres as Manchester and Birmingham, to which large supplies are constantly consigned, than in the small towns or even in the villages of the rural districts. People who require the greengrocer to call for orders, and afterwards to send to their houses vegetables worth a few pence, must expect to pay more than double, or perhaps four times what the grower receives; but there should be

markets in all towns where the poor can obtain their supplies at much less than the greengrocers' ordinary charges. Mr. Hunt says, that rail rates for green stuff from Evesham to many places, including London, are prohibitive, and are very high for everything; also that small growers are placed at a special disadvantage by the large extra charges on small quantities of produce. It is a common complaint, too, that the rail charges on vegetables for short distances in this country are much higher comparatively, and in some cases absolutely higher, than the rates for the same kinds of produce imported from France or Holland. Another grievance is that, whereas the foreign produce is conveyed by fast boats and express trains, the home supply of vegetables is mostly carried by goods trains, and 'shaken and smashed up,' as Mr. Whitehead expresses it, 'by the bumping and banging occasioned by "picking up" at the various stations.'

In respect to fruits, we find an admirable digest of the supply of Apples, Pears, Tomatoes, Grapes, Strawberries, and various bush-fruits, with the quantities grown and the value of the crops so far as can be ascertained. The writer, like many another, seems to have been in a little doubt as to whether to place Rhubarb amongst fruit or vegetables; and though he correctly says in a strict classification it would be placed among vegetables, but as it is used as a fruit, he lets it remain on the American compromise as the "Pie plant." He appears to be cognisant of the culture and forcing operations of Rhubarb in the Leeds district, which are more extensive than is generally known, though of course enormous quantities are forced in the market gardens round London.

The works consulted and duly acknowledged in the preparation of the article are Hogg's "Fruit Manual," Barron's "Apple Congress Report," and "Vine Culture," Whitehead's "Market Gardening and Fruit Farming," Wright's "Mushrooms for the Million," Rivers' "Miniature Fruit Garden," Bunyard's "Fruit Farming for Profit," the *Field* newspaper, and the "Agricultural Returns." Thus its comprehensiveness will be understood; but there is an important description of the garden farming in the Channel Islands which appears to be founded on personal inspection of the work, for the author observes:—"Without a visit to the scene of their untiring labour it is impossible to gain a fair conception of the excellent use which the Channel Islanders make of their land and their opportunities. Depression has been felt by them, it is true, but only to the extent of a diminution of great prosperity, which is almost entirely owing to the fall in the value of cattle and the failure of two banks, and has little, if anything, to do with garden farming. It is also true that the enormous prices which the pioneers in the supply of early produce obtained some years ago remain only as memories; but where one man obtained handsome returns from Covent Garden twenty years ago, there are now ten or more receiving thence much larger sums, and fair, though not such extravagant profits."

The extent of early Potato growing in Jersey, with the cost and profits of culture, are interestingly described, and it is stated that the export of 50,670 tons last year showed an average return of upwards of £67 per acre, the total cost incurred in production being estimated at about £45; but the land, we are told, "is becoming more and more occupied by Frenchmen." We are now tempted to cite a few paragraphs—a mere fragment of the article—of which they display its general character.

"The most extensive owner of glass houses in Jersey is Mr. George Bashford of St. Saviour's, who has now about 12 acres occupied with glass houses and the necessary roadways, and expects to have his whole garden of 13 acres utilised before the end of next year. The remarkable success of this enterprising garden-farmer, who entered into the business, which has grown so rapidly under his management, without any previous training as a gardener, is one of the wonders of the Channel Islands. Better management is probably nowhere to be found than Mr. Bashford's, and a brief description of his crops will serve as an illustration of those grown under glass in both islands. He has a great quantity of Potatoes in his houses, with Tomatoes planted between the rows, some being artificially heated, and others not. Mr. Bashford does not force his Potatoes, however, but plants those in hothouses a month later than those in cool houses, so that all come to be raised at about the same time; his opinion being that foreign Potatoes is not sufficiently remunerative. Last year the average price he obtained for his tubers was 7½d. per pound, and he commonly produces as much as 11 tons to the acre, and has grown at the rate of nearly 20 tons. In 1873 he sold Potatoes at 2s. 3d. per pound, but does not expect to realise such a price again. The price last year was 7d. to 9d.

"French Beans are grown in hothouses between rows of Tomatoes, to be picked in January and February, when they sell at 2s. to 2s. 3d. per pound. Some years ago the price was no less than 6s. per pound. Peas are produced in cool houses only, picking being begun early in April, when the price is 1s. 6d. per pound. Cucumbers also are grown, to be succeeded by Tomatoes for winter use.

"Mr. Bashford has sent 80 tons of Tomatoes to London in a year, and now that he has increased his area of land under glass he expects to grow 120 tons per annum in a favourable season. His average price last year was 6½d. per pound. Tomatoes, with or without French Beans or

* John Murray, Albemarle Street.

Potatoes, are produced in the same houses as Grapes, until the Vines cover the glass, after which the shading would be too much for Tomatoes, though early Potatoes can be raised and matured before the leaves of late Grapes cover the glass. In the middle of March, even in this late season, Mr. Bashford had begun to pick fruit from his earliest Tomatoes, some of which were 5 feet high. The bulk of those in heat are ready by the end of March, and those in cool houses come for picking by the end of June and in the following months to the end of autumn.

"Last year Mr. Bashford sent 25 tons of Grapes to London. He has two houses with double walls lined, as are the roofs and floors also, with sawdust, to keep out frost, in which he can store 12,000 bunches of Grapes, the stems being inserted in bottles of water. The fruit is thus stored in the middle of December, and kept for a month or two until the price is high.

"If Jersey is the Island of Potatoes, Guernsey may fairly be termed the Island of Glass. In or near St. Peter's Port there are several extensive establishments similar to that just described, though none at present as large, in which Grapes, Melons, Tomatoes, and early vegetables are produced. But what is more remarkable is the great number of glass houses on the small farms, and even in the cottagers' gardens. Nearly all of these are cool houses, in which late Grapes, Tomatoes, Peas, and Potatoes are produced, forcing being, as a rule, only practised by the extensive growers, and in gentlemen's hothouses. Flowers and salad, too, are cultivated for export by market gardeners, and Broccoli by the farmers.

"Guernsey is not so well fitted as Jersey for the growth of early vegetables out of doors, chiefly because the slope of the former island faces the north instead of the south, and frost is more common. It is not surprising, then, to see that the cultivation of Potatoes in Guernsey has declined, or that rents are much lower there than in Jersey. The total area of land occupied in 1887 in Guernsey and the smaller islands is returned at 11,773 acres, only 877 acres of which are under Potatoes, as compared with 1044 acres in 1877. Rents range from as low as £3 to nearly £10 an acre, but the most common sum appears to be £6 or £7, or about £3 less than in Jersey.

"An excellent instance of enterprise on the part of a Guernsey farmer is to be seen in the case of Mr. Le Pelly, who farms about 35 acres of land. He grows Potatoes, Broccoli, and other vegetables for export, and this year he has sold the crop of Broccoli as it stands at £36 an acre. Last year he erected an excellent glass house, 100 feet by 36 feet, at a cost of £230, and grew in it over 2½ tons of Tomatoes, sold at £74, which was a pretty good return for the first year on his investment. As an instance of a greater money return than that obtained for Broccoli by Mr. Le Pelly, we may state that the price for Tomatoes in the middle of March was 1½d. each in London, or 1d. clear of expenses of carriage and sale. As nearly 10,000 Broccoli are grown on an acre, the net value of the crop is over £40 an acre, which was realised on one farm visited last March; and these vegetables are off the land in time for another crop of some kind to be grown this year."

This exhaustive and valuable contribution to the "Quarterly" concludes as follows:—"Although we are far from underrating the natural advantages enjoyed by garden-farmers in the Channel Islands, we cannot fail to see that there is a great deal in their practice which might be extensively imitated in the United Kingdom. Early Potatoes, with other green crops to follow in the same season, might be grown in the south of Ireland, and in some parts of the south of England, to a greater extent than at present, and almost if not quite as advantageously as in Jersey; while a few enterprising Englishmen have already proved that the extensive use of glass in the growth of certain kinds of produce can be as successfully practised here as in Guernsey. No doubt it would be easy to overdo this description of enterprise, but it will be time enough to think of that when something more than a beginning has been made."

EXCESSIVE MANURING.

CULTIVATORS as a rule are anxious to give their plants and crops as much manure as possible, but in many cases this is quite overdone. I have had crops of Peas, Beans, Cauliflowers, and Onions pointed out to me that were said to be "growing in almost all manure," and yet they did not succeed as well as those in poorer soil. This could not be understood, but I think it is easily explained. In the hope of having extra good produce a piece of ground is opened for Peas. A thick layer of manure is placed at the bottom, a little soil on this, and the seed is sown. So long as the manure and soil are moist all may go well, but when the hot dry weather comes, such as was experienced last summer, the manure becomes dust dry. What roots were in it perish, no more penetrate it, and the plants have only the top and surrounding soil to live on. Further, this mass of dry manure acts as drainage, and the plants suffer more and more. I have seen Peas planted under these conditions hardly produce one gathering of pods in July and August. Onions, again, are very apt to fail from the same cause. A mass of manure is placed under them, the roots penetrate it, but when the dry weather comes they cease to form good bulbs, and terminate in only having "thick necks."

I am altogether opposed to those masses of manure where drought has to be contended against, and I neither use them nor recommend them. Where the manure is well worked through the soil it is quite different, as the roots have a substantial mass to take hold of, drought is slow in having any influence, and the plants are both substantial and fruitful. I am of opinion that soft pithy Celery is mainly produced by the plants growing in too much manure; and by using it in moderation, and, above all, mixing it well with the soil, the sticks are invariably firm throughout. This rule also applies to plants in pots. Where too much manure is used the plants only make long soft growth. They are almost constantly in want of water, and they are very apt to become too dry.—J. MUIR, Margam.

LEPTOSPERMUM BULLATUM.

AT several of the recent exhibitions Messrs. J. Laing & Sons, Forest Hill, Messrs. Cutbush & Son, Highgate, and other firms, have shown examples of this graceful greenhouse plant, and at the Temple Exhibition

FIG. 64.—LEPTOSPERMUM BULLATUM.

of the Royal Horticultural Society some specimens from Forest Hill were particularly noteworthy. It forms a compact shrubby plant, with narrow leaves and abundant white flowers, slightly tinged with red in the centre. Similar treatment to that accorded ordinary hardwooded plants suits it, and though the individual flowers do not last very long, there is a good succession.

ARTIFICIAL MANURES.

I SEE that my worthy opponent has been infusing new life into this pleasant and, I trust, useful controversy, by striking out right and left with renewed vigour, showing how my bold assertions require propping up, and then claiming the theory of those assertions as his own. He next turns his attention to a case mentioned by "B.," and after criticising him in one paragraph and applauding him in another, finishes by a desperate attack upon what he terms my "experimental trials," and my want of "experience" in conducting them. There are always two sides to every question, and the only way that I can account for the conclusions Mr. Coombe has arrived at is that he has been using those great advocative powers, which I have already pointed out he possesses, by placing those points that tell in his favour prominently forward, and in

his diligent search for them quite overlooking a few others, which I think should be kept in view.

Why he should consider I have finally settled the point regarding the use of nitrate of soda in his favour I cannot understand, as I have throughout this debate continually and consistently recommended changes of food to be given to plants, such as liquid manures from stables and cowhouses, to be varied at intervals with guano, nitrate of soda, and such stimulating substances, and I have already pointed out that the manure and urine of animals are rich in the solidifying agents, and in the case of pot plants the soil used is invariably rich in potash and phosphoric acid, and unless these elements are present in sufficient quantity the nitrate of soda will not have its full effect, as a vigorous growth cannot be built up without solidifying agents are present, but when they are present and too large a quantity of soda is given, it causes vegetation to draw out from the soil large supplies of these elements, and consequently to produce a greater amount of vigour than can be properly solidified by the influences of light and air. This is why I contend the best results are produced by using the nitrate in the way I have advocated. That is given whenever the result of daily observation shows that more vigour is desirable, taking into consideration the varying conditions of weather in each particular season. On his foundation my answer to his query, "Does the constitution of a plant improve because its bulk increases?" will rest securely. It is not altogether a question of keeping a plant merely in health, but also of enabling it to produce the greatest amount of vigour that can be attended with the best results. And I maintain that this is the better accomplished by applying stimulating substances at intervals instead of forming them into a "properly proportioned combination," so as to bring out the full productive powers in the soil at a time when the strain on the plant's energies is the greatest. This is no "fad," but a fact.

After having duly refreshed my memory by referring to what Mr. Coombe has already written on this subject, I fail to find a single instance in which he has taken into consideration the various stages of growth that plants pass through and the condition they are in at the time he would apply manures, but I do find that he has shifted his ground considerably. In one of his earlier contributions he pins his faith upon fanciful mixtures, which he dubbed by the euphonic title of "properly proportioned combinations of the elements needed," but I am glad to notice he is gradually abandoning that idea as unnecessary, if not impracticable. Unnecessary, because experience teaches us that for practical purposes no better results are obtained by the use of the minutely proportioned mixtures so long as the principal constituents of plant food are present, and impracticable because the method of compounding manures in the same way that a druggist does medicine, which the enthusiasm of my opponent led him to believe would become a special feature in gardens of the future, would be worse than useless unless gardeners had also sufficient scientific knowledge to analyse the soils they had to deal with, otherwise they would compound manures proportioned according to the constituent parts of plants to be supplied with it, while the soil in which they were growing would contain an excess of those elements and a deficiency of others, which would throw those calculations out of balance. But to do my opponent justice, I do not think he really believed seriously in such mysterious compounds. That idea was simply intended as an artistic embellishment for his article. But it is by results that these "fads" must be judged, and not by words.

I feel somewhat flattered by the generous tribute my opponent has paid to my rapid advance in the attainment of scientific knowledge, but I felt it behoved me to arrange a few scientific facts within my reach in such a way as to show that my practice is compatible with theory in its surest form—viz., when it has been proved to be correct; and I venture to suggest that possibly Mr. Coombe has been busy in that direction himself of late. I cannot admit that the system of giving plants such changes of food as are known to produce highly satisfactory results is a haphazard one, but I should call it both rash and haphazard to depend on a certain chemical combination manufactured according to the elements of which plant life is built up, without any regard to the quantities of each already in the soil, and by going in for these nicely proportioned combinations much needless expense is often incurred unless the soil is analysed to find out the exact quantities of each it contains; and even then, when we consider that sometimes a given crop takes up a much larger proportion than at others, which science as yet cannot explain, we are compelled to look for some other way of working, and on these lines I have striven to maintain this controversy, in the first place by advocating changes of food which are known from experience to be good, and in my latest article showing how that system agreed in the main points with scientific theories.

I have repeatedly observed ample proofs of the advantages to be derived from giving certain portions of plant food at various stages of their development, and we have recently had a notable illustration of the wisdom of that practice by applying lime to Peach and Nectarine trees during the stoning period, the result being even beyond our expectation—much better than when given at the winter dressing; and the conclusion I draw from this is that there must be a greater demand for that substance while the stoning process is going on than at any other stage of development, and consequently a supply is needed at that critical time.

The portion of Mr. Coombe's article in which he criticises the case mentioned by "B.," I need not enter into, as it will doubtless be dealt with by that writer with his usual force and clearness; but as my

opponent has devoted the two concluding paragraphs of his article to a vigorous attack upon what he chooses to call my "fads," and "the experience I hold so dear," I feel somewhat disposed to correct a few of his random statements. Referring to the question, Does nitrate of soda leave the soil in an exhausted condition? he says, "Can he (meaning myself) not see that the quotation he gives directly supports what I advised at the commencement, that it should not be used alone, but combined with other substantial plant foods?" I reply, Certainly I cannot, nor do I see by what process of reasoning he can do so, as the quotation I gave plainly shows how illogical it is to raise any objection to the use of nitrate of soda, because it transforms into produce the raw material at its disposal in soils and in manures, and thereby increases the yield. He also again repeats, but if the phosphoric acid and potash should unfortunately not be present in consequence of repeated applications of nitrate. Now he would not have asked that question in this case if he had not altogether overlooked one fact, that the quotation I gave pointed out the importance of returning to the soil the amount of phosphoric acid and potash the crop had taken from it before another crop was sown or planted, and then stimulating manures should again be used at intervals to produce the greatest amount of vigour found to be desirable. I stated in my last article that the nitrate and ammoniacal manures should not be combined with the other materials because they are not fastened up by the soil, but remain freely moveable, and a residue not quickly taken up by the plant would be dispersed, and consequently wasted. In answer to Mr. Coombe's charges of inconsistency, let me ask him to refresh his memory with a glance at his second article on this subject, he will there have the satisfaction of seeing he himself admits the inconsistency; and as to the anomalous position he asserts I have placed myself in, I am inclined to regard that statement as an exaggeration.—H. DUNKIN.

ROSE SHOWS IN 1888.

- June 26th.—Boston.
- " 28th.—Brockham and Ryde.
- " 30th.—Eltham, Colchester, and Reigate.
- July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
- " 4th.—Croydon, Dursley, Farnham, Hitchin, and Richmond (Surrey).
- " 5th.—Bath, Farningham, and Norwich.
- " 6th.—Sutton.
- " 7th.—Crystal Palace (National Rose Society).
- " 10th.—Gloucester, Ipswich and Oxford.
- " 11th.—Ealing and Tunbridge Wells.
- " 12th.—Birmingham, Carlton-in-Lindrick, and Winchester.
- " 14th.—New Brighton.
- " 16th.—Newcastle-under-Lyne.
- " 17th.—Leek and Ulverstone.
- " 18th.—Birkenhead.
- " 19th.—Helensburgh.
- " 20th.—Darlington (National Rose Society).
- " 21st.—Manchester.
- " 24th.—Tibshelf.

In the above list the only exhibitions not held by the National Rose Society, or by Societies in affiliation with it, are those at Birmingham, Boston, Carlton-in-Lindrick, Dursley, Manchester, Newcastle-under-Lyne, and Richmond. In the case of Birmingham and Boston, where the shows extend over two days, the date of the first day's exhibition only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

SEASONABLE WORK.

STANDARDS present but a poor appearance, so many of them being either killed or badly injured by frosts during the past winter. The dwarfs, notably those on their own roots, are, fortunately, in excellent condition, and, in fact, are improved by the rather severe shortening of the old wood, much of it having been killed to within 6 inches of the ground. All ought to have the young growths thinned where crowded, the useless spray especially. The early removal of a great number of side buds is also most beneficial, those reserved being much improved thereby both as regards size of blooms and the substance of the petals. In most instances the central buds are preferred; but if these are damaged in any way, or are deformed, they ought at once to be pinched off, and a prominent side bud reserved. It is also advisable to remove a few central buds on each bush, and this will insure a better succession of bloom, the side buds usually being the latest. A good look out for maggots ought to be kept. The ground about the Roses, being in a half-moist condition, is just right for receiving a liberal supply of liquid manure, such as the drainings from a farmyard, or a light surfacing of artificial manure, may be washed in with advantage. If fine show blooms are required something of the kind must be given, and even if not wanted for exhibition well "built up" flowers last much the longest in a cut state. Before a watering is given the surface of the ground should be lightly forked, and subsequently a liberal mulching

of strong manure, short grass, cocoa-nut fibre, leaf soil, spent tan, or even dry soil, ought to be given. If the manure proves objectionable, cover it with a little soil.

THE EARLIEST ROSES.

Yellow Banksians are among the earliest to flower against sunny walls, and in some seasons the white variety proves an excellent companion. This year, for some unaccountable reason the latter has not done well. Medium-sized well-ripened shoots produce wreaths of bloom, and they ought, therefore, to be preserved as much as possible, and the more rank growth cut away early. Madame Bérard, a variety much resembling Gloire de Dijon, and really superior to that old favourite, is now flowering grandly, and is very useful for cutting from. Early formed and fairly strong growths of both varieties will usually develop a bloom at nearly every joint in the autumn. They ought to be only lightly secured to the walls for a few weeks, and if, when the wood is firm, these shoots are given a good curve this will insure a plentiful supply of blooms. Climbing Devonensis is now flowering freely, and will continue to do so for several months. Young growths should be laid in or taken care of, this tending to keep the trees in good health. Safrano is one of the first to flower freely and in a bud state is very beautiful. A free use of the knife improves this variety as well as Madame Falcot. Catherine Mermet is very fine against a sunny wall, and care should be taken of the strong suckers pushed up from plants on their own roots, these branching and flowering strongly. Maréchal Niel was much injured during the past winter, and only a few blooms are formed or forming. Any long shoots on this variety should be tied or nailed to the walls, as it is these that will produce much the finest blooms next season. Old plants in pots, or any struck early and duly hardened, may be planted against a sunny wall, and will frequently, if given good loamy soil and well attended to, grow vigorously. It is quite a mistake to depend upon old plants of Maréchal Niel, the wisest course being to plant a few every year. The Bourbon Souvenir de la Malmaison flowers early and late against sheltered walls, and is also one of the first to flower in the open. It succeeds best on its own roots, the finest blooms being obtained from the strongly branching sucker growths. In the case of Teas and Hybrid Perpetuals generally it is a decided advantage to have early blooms, and these being cut as fast as they open causes an early second growth, and consequently a good succession of flowers.—W. I.

UTRICULARIA CAMPBELLI.

MR. F. BOYLE contributes to the June number of *Longman's Magazine* an interesting article upon "An Orchid Farm," in the course of which the following passage occurs relative to a new "scarlet Utricularia," which is imported in the axils of Vriesias.

"A little story hangs to the exquisite *U. Campbelli*. All importers are haunted by the spectral image of *Cattleya labiata*, which, in its true form, has been brought to Europe only once, forty years ago. Many thousands of pounds, many years of adventurous travel have been spent, in the aggregate, upon efforts to rediscover it; in vain. Some time since, Mr. Sander was looking through the drawings of Sir Robert Schomburghk, in the British Museum, among which is a most eccentric *Cattleya* named—for reasons beyond comprehension—a variety of *C. Mossiae*. He jumped at the conclusion that this must be the long lost *C. labiata*. So strong indeed was his confidence that he despatched a man post haste over the Atlantic to explore the Roraima Mountain; and, further, gave him strict injunctions to collect nothing but this precious species. For eight months the traveller wandered up and down among the Indians, searching forest and glade, the wooded banks of streams, the rocks and clefts, but he found neither *C. labiata* nor that curious plant which Sir Robert Schomburghk described. Upon the other hand, he came across the lovely *Utricularia Campbelli*, and in defiance of instructions brought it down. But very few reached England alive. For six weeks they travelled on men's backs, from their mountain home to the River Essequibo; thence, six weeks in canoe to Georgetown, with twenty portages; and so aboard ship. The single chance of success lies in bringing them down, undisturbed, in the great clumps of moss which are their habitat, as is the *Vriesia* of other species.

"It may seem unaccountable that a plant of large growth, distinct flower, and characteristic appearance, should elude the eye of persons trained to such pursuits, and encouraged to spend money on the slightest prospect of success, during forty years. But if we recall the circumstances thoughtfully it ceases to astonish. I myself spent many months in the forests of Borneo, Central America, and the West African coast—several years, if they be reckoned together. After that experience I scarcely understand how such a quest, for a given object, can ever be successful unless by mere fortune. To look for a needle in a bottle of hay is a promising enterprise compared with the search for an Orchid clinging to some branch high up in that green world of leaves. As a matter of fact, collectors seldom discover what they are specially charged to seek, if the district be untravelled—the natives, therefore, untrained to grasp and assist their purpose. This remark does not apply to Orchids alone; not by any means. Few besides the scientific, probably, are aware that the common *Eucharis amazonica* has been found only once; that is to say, but one consignment has ever been received in Europe, from which all the plants in cultivation have descended. Where it exists in the native state is unknown, but assuredly this ignorance is nobody's fault. For a generation at least skilled explorers have been hunting. Mr. Sander has had his turn, and

has enjoyed the satisfaction of discovering species closely allied, as *Eucharis Masteri* and *Eucharis Sanderiana*; but the old fashioned bulb is still to seek."

EVENTS OF THE WEEK.—Upon Friday next Messrs. Protheroe and Morris will have their usual sale of Orchids in the Cheapside Rooms. On Wednesday, June 20th, the second summer Show of the Royal Botanic Society will be held in Regent's Park, the schedule including liberal provision for plants, flowers and fruits, so that an extensive and representative show may be expected.

— THE WEATHER.—"B. D." writes from Perthshire:—"Little sunshine, latterly much rain, and generally cold, unpleasant weather, have been the features of the past week. During the night between the 9th and 10th inst. a severe gale, resulting in considerable damage to fruit and other blossom, prevailed over Central Scotland." In and near London the weather has been agreeable during the past few days, and generally favourable for vegetation. On Saturday last welcome and copious showers fell in some districts in the south.

— WE have to announce with much regret the death of Mr. THOMAS JACKSON OF KINGSTON, which took place at his residence in Fife Road on Thursday last. Mr. Jackson was only 37 years of age, and succeeded to the old-established nursery business of Messrs. Jackson and Son a few years ago, while he has been widely known for a considerable period as the Honorary Secretary of the successful Kingston and Surbiton Chrysanthemum Society. At the annual meeting last December he resigned this post on account of failing health, and Mr. Woodgate was elected his successor.

— A SUFFOLK VICAR sends us a description of an early variety of RHUBARB which he grows in his garden and proposes distributing, as the hardiest and earliest of all—"so hardy," the Vicar says, "that cold suits it, and of no other kind has it ever before been found that the severer the winter the earlier the Rhubarb." It is also said to be the sweetest of Rhubarb. If the Vicar will oblige by sending us a sample we shall be glad to examine it and to refer to the variety again.

— PROPOSED TESTIMONIAL TO MR. A. ROGER.—It has been suggested that the retirement of Mr. Roger from the position of Superintendent of Battersea Park, which he held with so much credit to himself during the long period of seventeen years, is a very fitting opportunity for some slight recognition of his services to horticulture being acknowledged by his friends. Mr. Roger is now in failing health; any sympathetic movement on the part of his friends will be very much appreciated by him. Mr. Harry J. Veitch, Royal Exotic Nursery, King's Road, Chelsea, has consented to act as Honorary Treasurer to any fund that may be raised for the proposed object.

— WE are informed that MESSRS. E. H. KRELAGE & SON OF HAARLEM have been appointed nurserymen and seedsmen to the King of the Netherlands.

— MESSRS. J. CARTER & Co.'s houses and frames filled with CALCEOLARIAS AND PETUNIAS constitute an exceedingly attractive feature at the Perry Hill Nursery at the present time. Special strains have been obtained of both these useful plants, the Emperor Petunias and Victoria Prize Calceolarias being the titles adopted for the diversified and richly coloured seedlings, every care being taken in selection and crossing to not only maintain their character but to improve them.

— SOME fine bushes of the DOUBLE GORSE, or Furze, are conspicuous at the present time in the gardens of Hackbridge Grange, Carshalton. They are loaded with bloom, and the flowers individually are far more attractive than those of the common Furze. If the effectiveness of this plant, and the fact that it will grow in almost any soil, even that of a poor, dry, sandy nature, were generally known, it would probably be seen more frequently, both in large and small gardens, than is now the case. Propagation is effected by inserting cuttings of ripe

shoots in sandy soil on an east border as early in summer or autumn as they become firm.

— "W. P. W." writes:—The far-famed Rhododendron beds at Duneevan, near Weybridge, the residence of Mr. J. McIntosh, are a wonderful sight at the present time. The house stands on an elevation considerably above the level of the beds, and as viewed from the fine natural terrace the thousands of huge trusses with their gorgeous flowers present a spectacle that is found in few gardens at this time, and of which the magnificence could only be depicted by the brush of a great painter. Rhododendrons have been made almost a life-study by Mr. McIntosh, and his knowledge of the varieties is equalled by few private growers. In the beds many scores of varieties are represented, their rich and striking colours harmoniously mingled, and several large standards on the lawn are conspicuously beautiful objects as loaded with brilliant clusters. Nor is the display so transient a one as might be imagined by some. The earliness of some varieties and the lateness of others, with the influence of site and aspect, insure a succession of flowers over a not inconsiderable period. Rhododendrons are in evidence everywhere at Duneevan, even fringing the side of a meadow remote from the pleasure ground, and so freely have they been planted, and so rapid has been their increase, that it is a matter of some difficulty to keep them within bounds.

— EVERY care having been exercised to secure a collection of the BEST VARIETIES OF RHODODENDRONS only, it is somewhat an invidious task to select a few for special mention, but the following may be noted as particularly striking:—Michael Waterer, scarlet crimson, represented by a noble standard 10 feet high; Fair Helen, white, yellow spots; W. E. Gladstone, rosy red; Mrs. Russell Sturgis, white, chocolate blotch; Fastuosum plenum, lilac, semi-double; Archimedes, rosy crimson, a fine standard plant; Sigismund Rucker, magenta, black blotch; Mrs. R. S. Holford, beautiful salmon-pink; Frederick Waterer, brilliant crimson; Vivian Grey, delicate pink; Album Triumphans, soft blush, fine truss; Kate Waterer, rosy red, greenish yellow blotch, very fine; Marchioness of Lansdowne, pale pink, conspicuous dark blotch; Mrs. W. Agnew, centre cream, edge soft pink; Meteor, distinct fiery red; Purity, white; Sylph, rose, without blotch; Doncaster, brilliant crimson, very fine; King of Purples, purplish mauve; Lady Armstrong, soft rose, very large fine truss; Old Port, plum colour; Helen Waterer, white, red margin; and Baroness Rothschild, bright rosy crimson. The hardy yellow Azalea Nancy Waterer shows to great advantage amongst the shrubs.

— THE TREES AND SHRUBS AT DUNEEVAN are also worthy of a note. To begin with, there is a grand old Oak, with a girth of 24 feet just above the roots; a fine Purple Beech, of which the spreading branches add a distinct feature to the garden; and noble specimens of Abies Albertiana, Cupressus Lawsoniana, and C. L. erecta viridis, the latter the finest specimen in the country. As a background to the Rhododendrons, the purplish blooms of Magnolia Soulangeana and the abundant racemes of some fine Laburnums perform their duty in a highly effective manner. There are many other features of interest in this beautiful garden, as might be expected from the fact of Mr. McIntosh's keen interest in horticulture being supported by the work of an able gardener, Mr. T. Taylor.

— THE annual Summer Show of the TWICKENHAM HORTICULTURAL SOCIETY will be held on Tuesday, July 10th, in the grounds of Orleans House, the residence of W. Cunard, Esq., who has again placed ample space at the disposal of the Society for the purpose, and a better situation could not be desired. The schedule enumerates seventy-nine classes for plants, cut flowers, fruit, and vegetables, the prizes ranging from £4 downwards. The Hon. Secretary is Mr. J. F. G. Pugh, 2, Heath Road, Twickenham. It is expected that a characteristically beautiful show will be provided by the numerous supporters of the Society in the district.

— MESSRS. HOOPER & Co. have an admirable exhibition of GLOXINIAS IN THE PINE APPLE NURSERY, Maida Vale, this week. The plants are tastefully arranged with Ferns to form a long bank in a house near the conservatory, with groups of Masdevallias at one end and Cypripediums at the other. The flowers are of good size and form, representing rich shades of scarlet, purple, and crimson, in contrast with the pure white Avalanche, and a great diversity of flowers dotted and banded with bright or dark colours on pale or white grounds. Caladiums, Masdevallias, Odontoglossums also fill several houses, Palms, Dracenas,

and general decorative plants of a useful character in all sizes being grown by thousands.

— AT Selborne, Leigham Court Road, Streatham, the residence of J. Southgate, Esq., an excellent display of CALCEOLARIAS is now provided. The gardener, Mr. C. J. Salter, having giving special attention to these plants for some years, has succeeded in forming a fine and varied strain, distinguished by the compact habit of the plants, the large size and good form of the flowers, the colours of which vary from the richest velvety crimson to pure yellow. Some are beautifully mottled and veined, and this diversity indicates the care with which the seed-bearing plants have been selected. One house is filled and part of another structure is also occupied with the plants, which are as well grown as in previous years, and this, as all who have seen them know, is ample praise.

— WE are informed that the ALEXANDRA PALACE ROSE SHOW will be held on June 27th and 28th next, under the management of Mr. R. Beale. Liberal prizes will be offered, and the prize money will be paid at four o'clock on the first day of the Show. Schedules are in the press, and it is also proposed to have fruit, vegetable, and Potato shows, cut flowers, and finally a good Chrysanthemum show in November.

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 20th inst., at 7 P.M., the following papers will be read:— "First Report of the Thunderstorm Committee—On the Photographs of Lightning Flashes," drawn up by the Hon. Ralph Abercromby, F.R.Met.Soc. "The Cold Period from September, 1887, to May, 1888," by Charles Harding, F.R.Met.Soc. "Observations on Cloud Movements near the Equator, and on the general character of the weather in the Doldrums," by the Hon. Ralph Abercromby, F.R.Met.Soc.

— GARDENING APPOINTMENT.—Mr. F. Betts, outside foreman at Mentmore, succeeds Mr. Page as gardener to A. Southard, Esq., Fern Lodge, Bracknell, Berks.

— MR. C. RAPLEY, so well known as an improver and raiser of CALCEOLARIAS at Bedford Hill House, Balham, has now an attractive display at The Cedars, Upper Tooting, the suburban residence of T. P. Parr, Esq., to whom Mr. Rapley is gardener. The plants are not so large as we have been accustomed to see them, a chief object having evidently been to have as many varieties as possible in the space at disposal, and there is not an inferior one among them. Some of the plants are extremely dwarf, stakes being quite unnecessary for their support, and a crimson velvet coloured variety forms an excellent companion to the cloth of gold.

— MR. JOHN LOVEL, Strawberry grower, Driffield, sends the following on BARREN STRAWBERRIES:—"It is a general cry this season in many places throughout the country that Strawberries are showing no flowers. We attribute this to immaturity consequent on the very dry summer and backward spring. There should be no difficulty in making the plants fruitful next year by encouraging early and complete maturity, and by stimulating the growth of fibrous roots, the two important essentials necessary for fruit production. Do not dig the plants up. Old plants fare worse than young ones, as they have weaker rooting powers and a greater quantity of crowns to mature."

— MR. HUGH HANAN sends us from Edinburgh samples of his PERFECTION PROTECTING LATE WHITE BROCCOLI. They were advised as having been sent by express on the 7th inst., and reached us on the 11th not in the best condition through their long confinement. The heads are quite large enough, and as good as any we have seen so late in the season. Mr. Hanan describes the variety as one of the hardiest with which he is acquainted with in the north.

— IT is announced that an INTERNATIONAL IRON AND METAL TRADES EXHIBITION will be held in the Royal Agricultural Hall, London, on November 12th to 24th of the present year, in which provision will be made for the display of horticultural implements and appliances. The Exhibition, however, is intended to be of very large scope, and to embrace articles pertaining to nearly all trades and households. Mr. Harry Etherington, who has had much experience in the conduct of exhibitions on a large scale, is the manager of the one projected, which is expected to be of great extent and wide interest. His address is 43, New Oxford Street, London, W.C.

— FLOWERS IN GERMANY.—It is said that “since the Empress Victoria inhabited Charlottenburg the rooms of the Palace are daily decorated, under her own direction, with the most splendid flowers, which in early spring were mostly sent from Italy. For the wedding of Prince Henry ten clever flower-wreath makers, assisted by ten soldiers, were employed in preparing flowers for the festivities. The flowers came partly from the garden of the palace and partly from Berlin florists. The ground of these decorations was chiefly formed of Elder flowers in immense masses, as they grow abundantly in the park, and a quantity of valuable china vases were called into requisition. On the staircase great imitation malachite vases were filled with Roses, which were also to be seen everywhere. The corridor between the rooms inhabited by the Emperor and Empress was beautifully draped with red stuff, blooming plants, and green bushes; tall Palms behind, and a row of Azaleas, and then of Elder, Lilies, Narcissus, and Hawthorn in front. In the chapel the niches behind and beside the altar were filled with Roses, which were also spread over the railings. The rooms of the bride showed a sea of blossoms, while the Royal table in the dining hall was adorned with cushions of Elder flower, on which eight large silver dishes and as many plates were filled with Roses, Lilies, Gardenias, and Orchids. Besides these eighty-eight glasses filled with flowers, and many pots of living plants, were spread over the table, and from one to the other wound a wreath, while before each of the hundred seats was a bouquet of Orange blossom. On the south wall stood the mighty basket of Roses sent by the town of Charlottenburg, above a pyramid of Orchids sent by Frankfurt-on-Maine.”

— A PLEA FOR THE SPARROWS.—A paragraph has been going the round of the daily papers to this effect:—“An almost unprecedented attack of maggot has taken place in the Kentish fruit plantations, and Nut and Apple crops have been in many instances grievously damaged, if not destroyed. Planters are making vigorous efforts to fight the pest, but the grubs are so numerous that hitherto they have defeated all attempts to get rid of them. The increase of insects is said by the farmers to be due to the scarcity of sparrows, owing to the wholesale slaughter of the birds which has been carried on in the district.”

— DRYING FLOWERS IN THEIR NATURAL COLOURS.—Dr. Schöndland gives in an Indian paper the details of his system of drying flowers:—“Take two pints of a saturated solution of sulphurous acid in water (which can be had at any chemists, and is very cheap if bought in large quantities); add to this one pint of methylated spirit. Keep this mixture in a wide-mouthed bottle, which should be so tightly closed that the contents do not evaporate when not in use. Leave ordinary flowers in this mixture for about ten to twenty minutes; inflorescences of Bromeliaceæ and Aroideæ must be left in it about one hour. In most cases the colour will completely disappear, but it will gradually return during the process of drying, or even after the plants have become apparently quite dry. Having treated the specimens with the mixture for a short time as stated above, take them out and shake off the adhering drops of fluid. Leave the plants in a dry warm place, in order to dry them superficially (they must not be allowed to shrivel), and then dry them in the usual way between blotting paper. If artificial heat is used in the latter part of the process, excellent results are obtained, and it is not even necessary to change the drying paper. If hot-water pipes are available it is very convenient to place on them the bundle containing the plant to be dried, which need not be subjected to very great pressure. As it is sometimes difficult to prevent flowers from collapsing when using this method of preservation, and as often it is almost impossible to spread out those flowers when they have collapsed, I often put them loosely between sheets of vegetable parchment before immersing them in the fluid.”

— LANDSCAPE GARDENING.—This division of the Crystal Palace School of Art, Science, and Literature is carried on in Mr. Milner's offices, situated on the Aquarium Terrace, Crystal Palace. The student secures both theoretical instruction and the advantage of practical outdoor work. During the employment of the student in practical work, a certain salary may be allowed. The profession which undertakes to improve land, and enhance its value by artistic and scientific treatment other than agricultural, has two main divisions:—I. Creating and arranging natural beauties of landscape, to adorn land for ornamental or recreative purposes, parks or gardens, public or private; including the architectural, engineering, and gardening works incidental thereto. II. The treatment of estates for remunerative purposes, such as plan-

ning and development for building, with incidental engineering and other works, whether voluntary or public and statutory. Prospectuses for either division of the school of art, science, and literature can be supplied, and students can inscribe their names only in the office of the school, in the library, Byzantine Court, Crystal Palace.

ORCHIDS AT ST. MARGARET'S.

AT The Baron's, St. Margaret's, Twickenham, Mr. H. Little has an extensive collection of Orchids, which is, however, especially noted for *Lycaste Skinneri*, the *Cattleyas* and *Lælias* comprising remarkably fine plants and varieties in all these genera.

The *Lycastes* as a collection are probably scarcely equalled, and though the flowers are nearly over now, a display has been provided from November until the end of May, at least 1000 flowers having expanded in that time. The plants are extremely strong, and have had from ten to sixteen flowers from one pseudo-bulb, ten or twelve each being a common occurrence. One plant of a magnificent variety named *grandis* has had thirty flowers open at one time, and there are many other beautiful varieties, from the pure white form through numerous delicate tints to the deepest rosy crimson. A lean-to house, 140 feet long, is chiefly occupied with the *Lycastes* and *Cypripediums*, *C. superbiens* being a favourite, and all are well grown.

Another range of similar size contains the *Cattleyas* and *Lælias*, of which Mr. Little is justly proud, and like the other plants they are evidently thriving under the care of the attentive gardener, Mr. Hill. Some specimen *Cypripediums* are also noteworthy in that house, *C. Lawrenceianum* having forty large flowers, and *C. barbatum superbum* fifty richly coloured flowers. Of *Cattleyas* *Mossiaë*, *Warneri*, *Sanderiana*, *Mendeli*, and *Skinneri* there are some good plants. One superb example of *C. Sanderiana* on a Tree Fern stem in a pan has forty grand flowers; *C. Skinneri* has thirteen racemes of seven and eight flowers each; and *C. Mossiaë aurea*, a pretty distinct variety, has thirty-two flowers. *C. Mendeli* Mrs. H. Little is one of the finest varieties of that section, and has been honoured with two certificates; the petals are broad and erect of a deep rosy colour, the lip open, white tipped crimson. *C. Mendeli grandis* has also been certificated, and is very handsome, the flower of great size, excellent shape, and the lip beautifully frilled. A most valuable plant is *Lælia elegans Littleana*, which was certificated by the Royal Horticultural Society in 1885. The plant is a strong one with seven pseudo-bulbs, its flowers large and peculiarly rich in colour. At the time of my visit there were nearly 1100 *Cattleya* and *Lælia* flowers expanded, and this will give some idea of the display.

Pelargoniums have long been specialties with Mr. Little, and some admirable specimens are advancing now that will no doubt figure conspicuously at Richmond, Twickenham, or other Shows in the district.

CYPRIPEDIUM GODEFROYÆ.

A singularly beautiful variety of *Cypripedium Godefroyæ* is flowering in one of Mr. R. H. Measures' Orchid houses at The Woodlands, Streatham, and it presents an interesting resemblance to the new *C. bellatulum*, but with smaller and fewer spots. The plant has ten flowers of exceptional size for *C. Godefroyæ*, the petals and dorsal sepals very broad and rounded, heavily spotted on a cream-tinted ground, with a neat lip after the *C. niveum* style. Mr. R. T. Measures of Camberwell has another variety with a white ground more nearly approaching *C. niveum*, and the intermediate forms between that species, *C. Godefroyæ*, *C. concolor*, and *C. bellatulum* constantly appearing show that they are nearly allied.—L. C.

THE CHELSEA AND COOMBE WOOD NURSERIES.

AN hour or two can always be advantageously and pleasantly spent in Messrs. J. Veitch & Sons' nurseries in the King's Road, Chelsea, and at Coombe Wood, but note-taking wanderers more seldom visit the latter, not because it is devoid of interest, but because it is not quite so quickly or conveniently reached as the Chelsea establishment, with which all are so familiar. The following remarks will therefore be devoted to indicating the leading features of the two nurseries at the present time, what may be termed the Veitchian June show, for nearly

every month has its special attractions where the collections of plants are so extensive and varied.

ORCHIDS.

Commencing at Chelsea the Orchids first demand a few observations for there is now an unusual display of flowers in all the houses, which means that some thousands of plants are contributing to the production of a brilliant effect. The great span roofed Cattleya house contains an assemblage of handsome healthy plants, affording abundant flowers of Cattleyas and Lælias in innumerable fine varieties. Cattleyas Mossiæ, Mendeli, Warneri, and Skinneri, with Lælia purpurata, constitute the major portion of the flowering plants, and some of these are very beautiful, with twelve to twenty large flowers each, or in the case of C. Skinneri the latter number is far exceeded. The varieties of C. Mossiæ and C. Mendeli are most numerous, including some of the best in form, size, and colour of the flowers, but they are rarely considered distinct enough for varietal names, their relative merits being indicated by crosses on the labels. This is a simple and effectual method, preferable to bestowing names upon every trifling variation that may appear in a collection. The C. Mossiæ forms in particular are wonderfully good, the lips superbly marked, the sepals and petals broad and highly coloured, fine bold well developed flowers. The C. Mendeli group comprises similarly charming varieties, the colours rich and clearly defined. C. Warneri presents an excellent contrast with the lighter forms of the preceding, the sepals and petals being of a deep purple tint, the lip white and golden in the centre, the upper half rich crimson. The profuse C. Skinneri is gay with its bright hue flowers, and the noble Lælia purpurata is conspicuous everywhere. That grand variety of the last named—*i.e.*, L. purpurata Russelliiana, is in admirable condition, one plant having four racemes of four or five large flowers each, the sepals and petals pure white, the lip broad, white in the centre, and charmingly veined with purple in the upper half. This magnificent house has been extended to meet the long range of Phalænopsis, Lycaste, Angræum, and Odontoglossum houses, so that the whole series of Orchid houses can be inspected without passing out of doors—a decided improvement.

The Cypripedium house adjoining the fernery contains a large number of flowering plants, C. selligerum majus being in stroug force, some of the plants having twin-flowers. A contrast of majus with the typical selligerum, also in flower, proves at a glance how greatly superior the former is to the latter. The beautiful C. Veitchi, or superbiens, is flowering freely, with C. superciliale, C. barbatum, C. Parishii, and C. Druryi, with yellow flowers, and a reddish central vein in the petals and dorsal sepal. The new C. bellatulum, the magnified C. Godefroyæ, with intensely deep bold spots, is a valuable addition to the group of allied Cypripediums. C. graude is handsome, and some of the young flowers have petals 13½ inches long, so that they will probably exceed this when they are mature, and nearly approach C. caudatum, which has petals 24 to 30 inches long. Though not in the same house, a hybrid Cypripedium, named C. Tautzianum, is flowering in one of the private departments that merits a special word or two of description. It resulted from a cross between C. niveum and C. barbatum, presenting a most interesting and beautiful combination of the characters of these species. The whole flower is 3½ inches from tip to tip of the petals, the latter being three-quarters of an inch in diameter, tinted, and veined with crimson, purple, or white, but the dorsal sepal is particularly handsome, nearly 2 inches across, white, charmingly veined with a fine crimson-purple tint, and having a few greenish veins at the base. The lip is like a large C. niveum, neatly formed, white on the under surface, and tinged with rosy crimson above. A plant of this hybrid was shown before the Royal Horticultural Society's Floral Committee, January 10th this year, when a first-class certificate was awarded, and though necessarily scarce at present it will become a great favourite owing to the distinctness and pleasing brightness of its colours.

Dendrobiums include scores of plants of thyrsiflorum, Deari, suavissimum, chrysotoxum, Jamesianum, Dalhousieanum tortile, Cambridgeanum, Parishii, and Bensoniæ, which fill one house of the range. The last two named are very handsome, a plant of D. Bensoniæ having three pseudobulbs crowded with white flowers tinged with yellow and having dark spots in the lips. D. Parishii is similarly distinct, the flowers deep purplish crimson, and two dark blotches in the lip. An interesting hybrid Dendrobium is noteworthy—namely, D. porphyrogastrum, which was recently shown at Westminster. It was obtained from a cross between D. Huttoni and D. Dalhousieanum, two very dissimilar species both in habit and flowers, the former having thin straw-like stems and small flowers, the latter a giant both in growth and flowers. The hybrid partakes curiously of both parents' characters, and is really a great improved D. Huttoni. The miscellaneous warm-house Orchids in flower are too numerous to name individually, but Aeriodes, Saccolabium, Dendrochilum latifolium, Thunias, Oncidiums, Sobralias, Anguloas, Angræums, and Calanthes. The cool house is remarkably gay with Odontoglossums, numberless fine varieties of crispum, Pescatorei, cirrhosum, vexillarium, maculatum, cordatum, and Cervantisi being represented, and contrasting with Masdevallia Harryana and Veitchiana, Epidendrum vitellinum, Oncidium nigratum, O. hastatum, O. leucochilum, and others.

GLOXINIAS.

For many years Messrs. Veitch & Sons have given special attention to the improvement of Gloxinias, and they have not only succeeded in securing varieties of marked excellence that have been deemed worthy of names, but they have formed a mixed strain of considerable merit; the result, in fact, of intercrossing all their best varieties in the different

colours. The display provided at the present time of these plants testifies in a very satisfactory manner to the care which has been exercised in the selection or crossing, and in the cultivation of the plants. A span-roof house in two divisions 120 feet long is exclusively devoted to Gloxinias, and they afford an extremely rich effect, the bright and soft colours being well proportioned and the arrangement tasteful. Only a few of the named varieties can be mentioned, as all are good, and each one has some special character to recommend it. A trio of brilliant scarlet varieties are Comet, Flambeau, and Irma, the flowers well formed, the colour pure and bright, and the habit good; the first, having a white tube, shows up admirably. In contrast to these is the pure white Virginale and the deep rich purple, The Moor, which arrests attention everywhere, and is most conspicuous amongst the lighter varieties. Other good forms are Celia, edged purple; Cygnet, pure white ground and throat, margined with delicate pale purple, very pretty; Sunbeam, scarlet, light centre; Jubilee, spotted purple, handsome; Cordelia and Jeanne Muret are two other beautiful spotted varieties; Argus, large, handsome flower, spotted with red; Estella, delicately spotted and veined with purple, capital shape; Delicata, margin white, rosy red zone and veins; and Orestes, dark scarlet, a massive, finely proportioned flower. Well-grown Gloxinias are most valuable at this time of year, and some delightful groups can be formed of them arranged with Adiantums.

GREENHOUSE RHODODENDRONS.

Few weeks pass in the year without finding some of the greenhouse Rhododendrons in flower, for which the Chelsea Nursery is so famed. Not only is the stock of proved varieties or hybrids an extensive one, but such numbers of seedlings have been raised that novelties are constantly flowering that possess some distinctive merits. Several of these are now flowering for the first time, and are interesting in several respects. The well-known white long-tubed R. jasminiflorum, R. javanicum, R. Teysmanni, and the varieties Princess Royal and Princess Frederica have been employed with R. multicolor Curtisi, an introduced variety with narrow leaves and small deep red short-tubed flowers, almost suggestive of some of the small Azaleas. One of the plants from Princess Royal and multicolor Curtisi has rosy crimson flowers, the colour of Curtisi and the shape predominating. A second from jasminiflorum and Curtisi has bright red flowers with tubes longer than the latter parent, and it might almost be termed a small red jasminiflorum. From javanicum and Curtisi a plant has been obtained with the foliage of the former and the flowers of the latter, both in shape and colour. A fourth cross is particularly interesting; it is from Princess Royal crossed with Teysmanni, having large orange buff flowers, the latter parent predominating in foliage and flowers, while in the first cross mentioned from Princess Royal and Curtisi the latter predominated in a similar manner, though the seed was obtained from the same plant in both cases. Another of the Teysmanni type was raised from seed borne by Princess Frederica, the flowers large, pale creamy buff, delicate and handsome. An older form, Star of India, is also flowering, having a large compact head of brilliant orange flowers, the petals round and broad. Three double varieties of the javanicum group of Rhododendrons have now been secured, one of the finest of which is R. balsaminæflorum album, double white, very pure, and of good shape (fig. 65, kindly lent by Messrs. Veitch and Sons). R. balsaminæflorum aureum is a golden form of the same type, and carneum has handsome rose-tinted flowers of excellent shape. These are all valuable additions to the greenhouse Rhododendrons, as the flowers last capitally when cut, and look well in bouquets or button-holes.

MISCELLANEOUS.

In one of the new plant houses is a new Fern that is likely to be both useful and ornamental. It is named Gymnogramma Pearcei robusta, and is a strong "sporeling" from the much more delicate and less satisfactory species. The fronds are of moderate good shape, and finely divided into linear segments. It is free growing, and quite small plants are well furnished with graceful lace-like fronds. The Anthuriums are bearing numbers of their bright spathes, but especially A. Schertzerianum varieties like Wardi. A. Rothschildianum is also in good condition, now showing many forms varying in the size or shape of the spathes and the mottling. In some there is a clear white ground on which the scarlet dots or marbling show up very distinctly, and in others the markings are more confluent with less white. All are striking, but the former are preferable, and some are beautifully marked. It may be remembered that Anthurium Rothschildianum was the result of a cross between A. Schertzerianum and A. Schertzerianum album, which was obtained by Messrs. Veitch & Sons and M. Bergman, Ferrières Gardens, about the same time, but the French plants flowered first, and it was then named. Of the first batch of Chelsea seedlings, one-half came spotted or intermediate between the parents, but from a subsequent batch only one in twenty came spotted, all the others being the ordinary red varieties of A. Schertzerianum.

With the flower house, which is bright with Pelargoniums, Rhododendrons, Roses, Spiræas, Azaleas, Ericas, and Hydrangeas, and fragrant with Mignonette and Heliotrope, we must quit the Chelsea Nursery and hurry to Coombe Wood for a few notes on the

HARDY RHODODENDRONS AND AZALEAS.

A visitor at Chelsea can proceed to Coombe Wood without much difficulty, as there are frequent trains to Clapham Junction and thence to Norbiton on the Kingston line, which is twenty minutes' or half an hour's walk from the nursery. This is situated partly in a valley and partly on the hill sloping to the south from the Kingston Road, conse-

quently commanding a variety of positions, soils, &c., to suit the various occupants, besides some pretty cross-country views to render the nursery more interesting to strangers. Much could be said about the wonderful collection of rare or beautiful trees and shrubs which flourish at Coombe; but my mission was to see the Rhododendrons and Azaleas, and to them I must confine my notes this week. Looking down upon the slopes from the higher ground the brilliant patches of colour afforded by the plants named have a remarkably beautiful effect, the Azaleas in particular glowing in the sun as if illuminated by coloured fires. Some of the Rhododendrons are also bright, but for distant effect they are lost beside the Azaleas of the Ghent and mollis types. The rich and pure tints of the former are, however, very notable, and the following are selected as the most telling or useful of the large collection.

Rhododendrons.—Baron Schröder, deep purplish, yellow centre; Countess of Normanton, pale rose with dark markings; Decorator, brilliant scarlet, very effective; Frederick Waterer, rich crimson, most showy; James McIntosh, rosy scarlet; James Marshall Brooks, dark

feet high. The small plants are well furnished, and the right size for beds, where immediate effect is required. The standards are exceptionally fine, with clear stems 2 to 3 feet high, and well proportioned heads. For cover planting and similar purposes *R. ponticum* is grown in quantity, but of many the named varieties are now so cheap that they are often used for woodlands and conspicuous situations.

Azaleas.—The Azaleas comprise the old varieties of the nudiflora or calendulacea types, together with the newer forms of *Azalea mollis*, but in richness of colours and powerful fragrance the older American Azaleas are unequalled, though the mollis varieties have much larger flowers. Of the old forms a few may be named as specially worthy of general culture. Belle Merveille, reddish orange, very brilliant; Altacienensis, one of the oldest, but still one of the best, the flowers are yellow with an orange tinge; Daviesi is the best white, very free; Leopold 1. has long tubular flowers, rosy bluish tinted yellow, suggestive of Honeysuckle, dwarf and free; coccinea speciosa, brilliant orange scarlet, one of the most effective; Marie Verschaffelt, rose and yellow;

FIG. 65.—RHODODENDRON BALSAMINÆFLORUM ALBUM.

scarlet with a dark blotch; John Walter, a handsome crimson variety, one of the best; Joseph Waterer, purplish crimson, very dark; Kate Waterer, rosy crimson, lighter centre, beautiful; Lady Annette de Trafford, blush with chocolate blotch; Lord John Russell, rosy mauve, finely spotted, free and effective; Madame M. Carvalho, pure white large compact truss, free, one of the best; Marchioness of Lansdowne, pale rose, dark spots; Michael Waterer, rosy scarlet, a good variety; Mrs. Holford, salmon, fine truss; Mrs. John Clutton, pure white, an excellent variety of good habit; Mrs. John Penn, rosy salmon, bright margin and light centre; Mrs. Shuttleworth, scarlet, light centre; Mrs. Tom Agnew, white blotched pale yellow; Old Port, rich deep purple, a fine contrast to the lighter colours; Purity, white, yellow centre, good; Sappho, white with maroon markings, truss large and flowers well formed; Scipio, rose with a dark spot; Sigismund Rucker, magenta with a dark blotch; Snowflake, pure white, flower large; The Crown Prince, bright rose with a lighter blotch, truss and flower large; Vivian Grey, rosy lilac, dark spots. Besides these the old varieties of the cutawbiense type, Everestianum, with pretty lilac coloured fringed flowers; fastuosum flore-pleno, of similar colour; and purpureum elegans, very dark rich purple.

The plants are in all sizes, from those three years old, which in some cases, as with Mrs. John Clutton, bear from eight to twelve fine trusses on compact little specimens, to substantial bushes, and standards 6 to 8

Grand Duke of Luxembourg, rosy dark bright red; Directeur Charles Baumann, Joseph Napoléon Baumann, and Madame J. Baumann are also leading varieties in this section of similar colours to those named.

The remarkable collection of Conifers, hardy trees, and shrubs, the beautiful varied Japanese Maples and other plants must be reserved for subsequent notes, but one handsome tree, *Styrax Obassia*, from Japan, then coming into flower, well deserved the certificate since awarded for it by the Royal Horticultural Society (see page 493). For the foliage alone this is worth a place in gardens, and it has proved quite hardy at Coombe Wood upon a slope in a rather exposed position.—RECORDED.

ROYAL HORTICULTURAL SOCIETY.

JUNE 12TH.

THE meeting of this Society's Fruit and Floral Committees on Tuesday last in the Drill Hall, James Street, Victoria Street, was exceedingly well attended by exhibitors of plants and flowers, forming one of the most interesting and diversified displays provided in the new quarters. Four stages extending nearly the full length of the hall, and a fifth across at the top of these, were filled with groups of plants or collections of cut flowers, at least three-fourths of the space provided being occupied by the numerous and important contributions from nurserymen.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair; and Messrs. John Lee, Harrison Weir, R. D. Blackmore, Sidney Ford, C. W. Cummins, C. Howe, G. T. Miles, W. Warren, W. Marshall, J. Roberts, J. Smith, J. Wright, and Philip Crowley. As is usual at this period of the year the duties of the Committee were light, and the members availed themselves of the time afforded for inspecting the plants and flowers, the display being one of the most varied and effective yet provided in the hall. First to be placed on the fruit table were some large and very handsome Melons from Mr. M. Gleeson, Clumber Gardens, Notts. The variety is the result of a cross between Luscious and Melting and Hero of Lockinge; fruit roundish to oval, skin thin, pale yellow delicately netted, flesh white, sweet, and juicy, but not highly flavoured. The fair quality of this Melon, combined with the superior appearance of the fruit, led the Committee to record it as a good one for market purposes, but not equal to Hero of Lockinge in flavour. Mr. George Munro, the well-known salesman, has found the fruits acceptable in Covent Garden. Mr. Miller, gardener to Lord Foley, Bexley Lodge, Esher, was adjudged a vote of thanks for a dish of dark coloured unnamed Peaches. Mr. G. Haslett, Queen's Road, Tunbridge Wells, sent a twin Cucumber, or two fruits about 18 inches long, united their entire length, a circumstance not uncommon; yet the example was sufficiently good of its kind to merit a vote of thanks. Mr. T. Lockie, The Gardens, Oakley Court, Windsor, again sent fruits of his Perfection Cucumber. The six specimens were as uniform as if they had been cast in a mould. They were a foot long, faultless in shape and proportions, scarcely ribbed, green, covered with a dense bloom, and were considered models of table Cucumbers, especially as the quality was highly satisfactory. A first-class certificate was unanimously granted. The variety appears intermediate between Cardiff Castle and Sion House, and, kept true, can scarcely fail to become a popular favourite.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair; and Messrs. J. Laing, G. Nicholson, H. Herbst, W. Bates, T. Baines, C. T. Drucry, R. Dean, C. Noble, C. Pilcher, H. M. Pollett, J. O'Brien, A. J. Lendy, B. Wynne, H. Ballantine, E. Hill, W. Goldring, Shirley Hibberd, W. Wildsmith, James Walker, and the Rev. W. Wilks.

From the Royal Gardens, Kew, a group of extremely interesting but not showy plants were sent, every one of which possessed some special character deserving of notice, but only the following can be mentioned here. *Masdevallia muscosa*, a curious small-flowered species from Colombia, with long peduncles closely set with glandular hairs, which apparently suggested the specific name; *Delphinium triste*, a particularly "sad" looking plant, the flowers very dark and dull, almost black; *Primula japonica alba*, a pure white-flowered variety; *Lisochilus Krebsii*, an Orchid with singular yellow and brown flowers; *Smilacina stellata*, a Liliaceous plant with graceful panicles of small white flowers; *Musa coccinea*, very showy, with a head of scarlet bracts and flowers; and *Thunbergia mysorensis*, flowers yellow and reddish brown in long drooping racemes. Several varieties of Water Lilies were shown, including the handsome large white *Nymphaea Lotus*, the bright rosy red and equally beautiful *N. kewensis*, a hybrid between *N. Lotus* and *N. devoniensis*, raised at Kew, and *N. tuberosa flavescens* with yellowish flowers. The charming *Nymphaeas* are well grown at Kew, the old Lily house near the Palm house being devoted to them, and in spacious circular tanks of that kind they are seen to much better advantage than when cramped in a small rectangular tank. Other notable plants were the yellow Composite, *Venidium speciosum*, the wax-like *Rhododendron Blandfordianum*, the Heath-like white *Pentaptera sicula* from Sicily, the golden *Onosma taurica*, the scarlet *Delphinium nudicaule*, and the pretty *Saxifragas valdensis*, and *Hosti* var. *McNabiana*.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking (gardener, Mr. Bickerstaffe), had a group of choice Orchids, including *Trichopilia crista marginata*, with fine rosy claret coloured flowers; *Masdevallia Harryana regalis*, the flowers of brilliant colour and good shape; *Cypripedium Stonei grandiflorum*, with large handsomely marked flowers, inferior only to *platytenium* in the breadth of its petals (vote of thanks); *Vanda Lindenii*, something like *V. Roxburghii* in the size and shape of the flowers, the sepals and petals yellowish, with a bronze centre and a small lip; *Cypripedium Wallisi*, with green striped sepals and long drooping narrow petals; and grand specimens of *C. superciliale* with fine large flowers, and *C. Swannianum*, having twenty beautifully delicate flowers. Baron Schröder, The Dell, Egham (gardener, Mr. H. Ballantine), exhibited a fine plant of the white *Cattleya Wagneri superba* (certificated), and the beautiful pale yellow *Sobralia xantholeuca* (vote of thanks). The Rev. J. P. Way sent a plant of the yellow and bronze *Oncidium Gardneri* (vote of thanks). G. Nevile Wyatt, Esq., Lake House, Cheltenham (gardener, Mr. Simcoe), exhibited the original plant of *Lælia Wyattiana*, described by Reichenbach, one of the *L. purpurata* type, the sepals and petals pure white, the lip tinged with purple. H. M. Pollett, Esq., Fernside, Bickley, sent a plant of an extremely fine variety of *Odontoglossum Halli*, named *magnificum* (certificated), and *Cattleya Mendeli bickleyensis*, a variety having white sepals and petals, the lip crimson in the centre and margined with white. From Blenheim came a plant of a dark variety of *Lælia purpurata*, named *blenheimensis*, the sepals and petals deep purple, the lip rich crimson.

