Pains should also be taken with the preparation of the sets as well as the soil for their reception. In the case of some kidneys, notably those of the Ashleaf and Lapstone types, the loss of the primary central sprouts simply spoils the set, and it is very unwise to allow any of the other rounds and kidneys to sprout prematurely, this greatly weakening them. What is wanted in all cases is one strong sprout, and this, if duly preserved, no other side shoots being allowed to grow, will eventually yield better crops and larger tubers than those sets that are allowed to develop a quantity of weakly and but little branching haulm. With the exception of the two types named it is not imperative to plant whole sets, but as a rule I prefer medium sized whole tubers, removing all but one strong sprout from them prior to planting. Cut sets to be similarly treated and also dipped in slaked lime, as this checks bleeding and keeps slugs away. Crowding either the rows or sets being unprofitable, the former ought to be not less than 3 feet apart and the sets from 10 inches to 12 inches asunder in the rows. I prefer to plant sets already sprouted to a length of 2 inches, these being first moulded over with the hand prior to levelling the whole of the soil about them. Thus treated an even row is secured, and when one strong sprout has taken the lead side shoots make no headway. Now, a few words as to artificial manures. I have tried many, and on the whole give the preference to superphosphate of lime. A hundredweight of this, which costs about 7s. 6d., will go a long way. It is best applied in the open drills prior to planting, and I cannot better state the precise quantity to be used other than by advising it to be sprinkled over the soil much as salt or pepper is used over cooked meat or vegetables, only enough to season it being given. Any other strong artificial or specially prepared manures must also be used in moderation, and failing any of these soot may be freely dusted along the drills.

Directly any of the shoots show through the soil protect them in some way, as if thus early frosted they seldom properly recover. Soil drawn up to and over them is the simplest way of protecting the tender haulm, but an enthusiast will not hesitate to use inverted flower pots with the holes covered, branches of evergreens, or straw litter, if a frost is anticipated after the haulm has grown considerably. When the haulm is about 6 inches high the ground on each side of the rows should be well loosened with the hoe and the final moulding-up given. I ought perhaps to add that it is advisable to thin out the haulm where unfortunately several growths have developed, this being done prior to moulding-up. Watering between the rows has been tried during a hot and dry summer, but I failed to detect any benefit derived therefrom. According to my experience, if the ground is well manured and carefully prepared, it must be a very dry season indeed that will spoil the growth of the Potatoes. What few rows of exhibition varieties we grew last season succeeded admirably in spite of the drought.

A good dish of Peas always counts well in a collection of vegetables, and at many shows there are also prizes offered for one or more dishes. With several kinds of vegetables it is possible to obtain good dishes for exhibition from the ordinary crops, but this rarely happens in the case of Peas. They must have extra pains taken with them, and they pay for the trouble. As most gardens differ materially in the character of the soil, it follows that its preparation ought also to be varied. Should it be naturally deep and well drained, double digging may safely be resorted to, plenty of solid manure being mixed with each spit. If the soil is cold and heavy, resting on a clayey subsoil, it is unwise to encourage a deep root run. A favourite plan with many Pea growers is to form Celery-like trenches for their rows, this concentrating the manure, and also admitting of water being more easily applied. I do not believe in the practice; in fact, am not sure it is wise even in the case of Celery. When the roots are confined to a narrow trench they are almost as much dependent on the watering pot as are plants in pots. If it is either impossible or unwise to trench or double dig the whole of the quarter, either double dig a space at least 3 feet wide for each row, or else be content with well manuring and deeply digging the whole of the ground, this encouraging the roots to spread right and left—an obvious gain. It is also of importance that the heavy ground be prepared early in order that the surface may become well pulverised, the seed germinating and the young plants growing away more freely under such conditions.

It is of importance that the Peas be at their best just when most wanted, the earliest pods usually being the best. No exact dates for sowing can be given, so much depending upon the weather experienced and the variety sown. As a rule they may be gathered in about fourteen weeks from the time of sowing, an extra week at least being allowed for known late varieties. They must also, whether tall growing or of comparatively dwarf habit, have plenty

of room. The rows ought to be as far apart as the Peas grow in height. For instance, a distance of 6 feet apart is not too much for either Telephone or Duke of Albany. Isolated rows, or those disposed 10 feet or more apart, the intervening spaces being planted with Cauliflowers, Broccoli, or somewhat similar crops, give the best returns, and this is a good method of arranging the ordinary rows of Peas. We always open the drills 6 inches wide, and in dry warm weather 3 inches deep is not too much. The seed is sown thinly and covered with good fine soil, this being brought from the frame ground if need be, rather than place hard lumpy soil on the seed. Instead of moulding up the rows when about 4 inches high, support them with spray, and finally stake before they are far advanced, taking care not to bring the points of the stakes too closely together, or a second lot of stakes will be needed to support the haulm. Prior to staking, however, thin out the plants where crowded, leaving them not less than 6 inches apart. When given good room, nearly all the exhibition varieties are encouraged to branch strongly, and as a consequence produce a long succession of fine pods. After the staking is completed raise a small ridge on each side, so as to form a basin 12 inches wide, this greatly facilitating the work of thoroughly watering the rows whenever necessary. Dryness at the roots ought always to be anticipated, as it is almost impossible to moisten the ground when once allowed to become dry. Driblets are simply thrown away, nor are ordinary rains of much benefit to the established rows of Peas. They also require frequent supplies of liquid manure, that obtained from a farmyard or by soaking good manure in a tub of water being excellent for the purpose, being diluted with water, in each case, according to its strength. When Messrs. Carter's famous Peas, Telegraph, Telephone, Stratagem, and Pride of the Market were first introduced, valuable prizes were repeatedly offered for dishes of them to be shown at South Kensington and elsewhere. The most successful exhibitor, if I mistake not, was Mr H. Marriott, Boston, Lincolnshire, and he attributes much of his success to a free use of blood fresh from a slaughter house. This was poured along the rows, and either washed in by the rains, or watered in in dry weather, and better Peas I have not seen, and very few to equal them. In addition to this liberal treatment, it is also advisable to pinch out the points of the haulm when the first pods are set, the pods also being thinned after it is seen which are most perfectly formed. Stopping the haulm also hastens the development of the pods. Retarding is not a very easy matter, but when it is seen the first-formed pods are too early, cut them off, and trust to the later ones. They will fill properly in from fourteen to twenty-one days, according to the time of year.