G. F. Wilson, Esq., Heatherbank, Weybridge, contributed several interesting hardy flowers, amongst them being specimens of the Edelweiss; *Cypripedium spectabile*; the bright red, graceful *Heuchera sanguinea*; the drooping pale yellow *Primula sikkimensis*; the tall, brighter *P. prolifera*; the dwarf *Hypericum scabrum*, and a plant of

Drosera binata. Mr. G. Bolas, Hopton Hall Gardens, Wirksworth showed flowers and leaves of a white *Nelumbium*, with a coloured sketch of the same (vote of thanks). T. W. Girdlestone, Esq., sent flowers of the beautiful Fortune's Yellow Rose, bronzy yellow deeply tinged with rose, the blooms fresh and of good size. S. Barlow, Esq., Stake Hill House, Manchester, sent a few flowers of florists' Tulips, representing bizarres, byblœmens, roses, and breeders (vote of thanks), all bright and beautiful, and sufficient to excite the wish that they were more frequently exhibited in the metropolis. Mr. F. Ross, Pendell Court Gardens, Bletchingley, exhibited some branches of *Mackaya bella*, laden with pale lilac and dark veined flowers (cultural commendation); also flowers of *Rosa lutea punicea*, the single scarlet Austrian Rose, and Fortune's Yellow Rose, both handsome; and W. Clay, Esq., Grove Road, Kingston (gardener, Mr. W. Hibbert), sent a group of *Pelargoniums* in pots. A group of double and single Ivy-leaf *Pelargoniums* from the Chiswick Gardens occupied a long cross table, the varieties comprising some of the best of the old and new introductions, well grown and flowering freely.

The nurserymen's exhibits were groups of Orchids, Gloxinias, Begonias, and miscellaneous plants, with collections of cut *Rhododendrons*, *Azaleas*, *Pyrethrums*, *Irises*, which were beautifully represented, and various hardy flowers. Messrs. H. Low & Co., Clapton, exhibited more largely than customary, contributing a handsome group of Orchids (silver-gilt Banksian medal), and a group of dwarf Heaths (silver medal). Amongst the Orchids were several varieties of the new *Cypripedium bellatulum*, one of which, named *roseum*, was certificated; *C. Sanderianum*, with long drooping narrow twisted petals; *Vanda Roxburghii*, with small bronzy sepals and petals, and a lilac lip; *Cattleya gigas Sanderiana*, *Phalenopsis Sanderiana*, *P. gloriosa* (certificated), *Vanda teres*, *Cypripedium Lawrencianum*, *Dendrobium Bensoniae*, and *Odontoglossum crispum* varieties were also well shown. The Heaths were chiefly varieties of *Erica ventricosa*, compact little bushes covered with flowers, the varieties being *rosea*, *coccinea minor*, *globosa alba*, *tricolor*, and *superba*, with *E. perspicua nana*. Messrs. F. Sander & Co., St. Albans, had a group of Orchids (silver medal), comprising a violet dotted *Acineta*, a dwarf variety of *Odontoglossum cordatum* named *splendens*, a large flowered variety of *O. nebulosum excellens* (certificated), and a wonderful imported plant of *Dendrobium Dalhousianum*, 4 feet in diameter, bearing seventy-five racemes of eight to ten flowers each, large creamy buff, with two rich crimson blotches on the lip. This was an extraordinary specimen, one of the finest ever exhibited. A beautiful group of Orchids and foliage plants from Mr. B. S. Williams, Upper Holloway, secured a silver Banksian medal, and a collection of Intermediate Stocks, named *Crimson Gem*, of very rich colour and compact habit, was recognised by a vote of thanks. The bold *Sarracenia Williamsii* (certificated), and *Asplenium amboynensis*, having long spreading fronds, 2 inches wide, were other novelties from the same exhibitor.

Messrs. J. Veitch & Sons, Chelsea, exhibited plants of the Gloxinias noted in another column (vote of thanks), also twelve baskets of *Rhododendrons*, *Azaleas*, *Grevillea sulphurea*, the white *Styrax japonica*, and *S. Obassia* (certificated), and a plant in flower of the New Zealand *Aciphylla squarrosa* (vote of thanks). Messrs. J. Laing & Son, Forest Hill, showed a group of their handsome double and single *Tuberous Begonias*, with the pure white *Gloxinia virginalis* (vote of thanks), and certificates were awarded for two of the *Begonias*, *Camellia* and *H. Adcock*. Messrs. H. Cannell & Sons, Swanley, exhibited some large double *Tuberous Begonias*, comprising Cannell's Triumph, bright pink, very large; Mr. Miller, double scarlet; and Mrs. W. B. Miller (certificated). Mr. Page, Teddington, sent a large variety of *Oncidium crispum* named *grandiflorum*, the flowers deep brown with a yellow base to the lip; and M. Linden, Brussels, showed a large variety of the green veined *Dendrobium macrophyllum* and a new *Anthurium*, *De Smetianum* (certificated).

The miscellaneous collections were as follows, for all of which silver Banksian medals were awarded:—*Rhododendrons* and *Azaleas* from Messrs. W. Paul & Son, Waltham Cross; hardy plants, including the large white *Rosa sinica*, the white *Linaria anticaria*, and the large purple-rayed *Aster diplostaphoides*, from Messrs. Paul & Son, Cheshunt; handsome single and double *Pyrethrums* from Messrs. Kelway & Son, Langport; an exceedingly beautiful selection of distinct German *Irises* from Mr. J. Walker, Whitton; hardy flowers in variety from Mr. T. S. Ware, Tottenham; and *Irises* from Messrs. Barr & Son, Covent Garden (bronze medal). Messrs. Collins, Bros. & Gabriel, Waterloo Road, had a collection of *Pyrethrums*; Mr. R. Dean, Ealing, some fine Giant white and scarlet Brompton Stocks; and Mr. Anthony Waterer, Woking, a collection of *Rhododendrons* and *Azaleas* (vote of thanks).

CERTIFICATED PLANTS.

Cattleya Wagneri superba (Baron Schröder).—An extremely beautiful plant, with nine large massive flowers, the petals nearly 3 inches in diameter, and, like the sepals, pure white, the lip also white, with a tinge of orange in the throat. A rare and valuable plant.

Odontoglossum nebulosum excellens (Sander & Co.).—Notable for the large size of the flowers, which are 3½ inches in diameter; the petals and sepals brown, heavily dotted with dull purple.

Phalenopsis gloriosa (H. Low & Co.).—One of the *P. anabilis* type, which it nearly resembles. The flowers 3 inches in diameter, pure white; the petals broad and rounded, with a few crimson dots at the base of the lip.

Cypripedium bellatulum roseum (H. Low & Co.).—Distinguished

from the form certificated at the previous meeting by the rosy tint running through the flowers, and the more confluent markings.

Anthurium De Smetianum (Linden).—An *Anthurium* with spathes of the style of *A. Andreanum* but smaller, dark scarlet, polished and irregular surface, the spadix white.

Styrax Obassia (J. Veitch & Sons).—A small Japanese tree with large roundish irregularly toothed leaves 8 to 9 inches in diameter, the flowers pure white; petals five, acute, in racemes 6 to 8 inches long.

Ramondia pyrenaica alba (Paul & Son).—A variety with pure white or very pale blush flowers, a pretty contrast to the ordinary purple type.

Begonia Camellia (J. Laing & Son).—A handsome double Tuberos variety with full symmetrical flowers, rich bright scarlet.

Begonia H. Adeock (J. Laing & Son).—One of the rosette-formed double Tuberos Begonias, of good shape, and dark scarlet in colour.

Sarracenia Williamsi (B. S. Williams).—A hold plant, the pitchers very large, the lips 5 inches broad, rounded, veined with dark red on green, as also is the tube.

Begonia Mrs. W. B. Miller (H. Cannell & Sons).—A fine double Tuberos Begonia with mauve creamy salmon-coloured flowers of capital shape and substance.

Pyrethrums (Kelway).—*Beatrice*, single, deep rosy crimson, broad florets; *Meteor*, double, dark crimson; and *Wega*, double, yellowish centre, pale blush ray florets, peculiar.

Odontoglossum Halli magnificum (H. M. Pollett, Esq.).—An uncommonly fine variety, the flowers having broad petals and sepals, yellow, boldly marked with brown.

SCIENTIFIC COMMITTEE.—Present, Mr. A. D. Michael, G. Murray, J. O'Brien, H. N. Ridley, Prof. Scott, Prof. Church. Prof. Church in the chair.

Mr. Linden (Brussels) sent for exhibition a plant of *Dendrobium macrophyllum*, var. *Bleichroderianum*, from New Guinea. A botanical certificate was proposed by Mr. O'Brien and seconded by Mr. H. N. Ridley. Mr. J. Douglas exhibited a plant of *Oncidium*, introduced with *Odontoglossum triumphans*. It was referred to Mr. Ridley for name.

Mr. Wolley Dod sent young leaves of a Weeping Ash which had turned black at the base of the petiole, and fallen off. He thought it might be due to drought, and the matter was referred to Mr. Murray and Mr. Michael. Mr. Wolley Dod also sent an abnormal flower of *Campanula Allioni* (Villars) with a double corolla, a sport of a typical plant. The Hon. and Rev. J. T. Boscawen sent two Primroses with phylloidy of the calyx. Mr. Ridley exhibited two flowers of *Catasetum macrocarpum*, from a plant obtained by him in Pernambuco, and flowered by Mr. Moore of Glasnevin Gardens. Mr. Veitch exhibited the flowers of a series of *Rhododendrons*, showing the effect of crossing with *R. Teysmanni*.

Lily Disease.—Mr. Murray, to whom specimens of diseased Lily stems were referred at the last meeting, reports that from fresh specimens sent him by Mr. Lewis Castle he has been able to determine the disease, which is caused by *Ovularia elliptica*, and an account of it by Rev. M. J. Berkeley may be found in the *Gardener's Chronicle*, 1881, p. 340.

Gentiana acaulis Varieties.—Mr. Scott reported on the abnormal flowers of *Gentiana acaulis*, which had five spongy outgrowths on the corolla, corresponding in position to the petals. The microscopic structure showed that they were due to excessive superficial growth of the external tissues, especially the epidermis. The outgrowths showed large irregular intercellular spaces. At many places they had coalesced so as to form closed cavities lined by epidermis. When vascular bundles were present, the position of scylem and phloem was variable. The upper end of each outgrowth was flattened, and here the bundles, though generally concentric, showed an approximation of the scylem towards the upper surface. There was no evidence that these abnormalities were caused by insects, but if so, the regularity of the outgrowth shows that their attack must have taken place at an early age.

COUNCIL MEETING.—At the Council meeting in the afternoon a Sub-Committee was appointed to consider the arrangements of the Society for 1889, and more especially to consider certain proposals made by Mr. Veitch in regard to appointing a Botanical Lecturer to deliver short popular addresses to the Fellows, and other matters of importance and interest. It was decided to ask certain members of the Stock Exchange to form a Committee to work in co-operation with the Society. The question of the early revision of the byelaws was taken into consideration, and a letter from the solicitors was read promising the revised copies at an early date. The suggestions of the Fellows' Committee in regard to Local Secretaries were adopted.

Forty-two candidates were elected Fellows, and Messrs. John Gardner and James Harris were elected Associates.

THE FLORISTS' TULIP.

TIME was when the gorgeous late-flowering florists' Tulips were much grown round London. A quarter of a century ago it was possible to see small beds in the rear of some of the houses on or near the Walworth and Camberwell Roads on the south side of the Thames; also at Clapham, Brixton, Hackney, Clapton, Holloway, and other suburbs of the metropolis. John Edwards of Holloway, and the brothers Williams of the City, were noted growers in those days. Groom, Goldham, Glenny, R. J. Lawrence, of Hampton; S. M. Sanders, of Staines; Willmer, of Sunbury, were the leading cultivators in Middlesex. A little farther afield were Charles Turner, of Slough; Joseph Hunt, of Wycombe; R.

H. Betteridge, of Abingdon; and Richard Headly, of Shelford, near Cambridge. An exhibition was held annually in London or in some one of the southern counties, probably up to 1870 or thereabouts. We remember seeing one at the Crystal Palace in 1855, and a few years later another at Cambridge, at which Samuel Barlow won the cup for twelve blooms, which had been regarded by some as a certainty for Richard Headly; and while the Tulip has advanced in point of variety, of beauty, and refinement, not a grower remains in the county of Middlesex, once so strong in valuable collections. It would now be difficult to find a bed of rectified Tulips within fifty miles of London.

The florists' Tulip is quite distinct from the early varieties so largely used for the spring decoration of flower gardens. It is both later in blooming and taller in growth. In some general characteristics it appears to be allied to the well-known *T. Gesneriana*, and what a singular physiology it has! The raiser from seed must wait five years before his seedlings blossom, and it matters not if his seedlings be raised from seed of feathered or flamed parents. When they first bloom they will, with very rare exceptions, bloom simply as self-coloured flowers. In this state they are denominated by florists as breeder Tulips, and some of them are very beautiful. And they will bloom in this self-state season after season until now one and now another, in no rank of order or age, will break or "rectify," as it is termed, into either feathered or flamed flowers, or some form that might be said to combine the two. A singular process goes on, which has been well described by the Rev. F. D. Horner:—"The breeder or mother colour is not simply driven or collected into beautiful markings on the rectified petals, but it disappears from the flower altogether as a mist or veil lifted off. The base colour floods the whole flower with its pure white or yellow, and a new and marvellous colour strikes in to feather or flame the petals." A few years ago David Jackson, of Middleton, flowered a Tulip for the first time from seed which never reached the breeder stage, but appeared at once in the form of a beautiful feathered bybloemen. But it is of very rare occurrence. When the breeders break they may take the feathered or the flowered form; it is all a matter of uncertainty, and they may be good or bad. The handsomest and richest coloured breeders by no means produce the best rectified flowers; in fact, the plainer and weaker colours not infrequently produce the richest rectified blooms.

It is comparatively easy to distinguish the classes of Tulips when they are yet in the breeder state. The class to which they belong is determined by the base colour of the breeder. "If the base is a circle of yellow the flower will be a bizarre; if white, a rose or bybloemen according to the body colour of the petal. Roses break from breeders having the white base, with pink, red, or scarlet self-coloured petals; bybloemens from a white base, with lilac or slate-coloured petals. Bizarre breeders have reddish and yellowish brown, dull red and mahogany sort of colour on their breeder petal, and occasionally bright scarlet, wherein the flower will break into a red bizarre, a very lovely and more recent development." The broken or rectified Tulips are divided into two main divisions, and these according to the ground colour as well as the markings upon the petals. The bizarres always have yellow grounds; in their petals the markings are laid on in black and red, or in varying tints of brown difficult to describe. The bizarres are both the strongest and the showiest class. The rose and the bybloemen are both white ground flowers, but they differ essentially in the character of their markings. The roses have a pure white ground, the petals marked with some shade of rose, red, or scarlet. This class has been described as "the fairest and gentlest among Tulips, and as if in common consent to this nearly all the varieties bear feminine names." The markings on the bybloemens range from some shade of purple, from light lilac to all but black, and it is the class that is scarcest of good flowers. The foregoing classes are again divided into feathered and flamed flowers; the latter is always feathered as well as flamed. The feather is laid on in beautiful styles of pencilling round the edge only of the petal, but when a beam of colour also runs up the centre of the petal striking into the feather it is then a flamed flower. "The feathering must not 'skip,' that is, break off anywhere round the petal edge before it naturally ceases near the base, nor the flame be scratchy, undecided, or insufficient to strike to the feather. The base of the flower must be pure white or yellow, as the case may be, and the stamens, six in number, each with its bold black anther, must be as pure as the ground colour. The property of purity has been gained after very many years of careful work with seedlings, and is of the greatest importance. Each flower is perfect at six petals, and cannot be exhibited with either more or less, or the circular outline of the cup is spoiled. Petals are to be broad, smooth on the edge, level as possible on the top, and of fine polished surface and substance, and so bending upward from the base as to first form a good shoulder."

Such is a popular description of the florists' Tulip. It is a flower full of interest; fascinating because of its rich beauty, and absorbing because it presents to the view of the vegetable physiologist certain singular phenomena that severely taxes his powers of interpretation.

THE ROYAL NATIONAL TULIP SOCIETY.

JUNE 9TH.

The annual Exhibition of the Society took place in The Gardens of the Manchester Botanical and Horticultural Society at Old Trafford, on the above date. The Society has now reached its thirty-eighth year, and Mr. Samuel Barlow, J.P., the President, exactly set forth the character of the present Tulip season when he said it was one of the most extraordinary known during that time. Fine and sunny warm weather, alternated with leaden skies and a low temperature, deepening to frost,

and amid such vicissitudes the flowers had to open as best they could. On his own beds he had more green buds so late as June 9th than buds showing colour. Contrasting 1888 with 1887, Mr. Barlow said that he scarcely before remembered so many good flowers as in the latter year, nor so many bad ones as in the present. The Rev. F. D. Horner had enjoyed a very fine bloom at Kirkby Lonsdale, but his feathered flowers were past, and he could not exhibit as usual, and the absence of Mr. James Thurstan of Cardiff, one of the veterans of Tulip culture, was generally regretted. The flowers were arranged on tables in the new exhibition house, and, as is usual, the breeder varieties were highly attractive from their rich colouring. There were but few striking novelties. Pegg's Seedling, shown by Mr. Barlow, and King of the Universe, shown by the raiser, Mr. W. Dymock, are good additions to a scarce class—the feathered byblœmens. The judging finished, the Judges and exhibitors sat down to a capital luncheon, under the presidency of Mr. Barlow, the Hon. Secretary, Mr. James Bentley, being in the vice-chair. Hearty good wishes were expressed for the future welfare of the Society, and earnest hopes that young growers would come forward to take the place of those who fell out of the ranks through old age and death, and may we not ask, When will a new generation of florists rise up in the south to hold aloft once more the banner of the Tulip? May it be soon, is our hearty wish.

In the class for twelve dissimilar Tulips, two feathered and two flamed in each class, there were five competitors, and Mr. Alderman Woolley, Stockport, was placed first in the bizarres, feathered, Sir Sidney Smith and Sir J. Paxton, the former having so broad a feather as to come under the denomination of a "plated" flower; flamed, Sir J. Paxton and Dr. Hardy, the latter very bright; roses, feathered Heroine and Mabel; flamed, Triomphe Royal and Mabel; byblœmens, feathered King of the Universe and Jaunette, two flowers raised by Mr. W. Dymock, Stockport, the former a fine addition to a class greatly needing additions; flamed, Chancellor and Walker's Duchess of Sutherland. Second, Mr. J. H. Wood, Royton, Oldham, with bizarres, feathered, Sir J. Paxton and Masterpiece; flamed, the same varieties; roses, feathered, Modesty and Mabel; flamed, Lady Catherine Gordon and Mabel; byblœmens, feathered, Bessie and Talisman; flamed, Friar Tuck and Talisman. Third, Samuel Barlow, Esq., J.P., Stakchill House, Castleton, with small flowers of good character, having bizarres, feathered, General Grant and Sir J. Paxton; flamed, Ajax and a seedling which broke from a mixed bed, and its identity is so far not quite certain; roses, feathered, Modesty and Mabel; flamed, Annie McGregor and Madame St. Arnaud, a somewhat old variety shown in fine colour; byblœmens, feathered, Pegg's Seedling, a very promising flower of marked individuality of character, and Friar Tuck. Fourth, Mr. W. Kitchen, Stockport. Fifth, Mr. A. Moorhouse, Wakefield.

In the class for six dissimilar varieties there were also five competitors, Mr. J. H. Wood being first with bizarres, feathered, Masterpiece; flamed, Sir J. Paxton; roses, feathered, Modesty; flamed, Mabel; byblœmens, feathered, Talisman; flamed, Duchess of Sutherland. Second, Mr. W. Kitchen, with bizarre, feathered, Masterpiece; flamed, San Josef; roses, feathered, Julia Farnese, a heavy plated variety; and flamed, Celestial; byblœmens, feathered, Bienfait; and flamed, Lord Denman. Third, Mr. Alderman Woolley, with bizarres, feathered, Sir Sidney Smith; flamed, Sir J. Paxton; roses, feathered, Heroine; flamed, Triomphe Royale; byblœmens, feathered, seedling, and flamed, Chancellor. Fourth, Mr. A. Moorhouse. Fifth, S. Barlow, Esq., having feathered bizarre, General Grant, with its striking deep red markings.

Then came another class for six Tulips dissimilar, the competition confined to half-guinea subscribers, and four stands were set up. First, Mr. Isaac Hesford, with bizarre Sir J. Paxton, one feathered and one flamed; roses, feathered Industry, flamed Mabel; byblœmens, feathered Mrs. Pickerill, and Talisman. Second, Mr. E. H. Schofield, Royton, with bizarres, feathered, Masterpiece and flamed Sir J. Paxton; roses, feathered Heroine; flamed, Aglaia; byblœmens, feathered Duchess of Sutherland; and flamed George Edwards. Third, Mr. Thomas Simpson. Fourth, Mr. A. Fearnley. There were seven stands of three feathered Tulips, one of each class, Mr. D. Woolley being first with bizarre Typo (Dymock); rose, Alice; and byblœmen, Adonis. Second, Mr. Isaac Hesford, with bizarre, Sulphur; rose, Mrs. Collier; and byblœmen, Sylvester. Third, Mr. E. H. Schofield, with bizarre, Waterloo; rose, Modesty; byblœmen, Mary. Fourth, Mr. J. H. Wood. Fifth, Mr. A. Fearnley. In that for three flamed Tulips Mr. A. Fearnley was first with bizarre, Sir J. Paxton; rose, Mabel; and byblœmen, Maid of Orleans. Second, Mr. W. Kitchen, with bizarre Sir J. Paxton; rose, Mabel; byblœmen, Lord Denman. Third, Mr. J. H. Wood, with bizarre Sir J. Paxton; rose, Aglaia; byblœmen, Lord Denman. Fourth, Mr. E. H. Schofield. Fifth, Mr. Thomas Simpson.

In the maiden growers' class for one feathered and one flamed Tulip there was but one entry, Mr. Thomas Holden, Royton, who had feathered byblœmen, Mrs. Jackson; and flamed rose, unknown. In the class for the same number of flowers, open to all, Mr. Thomas Simpson was first with Sir J. Paxton, feathered and flamed both. Second, Mr. E. Dymock, with bizarre flamed, Sir J. Paxton; and byblœmen feathered, John Hart, one of his own raising. Third, Mr. J. H. Wood, with bizarre feathered, Masterpiece; and flamed, Dr. Hardy. Fourth, Mr. Samuel Barlow, with bizarre feathered, Commander; and byblœmen flamed, Friar Tuck.

Then followed, as is usual, classes for the best single blooms in each of the three divisions as follows:—Bizarre, feathered.—First, Mr. W. Prescott, with Lord Lilford; second, Mr. A. Fearnley, with Duke of Devonshire; third, Mr. Hugh Housley, with Lord Lilford; fourth, Mr.

R. Wolfenden, with Masterpiece; fifth, Mr. E. H. Schofield, with Sir J. Paxton; sixth, Mr. S. Barlow, with General Grant. The other winning flowers following in order of merit with Sir S. Romily, Sulphur, Richard Yates, and Lord Lilford. Flamed.—First, Mr. D. Woolley, and second, Mr. H. Housley, with Sir Joseph Paxton; third, Mr. A. Fearnley, with Dr. Hardy; and fourth, with Duke of Devonshire; fifth, Mr. W. Dymock, with Garibaldi; and Mr. R. Wolfenden sixth and seventh, with Excelsior, Masterpiece, San Josef, and Ajax following in the order of merit. Roses, feathered.—First, Mr. D. Woolley, with Dymock's Lizzie; second, Mr. Thomas Holden, with the same; third, Mr. W. Prescott, with seedling; fourth, Mr. R. Wolfenden, with Heroine, and fifth, with Modesty; sixth, Mr. D. Woolley, with Mr. Lee, Mabel, Andromeda, Nanny Gibson, and Madame H. Arnaud following in order. Flamed.—First, Mr. H. Housley, with Annie McGregor; second, Mr. W. Kitchen, with Madame St. Arnaud; third, Mr. D. Woolley, with Mabel; fourth, Mr. J. H. Wood, with Lady C. Gordon; and sixth, with Annie McGregor—Aglaia, Lady Crewe, and Bertha coming in succession. Byblœmens, feathered.—First, Mr. D. Woolley, with King of the Universe; second, Mr. Thomas Simpson, with Fanny; third, Mr. W. Kitchen, with Violet Amiable; fourth, Mr. D. Woolley, with John Hart; fifth, Mr. H. Housley, with William Bentley, followed by Lady Denman, Coningsby, Adonis, Mrs. Cooper, and Janct. Flamed.—First, Mr. H. Housley, with Adonis; second, Mr. D. Woolley, with Talisman; third, Mr. W. Kitchen, with King of the Universe; fourth, with Chancellor; fifth, with Adonis; sixth, with Duchess of Sutherland; seventh, with Lady Denman; seedlings and Agnes making up the list. The premier feathered Tulip was byblœmen King of the Universe, shown by Mr. D. Woolley; and the premier flamed bizarre, Sir Joseph Paxton, also shown by Mr. Woolley. A first-class certificate of merit was awarded to Dymock's King of the Universe as a fine feathered byblœmen.

Breeder Tulips.—In the class for six dissimilar, two of each division, Mr. S. Barlow was first with some medium-sized flowers of fine quality, having bizarre seedlings; roses, Miss B. Coutts and Mr. Barlow; byblœmens, Glory of Stakehill and George Hardwick. Second, Mr. W. Kitchen, with bizarres seedling and Sir J. Paxton; roses, Mabel and Annie McGregor; byblœmens, seedling. Third, Mr. J. H. Wood, with bizarres Lord Delamere and Sir J. Paxton; roses, Miss B. Coutts and Mabel; byblœmens, Alice Grey and Glory of Stakehill. Fourth, Mr. A. Moorhouse. There were nine stands of three breeders, one of each, Mr. S. Barlow being again first with bizarre Hepworth's 29/6; rose, Miss B. Coutts; byblœmen Glory of Stakehill. Second, Mr. W. Kitchen with bizarre Sir J. Paxton; rose Annie McGregor; byblœmen Adonis. Third, Mr. J. H. Wood, with bizarre Horatio, rose Annie McGregor, and byblœmen Adonis. Fourth, Mr. D. Woolley. Fifth, Mr. E. H. Schofield. Single blooms, bizarres. First, Mr. T. Holden, with seedling. Second, Mr. D. Woolley with Sulphur; and third with Dr. Hardy. Fourth, Mr. S. Barlow with Richard Yates; and sixth with Sir J. Paxton; Mr. W. Kitchen being fifth with William Lea. Roses.—First, Mr. S. Barlow with Mabel. Second, Mr. T. Holden, unknown. Third, Mr. E. H. Schofield, with Annie McGregor. Fourth, Mr. S. Barlow with Miss B. Coutts; and fifth with Annie McGregor. Sixth, Mr. W. Kitchen, with Burlington. Byblœmens.—First, Mr. E. H. Schofield with Mrs. Hardwick. Second, Mr. S. Barlow with seedling 130/63; and third with Talisman. Fourth, Mr. T. Simpson, with Fanny. Fifth, Mr. S. Barlow, with Martin's 117; and sixth, Mr. Thomas Holden, with Alice Grey. The premier breeder was byblœmen Glory of Stakehill, shown by Mr. Isaac Hesford.

THE BATH AND WEST OF ENGLAND SHOW AT NEWPORT, MON. HORTICULTURAL DEPARTMENT.

THE annual meeting of this old Society began at Newport, Mon., on June 6th, and terminated on June 11th. Unlike the majority of agricultural societies, this one does not ignore horticulture, but encourages it liberally, making it a prominent section. The Hon. and Rev. J. T. Boscawen devotes much time, energy, and good taste to the perfecting of this department. Indeed, this gentleman is the heart and soul of it, and the arrangements are carried out under his personal supervision.

The Society provided a large tent for the exhibits, which were arranged in two masses in the centre, and margined with plants and flowers. The feature of the Show was undoubtedly the Orchids. They were there in hundreds. Mr. James Cypher of Cheltenham brought down many scores of his best and most wonderful specimens, and Messrs. Heath and Son, Cheltenham, had also a superb display, while Mr. Fowler, an amateur grower from Pontypool, had a group that did him infinite credit. The two Cheltenham groups were in the centre, and were beautifully arranged to agree in harmony of colour, the bright flowers being pleasingly relieved by a mingling and fringe of choice Ferns. Mr. Cypher had thirty fine plants of *Lælia purpurata*, none bearing less than fifteen flowers, and some having as many as thirty blooms. Twenty plants of *Cattleya Mendeli* were equally well flowered, and thirty of *Cattleya Mossia* represented this variety, the best having from three to four dozen flowers open and in fine condition. *Odontoglossums*, *Masdevallias*, *Dendrobiums*, and other Orchids in great variety were grouped amongst these, and the whole formed a display unequalled at any previous show of the Society. Messrs. Heath's group was uncommonly well arranged, but somewhat lacked the boldness and captivating features of the preceding. Mr. Cypher was awarded the first prize, a silver cup valued £10, and for the best single specimen Orchid he also

secured the first prize of £5 with a fine *Lælia purpurata* against Messrs. Heath, who competed with a plant of *Cattleya Mossiæ*, bearing eighty-four blooms. This was a good variety and a magnificent specimen. We did not hear of Mr. Fowler receiving any award, but his group was undoubtedly highly meritorious.

Being so early in the season the Rose classes were not filled so well as was anticipated, but some grand blooms, particularly of *Maréchal Niel*, were staged. Mr. T. B. Hall of Rockferry gained the £5 prize for eighteen blooms, all Teas, in fine condition. Plants sent in for exhibition made an imposing display. Mr. Pettigrew, gardener to the Marquis of Bute, Cardiff Castle, exhibited some finely grown Palms, Crotons, and other plants, and so did Mr. Roderick, gardener to Lord Tredegar, Tredegar Park, Newport; Mr. Watson, Newport; Mr. Taggart, Mr. Derham, and Mr. Parker, all of Bristol. Messrs. John Laing and Sons, Forest Hill Nurseries, London, had a splendid group of Tuberous Begonias in pots and cut blooms of the same. They were unnamed seedlings, huge blooms, single and double, of exquisite colour. Messrs. Richard Smith & Co., Worcester, had a wonderfully fine collection of Clematises in pots. These were neatly trained, and bearing many grand flowers. The best were *Sensation*, *Countess of Lovelace*, *Gloire de St. Julien*, *Lord Melville*, *Mrs. George Jackson*, and *Excelsior*. Mr. F. Hooper of Bath exhibited numerous stands of Pansies; Mr. Grindrod, Whitfield, Herefordshire, exhibited six bunches of Grapes, three being *Black Hamburg* in fine condition, and three *Muscate* of Alexandria rather green. Amongst numerous stands in the field that of Messrs. Edward Wehh & Sons, Wordsley, Stourbridge, was most conspicuous. It was the finest stand connected with horticulture in the Show, and contained large quantities of seeds and garden and field produce. The seeds were shown in endless variety; samples of Potatoes, new and old; samples of lawns, dense and green; and the new Turnips, Carrots, Radishes, Cabbage, Cucumbers, Tomatoes, Rhubarb, and other vegetables were capital samples. Messrs. J. C. Wheeler & Sons, Gloucester, had a stand on a much smaller scale. Messrs. Richardson & Co., Darlington, exhibited different kinds of glass houses, frames, boilers, &c., and Messrs. Foster & Pearson, Beeston, Notts, had greenhouses, hoilers, frames, &c., showing the advantages of their well-known and valuable inventions. Messrs. Wright & Holmes, Birmingham, were also exhibitors in the same line, and Mr. C. G. Warne, Weston-super-Mare, and the Newport Pottery Company displayed a fine assortment of vases, pots, &c. Rustic seats and arbours were very attractive from Mr. Henry Inman, Stretford, Manchester, and the garden furniture generally appeared to be highly interesting to the numerous visitors.

SNOW IN JUNE.

DWELLERS in the upland regions of Inverness and Moray shires had on Saturday and Sunday an experience such as has, fortunately, seldom been vouchsafed in mid-summer to the inhabitants of any portion of the British Isles. In the districts lying immediately north of the Grampian range of mountains, extending a distance of about fifty miles from Blair Athole to Grantown, a snow-storm raged for many hours, dense, fierce, and all-pervading as if the season had been midwinter instead of June. Snow began to fall in the Valley of Badenoch about four o'clock on Saturday afternoon, and for the next five hours the gale raged without intermission or abatement. About nine o'clock there was a temporary lull, and at that hour the landscape, from the distant peaks of the Cairngorms to the most sheltered hollow on Sir George Maepherson Grant's Home Farm of Invereshie, was discovered to present an aspect such as has rarely, if ever, been witnessed in this country during the height of summer. The face of Nature was one vast expanse of dreary white, almost as unbroken as at any period of the prolonged winter from which it was thought the country had at length emerged. It was calculated that in the lowest part of the Badenoch valley at least two solid inches of snow fell during Saturday afternoon, and more than that quantity actually lay on the ground at Sir Charles Mordaunt's shooting lodge, situated in a gully of the Grampians at the top of Glenfeshie. Of course most of the snow melted as it fell, but from six to eight o'clock there was everywhere on the low grounds a decided covering, the depths in most places being so great that hoisterous youths, and even vigorous veterans, were enabled to engage in energetic encounters with snow-halls! This formed an incident of the midsummer weather of 1888 that will remain long treasured in the memory of the inhabitants of Badenoch. There is reason to fear that the storm will have a most injurious effect on the grouse nesting season. Many eggs are already deposited, but the hens do not yet lie closely, and a proportion of damage can hardly be avoided, but the extent cannot as yet be determined. Snow fell heavily in Ballater throughout Saturday afternoon, and yesterday morning there was not less than half a foot on the surrounding hills, and it lay to the depth of 2 inches in the village and over this part of the country throughout Sunday. Such a storm in June is not remembered by the oldest inhabitant here. Snow fell on Ben Nevis on Saturday afternoon and rain yesterday, though the temperature was below the freezing point.

A correspondent, writing from Corgarff, Strathdon, on the 4th, says:—"This is the third day of a snowstorm in the month of June, to which no living person in this country has ever seen any comparison. Up to Saturday the weather was for some days very cold and frosty.

Upon Saturday the atmosphere assumed a very ugly tin-like colour, and about midday hail and snow began to fall, continuing up to the present date. The snow upon the highest range of hills cannot be under 2½ feet deep. Down in the low grounds the depth is not under 9 or 10 inches. The woods and shrubs wear a very weird and sad-like appearance, and in many cases great destruction has been done to all sorts of bushes and trees from the densely packed quantity of snow falling upon the branches. The condition of the animal world may be better imagined than described. The cattle were, as a rule, all newly out upon the grass, and had a night of cold starvation upon the Saturday. Yesterday bundles of hay and straw were dispatched to the fields, but as the storm was still increasing towards evening, all the cattle had to be removed and housed up. Some were driven into sheltered woods where indoor accommodation could not be had. Shepherds who were out all day upon Sunday looking after the sheep in the glens had their heads literally covered with tangles of ice. The state of the flocks is deplorable. In many cases the loss must be serious among the lambs, where for the last three days the hill sheep have been isolated in sheltered corners to keep them from being smothered; but as yet no information has come to hand whether or not any are sealed up under the large snowdrifts, where in many cases the men on the look-out yesterday after the sheep were going through up to the shoulders. As to the feathered tribe, their condition is truly pitiable. Blackbirds lay dead in our garden; and a robin redbreast has come to our doors with his young family, flying hither and thither, picking up fragments, and giving them to the little ones. The curlew, plover, swallow, and all the other migratory birds are gone away again (the lapwing excepted). The young hroods of grouse were in some cases seen coming up above the snow new fledged, and the shepherds put one or two hroods under Juniper bushes to give them shelter. The landscape, as far as the eye can see, is one of pure white—not one black spot to be seen."—(*Weekly Scotsman*, June 9th.)

A SERVICEABLE HOUSEHOLD REQUISITE.

KNIVES have to be cleaned in every household, but in the vast majority of houses rotary machines cannot be used. Mr. Thomas Chadborn, the London Manager of the Chadhorn & Coldwell Manufacturing-

FIG. 66.

Company, and proprietors of the excelsior lawn mowers and drills, is introducing a knife cleaner entirely new in character. It is adapted to the means and requirements of the majority of readers, hence we do not hesitate to direct attention to it. It is intended to supersede the dusty old knife board, and does its work quickly and well. It is something like a double razor strop, to which a rest in the form of a vice is held on the table with one hand for holding the knife, while the cleaner is worked to and fro with the other for polishing the blade. The powder is contained in a small box on the top, and falls as required by the movement of the cleaner. The contrivance is as useful as it is ingeniously constructed, and is worked with ease, due to the springs at each end. It is called the Crown Knife Cleaner, and is represented in the engraving.

BELGIAN WORK AND WAYS. AN AMATEUR'S GARDEN.

"WHAT is an amateur?" is a question that has been asked scores of times in print and answered in various ways, as it must be, because the term has different significations in different localities in connection with exhibitions of garden produce in England. At many local shows classes are provided for nurserymen, gardeners, and amateurs. In such cases a reasonable interpretation of the term amateur is a person who does not employ a skilled gardener. He may have a man in occasionally to dig and do such like heavy work, but everything he shows should represent his own skill, and not that of someone else in the background. In shows of a national character in which high-class culture is represented, such as those under the auspices of the Royal Horticultural and Royal Botanic Societies, only two sections of exhibitors are recognised—

namely, one representing commerce, and denominated nurserymen; the other, not representing trade, being amateurs, no matter how much skilled labour they may employ in growing the produce exhibited. So it is in Belgium. All cultivators who are not nurserymen (*horticulteurs*) are amateurs.

M. Jean Everaerts of Antwerp is quite in the front rank of Belgian amateurs, and to him I am indebted for one of the most pleasantly spent days in my gardening career; and to his daughter for an act of kindness I cannot forget—a drive round the capacious docks at Antwerp, an inspection of the famous cathedral, including the magnificent paintings of Rubens and an examination of the treasures in the Plantin Museum, in which all that pertains to ancient printing and engraving is represented. And marvellous some of the work is, and most interesting, while one of the outside walls is covered with a Vine said to be 300 years old. This was a memorable afternoon—one of the “ways” the Everaerts family have of making their guests happy, while they are made equally at home in the spacious town house in the Rue d’Aremberg. There we can see how flowers are cherished, both by their tasteful arrangement in the rooms as well as in the pretty conservatory, this replenished weekly from the garden we are now going to see. This is in the country, or beyond the stupendous fortifications through which we drive on a characteristic April day of sunshine and showers.

Vieux-Dieu is the name of the village near which M. Everaert’s mansion is situated, with pleasure grounds surrounding it of about 30 acres. Here we find a piece of Belgian “work,” which, regarded in all its aspects, has no equal in the kingdom, and there can be few parallels to it anywhere. The work in question is the rockery. Though not equal in extent to some of the largest in England, it differs from all I have seen, and represents a mountain of labour; and when it is remembered that the stones had to be brought from long distances, or several miles, and that every one was placed its position by the hands of the owner, and every alpine planted by him also, a feeling of astonishment cannot be suppressed that so much could be done by one man during the leisure hours of a busy life in town from 9 A.M. till 5 P.M. Hundreds of tons of material must have been requisite for completing the work that is now covered with plants in colonies, and which display their characters and charms as well as we could expect to see them in their native haunts—the Alps of Switzerland, whence so many of the alpins were collected by M. and Madame Everaerts. The summit of this remarkable rockery mound is crowned by a Swiss chalet-like summer-house, with an ice well beneath, that is filled from the adjoining lake. The top of the mound, which appears to be about 30 feet high, is reached by twisting walks, like chasms in the rocks, and rough stone steps here and there to make the ascent more easy. The slopes are entirely irregular—in some places nearly perpendicular, in others more resembling landslips, and these as if arrested in their downward course by rocks. Thus are formed plateaus for plants. Mounds, nooks, dells, and precipices are formed, all apparently reproductions from Nature, and all occupied with plants, mountain shrubs, and Conifers appropriate to their positions. The rockery mounds creep down in broken ridges and valleys between to the lawn and the water, the length of the out-juttings being upwards of a hundred yards.

As has been previously mentioned in the Journal, it would be impossible to enumerate in these notes the whole, or even the most beautiful, of the plants which occupy the rockery, and a few observations upon the principal features must suffice. The great display is made in the spring, April being one of the gayest months, for at that time a large number of early-flowering plants are at their best. *Aubrietias*, principally *A. græca*, occupy much space; the rich blue *Lithospermum prostratum* scrambles about over the stones in all directions. *Saxifraga oppositifolia* and others flower abundantly early in the year. *Silene acaulis* and *S. alpestris* furnish some lovely tints of pink, while *Veronicas rupestris* and saxatile supply blue tints. *Primulas* of many species and varieties, the delicate little *Soldanellas* with their charming fringed flowers, *Linaria alpina*, and *Daphne cneorum* are all conspicuous for their numbers. The humble namesake of a great botanist, *Linnaea borealis*, is thoroughly at home, creeping in all directions over the stones; while that difficult plant, the *Edelweiss*, could not be better in its native home. A few *Rhododendrons* are employed, and amongst these are extensive patches of *Saponarias*, which also hang over the larger rocks, clothing them most gracefully. *Omphalodes* and *Forget-me-nots* are abundant and strong, but one of the most telling features is *Erinus alpinus*, which is thoroughly established, seeding freely and flourishing in all parts of the rockery. A pretty dwarf shrub which succeeds well in the rockery is *Rhododendron hirsutum* or the Mountain Rose, as it is sometimes termed. With *R. ferrugineum*, *album*, and a few dwarf Himalayan species it grows and flowers profusely. *Andromedas*, *Pernettyas*, and *Ericas* are employed in the most exposed positions, while in the shady parts *Gaultheria procumbens* luxuriates. *Cypripediums*, such as *C. Calceolus* and *C. spectabile*, appear to be equally happy, but the latter is seldom seen in such fine condition, for some plants have borne between fifty and sixty richly coloured flowers. *Lilium auratum* thrives and gains strength yearly, all the protection that is given being an old door placed over the bulbs to throw off the rain, which does them more injury than the frost. Bulbs are planted freely, and yield their flowers in profusion, as also do the *Hellebores*, of which there is a good collection. *Sedums* and *Scempervivums* serve to clothe many of the rocks, and in the lower portions a collection of bog plants, such as the Buck Bean, *Pontederias*, &c., Water Lilies having a place at the margin of the lake. Such is a brief list of some of the plants which M. Everaerts has been successful with, and that have rendered his rockery so famous.

The entire work is a monument representative of persevering industry, good taste, founded on a close observance of Nature, and a deep love of plants, without which no such achievement were possible. Twenty years of thought, of recreative travel, and of labour, in odd moments have been devoted to the completion of this rockery, which affords, as it ought, so much pleasure to its fabricator and delight to his friends.

The entire gardens and pleasure grounds have been made by the proprietor, and the mansion enlarged and beautified. The country is flat, but the spacious lawn is not, and much labour must have been employed in producing the bold undulations, also in the formation of lakes, while planting both for shelter and ornament has been extensive. As a rule, no such care is taken in keeping lawns smooth in Belgium as in England. They are cut now and then with the scythe, but not regularly machined. M. Everaerts adopts our custom of keeping his lawn smooth, and the planting is not done in the straight line or formal style that is observable on the continent. Trees and shrubs are disposed in natural groups, and the home surroundings have a decidedly English appearance. The soil is sandy, and Conifers thrive well. *Abies Hookeriana* is 10 feet or 12 feet high, a handsome and most elegant specimen. This species of Hemlock Fir is very distinct, and its decorative value is recognised by M. Charles Van Geert, who has propagated it extensively. *Retinosporas* are very fine at Vieux-Dieu, as also is *Abies Nordmanniana*, *Cryptomerias*, and many others. The free and healthy growth of the trees and shrubs in such light soil, that must be very hot and dry in the summer, may be in a large degree attributable to letting the soil alone and allowing the leaves that fall from the trees to remain and decay. Bulbs and other hardy flowers are being established in the borders, and the leafy covering is as beneficial to them as to the trees, and the borders have a natural appearance that is preferred to extreme trimness and unsatisfactory growth.

Of hardy herbaceous plants there is a very large collection. They are grown in borders skirting the walks as they curve through the lawn, and add materially to the interest of a promenade, for something is to be seen to admire at every step, while flowers in their season can be cut in profusion. The soil is thickly mulched with manure on the approach of winter, the covering being left to decay, hence the excellent condition of the plants. These borders are very extensive and form a prominent feature of this cherished garden. A roseroy adjoins the kitchen garden, and a large assortment of the best varieties are grown in the enclosure.

A better representative collection of fruit and vegetables are seen than is usual to find in Belgian gardens, and it is evident their culture is understood. Grapes are grown on the English method under glass, and very promising the Vines looked; but as a rule glass structures in Belgium are occupied by plants alone. Peaches are also grown in a suitable range, and Strawberries extensively forced. Larger pots are employed for them than is customary with us, but the lighter soil may perhaps render that necessary. Various kinds of decorative flowering plants, Ferns, Palms, &c., are required and produced in a manner creditable to the cultivator, and every inch of space appeared to be occupied. The gardener was able to converse in English, and the teachings of the Journal, which he reads, were in many points reflected in his practice. A handsome house has been erected for him, and the many workmen in the gardens and on the estate are considered in sickness, and have pensions for good servitude when their strength fails. This places them at an advantage with labourers in England as a rule, though the same system obtains in a few good families. The wages are about 2½ francs a day in winter and 3 francs in summer, equivalent to 12s. and 15s. a week; but land allotments are provided in addition, and they appear to be well cultivated, and are doubtless of substantial benefit to the holders. M. Everaerts and his family must enjoy their garden greatly, and another luxury they evidently enjoy is doing good and making those happy around them. Their ways are ways of pleasantness. They have learned the great truth that it costs nothing to be kind, and we never heard their names mentioned otherwise than in sentiments of true respect, indicative of the esteem in which they are held in the city where they are best known, and in which they occupy such a prominent position.—A JUROR.

KITCHEN GARDEN.

SALTING AND STAKING ASPARAGUS.—Asparagus is such a favourite vegetable that no labour is considered too great which will increase it in size and quantity, and although the shoots are not often staked and tied it is a great advantage to do so. The stronger the roots the higher the growths, and the more apt are they to be blown over. If we look at the beds after a storm of wind it will be seen that some of the finest of the shoots are lying on their side. They nearly snap half way up, but give way from the connection with the root, and it is here the most damage is done, as in breaking off the crown of the root is liable to be damaged, as well as the growths near. It is therefore highly beneficial to stake and tie the strongest of the shoots before any of them are blown

over, and this operation should have attention at once. Place a good strong stake to the large plants and tie them firmly in two or more places. Salt is a good manure for Asparagus. It may be applied at any time, but the present has its advantages, as growth is active, and any stimulant will be at once beneficial. We do not apply it by weight or measure, but a small handful is sprinkled around each plant, and the first rain washes it down to the roots. Three or four applications may be given during the next month if it rains to wash it down, and under the latter favourable conditions we sometimes apply it twice a week.

SUPERFLUOUS FLOWERS.—These are appearing on Rhubarb, Seakale, and Sorrel. We often allow Seakale to bloom longer than is good for it that our bees may profit by the flowers, but we never allow it to seed, and as a rule the flowers should be cut as soon as they form. Rhubarb flowers are useless, and should all be cut off. Sorrel flowers are injurious, as they prevent the leaves forming, and they should all be cut away. We wonder if many of our readers have tried Sorrel as a vegetable and cooked it like Spinach. It is peculiar in flavour, but a good change. The Sorrel we grow is not the small-leaved variety, but one with foliage as large as a sheet of note paper.

OPEN AIR TOMATOES.—If these have to be a success they must be taken in hand promptly, and if well attended to the results will be highly satisfactory. Planting should be finished at once. Do not on any account transfer plants from a strong heat to the open ground. They would not recover for many a day, if they ever did, and it would be very disheartening for beginners, but plants that have been accustomed to the open air for a while will not take any harm. In favourable parts of the country they may be planted in the open quarters at a distance of a yard apart and staked like Raspberries, but in less favourable localities they should have the protection of a wall. Do not make the ground rich for them. Have the soil firm round the roots, secure them at once to prevent their blowing about, and from the first confine them to one or two stems. When allowed to make much wood and ramble about before beginning to train them it is impossible to get them to assume the neat forms they should possess. Should cold weather immediately follow their turning out hang an old net over them, and plant them so as to be as much exposed to the sun and as little to the wind as possible. This applies forebly to plants away from walls.

PARSLEY.—Plants of 1887 are all flowering, and although the stems may be cut off they will not be of much further use. Never trust to Parsley plants for a supply for more than a year, and as soon as the seed sown this year has produced plants sufficiently large to give a supply pull the old ones up and throw them away. When the seedling Parsley plants are about 3 inches high draw many of them up and transplant them elsewhere. We have planted thousands lately. They are dibbled into good ground in rows 1 foot apart and 6 inches from plant to plant. Sprinkle soot on them when it is raining.

MAIN CROP TURNIPS.—The Turnips from seed sown before this will soon flower and be over, but those from seed sown now will not do this so rapidly, and if a good breadth is sown they will form large roots and remain good for a long time in the autumn. They need not be sown in small quantities now but in a large plot. Veitch's Red Globe is a good sort for present sowing, and they may be put in any vacant piece of ground. We only secured a few roots from our first sowings of Turnips, then they were flowered and were at once cleared off to give place to other crops, but the Snowballs which are now ready are most useful.

SPINACH.—Our supply until lately was secured from the sowing of last autumn, but this began to seed and is cleared off to make room for Turnips. The spring sowings are now ready, but they too will soon bloom, and frequent sowings must be made to keep up a constant supply. It is no use in sowing in large quantities yet, as the heat of July will make it ready so fast that a large sowing would not be all used. A few rows sown once a fortnight will be ample. Thin young plants well, as it is only by this means that large succulent leaves can be obtained.

FRUIT FORCING.

MELONS.—*Setting in Frames.*—Difficulty is sometimes experienced in getting the flowers to set and fruit to swell freely. It usually arises from the plants growing too freely, the atmosphere being too moist, and the plants too crowded with foliage, accompanied by cold. Anything like crowding the foliage or shoots is fatal to a good set, therefore the shoots should be kept rather thin by removing every alternate lateral whilst quite small, for to remove them when large very often induces canker or gumming. The laterals retained will for the most part show fruit; if not, stop them at the second joint, and the sub-laterals will show fruit freely, when water should be given sparingly; but, if necessary, pour it between the shoots so as not to wet the surface of the bed to any great extent. Place hot dung against the sides of the frame, or grass mowings will do with a little litter over the grass. This will raise a gentle heat, admitting of a little ventilation being left on constantly day and night, which prevents the deposition of moisture on the blossoms, which is fatal to fructification. Fertilise the flowers when fully expanded. Admit air freely if fine weather permit, increasing the ventilation at 70°, allowing it to rise to 80° or 85°, or 90°, at which keep it through the day, closing at 80°, except the small portion before alluded to. When the fruit is set, two to four on a plant, and the size of a bantam's egg, commence watering by sprinkling the foliage at closing time, always keeping the water from the neck or collar of the plants; and besides the sprinkling give a good watering twice a week in hot weather, once a week will be ample in dull weather. Commence

ventilating at 75°, allow the heat to rise to 85° or 90, close by or before the temperature recedes to 80°, or between 4 and 5 P.M., with a gentle damping. The temperature will run up 10° or more, which will be advantageous to the swelling of the fruit. When the fruit is advanced for ripening keep the bed well lined with hot dung or grass mowings, and admit air freely, omitting the sprinklings, watering if necessary through the spout of the pot instead of through a rose. Cut the fruit a day or two after it commences giving off its aroma, placing it in a dry room, and in two or three days it will be in perfection, which is when the ripening colour pervades every part of the fruit, after which flavour is lost rapidly, and in a few days is entirely gone.

Second Crops in Frames.—Cut back Melons which have fruited, remove a little of the surface soil, and give fresh, also a good watering. If due regard has been had to keeping the soil moist for the first crop, and shoots retained from near the base of the fruited Vines, fresh growth will be quickly made, and fruit will speedily set and swell; indeed, we have had fruits set and swelling freely before the first fruits are cut, having encouraged fresh growth from near the collar of the plants. Some cultivators keep their plants so dry at the roots during the growth and ripening of the first crop as to completely exhaust them, and in many instances spoil the fruit, it ripening prematurely, and consequently is not solid and the flavour is poor. Plenty of moisture is necessary when the fruit is swelling, and enough should be given when ripening to preserve the foliage, there being no comparison of fruit ripened with foliage and that which has no foliage to aid it during the ripening process.

Late Crops.—Some consider Melons are worth little after the hot days of summer, but they are often good when the days are bright in September and October. Plants that were raised some time ago and have been put out, or should be at once, will set freely in the dog days and afford acceptable fruit in August and September. A last sowing should be made for growing in dung-heated pits and frames. It is advisable to make up the beds at once, or at the same time as the seed is sown, which should be in 4-inch pots about half filled with soil, placed in a frame or house. One or two seeds may be placed in each pot and supply soil around the stem as the plants advance, but not higher than half an inch from the seed leaves. When the bed is ready turn the plants out of the pots, place one in the centre of each light, planting to within half an inch of the seed leaves with the soil inclining from the stem, give a good watering, and shade from bright sun. Pinch out the point of the leader at the second rough leaf, which will induce side shoots, reduce those to four, take two to the front and two to the back of the frame or pit, rubbing off the laterals to within 9 inches of the stem all around, and every other lateral upon the primary shoots, stopping those at 6 inches from the sides of the frame. The plants will be showing and setting fruit in plenty early in August, and they will ripen in late September. All the stopping and disbudding must be done whilst the growths are small, for large reductions of growth only tend to promote grossness in the parts retained, and are unfavourable to the setting of the crop.

The grower who has well-heated light houses will have no difficulty in maintaining a supply of fairly flavoured fruit through October or November from sowing up to the third or fourth week in July.

CUCUMBERS.—Strawberry houses, houses occupied with Vines in pots, and structures employed for wintering bedding plants will be cleared, and may be utilised for growing a late supply of Cucumbers. Grow the plants in pots 12 inches in diameter, or larger, draining them well, and only partly filling them with compost so as to leave space for fresh additions, or they may be grown in boxes of about 15 inches depth, and 18 inches to 2 feet square. A wood or other trellis may be improvised at 15 inches from the glass. No fire heat will be necessary, the house being closed between 3 and 4 P.M., syringing then, the floors and every available surface being kept damp so as to secure a good moisture through the day, but do not syringe in the morning, it often being the cause of great mischief to the foliage. Admit air at 75°, and allow the temperature to rise to 85° or 90° with sun, and close between 80° and 85°, and if the temperature rise afterwards to 90° or 95° all the better. Train with a single stem to the trellis, rubbing off all laterals to that height, then allow them to grow, pinch the leader after it has advanced about two-thirds across the trellis. The laterals may be stopped one or two joints beyond the show of fruit.

In the Cucumber house fire heat will only be necessary to prevent the temperature falling below 65° at night, and to ensure 70° to 75° by day artificially. Attend well to stopping the shoots, removing bad leaves, well thinning the old growths, and watering with weak liquid manure about twice a week. To encourage surface roots sprinkle the bed with a few fresh horse knobs once or twice a week, and occasionally with a little soot, both of which will be beneficial from supplying ammonia to the atmosphere.

Pit and frame Cucumbers may be watered about 4 P.M., closing then or earlier according to the weather; but it is not safe to close so early as to raise the temperature above 90° to 95°. Liquid manure should be given occasionally, but it is not desirable to apply it over the foliage, nor too frequently. Keep the growths fairly thin, thinning out old growths and encouraging others in their place so as to keep up a succession of bearing wood. Stop one or two joints beyond the fruit. Avoid overcropping and allowing the fruit to remain on the plants a day longer than can be helped.

VINES.—*Late Grapes.*—These must be thinned immediately they are large enough, the berries swelling so rapidly at this season that they

soon become too large to be thinned properly and expeditiously; besides, when the work is too long deferred the size of the fruit is impaired. The laterals must not be allowed to extend so as to interfere with the principal foliage. The growth may be allowed to extend where there is space to admit of its full exposure to light, but not otherwise, overcrowding and overcropping being the cause of more failures than any other error of culture. Remove all superfluous, badly placed, deformed, or small bunches. Crop lightly, which means size, quality, and high finish, bulk meaning small fruit, bad colour, poor quality, non-keeping, and often shanking. Water thoroughly when necessary, one good soaking is worth many dribbles.

Vines Cleared of their Crops.—Syringe occasionally to keep the foliage clean, afford water to render the soil moist, a good mulching keeping the surface from cracking, and the surface moist will prevent the roots going down in quest of moisture. Allow a moderate extension of the laterals, and admit air freely above 60°. There is no fear of the wood not ripening, and the difficulty is to prevent the premature ripening and fall of the foliage.

Ripe Grapes will be the better for slight shade from powerful sun, some pilchard or a double thickness of herring nets drawn over the roof lights will mostly be sufficient shade, and a good spread of foliage will assist in Hamburgs keeping colour. Moderate air moisture will not injure the Grapes if accompanied by free ventilation. Keep laterals fairly under, but a little extension will assist in the retention of the principal leaves, and upon their continuance in health depends the maturity of the buds for next year's crop.

Grapes ripening should have a circulation of air constantly, with sufficient heat in the pipes to maintain a night temperature of 65° and 70° to 75° by day, with 80° to 85° or 90° through the day from sun heat. Avoid a very acrid atmosphere, damping occasionally, and do not allow the border to become dry. It is a confined stagnant atmosphere that does all the mischief in Grapes cracking.

Muscats and Lady Downe's completing the stoning process should have air abundantly, sufficient warmth being kept in the hot-water pipes to maintain a night temperature of 65° to 70°, and 5° to 10° more artificially in the daytime, as if they are kept cold and close they are, if the weather prove bright, liable to scald.

Stop Vines in pots when from 6 to 8 feet long, and pinch the laterals and sub-laterals at one joint as produced. This applies to Vines intended for fruiting next season; those intended for planting may be allowed to make all the lateral growth they can, and be cut back to two or three eyes at planting time. Get as much stored up matter into the fruiter as possible by judicious feeding, and cleanly foliage thoroughly exposed to the light.

PINES.—Fruit Ripening.—When the fruit commences colouring syringing must cease, but the supply of water at the roots must be continued as before when necessary, and to improve the colour and quality of the fruit ventilate liberally, but do not allow the temperature to fall below 80° in the daytime, gradually diminishing the moisture in the house, maintaining a night temperature of 70° to 75°. Plants of Queens and Providence started into fruit last February will ripen this month, whilst Smooth Cayennes and Charlotte Rothschild will require about a month longer to finish properly. Under the same conditions they furnish a good successional supply, which may be still farther extended by removing some of the fruiting plants to a cool airy place. Keep the heat at the roots from 80° to 90°.

Successional Plants.—Fire heat will not be necessary much longer, as the temperature, by the assistance obtained from the heated beds in which the plants are plunged, rarely allows the atmospheric temperature to fall below 65° at this season and for the next few weeks, and this temperature is more suitable for the satisfactory development of the plants than a higher one. Recently potted plants make growth quickly. Strict attention should be given to ventilation to prevent an attenuated growth, therefore admit air at 75° to 80, increasing it until 85° is reached, and above that ventilate fully, diminishing in the afternoon closing the house at a temperature of 80°, affording a light sprinkling daily when bright weather prevails.

Suckers.—From those on the early fruiting plants a sufficient number should be selected to meet the demand, and if started at once the plants resulting will be suitable for fruiting from this time onwards another season, and will be supplementary to those started in March, their requirements being identical, only shading must be more effectual.

PLANT HOUSES.

Gesneras.—These should be grown on from the start to the flowering stage without a check, and it is very difficult to retard them without injury, which often results in their failing to flower satisfactorily. The best and safest method when required for late flowering is to delay starting them into growth; the tubers keep safely for a very long time in dry soil or sand. The latest tubers are still plump, but will be started in gentle heat in boxes or pans filled with light material, composed chiefly of leaf mould and sand. They root freely, and can when large enough be transplanted singly into pots without the slightest check. We prefer this method to starting them singly in small pots, unless they can be plunged where the soil can be kept in a uniform condition for moisture. The earliest will be showing signs of active growth, and should at once be lifted out of pans or boxes and placed into 3-inch pots liberally drained. Employ a compost of loam and leaf mould in equal proportions, with coarse sand freely added. Water after potting, and stand the pots in a warm house on a moisture-holding base, where the

strong rays of the sun can be shaded from them. Be careful not to syringe or allow water to lodge upon their foliage. They delight in heat and moisture, but cannot endure syringing.

Tydæas.—Plants for early flowering will be sturdy specimens in 3 and 4 inch pots, or larger, where many tubers have been started together. These may be placed in 6 to 8-inch pots or pans according to the size of plants required. For decorative purposes 5 and 6-inch pots are the most suitable; in fact, when larger than these are required pans are better than pots, because these plants are not deep rooting and do not care for too much soil about their roots. Those ready for lifting out of boxes or pans to be potted for the first time will be found the most serviceable in many places, for they will be in full beauty at a time when flowering plants in the stove are rather scarce. At first they can be placed in the same compost as Gesneras, and when finally potted the soil may consist of good fibry loam, one-third leaf mould, one-seventh manure and a liberal quantity of coarse sand. These, like Gesneras, must not be syringed. Amongst the most useful of Tydæas are some of the evergreen varieties that make no underground stems or tubers, such as Madame Heine which must be perpetuated by cuttings. These flower naturally at a time when Poinsettias, Euphorbias, and Plumbagos are past. Cuttings rooted thickly together in pans as advised will now have strong luxuriant growths that may be taken off and rooted singly in 2-inch pots. They will root freely in any light sandy soil if kept close in the propagating frame and shaded from the sun. As soon as they are well rooted the points of the plants may be removed, which will induce them to branch freely. If larger plants are needed, those in the pans from which the cuttings have been taken may be allowed to break into growth, when they can be lifted out of the pans and placed singly in 5-inch pots.

Gloxinias.—Do not neglect the earliest plants as they cease flowering, but place them in frames where water can be applied as they need it until they ripen the whole of their foliage. It is a mistake to keep successional Gloxinias too warm; at this season of the year they will do well without the aid of artificial heat. All that is needed is a moderately close atmosphere with plenty of moisture and shade from strong sunshine. Place seedlings raised early into 5-inch pots, a capital size to flower them in, while those raised later and pricked into pans and boxes may be placed into 3 or 4-inch pots according to their size.

Achimenes.—More cuttings of these may be inserted in 5-inch pots, and if brought forward gently the plants will be useful for the conservatory as long as that structure is warm enough for them. When the cuttings have been removed, allow the plants that have been reserved for yielding cuttings to make a good growth and flower, or their tubers will be small.

FLOWER GARDEN.

Lawns.—Closely mown velvety green turf is most appreciated, and it is only by frequent attention that this can be attained. If neglected for a few weeks, or allowed to grow long enough to be made into hay, the grass becomes coarse, and many of the finer varieties are either crippled or killed. This season the grass grows rapidly, and unless a heavy machine is used it requires to be mown every four or five days. Light or hand machines will not cut a heavy crop of grass properly, and those owning small mowers ought to use them frequently, or they will soon be unable to work with them. At the outset, or at any time when the grass is too long to be cut by a machine, it ought first to be mown closely with a scythe, and the machine passed over it immediately after. Even where a heavy pony or horse machine is available, these will leave the turf in a much better condition if run over before the crop is heavy. When the grass is left more than a week it takes much longer to cut it, and the work is much heavier. Therefore mow frequently, and there will then be fewer complaints about mowing machines failing to do their work properly.

Newly Planted Trees and Shrubs.—If many of these, especially those transplanted late, do not get heavy supplies of water now, and also during the summer, the chances are failures will be numerous. It is quite a mistake to defer watering till they give signs of suffering from drought, a tree or shrub flagging badly in sunshine rarely recovering properly, no matter how often water is applied. Nor are mere dribbles of any avail. A thorough soaking should be given, and it is advisable to water a few every day rather than give a small or useless quantity to a greater number. Those moved with a good ball of soil and roots ought to have the ground near the stems opened out, so as to form a basin to hold all the water poured in. If the old ball is found to be at all dry, this ought to be pierced with pointed iron rod, or otherwise it will be almost impossible to thoroughly remoisten it. Overhead waterings are also most beneficial in hot evenings and dry days. Both new and old shrubberies will be benefited by a mulching of some kind, the grass from the mowing machine being very suitable for the purpose.

NOTES ON BEES.

UNLESS it was in 1842, no season within the remembrance of man has been so inauspicious as it has been recently in the north. On Friday evening, June 1st, the temperature sank to 40°, and

stood at that until Saturday at 3 P.M., when it sank to 38°, remain there till next day, when it reached 55°, then gradually sank till it reached 32°, varying between that and 50° up to the 6th inst. The thermometer is in rather a sheltered position, 5 feet from the ground, and the cold has been more intense on the surface, as many things are frosted, particularly Potatoes.

Bees have suffered greatly, the surface of the ground, both near and far off the hives, are thickly strewn with dead bees, and brood drawing has commenced at many hives to a greater extent than I ever experienced, and not for want either. Bee-keepers are at their wit's end what to do in the matter, as feeding only brings out the bees to perish in greater numbers. From some quarters the news comes of the bees succumbing altogether. Bee-keeping at the present time is not promising, but we hope for better days. Untoward as it is here, it has been worse further north. In some places there has been much frost, and I observe that in one case the thermometer was as low as 10°, so that everything not quite hardy has been frosted. One correspondent says, "Yesterday, the 3rd, was one of the worst days that has been here for years; blinding sleet and rain; the hills were all white; the snow was lying here for hours after it had settled." It will be necessary to feed the bees.

EMPTY COMBS.

The proper utilisation of empty comb has long been practised in well regulated apiaries throughout Scotland, but the practice for some time with some bee-keepers has either been abused or not understood so as to have satisfactory results, and many of the lessons given on the subject have been the direct cause of failure and disappointment. In order to make clear the best way to utilise empty but white comb, we must take a lesson from Nature. We are often hearing of bees busy making combs when no honey is stored in them, and bee-keepers are assured that these combs are meant to be filled with the pure nectar when that happy time arrives. Some advise feeding with sugar to encourage empty comb-building, the advice being as ungentle as the honey taken from them would be.

As our bees do not work in that manner, nor on these lines, presumably other bees will act in the same manner and as economically as our own do. It will therefore be well if bee-keepers dismiss from their minds the false impression that bee nature can be altered to suit the capriciousness of individuals. When bees are filling supers (it is the combs of these only I refer to) they do not work and make much empty comb in advance of the flow of honey, but only in a certain proportion to the income, and that proportion scarcely ever exceeds a fourth or a fifth, and very often much less. Whenever the flow of honey ceases comb-building generally ceases after twenty-four hours, and continues only that time if much loose honey is in the body of the hive.

Sometimes supers are all filled and well sealed at the close of the honey season, at others a proportion of the combs are empty. In the former case, although the supers are not removed immediately the honey stops, their purity will remain intact, but not so with empty or half-filled combs, because, as a rule, the moment the honey flow ceases the combs are gradually darkened by the bees. To make these combs available for another occasion they ought to be removed at once, hermetically sealed, and kept free from moths and dust. When such combs are to be used by the bees again they should only be given them as a second super, or only when honey is plentiful at the first, when they will be beautifully finished. The cause of the many disappointments to bee-keepers who get partially filled supers darkened is giving them to the bees at a time honey is not coming in. Supers wrought upon the Stewarton hive have their purity preserved by the bee-keeper regulating the slides according to the weather at the time the supers are on the hive, and the large brood nest with the slides closed over it prevents brood being deposited in the combs of the super. By the way, I may state before a queen will deposit eggs in a super, the bees must first have prepared the cells for their reception. I think the fore-

going will make it sufficiently plain how to utilise pure comb and have its purity preserved.

The purer the comb the more delicate the flavour of the honey, and honey extracted from combs that have been bred in is always more or less tainted. The closer covered we keep our supers, even in the hottest of weather, the purer they are. When ventilation is necessary do it from beneath; never uncover supers.

THE CALEDONIAN APIARIAN SOCIETY

Will hold its fifteenth annual Exhibition in Glasgow, in conjunction with the Highland and Agricultural Society, on the 24th, 25th, 26th, and 27th July. The prize schedule is very much as in former years, the largest prizes going to dealers, which, we believe, is contrary to the wishes of its patrons. We are of the opinion that while the money has been honestly distributed it has been imprudently allocated.

The list of patrons, office-bearers, and Committee appears to be in a great measure formal appointments, because in addition to the incapacity of some, others on the list have been dead for years, so that it will be a matter of impossibility to bring even the members of Committee together in this eventful year. The Society has been in a great measure a drag since its inception; never having been carried out on Scottish lines and systems, its members never held well together. We learn a change is to be made, if not altogether broken up. Should the Highland and Agricultural Society take it entirely under their own charge we hope the prizes will be directed towards those who at first were intended should reap the benefit.—A LANARKSHIRE BEE-KEEPER.

"THE BOOK OF BEE-KEEPING."*

THERE is no greater proof of the wide and far reaching popularity of bee-keeping than the large amount of literature on the subject which has been published during the past few years; in fact, the author of the present work seems to think an apology necessary when sending out into the world an addition to the already numerous, and in some respects unsatisfactory, standard works, practical manuals, and hand-books treating of bee-keeping in its various aspects. The object of this last manual is to supply a want, real or imaginary, and to place in the hands of the bee-keeper a book which shall not only be free from technicalities, but shall treat upon apiculture in its most modern aspect, and be so low in price as to insure its sale among the poorer bee-keepers of this country. The original conception was good, and if Mr. Webster had been content to work throughout on the simple lines he lays down on the first page of the work he would have achieved an even greater success; but on perusing the earlier pages we find paragraph after paragraph devoted not altogether to mere technicalities perhaps, but still to minute details and arguments, which, however interesting they may be in the abstract, are of very slight importance to one who simply desires to become a bee-master. Surely if a bee-keeper desires information as to the class of insects to which the bee belongs, and on other points of a somewhat similar nature, he would be led to purchase or borrow a book in which space is properly devoted to such portions of the subject, and most bee-keepers cannot but regard information, which may be most entertaining in itself, as out of place in a work written for the practical instruction of men who, above all other considerations, aim at making the greatest possible return on their outlay.

Again on page 4, by a delicate manipulation of figures, and by an ingenious mingling of facts within the author's own knowledge, the assertion that "no description of stock-keeping is such a financial success as bee-keeping" is bolstered up. Let us for a moment dissect the basis upon which Mr. Webster builds up this structure of "financial superiority of bees above other descriptions of stock kept by working men." He first gives a certain instance in which "he saw a bee-keeper who in one season took 200 sections from one hive; 135 of these he sold at 1s. each, the remaining sixty-five (Heather) at 1s. 6d. each." And then goes on to say that "Although this is an exceptional case in England, scores and scores of modern bee-keepers take on an average 60 lbs. from a colony. Even at 6d. per pound this will show a fine profit on the outlay—30s. per annum is not to be despised." Then follows a slight digression, but in the next paragraph a few quotations are given of amounts paid to individual keepers ranging from £6 to £29 in one season. Then comes the conclusion, "We think that the foregoing is a positive proof as to the financial superiority of bees above other descriptions of stock kept by the working man." To our mind the case is clearly "not proven," and there appears to be too much casuistry in the argument to recommend it to the common sense of the working man. To say that one man sells a certain quantity of honey at a high price, then to add that a man may expect an average yield of so much,

* By W. B. Webster. London: Elliot Gill, 170, Strand.

and that yield sold at even a low price will bring in so much, and then to add instances of abnormal profits, appears to be an unjustifiable attempt to puff the present possibilities of bee-keeping. Such profits are occasionally made, and no doubt if only those men became bee-keepers who were suited to the care of bees in consonance with the author's views on the subject, expressed on pages 2 and 3, such instances would be less rare; but in the present state of prices, and in view of results in different localities, it is certainly a mistake to give instances of great yields from good honey districts as criteria for the guide of one who wishes to become a bee-keeper if he can see that a fair profit may reasonably be expected from the pursuit.

Another space which might have been more profitably filled is occupied by an argument which centres round the statement that "wood, not straw, is the bee's choice of outside architecture." This is surely a most unnecessary digression; it seems like stating a case to show the advocate's skill in refuting it. After all, these are, perhaps, matters of minor importance, although we could have wished that by expunging exercises the book could have been compressed into a smaller space and sold at a less price.

As we might expect, the standard frame is recommended for the adoption of the bee-keeper, and due stress is laid upon the necessary observance of the rule to have all hives readily interchangeable in every part; in fact, the portion of the work treating on the practical management is admirably written and suitably illustrated, and we may congratulate the author upon the production of a very succinct and valuable manual. It is not too concise, but in the latter pages especially preserves an admirable mean; even the smallest points are noticed, provided they are of practical importance, and an instance of this is seen on page 26, where we read that when using "enamel cloth quilts next to the frames it is essential that plenty of warm coverings should be placed above them, and the stock very strong, or the condensation of the atmosphere will produce too much dampness." The instructions given in the paragraph devoted to "Quieting and Handling Bees" are well worth reading, but surely there is a mistake in the first few lines, where we read, "Confidence in a great measure is the bee-keeper's safeguard; skill, perhaps, ranks as second in importance." Surely skill begets confidence, at least equally as much as confidence begets skill, and, in our opinion, even in a greater degree; for without skill there can be no confidence, but with skill there is rarely, if ever, a want of confidence. The chapters on "breeding" are lucid and good, but we are most pleased to note the author's observation that the advice to "spread brood in spring time is the worst advice that can be given," and his "desire to see that manipulation banished entirely from the pages of bee manuals." At last, the triumph of common sense seems imminent!

Although the appearance of the volume is somewhat marred by the black type at the head of each paragraph, still, in a popular work, aiming at giving the greatest possible amount of information in the manner in which it can be most easily, not only digested when found, but found without trouble when required, it is not too much to say that appearance should give way to a great extent to usefulness, and there can be no doubt that the encyclopædia style of dividing up each portion of the work into paragraphs limited to the point specially under discussion must, in conjunction with an admirably clear and well-arranged index, do much to popularise a work, which in a certain space contains more information of value to a practical bee-keeper than we have seen in any other publication of a similar size.—FELIX.

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Gas-heating Apparatus (*G. Shrewsbury*).—The testimonial is a very good one, but we cannot publish it, as we should be inundated with others, for which it would be impossible to find room.

Sale (*E. S.*).—Why not try an advertisement in a local paper? There must be several purchasers in your district. The value depends on size and quality.

Pears Decaying on the Tree (*Elbow*).—It is no unusual thing for

Pears that have been attacked by an insect while in the bloom to swell to a certain size and then fall off. Many Apples, and Pears too, drop shortly before arriving at maturity in consequence of an insect which has either burrowed into their side, or its larva being deposited while it was in bloom, and it advances with the fruit. There is no preventive to this, but there are generally sufficient left unhurt for a crop.

Weevils on Roses (*G. H.*).—The small beetle-like creatures you send are highly destructive to Roses and several other plants. The name of the weevil is *Cureulio* or *Otiorhynchus sulcatus*. Catch all you can by examining the trees after dark with the aid of a light, and if the weevils are numerous quickly spread a white sheet on the ground for them to fall on, and they will then be easily seen, and can be taken care of. They may be also caught early in the morning. If not caught they deposit eggs in the ground, from which grubs emerge, and then are as destructive to the roots of plants as the perfect insects are to the leaves.

Ivies for Pot Culture (*W. S. S.*).—The small-leaved varieties, both green and variegated, are usually grown in pots for placing in vases. The plants can be trained to any form required by securing the growths to wire trellises. All the varieties are suitable for the purpose. You do not state the number required, and you may safely leave the selection to a vendor. Plants can be had in different sizes established in pots, but for obvious reasons the larger they are the higher is the price. They grow well in four parts of turfy loam, one each of leaf soil and decayed manure, with a little crushed lime rubbish and bruised charcoal for ensuring porosity. The pots may be plunged in ashes in the open ground, and the growth of the plants will be governed by the attention they receive in watering and cleanliness.

Propagating *Lychnis vespertina*, fl. pl. (*J. Wilson*).—It is now too late for propagating this fine perennial, unless the plant is an old established one, in which case the requisite cuttings may be present. In small plants they will not be forthcoming, as the flower stems are now making rapid progress. If you have convenience for doing so place your plant in slight warmth at the end of February or early in March. As soon as growth appears secure the radical shoots when 3 inches long or thereabouts, taking them off with a little hard wood attached. Insert in sandy soil in pots, and cover with bellglasses, having given a good watering previously, placing them on a cool base for a fortnight in a shady corner of the greenhouse. If at hand a gentle bottom heat will assist them considerably at this stage, but on no account give either cuttings or parent plant excessive heat, as both speedily weaken, and the cuttings then rarely make good plants at all.

Covent Garden Market Measures (*M. M.*).—These, being often made either of osier or deal shavings, vary triflingly in size more than measures made of less flexible materials. **Seakale Punnets**.—8 inches diameter at the top, and 7½ inches at the bottom, and 2 inches deep. **Radish Punnets**.—8 inches diameter and 1 inch deep, if to hold 6 hands; or 9 inches by 1 inch for 12 hands. **Mushroom Punnets**.—7 inches by 1 inch. **Salading Punnets**.—5 inches by 2 inches. **Half Sieve**.—Contains 3½ imperial gallons. It averages 12½ inches in diameter and 6 inches in depth. **Sieve**.—Contains 7 imperial gallons. Diameter 15 inches, depth 8 inches. A sieve of Peas is equal to 1 bushel; a sieve of Currants 20 quarts. **Bushel Sieve**.—10½ imperial gallons. Diameter at top 17¼ inches, at bottom 17 inches; depth 11¼ inches. **Bushel Basket**.—Ought, when heaped, to contain an imperial bushel. Diameter at bottom 10 inches, at top 14½ inches; depth 17 inches. Walnuts, Nuts, Apples, and Potatoes are sold by this measure. A bushel of the last-named cleaned weighs 56 lbs., but 4 lbs. additional are allowed if they are not washed. A junk contains two-thirds of a bushel. **Pottle**.—Is a long tapering basket that holds rather over a pint and a half. A pottle of Strawberries should hold half a gallon, but never holds more than 1 quart; a pottle of Mushrooms should weigh one pound. **Hand**.—Applies to a bunch of Radishes, which contains from twelve to thirty, or more, according to the season. **Bundle**.—Contains six to twenty heads of Broccoli, Celery, &c.; Seakale twelve to eighteen heads; Rhubarb twenty to thirty stems, according to size; and of Asparagus from 100 to 125. **Bunch**.—Is applied of herbs, &c., and varies much in size, according to the season. A bunch of Turnips is twenty to twenty-five; of Carrots thirty-six to forty; of Greens as many as can be tied together by the roots. Early in the season when produce is scarce the lesser numbers make up a bunch, later the bunches are larger.

Weevils on Vines (*T. W.*).—Your Vines are attacked by the destructive pest, which is referred to as follows by Mr. Barron in his useful work, "Vines and Vine Culture":—"The Vine Weevil (*Cureulio vitis*), otherwise *Otiorhynchus sulcatus*, otherwise *Otiorhynchus vastator*; and his smaller and less common congener, *Otiorhynchus pieipes*. The former is of a dull black colour, hard, round bodied, granulated, wingless, having six legs, a blunt proboscis, and two antennae. Its length is about three-eighths of an inch, and its habits are nocturnal. The larvae are of a dull white colour, legless, eurved, and maggoty of appearance, and seem to have a gregarious tendency. The pupa is soft, of a dirty white tone, and more sensitive than pupae are in general. In the larva state, living wholly underground for a period not yet ascertained, this creature feeds upon the Vine roots, and gnaws them almost to a stump, enjoying especially the out-push of young fibres, and following every tender growth. This is the most destructive stage. Then, after about a fortnight passed *in statu pupillari*, the weevil issues from the soil, and for several weeks perhaps feeds upon the foliage by night, and lurks about the neighbourhood by day. To strong and well-established Vines this pest may do much injury; to newly planted canes and those in pots it is often fatal. There seems to be no remedy—for who can

remove and burn the soil, as is lightly recommended, without destroying the Vine roots too?—except to catch the marauder in his nightly raid, and check the breed. This is done by laying white cloths or papers under the Vine stems, and throwing a bright light on them. Any weevils which do not drop, as some will do at the surprise, may generally be brought down by a sharp shake of the trellis. By frequent care of this throughout the spring and early summer the plague may be stayed, though nothing will entirely quell it when once set up. Above all permit no pot plants, such as Ferns, Spiraeas, &c., of tufty and thickety nature to stand near the Vines in springtime. In these the weevils harbour, and pursue their evil courses; and then the female descends the pot and the Vine roots support her issue."

Grubs in Soil (W. G.).—We are sorry to inform you that your ground is infested with a pest far more destructive and difficult to extirpate than slugs. The grubs you send are the larvæ of the fly commonly known as the daddy longlegs, one of the crane flies (*Tipula oleracea*). From the toughness of the skins of the grubs they are called Leather Jackets, and it is doubtful if anything can be supplied strong enough to destroy them without destroying vegetation also. The illustrations

Fig. 67.—1, Eggs; 2, Maggot; 3, Maggot case, protruding through grass; 4, Daddy longlegs (female).

show the grub, fly, pupa case, and eggs. A heavy dressing of gas lime before turning-in the turf might have been beneficial, but cannot be used effectively now. The grubs are usually the most active during the month of June, and generally change into the pupa state in July, but not always. In that state they do no harm. Strong Broccoli plants put out in July, the roots and stems thickly smeared with soot by drawing them through a thick puddle before planting, would be much more likely to escape injury than by planting in May; and a little petroleum, say a wineglassful to a gallon of the soot puddle, would probably improve it as a deterrent of attack by the grubs. Rooks and starlings are said to devour the grubs, and the starlings the flies also, and in some parts of the continent nesting conveniences are provided for aiding the increase of the birds. Superphosphate of lime, at the rate of 6 or 7 cwt. per acre, is good for Cabbages and all similar crops, growth being further accelerated by 1½ cwt. of nitrate of soda. Soot spread round the plants is also beneficial, and is freely used by many growers of vegetables for market.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*Senex*).—1, *Libertia ixioides*; 2, *Saxifraga cristata* var. *angustifolia*; 3, *Veronica saxatilis*; 4, *Arenaria balearica*; 5, *Valeriana Phu*; 6, *Cerasus Padus*. (*G. M. D.*).—It is a double variety of *Cardamine pratensis*, and has been observed before; it is, however, very interesting, but not worth sending to the Society your name. (*R. M.*).—1, *Cypripedium Godefroyae*; 2, *C. barbatum*; 3, *C. Lawrenceanum*; 4, *C. niveum*. (*Lady King*).—*Staphylea pinnata*. (*W. S.*).—1, *Wistaria sinensis*; 2, *Phlox setacea*; 3, *Daphne cneorum*; 4, *Berberis Darwini*; 5, *Azalea coccinea*; 6, *Negundo fraxinifolium*. (*Laleham*).—*Magnolia acuminata*.

Hive (R. C.).—If you had sent your name your letter would have been forwarded, and it can be yet if you make good the somewhat curious omission.

COVENT GARDEN MARKET.—JUNE 13TH.

FARMING REFORM.

THE incursion of the British Dairy Association into East Anglia has naturally given rise to much discussion not altogether friendly in tone to the members of that Association, not a few of the farmers of Suffolk and Norfolk asking the very pertinent question, "Do farmers in other parts of England understand our business better than we do?" It is freely conceded that butter and cheese-making in those counties is—speaking generally—much below par, but there are many striking exceptions to this faulty practice, where certain local dairies maintain a high standard of excellence in butter-making at any rate, and this is certainly as much as can be said of many or rather most parts of England. If the home-made article were really of general excellence is it likely that we should have the produce of Denmark and Brittany ousting it from the market? It is certainly a disgrace to British farmers that this is so, and we freely acknowledge that the Dairy Association will do good work in showing by precept and example how butter should be made, but it is clearly in the wrong if it intends farmers generally to regard dairy farming in the light of a panacea for the agricultural depression.

Take first of all the question of climate. In Ireland and the west of England the mean annual rainfall is so much greater than in the eastern counties, that the fact ought to bring conviction to every thoughtful mind that climatic influences must have gradually led up to the style of farming which is found to prevail in the east and west. In the moist climate of Cheshire there is a free growth of herbage, such as we vainly long for in Suffolk, but the less humid climate of the latter county is specially adapted for the harvesting of seed, and when land is fully turned to account for that purpose it is not unprofitable. If any measure of reform is possible here it is to be found in improved culture and in the selection of pure samples of seed for sowing. Red and white Clover, Sainfoin, Rye, Rye Grass, and Tares or Vetches are still profitable crops to grow for seed.

Reform in dairy farming, so far as it applies to the farms of Suffolk and ordinary farm dairies generally, consists really in the substitution of good management for bad. The test is simple enough, and no farmer of ordinary intelligence can possibly require extraneous assistance in applying it to his own practice. Let us once more enumerate the points of real importance in dairy farming, and first of all turn to

THE COWS.—In these we require neither pedigree nor imported animals, but rather well bred cows, either pure or cross-bred, of local breeds, such as are to be had in every county. As Suffolk is in question we may take the Red Polls as being deep milkers (the average yield being fifteen quarts daily), with milk of high quality, and as being large fleshy animals easily fattened for the butcher as they cease to be useful for the dairy. It is a noteworthy fact that, though not a dairy county, Suffolk has in the Red Polls so superior a breed of cows that they are alike useful for the dairy and stockyard, and there is a large and growing demand for them both here and in America.

THE FOOD.—This must be wholesome and nourishing, yet devoid of anything that can impart an unpleasant flavour to the butter. In summer it should consist entirely of green crops, beginning with Rye and following with Rye Grass, Lucerne, Sainfoin, Clover, Tares, Grass, Maize, and Sorghum. In autumn and early winter a mixed diet of Cabbages, Carrots, bran, crushed Oats, hay, and silage; later on Mangolds replace the Carrots, and Thousand-headed Kale the Cabbages. Each article of this dietary must be used in well balanced proportions, especial care being taken not to use enough Cabbage, Maize, or silage to spoil the milk for butter, as it is apt to do. Avoid oilcake altogether, and if Turnips are used they must be cooked and the water strained off. If possible use fresh spring water. The best arrangement we ever had was a flowing spring, from which the water was conveyed in pipes through cisterns in each yard.

YARDS AND LODGES.—These places should afford thorough shelter, be well drained, well littered with fresh litter daily, so that the cows always have clean dry bedding. We have seen admirable cow houses where no litter was used, and the asphalt flooring was kept scrupulously clean, the walls cleansed at regular intervals with limewash, and with thorough ventilation by means of louvres in the roof. Let no foul litter from stables be thrown into the cowyard, for cows will often eat this greedily to the detriment of the milk.

The dairy should be perfectly clean, sweet, and have thorough ventilation, and there should be nothing in its surroundings at all likely to cause the slightest foul odour to enter door or window. A floor of concrete faced with Portland cement is best, with slate shelving for the milk pans. Every utensil should be scalded and then rinsed in cold water after it is used. Churn at least twice weekly; stir the cream as each skimming is put into the crock; add no fresh cream at the time of churning, or for twelve hours previously, a slight ripening of cream being good for the butter. Test the temperature of the cream with a thermometer before churning, and see that it is 57°. In cold weather this is managed by putting the

cream crock in warm water, and in hot weather in cold water; but it is much better for the butter if the dairy itself can always be kept slightly below, or at this temperature. Rinse the churn before using with hot or cold water according to the season. Churn slowly, stop at once when the butter comes; withdraw the buttermilk, and wash the butter three times in fresh spring water, and once or twice in salt water by placing salt in a muslin bag in some water. This is the best way of imparting a slight salting to the butter, and avoiding the use of crude salt; do not touch the butter by hand, but make it up by using a butter worker and slices.

Given due attention to the whole of these details in cowyard and dairy, excellent butter may always be had, and there would be no occasion to have butter factories. We make particular mention of this, because we have reason to suppose that such factories are recommended as a remedy for bad butter now taken to the shops from farmhouses. But no factory can make good butter from cream that is spoilt by inattention to one or other of the simple conditions we have enumerated.

WORK ON THE HOME FARM.

As we sit down to write this note we are longing for a few hours' rain for the spring corn, grass, and root crops. The longing is all the greater because we know in many favoured localities rain has fallen, and without a dripping June we dare not hope for that full measure of success for which we have striven so earnestly. Corn-hoeing ended, and the hoeing among root crops so far advanced, we could welcome rain heartily, but if the weather proves unkind the hay crop will be small, and spring corn must suffer too. There are excellent crops of Winter Tares, Sainfoin, and Lucerne now in use, and we earnestly wish that farmers upon whom a premature sale of lambs and sheep has been forced simply for lack of food, would give more attention to these valuable green crops. Lucerne especially should be sown so extensively as to render a supply of it from spring till autumn a certainty for all the live stock on the farm. Once well established in the soil in rows so that it may be kept clean, it is certain to give a bountiful summer supply of green food for several years, for the roots penetrate so deeply into the soil that it is literally droughtproof.

The first crop of Clover has been eaten by the sheep upon many farms, where they are so fortunate as to have it, but the failure the Clover plant last year, owing to the drought, was so general that a full crop now is exceptional, and both stover and seed is likely to be scarce and dear next season. On poor pasture hay cannot be a full crop, but where manure has been used regularly and in good time growth is vigorous enough, but even that would be the better for rain. Haymaking will probably be late generally, and we must push on the work briskly when it is once begun. A short hay crop does not always point to high prices, for foreign Oats and other imported food come into competition with it so much as to keep down prices.

Sheep-shearing has been done, and the lambs are withdrawn from the ewes. All the ewes unfit for breeding another season are draughted from the flock to be fattened for sale. This is best done in folds, and much good may be done to land now and onwards to the autumn in this way. When the ewes have fully recovered from any wounds caused by the shearing they should be dipped in Cooper's mixture to destroy ticks and lice, and to keep off the fly.

REMARKS.

3rd.—A bright summer day.
 4th.—Generally bright, but cloudy at times in morning and evening.
 5th.—Cloudy and cool, with spots of rain in the afternoon.
 6th.—Dull and damp, with slight showers.
 7th.—Variable, with a very slight shower in the morning.
 8th.—Showery early, some sun-shine in the morning; showery afternoon, fine evening.
 9th.—Gloomy, with showers in the morning; hot sunshine and slight showers alternately in the afternoon.
 A very sudden fall of temperature between June 3rd and 5th, the maximum being 22.5° lower on the latter day. But for the heat of June 3rd the temperature of the week would have been below the average.—G. J. SYMONS.

THE DIFFICULTIES AND DUTIES OF GARDENERS.

DIFFICULTIES in some form or other have to be encountered by persons of every rank and calling, and gardeners have their share. Some possibly feel they have more than their share, but after a fair amount of experience, and not a very narrow field of observation, I have arrived at the conclusion that the greatest grumblers are not always the greatest sufferers. They think they are, of course, but they only know their own case, and are perhaps a little prone to magnify the disadvantages of the position and under-rate its privileges.

Less than two years ago a very good gardener felt himself so hardly used that he could "endure it no longer." On being somewhat closely questioned he had a difficulty in finding any other than a fanciful grievance. He received his wages promptly and regularly, and was surprised to hear of the possibility of difficulty existing on that score. He was not found fault with, which he accounted for on the ground that he did everything so well that there was no occasion for complaint; but still he was not happy. His chief cause of trouble appeared to be in receiving no praise. He was not applauded for everything he did. Compliments were not poured on him. If he had thought the matter over from the master's view as well as his own he might perhaps have comprehended that compliments and praise were not in the contract. In the end he left, on the chance of "getting a better place," and now would only be too glad to return to his old charge, which he ought never to have relinquished. He did not look at both sides of the question fairly, nor make allowance for the difference in temperament between himself and the master, who paid wages regularly and did not find fault. Encouragement, in the form of a word of approbation and appreciation now and then for work well done, is no doubt helpful to a man; it lightens labour, and incites to fresh effort, and though it may be conceded there are masters who are chary in dispensing even a smile of recognition, there are men who probably expect too much, and make themselves uncomfortable accordingly.

Let us look a little closer into the dual question—the duties and the difficulties of gardeners—fairly, and discuss the matter plainly, as it may possibly be of service to some uneasy fellow mortal who may be in a better position than he thinks, while it cannot make his lot any harder. The paramount duty of a gardener who is engaged as a servant, as all gardeners in private situations are, is to meet in the best manner possible the wishes of his employer, whose money he receives in consideration of services rendered. There are possibly men in the gardening ranks who may feel a little humiliated by being referred to as servants; but they are only the shallow-minded and vain, the great majority and the most able and genuine being proud of the positions they occupy when those in authority are considerate—that is, not unduly exacting or unreasonable. "Gentlemen born," as the Laureate puts it, are not as a rule oppressive, and those who are have relinquished the claim to the grand old appellation. They have their temper, trials, and difficulties; but the true servant will, in turn, be considerate, and avoid as far as in him lies giving occasion by words or acts to call into action those traits of character that contribute to the discomfort of master and man. Fire cannot burn without fuel, and this should not be applied except for a distinctly good purpose, never to feed the flame that may grow into a destructive conflagration.

It were useless disguising the fact that there always have been men in the position of gardeners who have pursued a policy that is to be regretted, and by injudicious acts have engendered a feeling of mistrust instead of confidence, not towards themselves alone, which would be a small matter, but towards a community. Short-sighted, vain, self-willed, and ignorant men have much to answer for in prejudicing the status of the body to which they belong. The best educated, most intelligent, and most capable members of the craft never forget their position; but by their fidelity, ability, and demeanour win the confidence and even the friendship of those whom they serve. It happens occasionally that a gardener, impelled by a sense of duty in the real interest of his employer, has to stand firm against a suggested innovation; but his attitude then will be calm and respectful, and he will bring the power of reason and experience to bear to enable the matter and its possible consequences to be fully understood. If he fail in thereby making an impression, and receives an intimation that amounts to an order to carry out a prescribed course, his duty is then clear—to obey or resign. It is utterly useless and a most serious mistake for a servant to wage war with his master, as they cannot meet on equal terms. There may be valour enough on one side, but to persistently display it is foolhardiness when all the real power is on the other; the weaker must ever capitulate, and he will be compelled to retreat, it may be ignominiously.

We now arrive at a crucial point to determine, or a crisis, which possibly occurs to most men at some time, and often early in life. They have to obey or resign. Let them consider long and calmly before adopting the latter alternative. It may be the easier of the two, and by far the more agreeable to the feelings. But before the final step is taken let existing facts and future contingencies be fully and fairly examined. First, what is it you are expected to do? It is something contrary to your wishes, and to yield you think is to show weakness. Foolish idea; the most weak-minded man can act in that way. Strength lies in overcoming a difficulty, not in running away from it, and one of the most formidable obstacles to surmount is often self-pride. Let the matter be looked at in this way. You are in the position of head gardener, and cannot comply with the wish of your employer because you think it unreasonable. You have men under you, and wish them to do something that they may not feel agreeable, and hence they either evade the task or refuse. What do you do then? Capitulate? No! They either have to obey—obey you, resign, or be discharged. You are the master then, and exercise a master's strength; but at the same time you are a servant, and expect the master of all to yield in the event of a conflict; but he will not yield unless he is weak, any more than you would to your subordinate, whether both of you were unreasonable in your expectations or not. This is a plain way of looking at plain facts, and they ought never to be obscured by prejudice or sentiment.

It is easy to resign; but there is a future. That ought not to be forgotten. Nor must a gloss be put on present circumstances by a disappointed man. It is dangerous to resign as well as easy. Here is a man who "cannot put up with" something. He has a family dependent on him for support, and after meeting their wants can save little or nothing. He throws up his appointment in a moment of irritability without any substantial assurance of future employment, and with perhaps not twenty pounds in his pocket. He casts himself on the world, and trusts to be taken into the nurseries. But these establishments may be full, and the world full too. Then he says both are cruel because they starve his children. That is a misconception. Nurseries are not charitable institutions for the succour of unfortunate gardeners, but their proprietors are only too glad to help all the men they can and in whom they trust; and as to the world, it is the most kind to those who make the fewest mistakes.

Among the greatest errors for gardeners to avoid are precipitate resignations. I write from experience, having been a victim, I

cannot say of misfortune, but of misjudgment, from which it took me long to recover; and though difficulties arise now and then I have learned to make the best of them, and am happy and well-to-do in comparison with an old bothyite, who once had a gentleman's life as the head of a great garden, and who is now glad to work as a labourer for 14s. a week. He took a first step by an ill-judged resignation, and, as is not infrequently the case, all his after steps were downwards. There are numbers of similar reverses of fortune, and they should teach a lesson in these days, when so many men are waiting and watching for vacancies, and regretting their precipitancy in making vacancies for others. No gardener should hastily resign a charge on the mere chance of obtaining another who is not in a position to wait for a year at least without employment. His clear duty is to do the very best he can, even if he cannot do as he wishes, for his employer, as he will then be doing the best for himself, till the time comes for taking a certain step onwards and upwards in the march of life.—
AN OLD SERVANT.

PETUNIAS.

THE usefulness and beauty of Petunias have been amply proved by many cultivators. They are cheap, easily grown, and the flowers present exceptionally rich, varied, or delicate colours, recommendations that entitle them to general attention. There is, however, a suspicion that Petunias have been somewhat neglected in recent years—why, it would be difficult to say, but it is a kind of re-action that seems to follow popularity; and flooding the markets and catalogues with scores of named varieties invariably has some tendency in this direction, as purchasers become tired of the minute differences found sufficient for new names and special prices. A different method is now being adopted in the trade, only the select few of unquestionably distinct varieties receive particular designations, the others are classed under a general name as a special strain. This is far preferable in all respects; it gives greater satisfaction to purchasers, as in a packet or two of such selected seed they obtain all the varieties desired, and it is assisting materially in restoring Petunias to the popularity they so well merit.

Numerous as are the forms of cultivated Petunias they have all been obtained from the union of two species, the remarkable breaking up and combination of their characters having been accomplished within a few years after their introduction. The first of the two known was *P. nyctaginiflora*, which was found late in the eighteenth century by Commerson on the shores of the Rio de la Plata, South America. Upon the specimens then collected the botanist Jussieu based the first published description, figures, and name, the latter being chosen from the resemblance of the flowers to the Marvel of Peru. Possibly plants may have been raised soon after on the Continent, but the plant does not seem to have been grown in England until the second decade of the present century, when Mr. Robert Sweet and Mr. Anderson of the Chelsea Botanic Gardens both cultivated it and assisted in bringing it into notice, illustrations appearing about the same time in the "Botanical Magazine" and "The British Flower Garden." In both cases the plant figured has broad ovate hairy leaves, with five-lobed rather bell-shaped flowers, pure white, with a few greenish veins. Mr. Sweet seems to have been very successful with it both from seeds and cuttings, and a year or two later he gives the following account of a remarkable plant:—"In October, 1826, I turned out of a pot a seedling plant about 6 inches high, with two or three shoots, into a border by the side of a wall facing the south, where it continued to grow rapidly all last winter, and never had a leaf injured. In very severe frosty weather I covered it with a mat, but left it exposed whenever the weather was milder. By the middle of March it was 18 inches high with numerous branches, about half of which I was obliged to cut away in the beginning of April, when I first tied it up to a stick. After this it grew very fast, and by the end of May began to be covered with flowers. By the middle of July it was above 6 feet high with many hundreds of its large white flowers open every day, each flower continuing in perfection two or three days, and by the middle of August it was 8 feet high and bushy in proportion, covered with flowers from the ground to the top, some thousands being expanded at one time, so that at a distance it appeared like a white sheet."

P. nyctaginiflora rapidly extended in general favour and soon became well known, but does not seem to have produced a single variation until another species, *P. violacea*, also named *Nierembergia phoenicea*, was introduced, when some surprising results were quickly secured. This was obtained from Buenos Ayres, whence

seeds were sent by Mr. Tweedie to the Glasgow Botanic Garden in 1830. It was of rather more slender growth than the other species, with smaller ovate leaves and reddish-purple flowers of moderate size, and was figured in several publications under the two names given. The idea of crossing these two distinct Petunias apparently occurred to several cultivators about the same time, and seedlings were recorded as flowering in different gardens in 1835 and 1836. In the former year an illustration was given in Sweet's "British Flower Garden" (new series, plate 268), of one of these hybrids under the name of *Nierembergia Atkinsiana*, raised by Mr. Atkins, a nurseryman at Northampton. The plant shown is intermediate in habit and size of flowers between the two species, but the colour is a uniform reddish-purple without any of the markings subsequently obtained. In 1836 flowers from a similar hybrid in the Manchester Botanic Gardens, but raised at Chatsworth, were figured in "Paxton's Magazine" (t. 173), where it is said Petunias could then be "purchased at moderate prices at almost every nursery around London and in other places." In this cross *P. nyctaginiflora* was the seed parent, and it differs slightly from the one figured by Sweet; the leaves are somewhat rhomboid, smaller than those of the seed parent, the flowers large of a deep blue purple, very handsome and similar to some of the purple coloured selfs still in cultivation.

It is rather strange and interesting that from the first crosses between these species of Petunias only self-coloured reddish or bluish purple flowered seedlings were obtained, and these results have been confirmed by subsequent experiments. A second crossing between the seedlings produced a remarkable change; the fixity of characters seemed quite lost, the colours were astonishingly varied, from white to the deepest crimson and purple, while still further intercrossing resulted in the colours running into veins, feathers, zones, and spots in a most diversified manner, such as are seen now in the best strains of seed. Not only this, but fringed flowers and double flowers in endless variety have been produced by a continuation of the crossing. As long ago as 1844, when a beautiful variety named *punctata*, edged with purplish blue, and dotted with crimson in a white throat like a *Gloxinia*, was figured in "Paxton's Magazine," it was said "the amazing numbers of beautiful varieties defy all attempts at classifying or even computing," and in florists' catalogues from that date to 1860 as many as seventy named varieties were often described. Now, it is rare that a list of named forms is seen, and from good seed the grower can raise his own new varieties and name them at his pleasure.

Seeds sown in moderate heat early in the spring yield plants that flower profusely during the summer months in the conservatory or greenhouse. They require a compost of light turfy loam, a little leaf soil, and a small proportion of well-decayed manure, a free porous soil without rank or coarse material suiting them best. Much care is needed in supplying water, as it is easy to give too much, and one of the enemies of Petunias under glass is mildew, to which they are particularly liable in dull weather if kept too close or too moist. To form specimens quickly several plants may be placed together in 32-sized pots, and secured to neat inconspicuous stakes. For baskets they are also well adapted, and in window boxes they look well. When out of doors, however, they are soon damaged in stormy wet weather owing to the delicate texture of the flowers, and bedraggled mud-spattered Petunias have an exceedingly woe-begone aspect.—L. C.

VEGETABLES FOR EXHIBITION.

CUCUMBERS.

(Continued from page 484.)

I HAVE had very fine fruit from plants in pits and frames, but they were obtained from quite young plants. Those cut from old plants, or which say have quite filled the frames, are rarely of good colour, and greenish yellow fruits stand but a poor chance to win prizes at an exhibition where the competition is at all keen. A gentle hotbed, formed largely of old hotbeds, such as stable manure and leaves, with about an equal portion of fresh and slightly prepared heating material well mixed with it, is very suitable, a depth of from 3 to 4 feet, according to circumstances, being ample. I prefer pits with a hot-water pipe round for top heat, this being of good service in dull weather, but a frame set on a hotbed answers nearly as well. Sufficient short manure, and leaves, if these are available, should be thrown into the frame to raise the soil when put in well up to the light, and the same remark applies to the pits, a good mound of turfy loam or compost to be placed in the centre of each light, and if the trial stake kept plunged in the centre of the bed can be borne in the palm of the hand the planting may safely be done. One plant to each mound is sufficient, this being stopped at the second or third joint two or three days prior to planting. They ought to be planted in a sloping direction,

this admitting of their being pegged down without injury to the stem, and being given a little warm water, the bed and sides of pit or frame also moistened, the lights put on and kept rather close, a good start will soon be made. Four or five main branches ought to be pushed out by each plant, and a second stopping must be resorted to, if necessary, in order to secure them. As fast as the roots spread through the soil top-dress and add more of the same as first used, and gradually lead them all over the frame, the haulm also being gradually trained over the whole of the space. The main branches being stopped when about 2 feet long will push a number of side shoots from which a few fruit may be at once taken—i.e., if wanted for a show, otherwise they should be cropped very sparingly till nearer, or about ten or twelve days of the time. Keep the growths thinly trained, timely stopping with the finger and thumb being preferable to later pruning with a knife. Long Cucumber glasses are of great assistance in keeping the fruit straight and clean, and these ought not to be bedded in the soil, or the under side of the fruit will be yellow instead of green. Lengths of bent zinc and other contrivances are frequently adopted for keeping the fruit straight, but most of them are apt to blanch the under sides, which, it ought to be generally known, is a great disappointment. Nor should the fruit be left too long on the plants, fat overgrown specimens always "going down" before fresh, moderately and evenly thick, and straight Cucumbers.

There yet remain a few remarks to be added, these being applicable to both house and frame-grown plants. Cold currents of air are most injurious to Cucumbers; in fact, a great amount of dry air is not good for them at any time. A "nick" of air at the top ventilators or at the back of the lights should be given soon after the sun shines well on the house or frames, the aim being to prevent a sudden great rise in the temperature, which may need much colder air to counteract. Supposing the night temperature ranges from 70° to 75°, and which is not very high for the summer months, air should be given before 85° is reached, and a little more added in order to keep the temperature near that figure. Some kind of light shading is very necessary, especially in the case of house-grown plants. This, if in the shape of thin blinds, should be put on before the sun has gained much power, and will lessen the need of giving more air than is good for the plants. Failing blinds, a permanent shading of "summer cloud" or a thin coating of milk and whiting applied with a brush must be given; the plants to be well syringed in the morning some time before air is given, and again when the house is closed early in the afternoon. The walls, paths, and soil should be damped whenever found dry, and with plenty of moisture thus maintained in the atmosphere the house may be closed early enough to run up the heat to 100°. Frames and pits to be very similarly treated, the aim being to enclose as much sun heat and moisture at all times consistent with safety, while daylight lasts especially, so as to be independent of any artificial heat. Very little fire heat, as a rule, is needed by the house and pit-grown plants, nor are any "linings" necessary for the frames on hotbeds. Red spider to be kept down with the aid of the syringe and an occasional coating of flowers of sulphur, this being mixed with the syringing water; thrips, green and black fly to be destroyed by gentle fumigations with tobacco paper or steam generated by pouring tobacco water on hot bricks or pipes, and mealy bug must be caught and crushed.

From the first the plants ought not to suffer by want of water at the roots, nor on the other hand should they be unduly saturated. The most judgment is required in watering after a top-dressing has been given, as it is possible for the fresh soil to be quite moist enough, and that underneath much too dry. Nothing but clear liquid manure should be used, as anything that clogs the surface, this including farmyard liquid manure and soot water, soon does much more harm than good. Very light sprinklings of Beeson's, Standen's, or other special manures, washed in, are safe and beneficial, and on no account use other than tepid water.

For exhibition purposes, Tender and True, when at its best, is unrivalled, but only a few succeed in growing it to perfection, and on the whole Carter's Model will be found much more reliable. It is of robust free-bearing habit and the fruits are handsome. Telegraph in good condition is also hard to surpass, and I have recently cut several very pretty fruits of Cardiff Castle. It is rather short, but this is its only fault.—EXHIBITOR.

MY AURICULAS IN 1887.

(Continued from page 483.)

AND now with regard to sorts. Are we to discard all the old varieties except three or four, and to regard the new ones only? In the name of the older school of florists I say, No. There are some, indeed, which must go. As I have said, through the kindness of friends I had a few of the newer sorts—viz., Conservative,

Sylvia, Mrs. Douglas, and F. D. Horner. The two former of these I flowered well, and I consider the former very much in advance of Sylvia. It is a fine flower, with a beautiful tube and dark body colour, with good paste; the edge is certainly not as pure a white as Reid's Acme or Taylor's Glory, or that of a flower much in favour in the north, Summerscale's Catharina. It is a most abundant breeder, and indeed the difficulty with it is to get a sufficiently strong plant, as it is so apt to go off into offsets, which of course take from the vigour of the plant. Sylvia, while it throws itself up well above the foliage and bears a large truss, is not so fine or chaste a flower as its half-sister Conservative. Mrs. Douglas, a seedling of Ben Simonite's, is a very pretty purplish blue self of good habit, while F. D. Horner is worthy, when at its best, of the name it bears. It is one of that rather restricted class the green edges, amongst which the northerners seem to be working very assiduously, and probably our children may derive benefit from their good work. The edge of F. D. Horner is a good green, and all its properties are good. It is also a good doer, which some of the older green edges were not. Page's Champion, almost unsurpassable in its bright green edge; Booth's Freedom, which I remember half a century ago, and Colonel Taylor, were all bad growers; indeed the first two are now almost like the Dodo or the Great Auk; and what grand blooms of Freedom I have seen in the days long past! It may be like the delusions of early days, which we exaggerate to our contemporaries of to-day, declaring that there were never such "cakes and ale" as we used to have; so perhaps when I picture to myself one of Dr. Plant's grand blooms of Freedom as far surpassing anything we now have, I may be drawing an ideal picture which, confronted with the original, would never stand a chance of being recognised. There are, however, I think a few varieties which we shall be glad to possess, which though they may not be equal to "the first three," still, like David's warriors, may stand a chance in the strife. In connection with this subject I have been not a little amused in looking through some old volumes of the "Florist" of thirty years ago and more, and am not of the opinion that as it was said that he was the best general who made the fewest mistakes. So it is in most things, and I should be very sorry to be pinned to the statements I or others made in those days with regard to the Auricula. At that time there were several able growers who detailed in its pages their opinions and experiences—such men as Mr. Jeans and Mr. Bromhall, who were the predecessors in this way of Mr. Horner, Mr. Douglas, and others. Their collections were, however, small, for I saw them, but their cultural knowledge was great, and they had the power of pointing it to others in a way sure to interest. In one of those volumes Mr. Jeans gives the following list of flowers that were indispensable in 1858, just thirty years ago.

GREEN-EDGED.—Booth's Freedom, Hudson's Apollo, Leigh's Colonel Taylor, Sutton's Emperor, Oliver's Lady Anne Wilbraham, and Page's Champion.

GREY-EDGED.—Chapman's Maria, Chapman's Sophia, Dickson's Unique, Fletcher's Mary Anne, Fletcher's Ne Plus Ultra, Grimes' Privateer, Headly's Superb, Lightbody's Sir Charles Napier, Maclean's Unique, Smith's General Bolivar, Sykes' Complete, Waterhouse's Conqueror of Europe, and of these he selects Grimes' Privateer as the best.

WHITE-EDGED.—Ashworth's Regular, Gairns Model, Heap's Smiling Beauty, Hepworth's True Briton, Lightbody's Countess of Dunmore, Lightbody's Fair Maid, Smith's Ne Plus Ultra, Taylor's Favourite, and Taylor's Glory.

SELFS.—Chapman's Squire Smith, Faulkner's Hannibal, Lightbody's Meteor Flag, Martin's Mrs. Sturrock, Sims' Eliza, Sims' Vulcan, Smith's Mrs. Smith, and Spalding's Blackbird.

Of flowers not then let out, but of high excellence, he gives Campbell's Admiral Napier, Smith's Lycurgus, Headly's George Lightbody, Lightbody's Mrs. Headly, Lightbody's Sir Colin Campbell.

He also gives a list of flowers with edges neither green nor grey decidedly, but coming sometimes pure in both, amongst which are found some of the most beautiful and perfect Auriculae.

Amongst these he enumerates Ashton's Prince of Wales, Dickson's Duke of Cambridge, Lancashire Hero, Oliver's Lovely Anne, and a number of others. As one reads this list it is like the roll call after the battle. How few, alas! now answer to their names. It shows what a difficult class the greens is, to find that five out of the six are still grown, and although defects may be found in them, yet I would not willingly discard Freedom, Apollo, Colonel Taylor, Emperor, Champion, or Lovely Anne. Then in greys I still keep Waterhouse's Conqueror of Europe, of which I had a very fine truss this year; Sir Charles Napier, and Maclean's Unique are worthy of a place, and of course Lancashire Hero. It is curious to read the high encomiums given to Grimes' Privateer by such a grower as Mr. Jeans, for it is a flower one hardly ever sees now. Then in whites

I would like to retain Smiling Beauty, Glory, Ne Plus Ultra, and Hepworth's True Briton, while amongst selfs surely Pizarro, Blackbird and Mrs. Stnrock should not be discarded.—D., Deal.

(To be continued.)

ORCHARD HOUSES.

SINCE the publication of the exhaustive paper in our columns as prepared by Mr. T. F. Rivers and read at Birmingham, inquiries have reached us for particulars of the orchard houses at Sawbridgeworth, and plans of them have been requested. As the sixteenth edition of the "Orchard House" is exhausted, and some time must of necessity elapse

FIG. 68.—Section of the Lean to Orchard House.

before the seventeenth can be issued, Mr. Rivers has obligingly placed at our disposal illustrations of his structures for the benefit of those of our readers who may desire to erect structures of a similar character.

THE LEAN-TO ORCHARD HOUSE.

I will suppose, says Mr. Rivers, an orchard house 30 feet long is required. A ground-plan 30 feet long and 12 feet 6 inches wide should be marked out. Then six posts of oak or good yellow deal, 5 inches by 3, and from 10 feet to 11 feet 6 inches in length; or of larch-poles 16 inches in girth, cut in two, and the flat sides placed outwards, must be firmly fixed 2 feet in the ground: the ground ends, before fixing, should be charred 2 feet 6 inches from the bottom, and then have a coat of boiling coal-tar, which adds much to their durability. They will form the back line of posts, standing 9 feet 6 inches in height from the surface of the ground. For the front wall six posts of the same thickness, 6 feet 6 inches long, must be firmly fixed 18 inches in the ground, so that they stand 5 feet out. Two posts will be required at each end (at one end, if only one door is wanted); these will form the door-posts. On these posts, both at front and back, must be nailed a plate 4 inches by 3, on which the rafters are to rest; the posts are thus arranged in two lines.

The rafters must be 14 feet long. A 9-inch deal—*i.e.*, a deal 9 inches wide and 3 inches thick, will make four, each $4\frac{1}{2}$ inches by $1\frac{1}{2}$, or nearly so. These are light, strong, and economical. The rebate should be half an inch wide for the glass to rest on (not too much for glass 20 inches in width). I find that scarcely any breakage takes place from frost owing to the large pieces being elastic; 16-oz. glass answers, the extra cost of 21-oz. glass is, however, worth incurring.

On and outside the back posts three-quarter-inch well-seasoned deal boards should be nailed. In the back wall thus formed sliding shutters in grooves 3 feet by 1 foot must be fixed to act as ventilators—two close to the roof and two 18 inches from the surface of the ground (the lower shutters in the back wall must always be on a level with the

FIG. 69.—Small Span-roofed Orchard House.

a, Iron socket; b, Boards to the ground; c, Ventilating shutters; d, Glass 18 inches wide.

ventilating shutter in front); if two more be added to the right and left of the lower shutters all the better: in summer it is impossible to give too much air.

The front and ends (except the doorway) must also have three-quarter-inch boards nailed on outside the posts; one of them, the upper one in front, to be on hinges, so as to let down the whole length of the

house: this, with the back shutters, when all are open in hot weather, will ventilate thoroughly.

Where there is a brick or other wall to serve as a back wall it may be built against it with a great saving in expense; but as sliding shutters cannot conveniently be let into such walls ventilators may be made at the top of the slope of the roof by having every alternate square fixed in a wooden frame, which should run in a groove and be drawn up and let down with a cord, to which an iron weight should be attached to keep the sliding sash in place; with this the ventilators can be regulated at pleasure. An equally or more convenient mode of ventilating at the top of the sloping roof is by a continuous shutter of wood in 10-foot lengths, on hinges opening upwards raised by a line and pulley; this should be 1 foot wide at least. In a house not more than 10 feet wide this mode of ventilating at front and at the top of the roof will do very well; but in lean-to houses of greater width it is necessary to have shutters in the back wall on a level with those in front, so that two currents of air may meet and "stir up" all the air in the house.

SPAN-ROOFED ORCHARD HOUSE.

I now give a description of my favourite sort of orchard house, the span-roofed. In houses of this kind Peaches and Nectarines do not, perhaps, ripen so early as in lean-to houses, but quite as early as on walls. Owing to their being detached they can be more thoroughly ventilated, and the fruit from them is generally piquant in flavour.

In the north of England and all cold or moist districts, of which England contains too many, in the Highlands, and in the cold stormy climates of the north of either Scotland or Ireland, it will perhaps be quite necessary to introduce hot-water pipes into houses in which Peaches, Nectarines, and Apricots are to be cultivated, not to force them, but to insure their ripening properly.

Height of my small span-roofed house at sides, 6 feet; height to ridge, 10 feet width, 14 feet. The roof rests on oak posts 5 inches by 3 inches, 5 feet apart; but I now find deal posts let into iron sockets are preferable to any other mode of building orchard houses of wood, and the usual way of building with brick foundations and sills may be adopted.

The rafters are 20 inches apart; the roof is glazed with 21-oz. glass, in pieces 20 inches by 15 inches. The two ends are glazed down to the lower edges of the glass at the sides. The rafters are 3 inches by $1\frac{1}{2}$ inc

FIG. 70.—Large Span-roofed Orchard House.

and are tied together at the apex of the roof by a light flat iron tie screwed to every fourth rafter.

The path is down the centre, and the rows of trees may be placed on each border 3 feet from stem to stem, so that the sun may shine on every leaf. This is most essential; for I have occasionally had some of my Peaches deficient in flavour, and on examination have always found the trees too much crowded, so as to shade each other. In these small span-roofed houses the trees placed as above form a charming avenue, and are looked down upon by the cultivator, so that every leaf and fruit is seen.

The small span-roofed house referred to will be found an agreeable and economic structure; but large gardens require large houses, and for these the following construction may be confidently recommended:—A cheap large span-roofed house 20 feet wide and 12 to 13 feet in height to the ridge may be built after the following manner:—Oak posts or deal posts in cast-iron sockets 6 inches by 4 and 9 feet long should be placed flatwise, so as to stand 5 to $5\frac{1}{2}$ feet clear out of the ground and the soil well rammed round them, or concrete poured in so that they stand firmly. These posts should stand in two rows 20 feet apart, 6 feet apart in the rows. On them should be nailed the plates, to receive the end of the rafters, which may be nailed on to them. These plates should be 4 inches by 3. The rafters should be $4\frac{1}{2}$ inches by $1\frac{1}{2}$, and nailed to the ridge-board at the apex of the roof, which should be 12 feet from the surface. The ridge-board should be 7 inches by $1\frac{1}{2}$. The rafters must be placed 20 inches asunder. The sides and ends of the house should be formed of three-quarter-inch boards; for ventilation a shutter 18 inches wide made into 15-foot lengths and opening on hinges downwards, the lower edge 18 inches from the ground, should be placed on each side: these are for the admission of cool air. For the egress of the heated air an aperture 1 foot deep should be made at each end just under the apex of the roof. To this a shutter on hinges should be fixed, and this should be kept open from the beginning of June till the end of September. The roof should be supported, and kept from going out either by light "collar-beams" of wood to every sixth rafter, by iron rods so disposed as

to tie the roof securely, or, best of all, by two rows of iron pillars formed of 2-inch gaspipes, which are very cheap, 6 feet from each side; the lower ends placed in the ground, and let into a small square of brickwork and cement, the upper ends let into the purlin. These pillars should be about 10 feet apart.

It will be seen from this description that a house built after this

FIG. 71.—End elevation of an Orchard House 24 feet wide.

a Glazed shutters on hinges, opening downwards. b Sash for egress of heated air, opening downwards.

method is a plain but useful structure, for its sides, ends, and doors (there should be one at each end in the centre) are all of boards, and its roof only of glass. Nevertheless, this description of orchard house will give fruit in as great abundance and of as fine a flavour as a house built ornamentally and at a great expense.

In June, 1860, a house was built here, which for strength, cheapness, and lightness of construction is both eligible and agreeable (see figs. 70 and 71). It differs from the houses formerly built and recommended in having no raised brick borders, by which a considerable saving is effected. No inconvenience will arise from the trees standing on the ground level, for it is only necessary to cultivate the trees as pyramids or half-standards for the central border and as dwarfs with stems a foot taller than usual for the side borders. It is 100 feet long, 24 feet wide, 12 feet high in the centre, and 5 feet 3 inches at the sides. Sides and ends are glass, and on each side and at both ends is a glazed shutter 18 inches wide, the lower edge 18 inches from the ground on edges opening downwards for low lateral ventilation, and below that glass to the ground. At each end, just under the gable of the roof, are openings 3 feet in depth, to which sashes are fixed; these are to be open all the summer to let off the hot air, and this is all the top ventilation necessary.

The roof, which is formed with light rafters $3\frac{1}{2}$ inches by $1\frac{1}{2}$, is sup-

FIG. 72.—Dwarf Peach Tree.

ported on each side by seven light pillars $1\frac{1}{2}$ inch in diameter fixed to a bar of iron, which is let into the rafters. Each row of pillars (f) is 6 feet from the sides of the house, so that there is a border on each side 6 feet wide and an area in the centre 12 feet wide.

In addition to the ventilation above described, Mr. Rivers adopts with great success a simple plan he has devised of admitting air through underground drain pipes, one end of these air ducts passing under the sill to the outside, the other rising through the floor about the centre of the house, or where required, and covered with a moveable lid for regulating the ingress of the air. Mr. Rivers attaches great importance to this method, as in cold weather and when forcing the side ventilators cannot be safely opened. Nothing could surpass the healthiness of the trees in a large house (from which Peaches were being sent to market early in May) in which this underground system of ventilation was mainly relied on for keeping the air sweet to the ground. The method will be shown in an illustration of a very fine structure in the next edition of the "Orchard House" which is now in preparation. The trees referred to were in pots, and are certainly not exaggerated in fig. 72. Pyramid and standard trees occupy the central border in the larger houses.

HARDY HERBACEOUS PLANTS FOR FORCING.

It is not generally well known to what extent hardy herbaceous perennials are suited for forcing, or what may with advantage be employed for the purpose named. Having some experience in this direction, and believing that I have, so far, been successful in my endeavours, I will enumerate some of those which I have found most useful, by which I mean those which I have found best adapted, either for the embellishment of the conservatory, for decorative purposes generally, and for cutting. There are hosts of such hardy plants which, if put to their greatest use, would prove of the utmost value to those who have to provide cut flowers in these times in such endless quantity. Left to themselves, some which I shall mention by-and-by are almost worthless, but if cared for and grown in a proper manner are well worthy the time bestowed and the cost entailed. For years past I have given more or less attention to the forcing of hardy plants, and have rarely found anyone speak disparagingly of the plants thus treated; in fact they could not when they beheld them in equally as good condition as they can be produced naturally out of doors, but some weeks before their flowering was dreamt of. In this particular I consider we have the fullest value for our labour, for if by judicious forcing the flowering season of any plant can be extended, we have certainly gained a point.