For exhibition late in May or early in June there is none to surpass William I., and a well grown dish of it is very telling in November, the seed in this instance being sown as soon as ripe in the summer. Telephone and Telegraph, the latter being the greener of the two, follow closely on William I. Stratagem and Pride of the Market, as far as the size and appearance of the pods are concerned, respectively resemble Telephone and Telegraph, but as they rarely exceed a height of 3 feet they are the best for small gardens. All may be materially forwarded by being sown in small pots, turves, or boxes under glass, and duly planted out before they are much drawn. Duke of Albany may be described as a late form of Telegraph, and is a fine handsome Pea for the July and early August shows. Prodigy (J. Veitch & Sons) is another handsome main crop variety; and Autocrat another of Veitch's novelties, promises to be grand for the August shows. Laxton's Walton Hero, a fine late variety, and Charmer, by the same raiser, though not large podded, is yet of good taking appearance and does well in a dry season. Ne Plus Ultra, when well grown, is yet hard to surpass, many judges having a "weakness" for this well tried main crop and late Pea.—EXHIBITOR.

(To be continued.)

THE CULTURE OF FREESIAS.

I VERY gladly give my experience in the successful culture of Freesias for the benefit of those readers who may not be acquainted with their requirements. I have reason to believe their cultivation is not yet understood by a large number of gardeners and others who would find these flowers most useful during the winter months; the number of failures and the inquiries respecting their culture confirm this belief. It would not perhaps be out of place to say that owing to our success, and the bulbs having increased so fast, we have been able to supply friends with bulbs which would have amounted to more than our present stock, and all these have been produced from six single bulbs purchased the first year they were sent out. Where failure occurs it plainly shows the plants are either neglected at some period, or their management is not understood. We have about 150 plants which have flowered, and these will make three times that number for next year, besides a quantity

of smaller bulbs, which would flower the following year if potted and grown precisely the same as those expected to flower. Our first plants were in bloom at the beginning of the year, others were brought on in succession, and there are some twenty in flower at the present time, giving us from twenty to thirty spikes of bloom each, and I think there would be no difficulty of extending their flowering period over three months if desirable.

As the plants finish flowering the dead blooms are picked off, for if the seed were allowed to remain on the plants it would considerably weaken the bulbs, and most likely failure would be the result next year. After this they are removed to our latest vinery, and watered the same as while flowering, for they are now perfecting the next season's flowering bulbs. The pots remain in this house until repotting is required, and have water supplied as they may need; but as soon as the foliage shows signs of turning yellow they gradually receive less water until the foliage is dead, when all further watering must be discontinued. After this we place them on a shelf close to the glass, the pots being laid on their sides: they remain in this position all the summer baked in the sun till the beginning of August, by which time they are ready for repotting.

The soil is shaken from the pots, the bulbs after being sorted into different sizes to be placed together, as then the growth will come of equal strength. The soil we use is a mixture of leaf mould, yellow loam, and silver sand. The pots are three parts filled with this soil, and then eight bulbs are placed in each 5-inch pot. They are stood close together in a cold frame and watered through a fine rose. After a day or two they are covered with ashes the same as our other bulbs. After three weeks or a month they must be frequently examined to see if the growth has commenced. If left so long under the ashes there is a great risk of breaking their small growths. When the growths are about 1 inch or so above the soil the ashes must be removed, and the small plants be kept partly dark for a week or so, gradually hardening them to the light, precisely the same as with other bulbs. They remain in the same frame until the nights get cold and there is danger from frosts, when they are again transferred to our late vinery and placed on a light shelf, and from there to warmer places any time when sufficiently strong from the beginning of December onwards, or let them bloom in any cool house where frost is excluded.—R.

FERTILISATION OF EARLY PEACHES.

NUMBERS of gardeners devote much time to the fertilisation of early Peaches, and various methods are practised. Some dust all the flowers with a camel-hair brush, a very tedious process, taking much time often wanted for other purposes where there is insufficient help; others use a rabbit's tail in much the same manner; and many now recommend slightly syringing the trees during sunshine, certainly a much quicker operation, but of its efficacy in early houses I am not quite certain. All of the above methods are dispensed with here, and the following simple plan adapted which invariably leads to good results. When the trees are in flower we make it a rule to have a little ventilation on the front of the house at night, which tends to maintain the atmosphere in a pure and buoyant state, keeping the temperature at 50° to 55° by fire heat. The ventilation is increased in the morning as the external temperature rises. Sometimes it is necessary to open the top ventilators, at the same time closing the bottom ones, for we never have both open at once, except in warm sunshine with the absence of cold wind, cold draughts being carefully guarded against. Two or three times during the day the trellis wires throughout the house are given a sharp rap with a stick, which causes the pollen to be abundantly dispersed. These are the only means used, and the good sets of fruit we obtain amply demonstrates the efficacy of the practice; in fact I have not noticed a single flower in either of our two early houses which has proved unfertile.—S. T. C.

AUTUMN-SOWN TURNIPS.

WE have found these very useful this winter, although little larger than fowls' eggs. If they are still in the seed bed no time should be lost in lifting them, as with the return of warmer weather they will soon produce top growth, which will spoil the roots. When drawn they should be trimmed ready for the kitchen, and then buried in sand or sifted ashes behind a north wall, where they will remain fit for use for a long time.

Turnip-tops are much appreciated in most places, hence, as "greens" are very scarce this winter, extra means should be taken to secure a good supply. If those roots too small for use be planted at once, 6 inches by 4 inches apart, some on a south and others on a north border, they will be found very useful, while the seed bed will be at command for other crops.

SWEDISH TURNIP.—We are just now cutting splendid tops of these from the Mushroom house; they are appreciated by all,

and in many instances preferred to Seakale. Owing to the drought last season many gardeners are at their wit's end to meet the demands for vegetables. I would advise such to procure some sound Swedish Turnips, and three parts bury them in light sandy soil in their Mushroom house or any warm dark place, and they will soon be rewarded with some beautiful delicate tops, which will compare very favourably with Seakale. Select roots with entire crowns, or they will throw up a quantity of small shoots instead of one large one.—J. H. W.

PROTECTING FRUIT BLOSSOM.

SOME years ago when living in what might be considered a favourable climate we did not think it necessary to protect Plum, Peach, Apicot, Nectarine, Pear, and other fruit tree blossom on the walls and some standard trees. Sometimes the crops were good, but in other seasons they were not. This did not satisfy us. We required a good crop every year, and the trees, although not highly trained, were in good health. It was not disease that made the crops deficient, but after adopting a careful system of protecting the blossom we proved conclusively that non-protecting had been the sole cause of our crops not being uniformly good.

Apricots are amongst the first fruit trees to flower, then come the Peaches and Nectarines, and finally the Plums and Pears. We have had the Apricots in flower in February, and they are always in by March. The weather then is often most unfavourable, and it is not always good in April. Indeed, it is no use depending on it being good when the trees are in bloom, and protection should always be applied, let the weather be what it may. If it does good in bad weather it certainly does no harm in genial weather, and it is most important that it be applied in time. The great point is to place the protectors on before the flowers are opened, and allow them to remain on until the fruit is formed.