But let us compare the relative value of forced and unforced plants, or, in other words, of flowers at their natural season against those produced by artificial means three or four months previously. Take for example *Spiræa japonica*, and the tens of thousands which annually find their way in and out of Covent Garden Market alone. This plant is almost valueless in England if allowed to flower at its natural time—i.e., July out of doors. It is doubtful, too, whether it is ever met in good condition in the open in this country on account of the late spring frosts, but view it as a pot plant flowering at Christmas and onwards, six months before its natural period, and we find a plant of high decorative value. Lilies of the Valley, again, we see in the florists' windows in midwinter at something like 2s. a bunch of six sprays; the same quantity, though perhaps a little inferior in quality, being offered in the streets in May for the modest sum of 1d.; or compare the price of a bunch of the golden double Daffodils in January with what they will command in the month of April; while for another instance we may look at the old white garden Lily, the Madonna Lily of the Italians. This one in itself is an extraordinary example of what early forcing may do, as by its adoption two crops of flowers may be had in one year—that is, those which are forced for Easter, or even earlier, may be had in flower again in the autumn and winter ensuing provided they are cared for after the first flowering and not turned out of doors as soon as the first crop of flowers are gathered. Only one other Lily has this tendency to produce two crops of flowers in one season, and this is *L. Harrisii*, but as the flowers of *L. candidum* are of a much more serviceable size individually, and produced in greater numbers from good bulbs, which latter may be procured at a mere fraction of the cost of *L. Harrisii*, it would not take long to decide in favour of *candidum*. But saying this I do not wish to underrate the value of *L. Harrisii*, which is undoubtedly a grand Lily. Instances, however, such as these might be freely multiplied, for there are numbers of plants whose value might be enhanced by the ready manner in which they submit to hard forcing. All these, however, are well known, and as they form a great feature with many market florists, and are consequently well known as good forcing subjects, I will now direct attention to some few things which are not generally regarded as suited to the purpose named.

To fully illustrate this I cannot do better than refer my readers to the groups of herbaceous plants recently exhibited at the Royal Botanic, Regent's Park, and the Royal Horticultural Society's grand Show held in the gardens of the Inner Temple. It is especially noteworthy that while these groups contained some of

our best and most striking perennials not one appeared drawn or weakly by having been subjected to artificial heat, in support of which it may be remarked that many were exhibited naturally and without sticks. As I took special note of one of the groups I will name some of the most worthy. A central position was given to *Lychnis vespertina plena*, also called the Double White Champion. This is one of our handsomest perennials. It is one of the most floriferous of hardy plants; it may be planted out in good rich soil, and if lifted in the end of September or before sharp frosts a rive, potted and placed in a cool greenhouse, it will continue to flower till Christmas, thus showing with a little timely assistance one of the very best hardy plants in cultivation may be had in flower for eight months of the year. When so much can be said of a plant with pure white double and fragrant flowers I think it only fair to assume that it is highly valuable if utilised to its fullest extent. It delights in generous treatment at all times. Another conspicuous plant was the double scarlet *Geum*, *G. cockineum* fl. pl., the vividness of which is fully equal to that of a scarlet Zonal Pelargonium. This is also profusely flowering and very ornamental.

Another telling plant was the Golden Columbine, *Aquilegia chrysantha*. This with its graceful and elegant foliage and long spurred characteristic flowers formed one of the most beautiful of the group. It is one of the most delightful plants of my acquaintance, and when grown under glass seems even more beautiful than in its natural element in the open border. Years ago I grew this plant under glass, and it always attracted a good deal of praise. The ladies were particularly fond of its flowers by reason of their picturesque and pleasing form. For vase decoration it is unique, while for several years past the ladies exhibiting at the horticultural shows in this district are always anxious to include this one in their arrangement, and right well it looks in large gardens, and particularly where plants are used for indoor decoration extensively this will be found most useful, and being quickly grown from seeds the outlay is not a severe item, while the return is almost without limit. Just imagine a fine plant of this 3 feet high and nearly as much through in the middle of May, not a mere pigmy this, but a veritable specimen such as any one may admire with ease. There were also the double crimson *Pæonia*, *P. officinalis rubra* pl., with its gorgeously coloured blossoms, and some varieties of single *Pyrethrums*, very pleasing and effective. The double and single *Pyrethrums* are excellent for forcing if treated properly, they are so pleasing and durable and very free flowering.

Yet another instance, *Doronicum austriacum*, which may be taken as the best of the genus. The flowers are beautifully formed, clear in colour, freely produced, one plant having nearly 200 flowers. In height it is not quite 2 feet, and is, therefore, self-supporting. The other forms under notice, as *caucasicum*, *Clusii*, *plantagineum excelsum*, are all good border plants, the last having very handsome flowers, but the plant for the purpose is *D. austriacum*. I well remember Mr. W. Spinks, of the Harborne Road Nurseries, Birmingham, trying his hand with this plant for early work some years ago, when the demand for such plants was at its height, and what a success he secured. It was grown in 6-inch pots, and from a decorative point of view eclipses all the *Marguerites* I have seen. It is not adapted to hard forcing, and is best brought on in a cool temperature, such as the cool conservatory. In such a place in early spring a few pots of this would enliven the surroundings beyond measure. I regard this *Doronicum*, taking into account its perfect hardiness, its easy culture, combined with its great usefulness, one of the most valuable plants either the amateur or professional gardener can be possessed of, while for spring bedding *en masse* it has no equal. Its natural flowering period is from the middle of March to the end of May.

Take again the German Irises with their exquisitely shaded blossoms. Particularly noticeable were the varieties Princess of Wales, Darius, Duc de York, the first named being the purest white among the Flag Iris. Darius has chrome-yellow standards, while the falls are bluish lilac reticulated with white and margined with pale yellow; it is an exquisite variety. The other variety named has flowers of a glistening rosy purple, and then there was the old blue Flag, bold and very effective, still one of the most showy of its race. Many of these Irises may be had in flower weeks before they can be had out of doors, which must be a great advantage. It is also worthy of note that these Irises will expand each bud in water after the first has opened, thus rendering their handsome flowers so characteristic of some Orchids still more valuable. Then if we would turn to *Liliums* we find the lovely *L. Harrisii*, *L. longiflorum eximium*, *L. davuricum erectum*, *L. colchicum*, and *L. pomponium rubrum* all well represented; the best of these, however, for forcing are the three first named, with *candidum* previously mentioned. Take again *Cypripedium spectabile*, which was in grand style, and here we have a plant in point of beauty

fully equal to the best tropical species and a long way ahead of many of them. To look momentarily at some more familiar we find *Spiræas japonica* and *palmata*, *Dielytra spectabilis*, and many more. It would, however, be difficult to name a more truly beautiful plant than *Hemerocallis flava*; in habit elegant, while its lovely fragrant golden blossoms is not surpassed by the most chaste of the *Liliums*. It is really difficult to understand why they are not grown under glass more than they are. Can it be that they are not sufficiently known to be so useful when forced with other things for early work? If this be so it is only fair to assume that the group in question has acted as a seasonable reminder of what may be done with some of our best hardy perennials.

But I will only ask the reader in conclusion to bear with me a few moments longer while I mention two commonplace plants made doubly valuable by subjecting them to a little artificial heat. They are the Winter Heliotrope, *Tussilago fragrans*, and the Buckbean, *Menyanthes trifoliata*. These are both common, though none the less beautiful or valuable. Everyone will readily admit that there is not too great a quantity of fragrant flowers at Christmas I am sure, but by including the Winter Heliotrope we have one of the sweetest flowers of the year. The strongest crowns should be lifted and potted three or four in a pot in September, and placed in a cold frame they flower finely for Christmas. It will succeed in almost any soil, preferably a stiff moist clay. The Buckbean is a native aquatic, sending up its white beautifully fringed spikes, which closely resemble those of the Horse Chestnut in form. To be successful with this it should be collected in quantity where it abounds in the month of November; and having freed it from mud and dirt simply cast it into the water tank in the greenhouse, or if an aquatic tank exist so much the better. In the early months of the year it will surprise all who have the pleasure of beholding this British weed in flower. It is abundant in many parts of England, and those who have not tried it should do so. Such, then, are some of our best hardy plants which may be forced.—J. HOWARD.

WATERING.

I THINK "A Kitchen Gardener" deserves the hearty thanks of every reader of the Journal for so carefully expounding the important practice of watering. It is a subject that has always deeply impressed me. When I first started using a watering pot I was taught to do so carefully, but at the same time quickly. I have since been thankful for the care bestowed upon me in my earlier career, for I have noticed repeatedly how common are the errors mentioned by "A Kitchen Gardener," not only amongst young men but amongst their leaders as well. It is surprising to note the time it takes some men to water a house of plants—men who are in the habit of attending to the same plants day after day, and who should know almost to a certainty which plants require water and those that do not; those that are root-bound and those that are newly potted; those that need an unlimited supply and those that require careful management; in fact, he should know the individual requirements of every plant. He will be easily guided by the weather and the external surroundings. There are some plants which can scarcely have too much water: take for instance a house of Ferns. If they are healthy and full of roots they require an unlimited supply, and without such a supply they will soon show signs of degenerating. All florists' flowers, such as *Pelargoniums*, *Hydrangeas*, *Marguerites*, &c., that are grown as large as possible in small pots for conservatory or house decoration must have abundance of water, especially during the summer months. This is a case where every plant can be watered without the slightest fear of doing injury. It is annoying to see a man rapping the pots with his knuckles, or feeling the soil in such a case as this. Certainly they may look a little damp on the surface early in the morning, but an observant man must know they will require watering half an hour after the sun strikes on the pots. I do not think there should be the slightest difficulty in watering soft-wooded plants; all that is necessary is a little common observation. But when we come to the hardwooded section more care is required; such plants as *Azaleas*, *Camellias*, *Heaths*, *Epacrises*, and the choice *Rhododendrons* always require careful management in watering. But I feel sure in the majority of cases hardwooded plants do not get sufficient water during the growing period. *Camellias* and *Azaleas* require an enormous supply during the summer. As "A Kitchen Gardener" mentions, it is ruinous to allow these plants to droop. How many *Camellias* have their young foliage scorched yearly through being too dry at the roots? How many cast their buds from the same cause? Why do we see hundreds of *Chrysanthemums* with 3 or 4 feet of leafless stems year after year? I have derived great benefit by using pans, as suggested by your correspondent, especially for stove plants grown in small pots for furnishing purposes. I find it impossible to keep *Palms*, *Dracænas*, *Dieffenbachias*, &c., in a healthy condition without them. For forcing *Strawberries* they are invaluable, at least I mean the later plants; for the early crops that are ripened in March I prefer pieces of turf. Early in the season the plants do not absorb so much water, and it is a nuisance to have to empty the water out of the pans, which if left in soon becomes sour, while it can drain steadily through the turves. But for all crops ripened in April, May, and June they are indispensable. I quite agree with "A Kitchen Gardener" as to the utility of syringing

the pots. I find it an excellent plan. When watering the stoves in the early morning water all the plants that require it, syringing the pots and plants heavily; this we do nearly every morning during summer, and I find it saves much watering, besides promoting a genial atmosphere in the house. I do not think there should be any difficulty in watering Peach houses or vineries, especially when it is known what materials the borders are composed of and the amount of drainage they possess. An intelligent man will always have these points before him, and with the weather, mulching, &c., to guide him no serious mistakes in watering should occur.—JAMES B. RIDING.

ROSE SHOWS IN 1838.

- June 26th.—Boston.
 „ 27th.—Alexandra Palace.
 „ 28th.—Brookham and Ryde.
 „ 29th.—Maidstone.
 „ 30th.—Colchester, and Reigate.
 July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
 „ 4th.—Croydon, Dursley, Farnham, Hitchin, and Richmond (Surrey).
 „ 5th.—Bath, Farningham, and Norwich.
 „ 6th.—Sutton.
 „ 7th.—Crystal Palace (National Rose Society).
 „ 10th.—Gloucester, Ipswich and Oxford.
 „ 11th.—Ealing and Tunbridge Wells.
 „ 12th.—Birmingham, Carlton-in-Lindrick, and Winechester.
 „ 14th.—Eltham and New Brighton.
 „ 16th.—Newcastle-under-Lyne and Christleton.
 „ 17th.—Leek and Ulverstone.
 „ 18th.—Birkenhead.
 „ 19th.—Helensburgh.
 „ 20th.—Darlington (National Rose Society).
 „ 21st.—Manchester.
 „ 24th.—Tibshelf.

In the case of the Alexandra Palace, Birmingham, and Boston, where the shows extend over two days, the date of the first day's exhibition only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSE PROSPECTS.

THE recent heavy showers of rain came at an opportune moment for my Roses, which in a somewhat light soil were beginning to suffer at a critical period, just as the buds were expanding. The result was that we have had several basketfuls of fresh plump blooms, and the supply has only been checked within the last few days by the cold winds and low temperature. Sunday, Monday, and Tuesday were very unseasonable, an east wind prevailing with leaden skies, quite wintery in fact, and slight frost was experienced early on Monday morning, the only perceptible damage, however, being noticed in the case of a few exposed Potatoes. Some of the delicate Teas and light coloured Hybrid Perpetuals show a little searing in the edges of the petals. We have an unpleasant proportion of hard green centres in the blooms this season, but green fly has not troubled us materially. Caterpillars have, however, been abundant and destructive, necessitating close watching, picking, and pinching. Blooms are numerous, and this is an important point with us, for we do not exhibit, and though we have a keen appreciation of quality, quantity stands first, as moderate sized flowers, if fresh, bright, and fragrant, are quite as useful as the huge examples sometimes seen at shows. *La France* and *Charles Lefebvre* are our two favourites, and within the past week the ladies have cut a couple of hundred blooms of these two varieties for themselves and their friends.—C. M. S.

A ROSE ENEMY.

I PRUNED several young standard Rose trees this year, and some animal or bird has eaten the bark off the very small piece of growth that remains. As I prune to two eyes in most cases, I do not leave much. As I never can see any grub on a Rose so eaten, and as many of my friends are anxious to know the culprit, I venture to ask if anyone can tell me.—H. V. M.

THE COMING SHOWS.

THE show season commences next week on Tuesday, the 26th, with Boston, followed on Wednesday by a revival of the Alexandra Palace Shows, on Thursday by Brookham and Ryde, and on Saturday by Eltham, Colchester, and Reigate. These will all possess considerable local interest, but it may be questioned whether the dates will not prove too early for many exhibitors. The first week in July will be a busy one, fourteen shows being fixed for the 1st, for the 3rd, 4th, 5th, 6th, and 7th. On the 4th are five shows, and amongst them Croydon, which is likely to attract more than usual attention this year. Prizes to the value of £175 are offered (not all for Roses), but there is to be a Rose trophy value 25-guineas, "open to all England, amateurs and gentle-

men's gardeners only." A photograph of the trophy has been forwarded to us, and it takes the form of a handsome silver eup of simple but elegant design. It is to be held by the winner of the year, and if won twice consecutively it becomes his property. The National Rose Society's Metropolitan Show at the Crystal Palace will, no doubt, be the chief event of the week; to this and the provincial show at Darlington, on July 20th, rosarians will eagerly look forward as representative gatherings.

THE PERSIAN YELLOW ROSE.

Is it not a little surprising that this charming Rose is so comparatively seldom met with in gardens? It is hardy, early, floriferous, and its soft yellow is highly pleasing. I find the flowers most acceptable for bouquets and vases, while for dress adornment they are much prized. For years a large bush of the Persian Yellow has afforded hundreds of blooms, and they are not the less welcome in being among the first Roses of the year. If not cut the bush at present would be like a huge yellow bouquet; this, however, is prevented by the opening buds being gathered every morning. If these were sold for buttonholes the crop would undoubtedly be remunerative. This fine bush is growing in rather poor and somewhat dry soil, and makes short firm wood that requires little pruning, and I suspect mistakes have been made in planting the Persian in rich soil, forcing strong growth, and pruning the same as Hybrid Perpetuals. It is not a Rose for exhibiting, hence its name is not often "seen in the papers," and perhaps that is one reason for its absence from so many gardens.—A. R., *Surrey.*

DIGGING.

A POPULAR writer has the following note in a serial publication on the benefits of digging, which will no doubt interest Mr. Abbey, though it considers the matter from a different standpoint:—

"Of all athletic exercises, with perhaps the single exception of cricket—and it is doubtful if that is an exception—the very best is digging. Probably every single muscle, vein, artery, and nerve in the body is vigorously exercised in the process. There is no constitutional, no aid to digestion, no cure for the blues, no receipt for a good night's sleep, no quietus for excited brain or ruffled nerves, to match half an hour at honest digging once or twice a day. Most of the above evils are born of mental strain, worry, anxiety, monotony of labour, the dreary treadmill exertion of counter or desk, and they fly like bats before the day-dawn, at sight, sound, or touch of gleaming bright spade thrust into the earth. Let the tired and the wearied, the drooping, those almost ready to faint, borrow leave to dig in their neighbours' gardens, if they can neither hire nor purchase one of their own. But meanwhile, let all the fortunate possessors of gardens hasten to do a whole or a part of the digging themselves. It is really the best work in the garden. Not a few owners slave over cleaning, dressing, watering it, and only have a man to do the digging. This is beginning at the wrong end—setting the labourer, in fact, to do the master's work. Custom has reconciled society to this order. But looking at it from a sanitary and business-point of view, it is nearly as bad as sending the porter to the bank while the merchant sweeps the office. Good digging is to the garden what the merchant's skill and forethought are to his profits; yet honest digging has almost become the exception; a sort of shambling, shuffling inversion of the soil the rule. And yet, properly understood, and skillfully practised, the former is more easy than the latter. . . . In the north, where the young gardeners do all the digging and take pride in their work, the art of digging has been elevated almost to the level of a science; and the lad or man who could not change hands at the end of his stitch, and dig equally well with his face to the ground he had dug, from left to right as from right to left, was considered an inferior workman. Hence, no sooner was the end of the brake or stitch reached than the spade was pitched up with a flourish, the left hand placed on the top instead of the right, and the digger faced round and proceeded in the opposite direction. In digging for health, this change of front and of hands is of very great importance. It brings the whole of the muscles of the body into more equal exercise, giving to each side of the frame exactly the same weight to lift and an equality of movement."

VINE ROOTS—HEAT AND MOISTURE.

I SEND with this a root of a Vine from one of the Muscat vineries here which I think rather curious. It attached itself to one of the sockets of the return hot-water pipe that leaks a little. Owing to a mistake in taking the levels it is nearer the border than I intended. When the mulching is put on it is close to the pipe. The root crept up the pier the pipes are resting on and attached itself to the pipe, and you can see how the fibres multiplied. I detached it in January when surface dressing the border, and put it in the canister intending to send it for your inspection, and forgot all about it till I came upon it to-day. The Vine from which the root came is a very strong one with two rods. There is an out and inside border, and by giving attention to watering and mulching the inside border is a mass of roots. The pipes, when the Grapes were finishing, were at times very warm, as I like to finish with a high temperature to insure the golden colour so essential to the Muscat Grape. I planted the Vines thirty-five years ago, and there seems to be no lack of vigour in them yet.—J. CRERAR, *Shabden Park, Redhill.*

[It is a remarkable mass of fibres, semicircular in form, 2 inches wide and three-quarters of an inch thick, so dense as to resemble whea-

cut through a piece of pressed tobacco. Constant moisture with warmth is evidently favourable to the production of surface roots in Vine borders, and that these are beneficial Mr. Crerar's experience affords adequate proof.]

EVENTS OF THE WEEK.—A meeting of the Royal Horticultural Society's Committees will be held on Tuesday next, the 26th inst., at the Drill Hall, James Street, Victoria Street; and on Wednesday, the 27th inst., the Alexandra Palace Rose Show will be opened, and continued until the following day.

— A LIST of the FELLOWS OF THE ROYAL HORTICULTURAL SOCIETY, corrected to April 30th, 1888, has just been issued, and contains in thirty-eight pages about 1700 names, but this number has been increased since the date of the list. The names of the Council and officers, honorary, foreign, and corresponding members, are also included.

— THE INSTITUTE OF FRANCE.—We have great pleasure in announcing the election of Dr. M. T. Masters, Editor of the *Gardener's Chronicle*, as a corresponding member of the Institute of France. Dr. Masters was elected to supply the vacancy caused by the death of Dr. Asa Gray, of Harvard, U.S.A., by thirty-nine votes out of forty-six. We heartily congratulate our friend on the acquirement of this distinguished and well-merited honour.

— MR. E. MOLYNEUX writes:—"I am very sorry to hear of the death of MR. T. JACKSON. I never knew a kinder man as Secretary of a flower show. He was always pleasant, always the same. I have good reason for knowing this, for going to Kingston five successive years, and arriving there each time early in the morning, after a night's journey, he never failed to give me a welcome and strove to make me comfortable; in fact, it was his manner that helped in no small degree to make my trips there so enjoyable. I much regret his early death."

— EARLY STRAWBERRIES.—In the Chiswick collection of Strawberries, which is extensive, King of the Earlies (Laxton) was the first to ripen this year in the open ground, the first fruit being picked on the 18th inst., fruit medium sized, excellent flavour, and crop good. Admiral (Laxton) was colouring at the same time, and has larger fruit, something of the Keens' Seedling type, but distinct, and decidedly earlier than that old favourite. Pauline, a much larger fruit, very conical, was also colouring, and will ripen with Black Prince, which, however, shows to great disadvantage by the side of the varieties named, though Pauline does not appear to grow well in the strong Chiswick soil. Laxton's Noble follows closely, a good crop of the most imposing fruit in the collection, and a variety to be grown where Strawberries of noble appearance are coveted.

— THE REV. J. L. PEACH will be much obliged if any of our readers can give him any advice or information about GARDENING IN CALCUTTA. He desires to know if Carnations can be well grown there, or any of our hardy plants. He has been asked to take some Roses out in October, and would like to know of varieties that would be suitable, and on what stocks they should be established.

— THE YORK SHOW.—We made arrangements for a special report of this Show, but it has failed to reach us. Whether it has been lost in the post or not, we have not yet ascertained.

— IN the grounds at Osborne House, Isle of Wight, are two examples of EUCALYPTUS COCCIFERA, which appears to be quite hardy there. One of these trees is 20 feet high, about 10 feet in diameter, well clothed with branches. Its deep blue shade of colour comes out in capital contrast with the light green shrubs making new growths in the background on a slope. It is very desirable for the shrubbery, being much more effective than the Eucalyptus globulus.

— MESSRS. WEST, NEWMAN & CO., 54, Hatton Garden, London, send us sample sheets of their BOTANICAL DRYING PAPER, stating that "It was formerly called Benthall's. It is made expressly for drying

flowers, Ferns, seaweeds, and other specimens for the herbarium. Being very absorbent, and free from acids or alkalis, it perfectly preserves form and colour. It is in use at various public herbaria, and was used by the naturalists on the Arctic ships, and also on the cruise of the 'Challenger.' The extra thick quality has been made in response to a demand for a paper such as is used in the American herbaria. It is more than four times the thickness of the ordinary paper, and is thus easy to handle and extremely durable; it may be used again and again for years." The paper appears to be admirably adapted for the purpose, the large sheets of the thicker quality being well fitted for strong or heavy specimens.

— HEAVY SNOWSTORM IN CORNWALL.—The *Daily News* of the 14th inst. gave the following paragraph:—"A snowstorm in Cornwall in the middle of June is almost unprecedented, but yesterday some parts of the county were visited by a fall of snow and hail which covered the ground for a considerable distance to a depth of about an inch. The morning was beautifully fine and warm, but towards noon heavy clouds covered the sky, and these were followed by pelting showers of rain, accompanied by loud peals of thunder and vivid flashes of lightning. The atmosphere suddenly became bitterly cold as if it were midwinter, and the rain was succeeded by hail and snow, which fell uninterruptedly for more than an hour. In the neighbourhood of Callington the hailstones were so large, and fell with such force, that twigs were cut clean off the trees. Fortunately no hail fell in the fruit-growing districts, and the fruit crops have escaped injury.

— GARDENERS' ORPHAN FUND.—The following report of the Sectional Committee on the subject indicated was presented at a meeting held on Friday evening last:—"Your Sub-Committee have to report that the fête held in the Flower Market, kindly lent for the occasion by His Grace the Duke of Bedford, and under the patronage of H.R.H. Princess Mary Adelaide, Duchess of Teck, on Wednesday evening, June 6th, proved a brilliant success. It was attended by the Marquis and Marchioness of Tavistock, the President, Sir Julian Goldsmid and Lady Goldsmid, the Right Hon. the Lord Advocate of Scotland, and many other members of the aristocracy, the total number of ladies and gentlemen present being nearly 7000. The Marquis and Marchioness of Tavistock and Sir Julian and Lady Goldsmid expressed themselves highly delighted with the extraordinary display of plants and flowers and the general arrangements. The Marchioness of Tavistock and Lady Goldsmid were pleased to accept handsome bouquets kindly presented for the purpose by Mr. T. A. Dickson of Covent Garden. The press notices, copies of which are submitted, were unanimously of an extremely favourable character. The total expenses of the fête amount to £74 8s. 7d. The amount of money collected in the boxes presided over by twenty-eight young ladies was £127 7s. 10d.; this, with the handsome donation of £100 from His Grace the Duke of Bedford and a few sums received subsequently, make up a total of £237 11s. 4d., leaving a balance of £163 2s. 9d. to the credit of the fund. Your Sub-Committee desire specially to express their hearty thanks to the various officials and growers connected with the Market for their liberal assistance so cheerfully rendered, and recommend that the best thanks of this meeting be accorded to them." Special letters of thanks were directed to be sent to the Duke of Bedford; Mr. J. R. Bourne, His Grace's London Steward; Mr. Assbee, market agent; the several growers and exhibitors of plants; and the ladies who gave their assistance at the fête. The thanks of the General Committee were also unanimously conveyed to Mr. W. Richards, who zealously discharged the duties as Secretary on the occasion.

— ENGLISH GROWN TOBACCO.—Messrs. Cope Brothers & Co., Liverpool, send us a sample of Tobacco which they guarantee to have prepared from the crop grown by Messrs. James Carter & Co. in Kent. It is the best sample of English Tobacco we have seen, and equal to much that is sold in country villages at 3d. per ounce. It is dark in colour, and in that respect alone might not find favour by town smokers who have choice of the best brands.

— THE FRUITS OF AFGHANISTAN.—The vegetable productions of Afghanistan are similar to those of India and Europe, with a few, such as Pistacia and edible Pine nuts, Madder and Assafœtida, more peculiar to itself. The Tobacco of Candahar is highly esteemed both in and out of the country. Cotton is grown in small quantities, but in addition to the usual crops suitable to the climate of different parts of the country, large quantities of Apples, Pears, Almonds, Apricots, Quinces, Plums, Cherries, Pomegranates, Limes, Citrons, Grapes, Figs,

and Mulberries are reared to a degree of perfection to which they have attained nowhere else in the East. In their fresh and dried state the Afghan fruits are carried all over Hindostan, and in value exceed the trade in horses and sheep's wool, which form the other considerable portions of the foreign commerce of Afghanistan. In return for their fruits, wool, and horses, the Lohani merchants take back indigo, muslins, chintz, broad-cloths, sugar, spices, medicines, salt, silk, and cotton fabrics, musk, and other British and Indian manufactures and products. But of manufactures proper the Afghans have few or none. They are a nation of warriors and shepherds, not of art-workmen, miners, or handicraftsmen. They make coarse cloth for their own use, turbans, felts, "postins," or sheepskin coats, and camels-hair cloaks, or "chogas," the three latter articles being extensively exported to the Peshawur frontier, and the adjoining portion of the Punjab, where they are valued—especially the postins—by the British Indian army, as a part of their winter clothing.—(*The Countries of the World.*)

— WEATHER DEPREDATIONS AT MIDSUMMER.—Mr. J. H. Goodacre, Elvaston Castle Gardens, Derby, writes:—"Fickle as the English climate is known to be, few would credit the serious damage from frost at this late date, that we often suffer in this locality, as samples of Potato tops, illustrate, herewith enclosed; but the mischief does not end here, as Beans, Marrows, and other tender vegetables were damaged by frost on the 15th of this month, also some kinds of Strawberries, such as British Queen, President, and those erect sorts that throw their bloom above the foliage. Some of the Apples are casting their fruit seriously, the bloom of which I never saw so fine before. Some of the white-flowered sorts were objects of great beauty. I measured some Gravenstein flowers fully 4 inches in diameter, and petals of great substance; the trees resembled massive plants of Fielder's White Azaleas than anything else. Pears, where exposed, are also casting the fruit." The Potato haulm showed unmistakable signs of injury, and we have heard of similar cases near London.

— ANOTHER winter has proved the value of the CAUCASIAN LAUREL. It is much superior to the common variety. In strong retentive soil it retains its colour much better, being a dense dark green, while the common one assumes in some instances during the winter a delicate sickly hue.* If pruned somewhat closely for a year or two after the cuttings are struck the Caucasian variety will make a dense bush in a shorter time than the other. This year the Caucasian variety has been covered with flowers, and they brighten otherwise dull spots in the shrubberies early in the season before many other shrubs are in blossom.

— A LIBERAL schedule of prizes is provided for the summer show of the RICHMOND (SURREY) HORTICULTURAL SOCIETY, which will be held in the Old Deer Park, on Wednesday, July 4th. We are reminded that entries close on June 27th. The Secretary is Mr. J. H. Ford, 22, George Street.

— A COLOURED illustration of BEGONIA LUBBERSI is given in *Le Moniteur d'Horticulture* of the 10th inst., with an account of the plant by M. Lucien Chauré. The plant was shown at the recent Ghent Quinquennial Show by M. E. Pynaert Van Geert, and it has been described both by M. E. André and M. le Comte Kerchove de Denterghem. The leaves are 2 inches broad at the widest part, tapering, and 5 to 6 inches long, red on the under surface, the upper surface dark green, with numerous silvery spots of irregular shape and size. The flowers are pure white, with two broad rounded petals and two small ones, and it is said they are freely produced. The Begonia was introduced by chance from Brazil to the Brussels Botanic Gardens in 1880 by M. Pedro Bruot of Petropolis, and was observed by M. Lubbers at the base of a Tree Fern stem; it was removed and potted, and flowered for the first time in October 1881. Botanically Begonia Lubbersi is referred to the section Gaertia of Klotsch, and is related to *B. maculata* (*B. argyrostigma*).

— GLADIOLI NOTES.—Messrs. Stuart & Mein write:—"In reply to Mr. Kelway's inquiry as to where our successes in Gladioli exhibiting took place, we beg to say we were first at the International Show in Edinburgh in 1886 and 1887. In 1869 we took the first prize at Edinburgh, and in the following year at the Crystal Palace, as the following extract from the *Kelso Mail* of September 10th, 1870, will show:—"Crystal Palace Autumn Show.—At this great Exhibition of flowers, held at the Crystal Palace, London, this week, we are glad to observe

that Messrs. Stuart & Mein, nursery and seedsmen, Kelso, have carried off the first prize for the best twenty-four spikes of Gladioli against all England. There were fifteen collections exhibited."

— THE ROYAL BOTANIC SOCIETY'S EVENING FETE will be held on Wednesday, July 4th next, in the Regent's Park Gardens, when an Exhibition of floral decorations, &c., will be provided as usual. The following are the principal classes:—Division 1.—Natural flowers and fruit: Floral decorations arranged for a dinner-table, 10 by 5. In this class no objects are allowed on the tablecloth except such as contain or are accessory to the holding of flowers. Floral decorations, dressed ready for dessert. These tables should be completely dressed for dessert for ten persons. The prizes will be awarded for general effect, without reference to the actual value of the plants and articles employed. Foliage and flowers, suitable for a sideboard; small group of growing plants, suitable for table; group of plants, arranged for the decoration of a recess in a room, for an alcove, or a fireplace; standing basket or vase, furnished with plants suitable for growing in a living-room; hanging basket, of any material, with growing plants; window box of plants. Bridal bouquet; ball-room bouquet. The Judges will be requested to ascertain that the bouquets are firmly made, by removing them from their stands and turning them over; excessive and disproportionate weight, or thickness of handle—*i.e.*, more than 1½ inch across, will be regarded as disqualifying. Glass shades or other covers will not be allowed. Group of flowers, stalks in water, and neither tied nor wired; flowers (either cut or on the plant) which expand only at night; arrangements of flowers and leaves, for personal adornment, such as wreaths, chaplets, and the like, and also for use in dress-trimming and ornament. Miscellaneous—Objects for purposes similar to the above, but not coming strictly into any class. Division 2.—Works of art in any material.—Accuracy of reproduction will be the qualification chiefly considered in these classes. Paintings, drawings, and carvings, of trees, plants, or flowers; groups of artificial flowers and foliage, arranged for the decoration of rooms; groups of artificial flowers and foliage, for table and sideboard; single plants or flowers, for table and sideboard; flowers or foliage for personal adornment. The prizes in division 1 range from £5 to 10s., and in division 2 they may consist of medals, plate, or money at the discretion of the Judges.

— THE TRADE IN FRENCH VEGETABLES IN ENGLAND.—The British Consul at Brest, in a report on the agriculture of his district, refers to the great eagerness shown by small farmers to find markets for their garden and other produce in this country. From Roscoff alone twenty-six different companies, composed of 406 members, visit a large number of towns along the English, Bristol, and St. George's Channels, the ports on the German Ocean being supplied from Belgium, Normandy, Picardy, and the Artois, and extend their operations from these towns in all directions—those for instance, trading to Newport going sometimes as much as 100 miles inland by rail, returning to Newport every Saturday night. In 1885 the exports of vegetables from Roscoff alone were 11,107 tons Potatoes, 4060 tons Onions, 4000 tons Cauliflowers, and 1800 tons Artichokes. Of Cauliflowers the northern part of Finistère furnishes the Western Railway Company with a million tons per annum, while large quantities are sent by steamer from Morlaix. Three hundred tons of Cabbages, several thousand tons of winter and summer red Onions, and enormous quantities of preserved Peas, Kidney Beans, and Shallots were exported from Morlaix last year to this country. The same port alone also sends seven million eggs, worth £16,000, and, owing to the establishment of a line of steamers to Bristol, this number is increasing rapidly.

— THE WAKEFIELD PAXTON SOCIETY.—Mr. T. R. Preston of St. John's Nursery was announced to read a paper before the members on the 21st of April, but owing to his indisposition the fixture was altered to the present month. In the meantime Mr. Preston had almost recovered from a severe illness, and had prepared an exceedingly useful and interesting paper on "Plants Suitable for Entrance Hall and Room Decoration." The essayist's practical experience, combined with his evident good taste, enabled him to convey to his hearers many valuable hints on grouping for effect, and the general management of plants during the time they are subjected to the extreme and varied unnatural conditions surrounding them when used for decorative purposes within doors. The paper was attentively listened to, and the essayist, who had evidently prepared it with great care, was warmly

applauded. Mr. Carbert, schoolmaster, Sandal, proposed a vote of thanks to Mr. Preston for his paper, and in doing so he referred to the essay in complimentary terms, and also expressed himself as a lover of plants and flowers. Councillor Howden, one of the Vice-Presidents, in seconding the motion remarked that it would be well if ladies could attend and hear such papers as Mr. Preston had read, because they would by that means acquire information which would enable them to keep plants in dwellings in bloom and in good condition for a much longer period than is often the case at present. Mr. George Gill of Eastmoor, and the President, supported the motion, which was heartily carried and suitably acknowledged by Mr. Preston, who was congratulated on his restoration to health and return to the gatherings of the Society. Councillor Mills presided, and Mr. Brown occupied the vice-chair.

— THE schedule of the NATIONAL CHRYSANTHEMUM SOCIETY'S PROVINCIAL SHOW AT SHEFFIELD, to be held in conjunction with the Sheffield and West Riding Society, augmented by the Sheffield and Hallamshire Gardeners' Society, in the Corn Exchange, November 16th and 17th is to hand. We have already referred to the principal open classes which are included in the National Society's schedule, but the local and amateur classes have been extended to provide for the exhibitors from the Sheffield and Hallamshire Society. The Hon. Secs. are Messrs. W. K. Woodcock, J. W. Jarvis, and J. W. Needham for the former, with Mr. W. Marshall for the latter Society.

— AN interesting account of a visit to DEVON ROSE NURSERY, that of Messrs. Curtis, Sanford & Co., at Torquay, is given in the *Torquay Times* of the 15th inst. It is stated there are between thirty and forty acres under cultivation, 60,000 stocks being planted for budding every year, and the glass houses extend to about 2000 feet ran. It is incidentally mentioned that a specimen of *Berberis Darwini* growing in the nursery is 20 feet high and 60 feet in circumference, and is considered the largest in England, having been planted thirty years ago by Mr. Curtis.

— THE schedule of the ALEXANDRA PALACE ROSE SHOW is issued, and enumerates eighteen classes, four for nurserymen, four for amateurs and gentlemen's gardeners, eight open classes, one for Roses in pots, and a class for miscellaneous exhibits. The prizes range from £5 as the premier awards in the nurserymen's and amateurs' classes for forty-eight and thirty-six Roses respectively, to 7s. 6d. as the third prize in several open classes. Special prizes are offered by Messrs. Wood and Sons, Wood Green, and Mr. W. Colchester, Ipswich. As previously stated, the Show will be held on June 27th and 28th, Mr. R. Beale being the Secretary.

— WE are requested to direct attention to JEYES' SANITARY COMPOUNDS. The article known as Jeyes' Sheep Dip, if used as a dressing for Wheat and seeds, is said to protect them against birds, while "a dilute solution of Jeyes' Perfect Purifier, when sprinkled or syringed upon the leaves, stems, flowers and fruit of plants, refreshes them and destroys insect pests."

— THE monthly meeting of the BELGIAN HORTICULTURISTS was held in Ghent on the 11th inst., when the following members were present:—MM. A. Peeters, Moens, V. Cuvelier, Metdepenningen, Alf. Van Imsehoot, Al. Dalliere, G. Von Eeckhaute, Laurent Masureel, C. Spae, A. Wallem and Jules Closon, M. Jules Hye-Leysen presiding, and M. J. Boelens acting as Secretary. Certificates of merit were awarded for *Dracenas Desmetiana* and *Comtesse de Kerebove* from M. Desmet Duvivier; for *Nidularium argenteum striatum* and *Lomaria platyptera* from M. Aug. Van Geert; for *Cattleyas Reineckiana* and *Mossia alba* with a species of *Laelia* from M. James Bray; for *Cypripedium Mastersianum* from M. A. Peeters; for *Cattleya Schroederi* and *Cypripedium Boxalli atratum superbum* from M. Jules Hye-Leysen; for *Cypripedium Godefroya bellatulum* and *Anthurium Andricanum* Mad. Ed. Pynaert from MM. Jacob Makoy et Cie; for *Thuia Lobbi aurea* from M. Alex. Dalliere; for *Odontoglossum crispum* and *Cattleya Mossia De Puydti* from MM. Vervaet et Cie. Cultural certificates and honourable mention were also accorded to several Orchids.

RHODODENDRONS AT HIGH BEECH.

THE High Beech Nursery is perhaps best known to the horticultural world as the home of Messrs. Paul & Son's Tea Roses. But though an enormous space is devoted to these delicate flowers, the nursery is justly famed for its Hollies, Conifers, and Rhododendrons, to say nothing of

the bog garden recently formed by Mr. G. Paul, and which has been a source of great interest to lovers of this class of plants. But it is in connection with a visit on the 7th of June, paid for the purpose of seeing the Rhododendrons in their full beauty, that I wish to write a few notes. Seedlings are raised in thousands behind the Yew and Beech hedges, chiefly for grafting stocks, but the propagation is not done there, both stocks and scions being taken to Cheshunt, afterwards returning again till they are disposed of. The plants are seen in all stages, some only a foot high, while many of the standards are 8 or 9 feet high and 5 or 6 feet through, all bearing enormous masses of brilliant flowers. I always think the merits of a variety are best seen when grown in a mass, the habit is marked, as well as their floriferousness. The soil at High Beech appears to suit them; it is a light peaty loam deeply dug, in which the plants seem to revel. Some of the early varieties were over, such as *Hendersoni* and the new *Mrs. C. Butler*, but enough was to be seen to judge it an acquisition. I have only taken the names of the most striking. Many of the varieties are old and well tried, but some of the newer ones are good both in habit and flower.

Everestianum, purplish lilac, carrying enormous trusses; *Lord John Russell*, rosy mauve, beautifully spotted; *Evelyn*, large white, with fine foliage; *H. W. Sargeant*, crimson, one of the best; *The Queen*, pure white, very distinct, with good habit; *Lady Emily Peel*, bright pink, neatly spotted; *Baroness Rotbschild*, red, fine truss; *Mrs. John Clutton*, good white; *Beauty of Cheshunt*, good pink, upper petals densely spotted; *Broughtoni*, bright rose; *The Princess*, beautiful white, with brown spots; *Princess Mary of Cambridge*, rosy purple; *Madame Van de Weyer*, fine crimson; *Mrs. Fitzgerald*, very bright crimson; *Rosabel*, deep blush; *Michael Waterer*, brilliant crimson; *Marguerite*, blush, with large trusses; *Frederick Waterer*, bright crimson; *J. Marshall Brooks*, scarlet, very distinct; *Mrs. Shuttleworth*, bright scarlet, spotted; *Sigismund Rucker*, magenta, heavily spotted; *Mrs. Heneage*, purple; *Mrs. F. Hankey*, salmon, pretty; and *Old Port*, fine large purple.—JAMES B. RIDING.

MUSHROOMS AND THEIR CULTURE.

THIS singular production at times baffles the skill of the most careful cultivator, whilst at other times it yields a large return to the roughest or most unexpected position that was ever tried for their artificial growth. It therefore becomes difficult to lay down definite rules whereby a certain supply can be obtained at all times. At certain seasons, say the autumn months, beds carefully made up are almost sure to bear, because at that season they are produced naturally out of doors; later on, however, the chances diminish; not but that equally good crops are obtained occasionally in February as in October, but the same treatment will not secure them at that time with a like certainty. All we can do in the way of reproducing the plant is by the mode common to many other plants—a fibrous root running through the ground sends up its produce singly, or in clusters, all around the origin of the spot from which the ramification took place. This fibrous substance, technically called spawn, is produced naturally in great abundance in some seasons and in certain places; at other times it is found in dung-heaps which have lain long enough to allow it to properly fix itself, and many good crops of Mushrooms are the result, not the less worthy of attention by coming unexpectedly. These matters, however, all tend to the conclusion that the propagation and culture of Mushrooms differ essentially from most other plants we are in the habit of bestowing much care on, and that, after all, disappointments now and then occur with the most experienced in such matters; but a little examination into the principles which govern their growth out of doors may assist us much in regulating our treatment of those we endeavour to grow artificially.

To make a bed with a view to ensure a crop, procure some good horse-droppings that have not been heated, some sheep-dung, if at hand, that has not lain long on the ground for the rain to wash away its richness. Let these be well mixed, and if there be any great quantity of it, let it be turned every day for a little time; then every two days, as the heat may seem to be, and when it gets so far moderated as to give tokens of sweetness and steadiness, the bed may be made, which, if inside some building where a little fire heat can be given, need not be more than 18 inches thick, and as long and wide as required; but if the place be open, and not any means of warming it, a greater thickness of bed, with a more careful preparation of materials, so as to ensure against their overheating, must be resorted to, supposing that a place on purpose is to be had, with shelves in the usual way. I would, in making up the beds, throw in pieces of half-decayed turf, and also pieces of spawn; this is on the supposition that the latter is plentiful, which it ought to be. A good beating or treading is necessary, and, last of all, a good coating of fresh maiden loam, preferably from a pasture where Mushrooms are known to grow naturally; this coating, however, had better be delayed a few days, until there be no danger of the bed overheating; at the same time, it must heat a little. Watering should not be done except for keeping the surface moist until the Mushrooms appear, when they may have a little; but if the bed seems to do well at first, it would be better to avoid heavy waterings until the bed begins to go off, or partially cease, when a heavy watering will sometimes revive it again, and another good crop will be the issue, with an extended season of bearing.

Where no shed nor outhouse exists in which to make up a Mushroom bed, and there is plenty of good horse dung to be had, a very

good bed may sometimes be made against a blank wall after the dung is sufficiently sweetened, a bed about 4 feet wide, well trodden down, and built something like a steep-pitched lean-to roof will be; but, in fact, very short dung cannot well be built up perpendicularly, neither would it be so well, for this lying against the wall presents a diagonal surface, which can easily be covered up to any extent. Spawning, covering with earth, &c., may be done the same as recommended above, and a deep coating of straw or litter will be all that is wanted, examining it from time to time to see that the heat does not decrease, and that the spawn does not expend itself uselessly in running into the litter, which it will sometimes do, to the injury of the crop. Very often a good crop is obtained in this way, the more liberal supply of dung making up in a great measure for the want of shelter. Even the wall itself may be dispensed with.

STYRAX OBASSIA.

A HANDSOME Japanese tree of moderate size bearing the above name has been growing in Messrs. J. Veitch & Sons' nursery at Coombe Wood for ten years, and has often attracted attention by its ample foliage. This season it has flowered freely, and specimens sent to the meeting of the Royal Horticultural Society on the 12th inst. were at once certificated when placed before the Floral Committee. Additions to our lists of flowering trees are not too frequent, and it renders any of sterling merit like this *Styrax* all the more acceptable. It cannot be claimed as a novelty in the strict sense of the term, as it was described and figured in the "Flora Japonica" by Siebold and Zuccarini in 1835, but it is

FIG. 73.—STYRAX OBASSIA.

I have had as good a crop of Mushrooms on a bed out of doors as I ever had in a house. The bed was made as above, only, instead of being a "lean-to," it was a "span," the dung being built up into a steep ridge-like shape, and well beaten, &c. A good heavy covering is the principal thing, and if the dung be in a good well-tempered condition in October, when the bed is made, it is not likely to lose heat until the Mushrooms are formed and a crop secured. A cellar is also not a bad place for a bed; and we all know that Mushrooms are now and then found in very singular places. I have seen some that were produced in a coal mine 400 feet deep. But, as winter is a time when most structures are in use, I would advise the amateur who has no accommodation that way to try the effects of a bed quite out of doors, as above. This he can do at little expense if he be living in a town where dung is plentiful. The result is likely to be encouraging, and very often the Mushrooms so produced are better in quality than others more assisted by artificial means.—R. J. K.

known to few except botanists and those who have made a special study of trees and shrubs. It is said to be a native of the province Senano in the Island of Nippon.

The leaves when of full size on the tree at Coombe Wood are 8 to 10 inches in diameter, nearly round in outline, frequently irregularly and deeply serrated at the apical margin, of a light soft green, much like the Catalpa. The tree is bushy in habit, producing its pure white flowers in racemes 6 to 8 inches long, the petals somewhat narrow and pointed, as shown in the illustration (fig. 73). The leaves depicted there, however, are those found at the base of the racemes on the flowering branches, and are not nearly so large as the mature leaves lower down the branches. It has proved quite hardy at Coombe, where it stands on a slope moderately sheltered by hedges.

ODONTOGLOSSUM VEXILLARIUM.

AT The Woodlands, Streatham, Mr. R. H. Measures has a grand display of *Odontoglossum vexillarium* in many varieties, all beautiful, and some of exceptional merit. The plants are in capital condition, and are arranged on a long wide stage to form a bank, between 500 and 600 racemes of large flowers being now expanded. A few plants of the bright orange scarlet *Epidendrum* are introduced amongst the *Odontoglossums*, which add greatly to the beauty of the group in contrast with the delicate tints prevailing in the latter. One vigorous plant of a good variety with three growths has fifteen racemes, or five to each growth. Another has nine racemes of sixty-seven flowers, a charming specimen, and several could be pointed out only slightly inferior to this in numbers. A variety named *pulchellum* has large well shaped flowers, white with a yellow base and a few crimson veins. *Cobbianum* is also pretty, though small, the sepals and petals rosy crimson, the lip pure white with a yellow base, but a variety with pure white flowers only faintly fringed at the base with yellow is one of the most notable, and the shape is excellent. The day temperature, both night and day, has been kept between 55° and 60°, and frequently it has not varied more than 2° or 3° in the twenty-four hours. An even temperature and absolute cleanliness are the two means relied upon for maintaining the health of the plants. One point Mr. Measures remarks this year, and that is the much paler colour of varieties bought in flower for their high colour, and he has observed what others have also noted—namely, that these and other Orchids often vary considerably under cultivation both in colour and size of flowers. Some advocate growing *Odontoglossum vexillarium* in a higher temperature to induce the perfection of colouring, but this is scarcely what is found to rule in other cases.

CATTLEYA BLUNTI.

Some Orchids have been overpraised by the discoverers and vendors, but this is certainly not one of them, for when seen as it has been at The Woodlands, it is enough to make anyone an Orchid admirer. The strong plant there grown has had three flowers, one of which is now before me, and amply deserves a few words of description, for most of the books dismiss it rather summarily. Mr. Williams, however, does it partial justice in his "Manual." It is distinctly of the *C. Mendeli* type, though it has been given almost specific rank by some, and with quite as good reason as many others. The sepals are spreading, nearly an inch in diameter at the widest part, tapering to base and point, the latter being slightly recurved, and are 3 inches long. They are white, with a faint scarcely perceptible blush tinge in the later stages, and spread equally from the base of the lip. The petals are the same length as the sepals, but 2 inches broad at the widest part towards the base, tapering gradually to an obtuse point, the upper margin being neatly undulated or frilled. They are pure white, and stand up from the sepals at a considerable angle like two beautiful wings half expanded. The lip is exquisitely formed; the expanded portion is oblong in outline, 2 inches by 1½ broad, very evenly and beautifully frilled, which reduces the breadth in appearance and gives the oblong form; with the tube it is pure white, relieved only by a faint dash of clear yellow in the throat and a few pale crimson veins quite at the base. It is now ranked in some works as *Blunt's* variety of *C. Mendeli*, and first flowered in the late Mr. Day's collection at Tottenham, having been introduced by the collector, Mr. H. Blunt, from Colombia.—C.

VENTILATING.

THERE is scarcely any subject connected with practical gardening which has received so little attention as this—one of the most important proceedings. This seems extraordinary. Is it that the thing is in its nature or character mysterious and indefinite, or that it cannot be reduced to anything like system? Certainly, it will not be expected that we can in such a case lay down cut-and-dry rules and state the amount and character of the ventilation to be pursued on any given day. This is impossible, inasmuch as our climate, although mainly divisible into four somewhat distinct seasons, yet is liable to amazing vicissitudes in most of them; and, of course, modes of ventilation must be modified accordingly. I may here, at the outset, state the objects of ventilation. They are mainly two—the escape of accumulated heat, and the correc-

tion of a vitiated atmosphere by a circulation of pure air. But the way in which these two objects are carried out are various, and dependent entirely on circumstances. Those who will consider the matter fairly should first of all look into the science of pneumatics, and ascertain the characters belonging to what is called the air—its relative gravity, modes of interchange, &c. One broad fact may be here named as a prelude to succeeding explanations—that the admission of air in severe winter weather is a procedure requiring much more caution than at other periods; the frosty breeze is of insidious character, and this, too, enhanced in proportion to the discrepancy between the respective temperatures of the inside and outside. Most readers must be aware of this latter fact by observing the effect of draught through crannies, when perhaps the Yule log is blazing, and the air outside a keen north-easter, of some 20° of frost. What could there be but a rapid interchange; the room within at a temperature of 60° to 70°? Here we have a discrepancy of some 50°, or nearly so. Well may the good folks inside complain that they cannot keep their feet warm. I may here, in returning to our garden structures, state the consequences which generally ensue from a neglect of ventilation. They are as follows:—The plants draw, or become weak and long jointed; a corrupt atmosphere gives an unhealthy colour to the foliage; stagnated damps are engendered in parts of the structure, frequently giving birth to Mosses, and other cryptogamic productions; the flowers are paler, and lose a proportion of their aroma; an indisposition to produce blossom is generally a concomitant; insects of all kinds increase more rapidly; and fruits are deficient in flavour. These are the evils which may be expected to ensue from bad ventilation: of course they do not all happen on every occasion, but receive their being and character according to the aggravation of those circumstances which engender them. In looking over the principles of ventilation we may at once see that in endeavouring to teach the uninformed it is necessary to adopt some division of the subject. This is not a very simple task, but since I have travelled thus far I must endeavour to do so to the best of my abilities.

First, then, I may observe that there are general principles of ventilation common to nearly all seasons, and next that there are many special cases which form an exception, either in mode or degree, or both. The special cases to which I allude consist mostly of singular tribes or families of plants, such as Orchids, Ferns, &c. But certain other families, which for the most part submit to the most ordinary treatment, have periods when a departure from the ordinary routine is of much benefit. Thus the *Camellia*: at this time my *Camellia* house is almost constantly shaded; but this is not the general practice. It is also kept very damp. But these would be serious conditions when the plants were in blossom through the winter. The house is scarcely ventilated at all whilst they are making their young growth; this, too, would not be the case at other periods. But these are only a few solitary cases—enough, however, to show to those unpractised in gardening affairs that mere set rules, founded on the practice of someone, and devoid of principle, is not the kind of armour that a modern gardener must depend on. Apart from tribes or families of ornamental plants we must look into the early forcing house, the warm pit, the old-fashioned hotbed. Then we may pass on to the cold pit or hibernatory, and cold frames.

Thorough ventilation consists in admitting a complete circulation, both by means of the escape of heated or contaminated air at the highest point, and a consequent influx of fresh air from the lowest level; but this has to be performed with a due regard to the wind, its violence and its characters. Lively currents of mild winds are, in the main, beneficial, although they may slightly agitate the vegetation in the interior; but when such are chilling to the human body they must be avoided. In managing this matter a due regard must be paid to the proportion the front air bears to that of the back. The greater the egress at the back or apex of the houses the greater will, of course, be the demand for fresh air from the front, and *vice versa*. In vineries or Peach houses it is very frequently necessary in summer to open as wide as possible both front and back ventilators, or the inmates become scorched, and on most occasions it is better to starve than to burn if a risk must be run. Nothing looks worse in vineries than to see singed foliage; it is not only a disfigurement to the Vines, but a most serious injury to their permanent welfare. In what is termed "catching" or fluctuating weather, the ventilation requires much attention, and to be attended to several times within half-a-dozen hours. In such cases there is frequently neglect—the parties, perhaps, have too many irons in the fire, and some burn. Hailstorms must be studiously guarded against; these sometimes occasion much mischief in a few minutes. They generally fall perpendicularly, or, at least, they seldom do much harm through the front sashes; on such occasions, then, and with alternations of bright sunshine—for bright indeed it generally is at such periods—the front ventila-

tion must be proportionately more liberal, and every attention given. This practice, however, refers more to summer management than to winter: the months of April, May, and June are more concerned than, perhaps, any others. In all cases the chief point is to know the character of climate and amount of temperature the plants or trees require, and that, too, with regard to their condition and the period. This kind of knowledge is not speedily acquired certainly, and I lament that I cannot impart it in a few words. The following may be taken as maxims generally correct:—A very copious admission of front air, and little at back or the apex, has a tendency to create a great disparity between the temperature at back and front, and to chill the frontage. Much back air and little front is likely to encourage a keen draught. When cutting winds or a very sharp air therefore prevail, it is frequently good policy to give no front air unless compelled. But there are no maxims which bear continual sway: as conditions change we must change our policy also.

In early forcing, such as Vines, &c., perhaps more caution is needed than in most things, particularly during the months of January and February, for then the sun has little power; but when the forcing gets into March he finds the case much altered, and this is generally his most trying time. With a bright sunshine and a cutting south-easter he is sometimes at his wits' end to keep things right. By-the-by, of all the winds that blow perhaps a south-eastern is the worst for glazed structures, especially lean-to houses. They are every moment robbing the roof of its warmth, and the roof borrowing from the interior. As for giving air, especially front air, extreme caution is frequently requisite, and when absolutely necessary in such circumstances, it would be well if we could have some finely pierced apparatus to riddle it into the house. We all know how the very early Cucumber forcer—in dung beds—occasionally takes the precaution of nailing a mat or canvas over the air-giving points in order to break the fierce action of the air, and, as it were, to riddle it through. As for the ordinary greenhouse, that is the easiest to ventilate of most structures, and I need not say much on that head.

Ventilation is frequently had recourse to as a preventive of drip, and very necessary too. I have a Camellia house which is notorious for drip, the house having been glazed some years since. I have Camellias in constant blossom from the early part of November until May, and we rarely have one blemished by drip. This is owing to the constant maintenance of air day and night, both at a high or a low level; and the constant use of very moderate firing, by which the hot-water pipes are always lukewarm. This induces a lively circulation of air, which dissipates the vapours before they can become condensed. One excellent adjunct in the prevention of drip would be a roof covering to prevent condensation, but such are very perishable and difficult to work during the alternations of frost and thaw. The prevention of drip, as to blossoming plants in winter and early spring, is a most important affair; and in conjunction with the pains taken over ventilation and firing much discretion should be exercised in the application of water, doing so sparingly and principally in the morning early.

There can be no doubt that long-confined and, by consequence, stagnant air is highly prejudicial to vegetation in general, especially to those plants with thin foliage and of speedy growth. There is every reason to believe in an analogy between animals and plants in this respect. Foul or stagnant air long continued casts a skin over the foliage of plants, and this, by partially closing their "breathing pores," of course vitiates their juices, or impedes reciprocity between the foliage and the root, which is of great importance. And how can we expect plants or trees to blossom in full vigour, with all their parts perfect, without that subtle, yet invigorating element—pure air? As to insects, fungi, &c., if you want any for special purposes, you will only waste your time by hunting hothouses where judicious ventilation is maintained, and where, by a cleanly system, all corruption or irritation is met half way. The drawing of plants or trees, alias weakening, alias elongation of the joints, with some other aliases, is, of course, clearly traceable to a want of free circulation, as also to too much closely confined damp-producing attenuation, and a scant of the colouring deposit in the leaves of plants, called chlorophyll. Let me here, too, warn the uninformed of that affair called excitability or a disposition to receive damage on any extreme of atmospheric conditions. The longer garden structures are kept badly ventilated the more this kind of tenderness increases. The colours of flowers, too, and the flavour of fruits are very incomplete without free ventilation.

Before concluding my explanations I must beg to offer an opinion that if all hothouses were properly constructed and properly heated, together with that full amount of provision for air moisture, which would, when necessary, prove equal to any demand, there is scarcely anything we cultivate but would be better for air-

giving night and day. This I have certainly never seen realised, and never had it in my power to carry out; but it is an old conviction, and I am by no means solitary in the opinion. Indeed, when it is considered that everything we cultivate in houses not only endures but enjoys such conditions in their wild state, how is it possible to doubt it? The great obstacle, it would appear, to a full recognition of this fact is the dread of over-dry indoor atmosphere, through the constant loss of vapour; but surely we have means in these times of producing as constant a supply. One thing may here be observed: that in severe weather, or when there is a certain amount of discrepancy between the inside and outside air, and air moisture continues to be engendered within, it is very apt to descend in drip, a thing by all means to be avoided. Now with a constant ventilation there is no need to fear this drip. Of course, such would consume a little more fuel, but this amount would not be found very material.

It is only proper, however, to remark here that, although constant ventilation might be congenial to the inmates of our houses in general, yet there are many special objects in gardening which demand other considerations. The early forcer, endeavouring to produce his Grapes, Pines, Peaches, &c., for sale or for exhibition, has frequently to push them forward by all possible means, and such circumstances require that a great amount of sun heat be enclosed betimes in the afternoon, and a high and moist atmosphere preserved during the earlier part of the night. I have here to confess that constant ventilation would frequently cause the loss of a week or two, and this is, in many cases, a serious affair as concerns market prices or exhibition days. Early Cucumbers seem particularly to enjoy this close shutting up; it of course hurries them forward. At the same time we all know that Cucumbers succeed in the very highest degree in warm summers, and under proper circumstances, albeit they are subject to winds, storms, and other vicissitudes.—N. E. R.

GLENSTAL CASTLE GARDENS AND THE RHODODENDRONS.

ONE of the most remarkable floral sights of Ireland is afforded by the outdoor Rhododendrons at Glenstal Castle, the residence of Sir Croker Barrington, Bart., imposingly situated on the southern slope of the Slieve Felim Hills. The Castle is comparatively modern, being principally built in the last generation by the late Sir Mathew, of a handsome variety of darkly marbled Caen stone found on the estate, and to which quarry, some three miles distant, a railroad was run. Though seemingly a freestone, time has written no wrinkles on its bold towers, turrets, or parapets. The top of the Sir Mathew tower is reached by a winding spiral stairway, and from its summit colonnade on a bright sunny day, such as we were fortunate in having, a lovely landscape greeted the eye in every direction. Limerick was due west, some dozen miles; the Shannon sweeps around through many scenic splendours to Castleconnell, less than half the distance, with its fishing, archaic, and historic attractions; while stretching away to the east and south, dotted here and there with cosy residences and gardens hidden in groves and dells, is the great plain of Limerick, terminating in one direction with the Golden Vale and great summit of Gattymore; while the rugged outlines of the Silvermine Mountain close out the north and east. The sparkling sheen of the lake below, with its swans and wild fowl, and the competition for a favourite piece of ground between two battalions of fallow and red deer, attract the wandering delighted eye to the park spread out and undulating below. From this vantage point a varied bird's eye view is obtained of many things of the forest—stately Oaks, venerable Elms, and spreading Chestnuts; while closely competing with those in height were many *Araucaria imbricata*. Except at Woodstock, the present fine residence of Lady Louisa Tighe, I have seen no finer specimens of Chili Pines than here. They are healthy, and seem about 70 feet high. The eye catches in the immediate park landscape many curious, and by no means common, specimens of various coloured Lilaes, *Philadelphus*, and double *Deutzias*; *Gymnocladus canadense*; and, sheltered by a wall, *Magnolia acuminata*, that the winter seemed to affect badly. Just underneath the terrace garden are miniature Heights of Alma, constructed in memory of that celebrated battle siege where so many Irish and Britons bravely lost their lives. The top rampart was planted with *Hypericum calycinum*, the second with *Fuchsia Riccartoni*, and underneath *Halesia tetraptera*. Though well protected from north and east, the winter of 1879 and 1880 was too much for them, and they were killed, leaving the "Heights of Alma" as bare as probably the Russian had their great prototype more than a quarter of a century since. With just a peep here and there at the many remarkable Coniferae, I propose to no longer pretend not to see the Rhododendrons. They meet the gaze at the entrance to the park; they stud the margin and islands of the lake; they front copses and skirt glades, peep out from gloomy ravines, and seem equally at home 1000 feet above yonder hill escarpment. But we shall ramble among them immediately. To see the Coniferae and Rhododendrons to advantage we must quit, reluctantly it must be, our perch with the coloured sentinel on guard in the Castle turret, and leave him to gaze admiringly on the Russian captured cannons below, and on as smiling a

landscape as the scene painter's eye ever gazed on. The tourist may search many a league of the wide world before coming on so enchanting a scene:—

"The eye can rest, suppose the soul to smile,
On thy dear diversity—Emerald Isle!"