Old fishing nets are cheap enough, and they form excellent protectors. A double net will insure us a crop of fruit. Where wide copings top garden walls suspend them from the front of these and secure them at the bottom. If they will not reach down all the way tie pieces of string here and there to them and attach these to pegs a few feet out from the bottom of the wall. If they will reach down to the ground peg the net to the soil. They must never be allowed to flap on the trees. This will injure the blossom as much as exposure. Where the coping is short and does not admit of the net being kept away from the trees use poles to keep it off. If these are placed against the wall at intervals of 5 feet or 6 feet and kept 3 feet to 4 feet out at the bottom the net may be stretched along and tied to them in such a way as to keep quite clear of the flowers. This is our plan of protecting fruit trees, and it is effective.—A KITCHEN GARDENER.

SIX GOOD BEANS.

THESE are not all of the same class. I do not know six good Broad Beans, six good Runner Beans, nor six good dwarfs, but for all that I can recommend six good Beans, and they will consist of two Broad, two Runner, and two dwarf varieties. There are more than half a dozen varieties to be found in each of these sections in the seed lists. Indeed, collectively, I know thirty-one varieties, but they will bear weeding severely, and my present half dozen are worth inspection and trial.

BROAD BEAN SEVILLE LONGPOD.—I name this because it is amongst the earliest of all, and it is very prolific. It is very hardy. It may be sown in the open in any of the winter months, and by sowing in February we have had it ready in May. The pods are from 9 inches to 10 inches in length; they are narrow, and well filled with delicate beans that are much valued as a first crop. For early shows this Bean is very suitable, and a dish of long tender pods is very attractive.

BROAD BEAN AQUADULCE.—It is not generally known that this is a splendid Bean, but I have grown it for ten years, and it has always proved true and fine. It is one of the largest of the monster-podded varieties; I have gathered pods of it 16 inches in length. When going to see a friend of mine last year I took a pod this length to show him. He asserted I was "trying it on" with an artificial construction, but when he opened it and eleven fine beans rolled out, he understood it better. It is curious that this fine variety is no one's "specialty," and yet it is undoubtedly the finest of all Broad Beans.

RUNNER BEAN LAXTON'S WHITE CZAR.—I may say at the outset this is the largest of all Runner Beans, and it is also the most prolific. I have gathered pods of it 14 inches in length, and they will all average 10 inches. As a rule they are produced in clusters of three, four, and five, and to see a row of it in full bearing is a grand sight. It is as hardy as any other, and grows very freely.

To see the stems and leaves do not give any idea it is such an uncommon bearer, but when in fruit it attracts everybody. Some object to large-podded Beans; I do not, because so long as the large pods are young they are as good in every way as the smaller varieties, and I should never wish to meet with a better flavoured Bean than this variety.

RUNNER BEAN MONT D'OR OR BUTTER BEAN.—The Butter Bean is distinct from all others. It is just as hardy, and may be sown at the same time and in the same manner. The pods are quite pale in colour, perfectly stringless, and remarkably fine in flavour. They may be cooked whole, when they form a delicious dish, and I am surprised this variety is not more grown.

DWARF BEAN COOLING'S NE PLUS ULTRA.—I have tried every Bean I could obtain for forcing, and I find this the best. It is very compact in growth, enormously prolific either under glass or in the open, and it is earlier by many days than any other sort. It is pale yellow in the colour of the seed, and there is no mistaking it. The pods average 4 inches in length, and the prolific way they are produced is very remunerative.

CANADIAN WONDER.—This is a well-known dwarf French Bean. It is useless for forcing compared with the preceding, as it grows too tall to be easily accommodated, and it is not half so prolific under glass as it is in the open. As a dwarf Bean for open air culture it has no equal. It grows robustly, fruits profusely, and produces the most handsome pods of all dwarf Beans. In this respect it has no rival, and I have often wondered to whom we are indebted for it. It is capital for exhibition, grand for the table, and it should be grown by all.—J. MUIR, *Margam*.

FALLACIES IN GRAPE CULTURE—LIME.

GRAPE-GROWING has been quite revolutionised within the last quarter of a century. It has not only improved, but extended to a degree little contemplated, and our thanks are due to the larger cultivators for recording their experiments, successful and otherwise, for the benefit of the small growers who have not the means to experiment for themselves; but I question the usefulness of some of the modern doctrines. I allude to the lime theory. Lime has been used in vineries for many years, but applied to the walls as whitewash, and I am inclined to think this is still the best place for it, although I am aware in some instances excellent Grapes are grown where it is reported lime has been extensively used; but it is also a fact, as I will hereafter show, that equally fine Grapes are grown where lime is not used. In order to substantiate this I will review a few of the most successful instances that have been recorded during the last twenty-five years. Since [t] at time Mr. Meredith was on the pinnacle of fame; he was the pioneer of the great growers. The secret of his success was supposed to be the extensive use of crushed oyster shells and the favourable atmosphere of Garston, which is during a "nor' wester" somewhat briny. Very little, if any, notice was taken of his fine loam and the improved structures at command; and not a few gardeners recounted the frowns of their employers because Grapes equal to Meredith's were not forthcoming from antiquated ill-constructed flue-heated places better adapted to destroy vegetation outright than for producing Grapes of any sort. Unfortunately it often happens that employers compare productions without considering advantages.

We will now take the case of Mr. Lane's of Berkhamstead, where another wrinkle was supposed to be gained in connection with the fine Muscats grown there about six'een or eighteen years ago. The secret of success was supposed to be the abundant water supply to the roots. It soon became generally known that a spring of cold water bubbled up at the foot of the Vine border, which produced a mania for the water pot. As some of us youngsters can testify, it soon became common practice to deluge Vine borders; no matter whether the soil was open or retentive, or the border drained or clogged, on the water had to go, with results that might be expected—wholesale shanking.

A few years later we had another surprise. Mr. Hunter of Lambton Castle Gardens came prominently to the front as a producer of fine Grapes, a position he still retains. There the largest Black Hamburg was produced, and the reported successes were attributed to the enormous quantities of warm liquid manure applied to the borders. Little or no notice was taken of other advantages, such as new and improved structures, well-drained new borders, &c. More recently we have had the magnificent Black Hamburgs from Eastnor to admire. The secret of this success is, I think, more to the point, as Mr. Coleman recommends those anxious to imitate them to use good loam and crop lightly, but there may be more important lessons to learn at Eastnor, but I think Mr. Coleman's advice is worth accepting. I think the above are as good representative instances of successful culture without the use of lime as can be found with the use of lime.

I will now venture to review a few instances where it is reported that lime has been employed extensively, and should like to hear whether anyone else can see any improvement in the produce from these establishments, because I cannot. Admitting the excellence of the Longleat Grapes, which are too well known to some of us to dispute, yet I am curious to learn if equally fine Grapes could not be produced even at Longleat without the use of lime the same as other places, as we are told fair Grapes were grown at Longleat years ago without lime, and what has been the cause of this state of thing? Taking the case of Mr. Stephen Castle, I beg to inform him that I saw his exhibits in Scotland some years ago. I saw them again at the Aquarium last November. I presume his Scotch exhibits were grown without lime and his Aquarium exhibits with lime. However this may be, I saw no improvement in them, and if lime produces no better results than is seen in his case I strongly advise my friend to abstain from its use altogether.—J. H. GOODACRE.

EVENTS OF THE WEEK.—On Thursday, the 15th inst., the Royal Society meets at 4.30 P.M., and the Linnean Society at 8 P.M. on the same day. The first spring Show of the season will be held by the Royal Botanic Society at Regent's Park, on Wednesday, the 21st inst., and the Liverpool Spring Show takes place on the same day, followed by the Shrewsbury Show on the 22nd, and the Crystal Palace on the 24th.

— **THE WEATHER IN LONDON.**—After a few days of mild weather, Monday and Tuesday in this week were bitterly cold, snow falling freely on Tuesday night. Yesterday (Wednesday) opened mild and bright, but the changing wind is not favourable to a continuation of genial weather.

— **AT THE ROYAL BOTANIC SOCIETY'S SPRING SHOW,** to be held at Regent's Park on Wednesday next, eighteen classes are provided for Azaleas, Primulas, hardy plants, Roses, Deutzias, Cyclamens, Hyacinths, Lilies of the Valley, Tulips, Narcissi, Crocuses, and Amaryllises, one class also being added for twelve pots of bulbous plants, distinct from any of those already named.

— **THE WEATHER IN SCOTLAND.**—"B. D." writes: "With the exception of last night (11th) there has been no frost during the past week. Heavy rain for two or three days brought down the streams in the south of the country in very heavy flood, and a good deal of snow is reported in the north. Saturday was a beautiful day, and several spring flowers bounded into bloom. In the evening the wind returned to the north-east, and it is again very cold."

— **AMORPHOPHALLUS RIVIERI.**—This remarkable plant has again flowered in the Oxford Botanic Garden, where the cultural treatment of it has been attended with a continuity of success that few establishments can boast of. When seen a short time since its solitary spadix had exceeded 18 inches in height, and gave promise of as fine an example of its singular attractiveness as any that have preceded it.

— **ADIANTUM SCUTUM.**—"S." writes—"Anyone requiring a good Adiantum for house decoration during the autumn and winter months would do well to take this one in hand. It makes a free growth during the spring and summer months when treated to a warm moist temperature, as, for instance, a vinery at work suits it well. Capital plants can be grown in 4½-inch and 6-inch pots. A compost of two parts good fibrous loam to one of peat, adding some old lime, mortar, and sharp sand suits it well. Abundance of water at the roots during the summer should be given. This variety of Adiantum has a graceful habit, yet the fronds are stout enough not to require support at any time. In a cut state the fronds last a long time in good condition."

— **FOR PRODUCING A QUANTITY OF PURE WHITE FLOWERS DURING DECEMBER AND JANUARY** the following two varieties of **WHITE-FLOWERED PELARGONIUMS**, Madame Ernest Ernoul and Niphotos, are excellent. They are both of free growth without being too robust, and flower abundantly if their preparation has been well carried out during the summer and spring months. Strike the cuttings in the early part of

February singly in small pots, transferring them eventually to 5½-inch pots, using a compost of two parts loam, one of leaf mould, a slight dash of bone dust, and some sand. Grow the plants near the glass to procure a stocky habit, placing them out of doors as soon as possible choosing a sunny spot, standing the plants thinly on the ground that they get abundance of light and air. Remove the plants to a cool house before the approach of autumn frosts. During the winter months give them a temperature of not less than 45° by night, with a corresponding rise by day. Supply the plants freely with liquid manure.

— **BARE SPACES ON THE BACK WALLS OF GREENHOUSES** can be rendered bright and useful by planting **IVY-LEAF PELARGONIUMS**. Such plants being naturally short-jointed, retaining their leaves a long time both during the winter and summer, alike renders them suitable as evergreen plants for the purpose named. Most sorts flower freely, lasting a long time in good condition either on the plants or in a cut state. For the latter purpose flowers from Ivy-leaf Pelargoniums are much prized for vase decoration, either by themselves or with other flowers. By removing a small portion of the soil from the present border and adding some fresh compost not too rich in character the plants will have a better start. Vigour can easily be maintained by applications of liquid manure when the plants are growing freely.

— **LONICERA SEMPERVIRENS.**—"For supplying cut flowers nine months during the year," writes "E. M.," "this *Lonicera* is very valuable. It grows well and flowers freely in an ordinary greenhouse where frost is excluded and its shoots can be trained close to the glass. The flowers last a long time in a cut state, and are very showy when associated either with its own foliage or that of other plants. The flowers are a bright red outside and yellow inside. When the roots are confined to pots copious supplies of water are needed at the roots alternated with liquid manure, as it roots freely. Provide a substantial soil for the roots, composed mainly of loam, when there is a likelihood of its occupying the same pot more than one year, and top-dress occasionally with bone dust, which is a good stimulant as well as a surface root producer. Vigorously syringe the foliage in the evening during summer. From early in March to November flowers are freely produced if attention be paid to the supply of water to the roots, smoking occasionally to keep down green fly, and training the shoots thinly."

— "J. L." remarks:—"I was much interested in Mr. Muir's article on **PLANTING SANDY WASTES BY THE SEA**. The plant he means I did not know, but thought it must be another name for our native Grass, *Elymus arenarius*, which does the same good service in many sandy districts by the sea. I hunted up some of my botanical books, but did not find it mentioned in any of them excepting 'Hooker's British Flora.' *Elymus arenarius* is there described as follows:—"Root much creeping in loose soil, hence it is of great value, like the *Ammophila arenaria* for preserving a considerable extent of our own coasts and those of Holland from the encroachments of the sea. The seeds are said to be made into bread in Iceland." We have other letters on this subject.

— **WE LEARN FROM THE SCHEDULE JUST TO HAND** that the **SHREWSBURY FLORAL FÊTE** for the present year will be held on August 22nd and 23rd, when the usual liberal prizes will be offered. For instance, there is a class for twenty stove and greenhouse plants with three prizes of £25, £20, and £15, besides several others in smaller open classes, ranging from £10 to £1. Fruit is well provided for, no less than £66 being offered for Grapes alone, and for a collection of fruit comprising twelve dishes the prizes are £10, £6, and £3. For vegetables £50 are contributed in numerous classes, the Veitch Memorial medal, and £5 being one of the attractions. Special prizes are also offered by several firms of seedsmen. A spring Show will be held on March 22nd, when provision will be made for all the principal forced plants. This Society is in a most flourishing condition, the balance in the banker's hand from last year's shows being £534, the interest on invested capital amounting to £72. Messrs. Adnitt and Nannton are the Hon. Secs., The Square Shrewsbury, from whom schedules can be procured.