We are kindly permitted, after our descent from cloudland—this time sunshine—to have a look through the library, various drawing rooms, picture and statuary galleries; the spoils of the chase; the family portraits, as well as the coats of mail of the Middle Ages of Sir Croker Barrington's ancestors that would fill a quarto volume to briefly describe. Two things particularly struck our party, and that I cannot describe fully, but yet cannot pass, the mediæval Flemish and Irish tapestry, and a modern balustrade carving in Irish oak by the boys of a local industrial institution from a design by a clergyman assisted by some members of Sir Croker's family that stands on the lobby of the grand Castle stairway. We cannot emerge from the courtyard without a greeting from "Gelert," the giant specimen of the Irish wolf dog or staghound that I have often seen pictured and read of in history, but never saw a live specimen before. He seemed, like Sir Croker's retainers, disposed to keep up the ancient custom of his now all but extinct species, and to give us a warm Irish welcome. Right in front is the bridge crossing the glen, where we pass a large specimen of *Rhododendron Nobleanum*, and to which I shall have to refer again. This bridge leads to the glass structures and the terraced gardens, but Mr. R. Weller, the experienced and courteous head gardener here, who acts as chaperone with Mr. McMahon, gardener to the Dowager Lady Barrington, and Mr. Morris, estate manager, decide that Mr. Crehan, Minella Gardens, and myself, must first see this wonderful wooded glen, more than two miles long, and through which a subterranean stream flows. This stream, after winding its way tortuously for some miles through the Ferns and Hazels, with an occasional glimpse of the sunlight from above and through the foliage of the tall trees, dips under ground and again comes to the surface a mile further down, near the aforementioned bridge, and below it widens into a miniature lake. The Ferns here attain an almost giant size, and are of many varieties. Recently, up in a cleft, between great boulders, Mr. Weller recently discovered a piece of Killarney Fern (*Trichomanes radicans*), the only piece I ever saw or heard of as naturally growing and thriving outside its native habitat. From its position neither the plant nor spores could have been placed there. Convenient were fine specimens of the Weymouth Pine (*Pinus Strobus*), *P. austriaca*, and *P. Lambertiana*, and on a southern slope, occasionally alternating with Cedars, *Abies Morinda* and *A. Nordmanniana*. Mr. Morris considers this last the "best timber tree of all the Silver Firs," and around here it suits in all positions, high or low. We were, however, not prepared to meet one in this highland retreat called *A. Albertiana*, extremely handsome in foliage, and in habit resembling the Cedar of Lebanon. *Cupressus* is represented by *C. Lawsoniana*, and the largest and seemingly the oldest, *C. macrocarpa*, I noticed elsewhere, with the exceptions of *Powercourt* and *Doneraile Court*, Wicklow and Cork. There are many rare and curious trees, shrubs, and ornamental plants meeting the visitor at almost every turn that would claim attention were your space no consideration; or the special train passing Boher—the nearest railway station—twenty-four hours later. We may, however, here notice what Sir William Hooker is said to have considered the oldest specimen of English Yew (*Taxus baccata*) in the world. It is of immense size in the trunk, one-half of which is dead, and planted beside the steps of the old terraced gardens, which Sir Croker and his ancestors maintain as arranged some centuries since, and before the present Castle was erected. The age is set down at 450 years, but Mr. W. Baylor Hartland of Cork, I understand, thinks it nearer twice those figures.

Coming to the immediate object of our visit—the *Rhododendrons*—though I feel with such surroundings on a glorious sunny day in leafy June, I need hardly apologise for digressing before specially noting the Glenstal specialty. And first I am tempted to ask you and your readers, Why are not hardy *Rhododendrons* more extensively planted? The number of varieties to select from are little short of 400. Thousands were planted here, and flowers can be seen nearly every day in the year. The majority of them are almost as cheap as common shrubs, while their evergreen foliage and floral beauty preclude comparison with most shrubs. There they seem to luxuriate in swamps or marshy retreats with the same apparent indifference as they do on the exposed hillside, beside the carriage drives, or in the partial twilight of the deep glens. Their adaptability and beauty are not their only commendations. Here, besides deer and the usual park game, hares and rabbits are found by the million. It is found in severe weather *Rhododendrons* are almost the only ornamental shrubs they never nibble or destroy. The common *R. ponticum* and the, if possible hardier, *R. catawbiense*, are found everywhere. There are ten miles of walks, and at no time do you lose sight of them. The customary method is to have those that contrast in colour and that are known to suit best the particular situations planted in juxtaposition. For instance, near the entrance lodge was noticeable Sir Charles Napier, rose; *Nobleanum*, shades of crimson; *Curricanum*, dark purple; *Album triumphans*, large white; *Concessum*, light centre shading to rose; *Victoria*, claret; *Nareissus*, dark spots on scarlet ground; *Speculatum*, pink; *Purity*, white; *John Waterer*, rich carmine; *Pictum*, orange spots on white ground; and *Sidney Herbert*, dark spots on dark crimson, and duplicates of the same in different positions generally alternating for contrast. As we had not time to see more than a fraction of the park and grounds and a portion of the numerous elumps, I cannot pretend to note more than a few of the leading varieties, many of them being planted by the thousand. A elump to the right of the main carriage

drive contained fifty distinct varieties alone, conspicuous being some of the foregoing, with *roseum superbum*, *oculatum nigrum*, *perspicuum*, *William Ewart Gladstone*, *Stella*, *Lady Dorothy Nevill*, *John Spencer*, *Mirandum*, *Dietator*, *Isabel*, *Faust*, *delicatissimum*, *Neilsoni*, *Scipio*, *Poussin*, *Raphael*, *limbatum*, *Michael Waterer*, and many others that did not seem strikingly different. The object seemingly aimed at was not in conspicuous positions to have any two similar varieties planted beside, and to have low-growing ones planted in front—all indicating an intimate acquaintance with the special characteristics—and gradually sloping from the grassy lawn upwards.

Another object aimed at seemed to be to have hardy early-flowering *Azaleas* interspersed here, so that the various masses should be attractive for the longest period. Where seeding is not desired in case of the best varieties it adds much to the vigour of the growth, and makes more certain the flowering the following year, to pick off the seed pods. *Rhododendrons* are a special attraction here from November to July. For instance, I forward a photo of *R. Nobleanum* taken by Lord Rosse the 17th of January. It being a snowy dull day this was difficult, and prevents the contour and blooms from being more defined.

Passing hurriedly to the gardens proper, I am afraid the exigency of your space will permit little more than a mere reference. The terrace garden, flanked by Russian cannon, commands a splendid view, and has in perfection the much-coveted springy moss-like carpet of turf closely shaven. The fountain garden, with its large herbaceous collections of alpine and perennials, all seemingly at home, was very attractive to me. *Gunnera scabra*, *Foxgloves*, *Japanese*, *German*, *Spanish*, *English*, and many rare *Iris*s, had each allotments. So had *Pyrethrums*, single and double; *Alstroemeria*, *Hemerocallis*, *Delphiniums*, *Thornium Clusi*, various *Papavers*, *Boeonia cordata*, *Violas*, *Mimulus*, *Paeonies*, *Potentillas*, *Geums*, *Phloxes*, *Campanulas*, &c.

The glass structures include a well stocked greenhouse, that a glance shows many rare and good things well grown. We have never seen *Regal*, *Fancy*, and *French* (spotted) *Pelargoniums* cleaner and more floriferous. The roof is covered on one side with *Maréchal Niel*, *Niphetos*, and *Souvenir d'un Ami Roses*; on the opposite, span-roof, the red and white *Lapagerias*. To the pillars are trained the old and seldom seen *Fuchsia corymbiflora*, *Teoma rosæfolia*, a rare beauty, and *Draecæna indivisa*. A large number of cool-house *Oreheids*, very promising, with *Gloxinias*, *Coleus*, *Bouvardias*, and *Libonias*, and the customary greenhouse plants well done. The next two houses were early and late vineries, the *Grapes* being colouring in the former. Among the *Vines* noticed bearing magnificent bunches were *Muscate of Alexandria*, *Black Hamburgh*, *White Tokay*, not seen as often as its merits seem, and *Buckland Sweetwater*. *Gros Colman* seemed very promising in the second house—young *Vines*. The stove came next. *Allamandas*, *Stephanotis*, and *Schubertia graveolens*—figured in *Journal*, if I remember rightly, but seldom seen—cover the roof, and a choice selection of tropical *Oreheids* look promising. Many brilliant foliage and flowering plants meet the eye around. But we must proceed and draw to a close after only a look into the orchard, *Peach*, and *Nectarine* houses, though, like "Yarrow unvisited," three large terrace gardens, the fruit and vegetable gardens are still unnoted, with remarkably interesting herbaceous borders. Permit us in concluding to warmly acknowledge Mr. Weller's courtesy, and Mrs. Weller's hospitable reception, and to note the creditable manner in which every department is conducted, indicative of still further progress.—W. J. MURPHY, *Clonmel*.

[The photograph shows wonderful growth, but too indistinctly for engraving.]

SPECIALTIES AT PERRY HILL.

CALCEOLARIAS.—Messrs. J. Carter & Co. have a large house devoted to *Calceolarias* in their Perry Hill nursery, and for several weeks they have afforded a beautiful display, well illustrating the high quality of the strain. The greatest care is exercised in crossing distinct forms and preserving those which show a marked advance in form and colouring, and there is now promise of a fine crop of valuable seed. The colouring is too diversified to be described, but all know what a surprising range of tints is displayed in a good strain of *Calceolarias*. Some are delicately spotted or reticulated in rich shades on a light ground, others have bold marbling, and others still have broad zones or are nearly self-coloured. From the deepest crimson, rosy purple, maroon, bronze, or orange to the purest yellow shades, the intermediate tints are numerous, and further recommendations are found in the compact habit of the plants, with their dense heads of large blooms.

PETUNIAS.—For some years special attention has been paid to these plants at Perry Hill, and Messrs. J. Carter & Co. have succeeded in forming a strain of exceptional beauty and variety. This has been termed the *Emperor* strain, and comprises a wonderful range of colours from pure white to delicate rose, the richest crimsons and deepest blue-purple, striped, spotted, veined, and diversified in the most beautiful or fantastic manner. A few of the types have received distinct names, and amongst these are the following:—*Single*, *Clematis* section, blue with white centre; blue veins, crimson or blue veined on a lighter ground; striped and spotted, crimson and blue on white, yellow throat; *Queen of Roses*, bright soft rose, white throat, very free and dwarf; *Duchess of Connaught*, bright crimson with a broad green margin, very peculiar and striking; *Danish Flag*, white centre, the lobes edged crimson; *Crimson King*, *White Pearl*, and *Purple Prince*, indicating their prevailing colours. Amongst the doubles the chief types are crimson and

white, maroon, rosy mauve, bright rose, blue, purple, white, rosy crimson, and white and crimson parti-coloured. In the mixed strain there is a combination of these characters, and the plants are useful alike for pots, windows, and baskets.

MIMULUS.—Three grand varieties or strains of these are Ruby, Queen's Prize, and Jubilee, and the groups recently shown at the metropolitan exhibitions attracted more than ordinary attention. The flowers are of great size like enormous Gloxinias, of fine substance and richly spotted or marked with crimson, maroon, and orange. For culture in pots or borders they are very valuable, and those who are only acquainted with the common garden Mimulus have no idea what an improvement has been effected in the size of the flowers and colouring.

Pyrethrums have been very gay, a large space of ground being occupied with the best named varieties. Some thousands of Stocks are advancing rapidly, and in another but important department is a trial of hybrid Wheats, which will constitute an interesting feature for agriculturists later in the season.

TREE MIGNONETTE.

IN March or April, better the middle of the former, select rather more of clean 60-sized pots than you wish for specimens of Mignonette trees, to make allowance for a few not turning out so well as the rest. Drain these pots, and fill them to within a quarter of an inch of the rims with rich light loam, such as might be made with two parts of brown hazelly loam, one part of very decomposed sweet leaf mould, half a part of heath soil, and less than half a part of silver sand; then drop a few seeds—say four—in the centre of each pot, covering them evenly. The common Mignonette answers very well. The large-flowering Mignonette will produce stronger stems and larger trusses; but we think the old common sort blooms in general more profusely—but either will bloom abundantly if well treated. When sown the best place for the pots is the back of a Cucumber or Melon bed, where the pots can be plunged, and air given to the young plants as soon as they appear. In such circumstances they will not be long before they make their appearance.

As soon as the plants are half an inch in height examine those in each pot narrowly, and select the one that seems the most bold and luxuriant, either pulling the others out, or, what is better, cutting their stems below the surface with the point of a penknife, so as not to injure the roots of the one plant left in each pot. Were it not for this power of selection, and the certainty of getting a good plant, it would be as well to sow only one good seed in a pot at once. By the time the plant is an inch in height any side shoot that offers to come should be disbudded, picking it out, but allowing the leaf next the stem to remain. When the centre shoot is from 2 to 3 inches in length a little twig should be set against it, and the little stem tied to it to encourage it to mount, nipping out every side shoot that shows, but allowing the leaf to remain, as that adds strength to the stem, and, besides, gives it a more furnished appearance. The little twig stake should be 1 or 1½ inch from the stem; and in the process of growth, as a larger and stouter stake becomes necessary, the lesser stake should be carefully taken out and the larger one inserted in the same hole, so as to run as little risk as possible of injuring the roots.

As soon as these little pots are getting full of roots, and before the roots meet the sides of the pot, shift each plant into a large 48-sized, and plunge the pot, and keep training the main stem and disbudding all side shoots as before. As soon as that pot is filled shift into a 32-sized pot, and let the soil be a little rougher, and give a little bottom heat as before. If the main shoot go on without showing flower it will be all smooth sailing, the disbudding of all side shoots being the principal thing; but if the leading shoot show bloom it must be nipped off, and then the best-placed shoot that comes you must train off as a continuation of the first stem; and sometimes if you want a tall stem, you may have to do this several times before you obtain the desired height. Whatever the height of the stem before the head forms, be it 1 foot or a couple of feet or more, no flowers should be allowed to remain until the stem is as high as desirable; nor even then until the head of the tree is pretty well formed.

When the 32-sized pot is about full of roots I prefer placing the plants in their flowerin' pots, and a pot of 12 inches in diameter and depth will support a very nice specimen. In this last potting—and the pot may be larger if an extra-sized specimen is desirable—the drainage must be well attended to, and the soil chosen of a more lumpy character, so as to avoid anything like stagnant water; and to help this still more, a few additional pieces of fibry heath soil, and some bits of charcoal the size of beans, may with advantage be added to the compost. This rough material should be squeezed together pretty tight, and the surface covered all over with fine material to the depth at the sides of at least half an inch, which will prevent the air entering the soil too freely. In all such shiftings care must be taken that the soil in the pot is moist, but not deluged, before shifting; and this will be best secured by watering thoroughly four hours or so before repotting. After this final repotting, if the pots can be partly plunged in a mild heat for a fortnight or so it will be all in their favour; but by July they will stand well in any pit or house where they can receive moderate attention. In such places the plants will do better when the pots stand on a shelf, or on the bottom of another pot reversed; as when the pots stand on the ground the drainage is apt to be injured, and the exhalations that rise from such wet ground are not at all in their favour.

Until the head is formed it is advisable to have a frill of leaves all

along the stem, but no side shoots; that, as above stated, not only furnishes clothing, but gives strength to the stem. As the head swells in diameter the leaves on the stem will most likely be robbed, and will then fall off. In general it would be best to have the shortest-stemmed plants for winter blooming, and the tallest for spring blooming, as the former may be supposed to perfect their heads sooner. In both cases the treatment is much the same, as the plants should not only be kept airy, but in a temperature of from 45° to 48° or 50° in winter, with a rise from sunshine.

In training many contrivances may be adopted with wire, &c., for supports. I will describe a very simple mode. I will suppose that the stem is high enough for the lower branches of the future tree. Well, the plant is held carefully, the old temporary stake removed, and a stout one, fully half an inch in diameter, is inserted firmly in the same place, and as much higher above the lower branches as we wish the point of the tree to be, say some 15 inches above the lower branches. Well, after tying the stem securely to the stake, the next operation is to make that secure in the pot, so as to carry the weight of the future head, and no simpler plan exists than taking two pieces of wire at right angles from the stake across the rim of the pot, and fastening them there. Then two holes at right angles a little apart from each other about the level of the lower branches, say 18 inches from the pot, will do for putting through two stout wires like the spokes of a wheel. A wire fastened to the points will form the circumference, and lesser wires between will furnish the means for tying the branches; 6 or 8 inches higher up other two wires should be inserted for a smaller circle, and thus the orbicular pyramidal head may be easily secured. There must be regular stopping and training, and nipping off all flower buds until the head is formed, and then each shoot may bloom as it likes.

When the head is forming, and also when in bloom, clear manure water, and not too strong, may be pretty freely used, except in very dark weather in winter. To keep the plants long healthy and producing abundance of bloom, no bloom should be allowed to remain when it is old or showing signs of seeding. One truss with seeds swelling will injure the plant more than a score of half-opened trusses. This continued pruning away of every flower when past its best, even though the point should be fresh, is the secret for keeping plants long in health. By such means we have seen a plant of common Mignonette grown in the common way, or hanging over the pot, very good after it had been in the same pot seven years. When these tree Mignonette plants are a full mass of bloom at one time this thinning of flowers must be done freely if the plant is to keep on long afterwards. By this free thinning, stopping and training in summer, and fresh surfacings of good soil, the same plant will continue for years; but there is so much trouble in keeping the soil in a healthy state in such large pots through the winter, that generally it will be the best plan to sow and grow one season for blooming during the earliest part of the next.

When I was fond of such plants I used to grow some as pyramids—that is, the base of the cone on a level with and falling over the rim of the pot, and the plant gradually lessening in width to the apex. Such plants from 15 to 20 and 24 inches in height are very pretty. The main features of management are the same, with the exception of securing the necessary and right-placed side shoots; and to produce them the stem had sometimes to be stopped, as there was little risk of that not getting up.

The above remarks, however, apply only to what are generally called tree Mignonette plants. There is but one little point concerning them which I have overlooked, and that is carefulness in watering if the last shift should be a large one. In that case only the new soil in proximity with the ball and the ball itself should be watered, and the bulk of the new soil at the sides of the pot should not be deluged until the roots are working in it. This rule applies to all large shifts, as otherwise the soil is apt to become soured; and if so, the Mignonette trees will not flourish.—H. R.

ROYAL OXFORDSHIRE HORTICULTURAL SOCIETY.

JUNE 19TH.

THIS was what is known as the Commemoration Show, as it always takes place during the week of the Great University Festival of Oxford, and it was held as usual in one of the College gardens, that of Worcester, a most delightful place for such an exhibition, with a large expanse of smooth green sward, shady walks, and magnificent trees, with the addition of a spacious lake. Three large tents were required to contain the exhibits, and even then some of the cottagers' products had to be provided for in the open ground. The day was unpleasantly cold, but there was a large and fashionable attendance, the cut flowers especially appearing to attract great attention.

CLASSES OPEN TO ALL ENGLAND.—*Plants.*—One of these was for nine stove and greenhouse plants in flower, Mr. James Cypher, nurseryman, Cheltenham, being placed first, with excellent specimens of *Ixora Williamsi*, *Dracophyllum gracile*, *Phœnocomia prolifera* Barnesi, *Bougainvillea glabra*, *Anthurium Schertzerianum* Veitchi, *Aphelaxis spectabilis*, *Erica depressa*, and two *Azaleas*. Second, Mr. J. F. Mould, nurseryman, Pewsey, Wilts, whose best plants were *Genetyllis fuchsoides*, *Dipladenia profusa*, *Franciscea calycina* major, *Clerodendron Balfourianum*, a very fine specimen, *Erica Cavendishiana*, and *E. austella*. Third, Mr. H. James, Castle Street Nursery, Lower Norwood. Mr. Cypher also had the best six Cape Heaths, staging good fresh specimens of *depressa*, *ventricosa grandiflora*, *tricolor* Wilsoni, *tricolor elegans*, *ventricosa hirsuta*, and *Kingstoniana*. Second, Mr. H. James, his best specimens

were tricolor Wilsoni, ventricosa tricolor, and Candolleana. Pelargoniums in twelves were also invited, and Mr. C. Turner of Slough has generally shown in this class, but could not on this occasion. The first prize withheld, a second being awarded to Mr. J. Mattock, Headington Hill, Oxford. Fancy Pelargoniums were also invited, but none were forthcoming.

Cut Flowers.—Mr. J. Mattock was the only exhibitor of twenty-four varieties of Roses, three trusses of each, his best blooms being Catherine Mermet, Souvenir d'Elise, Rubens, Perle des Jardins, Niphotos, Maréchal Niel, Devoniensis, Souvenir d'un Ami, Marie Van Houtte, Jean Ducher, Madame Lambard, and Grace Darling. Mr. Geo. Prince, nurseryman, Oxford, had the best twenty-four Roses in single trusses, staging capital blooms of Comtesse de Nadaillac, Maréchal Niel, Madame de Watteville, Princess of Wales, Souvenir d'Elise, Grace Darling, Adam, Alba Rosea, Duke of Edinburgh, Lady Mary Fitzwilliam, Niphotos, and Madame Lambard. Second, Miss Watson Taylor, Manor House, Headington (the addresses of gardeners are not given at Oxford), with Maréchal Niel, Xavier Olibo, Rubens, Devoniensis, Souvenir d'Elise, Perle des Jardins, Madame Lambard, La France, and Catherine Mermet. Third, Mr. J. Walker, nurseryman, Thame.

Dinner Table Decorations.—With three stands Mr. J. Mattock was first, arranged after the usual pattern, but showing the common fault of being too heavily loaded; J. S. Parker, Esq., Ifley, Oxford, being second. Mr. J. Johnson, Garsington, Oxford, had the best hand bouquet, a remarkably good one, composed wholly of white flowers; Mr. Geo. Jacob, White Lane Nursery, Witney, being second with one composed mainly of Orchids. The best single piece for table decoration came from Rev. H. A. Pickard, Canterbury Road, Oxford.

Members' Plant Classes.—The best eight stove and greenhouse plants in flower came from G. H. Morrell, Esq., Headington Hill, who had *Bougainvillea glabra*, *Justicia carnea*, with some fine spikes of bloom; *Tabernaemontana coronaria flore pleno*, *Impatiens Sultani*, and *Vincas alba* and *rosea*. There were no other exhibitors. With six specimens, Mr. Geo. Jacob, Mill Lane Nursery, Witney, was first with *Clivia miniata*, *Cattleya Mendeli*, *Oncidium sphacelatum*, *Anthurium Scherzerianum*, and *Cypripedium barbatum*. Mr. G. H. Morrell had the best six variegated and ornamental foliage plants, having good specimens of *Croton Warreni*, *Caladium Chantini*, *Dracana Shepherdii*, *D. metallica*, *Cissus discolor*, and *Pandanus Veitchii*. Second, Mr. Geo. Jacob, Witney. The best specimen stove plant was *Cattleya Gaskelliana* from Mr. Geo. Jacob; Mr. G. H. Morrell being second with *Ixora coccinea*. The best specimen hardy plant was a fine piece of *Cypripedium spectabile* from Mr. R. Price, Headington; Mr. R. H. Byass, Rousham Park, being second with *Deutzia crenata* fl. pl. The best ornamental foliage plant was a fine *Chamaerops excelsa* from Mr. G. H. Morrell; Mr. Geo. Jacob coming second with *Encephalartos villosus*.

Orchids.—The best four specimens came from Mr. G. Jacob, who had *Cattleyas Mossiae* and *Mendeli*, *Odontoglossum vexillarium*, and *Cypripedium barbatum*. Second, C. A. Bevers, Esq., Oxford, who had *Odontoglossum citrosimum*, *Dendrobium thyrsiflorum*, *Cattleya Mendeli*, and *C. Mossiae*.

Miscellaneous Flowering Plants.—These were shown in good condition by Messrs. Jacob and others. *Achimenes* were rather small, but nicely grown and bloomed. Some very good herbaceous *Calceolarias* were staged by Mr. J. Walker, Thame, and also by Mr. R. J. Johnson, the awards being made in the order of their names. *Fuchsias* were a good feature, some very nice free-growing and well-flowered plants from Mr. J. Walker being placed first, the varieties being *Rose of Castille*, *Charming*, *Grand Duchess Marie*, *Warrior*, *Mrs. Marshall*, and *Mrs. Rundle*; all good exhibition sorts. Second, Mr. J. Johnson with smaller specimens. Some fine specimens were also shown in the class for three varieties. *Begonias* (Tuberous) were a good feature also. Mr. J. Mattock was first with some capital varieties; Mr. R. Price of Headington being second. Pelargoniums in the members' classes were somewhat poor. Mr. J. Mattock had the best nine show varieties, Mr. Dallon, Norbury Gardens being second. Mr. C. Jacob had the best six varieties. Mr. Jacob also had the best six Zonals, showing fresh and well-bloomed specimens, Mr. J. Johnson being a good second. They were also shown in collections of four plants. Double varieties were shown in better form than the singles, Mr. Owen Grimbley, Summer-town, being first, and Mr. J. Johnson second. Tricolors were a good feature, well grown and coloured plants abounding. Mr. J. Mattock was first with six, having *Empress of India*, *Lady Cullum*, *Mr. H. Cox*, *Sophia Dumaresque*, *Elegans*, and *Diadem*. Second Mr. C. Jacob with much the same varieties. Ivy-leaved varieties in sixes were equally good, nice, bushy, well grown, and flowered specimens.

Exotic and Hardy Ferns.—These were well shown, but owing to the press of visitors it was impossible to glean particulars. The hardy Ferns were a remarkably good feature.

Cut Flowers.—It is a practice at Oxford to show small bouquets in twenty-fours, and they, as might be expected, are generally of an inferior character. It would be much better to substitute for these bunches of stove and greenhouse flowers. The best came from Mr. J. Johnson, Garsington, Mr. John Walker being second. Mr. T. Anstiss, Brill, Bucks, had the best nine bouquets, the Rev. H. A. Pickard, Canterbury Road, being second. Bouquets for the hand and buttonholes did not call for special notice. Zonal Pelargoniums in bunches of nine were also well shown, the best coming from Mr. J. Mattock, Mr. John Walker being a good second. We were pleased to see some of the florists' *Ranunculus*, and though not in good condition it shows they are still cared for. The best came from Mr. P. Southby of Bampton, Oxon.

Pansies of the fancy class were well shown by Mr. Joseph Lakin of Temple Cowley, who had the best twenty-four, Mr. John Akers of Stanton Harcourt taking the first prize for the best twelve. A dozen Pinks were shown by Dr. B. Ward, Warneford Asylum, but they showed the effects of an unkind season. Evidently attempts are still made to grow some of the old florists' flowers about Oxford. Pyrethrums in bunches of three blooms made a good feature, set up in nine varieties backed by their foliage; but the finest feature of all was the stands of twelve bunches of hardy herbaceous cut flowers. Here Mr. J. Lakin was first with a very fine lot in large bunches well displayed, Mr. R. Price, Headington, being second. There were several classes for Roses also, but the best varieties shown have already been given.

Fruit were limited in quantity, but generally good; the three best bunches of white Grapes were Foster's Seedling from Col. Miller, Shot-over House, Wheatley; Col. Lee, Aylesbury, being second with the same. Three good but unripe bunches of Duke of Buccleuch were staged in this class. Mr. Geo. Parker, Great Tew Park, had the best three bunches of Black Hamburgh Grapes, R. N. Byass, Esq., being second. Col. Lee had the best dish of Peaches, showing Alexander; Mr. P. Southby being second with Stirling Castle. The best Melon was Hero of Locking.

Vegetables were remarkably well shown, especially for the special prizes given by Messrs. Sutton & Sons of Reading, and Messrs. Webb and Sons, Stourbridge. There were several classes for these, Potatoes being perhaps the weakest display, which is not to be wondered at considering the late season. There was also a very good display of cottagers' vegetables, the collections of cut flowers being particularly interesting.

SOWING AND GROWING CABBAGE.

BEING asked by Messrs. Stuart & Mein to put on paper our mode of growing Cabbage, I have great pleasure in doing so; but would here remark that our time of sowing will not suit all, and that each gardener or amateur ought to have his own calendar to suit his locality. The first thing to attend to is the purchasing of the seed, and also the variety, and from some reliable firm. I have grown Stuart & Mein's No. 1 for some years, and find it our best early.

The soil for the seed beds should be light, moderately rich, and well pulverised. We sow our seed as near as possible about the 17th July, in shallow drills, the full width of a draw hoe, from a foot to 14 inches apart, covering thinly with fine soil, and finishing by beating it lightly with the back of a rake. By sowing in drills the plants can be easily thinned, and kept stirred with a hoe. By these means fine plants can be reared, which must not be allowed to become crowded, which will enable them to form good plants with fine roots without pricking out; and if all goes well, the plants are ready for planting the first week in September, which we always manage to do, on a piece of ground thoroughly prepared—trenched, if possible—as no one can grow good tender succulent Cabbages on the non-digging principle.

Cabbages like to grow on ground of a good substantial nature, which has been heavily dunged for a number of years. We use enormous quantities of farmyard manure, not much decomposed, which we bury to the depth of one spit below the surface. We do not use any artificial manure, as we think the farmyard manure keeps the soil open and acts as a drainage, which enables the plants to grow better in winter and spring. In planting out advantage should be taken of moist weather, if possible; but should the weather be dry, we always plant towards evening, puddling the roots in a mixture of soot and lime, and by carefully lifting the plants, planting firm, and giving a good watering, anyone can grow Cabbages to suit the most fastidious, and, if need be, "Go in and win."—D. INGLIS, *Howick Hall, Northumberland.*

[Mr. Inglis was the winner of the £5 prize for Cabbages offered by Messrs. Stuart & Mein last year.]

REVIEW OF BOOK.

Handbook of the Amaryllideæ, including the Alstrœmeriæ and Agavæ. By J. G. BAKER, F.R.S., F.L.S. London: George Bell and Sons, York Street, Covent Garden.

THIS useful work of reference is the outcome of a long experience and a close study of the plants on which it treats, for Mr. Baker states in the preface "During the twenty-three years I have been at Kew I have made notes of the characters of all the Amaryllideæ that have passed through my hands in a living state, and have had the opportunity of examining dried specimens of nearly all the species of the order. I have attempted in the present work to furnish cultivators and botanists with a compact working handbook, of which the main part consists of characters of the genera and species drawn up from actual specimens. I have not attempted to deal fully with the bibliography of the plants, or to trace out their pre-Linnean history, or to say anything about their cultivation, or to deal, except very briefly, with the garden hybrids, which are so numerous in this order."

The book comprises 216 closely printed pages of botanical descriptions in English of sixty-one genera and about 670 species, the principal references to authorities and figures being included, together with particulars of geographical distribution and many historical facts, especially in regard to the genera *Narcissus*, *Hippeastrum*. Though essentially a work of botanical importance, the descriptions are so clear and intelligible that the book will be interesting and useful to all horti-

culturists who are specially concerned in the numerous plants included in the Amoryllidæ. Some of the chief garden genera are *Narcissus*, *Galanthus*, *Leucojum*, *Hippeastrum*, *Vallota*, *Clivia*, *Hæmanthus*, *Crinum*, *Amaryllis*, *Eucharis*, *Panacratium*, *Alstroemeria*, and *Bomarea*. It may be mentioned that *Imantophyllum* is now reduced to a subgenus, and the numerous varieties grown in gardens must be ranked under *Clivia miniata*, *C. nobilis* and *C. Gardneri* being the only two other species. *Imantophyllum cyrtanthiflorum* is named as a hybrid between *Clivia miniata* and *C. nobilis*. A copious index of specific and varietal names increases the value of the work, which is well printed and neatly bound, and, it need scarcely be said, is thoroughly reliable.

ROYAL BOTANIC SOCIETY.

JUNE 20TH.

THE second summer Show of the year was held in the Botanic Garden, Regent's Park, on Wednesday, and though the plant exhibits were not quite so numerous as usual, owing, it is said, to reductions in the prizes, there were numbers of non-competing exhibits of a most interesting character, and the fruit Show was one of the best, both in quality and quantity, yet held in London at midsummer. The weather unfortunately was of a most unfavourable character, rain falling the whole of the day, and this deterred many visitors from attending, but the Show was visited by the Duke of Teck and the Princess Mary early in the afternoon.

ORCHIDS.—A fine bank of Orchids was again formed in the centre of the large marquee, many large specimens and choice forms being represented. In the amateurs' class for twelve Orchids Mr. F. Hill, gardener to H. Little, Esq., The Barons, Twickenham, won first honours for grand specimens of *Cattleya labiata* Warneri, *C. Mossiae*, *C. Mendeli*, and *C. Sanderiana*, each with some dozens of large flowers; *Lælia purpurata* and *L. purpurata splendens* were also noteworthy, the latter a handsome variety with broad rich crimson lips. *Cattleya intricata*, a supposed hybrid between *C. amethystina* and *Lælia elegans*, was interesting; *Anguloa Clowesi*; *Cypripedium barbatum superbum*, extremely fine; *C. Lawrencianum*, also good; and *Vanda teres* completed this admirable group. Mr. H. James, Castle Nursery, Norwood, took the lead in the nurserymen's class for a dozen specimens with *Cattleyas*, *Cypripediums*, *Odontoglossums*, &c., Mr. J. Cypher, Cheltenham, being second for a much more effective group, comprising good *Cattleyas*, a remarkable *Dendrobium Falconeri* on a block, capitally flowered, and a good variety; also *Calanthe veratrifolia*, and *Epidendrum vitellinum majus*, well flowered. Mr. Hill was also first for a group of *Cypripediums* and *Dendrobium*s, including small but healthy samples of *C. barbatum superbum*, *C. calurum*, *C. lævigatum*, *C. Dayanum*, *C. super-eliare*, *C. Crossianum*, *C. niveum*, *C. Warneri*, *C. ciliolare*, *C. Veitchi*, and *Dendrobium Dalhousieanum*, *densiflorum*, and others. Mr. Cypher was first for a group of *Dendrobium*s and *Cypripedium*s in the nurserymen's class, tastefully arranged with Ferns, and Mr. H. James was second with a much smaller and less beautiful group. Messrs. F. Sander and Co., St. Albans, exhibited a group of choice Orchids, comprising *Cattleyas*, *Odontoglossums*, including very fine varieties of *O. Alexandræ* and *O. vexillarium*, a richly coloured variety of the latter named *ruberrimum* being very noticeable.

Pelargoniums.—These furnished some welcome colour on the slopes near the entrance. Mr. C. Turner, Slough, had the best six plants of show varieties in the nurserymen's class, even neat specimens, with handsome flowers of *Maid of Honour*, *Gold Mine*, *Volonté Nationale*, *Despot*, *Prince of Prussia*, and *Prince Leopold*. Mr. Hill was first in the amateurs' class, *Hermit*, *Ruth Little*, and *Fortitude* being excellent in number and size of flowers. Mr. D. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, following with smaller plants. With six fancy *Pelargoniums* Mr. Turner was also first, *Ellen Beck* being a handsome example, over 3 feet in diameter and crowded with flowers. Mr. Phillips was first with the only exhibit in the amateurs' class for small but neat plants. Zonal varieties were shown by Mr. Hill, Mr. D. Phillips and Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, who secured the prizes in that order with good plants, scarlet varieties predominating.

Messrs. H. Cannell & Sons, Swanley, besides having a choice group of novelties had a collection of Tuberous *Begonias*, for which the first prize was awarded in the class. The varieties shown were *single*, *T. Moore*, *Mr. Murphy*, *Countess of Bessborough*, and *Fairy*; *double*, *Louis d'Or*, *Mrs. F. Wilson*, *M. Duvivier*, *Madame Aruault*, *Felix Crousse*, *Mrs. A. Paul*, and *Gabrielle Legros*. Stove and greenhouse plants were few and small, Messrs. H. James, A. Offer, and R. Butler securing the chief prizes in the several classes. Foliage plants and Ferns were shown by Mr. A. Offer, gardener to J. Warren, Esq., Handcross Park, Crawley, Mr. Eason, Mr. H. James, Mr. R. Butler, gardener to H. H. Gibbs, Esq., St. Dunstan's Lodge, Regent's Park.

FRUIT.—For such an early period in the season there was a remarkably good display of fruit, the only weak point being in the white Grapes, which were mostly somewhat green, as is customary at the early shows. In the Fruiterers' Company's class for a collection, Mr. J. Roberts, gardener to Messrs. Rothschild, Gunnersbury Park, Acton, won chief honours for admirable specimens of Black *Hamburgh Grapes*, with large bunches of *Foster's Seedling*, but rather green, and compact bunches of *Buckland Sweetwater*, a fine *Smooth Cayenne Pine*, good *Early*

Mignonne Peaches, handsome *Lord Napier Nectarines*, neat fruits of *Gunnersbury Gem* and *Hero of Lockinge Melons*, *La Grosse Sucrée* and *Keens' Seedling Strawberries*, *Brown Turkey Figs*, *Black Tartarian* and *Bigarreau Napoleon Cherries*. In all nineteen dishes were shown, a very creditable exhibit. The second place was taken by Mr. J. Edmonds, *Bestwood Gardens*, *Arnold*, *Notts*, who had excellent *Black Hamburgh Grapes*, good *Peaches* and *Nectarines*, and *Melons*. Mr. P. Blair, gardener to the Duke of Sutherland, *Trentham*, was third, showing two handsome *Pines*, with fine *Peaches* and *Nectarines*. A large bronze medal was also awarded to Mr. W. Robins, gardener to Col. E. D. Lec, *Hartwell House*, *Aylesbury*, for a collection of twenty-one dishes, comprising eight *Melons*, *Grapes*, *Peaches*, and *Nectarines*.

For one *Queen Pine Apple*, Mr. H. Cakebread, gardener to Sir P. F. Rose, *Rayners*, *Bucks*, was first with a fine even fruit. Mr. T. Coomber, gardener to J. A. Rol's, Esq., *The Hendre*, *Monmouth*; and Mr. T. Dawes, gardener to the Hon. Mrs. Ingram, *Temple Newsam*, *Leeds*, were second and third. For any other variety, Mr. J. Muir, gardener to C. R. M. Talbot, Esq., *Margam Park*, *South Wales*, was first with a good *Smooth Cayenne*, followed by Mr. W. F. Smith, gardener to Mrs. Byass, *Nevill Court*, *Tunbridge Wells*, with *Charlotte Rothschild*, and Mr. Hare third. Messrs. T. Hare, J. Douglas, and J. Hollingworth were the prizetakers for *Melons*, ten fruits being shown.

GRAPE.—An extensive display of black Grapes was provided. Mr. Edmonds had the best basket of *Black Hamburghs*, large berries and capitally coloured. Mr. Osman, gardener to C. J. Baker, Esq., *Ottershaw Park*, *Chertsey*, was a good second, and Mr. Hollingworth third, amongst nine exhibitors, all showing well. For a basket of white Grapes, Mr. R. Grindrod, gardener to Mrs. Greathed, *Whitfield*, *Hereford*, was first with fine clean *Muscat of Alexandria*. Mr. G. Clinging, gardener to *Walpole Greenwell*, Esq., *Marden Park*, *Caterham*, was second with *Foster's Seedling*; and Mr. Hollingworth third with the same variety. Five competitors entered. The class for three bunches of *Black Hamburgh* was well filled, ten exhibitors staging good samples. Mr. Edmonds was first for beautifully coloured even bunches; Mr. T. Osman a close second, and Mr. G. Clinging third, with neat bunches and small berries, but bearing a dense black bloom. In the any other black variety class, Mr. Roberts took the lead with *Madresfield Court*, handsome in bunch and berry, but not fully coloured. Mr. Cakebread was second with smaller bunches of the same variety, and Mr. G. Thomson was third.

Amongst the six exhibitors of three bunches of *Muscat of Alexandria*, Mr. G. Gummett, gardener to A. Richards, Esq., *Blenheim Park*, *Hounslow*, was first, Mr. P. Feist second, and Mr. Cakebread third, but all were deficient in colour, though fine in bunch and berry. In the any other variety class there were eight entries, Mr. W. Chuck, gardener to P. Thellusson, Esq., *Brodsworth*, *Doncaster*, won first honours with excellent bunches of *Duke of Buccleuch* very fine in berry, and clean. Mr. Roberts was second with large solid bunches of *Foster's Seedling*, and Mr. Clinging third for the same variety, well coloured, but smaller.

With two dishes of *Peaches*, Mr. W. H. Divers, gardener to J. T. Hopwood, Esq., *Ketton Hall*, *Stamford*, won first prize, showing *Royal George* and *Early Albert* large and highly coloured. Mr. W. Robins was second with *Acton Scott* and *Alexander*, and Mr. Gilman, *Ingestrie Gardens*, *Stafford*, third with grand fruits of *Violette Hâte*, but rather weak samples of *Royal George*. For two dishes of *Nectarines* Mr. P. Blair was first for *Lord Napier* and *Violette Hâte*, the former large and the latter richly coloured. Messrs. Hare and Gilman were second and third respectively. Messrs. Divers, *Worthing*, and Hare were the successful exhibitors of *Strawberries*, and Messrs. Blair, Hare, and Palmer with *Cherries*; a bronze medal being awarded to Messrs. T. Rivers & Son, *Sawbridgeworth*, for a capital collection of *Peaches* and *Plums*, and a small silver medal to Mr. T. Coombe, *The Hendre Garden*, *Monmouth*, for six fine even *Queen Pine Apples*.

CUT FLOWERS.—These occupied a large space in the first tent, *Roses* being particularly fine. Some of the chief winners were Mr. P. Perry, gardener to Mrs. Rowlett, *The Woodlands*, *Cheshunt*; Mr. W. Robius, *Rev. D. King*, *Cambridge*; Messrs. C. Turner, *Paul & Son*, *Keynes*, *Williams & Co.*, and *J. Burrell & Co.*, *Cambridge*. Miscellaneous flowers and Orchids from Mr. H. James, J. Cypher, and J. Douglas, who was first in the class for twelve varieties of Orchids. *Roses* were extensively shown, the prizes being awarded to Messrs. Barr & Son, *T. S. Ware*, and *Paul & Son* in that order.

MISCELLANEOUS.—The miscellaneous exhibits as usual constituted a very important portion of the attractions, and amongst them were the following:—A large handsome group of Orchids, with stove and greenhouse foliage and flowering plants from Mr. B. S. Williams, *Holloway* (large silver medal); a brilliant group of Tuberous *Begonias*, *Caladiums*, *Gloxinias*, *Ferns*, and *Palms* from Messrs. John Laing & Sons, *Forest Hill* (large silver medal); a most tasteful collection of *Petunias* and ornamental Grasses from Messrs. J. Carter & Co., *High Holborn* (large bronze medal); a group of handsome *Cattleyas* from Mr. Little (small silver medal); a tasteful group of Orchids from Mr. G. Elliott (small silver medal); and an effective group of Orchids from Messrs. Low & Co., *Clapton* (silver medal). Mr. R. Scott, gardener to Miss Foster, *The Holme*, *Regent's Park*, had a group of *Fuchsias*, *Hydrangeas*, *Spiræas*, *Gloxinias*, and *Ferns* (small silver medal).

Messrs. J. Veitch & Sons, *Chelsea*, exhibited a large group of Japanese *Maples*, *Lilies*, the variegated *Arundo Donax*, the elegant *Eulalia gracillima*, and a number of choice shrubs, comprising *Eleagnus macrophyllus*, *Rhus glabra laciniata*, *Spiræa opulifolia lutea*, and the golden *Ligustrum vulgare aurum*, *Weigela rosca Looymanni aurea*, with

the handsome Rhododendron-like *Daphniphyllum glaucescens*, and large plants of greenhouse Rhododendrons. All these were most effectively arranged, and there was also a fine collection of Irises and hardy flowers from the same firm (large silver medal).

Mr. T. S. Ware, Tottenham, was first with a group of hardy flowers, followed by Messrs. Paul & Son. Messrs. Collins Bros. & Gabriel, Waterloo Road, had a large group of hardy flowers (certificate). Messrs. Barr & Son, Covent Garden, a similar but more varied group (bronze medal). Mr. T. S. Ware also had a large group of hardy flowers (large bronze medal). Messrs. Kelway & Son, Langport, sent nineteen boxes of Pyrethrums and Pæony blooms, most varied and brilliant in colour. Messrs. Paul & Son, Cheshunt, had a collection of choice alpine and other plants.

Messrs. T. Rivers & Son, Sawbridgeworth, exhibited a most interesting group of fruit trees in pots, admirably grown specimens of Peaches, Plums, Pears, Apples, &c., all bearing fine crops of fruit. In the corridor this group attracted much attention (silver medal). Mrs. Harry Turner, Horsemoor Green, Langley, Bucks, sent a handsome plant of Carnation Souvenir de la Malmaison, with ten fine blooms (commended). Messrs. J. Peed & Son, Roupell Park Nursery, had a group of Anthurium Schertzerianum and Ferns (large bronze medal); and Mr. H. Eason sent a group of Gloxinias and Ferns (certificate).

Large numbers of certificates were awarded for new plants, but we must refer to them in our next issue.

HARDY FRUIT GARDEN.

CHERRIES.—In some districts extra heavy crops of these are swelling, and those on the walls especially will well repay for a timely thinning out. When too many are left on the trees the fruit is apt to be small and poor in quality, whereas choice Cherries cannot well be too large, always providing they are grown in a sunny position. A pair of Grape scissors is most suitable for the work of thinning the fruits, and in many instances fully one-half of the fruits may be cut off with advantage. Left to themselves the trees will frequently refuse to swell the whole of the crops, but this natural thinning-out process has a most weakening effect, and ought to be prevented. All leading growths to be laid in to their full length, but the laterals ought to be at once stopped at the seventh or eighth joint, this favouring the formation of numerous fruit buds at their base. Morellos may also be improved by being thinned out in good time, but as these fruit on the one-year-old wood, the young growths should only be thinned, reserving sufficient to lay in between the old wood or to take the place of shoots fruiting this season. Not being of very rank habit of growth the young growths need not be laid in; in fact, it is better for the fruit now hanging on the trees that no attempt should be made to nail or tie in the young growths.

PLUMS.—The commoner varieties are the surest setters, many of the Gages, as well as Jefferson's and Kirke's, failing to set more fruit than the trees are capable of supporting. Not so Rivers' Prolific, Victoria, Early Orleans, Prince of Wales, and Goliath, these being literally crowded with fruit, none of which will be of any real value unless the crops are freely thinned. The thinning may be done gradually, commencing at once, the later thinnings being given when the fruit is large enough for cooking purposes. Green Plums also make good preserve, and whether thus utilised or not they ought not to be left in a crowded state on the trees. Young growths may be laid in to their full length wherever there is wall space to be filled, but that not so required ought to be thinned, and those reserved and which are best springing out from the walls should be stopped at the sixth or seventh joint. Trees long in one position and bearing a heavy crop may well receive liberal supplies of liquid manure as well as a mulching of strawy manure, and orchard trees should have a number of holes pierced with an iron rod in the ground about the roots, and then receive a few tubs of farmyard liquid manure at the same strength as applied to meadows.

INSECT-INFESTED TREES.—Caterpillars have been very troublesome among both Apple and Pear trees, these eating many of the leaves and young fruit. The only remedy is to examine the trees and crush all found coiled up in the leaves, at the same time thinning all clusters of fruit where the caterpillars are most to be found, leaving only the soundest of the former, and crushing the latter. It was the abundance of bloom that favoured the lodgment of the eggs by tiny moths, the petals hanging about the clusters of fruit till either removed by the hand or washed off by heavy rains. The black fly is very thick on some of the best Cherry trees, and unless washed off will soon spoil the fruit. Soapy water applied forcibly by a syringe or engine and followed by clear water will dislodge the greater portion of them. A weak solution of tobacco water is also effective. A free use of the engine is necessary in the case of aphid-infested Plum trees, and as the water is beneficial to the roots no better remedy can be applied.

PLANTING FORCED STRAWBERRIES.—Plants of Vicomtesse Hericart de Thury fruited early in pots will, under ordinarily good treatment, yield a second crop in the autumn. The fruit can be ripened in the open, or if need be the plants may be lifted, repotted, and set on a shelf in a cool house to ripen the fruit in October and November. Another plan, which answers equally as well, is to plunge the plants in the pots so as to quite bury the latter, a border near to a pathway being the best position. Being kept supplied with water the roots soon find their way into the surrounding soil, and this materially assists the plants. When lifted in the autumn much of the soil and the outer roots may safely be cleaned off the pots, and with the aid of small saucers of water extra fine late crops result. Plants of Sir J. Paxton, President, Sir C. Napier, and other favourites that have been either forced or fruited under glass, duly planted out, will not, as a rule, fruit again this season, but next year will produce exceptionally heavy crops. They require deeply worked fairly rich ground, should be watered prior to planting, the hills must be buried well below the ordinary garden level, and have the soil very firmly packed about them. The rows should be not less than 3 feet apart, a distance of 2 feet dividing the plants in the rows. For a few weeks they will require to be kept well moistened, a mulching of short manure further serving to keep the old hills of soil and roots in the requisite moist condition.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early Forced Trees.*—Continuous early forcing to ripen the fruit in May is a great strain upon the energies of the trees, as they have to make the growth during the early spring months, and mature it in early summer. After the fruit is all gathered, ventilate to the fullest extent, if possible removing the roof lights entirely by the early part of July, or earlier if the weather be hot and the trees sufficiently matured. If the roof lights are not moveable, in addition to full ventilation the border should be frequently damped and duly watered, so that no check is given likely to induce the premature ripening of the young wood and leaves. Keep the latter free from red spider by syringing occasionally, and if necessary apply an insecticide, as it is of the greatest importance that the foliage be kept healthful and ripen naturally. Laterals must be stopped, but where there is space to allow of growth being made without overcrowding encourage it, as a steady and continuous growth by promoting root action will prevent the buds and foliage maturing too early. All shoots that have supported fruit, and are no longer required, should be removed to admit light and air freely to the growths, and if there is too much crowding of the shoots for next year's bearing thin them well to make space for the free admission of light and air, and the action of water upon the foliage to cleanse it of red spider.

Houses with Fruit Ripening.—Gentle fire heat is necessary during cold nights and on dull days to admit of a steady progress, and the admission of air, a little constantly, to insure flavour. It is also necessary to assist the later varieties in swelling and finishing. Afford a moderate air moisture for the benefit of the foliage, and do not allow the borders to become dried and cracked, but afford water as required to keep the soil moist, and a mulching of rather strawy material will keep the surface in a condition favourable to the keeping of the roots active there, and that without undue atmospheric moisture. If the weather be very bright some netting spread over the roof lights will be an advantage in preserving the thin or delicate skinned varieties, such as Nohlesse, from being unduly heated by the sun's rays, causing the fruit to ripen at the apex, greatly in advance of those on the lower parts, and the fruit not infrequently decays there through over-ripeness, whilst the lower part is scarcely fit for use. These, indeed all fruits, are better ripened gradually than roasted as is sometimes done under the large and clear panes of glass rightly employed in modern fruit houses. It is easy in a period of very hot weather to apply a double thickness of herring or a single thickness of pilchard net, which will sufficiently break the force of the most powerful sunlight, ensuring the fruit an evenness of ripening.

Young Trees.—These will have been disbudded, and the shoots regulated so that the principals will be 12 to 15 inches apart, and the shoots for next year's fruiting originated from the previous year's shoots disposed about 15 inches asunder along them, stopping them if requisite at 15 inches of growth, and the laterals to one joint as produced. The extensions or main shoots should be trained in their full length, provided they are evenly balanced. If the shoots on one side are stronger than the other depress the strong and elevate the weak, so as to induce an equal distribution of vigour throughout each tree. Any gross shoots may be stopped, as they are a great inducement to gumming. Trees marked by gross wood when young seldom turn out healthy, therefore it is better to cut out excessively strong wood, encouraging the short-jointed and sturdy. Ventilate early in the day, increasing it with the advancing temperature, avoiding a close vitiated atmosphere. It is essential that the growths be trained sufficiently thin to allow of the sun and air having free access, the growths being thoroughly solidified as made, the foliage kept clean and healthy, so that the buds may be duly supplied with nutriment and accumulation made in the adjacent wood of elaborated matter for the due setting of the blossom and the stoning of the fruit in the ensuing season.

STRAWBERRIES IN POTS.—The outdoor fruit is late, therefore the resources of the cultivator will be taxed to make those in pots afford a supply of fruit until those in the open ground come in. Our latest supplies will be obtained from plants in a span-roofed structure used principally for wintering bedding plants, and from those on shelves in

wall cases. The Strawberry that has been most satisfactory with us this season has been Sir Joseph Paxton, which we use along with President for starting after the new year; La Grosse Sucrée, Vicomtesse Hericart de Thury, and Sir Harry or Keens' Seedling being put in at the same time. Noble is useful for forcing, as it sets and swells freely, is free from mildew, the fruit is of an even form and good size, and finishes well. Mr. Radclyffe and James Veitch are grown for their size. Sir Charles Napier is perhaps the most taking in appearance of Strawberries, and Marguerite is large and brilliant. For late use none rivals British Queen, Dr. Hogg, and Cockscumb.

PLANT HOUSES.

Chrysanthemums.—Plants intended for the production of large flowers will be growing and rooting freely in their largest pots. Supply water carefully, and syringe liberally twice daily when the weather is bright and warm. Side growths as they appear should be removed, and the main shoots secured to stakes or other supports as they extend. Aphides are very liable to attack the plants at this stage of their growth, principally in the points. The best remedy is to syringe lightly and then dust the affected parts with tobacco. This will destroy the insects in a short time, and the powder should then be washed out of the shoots by the aid of the syringe. Where loam in a moderately fresh state has been used for potting, grass will grow on rapidly; this can be kept down by constantly stirring the surface. It is bad practice to allow it to grow until it is large enough for pulling up. Plants potted at the same time and intended for bushes may have their shoots pinched back for the last time, or they may be allowed to extend without. The only difference will be taller plants by the last method and a smaller number of shoots, but better blooms can be secured. Length in the stems is of no moment with us, and therefore Elaine and all the early-flowering section will not be pinched again. Later plants will have all the leading points removed, inserted singly in 3-inch pots, and rooted in cold frames. Plants raised from cuttings now will be useful for decoration in 5 and 6-inch pots, with one to three flowers on the top of the stems. Pinch all intended for late flowering, and when they have started into growth place them in their largest pots. Cuttings rooted at the end of April in boxes and pinched are ready for placing in 6-inch pots. These will be pinched once after they are established in this size, and will then become dwarf and useful for furnishing purposes. Large bushes intended for supplying cut flowers need not have the whole of the shoots staked singly, four or five stakes at the most according to the size of the pots will be ample placed round the sides, sloping outwards. These can be supplied as opportunities present themselves; round these matting can be tied, so that the branches cannot be blown out or broken by the wind. As the plants grow another row of matting can be secured to the stakes, and so on until the end of the season, provided the stakes at first are long enough. This is an easier, quicker, and better method than trying to secure the plants to one strong stake; they are liable to be crowded by this method, but not by the other. The stakes and matting, if the plants are well grown, are at the end of the season hidden from view by their stems and foliage.

Hydrangeas.—Plants that have missed flowering of the varieties of *H. hortensis* should have the points taken out and rooted. These if taken near the top root freely in handlights under the shade of Cucumbers or Melons, in fact in any moderately warm close structure. If the cuttings are kept moist they will quickly emit roots from the stem on the surface of the soil. Place the cuttings in 2-inch pots, and confine them to these until they are mature. The object is to prevent their growing, so that when placed in their largest pots they will be furnished with leaves to the base when they flower. This cannot be accomplished if the plants are allowed to attain more than a few inches in length before the autumn. The plants from which the cuttings have been removed should be cut closely back. These if plunged outside without repotting them will make and ripen three or four sturdy short growths, each of which another season will bear heads of bloom.

Tree Carnations.—Carnations intended for autumn flowering will be growing freely in 6-inch pots. They should be plunged in a sunny position, and every care taken that the soil never becomes dry. Insufficient water brings the plants into a woody stunted condition, and instead of making abundance of growth they will be constantly producing flowering shoots. Any of these that may appear should be pinched off at once, and the plants encouraged to make as much growth as possible. The whole stock, except those rooted late, will now be better outside than in frames. Repot as the plants become ready, and be careful not to allow them to become root-bound before the work is done. Failure in the growth of these plants is often due to this cause alone. Watch for red spider, which is liable to attack the plants if once they become checked. The best and quickest method of eradicating it if it becomes established on the plants is to dip or syringe them thoroughly in a solution of water and sulphur, a 3-inch potful in three gallons of water will be ample for the purpose. Plants of *Souvenir de la Malmaison* placed in 6-inch pots early in the season, and with the centre removed as soon as signs of flowering were visible, will now be strong with from four to eight good shoots at the base, and may be shifted into 9-inch pots, and large specimens for next year's flowering will be the result. In potting press the soil moderately firm in well drained pots. Employ good loam, one-seventh of decayed manure, one-third leaf mould and sand. Do not feed these plants with strong stimulants.

Calceolarias.—Sow a little seed on the surface of fine soil in a pan. Do not cover the seed, but water gently with a fine-rose can. A square

of glass should then be placed over the pan and damp moss on the surface. Place the pan in a cool shady frame until the seed germinates.

Rhodanthes.—The later *Rhodanthes* should be sown at once, and flowering plants will then be had in September. Sow the seed in 5-inch pots, lightly cover with fine soil, and stand them in a cold frame until germination has taken place. The soil may be watered and the frame shaded. Keep the seedlings in a cool situation.

THE BEE-KEEPER.

THE MANAGEMENT OF SWARMS.—No. 3.

IN the old days when skeps were almost universally in use, it was comparatively easy to hive swarms, but by the use of frame-hives some little additional difficulty has been occasioned. The swarm may be hived in any convenient receptacle, and although a skep is generally as convenient as anything else, a bucket, box, or something of a like nature may be used with equal success. Most bee-keepers know how to hive a swarm in the first instance, and it will therefore only be necessary to say that care should be taken to hold the skep well under the cluster, and to give one good firm shake rather than several feeble ones. If the queen falls into, or is placed in the skep, the bees will as a consequence also cluster within it, and bearing this in mind our only anxiety is to insure the queen's presence in the skep. The swarm will in a very short time, say twenty minutes, cluster in the skep, which should, immediately after the bees were shaken into it, have been turned right way up on a sheet, and the swarm will then be ready for hiving in its permanent home. When there is rank grass just under the clustering swarm a sheet should be placed beneath to save the bees not falling into the skep, when the twig on which the cluster rests is shaken, from tumbling into the grass and becoming entangled, and consequently being longer in rejoining the queen, and so delaying the final operation. Sometimes swarms cluster in very inconvenient places, and in such instances each bee-keeper must exercise his ingenuity in hiving them, bearing in mind that a feather dipped in carbolic acid, or a strong smoker, will cause a swarm gradually to leave any position which it may have taken up. When once the swarm has joined the queen the second part of the manipulation must be taken in hand, because the bees will very soon begin to work, and as they leave the skep will note their position and return to it. By removing the swarm to a new position these bees are compelled to return to the old stock, and as a result the swarm is weakened.

There are several ways of placing a swarm already hived in a skep into a frame hive, but perhaps the simplest, and in the hands of an unskilled bee-keeper the most certain, method is to fasten a sheet to the floorboard of the frame hive and to place a brick at each corner of the sheet where it touches the ground, thus forming a kind of gentle incline from the earth to the hive entrance. The hive itself may be raised an inch or more above the floorboard, and the bees must then by a sudden jerk be thrown from the skep on to the sheet. They will at once commence to run into the hive, and the swarm will very shortly be clustered within. The hive may then be allowed to fall into its proper position on the floorboard, and the manipulation is ended. If the bees do not begin to run up at once a handful or so may be placed at the entrance, when with a joyful hum they will tell the good news of a home found at last to those still remaining on the sheet, and the whole swarm will at once begin to move, and soon a vast continuous march of the thousands of happy insects will fill the bee-keeper with gladness, and make him certain of the success of the manipulation. There is, however, always a chance if the queen has not been seen that she has been left behind, and the swarm will then leave the hive and return in a body to the old stock; but provided that the queen has been secured, the swarm will not leave the hive unless the bees are compelled by some very untoward circumstance—such as great and unbearable heat—to seek a more comfortable home.

If an extra strong swarm is to be secured, then the hive containing the swarm must be placed in the exact position previously occupied by the old stock, and the latter must be placed in a new position. The swarm will then be increased in numbers at the expense of the old stock. Two things must be remembered in connection with hiving swarms as necessary to success:—

- 1, The presence of the queen is essential.
- 2, Moving the swarm as early as possible to the position it is intended permanently to occupy.

Swarms may be expected to issue at any time during this month if proper attention is not given to crowded stocks, and if through such neglect a swarm does issue, it is better, notwithstanding the desire of the bee-keeper to manage his stocks on a non-swarmling system, to accept the evil rather than to attempt to remedy it by returning the swarm to the present hive. Such attempts are rarely satisfactory, are always risky, and are therefore unprofitable. Attention in the past will, to a great extent, prevent swarming in the present, and will insure, so far as it is possible to do so, a large harvest of honey in the future.—FELIX.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Weevils on Ferns (*W. J. Winchester*).—The weevils sent are the destructive *Otiorhynchus sulcatus*, which seems to be unusually plentiful this year. You will find information respecting it in reply to two correspondents on page 500, last week.

Tacsonia (*W. S.*).—Judging from the specimens sent the variety appears distinct both in flowers and foliage. Are the whole of the flowers of the same character as the two sent? On hearing from you we will refer to the variety again.

Souvenir de Malmaison Carnation (*H. Coster*).—The blooms, 5 inches in diameter, are very good indeed, and half a dozen of such, produced by plants in 6 and 7-inch pots, indicate excellent cultivation. All the best Carnation growers thin the buds for obtaining superior blooms.

Oak and Elm Trees Bleeding (*W. M. D., Bucks*).—We fear you will have some difficulty in preventing the escape of sap from the trunks of your trees. Cement plasters might be tried, paring the bark to reduce the corrugations for the more effectual application of the cement. If any of our readers can suggest a better remedy, or point out a method they have found to answer in such a case, we will readily publish it.

Duchesse d'Angouleme Pear (*Alton*).—You ask if this variety is less hardy when blossoming than others, on the ground that your "two trees of it which flowered profusely cast nine-tenths of the flowers, while *Beurré Hardy*, *Beurré d'Amanlis*, *Maréchal de Cour*, *Doyenné du Comice*, and several others in the same row set too thickly by half." We have had similar experience in more than one season, and have been led to regard the variety in question as having somewhat tenderer blossoms than some others. This, however, may not agree with the experience of other cultivators, who may perhaps have something to say on the subject, and, if so, we shall be glad to hear from them.

Diseased Tomatoes (*An Old Reader*).—Your fruits are apparently attacked by a fungus described under the name of *Sporocybe lycopersici*, which causes the decayed spots and blotches at the crown of the fruit. Some practical growers, however, consider that it is occasioned, or at least facilitated, by imperfect fertilisation, and an examination of the fruits seems to confirm that view. Deformed fruits are

caused in a similar way, as a deficient vitality leads to the attack of disease. Remove and burn all affected fruits, and it is probable, if the disease has not spread much, that the later fruits, fertilised under more favourable circumstances, will come satisfactorily. Do not allow too much moisture in the air.

Pansies (*D.*).—The yellow ground is very rich and the flower of good form, but the band of colour in the top petals not clearly defined. We can understand an earlier flower being larger and better, and even equal to some named varieties. The double flower is rich and good for garden decoration, but the petals are not smooth enough at the edges for exhibition purposes. We have a variety similar, if not identical, obtained from a packet of seed, and others from the same batch superior in form—more circular. We think the yellow ground the more meritorious, and it closely resembles the variety *Evelyn Bruce*. The Pinks apparently belong to the *Dianthus deltoides* group, but such fragments cannot be determined.

Grapes Shrinking (*W. H. G.*).—If there is no mildew on the Vines, and we fail to perceive any on the few berries sent, we conclude they are what gardeners term "scalded." Some Grapes are more tender and liable to injury in the early stages than others. On page 408 last week, it is stated that "Muscats and Lady Downe's completing the stoning process, should have air abundantly, sufficient warmth being kept in the hot-water pipes to maintain a night temperature of 65° to 70°, and 5° to 10° more artificially in the daytime, as if they are kept cold and close they are, if the weather prove bright, liable to scald." To this we may add, the danger is still greater if the ventilators are kept closed too long in the morning, then opened too widely at once for reducing the temperature. We have known a house of Grapes at the same stage as yours to be spoiled by one mistake of that kind on a Sunday morning.

Grubs in Strawberry Bed (*Swanhill*).—The grub sent is the larva of the Rose chafer—a beetle about three-quarters of an inch long, and shining golden green in colour, which deposits eggs in the ground in the summer, where maggots hatch from them and feed for two or three years. It is questionable if anything will destroy them without injuring the plants, and the best thing you can do is to prepare ground distant from the present bed, and if strong well rooted runners are planted now or early in July they will bear next year. By planting them a foot apart, or three triangularly at 2 feet intervals, we have had as many and as fine Strawberries the following year as from old established beds. You might try the effect of soaking the ground with clear lime water, ammoniacal liquor from gas works diluted with five times the quantity of water, or with soapsuds, into which a wineglassful of petroleum is briskly stirred in each gallon, keeping it off the foliage of the plants. Your safe course, however, is to establish a new plantation and destroy the old bed, digging gas lime into the ground thus vacated at the rate of a quarter of a pound to each square yard of surface, and not cropping for two or three months afterwards.

Irises not Flowering (*Cambridge*).—We presume your plants are *German* or *Flag* Irises, of which there are many beautiful varieties. Some of these are less vigorous and floriferous than others, but the great majority grow and flower well in fertile soil, and not heavily shaded or overgrown by trees and shrubs. When left undisturbed for several years large clumps form, these being composed of a number of weak growths that cannot flower, their weakness being the result of overcrowding, coupled with necessarily impoverished soil. Now, or whenever the weather is showery, well rooted divisions of the best offsets should be planted in free and fertile soil, made so by adding manure, if poor, and gritty matter if of a close heavy nature. Autumn or spring is the time usually recommended for planting, and is generally convenient, but if good divisions are planted now, kept fresh by watering as may be required, and spreading manure on the ground over the roots, a season will be gained in your case, as the plants would in all probability be strong enough in the autumn for flowering next year. We planted a number of moderate sized offsets last June, and they are now strong plants with stout stems bearing from three to six handsome flowers in colours as rich as *Cattleyas* and more diversified. There is a magnificent display of *German Irises* at *Chiswick*.

Early Peaches (*J. E. S.*).—You are quite right in regarding *Early Beatrice* as one of the most useful, though, as you say, the fruits are not large, though their size depends very much on the condition of the trees and the weight of the crop. The description of *Alexander*, for which you ask, is as follows; it is larger than *Early Beatrice*, and we think the first that *Mr. Rivers* sends to *Covent Garden*:—"Fruit, about medium size; round, with a well-marked suture, which terminates at the apex in a depression, in which there is a small point. Skin, completely covered with bright red approaching to scarlet where it is exposed to the sun, and this is coloured with broken streaks and patches of dark crimson; on the shaded side it is yellow, slightly stained with crimson. Stalk, inserted in a deep and wide cavity. Flesh, pale yellowish white, without any stain of red even round the stone, to which it adheres firmly; remarkably delicate and very juicy, with a fine briskly vinous flavour. Flowers, large. Leaves, with round glands, which have sometimes a tendency to be kidney-shaped. A very early Peach, which ripens in an unheated orchard house from the 12th to the 20th of July. Its only fault is being a clingstone, for its flesh is so tender it quite melts before it can be separated from the stone. It was introduced from America by *Mr. Rivers*, from whom *Dr. Hogg* received it in 1878."

Destroying Ants (*H. B., Leicester*).—We do not suppose the ants will eat the roots of your Melons, but if they form nests in the bed

they will injure them by displacing the soil. There are various ways of extirpating ants which are often injurious, though where they abound we suspect the presence of insects (aphides). A correspondent not long ago found that by half filling some smooth jars with treacle and water, and sinking these in the soil the ants were tempted in in shoals, and could not extricate themselves. Last year Mr. A. Douglas wrote in the Journal—"I can vouch for the efficacy of the following in the destruction of ants. Take a small quantity of cyanide of potassium, dissolve in a little water, in this solution saturate small flocks of cotton wool, then place them on the ant runs and round the nest. A few minutes' observation will convince anyone that this will only require to be repeated a few times to have the desired effect. Here, some time ago, we were overrun with ants, now we have only the nucleus of one small colony. Cyanide being a strong poison should be handled carefully." Mr. C. Collins caught many with treacle, without, however, materially increasing the number, then he placed hollow bones about their haunts, and finally procured cow's liver from the butcher, cut it into pieces, and laid them about the houses. The raw liver appeared to entice them, for they swarmed on to it, and by going round every hour or so with a can of hot water, and dipping the liver into the water when covered with ants he succeeded in exterminating them. "Delta" had a very fine Maréchal Niel Rose in a Fig house, and during last spring and summer a strong colony of ants made their abode at the roots. He tried every means he could think of to get rid of them, but failed, and at last he steeped some cotton wool in coarse petroleum, and laid it round the base of the plant over their abode. In two days they had all decamped, he knew not whither. Another correspondent had an attack of ants to deal with where he could not with safety apply boiling water. He discovered them eating the pistils of early Peaches, apparently not touching the stamens—in fact they went right down into the flowers after the embryo fruit as well. He laid some pieces of loaf sugar about, and lodged some up in the tree, and in a few hours he had the pleasure of seeing them leave the Peaches for the sugar, and were, of course, at once destroyed. He then placed a small quantity of moist sugar in a saucer at the foot of the tree, and every evening for a fortnight went once, and sometimes twice, and emptied them, sugar and all, into some hot water, baiting the saucer each time with fresh sugar. Result: saved the Peaches and exterminated the ants. By adopting one or other of the methods indicated you ought to succeed in either catching or banishing the troublesome ants.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (R. A.)—The Peach you send is the Alexander, of which a description is published by request of another correspondent.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (G. H.)—*Cercis siliquastrum*, the Judas Tree. (W. H. G.)—Specimen insufficient, perhaps *Sempervivum calcareum*. (W. N. C.)—*Tragopogon pratensis*. (G. H.)—It is a good variety of *Odontoglossum vexillarium*. (B. R.)—1, *Polemonium Richardsoni*. 2, *Thalictrum minus*. 3, *Arenaria grandiflora*. 4, *Aquilegia chrysantha*.

COVENT GARDEN MARKET.—JUNE 20TH.

Market quiet with good supplies. Prices generally easier.

FRUIT.

RATES, TITHES, AND TAXES.

THAT the land is oppressed by a burden of taxation which it is unable to bear is an acknowledged fact. Relieve it of the burden, and both landlord and tenant will cease to feel the strain of agricultural depression in no inconsiderable degree. But how to do so is a question beset with difficulties, to the consideration of which attention is earnestly invited. If relief is possible by all means let us strive for it to the utmost, and at any rate get such remission of taxation as we can. Farms that are tithe free, and have the land tax redeemed, are few and far between; but even such favoured spots are not free from parochial rates and income tax, and upon most farms lies the incubus of rates, tithes, and taxes.

By way of example we may take a small heavy land farm of 160 acres which we have in hand. Last year the claims upon this farm were:—

	£	s.	d.
Poor rate	8	18	0
Highway rate	8	0	11
School rate	1	10	2
Income and land tax	9	13	10
Tithe rent charge	40	18	8
Total	£69	1	7

Or a fraction over 8s. 7½d. per acre. Now this farm came upon our hands three years ago from a bankrupt tenant "farmed out" in the fullest sense of the term, and notwithstanding our strenuous efforts it has not yet afforded a margin of profit per acre at all approximate to the charges made upon it. We are bound to admit that we have obtained a remission of income tax from Somerset House, at first only upon Schedule B, but now upon Schedule A also. It is important that this should be known generally, and we may usefully quote from Chapman's "Income Tax" that "The occupier of land, if at the same time owner, can claim relief if his profits fall short of his assessment. It is no longer necessary that he should gain his living principally by farming.

"The profits falling below £400 entitles the claimant to abatement as well as to relief on diminished income, and falling below

£150 entitles him to repayment of all tax paid, except what he has a right to deduct from payments he makes to others."

"In regard to lands, owners whose farms have been thrown on their hands, and from which no profits have been made, can claim back income tax, subject to the following conditions:—That farms usually held in hand be excluded, that the owner prove that he has unsuccessfully attempted to get a tenant on reasonable terms, and that the claim be made within twelve months after the expiration of the year of assessment."

It may, we hope, further assist our readers if we append a copy of the official appeal form which we use, and which surveyors of taxes are bound to receive.

INCOME TAX APPEAL UNDER SCHEDULE B.
PROPOSED STATEMENT.

Payments.	Receipts.
Live stock bought.	Live stock and wool sold.
Corn and seeds bought for seed.	Corn and seeds sold.
Feeding stuffs, oilcake, and manure.	Dairy produce and poultry sold.
Rent and tithes.	Other produce, including hay, straw, or roots when sold.
Rates, taxes, and insurance of farm stock.	Labour, stock, implements, &c., hired out.
Labour on the farm.	Value of farm produce used by household.
Tradesmen's accounts for goods supplied, or work done upon the farm.	
Sundries.	

FORM OF DECLARATION TO BE APPENDED.

I solemnly and sincerely declare that the amount of live and dead stock and produce upon my holding on* day of 18 did not differ materially for the purposes of this account from the average amount on the corresponding day of previous years († except in the particulars stated below, which are true to the best of my knowledge and belief).

PARTICULARS OF DIFFERENCE REFERRED TO ABOVE.

Description of stock and produce.	Increase.	Decrease.

Signature.

Date.

We have had copies of this useful form prepared for tenants of farms upon the estates under our management, which have proved most serviceable, for tenant farmers frequently find the preparation of a simple statement of fact a difficult matter. A close valuation for the declaration is unnecessary, an approximate one being sufficient for the purpose. We must, however, insist upon correct accounts being kept of every item of expenditure under the two headings of payments and receipts.

Farmers have been told recently that they have the option of being assessed under Schedule D instead of Schedule B, and they have been advised to avail themselves of this as an advantage. We consider such advice erroneous and misleading, simply because the assessment under Schedule D is unlimited, while assessments under Schedule B have advantages worthy of the close attention of farmers, and we cannot do better than advise our readers to get a copy of "Income Tax," published by Effingham, Wilson & Co., price 1s. in which useful little manual they will find explicit instructions for assessment, appeal, and return of tax.

It will thus be seen that relief is afforded from what is technically termed imperial taxation, but relief from parochial rates is a far more difficult matter; in point of fact such relief for individual cases may be said to be practically non-existent. The Assessment Committee generally consists of a certain number of guardians of each union, and although most of these gentlemen are farmers or landowners, they test the merits of any individual case by the value of land surrounding it, and not by its own value, so that if a farm which has been in bad hands falls upon the landlord in such low condition as to involve a considerable outlay upon which there is

* Name the day to which the accounts are made up.

† Strike out the words in the brackets if the amount is the average one.

little if any profit for two or three years, he generally—almost invariably—has to pay rates upon an imaginary income. The reason is quite apparent, for if upon appeal he obtained relief, the rates would fall more heavily upon his neighbours, some of whom are probably upon the board of guardians.

Of the tithe rent charge, we can only say how urgent we consider the want of a general scheme of tithe redemption to be. Under its present conditions a feeling of antagonism between tithe owners and tithe payers is unavoidable, and it would be for the relief of all concerned if the land could be relieved from a burden which now not unfrequently represents an amount beyond what is possible to realise from our crops under present low prices.

WORK ON THE HOME FARM.

Frequent showers have imparted to the month very much of the aspect of a "dripping June," and notwithstanding the fact that we still have arrears of rainfall, yet the appearance of the crops is most satisfactory, and we may now indulge reasonable hopes of a year of plenty. The improvement in winter Beans during the past fortnight is certainly remarkable. At the end of May the plant was remarkably dwarf and just bursting into flower, so that a short crop was predicted; subsequently, however, the plant has "run" so freely that the crop has now an aspect of strength and fulness all the more pleasing because we have been able to render the soil thoroughly clean between the rows. Peas, too, are growing freely, the dark hue of the foliage showing the beneficial influence of manure. Autumn-sown Peas are also a good crop, and we were amused last market by two of our tenant farmers at our market stand. One of them had been telling us that his winter Peas were "off the flower," and were just showing pods, and he should have them picked when ready for sale as Green Peas. So early did he consider them that he gave vent to his anticipations of obtaining a high price for them. The other farmer, after listening quietly to all this, pulled out a handful of pods from his pocket with large peas in them ready for use. "Sangster's No. 1, sown last November," said he with a smile, and other man saw clearly that he was forestalled.

A little more Thistle hocking has been done among late Barley, and some of the worst pieces of Charlock have been pulled by hand. After all we can eradicate Couch Grass, but Charlock can never be said to be finished. It is the pest of pests, and is our greatest robber of fertility from the soil; it seeds so freely that if only a few plants are left among a crop it quickly spreads far and wide again. Talavera Wheat is now richly in ear, so, too, is Rye, but the straw of second crop Rye will be short in length.

Root crops that have been singled are growing so freely that they will be well established before the haymaking becomes general. We hear complaints of the ravages of Turnip fly upon light land crops, but our own Swedes have been singularly free from them. Mangolds are a good plant generally, and are free from rampant weeds. Horse and hand hoes will be kept briskly going among them as long as possible.

OUR LETTER BOX.

Testing Milk (G. B.).—You may find a lactometer useful, but unless used with care it is apt to prove misleading. There is so much difference in the quality of milk that no positive quantity can be given, but it is certain that it requires from two to three gallons of milk for a pound of butter. This subject will be dealt with more fully in an early issue. We cannot undertake what you suggest at the close of your letter.

REMARKS.

10th.—Fine and bright.
 11th.—Bright and fresh.
 12th.—Fine and bright till about 5 P.M., then cloudy and showery.
 13th.—Bright and fresh.
 14th.—Wet early, cloudy morning; thunder and lightning with heavy rain from 1.45 P.M. to 2.5 P.M., and from 4 P.M. to 4.15 P.M.; fair evening.
 15th.—Showery morning; wet afternoon and evening.
 16th.—Fine and bright; solar halo at 6 P.M.
 A week of nearly average pressure and temperature. The night minima remarkable for their uniformity, the entire difference being only 4.3°.—G. J. SYMONS.

ARE not many flowers cut too late, not in the morning alone, though that is a point not to be lost sight of, but at too late a period of their own short career? Since flowers are now so much in demand for the adornment of homes, not only of the affluent, but also, and happily, of the more or less humble, in whose gardens they may not be over-plentiful, it is of importance that they be kept fresh and bright as long as possible after they are arranged in dwellings. There are no rooms so richly furnished that are not made more attractive and home-like with flowers tastefully disposed, and none so lowly as to suggest that flowers in them are out of place; elaborate paintings might be, and certain works of art and vestments, but not flowers. Like rays of sunshine they clash with nothing; and neither the rich begrudge the poor, nor the poor begrudge the rich their possession. They cheer and gladden wherever they are, and the wish is natural with the great majority of persons to preserve the charms of flowers in dwellings as long as they can.

When that is the predominant object it is well to remember that each flower under the most favourable conditions has only a certain time to live, and that time is short. When allowed to develop fully, or nearly so, in the garden, half of its period of beauty is spent, and its term of freshness when cut is in that degree limited; or, in other words, the longer its garden life is, of necessity the shorter its room life must be. To have flowers fresh then, over the longest possible period after they are gathered, it is essential that they be cut when young—in the period of childhood, so to say, with nearly their whole life before them, for if left to attain maturity on the plants, their most sparkling, sprightly, juvenile career is over, and nothing remains but steady decline, a term of fading to the end. If pleasure is desirable, and undoubtedly it is, in watching flowers fade, because in instances innumerable they are only received when at their best, or past it, how much greater should the enjoyment be in observing them grow into beauty—seeing their petals unfold and their colours come without visible movement, yet not the less certainly, like light at the dawn of day? All flowers are, however, not so slow in developing; the Evening Primrose, for instance, which may be seen to open rapidly when the right moment comes. It passes from the bud stage to the full blossom, 2 or 3 inches in diameter, in about as many minutes. The interesting process of expansion can be heard, as well as seen, when the divided calyx flies back with a click. It is interesting to watch the birth of flowers, and if we would have them spend their whole life with us in our homes we must cut them on the eve of expansion.

Some kinds of flowers when cut in the advanced bud stage open as well in water as they do on plants, and last as long if not longer. They may not become quite so large as when supported with nutriment from the roots, but that is not a matter of the first importance. If form, colour, and freshness are combined, flowers answer all the purpose for which they are required in vases, and the prolonged term of beauty is ample compensation for a trifling deficiency in size. Everybody knows, or ought to know, that if spikes of the *Gladiolus* are cut and placed in water when the lower buds show colour all those above them will expand nearly or quite as certainly as if on the plants, only, as intimated, the flowers may be smaller. That circumstance is of great importance in packing, for not only can far more spikes be arranged in the bud than in the

flowering state in a box, but in the former case there is no crushing of the petals in transit. It is the same with many other flowers, notably those with soft fleshy stems, but those with hard thin stalks are not amenable to the same treatment, while some again are naturally fugacious. The flowers of most kinds of bulbs cut young, when the first buds are expanding, last long in water, but Hyacinths and Narcissi are more durable, so to say, than *Ixias* and *Freesias* with their wire-like stems. Late Tulips are splendid flowers for large vases, whether in self colours or broken into flames and flakes; but if we wait until the blooms fully expand it is not easy to pack them without injury, while if they arrive at their destination uncrushed their beauty is of short duration, for the first and best half of their life has been spent in the garden; but cut them immediately the buds split and the first streak of colour is seen, packing is obviously easy, and if they are kept close in transit, so that moisture cannot escape from them, they expand in water with certainty and freedom, and continue attractive for a fortnight or three weeks. This year some buds were cut and placed in water in a room and the blooms expanded, keeping fresh even longer than those did that were left on the plants in the garden.

German Irises are magnificent flowers for vases, and are represented in a richness and diversity of colour scarcely excelled by any other flowers, while the gold and silver pencillings on lustrous purple and bronze red grounds are chastely conspicuous. But the flowers are large, and if we wait till all, or nearly all, expand on a stem before cutting, not only two or three dozen require a large box to hold them, and when removed from it after a day or night's journey, or both, they are not quite the same as when cut from the plants, and can never be made so; they may be freshened and have a gay appearance for a few hours, but their beauty at the longest is of short duration. Very different is the result when the spikes are cut when the first flowers are showing colour. In this form packing is of the easiest, the greatest number can be arranged in a given space, and placed in water without delay when unpacked, the buds then quite closed, open in succession, and no one will then say that "Irises pack badly and are soon over." Some vases filled with them a fortnight ago are attractive, yet simply because the spikes were cut young and the stalks not dried in transit from the garden to the receptacles they now adorn. Single blooms of *Liliums*, such as *L. auratum* or others, are very handsome in shallow dishes, which in various forms are so largely used as to have become "quite fashionable, you know." But how are the expanded blooms to be packed so as to arrive in the best condition after a long journey? It is a thankless task sending fully developed Lily blooms a long distance by road or rail, for the risk of injury is great, and at the best their beauty transient; but cut the buds when they open slightly at the tips, and they may be packed like cigars, each in a Lettuce or Spinach leaf, or embedded in fresh, but not wet, lawn mowings, and if the box is made practically air-tight it may be sent by post in the certainty that the flowers will expand when placed in water after twenty-four or even forty-eight hours' incarceration.

Roses sent from country gardens to city drawing rooms should always be cut young—just as the petals are unfolding; and when they travel in the daytime, as is most likely the case, they should be cut early while the dew is still on them, but not dripping wet, and if arranged so that they cannot be displaced in a close box in which the moisture is retained they will be as fresh when taken out several hours afterwards as when severed from the plants, and far fresher than thousands are before being sent off through having been cut too late in the day and too much expanded. Sent in the advanced bud stage and damp with dew they require no packing to keep them fresh, but something may be needed to keep them firm, and soft green leaves cannot be surpassed for this purpose. Paper, if not damp, should be kept from them, and dry cotton wool is an abomination. When buds open in the daytime, and

are not desired to expand on the plants, they should be cut and placed in water in a cool dark place, and they will be right for sending off the next morning. Exhibitors of Roses are quite aware of the advantage of cutting young blooms bespangled with dew, and of the necessity of placing them promptly in water instead of letting them "lie about" to become partially withered—a thoughtless habit on the part of some when collecting flowers for sending away, and fatal to their fresh arrival and long continuance.

Chrysanthemums for decorative purposes when cut in the expanding bud state and the stalks placed in water develop in rooms into most attractive flowers, and with a little care will there do duty for a month. The leaves should be removed from the stalks and flowers except above water, this changed occasionally before it becomes turbid, and a small portion cut off the stalks with a sharp knife for leaving open the sap vessels. If blunt scissors are used the sap vessels are bruised and rendered in a measure inoperative. Wet sand, obscured by foliage, is as good as water, if not better, for keeping flowers fresh, and a few can often be disposed to better advantage than in water alone, the sand holding them in the desired positions.

Some persons add salt, ammonia, and other ingredients to water for prolonging the beauty of flowers. I have not tried any of those supposed aids to floral longevity, and shall be glad to hear if they have been fully and fairly tested, and with what results. Hot water will freshen fading flowers and withering foliage much quicker than cold will, as anyone may prove by letting a number of Mignonette sprays get quite flaccid, then place some of them in cold and others in hot water. These latter will revive long before the others, some of which if very far gone may be beyond recovery in cold water, whereas the hot would have restored them. But how hot should the water be? If the hand can be borne in it for a quarter of a minute it will not injure the stems. This is an old practice, but none the worse on that account, and is worth a trial under the circumstances indicated.

Close-fitting tin boxes answer admirably for sending flowers in, and unless these are naturally moist it is well to give the boxes a rinse out, and the confined moisture will keep the contents fresh. Wooden boxes similarly treated also answer well if made as nearly air-tight as possible. That is the main point, for the simple and sufficient reason that without evaporation and the escape of moisture out of the boxes there can be no flagging in them if flowers and foliage be packed in a perfectly fresh state. Cut flowers young, cut them early, pack them quickly, and secure them closely, and the fresher they will reach those for whom they are intended, and the longer they will remain attractive when arranged in rooms.—*EXPERIENTIA DOCET.*

ABOUT FRUIT—TREES IN POTS.

Do you, or any of your readers, know a Pear called Blanche Claude? We have one tree here in a 10-inch pot from which we gathered a dish of fine fruits on June 9th. It was brought into heat along with others on February 23rd, and has therefore taken about fifteen weeks to ripen. As an early Pear it is a decided acquisition. The fruit is of good size, with a handsome greenish-yellow skin.

What a striking contrast there is at present between our inside and outside fruit. If anyone has doubts of the advantages of providing good orchard house accommodation in establishments where a supply of first class fruit has to be maintained, especially in localities so cold and backward as ours, a visit here at the present time would soon alter their views. Outside at the present time (June 22nd) Apples are just set, Pears not much further advanced; even the earliest varieties are not yet the size of marbles. We have had very cold cutting winds for some days past, the temperature seldom rising above 50° in shade, with a corresponding fall at nights. Inside we have dozens of Pears and Apples in pots laden with fruit in all stages. Many of the earliest varieties of both Apples and Pears are changing colour. Pears on trees in pots are very fine with us this season. I counted over three dozen fine fruits of Beurré Diel on a tree in a 12-inch pot. Trees of Pitmaston Duchess in a 10-inch pot carry seven fruits, each measuring 9 inches in circum-

ference. Some fruits of Beurré Diel are 10 inches in circumference, and both these varieties are only half swelled. Souvenir du Congrès, Marie Louise, Marie Louise d'Ueele, Beurré Hardy, Louise-Bonne of Jersey, and many others are also fine. It is remarkable what a weight of fine fruits can be taken from trees in comparatively small pots when placed in a position where they are exposed to light, never allowed to suffer for lack of water, with judicious feeding. The only stimulant we use here is Thomson's Vine and plant manure, the trees being dressed with it several times during the growing season.

AMERICAN BLIGHT.

If anyone is troubled with this destructive pest I would advise them to make up their minds to give their trees a dressing with tar and clay as soon as the foliage is off. Our Apple trees in pots were very badly infested with it last year, both root and branch. In winter we dressed each tree with the tar and clay mixture, and out of about 200 so treated on only one has the slightest trace of the pest been discovered, which can be kept in check till the coming winter, when we trust another application will finally eradicate this dangerous insect. The mixture was composed of five parts clay to one of coal tar. This strength will not injure the trees, as ours are clean and healthy and bearing fine crops. The surface soil is scraped off and a good dressing of soot and fresh lime given to kill any insects which may be on the roots. The tar mixture is applied with a hard brush, and well rubbed into every crevice, over buds, and every piece of wood. Half the remedy in this, as in most similar cases, depends on the thoroughness of the operation, and unless those entrusted with the task are determined to spare no pains in seeing that every bit of wood is well rubbed they had better be at something else. Have any of your readers ever seen this insect on any other tree but the Apple? I have not; though it has been scattered with the hose over Pears and many greenhouse plants, it never seems to take to any but the Apple.

I intend photographing some of the trees here shortly, also some bunches of Grapes. If they turn out well I will send you a few samples.—D. BUCHANAN, *Lambton Gardens.*

MY AURICULAS IN 1887.

(Continued from page 506.)

It will thus be seen that very few of the earlier raised sorts—sorts that were in vogue thirty years ago—are now considered desirable or worthy of a place in a select collection. I now come to varieties raised since that period. Mr. Jeans, as we have seen, wrote of George Lightbody as not then out, but it came out shortly afterwards, and has remained to this day, notwithstanding all that has been done, the best Auricula in growth, and yet it is not perfect. One would like, as I said when I first saw it, a little more body colour, but take it all in all I have seen nothing that can yet touch it. Wherever it is exhibited in good form it is pretty well sure to take the first position in the classes for single blooms, and not unfrequently that for the best bloom in the show. I have not found it so vigorous as many other sorts, but neither is it a delicate grower. This variety was then, as we have seen from Mr. Jeans' note, on the border land between the old sorts which had been grown for fifty to a hundred years, and the newer varieties which we were told to expect with so much interest, but which now we are assured we must reject, and yet I think there are a few which one may hope will escape for a while at least this sweeping ensue.

In the class of green edges there have been but a few flowers which can claim a prominent place. Some have been introduced, but they have not held their ground for one cause or another. For many years we were accustomed to see General Neill pretty often. It was a great breeder, and growers' stocks of it soon multiplied, but I do not think that it will be often found now in good collections. There was a common look about it, which was very unusual in the Auricula. Lord Palmerston (Campbell) was another fairish flower, but small, and with an indifferent tube, very prolific in producing offsets, but not holding a place now of much estimation. The Rev. George Jeans is another of Mr. Traill's flowers, only second rate. St. Augustine (Cunningham) has a bright paste and good body colour, but is goggle-eyed, deserving the cutting remark of a worthy friend of mine, who looking on it one day at the National Show, quietly said "Who canonised that saint?" Talisman (Simonite) is a flower with a good edge, tube, and body colour, but inclined to be a little coarse, yet it is a flower we cannot discard; and then there is that very favourite and still scarce flower Prince of Greens (Traill), in some points unexcelled, a beautifully bright green edge, very dark and solid body colour, but with, unfortunately, a dull light coloured tube; had it the tube of Richard Heady it would be a marvel of beauty. As it is it is very fine, and no grower would desire to be without

it, but this washy tube gives it a dead-alive sort of appearance; occasionally, too, the truss is sprawly, like a spider's legs, but not always so, and when at its best, fresh and clear in colour, it is pretty sure to beat any green edge in cultivation. I had a fine bloom of it this year. It is miserably slow in giving offsets, and this I have no doubt is the cause why it still keeps up its price, and why it is so difficult to obtain. I have had my plants of it for four years, and have never yet had an offset.

Grey edges are more plentiful than any of the other classes, and there are many really good varieties besides George Lightbody. There is first of all Charles Edward Bunn, his twin brother, for I believe they were both raised from the same pod of seed, and then without artificial crossing. This variety I have had this year nearly as fine as George Lightbody, and at times it does come so. It is a very vigorous grower and prolific, so that one rarely pots a plant of it without getting one or more offsets. As far as my judgment goes it is a variety well worthy of a place even in a select collection. Then there is Alexander Meiklejohn (Kaye) a very choice flower, with perhaps at times an uncertain edge. It is not always to be had good, and very few good blooms of it were seen this year. It has perhaps the fault that many seedlings have in their growth—inconstancy. Another variety I should not discard would be Dr. Horner (Reid). It is like most of Reid's flowers, refined in character without any coarseness. Another good though inconstant flower is John Waterston (Cunningham), with an undecided edge, sometimes white and sometimes grey. Colonel Champneys (Turner) is a flower which has not one good property. Taking it critically (except its vigorous growth), the tube is washy, the flower cupped, body colour very brilliant, but far too heavy, and with a "chiny" edge, neither white nor grey, yet the brilliancy of the body colour is sure to attract the uncritical eye, and "What a beauty!" is the exclamation with which it is generally favoured, and yet one cannot quite banish it, and a plant or two must be kept. Frank Simonite (Simonite) is a flower somewhat similar, perhaps a little better, but still with the "watery" eye. Ben says he thinks it is hardly possible to get the brilliant blue-black of this variety with a yellow tube. Robert Traill (Lightbody) I would not discard, although it seems to me to be difficult to get a good-sized truss of it. Then there is Richard Heady (Lightbody), which we may be sure the raiser thought highly of or he would not have dedicated it to his dearest friend. It is a beautiful and refined flower, but unfortunately very late, rarely coming in time for the shows. I was unfortunate with my plants, as I have said, this year, and on examining them I find a great deal of rottenness at the root, and I am afraid my fine plants are worn out, and that I must depend on offsets.

Of white edges we have had some really fine additions. Smiling Beauty (Heaps) is a very fine refined flower, and in some seasons is super-excellent. Then there is Traill's Beauty, one of the freest in growth and most prolific of all Auriculas, and one's frame soon gets full of it; but the greatest addition to the white edges, leaving out of sight the new ones, has been Acme (Reid's) although it, too, has its defects. It is for ever throwing offsets and weakening the plant, and it does not throw its truss as much above the foliage as is desired, but it has a most lovely edge, solid paste, and bright yellow eye, and is, I think, the best white edge in cultivation. It did not bloom well with me this year, and I think it was but poorly exhibited.

Passing on to selfs. Surely I am not, because we have three in Heroine, Sapphire, and Mrs. Douglas, to get rid of all our cherished selfs. Since the time I have alluded to we have had Campbell's Pizarro, which we used to think highly of; then there is brilliantly coloured Lord of Lorne, and still more brilliant Duke of Argyle, which both bloomed well with me, although the latter is delicate in constitution, and the brightness of the former of the two thus upon the stage makes it a most attractive flower. Then Charles J. Perry (Turner) is a brilliantly coloured blue flower, reminding one of a florist of bygone days. I had it very fine this year. Topsy, too, very dark and good at times, taking a high position, and very vigorous in growth. It may be exceeded by some of the new ones, but where are we to get these? and until that happy time comes we must fain cherish such flowers as Topsy and Charles J. Perry.

In recording thus my own experience during the last season, I have at the same time endeavoured to show that we are not to be quite so wholesale in our condemnation as some would have us to be, and that we unfortunates who are not in the "Auricula ring" (I do not use the word in any objectionable sense) must be contented with flowers which, after all, may prove equal to any of the new comers. Yet who can tell? The day may come when the Auriculas of the present day will be as little thought of as those of a century ago. I have before me a MS. list yellow with age, and quaint in its writing. To whom it belonged I know not, but it is dated March 15th, 1744, and contains about fifty varieties, some

with very old names, Old King of Prussia, Charles III. of Spain, Quadruple Alliance, &c., and yet not one of these is now known. Some were marked with X as being extra fine; but, alas! they are gone. Who were the Herberts, Drovers, Uptons, Masons, Holts, Savages, &c., whose names figure in the list as raisers, no one can tell; and so, my dear fellow workers, it will be by-and-by with ourselves; the lists of to-day will be forgotten, and people will ask, Who were the Turners, Headlys, Traills, Lightbodies, Horners, &c., whose names are attached to this list? Ask some of our younger Auricula growers now, and they know nothing of Reid, the raiser of Market Rasen; of old George Lightbody, the retired paymaster of the Royal Navy; of Mr. Jeans, the genial and brilliant parson of Alford. So let us be taught humility! And while I thoroughly appreciate the labours of all engaged in this good work, I endeavour to console myself with the reflection that the flowers I have give me a vast deal of pleasure during many years.—D., Deal.

A CHAPTER ON TOMATOES IN THE OPEN AIR.

THE other day an excellent judge of the flavour of Tomatoes told me he preferred fruit from the open air to that from under glass, because the former were decidedly superior in flavour. I could not argue on the point, as I am of the same opinion, and I believe all who have had the opportunity of testing the matter fairly are in favour of the open air fruit. Tomatoes are now so well known and esteemed that it has been generally found they are more than mere ornaments, and besides size and appearance, flavour has become an important character; indeed it is a leading feature, and if the fruits are best flavoured in the open air, this ought to be an additional inducement for their culture in this way to be taken up more and more. I am not surprised at anyone asserting open air Tomatoes are the best in flavour, as the Tomato is an air-loving plant. It never does well in a stifling atmosphere, and I never knew the flavour of any fruit to be excellent in an atmosphere that did not agree with the healthy development of the foliage. I have heard some say, "We do not need to trouble with Tomatoes in the open, we have plenty under glass." I do not agree with this. Tomatoes are no "trouble" in the open, and as to having plenty under glass, that is doubtful, as I seldom knew anyone have too many Tomatoes, particularly in the open air, where they swell so well in August, September, and October. I know many instances where a great deal of attention is given to growing Tomatoes under glass, but where no attempt whatever is made to cultivate them in the open air, and open air culture is still far from general. No one can argue against it, but they have an impression that Tomatoes in the open air are uncertain, so that they are not worth trying; but this is utterly without foundation, and all who grow Tomatoes in the open in anything like a practical way will be highly gratified with the result. Do not treat them, however, as if they must fail, because when plants are grown under this impression many little attentions are withheld from them that would be given to others.

Another mistake with open air Tomatoes is to place out inferior plants as being "good enough to turn out." The fact is they cannot be too good, and the secret of securing early ripe fruit and plenty of it is to deal only with good plants. We have just placed out a number that have been carefully prepared. The seed was sown in March, the plants were potted as necessary, they were not overcrowded at any time, neither were they drawn up to unnatural dimensions, but by keeping them in the full light and plenty of air they retained a dwarf robust habit. They bloomed when about 1 foot high, and many little fruits were formed on them before they were placed out. By careful planting these have not received the slightest check, and they will go on swelling and ripen in July. By that time other fruits will have formed, and a constant supply will be produced all the autumn.

A plan we have followed with much success is to have the plants established in 8-inch or 10-inch pots and plunge these over the rim in the soil in the position the plants are to occupy. It is impossible for them to be checked in this way. The roots being confined causes the plants to form very short-jointed fruitful wood, and by the time a heavy crop has been formed the roots have run over the rim of the pots and through the bottom into the soil in which they are plunged, and from this they gain a stimulant which agrees with them admirably. We fruit Tomatoes in many corners in the houses in the spring months, but these often outgrow their place at this season. Some of them are thrown away, but the best are taken out, put into frames to harden off a little, and then the pots or boxes in which they are growing are plunged, fresh and profuse supplies of good fruit being soon obtained.

These three systems of growing them all merit commendation. By following them excellent crops are insured, and the result is greatly superior to any derived from backward plants. The other day I was

in a market garden. Some thousands of Tomato plants were growing in frames. They were about 1 foot in height and grown 3 inches apart. They were to be planted out in a day or two, but I question very much if they will ever prove a success, as being grown so close they could not be lifted with any soil to the roots. It would take them a long time to become established or make any progress, and I would undertake to secure more fruit during the season from a dozen well prepared plants than could be had from fifty such as those. Indeed our plants would be producing ripe fruit before these had formed any. I pay more attention to growing a few plants well than hosts badly. As a rule open air Tomatoes are planted in too much manure. Cultivators think that by using plenty of manure they are sure to secure plenty of huge fruit, but unfortunately this is seldom the result, as the plants make an enormous quantity of shoots and form very few fruit. Tomato plants are always most fruitful when of medium strength, and as their disposition is to make wood rather freely they will make it of medium strength in what some would regard as a poor soil. I would rather grow them in a very poor soil than in a very rich one, as when in the former they fruit most freely, and it is always an easy matter to give liquid manure and rich top-dressings to assist the crop.

In cold and backward districts they will not ripen well unless planted at the bottom of a wall, fence or house, and trained up to face the sun; but in many other parts of the country they may be grown as standards or bushes. In the latter case they should be planted from 2 feet to 3 feet apart, and be staked and tied up from the first. It will never answer to allow them to scramble about on the ground for a time, and the growths should be trained from the beginning. The one-stem system is the only one likely to succeed with standard plants. Every side growth should be pinched out before it has attained a length of 2 inches. There is no danger of the main stem running up too far. It is only when it is surrounded with superfluous side growths that it gets out of proportion and fails to produce clusters of flowers and fruit at every joint. Plants trained against walls may be allowed to form two or three main stems, but not more, and the side shoots must be kept closely pinched off each. Do not on any account neglect this from the first; it is a mistake which no after attention will remedy.—A KITCHEN GARDENER.

DIGGING AND STIRRING THE SOIL.

(Continued from page 482.)

TURNING over soil with a spade is different from stirring or digging to the same depth with a fork. In digging with the spade the soil is turned upside down in rectangular masses, and however rough it may be left it is much more solid, therefore less exposed to the action of frost, consequently less pulverised and aerated than soil dug with a fork, which breaks it up far more than a spade does. The soil derives most of its fertility from the atmosphere, consequently the rain and air entering solve stubborn material and evolve by the decomposition of substances therein the elements that support plants. The disintegration and divisibility of the soil is best effected by the fork. It leaves the soil lighter, and is not so soon resolved again into the solid form. Better still, the fork effects a more even tilth, and the crops are more regular through the more even permeation of the soil by the roots, the food of which they are in quest being more generally diffused and assimilated therein. The work, too, is more readily effected by a fork than spade. Where the ground is foul with couch or Bindweed, or other description of weed requiring extraction, it is more surely effected with a fork than a spade, the latter being a direct means of multiplication of the soil. So convinced must all be on trial of the great advantages of a four-tined steel fork over a spade for general digging, that the lighter and better cultural implement has or will supersede the more laborious and less efficacious spade.

Respecting the time of digging, it is unquestionably best done when the ground is dry. It is difficult to turn up some soils after spring or summer crops for the rotatory ones, in some instances almost impracticable, with a spade, from the ground being, as the workmen say, "dry and hard." This, however, apart from the increased labour entailed, is the very best time to break up the soil. No matter how hard and dry it will yield to the fork, it may be in narrow breadths, and need a determined will, but it gets such a breaking up as to let in more sun, more air, and more nutriment is abstracted from the atmosphere in a day of summer than in a month of winter. If anyone doubts this let a trial be made. So enriching is digging the ground after spring or summer crops in preparing for autumn or winter ones, that some cultivators prefer to plant in the solid or firm unbroken soil lest the crops should grow too luxuriantly, and so become tender, unable to withstand the rigour of winter frosts. This is explained on the lines that the plants

forming the crop root less slowly in the firm than in loose soil, and the growth is more sturdy and better solidified. Non-stirring may in measure preserve the fertility of the soil for future crops, but it is doubtful if not more is lost through the surface being in so firm and close condition as to derive little of the enriching influences of the atmosphere. Firm soils are, of course, well-known cultural aids in the prevention of gross growths, alike from the mechanical condition of the soil and the resistance offered to the roots there is less food available, and what is gained one way is lost the other, so that to make up the deficiency mulchings are given, which supply at given periods an increased supply of nourishment and promptly by its exposure to the full influence of the acting atmospheric air and moisture, which has been so studiously prevented acting by the firm close condition of the soil. The hard surface so much clamoured about in respect of fruit culture is the most distressing to growth and disastrous to crops during drought. The soil literally bakes and cracks under powerful sun, being quite as free in evaporation without the advantages of absorption of night dews, as where the surface soil is loose and open to a depth not interfering with the roots. Mulching, of course, prevents evaporation in a sense corresponding to a loose surface of ameliorated soil with the advantage of affording enrichment, attracting the roots to the surface, and the value of mulchings equally with the soil's surface depend on their lumpiness or porosity. Lumpy manure is better in every way for mulching through its freely admitting air and moisture than a close heavy mass which excludes air and rain, becoming soapy and impervious. Therefore, whether the object is to encourage growth or to sustain it, we must have a surface that will allow of the sun's warmth, the dew, rain, and air passing into it, which must of necessity be a loose one of ameliorated soil if benefit to the full is to be derived by the crops from the assimilated matter in the soil through the prevention of evaporation.

Stirring the Soil.—A practice used to obtain in gardens of stirring the soil with a fork in addition to the ordinary digging in of manure in autumn. In the case of heavy soil there was the indispensable turning over of ground that had been thrown up roughly for the winter so as to bring it into an even surface preparatory for cropping. In some cases it was considered necessary to turn over vacant ground whenever the opportunity offered, and rare indeed were crops put in without stirring the soil a few days before, especially if it had lain awhile so as to become at all solid. It was done to sweeten—i.e., aerate the soil, and that it had a beneficial effect was amply proved by the crops that followed—the more the ground had been stirred the better the result. The stirrings certainly had the effect of mixing manures thoroughly with the soil, cleansing it of weeds, disturbing predatory pests, and producing a good tilth. Those practices are now almost obsolete. Why? Is it because land pays better tilled to produce 3 to 4 quarters instead of 4 to 6 up to 8 quarters of corn per acre? Can it be that cross-ploughing, dragging, cross-harrowing are needless operations?

Ground should never be dug or stirred when it is soaked with rain or very wet, and ought never be worked when it is frozen or covered with snow. Whenever the soil is so wet as to clog it is not in a fit state for digging or stirring. This more particularly applies to heavy or clayey soil, as that of a light nature or that resting on a gravelly bottom may be worked at most times with facility, yet digging and stirring is best performed on all in dry weather, and never ought to be practised on any other than when somewhat dry or in good working order. Ground that needs aeration is perhaps more favourably treated with a certain degree of moisture and tenacity existing. All the same working ground when wet converts it into puddle, and gives it a solidity unfavourable alike to pulverisation and aeration.

Stirring Soil about Growing Crops.—The object in this case is primarily to destroy weeds—to retain the resources of the soil for the benefit of the crop, as weeds equally derive their support from the soil. Every weed that is allowed to grow up with the crop proportionately deteriorates its value. How much the value of grain crops are depreciated when seen as masses of yellow because of Charlock or a blaze of scarlet through Poppy is seldom calculated, and a growth of couch almost if not equally strong with the cereals takes correspondingly from the quality and quantity of the resultant grain. Hoeing is a necessity of cleanliness, and it has the advantage of not only preventing weeds interfering with the food supplies of the crop, but keeps them from growing with and choking the useful plants, which must be kept sturdy, and need all available light and air. As soon, therefore, as the crops are sufficiently advanced the ground should be stirred, run over with a hoe whenever the ground is in a fit state, which it always is when it does not clog. To work it when wet is only to make it more firm or close and impervious to rain and air. The only time, therefore, for stirring with a hoe is when the soil works well. It is useful in spring, summer, autumn, and winter, whenever and wherever there are weeds to destroy and a surface that is becoming close to loosen

It is a modified sweetening of the soil, and its value to autumn and winter crops is mainly resulting of aëration; hence to stir the soil between the rows of Lettuces, spring Cabbage, and winter Spinach is invigorating. Paradoxical as it may seem, stirring is good against winter cold and summer heat—*i.e.*, plants in an aërated soil are not nearly so injuriously affected by cold, nor do they suffer to anything like the same degree from drought as those growing in a soil the surface of which is close. Stirring, of course, should never be practised longer than is safe—*i.e.*, it must not be persisted in when damage is likely to be done to the roots of the crop plants. Whenever the crops are above ground the hoe should be set to work at once, the weeds not being allowed to get beyond the seed leaves, and the hoeings should be followed up as required to keep the weeds well under and have the crops perfectly clean until it is impracticable to continue the stirring on account of certain damage to the tops and roots. Deep stirring is, of course, sometimes necessary to insure soil for earthing Potatoes, and even forking, &c., between the rows being had recourse to on heavy soils, when it is desirable to form a free-rooting medium for the plants, it being done in advance of the roots. The stirring is an essential of successful practice. In autumn and winter it is necessary to allow the rain and air to enter freely, and for evaporation, which if it tend to reduce the temperature of the soil one way is counterbalanced the other through the less danger from cold of the light aërated surface as compared with the close and wet; indeed, the open loose surface of ameliorated soil is some degrees warmer, which assists crops in winter or cold periods to resist cold. The well-stirred surface is equally effectual against drought through the increased depth of the ameliorated soil, which is a great absorbent of heat, of rain, night dews, and air, the latter being the best of non-conductors; hence plants growing on land with a good surface of loose ameliorated soil are not so liable to injury from cold or to suffer from the vicissitudes of our climate as those in a soil which does not dry quickly after rain, if indeed the rain instead of entering the soil must run off or lie to be evaporated. The soil must be sweet and clean, rain and air must pass into and through it, and the plants kept clean and healthy, which can only be had by stirring the soil both before and after cropping in order to secure the fullest, earliest, and best quality produce.—G. ABBEY.

THE FLORISTS' TULIP IN THE SOUTH.

I do not think that I am committing any breach of confidence when I state there is a warm desire on the part of a few of the leading Tulip growers in the north that the florists' Tulip should be again grown and exhibited in the south. But how can this interest in the flower be aroused, in the London district for instance? It is not easy to purchase good florists' Tulips, indeed they are now almost altogether in the hands of private growers, and the choicest sorts increase but slowly. It is true that the Dutch florists offer late show Tulips—bizarres, roses, and byblœmens; but I fear it would be difficult to find one among them that could pass muster at a Cheshire or Lancashire Tulip show. It is a waste of energy, time, and money for anyone to trouble to cultivate these in the hope of finding among them flowers up to exhibition form, unless, indeed, a new generation of southern growers were to make the attempt with flowers of a low type of quality, which would be a misfortune.

I think I might go a step further and say (although I do it with due reservation) that I think the President of the Royal National Tulip Society at Manchester, Mr. Samuel Barlow, J.P., will be found willing to co-operate, not only in a hearty, but also in a practical manner in the direction of endeavouring to raise up a new generation of Tulip growers and exhibitors in the south. When at Manchester recently, I had an opportunity of talking over with him the matter of a Tulip revival in the south, and the idea that seemed to be present in his mind was this—that he would be willing to give, from the overflow of his beds, a collection of choice Tulips to anyone in the south willing to undertake their cultivation, provided they would be willing to hold a competitive exhibition at the proper season. I do not wish this to be taken as absolutely authoritative until some announcement of the kind is made by Mr. Barlow, but I think it will shortly appear. He informed me, in course of conversation, that he was on the point of supplying a few of the florists at Reading who grow Auriculas, Carnations, and Picotees so well, with collections of Tulips, their desire being to hold a competition with them at the spring show of the Reading Horticultural Society, which is generally held about the third or fourth week in May. But were a larger southern circle interested, and especially were they set up with hubs in some such generous way as that I imagine to be in the mind of Mr. Barlow (and I think there would be a combination among some of the northern growers to render assistance), it would both be possible and highly beneficial to hold an exhibition in connection with one of the meetings of the Royal Horticultural Society. This is the period of floricultural revivals, and a movement that reaches the florists' Tulip is, I think, possible, probable, and highly desirable.

The question is, What sort of Tulips may be said to be procurable? I think I may go to the length of stating that the following are fairly plentiful in the midland districts and the north:—Bizarres, feathered.—

Sir Joseph Paxton, Masterpiece, Commander, Lord Lilford, Garibaldi, Sir Sidney Smith, a variety with a heavy or "plated" feather; Royal Sovereign, George Hayward, and William Willison. Bizarres, flamed.—Sir Joseph Paxton, Ajax, Dr. Hardy, Masterpiece, Orion, and William Lea. Roses, feathered.—Mabel, Heroine, Modesty, Industry, Charmer, Annie McGregor, and Aglaia. Roses, flamed.—Mabel, Annie McGregor, Madame St. Arnaud, Rose Celestial, Triomphe Royale, Aglaia, and Lady C. Gordon, only that in the case of the last named it is so difficult to bleach the base clear of the yellow that so often taints it. Byblœmens, feathered.—Talisman, Friar Tuck, Bessie, Adonis, Martin's 101, and May Queen. Byblœmens, flamed.—Friar Tuck, Talisman, Chancellor, Lord Denman, Adonis, Duches of Sutherland, and William Parkinson. Breeder Tulips, bizarres.—Excelsior, Horatio, Sir J. Paxton, Richard Yates, and Dr. Hardy. Roses.—Mabel, Annie McGregor, Miss Burdett Coutts, and Mr. Barlow. Byblœmens.—Talisman, Glory of Stakehill, George Hardwick, Martin's 117, and Alice Grey.—TULIPA.

STENOGASTRA CONCINNA.

AN attractive little stove plant is that bearing the above name, though it is by no means so showy as some of its relatives in the Gesnera family. But the interest of plant houses does not solely depend upon occupants with large or brilliant flowers, and sometimes a neat little plant like this *Stenogastria* is quite as much admired as those of more striking character. It is not a common plant, but is occasionally seen flowering in the Royal Gardens, Kew, and from that establishment

FIG. 74.—STENOGASTRA (ISOLOMA) CONCINNA.

some time ago a specimen was shown which is depicted in the illustration (fig. 74). The leaves are small and oval, the growths short, and the flowers rise in slender stalks only an inch or two above the soil. They have a narrow funnel-like tube, with an expanded limb of five lobes—the two upper very dark purple, the lower a lighter shade of purplish lilac and white, a dark stripe running down the upper part of the tube outside, and inside are numerous dark spots. Flowers are produced freely, and clustered over the plant have a pleasing appearance.

Under a somewhat more euphonious generic name this species is ranked by several modern botanists—namely, *Isoloma*, to which several other species, previously regarded as of distinct genera, have also been added. An example of this is *Isoloma hypocyrtiflora*, which has been called *Hypocyrtia brevicalyx*, *Gloxinia*, and *Pearcea*. *Stenogastria*, or *Isoloma concinna*, is a native of India, whence it was introduced in 1861, and the plant thrives in moderate heat in a compost of light turfy loam, peat, and leaf soil, or the two latter alone will suit it.

SELECT ALPINE PLANTS.

GENTIANA ACAULIS.

MY own ideas of a really good alpine are not based upon any particular plant or plants by reason of its rarity, or because it does not lend itself readily to the various modes of culture to which it is subjected in our English lowland gardens, nor yet because it is necessary to get on one's hands and knees to see its beauty. I much prefer showy plants, such, for example, as *Gentiana acaulis*.

This grows and flowers freely in most places, except where cold stiff clay abounds, on this it will not thrive. For twelve years I have been endeavouring to induce some apparently healthy tufts to produce flowers, but in vain. Certainly there has been a flower or two, but not in its usual way, while in the same bed the *Helleborus niger* vars. *Dodecatheon Jeffrayanum*, *Campanula carpatica pallida*, *Iberis*, *Antheicum Fair Maid of France*, *Horminium pyrenaicum*, *Gaillardias*, *Phloxes*, and the like grow to perfection, to say nothing of standard and dwarf *Roses* in abundance. The only plant which evidently will not thrive is this *Gentian*, and I believe it thoroughly dislikes the soil. I have grown it to perfection on light sandy soil overlying gravel, on soils overlying the red sandstone, on a good sound loamy soil, and in beds of American plants, and the difference was very trifling either in growth or flower. Such a plant as this, then, must be one of the best. I have planted it at all seasons from September to June inclusive, but I give preference to the month of October, paying special attention to firm planting at all seasons. It is surprising how well this *Gentian* does for edging beds or walks in the garden, and how well it flowers when used for the purpose named. I have this impressed on my memory by the fact that some sixteen years ago the specimen *Phlox* beds at the Exotic Nurseries, Tooting, were edged with it, and by reason of the traffic to the *Phloxes* they became as firm in their positions as the paths themselves. The *Phloxes* were copiously supplied with water, consequently the *Gentians* came in for a share, and flowered with the greatest freedom. From this apparently trivial circumstance I learnt the lesson of firm planting, which I now adopt for all *Gentians* having any inclination to produce stoloniferous growth, such as *G. excisa*, *G. alpina*, *G. verna*, and its forms.

ARNEBIA ECHIOIDES.

"The Prophet Flower," undoubtedly the finest spring-flowering Alpine in cultivation, but I have seen it as good in October as in May, which inclusive embraces a lengthened period for flowering. Given a free light rich sandy loam it will quickly establish itself without difficulty, and has no equal amongst Alpines either from a decorative point of view or for exhibition purposes, while for spring gardening when sufficiently plentiful it will be excellent. It is a remarkably interesting plant by reason of the characteristic changes through which its flowers pass in the earlier hours of their expansion. When first open the flowers are of a pleasing shade of soft yellow, but on the second day a dark blotch appears on each of the petals, which eventually become black; afterwards they gradually fade, and ultimately disappear altogether. In well flowered examples these varying stages may all be witnessed at one time. I have found by experience that it is not nearly so impatient of removal as some may imagine, though let it alone by all means if this course can be adopted. The methods of increase are three-fold, and if each of these can be carried on successfully a stock may soon be raised—namely, by dividing the stools, by seeds, and by root cuttings. The first named is best done in early spring, and will need to be done carefully, shaking all the soil away previously, so that an opportunity may be afforded for examining the stool and see where division can best be made. Pot the plants and place them in a cold frame, taking care to shade from sun till well started into growth again. Seeds may be sown at any time as soon as ripe; but with regard to these I may say that they are not usually abundantly produced from young plants, while established clumps will produce them in a manner verging on freedom. The root-cutting operation can only be performed in winter and very early spring when the plants are at rest. It is a native of the Ural Mountains, and when established attains a foot or 18 inches high, a very suitable height for rockery or herbaceous border. I first made its acquaintance some eight years ago in that richly stored garden then presided over by the Rev. H. Harpur Crewe at Drayton Beauchamp Rectory, Tring, where it merely figured as a unit among a host of choice and well cared for plants.

CHEIRANTHUS ALPINUS.

This Alpine Wallflower should be a common plant for spring gardening, for it is easily managed, and furnishes bright pleasing masses of colour which always satisfy. It is a really good alpine, flourishing in any good ordinary soil, clay excepted. For the rock-work in large patches it is most effective, and equally so on the flat surface of a bed. In height it is about 8 or 9 inches, and spreads into compact tufts, which in turn are completely covered with soft sulphur yellow flowers, a colour which in fact forms a good imitation for the *Arnebia* were it not for the presence of the spots on the latter. The *Cheiranthus* is readily increased by cuttings taken in July, which should be torn off with a heel attached and inserted in sandy loam. In the cutting state they are impatient of moisture, and succumb to it quickly, so that an old light or frame into which abundance of air can be admitted forms the best place to root them. A close moist atmosphere they cannot endure. A good

stock of it may soon be had from seeds, which are produced somewhat freely, and these sown as soon as gathered will, with good culture, make fine plants by the autumn. An excellent companion plant is *C. Marshalli*, with rich orange-coloured blossoms. It is not such a free grower as *C. alpinus*, hence its comparative rarity.—J. H. E.

(To be continued.)

ROSE SHOWS IN 1888.

- June 28th.—Brockham and Ryde.
- „ 29th.—Maidstone.
- „ 30th.—Colchester and Reigate.
- July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
- „ 4th.—Croydon, Dursley, Farnham, Hitchin, and Richmond (Surrey).
- „ 5th.—Bath, Farningham, and Norwich.
- „ 6th.—Sutton.
- „ 7th.—Crystal Palace (National Rose Society).
- „ 10th.—Gloucester, Ipswich and Oxford.
- „ 11th.—Ealing and Tunbridge Wells.
- „ 12th.—Birmingham, Carlton-in-Lindrick, and Winchester.
- „ 14th.—Eltham, Manchester, and New Brighton.
- „ 16th.—Christleton and Newcastle-under-Lyne.
- „ 17th.—Leek and Ulverstone.
- „ 18th.—Birkenhead.
- „ 19th.—Helsburgh.
- „ 20th.—Darlington (National Rose Society).
- „ 24th.—Tibshelf.

In the case of Birmingham, where the show extends over two days, the date of the first day's exhibition only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSE PROSPECTS.

THE *Roses* about here look like being very much later than usual, I hope Christmas will not intervene before the blooms come on, but if the present cold biting east wind continues much longer I expect Christmas will be here first. The early foliage of my *Roses* is pretty well shrivelled, owing evidently to a wave of frost at a recent date. This has put the growth back and given a severe check to everything. The leaves of all the trees in the neighbourhood seem to have suffered in the same manner, and no doubt from the same cause. It is probable that the east wind, of which we get the full benefit at 1000 feet above sea level, has helped matters in this direction. However, I look forward to a fine autumn show of bloom.

HER MAJESTY.

Some time ago I wrote saying I had a hundred of these planted out, and that I had pruned a few down to the ground, the bulk being cut about 1 foot to 15 inches only. These latter I find are carrying a lot of bloom buds. The shorter pruned ones being later, in consequence of the treatment, are not yet showing many, but I expect they will bloom freely, just as *Baronne de Rothschild* or *Merveille de Lyon* does. The foliage of *Her Majesty* is superb, more beautiful than either of the two *Roses* just mentioned.

A ROSE ENEMY.

If your correspondent "H. V. M." will procure a dark lantern and a white cloth, and will visit his *Rose* trees about eleven o'clock at night, he will find them swarming with weevils, which seem to be taking a benefit this year, though I have none. The cloth should be spread on the soil, and then if he is not squeamish he can crush a good many of his enemies with finger and thumb; leather gloves are cleaner than bare hands. Those that fall on the cloth must be attended to before they crawl away. Two or three visits on different evenings will get rid of the whole lot.

THE PERSIAN YELLOW.

I have a thicket of this charming little *Rose* in my garden. In its lasting qualities it is a good deal like the foam on the river we read about—

"A moment seen, then gone for ever."

I have once or twice attempted to cut a branch or two to place in water, but the flowers fade and die almost at once. Possibly I did not place them in water soon enough. My trees are now about to burst into bloom, at which time they are a lovely sight. There is no doubt about its being hardy, as it grows and increases here just like a wild Briar. It requires no pruning, the simple removal of the old wood being not even necessary. Generally speaking, the wood made the preceding season carries a bloom springing from each bud. I am not sure whether the variety growing here is *Harrisoni* or the old *Persian Yellow*; one of

these is hardy, the other not. From the fact of the relatives of my plants having been growing here in an old garden close by for many years, I presume it is Persian Yellow.—D. GILMOUR, JUN.

CLIMBING DEVONIENSIS.

WE have growing here against a south wall a very fine specimen of Devoniensis Rose, and I write to ask if we were to have it photographed if you would accept a copy for the Journal? If so, I shall have much pleasure in sending one. It is a tree of rather unusual size. Its length is 38 feet and height 8 feet, with nearly 400 blooms on it (open), and I should think quite as many buds. The tree is the admiration of all who see it.—C. SEDGBEER.

[We cannot possibly undertake to engrave from photographs without seeing them, and possibly the one suggested may not do justice to the Rose. We do not request that one be specially taken for us, but if you have one taken for yourself we shall be glad to see a copy.]

ROSES IN WINTER.

DURING the early months of the year the temperature in the first and second division should not by fire heat exceed 55° at night, and even a few degrees lower during severe or very cold weather will be much better for the plants. In fact, the most successful results in Rose-foreing are attained by regulating the temperature according to external conditions. When foreing is conducted on these principles the temperature may range from 50° to 60°, the latter only on mild occasions, when no harm whatever will result. It will be found that when the thermometer stands at 45° outside, the house would naturally stand at the intermediate temperature given without the aid of artificial heat. During such nights the pipes should be kept gently warm, even if the temperature exceeds 60°. Thus the higher temperature, instead of doing harm, will prove beneficial to the plants. The temperature during the day will vary considerably according to the weather, often rising to 85° or 90° at the end of March and the following month. No attempt is made to lower the day temperature by opening the ventilators. Although the temperature by sun heat often rises higher than is really desired very little harm follows; but, having to choose between a high day temperature or ventilation, we practise the former, because of the two evils it is much less likely to subject the plants to injurious results. The principal objection to ventilating early in the season is the danger of giving the plants a check, and if cold air is allowed to rush in upon the plants they are certain to be attacked by mildew. If the house is provided with side ventilators that do not fit closely it will be near such positions that the first signs of mildew are visible.