— **EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY.**—The annual meeting of this Society has recently been held, and the Treasurer's balance sheet showed a sum of £37 10s. carried forward to the current year. Two exhibitions will be held in 1888. The summer Show in the grounds of the Royal India Asylum at Ealing on July 11th,

when valuable prizes are offered for cut Roses, open to all comers. On this occasion H.R.H. Princess Mary, Duchess of Teck, has promised to attend and distribute the prizes to the successful competitors in the allotment and cottage garden competitions. Ealing has now some 300 or more allotment gardens of one-eighth of an acre in extent, and many working men are still anxious to obtain one. The usual autumn Show of Chrysanthemums, &c., will be held on November 14th, which it is hoped will take place in the new and spacious Jubilee Hall now in course of erection, and which forms a part of a very handsome block of new municipal buildings.

— REFERRING to the AMARYLLISES mentioned last week, "W. J." remarks that he intended saying, "the nine spikes were on two bulbs, four and five each respectively, not nine from one bulb."

— JUDGING BOUQUETS.—A correspondent writes:—" 'Florist,' 'Onlooker,' and others who took part in the bouquet judging discussion, will be glad to hear that their efforts are bringing forth fruit, the Bristol Society having inserted a limit as to size of bouquets in their spring Show schedule."

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, established 1850, incorporated by Royal Charter 1866, to be held at 25, Great George Street, Westminster, on Wednesday, the 21st instant, at 7 P.M., an address will be delivered by the President, Dr. W. Marcet, M.D., F.R.S., on Atmospheric Electricity, illustrated by experiments; after which Mr. G. J. Symons, F.R.S., will make a short communication on The non-existence of Thunderbolts; elucidated by accounts of searches after them and the exhibition of specimens. The meeting will then be adjourned, in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of apparatus connected with atmospheric electricity, including lightning conductors, photographs of lightning, and damaged objects, and of such new instruments as have been invented and first constructed since the last exhibition. The Exhibition will, at the request of the Secretary of the Institution of Civil Engineers, be open in readiness for their meeting on Tuesday evening, the 20th instant, and will remain open till Friday, the 23rd instant.

— A HORTICULTURAL Congress has been organised by the SOCIÉTÉ NATIONALE D'HORTICULTURE DE FRANCE to be held at 84, Rue de Grenelle, Paris, during the progress of the Exhibition, which will be opened on the 25th to the 31st of May. The first sitting of the Congress will take place on May 28th. It is proposed to discuss a variety of questions on scientific and commercial horticulture. Several subjects have already been decided on, including railway tariffs for horticultural produce, horticultural instruction in schools, heating apparatuses, profitable fruit culture, the propagation of hardy plants, and the diseases of Zonal Pelargoniums. Other questions may be proposed for discussion than those included in the programme now issued if notice is previously given to the President of the Committee, M. A. Hardy.

— MESSRS. WOOD & SONS send us samples of Orchid peat and loam, both as good as we could desire to use, the former sweet and all fibre, the latter turfy and "unctuous."

— GARDENING APPOINTMENT.—Mr. Robert E. Filkins, for the last four years gardener to P. J. Slinger, Esq., St. Mary Cray, Kent, has been appointed gardener to G. Buchanan, Esq., Tower Fields, Keston, near Beckenham, Kent.

— TESTIMONIAL TO MR. PAUL OF PAISLEY.—The friends of Mr. Paul (late of Crossflat Nursery) propose giving him a testimonial, in recognition of his services to floriculture, on the occasion of his removing from Paisley to continue the florist business at his new grounds at Bridge of Weir, nearly midway between Paisley and Greenock. Crossflat, where so much has been done in the improvement of florists' flowers, notably of the Pansy and the Pink, has suffered from the erection of various manufactories in the immediate neighbourhood. Mr. Duncan Keir, The Gardens, Sherwood, Paisley, is the Secretary to the testimonial fund.

— THE EMPLOYÉS OF THE ROYAL HORTICULTURAL SOCIETY.—It has been suggested that the occasion of the vacation of the South Kensington premises by the R.H.S. is one that should be taken advantage of to invite the employés of the Society at South Kensington and Chiswick to an entertainment, by way of expressing some sense of the

uniform courtesy and attention they have at all times shown towards exhibitors, the members of the Committees, visitors, and others. The men employed at South Kensington have to leave the service of the Society consequent upon the change of home; and it is rumoured that those at Chiswick may have notice to leave, though the order is not intended to be enforced at present. Before they are dispersed it is thought they should be invited to a supper, and I shall be very glad to receive the names of any gentlemen who would be willing to co-operate by forming themselves into a Committee to carry the proposal into effect.—RICHARD DEAN, *Ranelagh Road, Ealing, W.*

UNDER GARDENERS AND EXHIBITORS.

THIS seems, in my opinion, to be a subject well worthy of discussion, and it is hoped that under gardeners, as well as others, will benefit thereby. I was very pleased to see Mr. W. Bardney's name approvingly mentioned on page 158 as I had the pleasure of serving under him for two years. We had plenty of work at Norris Green, but the knowledge that we were doing it for a friend as well as a master helped us to pull through the hardest of it with pleasure.

On the other hand it is as well not to lose sight of the fact that men must understand that we, not they, are responsible. Young men are met with who before they have been in a place long know far more than the head gardener does, and seem to feel they should do as they like. Walking through the houses with my employer we found water running to waste through a tap which should have been stopped by a young man who had been syringing, but I was politely told the fault was mine, and if the young man did not carry out my orders I was to discharge him.

In reference to the question of exhibiting, I think that young men should receive some recompense if they work overtime in helping the gardener with his exhibits. I am only a young exhibitor, and I find that I have exceeded my prize money in expenses this year. Where a gardener has all expenses to pay, and stands and other necessaries to provide for showing, his first season will, in nine cases out of ten, be unremunerative; he may win honour, and that is all. But I have endeavoured by kindness to repay all my young men for their assistance, and I believe to their satisfaction, and should I be as successful this year I feel sure they will not have reason to complain that they have assisted me in vain. I hope this discussion will create good feeling and mutual confidence between master and man. As a parting word to those who feel they are, "like I once found myself," in a place not exactly to their liking; let them do their duty as long as they are in it, hoping for better times, which are sure to come.—P. T. D.