A high temperature from sun heat, as long as abundance of light can reach the plants, will not result in soft weak growth unless hard firing at night is resorted to. Whether the plants are young or thoroughly established do not ventilate until the weather outside is genial and the air warm. From the middle of April a judicious system of ventilation may be followed. Let it be remembered that very frequently after that time the house is better closed than open, for cold days often succeed a few warm genial ones. If care is taken until the close of May I shall be safe in saying a free and liberal use of the ventilators may be made. Artificial heat may be dispensed with by the end of May, except on solitary occasions, when the night proves exceptionally cold. On all fine warm days, whether they are in March, April, or May, artificial heat should not be used when the temperature can be kept high enough without it. Considerably more harm is done in Rose-foreing by a too free use of artificial heat than by sun heat, however high the temperature may rise.

In June, when the temperature externally is warm, too much air cannot be admitted to the plants, for the object to be attained is firm, hard, thoroughly matured wood. I advised moveable lights for the roof, and if the house is constructed on this principle I do not advise their removal the first season. Good Roses can be grown without this accommodation, and I should not have referred to the matter again had not inquiries been made on the subject. It is not really necessary, but two advantages are gained by this method of construction that cannot well be overlooked. The first provides for the maturation of the wood in a natural manner, and the plants entail less labour to keep their foliage free from red spider. Under glass Tea Roses will persist in growing, and early forced plants have the peculiarity of starting vigorously into growth in autumn when they should be at rest or going to rest. When they are covered the whole season with glass, rest, to a great extent, has to be forced upon them by drying the soil at their roots, and other devices that I do not approve of. The cooler days, especially nights, of late summer and early autumn naturally bring them to rest. Being exposed, the first early frost that may be experienced has the desired effect. They start, when required to do so, with greater freedom after exposure to frost than if protected from it by glass.

The second reason is a very important one, especially to those engaged in growing for the market. It is scarcely necessary for me to point out what could be grown by the aid of the sashes. Even to the private gardener rude frames that could be covered with lights would be found invaluable for the culture of many plants, for frame room is seldom too plentiful in the majority of gardens. If the lights were to be taken off and stored away, then it is useless to go to the extra cost that would be necessary in construction. But I must return to the plants, and consider them from the time they are freely ventilated and artificial heat dispensed with. Whether they have been flowered or not in their early stages makes very little difference with their treatment from this time, for the whole of the buds must be kept off as they appear. The

plants will be strong, for they should have pushed up luxuriant growths from the base, and others will still continue to make their appearance. Two weak growths that the plants possessed when they were placed out, or when they were restarted into growth, may be cut clean away, so that light and air can penetrate freely to the stronger ones that issued from the base. On these strong growths good flowers the next season should be produced. Those who want buds only and in quantity in preference to finer but fewer flowers, may leave these weak growths to be carefully thinned out at pruning time. Amongst a number of plants some may not have pushed so freely from the base as others. I have to-day been looking at some that have developed what we may call their first shoots, no growths having issued from the base. In such cases no pruning in the present stage should be done.

Those restricted to the culture of the Rose in pots for flowering at the period of the year we are considering should transfer the plants at the end of May or beginning of June into at least 10-inch pots. If on their own roots 9-inch pots will be large enough for the plants. In potting do not disturb the ball farther than the removal of crocks from the base. Pot about half an inch deeper; that is, cover the surface of the old ball with about half an inch of fresh soil. If potting is done carefully the plants will receive no check; and if kept under glass until the middle or end of August, and then placed in a sunny position outside to harden, they will be in admirable condition for forcing.—WM. BARDNEY.

(To be continued.)

MEREWORTH CASTLE.

THIS, the Kentish residence of Lord Falmouth, is situated close to the main road from Maidstone to Tunbridge Wells, and in one of the most picturesque localities of the "Garden of England." The castle is an ancient building of massive appearance, no attempt having been made to embellish the exterior of it with carvings, projections, or elaborate stone facings. The first glimpse we caught of it from the woodland drives beyond conveyed the impression of imposing grandeur, the large central dome having a striking resemblance to that of St. Paul's. The castle and flower garden around it were at one time bounded by a moat, of which only a deep excavation remains on three sides, the other being still beautified by the clear waters of a broad running stream. From many parts of the grounds delightful views are obtained of the undulating and diversified scenery for which Kent is justly famed. For miles around may be seen the fruitful orchards, climbing Hops, and verdant pastures, with here and there a tall church spire amongst clusters of trees, or standing boldly out, as if to serve as a landmark from the hills beyond.

My object in visiting Mereworth was to inspect the gardens rather than admire the surrounding scenery; I will therefore relate the impression I formed of them during a few pleasant hours I spent there on June 1st. The flower garden is of considerable extent, the principal portion of it being around the castle, and is laid out in the Italian style, the beds being enclosed in Box edgings with gravel walks between. These beds are in some cases somewhat intricate in design, but as the curves are glowing and graceful have doubtless a very good effect when planted; but the principal defect of such designs being there is not sufficient breadth for masses of colour, which are always so telling when the surrounding features are on a large and bold scale. Great changes are, however, contemplated in this department. The Box edgings having through age become somewhat tall will another season probably be removed, the whole space turfed down and suitable beds cut in the grass, which will doubtless prove a vast improvement. On one side of the castle a curious design is worthy of notice. It very much resembles an old Gothic window, and is worked out in Box with gravel between, none of the enclosed spaces being planted. The design was taken from a very old drawing, and must have required a considerable amount of both skill and patience to draw out and plant accurately. At the time of my visit hedging-out was being pushed on, the principal plants being Pelargoniums, Lobelias, a few annuals, and Tuberous Begonias, the latter being especial favourites, 1000 plants being raised this year, the stock of plants altogether being about 2588. Of Messrs. J. Laing's splendid strain this year the best varieties are selected, and I noticed a fine stock of sturdy plants coming on in frames. Near to the flower garden is a rosery, surrounded on three sides by flowering and evergreen shrubs, several fine specimens of Coniferae and Berberis Darwini being noticeable. The Roses which were lifted a couple of seasons ago were making vigorous and healthy growth, and promise to give an abundant harvest of their fine blooms.

KITCHEN AND FRUIT GARDENS.—Leading from the Castle to extensive woods beyond is a fine broad drive of imposing appearance running straight as an arrow for a mile in length, and then slightly curving for another mile. On either side of a part of this drive the gardens in question are situated, and a close inspection of them shows plainly that they are under the management of one who has been trained in a good school of gardening. Close cropping, the absence of weeds, and the systematic manner in which the various crops are arranged, speak for themselves. As far as the gardens extend the drive is margined with grass about 6 feet wide on each side; next the grass are two grand lines of tree Peonies upwards of 200 yards in length, studded with flowers, just beginning to open when I saw them, and which, doubtless, have a very striking effect when fully expanded. Beyond the Peonies on either side the principal portion of the vegetables are

grown, and in planting particular attention is paid to have each side correspond as nearly as possible to the other.

The whole of the vegetable crops were in a very promising condition, a fine bed of Ellam's Early Cabbage and another of Broccoli being especially noticeable. The heads were of medium size, solid, and in excellent condition for kitchen use. The vegetable quarters are bounded on both sides by well built brick walls, which are being rapidly furnished with Peaches, Nectarines, Pears, and Cherries, the trees being remarkably clean, healthy, and well trained, and the varieties comprising most of the best in cultivation. Among Peaches Gros Mignonne, Stirling Castle, Bellegarde, A Bee, Dymond, Barrington, Princess of Wales, and Alexandre Noblesse are held in great repute. Nectarines Elruge, Lord Napier, Pine Apple, Pitmaston Orange, and Humboldt. Among the numerous varieties of Pears grown the following are found the most satisfactory—Marie Louise, Doyenné du Comice, Beurré Superfin, and Glou Morceau. Many of the walks are edged with dwarf horizontal cordon Apple trees of such large and useful varieties as Emperor Alexander, Red Astrachan, Celini, Golden Noble, and ReINETTE de Canada. The outdoor fruit trees at Mereworth are a very fine collection, and as they are all young, and in the majority of instances well set with fruits, they will produce many fine specimens during the summer months. The fruit houses are numerous and admirably adapted for the purpose for which they are intended. A close inspection of these houses is amply sufficient to show that Mr. H. Markham, Lord Falmouth's skilful and energetic gardener, is an adept at fruit culture, and as he was at one time a pupil of Mr. H. W. Ward at Longford, and at another of Mr. R. Gilbert of Burleigh, it must be gratifying to these prominent gardeners to know that the sound practice he acquired while under them has been turned to such good account.

The vineries are four in number, the Vines in perfect health and carrying good crops of fine compact bunches, such as are in great demand for keeping up a regular supply, and in many cases the bunches promise to be such as might with advantage be placed upon the exhibition boards, in which case many of the Kentish growers must look to their laurels, or they may be deprived of some of their usual victories. The earliest house is occupied solely by Black Hamburgs, from which the first bunches were cut in May, all of them being well coloured, the berries large, and in many cases the bunches too. All the Vines in this house are young, and between the permanent ones pot Vines have been grown for this season, to be taken out and planted elsewhere as soon as the crop is cleared, and it was a noticeable fact that the Grapes produced on the pot Vines were equal in any case, and in many superior to those on the permanent ones. Another house is occupied principally by the same variety, which is a great favourite on account of its good flavour. The Vines in the Muscat house are carrying an exceptionally fine lot of bunches, which have set as freely as Hamburgs, in fact I have never seen a better set, many of the bunches promising to be fine solid specimens. At one time the berries shrank badly, but in 1885 Mr. Markham lifted the Vines and relaid them in fresh soil, carried them on very slowly the following year without loss of the crop, and took up a young cane to each rafter so as to stimulate root action; since that time they have been rapidly improving, till they are now in the highly satisfactory condition above described. I should mention the excellent set obtained is attributed in a large degree to the fact that when in flower the bunches were lightly syringed between five and six o'clock every evening. In the late vinery Lady Downe's, Gros Colman, Gros Maroc, Muscat of Alexandria, and Golden Champion; the last named variety produces good bunches and berries, but it generally becomes spotted when ripening, which could probably be prevented if a house could be devoted exclusively to that variety, by ventilating more freely and keeping a drier atmosphere.

Three houses are devoted to Peaches, the whole of the trees being in splendid condition, the training being perfect, and the fine crops of fruit such as anyone might be justly proud of. Last year many of the fruits weighed 8 ozs., and they promise to be equally fine this, the varieties being Hale's Early and Royal George. In 1884 Mr. Markham planted the other two houses with good sized trees, which now cover a space of trellis 14 feet by 14 feet, and are carrying from ten to twelve dozens of fruit each, Waterloo and Grosse Mignonne occupying one house, the former being a great favourite on account of its ripening six weeks earlier than any other variety in the same house. At the time of my visit the fruits were colouring rapidly, and were a wonderfully fine even crop of good sized fruits, although this variety is generally considered a little undersized. Grosse Mignonne is considered here to be unsurpassed for quality. Stirling Castle and Bellegarde are the varieties planted in the other house, and cover the same amount of space as those previously mentioned. All the fruit houses are three-quarter span, the back walls and half-span portion of the roof being occupied by Figs either in pots or planted out, those in pots being the most fruitful. Only one variety of Melon is grown—Green Gem being the favoured one on account of its exquisite flavour. The same plants are grown throughout the summer. A few fruits have already been cut, and between forty and fifty were still hanging, which were a very fine lot, averaging from 2½ to 3 lbs. in weight, and I was particularly struck with the regularity with which they were distributed over the plants and the fine healthy condition of the foliage.

Strawberry forcing is a specialty at Mereworth, 2000 plants being grown in pots, and two houses are devoted to them during the forcing season, and it is questionable if a finer lot of fruits can be seen anywhere, grand solid fruits of very large size, and being well exposed to the light throughout ensures good colour, and makes them the

better travellers when ripe. As soon as the fruits are set the leaves are fastened back by means of a strong peg, and the fruit supported with sticks, the arrangement being extremely simple and effectual. Sir Charles Napier is the sort almost exclusively grown, a few of La Grosse Sucrée being tried this season with good results. No plants whatever are allowed in the fruit houses, which admits of the fruit trees receiving the attention they require without the cumbersome inconvenience of a host of plants beneath, which only too often harbour colonies of insects so detestable to fruit growers, and also prevent the pressing work of stopping and tying the shoots and thinning the fruits from being carried out with that expedition that is so necessary. Two houses are devoted to plants, Bougainvillea glabra and Plumbago capensis being thickly trained over the roof, the beds and stages being occupied by a mixed collection of useful plants, conspicuous among them being healthy thriving specimens of Adiantum farleyense and A. gracillimum. —VISITOR.

EVENTS OF THE WEEK.—Rose Shows to be held during the ensuing week will be found on page 530. Thursday (this day) is the date of the Royal Horticultural Society of Ireland's Show. On Monday, July 2nd, the Kettering Show will be held. Next Wednesday is the Forty-fifth Anniversary Festival of the Gardeners' Royal Benevolent Institution, at which the Right Hon. Joseph Chamberlain, M.P., will preside—the date also of the Royal Botanic Society's Evening Fête. The Richmond (Surrey) Horticultural Show will also be held on the same day, in addition to the Croydon Show, so that metropolitan horticulturists will have a rather busy time.

— RETIREMENT OF PARTNERS.—Messrs. Sutton & Sons, seed merchants, of Reading, and 5, Westminster Chambers, S.W., announce the retirement by effluxion of time on May 31st last of Messrs. Martin Hope Sutton and Alfred Sutton, who have been members of the firm for more than fifty years. The firm of Sutton & Sons will be continued in future under the same style and title by the sole proprietors, Messrs. Martin John Sutton, Herbert Sutton, Arthur Warwick Sutton, and Leonard Goodhart Sutton, who have for several years past been the acting partners.

— THE WEATHER.—Rain has fallen copiously this week in the metropolitan district, and as a high temperature has also prevailed the conditions are favourable for plants recently bedded out and the growth of crops generally, but not for haymaking, and most of the Grass is "down" in the south.

— AT a meeting of the ROYAL BOTANIC SOCIETY, Regent's Park, held on Saturday, the Duke of Teck, President, in the chair, the Duke of Newcastle and Mr. F. Meeking were elected Fellows. After the ordinary business had been disposed of, the President presented a gold medal and purse of fifty guineas to Mr. Ellis, L.R.C.P., of Liverpool, the winner of the Queen's Jubilee Prize, given by the Society for the best essay upon the plants and vegetable products introduced into the United Kingdom for use in the arts, manufactures, and for food during her Majesty's reign.

— THE BEGONIA EXHIBITION OF MESSRS. JOHN LAING AND SONS at Forest Hill is open to the public every day, Sundays excepted, from the present time till the end of September. The collection of Begonias in pots is richer than ever, both doubles and singles being represented in splendid varieties, while new colours are being produced in each successive batch of seedlings. The plants now flowering are remarkable for their sturdy vigour and massive blooms; and eventually, when the 150,000 plants, occupying upwards of an acre of ground in the open nursery, are in full beauty the sight will be worth a long journey to see. Caladiums are now a feature, and the Orchids will bear examination. Catford Bridge station, reached in half an hour from the City, is only about half a mile from the nursery.

— THE CRYSTAL PALACE.—Music and flowers are more closely associated on the Continent than in this country as a rule, but there are exceptions. During the past and present week the grandest of musical

entertainments have been provided at the Crystal Palace in the triennial Handel festival, and during the season the series of horticultural exhibitions will rank with the best of the year; but music has just now the pre-eminence. The general rehearsal of the choirs last Friday, the famous "Messiah" on Monday, the grand selection on Wednesday, in which some 4000 trained vocalists and instrumentalists took part, including those of world-wide fame, will not soon be forgotten by the vast concourse of visitors. The festival closes on Friday in this week with the great Oratorio "Israel in Egypt." The Palace and grounds are now looking well, and illuminated at dusk the spectacle is a brilliant one, and worthy of inspection by gardeners and others visiting London during the summer months.

— REFERRING to RHODODENDRON FORTUNEI MRS. BUTLER, recently noticed in this Journal, Mr. G. Aslett writes that it was certificated by the Royal Horticultural Society, May 9th, 1882, and the specimen is now 10 feet high, 6 or 7 feet in diameter, and has had hundreds of blooms this season.

— THE YORK SHOW.—We are informed that a full report of this Show was posted to us on the 19th inst. It did not reach this office; and a second report arrived too late for insertion this week, so there ends the matter. We cannot occupy our space with reports of shows three weeks or a month after date.

— MR. HENRY V. MACHIN, Gateford Hill, Worksop, Nottinghamshire, writes:—"One of your readers asked, a week ago, if anyone would inform him with what success they had grown Mushrooms in a disused ice-house. I beg to inform him that I had a bed spawned at that time in an ice-house. The inside measurement of the house is about 14 feet by 9 feet 6 inches. I had some disused beer coolers about 11 feet by 3 feet 6 inches, and have made my beds in them and other receptacles. I can only inform your correspondent that, although my beds are 11 and 9 inches deep, I am very much pleased with the show of Mushrooms."

— AN exhibition of plants, cut flowers, fruits, and vegetables will be held in the PALACE GROUNDS, WELLS, SOMERSET, on August 15th. Classes are provided for groups of flowering and fine-foliaged plants, Fuchsias, Begonias, Lilliums, and Ferns, and fairly liberal prizes are offered for cut Roses, Dahlias, Gladioli, Asters, and other cut flowers. A special feature is to be made of table decorations, and there are also classes for all kinds of fruit and vegetables in season. It is open to all comers. Mr. R. Harris is the honorary Secretary.

— NATIONAL CO-OPERATIVE FLOWER SHOW.—In reference to the above Exhibition to be held this season in the Crystal Palace, Sydenham, Mr. Broomhall sends the following note:—"The Council of the Royal Botanic Society, in communicating with the Secretary of the National Co-operative Flower Show, states, 'That although it does not come within the province of the Society to offer or award medals or prizes other than at its own exhibitions, and has never done so, yet in consideration of the special features of your national festival and exhibition the Society will be pleased to add one of its large bronze medals to your list of prizes.' We understand that the medal will be offered for the best collection of botanical specimens."

— HARDINESS OF CHOISYA TERNATA.—A correspondent writes: "It is not generally known that this beautiful shrub is quite hardy—at any rate in the southern counties—or otherwise it would be more frequently planted out. At Rood Ashton, Trowbridge, Wilts, there is a fine specimen in the pleasure grounds that Mr. Miller states was planted eleven years ago. It is on a sloping bank facing south-west, and is sheltered by other trees and shrubs from the coldest winds. The height of this specimen is fully 9 feet, and the front of it measures 12 feet through. During severe winters much of the foliage gets browned somewhat, but the points are uninjured and never fail to flower abundantly. When I saw it about the middle of this month much of its beauty was over, and the young growth fast pushing out. At its best it must have been very beautiful, the flowers being nearly as pure white as on those plants grown in pots."

— Some time ago we had the pleasure of inspecting the interesting and admirably kept gardens of John Crosfield Esq., at WALTON LEA, near Warrington. The magnificent specimen Hollies in the pleasure grounds and Camellias under glass were the most striking features, and we must travel far to find their equals, though every department

affords evidence of the ability and attentiveness of Mr. William Kipps, the gardener. We are reminded by a report in a local paper that Mr. Crosfield allows his neighbours to share the pleasures of his garden, and not only invites residents of the busy town and neighbourhood in hundreds from time to time to his pleasure grounds, but entertains them when there as personal friends. One of these garden parties have recently been held, the guests consisting mainly of persons engaged or interested in elementary education in the district, and teachers and pupils found much to admire and something to learn on this occasion. Such kind and thoughtful acts are worth recording in these columns.

— THE Rev. Hugh Berners, Harkstead Rectory, Ipswich, desires us to announce that the IPSWICH HORTICULTURAL SOCIETY'S SHOW will be on Wednesday, July 11th, instead of Tuesday, the 10th, and that the schedules can be obtained on application.

— EARWIGS.—A correspondent, "M. A.," desires information on preventing injury by earwigs by destroying their eggs. We suspect the chief difficulty will be in finding them, but perhaps some of our readers may be able to say something on the subject in question.

— MR. T. GRANT, The Gardens, Ossemsley Manor, Christchurch, writes:—"I can fully endorse your correspondent's remarks on page 511 of your last issue with regard to the Caucasian Laurel. Four years since, when enlarging the pleasure grounds here, we planted in a mixed shrubbery a large quantity of them, which have grown very freely, forming thick compact shrubs of intensely dark green foliage, and not only have they withstood the frosts of winter, but during the drought of last summer they shed but little foliage, while the other variety was in some instances nearly bare. I find that they also bear transplanting very well. Out of some dozens we moved during the planting season of 1886-87 we lost but very few during the late dry season."

— SOUVENIR DE LA MALMAISON CARNATION is grown on a scale that is equalled in few private establishments at Dover House, Roehampton. Nearly 1000 plants are cultivated in pots solely for yielding cut flowers, of which immense numbers are gathered. The variety is an especial favourite with the proprietor. But Mr. Morgan not only likes abundant supplies of his favourite flower in the rooms of his residence, but also to present to visitors—charming "souvenirs" indeed. Hence, though the blooms are produced in thousands, they are not too numerous. The majority of the plants that have been flowering during the past few weeks are two and three years old. They were from layers made in summer, the plants being pinched back and not allowed to flower, but potted as required in loam, peat, and sand. Some three-year-old plants were fine bushes, with thick woody stems, and bearing twenty or more blooms each.

— ANOTHER interesting sight in this garden at the present time is a HOUSE OF TOMATOES. The structure in question may be described as a three-quarter span-roofed pit, the plants being grown in large pots and trained up the roof. Cutting commenced the second week in May, and abundance of fruit is now ripening. Only one variety is grown—Haekwood Park Prolific—and it has been found so good as to be relied on absolutely, its only fault being a slight shyness in setting. It is not often that a better house of Tomatoes is seen than this, nor is it every day that a garden is entered in which all departments bear so strong an impress of able superintendence. No model garden could be kept more scrupulously clean and orderly, and this result is not gained by the sacrifice of the satisfaction derivable from first-rate crops.

— ALEXANDRA PALACE ROSE SHOW.—The Exhibition arranged for June 27th and 28th was opened on Wednesday, but owing to the late period at which judging commenced we are unable to give the awards. There was a fair number of entries, but the blooms generally seemed rather the worse for the storm on the previous day, though good examples were found in several stands. A large portion of the space was occupied by groups of plants and flowers not in competition, comprising an extensive collection of choice stove and greenhouse plants from Mr. B. S. Williams, Upper Holloway, similar groups from Messrs. Hooper and Co., Covent Garden, and Messrs. Cutbush & Son, Highgate. Mr. May, Edmonton, had a fresh and pleasing group of small Ferns and Crotons, while Mr. T. S. Ware, Tottenham, contributed one of the most tasteful groups of hardy flowers he has shown this year. Very conspicuous amongst these were mounds of the white, orange and yellow

varieties of *Papaver nudicaule*, surmounted by the bright *Lilium chalcodonicum*. Several exhibits of horticultural sundries also occupied considerable space.

A WELL-FLOWERED ORCHID.

IN one of the plant houses at Fairlawn, Frome, the residence of John Baily, Esq., there is a fine piece of the good old *Oncidium divaricatum* beautifully in flower. It has four strong spikes, the best of them being not less than 4 feet in length. All are branching nearly throughout the entire length, and 750 flowers were counted well expanded at the same time. No special treatment has been given to nor is required by this *Oncidium*, the plant under notice being grown in company with a few other serviceable Orchids, with a mixture of *Crotons*, *Dracenas*, and *Eucharises* in an ordinary plant stove.—I.

ONCIDIUM LANCEANUM.

A SPECIMEN under the above name has been flowering most freely in one of the houses at Fairlawn for the past three weeks. The floriferous condition of this plant and its value for cutting or decorative purposes may be estimated from the fact of its producing on four branching spikes the large number of 756 blooms of a yellow and brown colour. The longest spike measures 6 feet in length and branches within about a foot from the soil.

It is growing in a mixed plant house, and has received but ordinary treatment, a fact that should commend itself to the notice of persons who are not favoured with special accommodation for these highly desirable plants. It appears to belong to the same strong-growing section as *O. sphacelatum* and *O. altissimum*, which are of strong constitution, and consequently of easy culture. It is adapted to pot or basket culture, and revels in abundant supplies of water when provided with good drainage and an open yet substantial compost.—W. S., *Frome*.

EPIDENDRUM ATRO PURPUREUM VAR. RANDI.

THIS plant was shown at the Drill Hall on Tuesday last as *E. Randi* both by Sir Trevor Lawrence and Mr. F. G. Tautz, but the Committee determined it to be a variety of *E. atro-purpureum*, though flowers of the latter brought by the gardener, Mr. Cowley, for contrast were very distinct in form as well as colour. The variety has light brownish lanceolate spreading sepals and petals slightly undulated at the margin, which is of a paler colour. The lip is 1 inch broad, white, with two broad expanded lateral lobes, the centre one rounded streaked with crimson in the centre, a few similar streaks also being noticeable at the base of the lateral lobes, partly concealed by the broad flat column. The plant shown had a raceme of seven flowers, each over 2 inches in diameter, long narrow dark green leaves, and small conical pseudo-bulbs. The flowers of the form regarded as a typical *E. atro-purpureum* had deep brown narrow sepals and petals, a soft rosy crimson lip with a darker centre, and two small lateral lobes enclosing the column.

TWO ORCHID CURIOSITIES—ORNITHOCEPHALUS.

With the *Epidendrum* described above Mr. Tautz showed a plant of *Ornithocephalus grandiflorum*, a member of the *Vanda* tribe of Orchids, and as Dr. Masters states, it is "specially remarkable for the long slender rostellum to which the stalk of the pollen masses is attached by means of its terminal glandular disk. This long rostellum on a side view is very like a bird's bill, hence the name of the genus." It will be thus seen that the plant is interesting structurally, and in fact this is its only recommendation, for the flowers are small, in racemes 6 or 8 inches long, the sepals and petals white, green at the base, with a small green lip, and narrow leaves arranged in a distichous manner. The floral structure is, however, so peculiar and unusual, that it is suggestive of some strange method of fertilisation such as Darwin might have dealt with fully. He does, indeed, mention an *Ornithocephalus* in which "the pedicel of the pollinia when freed from the column suddenly bends into a curved form, and soon afterwards, owing to the hygrometric contraction, curls up oddly, and when placed in water it resumes its previous form." An illustration is also given in the "Fertilisation of Orchids," but no explanation is furnished of the exact bearing of the structure has upon the fertilisation.

PHYSOSIPHON LODDIGESI.

The other curiosity from the same garden was the *Physosiphon* named above, a strange little Orchid related to *Stelis* and resembling *Pleurothallis* in habit. It has a long slender spike with very small flowers, the sepals united below into a greenish tube, and the expanded portion being oval and pale brown, quite concealing the petals, lip, and column within the tube, which from its supposed resemblance to a "bladder" gives the generic name to the plant.—C.

THE STRAWBERRY.

IN Chicago a few days ago the first outdoor Strawberries of the season were being disposed of in large quantities as low as 5d. per quart, while at the same time in the London markets worth from 1s. 3d. to 1s. 6d. per pound. As the season has again opened for the same, a brief reference to this fruit may be of interest, especially to those who have not yet experienced the pleasures that attend its seasonable use as food.

In 1745 a well-known physician certified that Strawberries create an appetite, contain essential salt, and a small quantity of fine oil; they agree well in hot weather, besides strengthening the heart and keeping the liquids of the body in a just fluidity. In France, it appears, a pleasant and popular drink was extracted from Strawberries for summer use; this was obtained by pressing the fruit through a fine sieve, and adding a sufficient quantity of water and sugar; when complete it was known by the name of Strawberry wine. This wine was made from both wild and cultivated fruit, but of course the superiority of the latter over the former, though so marked, only arises from the fact that the garden fruit receives the full benefit of the sun, whilst the wild plants growing in the wood are shaded by the thick foliage of the trees; hence their pale appearance, diminutive size, and watery flavour arise solely from the lack of heat.

One of the latest and most important facts which has been brought to light, supported by chemical science, is this, that the therapeutic properties of fruit consist in the abundance of health-imparting acids and alkaloids they contain, which, when partaken of freely as food, act in such a direct manner as to cleanse the whole system from impurities; and in fever, ague, biliousness, liver, blood, and kindred complaints, enable one to be independent of nauseous drugs, vegetable extracts, or medicinal herbs of any kind. I do not expect, although we know, as Seneca puts it, "the beaten track is the most dangerous," that man will suddenly alter his diet from meat to fruit, and, if he did, neither should I consider it expedient, for progress is a plant of slow growth; yet, as a fact, chemical science truly says, "Man may live entirely upon fruits, and in better health than the majority of mankind now enjoy." In conjunction with pure wholemeal bread, fresh fruit at any time and at either meal forms a dish fit for a king. To those who do not unfortunately enjoy the best of health, to those who are continually out of sorts, and who are not only low-spirited but scared with "presentiments" of an imaginary and evil kind, I say the remedy is in your own hands, since a diet through the summer season based upon a liberal use of fruit at every meal will assuredly effect a cure. In the delicious Strawberry we have a case in point. Partaken of regularly and at meal time only, for they are rich in mucilage, pectine, sugar, citric, malic acid, and pure water, they not only purify but strengthen, and enable one to relish their food as they have never done before. It should be remembered that the juices of all fruits thin the blood, impart elasticity to the bones, and stave off, if they do not effectually prevent, the accumulation of earthy matter in the system.

In this country they are raised upon a very extensive scale, both under glass by the aid of heat, under frames, and in the open air. The first consignments that reach the English markets, however, come from France; but at their best, these Strawberries are very insipid and inferior, and in no way to be compared to those home-grown. After these consignments, we have our own from the Southampton districts, where they are raised by the ton, then come the supplies from Sandwich, Swanley, and numerous parts of Kent. The Middlesex growers, though a little later, are in the habit of producing some of the finest samples of outdoor fruit grown; this is mostly put up in shallow, flat punnets, holding, as a rule, a full pound each, and on account of their size, colour, and quality, generally meet a ready sale at very profitable rates. For flavour, I suppose, no variety can be said to equal the "British Queen;" and for solidity, size, colour, and popularity "Sir Joseph Paxton" stands without a rival. I might add that during the first week of the season choice fruit from the hothouse early in March has made as much as 1s. 6d. and 1s. 9d. per ounce first hand, or at the rate of 24s. and 28s. per pound. In the height of the season, for some weeks, so plentiful is the supply of this healthful fruit, that if anyone is wise, and will adopt the "Strawberry cure," he may do so to his heart's content, for when sound fresh fruit may be obtained at the rate of 3d. and 4d. per pound, there is no reason why the masses should not, at any rate, consume from two to three pounds daily, for whatever view we take of the suggestion, we shall find that it will, in conjunction with pure bread, be found to be cheaper, more nutritious, and certainly far more wholesome, especially during hot weather, than either beef or beer.—SAMPSON MORGAN, *Covent Garden*.—(Echo).

AMATEUR.—With this letter I send you a few forced Strawberries from our last forced plants for your opinion. I had the variety some years ago under the name of Amateur. We find it good for forcing as a mid-season variety. We have had larger fruits than those sent from pots,

but they are about the average size. As an outdoor Strawberry we find it wonderfully prolific, coming in about the same time as Dr. Hogg. Having heard so little of this good Strawberry must be my apology for bringing it under your notice.—G. R. ALLIS.

[Large and of good quality. This variety was raised by Mr. Bradley of Southwell, the raiser of Dr. Hogg and other good Strawberries.]

EARLY FRUITING STRAWBERRIES—LAXTON'S NOBLE.—I see in your "Notes and Gleanings," page 510, the earliest to ripen in the open air at Chiswick was Laxton's King of the Earlies, fit for use on the 18th inst. I have recommended all Laxton's specialties in Strawberries among surrounding gardeners, and, as in my own case, they find Noble not only the finest in quality but the earliest. I had fine fruits on the 10th inst. in the open air here, and without any eoddlng or forcing. Mr. Crehan, head gardener at Minella, while speaking warmly of Noble, gives the preference, as at Chiswick, to King of the Earlies as a first crop. I should like to ask correspondents what they have found the best dressing under the berries, everything considered. At Minella a

the less decayed part towards the base of the leaf small nematodes or eelworms with their eggs are abundant, such as are illustrated enlarged 160 diameters in the middle of the block. These minute threadworms are identical, or almost so, with similar worms found in Cucumber and Carnation plants. The nematodes can be easily traced into the bulbs. An exactly similar state of things exists in one form of disease in Lilies. Whether the fungus named *Ovularia elliptica* by Mr. Berkeley is able to attack Tulips is more than I can say; all I can say is I could find nothing like an *Ovularia* on the material sent to me. The putrid part of the leaf was covered with the fungus known as *Polyaetis vulgaris*, a common fungus on decayed vegetable matter. It does not cause disease, but grows on dying tissues. An illustration of the *Polyaetis* from the Tulip is illustrated on the right hand of fig. 75. Its spores are not half the size of the reported spores of the *Ovularia*. *Polyaetis vulgaris* grows on diseased Lilies exactly in the same style as in the growth on Tulips. My idea is the abundant nematodes which

Fig. 75.—TULIP DISEASE.

preference is given above all else to dried or spent Hops; with rain or sunshine nothing seems to have so many advantages, and slugs and snails seem to avoid the covering.—W. J. MURPHY, *Clonmel*.

[Dishes of both these varieties were gathered on the same day at Chiswick, Noble being much the larger, but King of the Earlies superior in quality.]

TULIP DISEASE.

TULIPS this year appear in some places to be attacked by a disease identical with one form of disease in Lilies, for it must not be assumed that certain plants are only killed by one special disease. The accompanying illustration, fig. 75, shows on the left a Tulip leaf sent with other leaves and bulbs for examination by Dr. Hogg. The illustration does not show part of a leaf only, but an entire leaf. The upper portion tinted with a dark shade is putrescent with decay. It will be noticed that the lines of putrescence run downwards towards the bulb. Within the thoroughly decayed part of the leaf nothing can be detected, but in

live and breed within the tissues of the leaf are the cause of this form of disease in Tulips; that they agree with similar nematodes found in Lilies, Onions, Carnations, Cucumbers, corn, &c.; and that the *Polyaetis* plays a mere secondary part, just as it does in Cucumbers, Lilies, and other plants. Three eggs of the eelworms are shown in the illustration with the yet unborn worms within the eggs. These infant worms move restlessly about within the eggs, and rock them from side to side. At length, when the contained nematodes are ready for birth, the thin shells split open and the eelworms emerge. Dr. Hogg reports that he has large beds of Tulips completely destroyed, and that the disease is spreading so rapidly that there will soon be no foliage left to nourish the new bulbs which are now being formed. The eelworms appear to be derived from the ground; they would probably get into the old bulb from the ground and work their way from the bulb to the tips of the leaves. When the leaves fall into putridity the eelworms reach the ground once more. The "gumming" of harvested bulbs in the winter and spring is caused by nematodes within the bulbs; the eelworms bite minute pieces from

the interior substance of the bulbs, and this starts the gumming. Eel-worms are easily killed in the ground by any slightly corrosive solution. The worms are often conveyed to greenhouses in infested water; sometimes, too, they fall in rain.—WORTHINGTON G. SMITH, *Dunstable*.

ROYAL HORTICULTURAL SOCIETY.

JUNE 26TH.

PÆONIES, Irises, hardy flowers, Pelargoniums, Tuberous Begonias, and Orchids formed the principal groups in the Drill Hall on Tuesday last, the greater portion of the available space being filled, but the meeting was less interesting than the preceding one.

FRUIT COMMITTEE.—Present, Dr. Robert Hogg in the chair, and Messrs. John Lee, Philip Crowley, R. D. Blackmore, Joseph Cheal, G. W. Cummins, Sidney Ford, T. Francis Rivers, William Warren, W. Marshall, W. Denning, Charles Ross, Harry J. Veitch, T. J. Saltmarsh, G. Norman, J. Wright, and J. Willard.

Early Strawberries, a new Grape, and new Melons were placed on the table for examination. The first Melon cut was from Mr. Benwell, Cobham, a small fruit decidedly overripe, and on that account was passed. Mr. Gleeson, Clumber, sent a handsome and well grown fruit of his seedling that was exhibited at the last meeting, and described in our report on page 492. Its superior appearance and sweetness led the Committee to record it as a good one for market purposes, but not equal to Hero of Lockinge in flavour, and that record was unanimously confirmed on the present occasion. Mr. Alfred James, gardener to Rev. G. Coventry, Woolstone Rectory, Cheltenham, sent fruits of a medium sized handsomely netted Melon, the result of a cross between Hero of Lockinge and Blenheim Orange. The flesh is scarlet, but the quality, though good, was not considered equal to existing varieties; the fruits, however, did not appear to be in the best condition, and were decaying round the stalk. Mr. William Hüssey, Hains Hill, Twyford, sent a wire Melon rest—a wire skeleton hat-shaped contrivance for suspension and holding the fruit; a larger size would be required for fruit like Mr. Gleeson's. It was passed by the Committee. Mr. Ross, Welford, sent his new Grape Mrs. Eyre. It is a seedling from the Black Monukka. The berries are large, oval-shaped, borne on thin footstalks, greenish-white, but had a suspicion of sourness, as if not fully ripe. As a Vine is fruiting at Chiswick the Committee deferred their decision till an inspection of it when the crop is ripe.

Mr. George Paul was accorded a vote of thanks for bunches of fruit of Laxton's Noble Strawberry. A dish of splendid fruit of it was also sent from Chiswick. The fruits are indeed noble in appearance, very early, and though not rich are of good quality, and the certificate awarded last year was considered to be well merited. This variety is sure to be extensively grown. King of the Earlies (Laxton) was also exhibited and highly approved. The plants bear medium-sized, well-coloured, and richly flavoured fruits abundantly. It was also regarded as having been properly certificated, and plants will find their way into many gardens. Lieutenant and Admiral were also placed on the table, but would not bear examination after the two first referred to; but three fruits of Crown Prince, large, symmetrical, and handsome, indicated this to be a variety of promise, and will be looked for again. It was introduced to Chiswick by Mr. J. Smith of Mentmore.

FLORAL COMMITTEE.—Present, G. F. Wilson, Esq., in the chair, and Messrs. J. Laing, W. Goldring, H. Herbst, W. Bates, G. Paul, W. Holmes, R. Dean, T. Baines, C. Noble, H. M. Pollett, J. O. Brien, G. Duffield, E. Hill, B. Wynne, A. J. Lendy, Rev. M. Wilks, and Dr. M. T. Masters.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking (gardener, Mr. Bickerstaffe), had a small group of Orchids, comprising a wonderfully fine plant of *Dendrobium Bensoniæ*, with seven long growths densely crowded with flowers, the white sepals and petals contrasting with the gold-centred lip in which the two black dots stand out boldly. Three plants of *Masdevallia Harryana* Bull's Blood also came from Burford Lodge, each having several large intensely rich flowers, and *Cattleya Mossiæ Reineckiana* had five handsome flowers, the sepals and petals white, with a crimson-veined lip. F. G. Tautz, Esq., Studley House, Goldhawk Road, Hammersmith (gardener, Mr. J. C. Cowley), showed several interesting Orchids, amongst which, in addition to the *Epidendrum* certificated, were the following:—An uncommonly good variety of *Cattleya Acklandiæ*, with large finely spotted flowers; *Saccolabium Rheedii*, having small white flowers spotted with mauve in a dense spike; *Acanthophippium striatum*, the creamy tinted flowers striped with crimson; and two curiosities—namely, *Ornithocephalus grandiflorum* and *Physosiphon Loddigesi*, which, with the *Epidendrum*, are described in the Orchid column. G. T. White, Esq., Drayton Villa, Winchmore Hill, sent flowers of two *Brassias*, and Messrs. H. Low and Co., Clapton, exhibited a pretty group of Orchids and Ferns, comprising fine varieties of *Cattleya Mendeli* and *gigas*; *Cypripedium concolor*, pale; *Regnieri*, yellow, with small dots; the new *C. bellatulum* in several varieties; *C. Laurenceanum*, *Lælia purpurata*, *Vandas teres* and *Roxburghi*, and *Dendrobium suavissimum*.

The Rev. W. Wilks, Shirley Vicarage, Croydon, sent a collection of "Shirley Poppies," representing numerous beautiful varieties, and a remarkable strain of seed described as having been obtained by selection from the Field Poppy, *Papaver Rhœas*. We have previously referred to the range of soft and rich colours in these Poppies, and an illustration was given on p. 367, Oct. 21, 1886, of the principal variations in the markings. In some the colouring is confined to the margin with a light centre, in others there is a pale or white edge to brighter body colours, and all are

handsome. From pure white to blush, pink, and scarlet the intermediate shades are innumerable (vote of thanks). G. F. Wilson, Esq., F.R.S., Weybridge, exhibited several interesting plants and flowers, comprising an *Anemone* allied to *A. polyanthos* with white flowers and large leaves divided in a somewhat trifoliate manner; *Campanula* G. F. Wilson, raised by Mr. Isaac Anderson-Henry, a dwarf variety, having deep blue shallow cup-shaped flowers; the magnificent *Cereus Alice Wilson*, one of the hybrids raised by the late Mr. Hovey, and remarkable for the size and rich crimson colouring of the flowers; and *Milla laxa* with mauve flowers in tall loose heads (vote of thanks). Mr. C. Ross, Pendell Court Gardens, Bletchingley, brought flowers of *Aristolochia trilobata*, large, veined with dull reddish purple on a pale ground (vote of thanks).

Messrs. J. Veitch & Sons, Chelsea, exhibited some of their new greenhouse *Rhododendrons*, one of which, *Hippolyta*, was certificated; the others were *Portia*, pale yellow, from *Taylori* crossed with *Teysmanni*; and *Juliet*, large buff yellow flowers of good shape, from *Taylori* crossed with *Teysmanni*. Flowers were also sent of the typical *R. Teysmanni*, having yellow flowers and reflexed segments; the fine yellow *Queen of the Yellows*, the red multicolor var. *Curtisi*, and the well-known *Taylori*. From the same firm came a group of hardy shrubs, which in addition to those certificated included some distinct Japanese Maples; *Philesia buxiflora*, with small *Lapageria*-like flowers; *Elaeagnus pungens variegata*, having neat foliage; *Escallonia macrantha sanguinea*, the flowers bright red instead of crimson; *Raphiolepis ovata*, *Robinia hispida*, and the white-flowered *Escallonia exoniensis*.

Messrs. Paul & Son, Cheshunt, had a choice group of alpine and other hardy plants, a cultural commendation being awarded for a good specimen of *Phyteuma comosum*, grown in a pot. A large collection of handsome *Pæonies* also came from the same nursery. Mr. C. Turner, Slough, sent a group of show, fancy, and decorative *Pelargoniums*, and besides the two certificated there were many handsome varieties. Messrs. J. Laing & Sons, Forest Hill, contributed an extensive group of single and double Tuberous *Begonias* in all the brilliant colours characteristic of the Stanstead Park varieties (silver medal). Messrs. Kelway & Son, Langport, filled one side of a table the whole length of the hall with massive double and single *Pæonies*, *Pyrethrums*, stately *Delphiniums*, and *Gaillardias*, and seven certificates were awarded, besides a silver-gilt medal. Mr. J. Walker, Whitton, had a most beautiful and tastefully arranged collection of *Irises* and *Pæonies*, with the white *Gladiolus Colvili* albus, all of which are now grown so extensively for market (silver-gilt medal). Mr. T. S. Ware, Tottenham, showed a handsome group of hardy flowers, *Lilies*, *Irises*, and *Pæonies* predominating (silver medal), and Messrs. H. Cannell & Sons, Swanley, sent a group of Tuberous *Begonia* plants, with a box of select flowers, chiefly double varieties. Messrs. E. Collins & Sons, Willesden Junction, showed two large plants of *Carnation Gloire de Nancy* with massive full white flowers, and from Chiswick came plants of *Pelargoniums zonale* and *inquians*, interesting as two of the earlier forms from which the modern Zonal *Pelargoniums* have been derived.

CERTIFICATED PLANTS.

Rhododendron Hippolyta (J. Veitch & Sons).—The several interesting hybrids obtained from crosses in which *R. Teysmanni* and *R. multicolor* var. *Curtisi* have been employed as parents have been previously noted, and the above is one from seed borne by the last named crossed with *Queen of Yellows*, a fine yellow variety, also a seedling secured before at Chelsea. The flowers are of moderate size, neat, and partaking of the *Curtisi* characters; they are borne in a compact head, and the plant appears to be of good habit.

Cæsalpinia japonica (J. Veitch & Sons).—Many *Cæsalpinias* are known, but they are mostly trees, natives of tropical countries, requiring to be cultivated in stoves, or at least in warm conservatories in this country; but *C. japonica* is a native of Japan, and would, no doubt, be found as hardy in many districts of England as it is at the Coombe Wood nursery. The leaves are pinnate, the pinnae small, narrow, and bright green, the bright yellow flowers being produced in erect racemes 8 or 9 inches long.

Daphniphyllum glaucescens (J. Veitch & Sons).—This also is a Japanese plant, an evergreen shrub found in the centre and northern parts of Japan, where it grows to the height of 8 or 9 feet, and compact in habit. At Coombe Wood it succeeds well, and at first glance it might be taken for a *Rhododendron* with exceptionally beautiful foliage. The leaves are elliptical, about 6 inches long and 2½ inches in the centre, of a soft pale green on the upper surface, with a glaucescent under surface, the petioles and midribs being of a deep red colour, and somewhat of this tint is seen in the bark. As an ornamental shrub, for its foliage alone, this is a distinct acquisition, and novelties amongst shrubs are by no means numerous.

Eulalia japonica gracillima (J. Veitch & Sons).—A slender and exceedingly graceful plant with narrow arching green leaves 3 or 4 feet high. For grouping this plant is most valuable, and arranged as it was with green and red-leaved Japanese Maples, the *Daphniphyllum*, and other shrubs, it had a fine appearance.

Rose Striped Briar (Rev. H. H. D'Ombra).—This was certificated subject to its examination at Kew, apparently with the object of determining its correct name or giving it a fresh one—a very unusual course. It is a very pretty variety, judging by the one semi-double white and bright rosy crimson flower exhibited.

Calochortus venustus var. *citrinus* (T. S. Ware).—A distinct variety with bright clear yellow flowers, with a maroon blotch in the centre of each petal, and a few spots at the base.

Pelargonium Ambassador (C. Turner).—A charming variety of the fancy section, the flowers neat and rounded in shape, of an extremely soft pink shade, with a white centre.

Pelargonium Spotted Beauty (C. Turner).—One of the spotted decorative section with large well-formed flowers, the ground colour being a soft blush, the three lower petals having a reddish spot in the centre of each, the two upper having a rich maroon centre and a light edge.

Double Paronies (Kelway & Son).—*Cyclops*, very dark crimson, handsome; *Miss Salway*, white, with sulphur central petals; *Lady Carrington*, broad petals of a delicate flesh tint; *Maria Kelway*, pink guard petals, pink and white central petals; and *Agnes Mary Kelway*, soft blush with narrow sulphur tinted central petals.

Delphiniums (Kelway & Son).—*Bassanio*, single brilliant blue, white centre, tall compact spike; *Pigaro*, double deep blue, bronzy purple centre, bold and distinct.

Epidendrum atro-purpureum var. *Randi* (Sir T. Lawrence, Bart., M.P., and F. G. Tautz, Esq.).—This Orchid is described fully on page 534, in the Orchid column.

COUNCIL MEETING.—At the Council meeting held in the offices, 111, Victoria Street, on Tuesday afternoon, a report was read from the Fellows' Committee in regard to the arrangements for 1889, and it was decided to give publicity to the following notice:—"That the Council having now in hand the composition of the Fruit and Floral Committees for 1889 would be glad to receive suggestions from the general body of Fellows as to any Fellows of the Society whom they may consider to be suitable persons to serve on either Committee." Letters of thanks were read from the Royal Society, the Linnean Society, and the Society of Antiquaries for the contribution of flowers and foliage plants sent on the occasion of their respective annual soirées. A letter was read from the solicitors to the Society promising that the new by-laws, duly revised, should be put before the Council within a fortnight.

At the general meeting, Sir Trevor Lawrence, Bart., M.P., in the chair, thirty-two candidates were duly elected Fellows of the Society.

RAMIE OR RHEEA.

THE *Kew Bulletin* for June gives the following particulars concerning *Boehmeria nivea* var. *tenacissima*, together with several letters containing information on the manufacture.

The plant known under the several names of China Grass, Ramie, or Rhea, belongs to the natural order Urticaceæ, and hence it is not a Grass at all, but a species of Nettle, somewhat resembling in appearance and habit of growth the common Nettle of Europe.

The China Grass plant, first known and long cultivated by the Chinese under the name of Tchou Ma, is the *Boehmeria nivea* of botanists. The specific name, *nivea*, was given to it on account of the white appearance on the under side of the leaves. A plant called in Assam, Rhea, and in the Malay Islands, Ramie, was believed by Roxburgh to be distinct from the Tchou Ma of the Chinese, and it was named by this botanist *Boehmeria* (*Urtica*) *tenacissima*. In this plant there is an absence of the white-felted appearance on the under side of the leaves, so characteristic of the China Grass plant, but in all other respects the two plants are identical in their botanical characters.

For purposes of classification, the Tchou Ma, or China Grass plant, *Boehmeria nivea*, may be accepted as the typical species, and the Rhea or Ramie retained as a geographical variety of it, under the name of *Boehmeria nivea* var. *tenacissima*. This latter is sometimes known as the green-leaved China Grass, a name which may be conveniently retained for it.

The fibre yielded by these plants has been long recognised as pre-eminent amongst vegetable fibres for strength, fineness, and lustre. Hence numerous attempts have been made to cultivate them, and to prepare the fibre in large quantities for commercial purposes. The plants are exceedingly easy of cultivation, and thrive in all soils, but preference should be given to those of a light loamy character. It is essential that the climate be moist and stimulating, in order to produce abundant and frequent crops of stems. The plants may be raised from seed, but the more ready method is by root or stem cuttings. The roots being perennial, the stools become stronger and more vigorous every year, and from these fresh sets are easily obtained for extending the cultivation.

Numerous attempts have been made during the last ten years to extract the valuable fibre which exists in this plant. The experimental processes hitherto employed may be briefly classed as either mechanical or chemical. In the first, it has been sought to extract the fibre from the green stems, by means of rapidly revolving beaters attached to a drum driven by steam power. In some cases water is used to wash the fibre while under the beaters. The chief difficulty experienced in this method is the small quantity of fibre cleaned per day. This has enhanced the cost to such an extent as to render the process practically unremunerative. In the chemical processes, the Ramie stems are treated green or dry. The object sought is to treat the stems either under great pressure with steam or with chemicals, so as to dissolve the gum in which the individual fibres are immersed. After being thus treated, the fibres are easily detached from the stems by hand or by machinery, and are sent to market in the form of ribbons. The question of cost is here also very important, and it is felt, under present circumstances, that China Grass can only be satisfactorily grown and prepared where there is an abundance of cheap labour.

It is a fact universally known that the fibre of the China Grass is

one of the finest and strongest known. If a process could be devised that would extract and clean the fibre at a cheap rate, the results would prove of the greatest possible interest to all our tropical colonies. The China Grass plant can be grown as easily as the Sugarcane, but in spite of many years of continuous effort, the problem how to prepare the fibre on a large scale, and place it in the market at remunerative rates, is apparently still unsolved.

NOTES ON SUMMER TREATMENT.

THE months of June, July, and August is a busy time amongst growers of Chrysanthemums, but especially so where a large collection is cultivated with a view to exhibition, numbering from 400 to 600 plants, and at this time many other duties press heavily on gardeners. I am afraid during the time named many collections of plants, small as well as large, are spoilt through neglect at this season of the year. It is a mistake for any cultivator to attempt to grow too many plants. Far better would it be to grow fewer, that they might have all the necessary attention given them when required. One of the greatest mistakes made by beginners in Chrysanthemum culture is neglecting to place their plants into the largest pots soon enough. Often they are left until time can be found after the hedding-out has been completed, or sometimes it is the want of a sufficient number of pots that is the cause of delay. However that may be, failure may often be traced to this cause—delay in potting. All plants should be at once potted with the least possible delay. The pots must not be too large. Those 9 inches in diameter are best suited for the majority of single plants. Some weak-growing varieties, such, for instance, as *Princess Beatrice* among the incurved, and *Criterion* as a Japanese variety, may have pots 1 inch less in size than for the bulk of the sorts. It is a mistake to place weak-growing varieties in pots which they never can properly fill with roots, and they can never be safely supplied with stimulating foods with the same chance of success as when the pots occupied are full of healthy roots. The constant application of water renders the soil sour and not at all adapted to the requirements of weakly rooted varieties. Where larger sizes of pots are in store than those named, it is much better to place two plants in one pot; a great saving of space and time is thus gained, and the results are more satisfactory.

The soil used should be tolerably rich, as the Chrysanthemum, having such a short season of growth, requires the soil of a good character wherein its work may be quickly effected. Where the soil is heavy means should be taken to lighten it by the addition of partly decayed leaves, wood ashes, charcoal, and sand. The plants should be potted firmly, again making allowance for the nature of the soil; that of a heavy class will not require so much firming as the lighter sort. The last-named cannot easily be rammed too firmly into the pots at the last shift. The growth then is made in a much more solid manner. It may not be so quick at first, but the quality of the wood is more easily gained by firm potting than by potting loosely, which produces gross growth, all other conditions favourable; but the quality of the flowers produced, notably the incurved section, is never so high as when firm potting is practised. The blooms may be as large, possibly larger, in diameter, but they lack those most essential points which stand almost first in an incurved bloom—depth and solidity—of course taking into consideration that the bloom is of reasonable size.

The next detail in successful Chrysanthemum culture, where large blooms are required, is the manipulation of the shoots at critical times. I have seen many collections of plants spoilt at an early stage of their growth through neglect or ignorance in dealing with the branches in a manner best calculated to induce satisfactory results. Where plants are grown by what is generally termed the natural way of training them—that is, allowing them to grow away from the cutting without topping the main shoot or leader, the first natural break into additional branches generally takes place from the middle of May to the same time in June, varying according somewhat to the time the cuttings were struck and the manner in which they have been cultivated. The "first break," as it is called, is caused by the formation of a flower bud in the point of the leader or stem. During the time this is forming growth at that point is checked. Nature provides for this check by the growth of an additional shoot from each node. Now is the time when the object for which the plants are being cultivated should be declared. If the finest flowers are the object, the growths named must be restricted to three of the strongest, which are generally those nearest the point where the flower had formed. Remove all other shoots but those chosen to produce the number of flowers required as soon as they can be handled with safety, pinching out at the same time the flower bud formed.

Secure to support the new growths as need be, remembering that loss of any of these means a loss of flowers. Daily attention is required at this time to see that none is broken through being tied too tightly or other causes. The best means of securing the growths is that of erecting a temporary trellis of wires, stakes, or other contrivance most convenient to the cultivator, and sufficiently high to allow for the whole summer's growth. Such trellis should be erected in the place the plants are to

occupy during their stay outside, say from the early part of June to the first or second week in October at the latest in almost any district. The method of fastening the shoots to the trellis is this:—In each pot place a stake sufficiently long to allow the whole season's growth to be fastened to it. Fix the stake midway between the plant and the side of the pot, as in this manner the risk of damage to the roots by the insertion is not so great as by placing the stake close to the stem of the plant. Secure this stake to the trellis cross supports, which keeps all steady. To this stake the centre growth is tied, the shoot on each side of the central one should be tied to upright small stakes fastened to the cross rails temporary. When housing the plants the side branches are tied loosely to the centre stake. By spreading out the branches in this manner sturdy growth is made during the summer, which becomes more solidified as it proceeds, owing to the thorough light and air each separate branch obtains over the plan of tying the three stems to one centre stake. Disbudding the shoots or lateral branches is more easily accomplished in this manner, and mildew is not so liable to attack the leaves as it is when the leaves are huddled together.

The position the plants occupy during the summer is important. Some growers are more favoured in this than others. What is required is an open space where the plants will receive the whole day's sun and still be protected from east, north, and south-westerly winds. The two former cause a serious check to the tender growth in the early part of the year when the plants are newly placed into their largest pots, as about that time winds are prevalent. Although the plants may not be so seriously injured as to be broken, yet the leaves are often bruised, which must give a check to the plants. Cold winds also prevent that quick start into new growth after potting so desirable to establish the plants in their new quarters. We generally arrange one row on each side of a kitchen garden path, as there they obtain the whole sun's influence. Where the plants must stand in a block good space must be allowed between the rows.

Watering the plants at this season of the year is an important point in the successful cultivation of Chrysanthemums. After potting too much water can easily be given to the roots, which causes the soil to become sour and stagnant before the roots can possibly have taken possession of it. If the soil was moist when potting was performed the plants will not require any to the roots for four or five days, except the sun be very powerful or a strong drying wind prevails. Much better is it to syringe the leaves of the plants twice daily until new roots are running into the fresh compost. Afterwards much care should be exercised in allowing sufficient water, and no more. Retentive soils are much worse to deal with than are light soils. The former needs more exactitude in supplying the roots with water only when needed. Rapping the sides of the pots with the knuckles is the surest means of judging of the requirements. The size of the pots, vigour of each variety, and position the plants occupy all influence the supply. During hot days in summer three times is not too often to apply water to the roots in some instances, while others will need no more than two applications. The quality of the water is important. Much may be done to minimise the difficulties contained in some kinds of water to the proper development of plant life. Where it comes direct from companies' waterpipes it should be allowed to stand in the sun some time before being used. In any other way a chill is given to the roots by applying it direct from the pipes, and is a great cause of the spread of mildew. Water which contains a large percentage of carbonate of lime in solution is bad for the plants, and should be softened before using by some process, such as by dissolving common washing soda at the rate of a quarter of a pound to 36 gallons of water, or by the use of anticalcaire, more commonly called milk of lime. To 250 gallons of water add 1 lb. of the latter, allowing it to stand for twenty-four hours, when the chalk will be precipitated to the bottom of the tank, and the water will be rendered soft. When a supply of rain water is obtainable much less trouble is necessary, and better results obtainable generally. During bright weather the plants should be vigorously syringed in the evening of such a day. It cleanses the leaves from dust and refreshes the plants after a hot day.

Insects are particularly troublesome this season, rendering a sharper outlook necessary, and the applying of prompt measures to secure quick eradication, which is easily done if time is taken by the forelock, procrastination being not tolerated. Green and black fly are easily got rid of by dusting the parts affected with tobacco powder; mildew by the use of flowers of sulphur sprinkled on the affected parts twice—if once is not enough. During the month of June the Celery fly becomes most persistent in its endeavours to destroy the foliage. This is a small grub which is secreted between the two skins of the leaves, burrowing away until the leaves are so disfigured in appearance that their complete removal is requisite. The leaves nearest the soil are those generally first attacked, and if not at once checked, which can only be done by hand-picking, the whole stem for 2 feet upwards is quickly destroyed in appearance by the loss of foliage. Earwigs, too, have commenced their depredations sooner this year than common; they secrete themselves amongst the young leaves at the point of the main stems, burying themselves out of sight by eating away the heart of each point. The moment a leaf at the point shows signs of curling it is a sure indication of an intruder which must be caught and killed.—E. MOLYNEUX.

ROYAL METEOROLOGICAL SOCIETY.

THE concluding meeting of this Society for the present session was held on Wednesday evening, the 20th instant, at the Institution of Civil

Engineers, 25, Great George Street, Westminster. Dr. W. Marcet, F.R.S., President, in the chair.

Mr. F. de B. Collenette, L.R.C.P., M.R.C.S.; Mr. J. Ewart, M.R.C.S.; Mr. F. A. Velschow, and Mr. J. T. Wills, F.R.G.S., were elected Fellows of the Society.

The following papers were read:—

(1), "First Report of the Thunderstorm Committee." This report deals with the photographs of lightning flashes, some sixty in number, which had been received by the Society. From the evidence now obtained it appears that lightning assumes various typical forms under conditions which are at present unknown. The Committee consider that the lightning flashes may be arranged under the following types:—1, stream; 2, sinuous; 3, ramified; 4, meandering; 5, beaded or chapletted; and 6, ribbon lightning. In one of the photographs there is a dark flash of the same character as the bright flashes, but the Committee defer offering any explanation of the same until they get further examples of dark flashes. As the thunderstorm season is now coming on the Committee propose to publish their report at once, along with some reproductions of the photographs by the autotype process, in order that observers may be prepared to notice the various forms of lightning.

(2), "The Cold Period from September, 1887, to May, 1888," by Mr. C. Harding, F.R.Met.Soc. The mean temperature for each of the nine months from September, 1887, to May, 1888, was below the average, whilst in the case of October there has been no corresponding month as cold during the last half century, and only three colder Aprils. In London the mean temperature for the period was only 42.4°, and there has been no similarly low mean for the corresponding period since 1854-5, which will be remembered as the time of the Crimean war, and only three equally cold periods during the last fifty years. The temperature of the soil at Greenwich at 3 feet below the surface was below the average in each month from October to April. In October and April the temperature at this depth was the coldest on record, observations being available for the last forty-two years, and in November it was the coldest for thirty-seven years.

(3), "Observations on Cloud Movements near the Equator, and on the General Character of the Weather in the 'Doldrums,'" by Hon. R. Abercromby, F.R.Met.Soc. The author gives the results of observations made during four voyages across the equator and the "Doldrums," with special reference to the motion of clouds at various levels. Two voyages were across the Indian Ocean during the season of the north-west monsoon, and two across the Atlantic in the months of July and December. The nature of the general circulation of the atmosphere near the "Doldrums" is discussed as regards the theory that the trades, after meeting, rise and fall back on themselves, or, according to the suggestion of Maury, that the trades interlace and cross the equator, or as following the analogy of Dr. Vettin's experiments on smoke. It is shown that the materials at present available are insufficient to form a definite conclusion, but details are given of the general character of the weather and of the squalls in the "Doldrums," with a view of showing what kind of observations are required to solve this important problem. The old idea of a deep trade—with a high opposite current flowing overhead—is certainly erroneous, for there is always a regular vertical succession of the upper currents as we ascend, according to the hemisphere.