UNDER the above heading your correspondent, "Head Gardener," strives to relieve his mind, and exhibits much sympathy on behalf of his so-called unfortunate brethren. Being in doubt as to the meaning of "Head Gardener's" opening remarks, I must wait for his further elucidation of the subject, and pass on to the more particular part of his paragraph—viz., the denunciation of head gardeners. I need not, I think, remind "Head Gardener" of the fact that we are agreed upon the matter of there being good and bad gardeners, for he admits the fact of winning golden opinions of some. But when he so far forgets the responsibility of his position that he requires the intercession of his employer to settle trifling disputes arising between himself and his subordinates, I confess I shall be greatly astonished if he succeeds in winning the golden opinions of many upon that subject.—J. P. L.

I HAVE read with interest the different letters that have appeared in the Journal about young gardeners and exhibiting, and I cannot help thinking that those who write about their bad treatment from head gardeners are those who do not take much interest in their work. When an under gardener I only lived at two places where exhibiting was done, and then we were at work late at night and early in the morning, and not paid for overtime. We did our work with pleasure, and did not even think about being paid or getting any of the prize money. We did our work because we took perhaps as much interest in it as the head gardener who was receiving the prize money. I think if under gardeners looked at things in the right way, and looked forward to being head gardeners themselves some day and getting the credit as well as the prize money, it would go a long way in helping them over their grievances. No doubt there are head gardeners who are never satisfied with their young men let them do their work ever so well. But such, I think, is not the rule.

Mr. "Spectator" has a good paragraph on the subject of pay for overtime in regard to Grape-thinning. I have spent many an hour of an evening thinning Grapes and never had any pay for it. Some may think I advocate the no pay overtime system, but I am far from that. I do not ask my young men to work at night more than can be avoided, but sometimes Grapes and other things are all wanting attention at the same time, and cannot be seen to in the ordinary working hours. I should not think much of a young man who refused to assist for an hour or two in the evening just to pull things straight. I remember the subject of "Pay for overtime" was taken up in the *Journal of Horticulture* some eight years ago, and I think it was Mr. Gilbert who wrote, "If a gentleman has more Grapes than he can afford to pay for being thinned let them go without thinning." But I venture to think no one with a love for the art could attend to a vineyard with the Grapes hang-

ing unthinned all the season; and if he could he would most likely have to bid farewell to the Vines when the time came for sending the Grapes to his employer's table. My advice to all under gardeners is, Never be particular about working an hour or two overtime when asked, and you will not be the losers in the end.—G. HILTON.

I AM very pleased to see that there is at least one head gardener (page 158) who dares and is willing to say a word for subordinates. There are certainly instances where young men have cause to complain of their treatment, but few venture to write to any of the periodicals about it, for the simple reason that they believe there will be so many to criticise and so few to say a word in their favour; but let them remember that the oldest and most experienced writers are criticised, and they must also remember that a little mild criticism will do no harm, but rather improve them; and as everything must have a beginning they may as well begin at once, for the longer they leave the little talent they have undusted on the shelf the longer it will take to polish it when they do reach it down. Many head gardeners seem to think the young men are all very careless, and have no talent. They appear to forget that it is from the acorn that we must expect the Oak, and that it is the schoolboy that must become the professor, and likewise the young man of to-day the future head gardener. Some seem to think that when they are gone there will be nobody fit to take their places. They say, "I can't think how it is that my young men are all so careless." There is a reason, and if the Editor will allow me I will try to explain it in a future issue. They are not all bad, but in many places young men really do become careless from various reasons, but I think if they were to write a little more they would find themselves benefited by it, for there must be many young men in the country with sufficient talent to write a decent letter; and if at first they could not produce anything very elaborate, they would find that with practice and the experience gained by it, they would in time be able to place themselves on a level with some of the best writers of their day. After the encouragement given by "Spectator" on page 147 I think they need not be held any longer in suspense.—A FOREMAN.

METROPOLITAN PUBLIC GARDEN ASSOCIATION.

THE fifth annual report of the above Association has been issued, and from it can be gleaned full information of the work being done in securing open spaces in our great metropolis for the benefit of the masses. They commenced their work on the site of the old Horsemonger Lane Gaol, which to the extent of 1 acre 3 roods was opened as a public recreation ground in 1884. The Association has laboured successfully since then up to the present time. By the aid of donations and subscriptions they have been instrumental in giving to the public use as pleasure gardens nearly 60 acres of open spaces, the majority of which were disused burial grounds.

"The object of the Association is to provide pleasant resorts for the old and playgrounds for the young in the midst of densely populated localities." The report says, "Only those who live among the artisan and labouring classes, or who personally interest themselves in their welfare, can form any conception of the sad condition when contrasted with that of those who are periodically able to change the scene under which tens of thousands of them live and die. Unless in the neighbourhood of one of the parks the only opportunity of relaxation and recreation is in the thoroughfares where every inhalation of air is laden with dust; their children for the most part have no playground but the gutter and the pavement. The majority of those who live in the poor and crowded districts seldom escape from their dismal surroundings."

"Now the provision of garden and playground, though of course no panacea for human suffering and misery, will largely help to brighten the lot of those who live as above described. London is year by year becoming more and more packed, and populated, and extended to a degree that must fill every reflective mind with concern. This can have but one possible effect, and that is to render London less and less the place where the bodily functions can have full and natural play, where bone and muscle in the young may be developed, and where constitutions are able to ward off disease and decay."

The Association believes that by securing open spaces it is adopting the best method of meeting the evil which is threatening London, besides finding work for the unemployed, as nearly all the work of the 60 acres above mentioned has been done by the men found in the ranks of the unemployed. At the present time they have other works in construction which is finding daily work for about 300 families. At Camberwell upwards of 200 men are employed in turning a large market garden into a public park, and from a horticultural point this is interesting, as it preserves from the encroachment of the builder a portion at least of those grounds that have in the past associated with the familiar name of "Myatt." Where Myatt's famous British Queen Strawberry grew to perfection, Myatt's Rhubarb, and Myatt's Early Ashleaf Potatoes were once famous, in future will be an open space embellished by gracefully sweeping walks, tastefully planted shrubberies, well kept lawns, and fountains. For some weeks 240 men were employed here, and it is natural to suppose that many from not being used to the work suffered very much, being poorly clad and ill fed. Some have come from a great distance, walking both morning and night from Holloway, Highgate, Bethnal Green, &c., to Camberwell. Many also suffered with bleeding hands, being unused to the work. French polishers, painters, carpenters, in fact men of all trades, have been here struggling to tide over the long and wearisome winter, therefore the objects of his Association are

manifestly of a twofold character. 1, To find employment for deserving men, and secondly to expend that labour on some lasting and useful memorial for the masses. By a scheme of a committee of gentlemen acting in concert with the Lord Mayor, all that are employed at Camberwell and deserve help of a permanent character are being assisted. Various methods are being adopted, but the easiest apparently is emigration. Many are availing themselves of this privilege.

Altogether there were 420 disused burial grounds within the metropolitan area; sixty-nine are open to the public as gardens or playgrounds for the young, mainly through the aid of the above Association; 116 burial grounds which at one time existed have entirely disappeared, their sites being now occupied by buildings of all kinds; thirty-eight are used for various purposes, and 197 disused burial grounds still exist closed to the public, and it only requires public sympathy and assistance to transform these so dreary grounds into attractive miniature parks.—J. W. MOORMAN.

TOMATOES IN TRENCHES.

A SIMPLE and very useful method of growing Tomatoes in the open air is practised by Mr. J. Forbes in the gardens at Dover House, Rochester. On a sheltered plot of ground sloping sharply to the south a trench is dug about 4 feet wide, as if preparing to grow Celery on the bed system, and strong Tomato plants planted in suitable soil at the

Fig. 26.

proper time. The trench is covered with rough open latticework, through which the plants grow and are trained down to it. With attention to thinning the growth for the admission of sun to the fruit ripe Tomatoes in abundance are produced in the summer in the manner represented in the engraving.

ROYAL HORTICULTURAL SOCIETY.

MARCH 13TH.

COUNCIL MEETING. — A meeting of the Council was held on the date named, when the privileges to be given to the Fellows according to the rate of their subscription was finally settled. Nominations were received of thirty-six new Fellows. The Council interviewed several of the candidates for the Assistant Secretaryship, and after much deliberation determined to appoint Mr. Charles J. Grahame to the post. The agreement for the premises, 111, Victoria Street, was finally adopted, and the seal of the Society was ordered to be attached to it. Sir Trevor Lawrence, Mr. W. T. Thistleton Dyer, Dr. Masters, and Mr. Veitch were appointed a deputation to wait on the Lord Mayor with reference to the projected Show in the City of London this year. The bye-laws, as altered and amended by the sub-Committee, were ordered to be printed and circulated before being presented for adoption. The following gentlemen were requested to act as an Exhibition Committee to draw up a programme for the present year—viz., Messrs. G. Bunyard, Barron, Douglas, Haywood, Laing, G. Paul, Rivers, Turner, Veitch, Walker, and Wildsmith, with power to add to their number. The Council will meet again on Tuesday, March 20th.

SUMMARY OF THE PRIVILEGES OF FELLOWS AND ASSOCIATES FOR THE YEAR 1888.

A FELLOW PAYING FOUR GUINEAS A YEAR IS ENTITLED—

1. To a family ticket admitting to all the Society's Exhibitions and Meetings at 12.30 o'clock, being an hour earlier than the general public.

2. Personal admission to all the Society's Exhibitions and Meetings at 12.30 o'clock, being an hour earlier than the general public.
3. To personal admission daily, between the hours of 10 A.M. and 5 P.M., to the Society's Rooms and to the Lindley Library, except on Sundays and holidays.
4. To personal admission, between the same hours and with the same exceptions, to the Society's Experimental Gardens at Chiswick.
5. The privilege of sending fruit, flowers, and seeds to Chiswick for trial.
6. To a share of such seeds, plants, cuttings, &c., as the Society may have in sufficient numbers for distribution.
7. To purchase such fruit and vegetables grown at Chiswick as are not required for the purposes of the Society.
8. To a copy of all publications of the Society.
9. To the right of voting at all meetings.

A FELLOW PAYING TWO GUINEAS A YEAR IS ENTITLED—

10. To a transferable ticket admitting two persons to all the Society's Exhibitions and Shows.
11. To the same privileges as mentioned in Nos. 2, 3, 4, 5, 6, 7, 8, and 9.

A FELLOW PAYING ONE GUINEA A YEAR IS ENTITLED—

12. To personal admission to all the Society's Exhibitions and Shows.
13. To the same privileges as mentioned in Nos. 2, 3, 4, 5, 6, 7, 8, and 9.

AN ASSOCIATE PAYING HALF-A-GUINEA A YEAR IS ENTITLED—

14. To a non-transferable ticket admitting to all the Society's Exhibitions and Shows at 12.30 o'clock.
15. To be present at meetings, but without voting on any matters relating to the affairs of the Society.

N.B.—Associates must be *bona fide* gardeners or employés in a nursery, market garden, or seed establishment, and must be recommended for election by two Fellows of the Society.

The Society being incorporated by Royal charter the Fellows and Associates incur no personal liability beyond the payment of their annual subscriptions.

The Society's Exhibitions and Shows are held in the drill hall of the London Scottish Volunteers, James' Street, Westminster, about equidistant from the Victoria and St. James' Park stations of the District Railway, and close to the Society's rooms at 111, Victoria Street, and to the Army and Navy Stores.

Note.—Any lady or gentleman desirous of joining the Society may obtain forms and full particulars on application to the Secretary, the Society's offices, South Kensington, up to the 25th of March, and thereafter at the offices, 111, Victoria Street.

GENERAL MEETING.—At a general meeting of the Society held the same day in the Conservatory (Maxwell T. Masters, Esq., M.D., F.R.S., in the chair), the following candidates were duly elected Fellows of the Society—viz., John G. Adams, F. Hayman, A. Lovesay, A. S. Montgomery, T. Y. Moore, William Podger, John Reid, W. G. Rowlett. It was announced that twenty-eight guinea Fellows whose names had been received would be proposed for election at an early date.

COMMITTEES.

THE last of the Committee meetings at South Kensington was held on Tuesday in the conservatory, and the event was not signalised by many remarkable exhibits. Several interesting groups were contributed by nurserymen and amateurs, which occupied a portion of the tables, but neither in quality nor quantity was the display equal to many of its predecessors. Those who remember the grand opening day on June 5th, 1861, and who witnessed the practical termination of the Society's occupation of the gardens on Tuesday last, would perhaps feel inclined to moralise. Cordial wishes were, however, expressed that the change being made might prove the commencement of a more satisfactory and prosperous career elsewhere.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair, and Messrs. John Lee, Harrison Weir, G. W. Cummins, C. Howe, John Woodbridge, Alfred J. Pearson, Sidney Ford, G. T. Miles, J. Smith, G. Norman, John Burnett, J. Willard, J. Wright, R. D. Blackmore, J. Cheal, and Philip Crowley. The duties of the Committee were very light on this the last occasion of sitting at South Kensington. Mr. W. Divers, The Gardens, Wierton House, Maidstone, sent a collection of nineteen dishes of Apples and Pears and a dish of large Oranges unnamed. The Apples were very good and well kept, the Oranges of excellent quality. A vote of thanks was awarded. Mr. J. Crook, gardener to Mrs. Sherwin, Farnborough Grange, Hants, sent eleven dishes of Apples and two bunches of Lady Downe's Grapes, one grown on a Vine grafted on the Cannon Hall Muscat; the other by the side of it on its own roots, the berries of the former being decidedly firmer and fresher (vote of thanks). A similar mark of approval was granted to Mr. Burnett, Deepdene, for a dish of Calville Blanche Apples grown on a south wall at Deepdene. This fruit was of good size, greenish yellow, deliciously sweet and tender. A vote of thanks was also accorded to Mr. J. Hudson, who sent from Gunnersbury House, Acton, a dish of Golden Noble Apple, beautifully clear, firm, and fresh. A clump of Mushrooms in one cluster weighing 2 lbs. was exhibited by Rev. G. Henslow, and described by him as having been grown from spawn supplied by Messrs. Cutbush & Son.