PLANTS OF THE ISLAND OF PORTO-RICO.

THE interior of the island is very charming, with its multitude of rivulets, rivers, Coffee plantations, and hills, still covered in some places with the *Cecrelia odorata*, *Dacryodes hexandra*, the *Mimusops*, the *Hedwigia balsamifera*, and many other valuable trees of the primitive flora, with a variety of Ferns, Orchideæ and graceful Palms raising their crowns high above the dense underwood, which reveals the loveliest and brightest flowers in wild profusion, filling the air with their perfumes.

It is a source of pleasure to behold along the banks of rivulets the graceful *Jambosa vulgaris*, *Bambusa*, *Piper caudatum*, *Bixa orellana*, several varieties of Citrus and the *Heliconia caribea*, the plant of the poets, showing its beautiful racemose scarlet flowers, and inviting the traveller to rest. The *Hibiscus liliaceus* and the *Bromelia Ananas* grow side by side, protecting plantations of Maize, Rice, Potatoes, and pastures of several species of indigenous Gramineæ, which never grow so luxuriously as the exotics, giving room for the intrusion of Poppies, Vervain, and other flowering plants, so that the landscape of the fields is more beautiful than that of the coasts, and resembles somewhat that of Southern Europe. On the hill slopes and ravines are the great plantations of *Coffea arabica*, protected by other taller forms of vegetation, among them the fruit-bearing tree *Mimosa Inga*. In the same formation the *Theobroma Cacao* is also cultivated, but not to the extent that it ought to be. The tree grows there quickly, and the product is of the best quality. Several species of Plantain and Banana, Potatoes, Rice, Corn, Yams, Maranta, Ginger, Pignut, Oriental Oily Grain, and other economic plants are cultivated all through this fertile zone, producing food sufficient for the consumption of its inhabitants. This explains in part the increase of the population, which is to-day about 800,000, the great majority white.

The *Caladium aquatile* and the *Arum arboreum*, growing wild, the first at the margin of the streams, are also eaten by the poorer people. In the hills bordering the southern coast towards Salinas and Coamo, the *Zamia intermedia* grows wild with its feculent rhizome. This is

another help for the poorer classes, who extract the starch by the same process as used for the Manihot, eating the pulp the same as Casabe.

Lately, it has been stated that the leaves and buds of this plant when eaten by cattle produce a kind of paralysis of the extremities. I do not know to what extent this is truth, but I know positively that the rhizome is as poisonous as that of the "bitter cassava," and that the acrid principle is got rid of by repeatedly washing the pulp.

The Cocoa-nut Tree (*Cocos nucifera*) is met with all over the island, but it is more abundant on the marine zone, or litoral, where the fruit is collected and shipped. The oil is extracted, and it is of some economical importance. In moist places semi-aquatic plants will be seen growing, as the *Echinodorus cordifolius*, *Nymphaea crenata*, and other pretty ones. Besides the white native Rose, the common Rose, both red and white, has been long introduced, with many more exotic flowering plants now abundantly cultivated in gardens. Besides these almost all the garden plants of colder climates grow or are cultivated wherever there is a plentiful supply of water. Several new species of handsome Ferns are found on the highest ridges, as between Maunabo and Jabucoa on the Sierra de la Pandura, among granitic rock, forming a vegetation peculiar to these regions.—(*Pharmaceutical Journal*.)

ERICA SPECIOSA.

A PARTICULARLY handsome summer-flowering Heath is *Erica speciosa* when seen at its best, but unfortunately this is too seldom now,

FIG. 76.—ERICA SPECIOSA.

as, with many other beautiful members of the same genus, it has gone out of favour because it requires rather more attention than a Zonal Pelargonium. The plant is of bold distinct habit, the leaves deep green, slightly hairy, and arranged closely on the branches in threes. The flowers (fig. 76) are generally produced three or four together from the little branchlets, the tubular corollas often exceeding an inch in length, rich red in colour except a tinge of bright green at the tips. It requires similar treatment to other hardwooded Heaths, a little extra care in the supply of water being advisable.

GREVILLEA ROBUSTA IN CEYLON.

FAMILIAR as this plant is in British gardens, it is rarely seen in flower, but it appears from the following note in "The Tropical Agriculturist" to be particularly happy in Ceylon:—

"We have said that this tree is 'distinguished by its large masses of comb-shaped, orange coloured flowers,' and these words are necessary to a proper description of the very striking *Grevillea* flowers, forming such

a contrast of vivid colour to the wealth of green, graceful, Fern-like foliage with which the tree is clothed. *Grevillea robusta* is one of the most ornamental as well as one of the most useful sylvan gifts which Australia has bestowed on Ceylon. Here the tree does not compete with the Blue Gum in rapidity of upward growth, but in thickness of stem in an equal number of years it exceeds most of the Eucalypti. Many of the latter which have thick stems within a few feet of the ground have a habit of tapering away almost to a point as they get up higher and higher, some of them attaining 100 feet, or even 150 in ten years. In its own native habitat (New South Wales and Queensland), the *Grevillea* tree (the 'Silky Oak' of the settlers), attains on rich alluvial banks of rivers a height of 100 feet. Specimens fourteen years old in Ceylon are about 60 feet in height, judging by the eye, but careful measurements may correct this estimate. Of course the trees in the loose, accumulated soil on the sides of the Lorne Road, to which we alluded as having become fine trees in seven years, are in very favourable circumstances for rapid growth. But like most other trees they ought to be planted in groves and pretty close together to secure perfectly straight trees. A good many of the trees in the single row along the Lorne Road have indulged in some curious bends and contortions under the influence of winds and loose soil. But we suppose that even crooked timber is useful for 'knees,' wheel tires, and so forth. We may repeat that in Australia the timber of *Grevillea robusta* is the favourite for staves of tallow casks. It might, therefore, be useful in Ceylon for oilcasks. The genus to which this tree of equally beautiful foliage and inflorescence belongs, is described as 'very large, comprising some beautiful and interesting Australian flowering shrubs and trees. Nearly 200 species have been described, all, with one or two exceptions, indigenous to Australia, and two-thirds of that number belong to Victoria. They are chiefly admired and cultivated for their flowers; some of them are of a dwarf, Heath-like habit; others are trees of considerable size.' Amongst the Eucalypti which have made the best growth at Hakgala, and on poor soil, is *E. marginata*, the grand jarrah, which gives the finest timber of all the species, vieing with oak in quality and with mahogany in beauty of colour and polish. This noble and useful tree seems to take more kindly to the Ceylon hill regions than most of the Eucalypti. The Red Gum (*E. rostrata*), with its clean stems and elegant drooping foliage is very beautiful, but it seems difficult to grow, and has an unfortunate habit of dividing into two or more stems. The most ready grower is the Blue Gum (*E. globulus*), and the more we learn about the timber of this tree, the more favourable is our impression, if only the timber is well seasoned. Darkened with oil the wood resembles fine sapu."

PRACTICE AND SCIENCE.

A RECOGNISED authority on Rose culture writing about feeding Roses, affords the following text:—"Liquid or any other manure is only of use when the plant is in full growth and health; at all other times it is poison." This text is good for a long and profitable discourse, but it need only serve here as an introduction. Are we in our artificial modes of plant culture, propagating, sowing, manuring, &c., sufficiently scientific or not? This is not begging a question, because all practical culture is more or less scientific. Taking the subject of manuring, can we say that the customary methods are the only correct ones, or even the most correct? One can sympathise with the worried gardener in his everyday vocation, for as he looks around his stocked houses and borders the feeling that "he knows enough" is sure to arise. But is there another side to the question? There is an old saying that "one side of a story holds good till the other is told." That saying opens out the side of a contention which may be said to be antagonistic to the experience of generations. Who is so likely to guide us and decide for us in our attempts to vie with Nature as Nature herself? These are Nature's methods and agents of plant culture in a manurial sense: Supplying carbonic acid gas for absorption by the leaves, with oxygen, hydrogen, carbon, and nitrogen for absorption by the roots; providing earths, silicates, and other mineral substances, such as sulphur, iron and alkaline salts, from which the various compound elements in the elaborated plant are derived; the unceasing round of growth, fructification, decay, and decomposition ever going on in the vegetable world, serving to balance the work. Does it ever strike observers how exactly true the provisions in the latter respect are? The air we breathe would shortly become unbreathable were it not for the plants, trees, grasses, and flowers. The supply of the food we eat would soon be at an end if its restoration to earth was not provided for, there to renew its existence, or stimulate that of other and succeeding races. Nature sows seeds by an unfailing and unerring plan. She covers them with the sweetest top-dressings, or deposits them gently in the shaded and moist places most suitable for their reception.

On the other hand, Nature does not teach us to foul the soil, to clog it, to stint or limit the free passage of air and of water. Nowhere, except by accident, are decomposing animal and vegetable matters brought into immediate contact with the roots of plants. Our artificial methods of culture, in so far as they relate to the best mediums for root action and root ramification, are considerably at fault if the foregoing reasoning is accurate. Perhaps in no particular lines are they more so than in those of sweetness and porosity of the soil. We compound potting and rooting materials that serve to generate or develop fungoid growths, parasitical organisms, and stagnation of root action. Will any of the readers of this paper ask themselves if they can recall what has been the result on the first succeeding crop, when they have been led to apply a heavy dressing of freshly slaked lime to a plot of manure-

sick soil? Foliage was rampant, was it not? The liberation of formerly inert elements was too excessive, hence the results.

I maintain that in ordinary pot culture we can avoid all these excesses. Why should we insist on using leaf mould to the extent we do? If we must add elements that are of a manurial nature we should see that they are not such as will foul the soil. The most intelligent and enterprising gardeners of the present day are more than ever convinced of the truth of these assertions. Charcoal and burnt earth for giving sweetness and porosity are consequently more than ever in demand; and where the need of such elements as phosphates exists these elements are supplied in a more natural and a more simple form than they were formerly. That fertilising moss is a suitable medium for plant culture has been proved. There is nothing new or uncommon in the practice of placing balls of moss round the roots of plants. One of the largest collections of plants in London for open-air bedding and decorative purposes is being so treated this season. That anyone should have succeeded in causing moss to take up and retain the more frequently required elements for stimulating the growth of plants is a fact worth recording. That moss—sphagnum or any other variety—has of itself an elasticity, and that it gives lasting porosity and so affords free passage for air and water, is freely admitted by all who have used it. Sphagnum moss is expanded by fermentation, and charged when in that condition with the alkaline salts and nitrogen matters so necessary as plant stimulants. As an auxiliary to loam, or when used with equal proportions of it, it will be found all that is desired.—A. B. W.

KITCHEN GARDEN.

CAULIFLOWERS GOING BLIND.—This is a complaint well known to all who grow many Cauliflowers. The plants may have a good centre when planted out, and shortly afterwards it may be noticed that they have no centre, but are only composed of a few outer leaves. They are completely blind, and will never become of the slightest use. Many plants of Veitch's Autumn Giant have lately behaved in this way with us, while in another quarter of Eelipse very few indeed have been lost. We have noticed that when we persisted in dusting the plants frequently with lime or soot a blind plant is an exception, and the attention devoted to them in this way is not labour thrown away, but it occurs oftener in the spring and early summer months than now, and autumn plants are rarely effected, but should they be so dusting with soot and lime should begin as soon as it is noticed. Look over all quarters now, pull up the plants that have no centre, and place good plants in the vacancies. Unless this is done the crop will be very patchy and unprofitable.

SAVOYS.—We often hear of some being planted to form an early supply. This is a mistake. Early Savoys are rarely required and never desirable. We have had many of them, but the bulk of them were not used. They burst before winter, and now we never make an attempt to have early Savoys. They are not palatable until vegetables are becoming scarce, but from the middle of November onwards they are fit for any table, and it is for a supply beginning at that time that all should grow them. If seed is sown now of Little Wonder, the plants will head at the season named, and in no case should any be planted in their permanent quarters until the middle of July.

MINIATURE DRUMHEAD CABBAGE.—These are equally as hardy as Savoys, and they are certainly more agreeable, as they are of excellent flavour in the winter. Some grow the large Drumhead, but it is very coarse, not fit for a good table, and the miniature variety possesses all its properties except size, which is no recommendation. If these little Cabbages are put out at the same time as the Savoys, their owners will appreciate them before midwinter.

ENDIVE.—We see this in the markets now, but it is not a favourite in summer when the Lettuces are good and plentiful, and it only becomes a general favourite in the autumn. The Moss-curl is the best for autumn, and the Broad-leaved Batavian for winter. Sow a little of the former now, but a pinch of seed will produce as many plants as are needed at once, as Endive soon runs to seed in the summer months. The seed may be sown in a row or broadcast, covered to the depth of half an inch, and plant as soon as the seedlings are 2 inches high, keeping them 1 foot apart each way.

EARTHING EARLY CELERY.—The first Celery is now about 1 foot high. It will be in good order by August. Give it a thorough soaking of liquid manure and then earth it up a little. We break down some of the soil on each side of the trench, and then work it round the plants to the depth of 4 inches. Take a few of the short outer leaves off before earthing, and if well watered now it will not require any more, as the soil that is put over the roots will prevent their drying too much again. Give young late Celery plants abundance of water constantly, but do not plant them in trenches until the middle of July or later.

LARGE LEEKS.—Those who grow these for show generally have them of a fine size by August, but size is nothing unless they are well

blanched, and to effect this they must be earthed up. The early ones are ready for this now, and a good quantity of soil should be put to the stems at once. Water freely before earthing, and give them liquid frequently afterwards. They will take any amount of rich feeding.

PEAS.—We gathered our first Peas from plants raised and grown in the open on June 15th. Should the weather become dry thorough watering will be needed. Mulehng is also beneficial, the material being spread along each side of the rows, and almost anything will do, as the object is to retain the moisture at the roots. The mowings of grass if a little decayed answer capitably. All Peas should be staked before they fall to one side; and although Peas may be grown without the aid of stakes and by allowing them to rest on the ground, the pods are not so fine nor the crop so abundant in this way as when staked. Sow more seed to produce a supply about the middle of September, and in all cases practise the trench system so often advocated in this column.

KIDNEY BEANS.—Runners are sometimes grown without stakes, but it is not so profitable as when stakes are employed. If the stakes cannot be had from 6 feet to 8 feet high, use them 3 feet or 4 feet, so as to give them a little support at first. Very cheap and good stakes may often be had from odds and ends about saw mills. Runner Beans do not suffer so much as Peas from drought, but watering in dry weather benefits them, and if time and water can be spared they may have this attention. As a rule Runner Beans are sown too much together and too early, as the Beans are generally plentiful and good in August and September, but by October they are mostly over; but by sowing in July tender pods may be secured as late as October, or indeed sometimes in November. Dwarf Beans are the first to bear, and the whole of these should now have a quantity of earth drawn to the stems in the form of an earthing up. Immediately after this operation we have seen the plants turn a dark green colour from a previous pale yellow hue.

PLANTING BRUSSELS SPROUTS AND BROCCOLI.—These two useful winter and spring vegetables should be planted out as soon as possible. Broccoli may do a few weeks after this, but late-planted Sprouts never gain a useful size, and they should all be planted by the end of June.

EARLY POTATOES.—We are now digging very good Ashleafs from the open border, and where space is wanted urgently for other crops Potato digging should begin as soon as they are ready. They are so acceptable at this time that if not quite matured they will be very superior to the old tubers.

FRUIT FORCING.

VINES.—*Early Vines.*—Those from which the fruit has been cut must be well syringed every evening to preserve the old foliage as long as possible in a healthy condition, for when the foliage dies early from red spider or other cause second growth not unfrequently sets in when they ought to be going to rest. Admit air to the fullest possible extent, and maintain a moderate degree of moisture in the border, particularly at the surface, so as to keep the roots there instead of allowing it to become dry, and so causing them to descend in quest of moisture. A moderate extension of the laterals will not do any harm, but irregularities of growth, and particularly gross ones, should be checked by pinching or entirely removed.

Grapes Swelling.—Afford every encouragement; nothing helps so much as a genial condition of the atmosphere, which should be secured by a gentle warmth in the pipes, and sprinkling available surfaces in the morning and afternoon, particularly the latter, the border being mulehed with short rather fresh lumpy stable manure, additions being made from time to time so as to insure a supply of ammonia to the atmosphere and organic matter for washing into the soil each time water is required. The mulching should be kept moist. Avoid a close vitiated atmosphere, particularly in close dull weather. A little ventilation almost constantly at the top of the house will make all safe, but it is desirable to close the house in the afternoon, well damping at the same time, allowing the temperature to rise to 90° or 95°, and after the sun passes the west, or at six o'clock, provide a little ventilation at the top of the house. It will allow of a change of air taking place, prevent excessive deposition of moisture through the night, and the foliage will not be so nearly liable to be scorched should the sun act powerfully on it before the ventilation is increased, which it ought as soon as its rays act on the structure sufficiently to raise the temperature. The great cause of scorching is inattention to early morning ventilation. It will be sufficient to ensure a night temperature of 65°, and a day temperature of 70° to 75°, having recourse to artificial means if necessary. Commence increasing the ventilation between 70° and 75°, allowing it to advance to 80° or 85°, between which keep through the day, and close so as to rise as before stated to 90° to 95°. Allow a steady growth of the laterals, it keeps the roots active, but avoid overcrowding, not allowing the laterals on any account to interfere with the free access of light and air to the leaves that are elaborating and storing food in the buds at their base, those being the pruning buds. Afford full supplies of water or liquid manure as required. The outside borders should not be neglected where the rainfall is insufficient, and a mulehing of fresh lumpy stable manure will lessen evaporation without depriving the soil of the beneficial action of air, warmth, and the moisture of dew and rain.

Grapes Ripening.—Still continue a fair amount of atmospheric moisture, and give the inside borders, and outside as well if the weather be dry, a good soaking of tepid water or liquid manure, and muleh at once with some rather dry litter but short, 2 or 3 inches thick. This will mostly be sufficient for perfecting the Grapes. Directly they begin

to colour afford plenty of air, a little fire heat being essential to their higher perfection, especially in flavour, insuring a circulation of warm rather dry air, but allow the temperature to fall to 65° at night, otherwise securing by artificial means a temperature of 70° to 75°, and 80° to 85° through the day for Black Hamburgs and similar varieties, and Muscats should have a night temperature of 70° to 75°, 80° to 85° by day up to 90° or 95° from sun heat.

Grapes Stoning.—The weather we have had recently—dull and cold with occasional gleams of sun—is the worst that can be for scorching and scalding. The best means of preventing both is a rather high night temperature, early ventilation and free by day with a little at night. It is not desirable to close early at this critical period—the close of the stoning process; but do so carefully, and as the liability to scalding does not extend over more than a fortnight to three weeks particular attention should be given to ventilation. If the weather be very bright, and there is most to be dreaded on bright weather succeeding a dull and moist period, a slight shade over the roof lights is very beneficial. A double thickness of herring nets will afford all the shade required.

Late Houses.—Grapes to hang through the winter require more thinning than those not intended to keep for any lengthened period. The high and dry borders of modern culture do not receive as a rule anything like the quantity of water they require, especially inside borders. They should be well mulched and very liberally watered. Keep free from all gross laterals, but allow a little extension, always taking care not to allow any encroachment on the principal leaves, which to duly perform their offices must have full exposure to light. The thick-skinned varieties and Muscats like plenty of heat. Employ fire heat to insure a day temperature of 70° to 75°, and 65° at night. Through the day maintain by sun heat a temperature of 80° to 85° or 90°. Black Hamburgs need not be hurried. They will come on quite fast enough without artificial heat for the next two months, and when ripening as they should do, if they are to keep well by early September, fire heat can be given as necessary.

Pot Vines.—Those that have completed their growth should now have less moisture, syringing being discontinued, and the supply of water at the roots moderate, air being freely admitted, and afford the principal foliage all the light practicable.

FIGS.—**Early House.**—The first crop will be all gathered and more moisture in the atmosphere will be desirable, therefore resume syringing the trees twice daily and damping available surfaces whenever they become dry. Thinning the fruit for the second crop if plentiful must be free, reserving those which are nearest the base of the shoots. Tie in the growths to the trellis as they advance, stopping or removing such as are not required, regulating those retained so that they may receive the beneficial effects of light and air to mature them perfectly. Do not allow the trees to suffer by want of water; those in borders of limited extent will require water frequently, affording on every occasion liquid manure, or a little fertilising agent may be sprinkled on the border and washed in.

Fruit Ripening.—Where crops are ripening constantly maintain a free circulation of dry warm air, which is essential to Figs ripening perfectly. A moderate air moisture is, however, necessary for the benefit of the foliage, and, though less moisture in the soil is advisable when the fruit is ripening it must not be allowed to become parchingly dry or the trees will suffer. If necessary afford fire heat to maintain a night temperature of 65°, and 70° to 75° by day, and to admit a free circulation of air.

Trees in Pots.—Those required for early forcing must not be neglected in syringing, as the foliage must be kept clean and healthy, exposing the plants to light, and ventilate freely. Attend with regularity to the watering, supplying liquid manure on every occasion.

CUCUMBERS.—A few seeds may now be sown for late summer and early autumn supply of fruit. They will germinate and the seedlings be fit to plant out in about a month. Attention must be given to plants in full bearing by way of thinning out the exhausted growths and foliage, laying in young bearing wood, stopping one joint beyond the fruit, and earthing up the roots periodically. Copious supplies of water or liquid manure will be required about twice a week or as may be necessary, but avoid applying it too strongly, syringing at closing time, and maintaining a good moisture all day by sprinkling every available surface as necessary, but more frequently in hot weather than when dull. Do not overcrop young plants, and do not allow the fruits to hang too long, as upon attention to this depends in a measure a good and continuous supply.

PLANT HOUSES.

Poinsettias.—The earliest rooted plants should be transferred into 6-inch pots and placed in an intermediate temperature until they have commenced rooting freely amongst the fresh soil. They may need shading lightly for a few days or a week after potting, but be careful not to draw them up soft and weakly by overshadowing them. When root activity has fairly commenced, gradually prepare them for cold frames by the admission of air and a lower day and night temperature. Every care must be taken not to bring growth to a standstill by removing them to cool positions. At first they should be kept moderately close, and the frame closed early in the afternoon while the sun is still upon it. Poinsettias are often grown too warm, and only draw up tall and weakly in consequence. When once they are well established in their pots air should be liberally admitted to them, and very little, if any, shade employed. Such treatment will result in dwarf plants with solid wood that will not fail to produce at the proper season large brilliant bracts. As successional plants are rooted remove them to cooler quarters, and prepare them for removal to cold frame treatment

by the time they are ready for their flowering pots. Cuttings may still be rooted, and useful decorative plants will be produced if this is practised until the middle of July. Use for a compost good fibry loam, one-seventh of decayed manure and sand. Water carefully, but never allow them to suffer by an insufficient supply.

Euphorbia jacquiniæflora.—If the method of preparing the plants for yielding cuttings previously described has been practised, the necessary stock of plants will have been rooted. The earliest are ready for 5-inch pots, and when established in these cut them back, and the result will be plants with three or more shoots instead of one. In some cases plants with one stem are the most serviceable for furnishing; in such cases allow the plants to extend without cutting them back. Merely pinching out the points of the plants to induce them to branch is useless, for they will start away with one shoot only, but if cut back to the firm wood they will branch freely. Later plants may be grown on without pruning. Cuttings can still be rooted for flowering in 3-inch pots. The old stool plants can be cut back and started into growth in heat; when they have broken repeat them. Do not overpot these plants, for they do better when confined at their roots, and are much less liable to fail. Do not grow them too warm, and fully expose them to the sun. After the middle of next month they will do in cold frames. Shading only draws them up and prevents the wood ripening thoroughly, which is essential to ensure profuse flowering.

Plumbago rosea.—Sturdy plants of this and the variety *coccinea* in 3-inch pots should now be ready for placing at once into 5 and 6-inch pots. For at least a month or six weeks the plants may be grown on in an intermediate temperature; slight shade may be given during the hottest part of the day, and the shoots pinched about twice more. Before subjecting the plants to cool treatment the flowering growths should be about an inch in length after the last pinching. Watch for thrips, which are very liable to attack these plants if grown in a dry atmosphere and not liberally syringed. These, as well as Euphorbias, will do well in the compost advised for Poinsettias.

Linum trigynum.—If these have been grown up to the present time in an intermediate temperature, the plants will be ready for placing into 6-inch pots. Prepare the plants afterwards for cold frame treatment, and syringe freely twice daily, for this plant is very liable to be attacked by red spider. If they are attacked, syringe thoroughly with a solution of sulphur and water, a 3-inch potful in three gallons of water will be ample. Leave it on the plants for two bright days, which will be ample to destroy the spider, then wash it off with tepid water. Pinch the shoots from time to time as they need it until the middle of next month. Use the compost advised for potting Poinsettias.

Libonias.—Transfer these from small 60's into 4 and 5 inch pots; encourage them to grow for some time in an intermediate temperature until bushy plants have been produced. To flower them well the shoots should afterwards be allowed to extend without pinching, and the plants fully exposed to the sun, with liberal ventilation.

Eranthemums.—Where large plants of *E. pulchellum* are appreciated, those earliest rooted will be ready for 6 or 7-inch pots; if placed in the first they may when ready be placed in others 2 inches larger. Cuttings may still be rooted, and if pinched once or twice will be useful plants in 5-inch pots.

FLOWER GARDEN.

Bedding Plants.—Seldom has there been a more favourable season for bedding out, the dull showery weather experienced quite obviating the use of the watering pot beyond, perhaps, the first watering. All have commenced active growth, and that, too, in spite of a series of cold nights. When once Pelargoniums, Heliotropes, Ageratums, Calceolarias, Marguerites, Petunias, Lobelias, Pyrethrums, Iresines, Coleuses, Alternantheras, and numerous trailing plants are well established they rarely require any further assistance in the shape of watering, they do better without it in fact. Verbenas and Violas, however, require to be kept moist at the roots, and in addition are much improved by occasional supplies of liquid manure. Most annuals if planted in fairly good soil will do well without being watered, but if extra fine Asters, Zinnias, Stocks, Marigolds, and Dahlias are wanted these ought to be fed with weak guano or some kind of artificial manure, this being either sprinkled over the surface of the soil and watered in, or else dissolved in soft water prior to applying it. Strong doses should not be given or the roots may be injured, and in every case pond water, or any that has been well exposed to sunshine, ought to be used.

Regulating the Plants.—There being no further necessity to water the beds, the next proceeding ought to be regulating the plants so as to present as even a mass of colour as possible. First, however, the surface of the ground ought to be lightly stirred and levelled, this being most easily done with the aid of a small flat hoe. A careful workman ought with this tool to be able to leave the beds with a neat appearance without cutting up any of the plants, and this loosening of the soil is a preventive of drought and cracking. In dry hot positions it is also advisable to mulch the beds with either leaf soil, spent tan, or cocoa-nut fibre. Where there are numbers of beds forming a design, the best effect is produced by a flat surface of colour, and this can easily be done by planting in a sloping direction all stiff-growing subjects, this admitting of their being spread out and pegged down where required. For Pelargoniums rather strong pegs are needed, nothing answering better than the winter prunings from large Apple and Pear trees, the ends of these being pointed and then inserted in the ground so as to enclose and fasten down the strong shoots. Serviceable pegs can be cut from the common Bracken Fern or from shrubberies. Lighter pegs will

answer for Calceolarias, Heliotropes, Verbenas, Iresines, and Petunias, and these may be cut from old birch brooms and faggot wood, or hair pins may be used for the least sturdy growers. Those performing this rather delicate work ought not to step among the plants, but should use boards supported with strong inverted flower pots, and from these reach the centre of the beds. Isolated beds are most effective when rather high and full in the centre, and in this case it is advisable to stake up any that are not so erect as wished for.

Thinning and Transplanting Annuals.—Many annuals sown in the open borders have come up better than usual, and as a consequence there is all the greater need for judicious thinning out. Crowded together they are certainly very gay for a time, but this is a most fleeting display. Freely thinned out the majority will branch strongly and produce finer bloom for a much longer period. Three Mignonette plants are ample in a patch, and Poppies, Balsams, Candytuft, Marigolds, Eschscholtzias, Godetias, Cornflowers, Convolvuluses, Chrysanthemums, Larkspurs, Nasturtiums, Sweet Peas, Salpiglossis, and various other annuals, all ought to be given good room to develop. Very few of them transplant readily, but in showery or dull weather the attempt may be made to move a few, patches being lifted and replanted with the aid of a trowel. When watered and shaded, if need be, those moved may yet flower well.

Pinks and Carnations.—Cuttings or slips of the former ought now to be put in, it being necessary or advisable to propagate a number of plants every season. Old plants will last for many years, but those newly raised are always the earliest, and produce much the finest flowers. In most districts they strike readily in handlights or frames placed against a north wall, and not unfrequently they may be rooted in a similar position without the aid of glass. Where either of these plans fail a slight hotbed should be formed for a frame in a cool position. In any case a layer of about 4 inches of fine loam, and sand freely added, should be placed in the frames or handlights, and where neither of the latter are employed it should be used in preference to the ordinary soil. Select short, well-ripened shoots. Pull these off the old stems, and remove all dead scales or leaves, this being all the preparation needed. Dibble them in firmly and rather closely, water, and keep rather close and shaded during the hottest part of the day till rooted. If partially ripened cuttings of border Carnations can be obtained these may also be prepared and rooted similarly to the Pinks. These, however, may be put in later on, or, better still, layered in July or August. Seedlings when of good size ought to be pricked off thinly in boxes of good loamy soil and kept in cool frames for a time. When sufficiently strong they may be finally planted out in an open border.

Seeds to be Sown.—Now is a good time to sow Pansy and bedding Viola seed in pans or boxes, placing these in a cold frame, or the seed may be sown in the open. In the latter case it will be necessary to mix plenty of leaf soil with the ordinary mould, damping this prior to sowing the seed and lightly covering with fine sandy soil. Choice Primroses and Polyanthus may also be raised in a similar manner, the plants obtained giving a few flowers next spring. Brompton Stocks may yet be sown, and as a rule the seed will germinate more surely in boxes set in a cool frame, the seedlings being eventually put out in an open border. Hollyhocks and Aquilegias should also be sown now either in the open or in boxes, the seedlings of the former thus obtained being wintered in cold frames, and will flower next year; the Aquilegias may be wintered in the open, these flowering next June.

accomplish this a young queen is the first consideration, the hive the second, and the stores the third, and the protection from storm and internal damp the fourth. I have previously made these matters plain, but the external coverings should be the same during all times and seasons, no uncovering at any time, and all these points must go together. Double-cased hives are losing favour with me every year (I never was a lover of them). They are liable to damp, vermin, and rot, that single-cased hives are not, while their extra size renders them unfit for moving about. I have never observed a single writer touch upon this point of bees breeding in winter, but as bee-keepers are thinking for themselves now, we hope they will turn their attention more to Nature than Art, and they will reap more advantage.

THE MANAGEMENT OF SWARMS.

At pages 521-522 "Felix" gives some sensible advice, but I do not agree with him in all he says, so state my reasons for differing in my management regarding the shaking of bees from the receptacle they were at first hived in. The advice given how to introduce bees into their permanent frame hive is but another proof of its defectiveness. However, he has no doubt given the advice faithfully how to put bees into a defective hive, which is far better than the advice given by some to introduce the bees from above, being the most unnatural plan possible. We might as well expect water to run up hill as to expect bees to run down without much bother and risk of their taking wing again, as certainly they are liable to do. When bees are shaken they do not all remain where they fall; many rise, and sometimes all of them, to settle in another or the same place as they did at first, which under any circumstance is provoking.

Some varieties of bees are not so liable to take wing as others when being re-hived, but all of them are more or less inclined to do so, and either to hive anew, partly or whole fly back to where they first alighted or to the old stock. Of course, I mean when the manipulation is done shortly after the bees have been secured, as it is the only commendable plan. Waiting for some hours the risk of the bees taking wing is lessened, with the loss of valuable time. We do not always have our swarms when the sun is shining, very often it is when a heavy thunder shower is coming on, or it may be windy and chilling for the younger bees, and to cause them to take a second flight means the loss of many. In previous articles I have both shown how to secure a swarm and how to introduce one into its permanent hive, where it was impracticable to place them in it at first.

When the bees cluster in a convenient place at first we never hesitate to shake the cluster bodily into a hiving box, but it is seldom we have the opportunity to do so, as most of our swarms go right into the centre of a thicket in the hedge or in some inaccessible place high up upon the dark limb or thick branch of a tree, so that we have very often to lift them in handfuls into the hiving box, or by the aid of carbolic acid cause the bees to retreat to a more convenient spot. By whatever means we secure the bees (we have often difficulties with them) we are sure to have them into a hiving box if not the permanent hive; if in the latter there is no further bother; if in the former it is either placed right under the permanent hive or slid underneath it in an inverted position, and the trap floor allowed to fall, when the bees at once begin to go up without the risk of being overtaken in a shower or of their flying away again; a narrow slit on the top of the box admitting a carbolic feather hastens the ascent of the bees.

Our poles, which can be extended to any convenient length, are admirably adapted for securing a swarm when located high up on a tree where it is difficult to get at it, and cutting the branches is not permissible. The hiving box, which is suspended by a cord to the top of the poles, and carried over pulleys for raising or lowering, ought to be very light. The best and lightest material I can suggest is plaited straw bound with wire, ending in a loop on the top, whereby it is suspended. Anything heavy causes unsteadiness in the poles, rendering the task difficult. A swarm of bees is heavy

THE BEE-KEEPER.

NOTES ON BEES.

WINTERING BEES—SPRING DWINDLING.

NUMEROUS plans and devices are recommended by modern writers for successfully wintering bees, and abundant advice is given as to certain manipulations, as if bees did not know how to get along without man interfering with them and their internal economy, at times, too, when it would be wisdom to let them alone, as the acts performed during winter and spring are all detrimental. It is a wonder after all these manipulations that spring dwindling is not more common than it is. What is more absurd than to hear people instructing others about the proper time to start the queen to lay? Bees that are nursing and rearing brood during the winter months by their activity keep up a greater heat in the hive than those having none. With the former, even although the thermometer is some degrees below zero, dead bees will never be found inside the hive, as is often the case with the latter, even when the temperature is much higher.

We are never desirous to have queens laying abundantly during the winter, but are so to have always a moderate quantity of breeding going on, and that, too, in a natural way and condition. To

enough without much additional weight, as the longer the pole the more difficult it is to steady. Four feet is long enough for each pole. The joints should either be with sockets or screws; if the former pins should be pushed through to prevent slipping. The shortness of the poles makes it easier to undo if necessary, and for storing.

Here again carbolic acid assists us. A second light rod with carbolised feathers drives the bees in the direction wanted, or displaces them altogether. When bees are full of honey they are not so flighty as with empty stomachs. Some queens are more lively than others, and where more than one is present the swarm is more liable to fly away, especially so after being hived.

Carniolian bees are perhaps more liable to fly back to their first hiving place than any other variety if shaken, and it is sometimes difficult to secure these bees. The queen's nature of flying from twig to twig or place to place causes the bees to be in many clusters, and when once the queen has alighted upon a place the bees cling as tenaciously to the spot as if the queen was there, and it is often difficult to keep them from it, carbolic acid being effectual, but often clusters of bees will be found dead long after the swarm has been secured. This year it took two days before I could induce the bees of a swarm to cease going back to cluster where the queen had been. When observed I cut the spray or twig and place it in my straw hat, thereby encouraging the bees to enter and drawing them away from the attractive spot, and I sometimes secure the bulk of the bees in it, being light and every way adapted for the purpose, but to shake Carniolian bees from a service to a permanent hive as advised by "Felix" would cause many, if not the whole of them, to return either to the parent hive or to the spot where they first alighted.

Then there is always the risk of having the queen killed by stranger bees when she is exposed from the centre and protection of her own subjects, and where many hives are near each other and swarming general the risk is greater, as many bees are on the wing, but not for working purposes, and it appears to be their nature to kill every queen not their own that falls in their way. My advice to bee-keepers is, however successful they may be at times with the shaking process, abandon it; there are always shoals ahead, but we need not run direct upon a visible rock when the consequence is clear, as it has been long since to—
A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

E. H. Krelage & Son, 19-27, Kleinen Houtweg, Haarlem, Holland.—
Wholesale Catalogue of Bulbs and Plants.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Suggestions (*Mr. C. & D. G.*).—We are greatly obliged, and the matter will have attention.

Abnormal Mint Growth (*J. H. W.*).—It is peculiar and unusual. We sent it to the Scientific Committee of the Royal Horticultural Society, and it will be referred to in the report of the meeting next week.

Single Pyrethrum (*E. Draper*).—The variety sent is a very good one, but not superior to others in cultivation, nor equal to some. It resembles one named Lord Lansdowne that we have seen in collections of these flowers in the Royal Horticultural Society's Exhibition Hall at Westminster.

Caterpillars on Apple Trees (*William*).—They are caterpillars of the Little Ermine moth, *Yponomeuta padella*, of which particulars appear on page 479. This appears to have been universally prevalent this year, and much injury has been done in many gardens by the caterpillars. They also attack the Hawthorn and some other trees.

The Crown Knife Cleaner (*J. E.*).—Mr. T. Clarke is the London manager of the Chadborn and Coldwell Manufacturing Company, and not Mr. Chadborn as accidentally stated on page 495. Mr. Thomas Coldwell is the inventor of the article, also of the Excelsior lawn mower, and we understand is the oldest maker of lawn mowers in the United States. He is the President of the Company in question.

Destroying Woodlice (*W. T. S.*).—Cut a raw Potato in two equal parts, scooping out the cut part a little with the knife, and then place the half-Potatoes, with the cut or hollow side downwards, by the side of the eaten Ferns. Every morning treat the woodlice to a boiling bath; you will find them secreted under the Potato and adhering to it in the hollow. As your Ferns are so much eaten examine the plants after dark with a lantern, and you will, not improbably, find some slugs at work; if so, pick them off into a flower pot, and sprinkle some salt over them; or if you have any ducks they will thank you for the present unsalted.

Turf Walls and Furze (*Bailiff*).—We have seen many fences made of turf and covered with Furze. When turf walls are not covered with anything they are often much injured by the atmosphere and the rubbing and butting of cattle. To guard against this they should be planted or sown with the *Ulex europæus*, or Furze. The roots of this plant will soon penetrate the turf, and tend to bind the wall. The plants not only make a good fence, but afford shelter for cattle, but add to the height of the wall, and give it a formidable appearance. When walls are made for this, the foundation should be 3 feet wide and tapering to 15 inches at top. As the plants advance in growth they should be regularly trimmed with the shears: by proper attention to this they will be prevented from growing too tall and thin at the bottom. If this is annually repeated the plants will be longer preserved in a healthy and vigorous state. Clipping has also a good effect in checking the Furze from spreading over the field. A good and substantial fence may thus be quickly formed on a soil that will not produce a biding fence of any other kind.

Thinning Grapes (*J. E.*).—The illustration referred to is not what you suppose. You can only, so far as we know, find what you wish in Barron's "Vines and Vine Culture," which can be had from this office, post free for 5s. 3d. As you are interested in Vine culture you would find the amount so expended a good investment. Thinning cannot commence too soon after the berries are set, and the work should be completed before they touch each other. Do not take many from the upper part of the top shoulders, but rather thin from the under part and the centre of the bunches. A small stick in one hand for raising up the shoulders, and a pair of Grape scissors in the other, enables the work to be done, as it should be, without touching the berries. The number to be removed can only be determined by the "set" and by the size the varieties attain when ripe, Gros Colman requiring much more room than Foster's Seedling for instance. If you commence thinning when the berries are very small, those retained may be at a sufficient distance apart for the tip of your little finger passing between them without rubbing the fruit. Thin out the small as far as possible, leaving those of uniform size to swell to maturity.

Vines Scorched (*F. J.*).—Judging from the leaves and berries sent we suspect the air of the vinery is kept too dry, and possibly the roots of the Vines also, but the main cause of the injury is faulty ventilation. If you had described your method we could possibly have told you where you err. It is certain that having the ventilators close till the thermometer registers 80° or thereabouts in the morning, then throwing open the top and front ventilators to reduce the heat, will cause scorching and shrivelling. The most precise instructions have been repeatedly given, and it is impossible to repeat them just as we are going to press. Briefly, the top ventilators should never be entirely closed, and should be opened a few inches wider half an hour after the sun shines on the house in the morning, or as soon as a shaded thermometer registers above 65°; at every 5° rise admit more air; then, when the top ventilators are wide open, if the temperature threatens to rise above 80°, open the front ventilators slightly, increasing the openings to prevent the heat as shown by the shaded thermometer exceeding 85°. Damp the house frequently with the increasing heat. See also "Work for the Week." We suspect you are drying the air too much by excessive front ventilation. There is not much difference in the time of ripening of the two Potatoes as you will soon find out.

Fungus on Peach Trees (*Granger*).—The scraps you send are quite inadequate for enabling anyone to understand the actual condition of your trees, unless, indeed, there are no better leaves on them than those before us. We can scarcely think that such is the case, but if it is the trees are practically beyond recovery. One leaf is blistered, and both infested with fungus. Blistering is the most prevalent during cold springs when dry piercing winds prevail, and fungus follows the blister. It may possibly cause it in some instances, but is, we think, usually a result. You ought to have endeavoured to subdue the fungus

long ago by syringing with softsoap and sulphur solutions that have been so frequently recommended, and these failing you could have tried sulphide of potassium or Jeyes' remedies as advertised. No matter what kind of soil you provide for the roots, it is impossible the trees can grow in it if the foliage is destroyed. If you wish to send your Carnation to one of the Royal Horticultural Society's meetings you can obtain the requisite instructions from Mr. A. P. Barron, Chiswick. The value depends very much on the habit and floriferous nature of the plants. The bloom itself is not strikingly meritorious.

Fungus on Shrub (R. V. A.).—We have examined the specimen sent. There is abundant evidence of an attack upon the twigs by some scale—i.e., either a coccus or aspidiotus. As to the particular species we cannot say. There are not any living insects, but dried shields and dross. Fungoid growths frequently occur upon insect refuse, and we have seen them thickly on the cast off skins of caterpillars and on old cocoons of moths. Syringe forcibly and thoroughly with a solution of softsoap and petroleum, made by dissolving 2 ozs. of softsoap with a lump of soda the size of a nutmeg in a gallon of boiling water, stirring in very briskly when hot a small wineglassful of petroleum. If the mixture is supplied at a temperature of 120° it will be the more effectual, holding the barrel of the syringe in a thickly gloved hand. The work should be done soon enough in the evening for the shrubs to be dry before night, as if wet in the morning and hot sun follow the leaves may be scorched. If the roots are in dry poor soil make some holes here and there for holding liquid manure and conveying it to the roots. Insects are prone to attack enfeebled growths, and the sprays sent do not indicate vigour. By far the greater number of replies published in this column are of interest and service to many besides those who elicit them.

Early Rhubarb (Suffolk Vicar).—We thank you for the stalks of the "hardest, earliest, and sweetest Rhubarb grown anywhere in this country," and which you appear to feel justified in investing with a distinctive name and selling roots of the variety at a high price, 7s. 6d. each small, 15s. each large. May we advise you to send a fair sample of the stalks, say a dozen, with leaves, for examination by the Fruit and Vegetable Committee of the Royal Horticultural Society before carrying out your project? If the variety is considered by the Committee distinct from others in ordinary cultivation, you can then name it and make the best you can of it; but if it should prove to be identical with an existing variety well known and recognised, you will not be placed in a very pleasant position, as it is a rather serious matter sending out old varieties of anything under new names, and at prices that lead the public to believe they are novelties. We have read your circular and letters with great care, and should be very pleased to aid in distributing a really new Rhubarb possessing distinct advantages, but we cannot regard your experience as adequate for determining the point, and suggest an easy course that we hope you will follow. We admit the variety to be distinct from the St. Martin's, but that is not the earliest Rhubarb in cultivation. The next meeting of the R.H.S. Committees will be held on July 10th, and anything reaching the Secretary at 111, Victoria Street, Westminster, the night previous, will be placed on the table for examination by competent horticulturists, glad to recognise anything new, distinct, and good that may be put before them.

Ammonia in Rain (J. W., Leeds).—No doubt you are right. Dr. Storer says fresh rain water may contain from one to three-millionths of its weight of ammonia; fog and dew, from two to six millionths; and snow and hail, about as much as rain on the average. Those portions of rain that fall at the beginning of a storm or shower generally contain a larger proportion of ammonia than those which fall subsequently. The first portions of water wash the layer of atmosphere between the cloud and the earth, and collect almost the whole of the ammonia that was contained in it. The rain that falls afterwards merely dilutes the ammoniacal solution first obtained. Towards the close of a long-continued rain the water that falls is wellnigh absolutely free from ammonia. The rain water collected in cities contains far more ammonia than that which falls in the country; as much as thirty parts of ammonia in a million parts of water have been observed. It has sometimes been noticed, also, that the amount of ammonia in rain may be comparatively large when the rainfall occurs after long-continued dry weather. In the year 1855 Mr. Lawes erected a large rain-gauge at Rothamsted, having a surface of one-one-thousandth of an acre, and the waters collected in it have been analysed from year to year, and even from day to day at times. Warrington has recently reported that the average amount of ammonia nitrogen in the water of this rain-gauge is about 0.3 part in 1,000,000 parts of water. But the amount of ammonia varies widely in the waters of different showers, so that the amount of ammonia nitrogen ranges from 0.043 to 5.491 parts to the million. Warrington computes that about 2½ lbs. of nitrogen in the form of ammonia fall upon an acre of land in one year at the locality in question. In addition to the ammonia nitrogen, about a pound falls as nitric acid and another pound in organic combination, making altogether about 4½ lbs. of nitrogen to the acre. Earlier observations, obtained by rather less accurate methods of analysis, gave larger amounts of ammonia. Thus Way, in 1855, found 7 lbs. of ammonia to the acre, and, in 1856, 9½ lbs., in the waters of the Rothamsted gauge, which amounted to rather more than 600,000 gallons each year. German observers obtained in their turn 6½ lbs. and 9½ lbs. of ammonia in yearly rainfalls of 400,000 and 500,000 gallons.

Apples Wearing Out (Man of Kent).—You appear to be possessed with the Knightian theory, which was not well founded. It is referred

to by Dr. Hogg in the "Fruit Manual" as follows:—"Towards the end of last century Mr. Thomas Andrew Knight entertained a theory that the Golden Pippin, and all the old varieties of English Apples, were in the last stage of decay, and that a few years would witness their total extinction. This belief he founded upon the degenerate state of these varieties in the Herefordshire orchards, and the opinion that no variety of Apple will continue to exist longer than 200 years, after which period the original tree and all its progeny will fall to decay. It would be needless to enter into any further discussion upon a subject concerning which so much has already been said and written, as there is sufficient evidence to confute that theory. The Pearmain, which is the oldest English Apple on record, shows no symptom of decay, neither do the Catshead, London Pippin, or Winter Quoining, those only of the old varieties having disappeared from our orchards which were not worth perpetuating, their places being supplied by others infinitely superior. It was towards the end of the last century that this doctrine was first announced, and though many of the old diseased trees of the Herefordshire orchards of which Mr. Knight spoke have passed away, we have the Golden Pippin still in all the luxuriance of early growth, where attention has been paid to its cultivation and it is grown in a soil congenial to it, and it exhibits as little indication of decay as any of the varieties which Mr. Knight raised to supply the vacancy he expected it to create. But this alarm of Mr. Knight for the safety of the Golden Pippin, and his fear of its extinction, were based upon no new doctrine, for we find Mortimer a hundred years before equally lamenting the Kentish Pippin. After speaking of manures, &c., for the regeneration of fruit trees, he says, 'I shall be glad if this account may put any upon the trial of raising that excellent fruit the Kentish Pippin, which else, I fear, will be lost. For I find in several orchards, both in Kent, Essex, and Hertfordshire, old trees of that sort, but I can find no young ones to prosper. A friend of mine tried a great many experiments in Hertfordshire about raising them, and could never get them to thrive, though he had old trees in the same orchard that grew and bore very well. I likewise tried several experiments myself, and have had young trees thrive so well as to make many shoots of a yard long in a year, but these young shoots were always blasted the next year, or cankered; which makes me think that the ancients had some particular way of raising them, that we have lost the knowledge of.' Although this was written in the beginning of last century, we have the Kentish Pippin still, as vigorous and healthy as ever it was."

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. —(H. H.).—*Crataegus coccinea*. (Somerset).—1, *Festuca duriuscula*; 2, *Festuca ovina*; 3, *Bromus sterilis*; 4, *Bromus arvensis*; 5 and 6, *Bromus mollis*. (S.).—1, *Centaurea montana*; 2, *Veronica spicata*; 3, *Saxifraga ceratophylla*.

COVENT GARDEN MARKET.—JUNE 27TH.

Outdoor Strawberries have now made their appearance, principally from the neighbourhood of Southampton. Supplies good, with trade more active.

MILK.

IN our article upon Farming Reform it was laid down in general terms that for the ordinary farm dairy neither pedigree nor imported animals were required, but rather well-bred cows, either pure or cross-bred, of local breeds, such as are to be had in every county. It appears desirable to qualify this statement by insistence upon the importance of the really careful selection of such cows. For example, we should never recommend the ordinary pure-bred Sussex cow for the dairy, for it is a large fleshy animal yielding very little milk, but ripening so early for the butcher that many gentlemen in that county have two distinct herds—one of Channel Island cows for milk, another of Sussex cows for beef. This is all very well from a picturesque point of view, but a tenant farmer requires in his cow a fairly lusty condition combined with an abundant yield of rich milk. Such desirable points, are, we believe, capable of development in every breed of cows; but, mark this! they must be developed by careful selection, for the development of such points may occasionally be obtained by accident, but, as a rule, it is done by breeding from cows having some points of superiority over others. Take again, for example, the Shorthorns. Here we have results from selection which give distinct classes of this famous breed. In one herd of them we find beef and nothing else, in other plenty of deep milkers. It must be owned the milk is frequently of poor quality, but then dairy Shorthorns are generally kept for an abundant yield of milk for sale, without regard to quality. Plenty of milk is wanted, and stimulating food is used to induce the cows to give it, yet if quality of milk were required it could soon be imparted.

Food has doubtless very much influence upon the milk yield. It was proved to demonstration long ago that by judicious feeding the milk yield of a cow can be almost doubled; and let it not be forgotten that rich food generally means rich milk. Cows have been so well bred and well fed that each of them has produced 500 lbs. of butter in a year, but that is far beyond the ordinary quantity, for it must not be forgotten that it requires from two to three gallons of milk to produce a pound of butter. Another word about Shorthorns. From a dairy point of view they may be said to have deteriorated from over-selection, for three-quarters of a century ago the Durham cows, from which the Shorthorns have descended, were celebrated as much for the quality of milk as for their capacity to fatten quickly.

In the selection of dairy cows it should be remembered that soft fine hair and a smooth skin generally indicate high quality in

the milk, but there are exceptions to this as to all rules. The class of cows we recommend for tenant farmers—that is to say, cows good for the dairy and fattening as well, are always kindly animals in excellent condition, with a soft skin and tolerably lusty condition. Remember the selection is not solely for quantity, but quantity and quality of milk in perfect combination. A very deep milker is usually “a bag of bones;” the entire economy of the animal is given up to the secretion of milk, but the milk is often of superior quality. One such cow we had that continued a wonderful yield of milk to the last, and we were so accustomed to see her in low condition that we had no idea how severely the system was taxed till one morning she was missed at milking time, and was found in a thicket dead.

It has been laid down by a high authority on dairy farming that a dairy cow giving no more than 300 gallons of milk in a year is unprofitable. This low rate of yield may arise from careless breeding or careless feeding. If the former, the cow is not worth keeping for the dairy, if the latter an improved dietary is the remedy. No doubt very many dairy cows are sadly underfed even when turned out upon pasture. We like to see cows that are milked at 6 A.M., and at once turned out to grass lying down and ruminating by 10 A.M. But if on the contrary they have to keep wandering the greater part of the day in search of food, the yield of milk is unlikely to be so abundant, or the quality so high as it ought to be. A cow requires some 80 lbs. of food daily, yet many a cow probably does not get above half that amount. Well has it been said that poor land produces poor milk, and it is ridiculous for any farmer to attempt keeping dairy cows upon insufficient means. We have a neighbour who has three cows—wretched starvelings all of them, yet if he had only one well fed animal he would certainly obtain more and better milk than he now has from three. We hope these general hints may be useful to our readers, but to any of them requiring more particular information we will gladly be of use.

WORK ON THE HOME FARM.

Farming work is so much affected by weather that no inflexible rules can be laid down for general guidance. In point of fact we wait upon the weather and adapt our plans to it as best we may. The “dripping June” weather still prevails, but we have had some trying alternations of cold—so trying that newly shorn sheep have suffered, and we have done what we could to afford them some shelter. Wheat coming into ear, as well as winter Oats, is short in straw, but we hope all corn will prove heavy in ear, for though somewhat backward in growth it is full of promise. The early crop of Peas which we mentioned in our last work note proved profitable to the grower, who realised 10s. per bushel for it at a local market. It is precisely the man who farms well, and is on the alert to take advantage of every opening, who continues to thrive. Much Rye Grass and Sainfoin has been mowed for hay, but the dull weather has retarded earing, and most of it is still out upon the land. The showery weather promotes free growth in the late grasses, and the haymaking is kept back, both by weather and a desire to secure a little more bulk per acre. Care must, however, be taken not to leave the grass unmown till seed is fully developed, or there will be much loss of quality in the hay. Just as the Grass is passing out of the flowering stage is the best time to mow, but where some hundreds of acres has to be mown this is not an easy matter, but by the exercise of a little care all the grass can usually be had in fair condition for hay. Enthusiastic makers of silage declare there need be no more roots grown, and therefore a considerable saving may be effected. We never advocate extreme views, and certainly we do not propose to discontinue growing some roots, but we have curtailed the average of roots considerably, and take care to cultivate the remainder as well as possible. Much land is wasted in root culture by having the rows too far apart. The only good reason for this is upon foul land to afford ample space for the free use of horse hoes between the rows; but when the land is clean we prefer having the rows as close as possible, and sowing upon the flat, not on the ridge. Very little thought is, we fear, put into such matters; custom and habit insensibly affect farming work, yet a little thought sometimes suggests better methods.

MANURES FOR PASTURES.

THE DYSON'S WOOD EXPERIMENTS.

DYSON'S Wood, Kidmore, Oxon, is the residential estate of Mr. Martin J. Sutton. The district is charmingly rural, the estate well wooded, and the ground agreeably, in some places rather boldly, undulated. The commodious and substantial residence is pleasantly situated among the trees, and the well-kept

lawn, with flowers and shrubs surrounding, betoken a cherished home. One of the walls of the building is quite covered with a splendid Gloire de Dijon Rose bearing a wealth of lovely blooms, and the most attractive flower bed was a mass of seedling Pansies of a superior strain. Beyond are the fields, of which glimpses are obtained between the trees, and in some of those fields are the experimental plots that a number of practical and scientific agriculturists inspected on Wednesday, the 21st inst.

In the spring of 1886 Mr. Martin J. Sutton, aided by Dr. J. Augustus Voelcker, arranged a series of experiments on permanent and temporary pastures for the purpose of ascertaining the effect of certain manures, alone and in combination, on crops of grass. The quantities were such as might reasonably be applied in ordinary agricultural operations, and such as any grass land farmer would be willing to pay for in the event of their proving profitable. The trials were arranged in six fields on poor brashy soil resting on chalk, and therefore particularly suited for these experiments. In 1886 six plots were set apart in each field. No. 1 was not manured at all, and is the standard with which the other plots are compared. In 1887 twelve more plots were added to four of the fields, and the same rule followed applied to these plots also. Every plot measured exactly 100th part of an acre, and was enclosed with galvanised iron wire. This separation of the several plots has been maintained from the commencement of the trials. Each group of plots is surrounded with hurdles at a suitable distance to keep off cattle and ground game. Extreme care has been taken in every field to choose a portion which fairly represents the whole in herbage and in aspect. The manures were selected and approved, and several of them were analysed by Dr. Voelcker, and when sown screens were employed to keep every particle within its proper boundary. Weekly inspections have been made through the spring and summer of each year, and the progress of the various grasses and Clovers in every plot carefully recorded. Immediately each crop was cut it was weighed, then dried on its own plot, and finally weighed as hay. The drought from which the neighbourhood suffered up to the end of the first week of October, 1886, caused the aftermath to be exceedingly slight in that year, but the second crop was cut, carefully weighed, dried artificially, and weighed again as hay. In 1887 the prolonged drought, followed early by severe and autumnal frosts, proved so detrimental to the aftermath that it was a failure. That is the explanation given by Mr. Sutton in his carefully tabulated record of the trials, printed in manual form, and the work is highly worthy of perusal.

The object of the experiments is wholly educational and intended to show the effects of different manures on existing pastures with the view of ascertaining which could be profitably applied, for it is a fact that money can be lost by injudicious expenditure on fertilisers, while on the other hand wise investments may be made in them for pastures and other crops; but the experiments under notice apply to pastures alone, a subject to which Mr. Sutton has given great attention, and his knowledge is embodied in his standard work thereon. The cost of the manures per acre as represented by each plot in the fields is given, and the loss or gain resulting clearly stated. This, the third season's experiments, show two things very clearly. First that the real value of manures cannot be tested in one year because of the differing residues and their influence on the succeeding crop, and secondly that a combination of nitrogenous with mineral ingredients is necessary for achieving the best results, because as the plots demonstrate, where either nitrate of soda or sulphate of ammonia are used alone, a strong growth of the coarser grasses are favoured at the expense of Clovers and full and fine bottom herbage; and where those quick manures are excluded the reverse occurs, and the crops as a rule lose weight. Good farmyard manure contains all the elements, with humus, hence proves its value at Dyson's Wood. It did not, however, show this the first year, for every plot which had a dressing at the rate of ten tons per acre in the spring of 1887 resulted in a loss that year, but the same plots this year, to which nothing else has been applied, will show a substantial gain, as they are among the best in the series. But it must be borne in mind the manure was from covered yards and cake-fed animals, much so-called farm manure that is used on land being delusive—a mere apology for the genuine article. The advocates of "muck" were a little jubilant after inspecting the crops, and not without reason; but in very few instances is it so good as in the sample used, or produced in sufficient quantity for adequately enriching the ground; and, as Dr. Voelcker explained in his most interesting address, chemical manures can be profitably used either in addition to it, which he advocates where practicable, or instead of it in its absence.

It may be stated as a rule throughout the experiments that nitrate of soda is somewhat a brisker stimulant than sulphate of ammonia, inasmuch as the grass is riper, but it is doubtful if the

crops will weigh heavier, and the results this year will perhaps show that there is a little more "wear" in the latter than the former. It should be said that in some of the series of plots this point will be tested, as nothing has been applied to them since 1886, and some of them will be left without further dressings. Possibly nitrate of soda, broadly speaking, may be preferable for dry soils and districts, sulphate of ammonia for those of a wet, cold nature. In some of the plots basic cinder is placed in comparison with coprolites, both mixed with kainit, to the apparent disadvantage of the former, the superphosphate of lime plots also comparing favourably with the cinder. Bones dissolved, boiled, and raw, are in comparison with no great difference in the crops judging from appearances, but those dressed with the first-named are perhaps the best in three cases out of four. A good profit was derived last year with nitrate of soda and muriate of potash, an outlay of 17s. 6d. per acre yielding a gain of £2 16s., and this year's crop, without a further dressing, is very promising both in bulk and quality, as it shows a fair mixture of Clover. The tide appears to be rising in favour of muriate of potash over the sulphate or kainit. The guano plots are weak, this "hot" manure not being good for dry soils in dry seasons. Further reference will be made to these valuable and suggestive experiments, and deductions drawn from them and others by our able agricultural coadjutor.

At the close of the inspection upwards of thirty gentlemen were entertained at luncheon by Mr. Sutton, who gave a cordial welcome to all, and invited a free informal discussion on the whole subject of manuring. Expressions of opinion were delivered by Dr. Fream, and Messrs. Simmons, Farmer, Hunter, Pringle, Luckhurst, Caird, Milton Druce, and others, Dr. Voelcker summing up the various suggestions and analysing the observations in a masterly address. A rather heavy and prolonged shower suggested that method of utilising time, and though much of interest was doubtless missed outside which would have been seen had the afternoon been fine, yet none appeared to regret the rain keeping them in the marquee, and perhaps Mr. Sutton will feel the desirability of holding a similar parliament of professors, cultivators, and students (of which a number attended from the Downton Agricultural College) on a future occasion.

BRITISH TOBACCO.

BEFORE the cultivation of Tobacco in Britain is absolutely condemned we ask to be heard in its defence, inasmuch as we have spent several hundred pounds in the interest of the British agriculturist with a view to establish the fact whether Tobacco could or could not be grown here, and we believe the evidence we offer will more than justify further experiments. With regard to the manufactured Tobacco sent out by Messrs. Cope, in common fairness it ought to be understood that no foreign element in the shape of scents or flavourings has been used, whereas we are given to understand that the custom prevails to add some form of flavouring or perfume to the various grades of Tobacco sold by the manufacturers. It is therefore not surprising that after the public taste has been educated to the use of the blended and artificially flavoured article it should object to the novel character of the real and pure Tobacco. We maintain that the fairer test would have been, either to have given the artificial assistance usually added to the foreign Tobacco, or to have sent examples of the latter, pure and dressed in the same way as the British grown.—JAMES CARTER & Co.

REMARKS.

17th.—Overcast all day.
 18th.—Cloudy, and very cold throughout.
 19th.—A little rain early; dull and raw day; showers at night.
 20th.—Dull early, wet till 3 P.M., then showery, with one glimpse of sun; bright moonlight night.
 21st.—Dull, with occasional slight showers; heavy rain, with distant lightning and thunder, at night.
 22nd.—Dull morning, fair afternoon, with some sunshine.
 23rd.—Fine and bright; heavy rain after midnight.
 An uncomfortable week, with some very cold days, the mean temperature being scarcely that due to the middle of May. On several nights the 9 P.M. temperature lower than has sometimes been observed in January.—G. J. SYMONS.