At the close of the business Mr. Veitch in a few well-chosen words

referred to the meeting as the last they would attend there, expressing a desire that all the members of the Committee would meet on the 27th inst. in the Exhibition hall at Westminster, and in every way in their power aid the Society in its future career. Different views might be entertained in respect to the course to be pursued, but there could only be one desire amongst them in seeking to place the Society in the position it should occupy in the horticultural world. Unanimous assent given to the Chairman's remarks.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair; and Messrs. J. Laing, W. Wilks, G. Nicholson, M. T. Masters, H. Herbst, W. Bates, J. H. Lowe, G. Duffield, G. Paul, W. Holmes, R. Dean, H. Ballantine, B. Wynne, C. Pilcher, J. Dominy, H. M. Pollett, A. F. Lendy, J. O'Brien, E. Hill, W. Wildsmith, Shirley Hibberd, and W. Goldring.

Only three certificates were granted on this occasion, but four plants were found worthy of cultural commendations, and four medals were awarded to the nurserymen. A. H. Smec, Esq., The Grange, Wallington (gardener, Mr. G. W. Cummins) showed large panicles of *Cyrtopodium Saintlegerianum*, one with 106 and the other with 108 flowers, the latter being a much more highly coloured variety, the wings of the lip reddish chocolate, the sepals copiously spotted with a similar colour, and the petals yellow (cultural commendation). An illustration of the plant was given in this Journal, page 255, April 1st, 1886. A vote of thanks was also accorded for a good variety of *Cœlogyne cristata*. G. C. Raphael, Esq., Castle Hill, Englefield Green, sent a plant of *Lycaste plana*, which has greenish sepals, and white petals dotted like the lip with rose (vote of thanks). Mr. J. W. Machattie, Newbattle Gardens, Dalkeith, showed flowers of a seedling *Rhododendron* with bell-shaped white handsome corollas. Mr. H. Perkins, The Greenlands, Henley-on-Thames, exhibited a plant of *Dendrobium Cooksoni*, Greenland's variety, which had eight flowering growths and some scores of its peculiar flowers, the petals coloured and marked exactly like the lip (cultural commendation). F. G. Tautz, Esq., Studley House, Hammersmith (gardener, Mr. Cowley), showed three *Cypripediums*, *C. Harrisonianum* vivicans being much the best with dark reddish polished flowers; *C. Measuresianum*, of a yellow tint; and *C. Dauthieri marmoratum*. T. Wigan, Esq., Clare Lawn, East Sheen (gardener, Mr. D. East), was awarded a cultural commendation for *Dendrobium Wardianum*, with a number of growths 3 to 4 feet high, stout, and bearing abundance of large flowers. It was said to have been imported in February, 1887. The small white *Cœlogyne sparsa* also came from the same garden (vote of thanks).

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, contributed some Orchids, besides the new *Utricularia*, which was certificated. *Angræcum Sanderianum* was represented by a vigorous plant with four long racemes of white flowers. There was a fine raceme of the remarkably rich-tinted *Phaius tuberculatus superbus*, and the small *Cœlogyne sparsa* already noted. H. M. Pollett, Esq., Fernside, Bickley, sent an uncommonly well-grown plant of *Odontoglossum blandum*, bearing seven racemes of its neatly spotted flowers (cultural commendation); and a distinct variety of *O. crispum*, the sepals heavily blotched with reddish chocolate, the petals white with one or two spots each (vote of thanks). F. C. Jacomb, Esq., 11, Amherst Park, Stamford Hill, showed a group of *Odontoglossums*, comprising choice varieties of *crispum*, *Wilekeanum*, *triumphans superbum*, *Andersonianum*, *Rossi majus*, *maculatum*, and *Pescatorei*, forming a pretty group that deserved some other recognition than a vote of thanks. Mr. Crook, The Gardens, Farnborough Grange, Hants, sent a fresh and beautiful collection of forced Rose blooms, comprising William Allen Richardson, Gloire de Dijon, Fortune's Yellow, Niphetos, Rêve d'Or, and Adam, together with blooms of *Primula obconica*, *Lachenalia pendula*, and *Tremandra ericæ-folia* (vote of thanks).

Flowers of *Beaumontia grandiflora* from Mr. J. Anning, The Gardens, Digs Well House, Welwyn, Herts, were greatly admired. They have tubular corollas 6 inches long by 4 in diameter at the mouth, the five broad lobes recurving slightly and pure white (cultural commendation).

Of the nurserymen's exhibits the most important were the following:—Messrs. J. Veitch & Sons, Chelsea, had a group comprising the bright yellow and early *Azalea pontica altaclerense*, the beautiful free-flowering *Boronia heterophylla*, loaded with its rich rosy crimson bud-like flowers; *Rhododendron Early Gem*, one of the *præcox* style, dwarf in habit, with numerous rosy tinted flowers, very free and useful for pot culture; *Primula obconica*, *Trillium discolor atratum*, very dark-coloured flowers, and a white-berried *Aucuba japonica* (vote of thanks). Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, contributed a large and choice group of Daffodils and hardy flowers effectively arranged (silver Banksian medal). Messrs. R. Veitch & Son, Exeter, sent plants of the dwarf bulbous *Tecophylæa eyanoerocroc* with pure bright blue flowers, and a variety named *Leichtlini*, in which the flowers are white edged with pale blue (vote of thanks). Messrs. Paul & Son, Cheshunt, had a collection of choice alpine plants and a new H.P. Rose named *Lady Alice*, of the same style, but paler in colour than *Lady Mary Fitzwilliam*, also a pretty little *Fairy China Rose* named *Red Pet* (bronze Banksian medal). Messrs. Barr & Son, King Street, Covent Garden, showed a large and interesting group of selected Daffodils and hardy flowers (bronze Banksian medal).

CERTIFICATED PLANTS.

Utricularia rhyterophylla (Sir Trevor Lawrence, Bart., M.P.).—An interesting and very distinct *Utricularia*, which recently flowered in Messrs. Sanders' nursery, at St. Albans. It has long narrow strap-like leaves and tall slender racemes of flowers, the colour being a peculiar

purplish violet. The lower lip-like portion of the corolla is rounded, and about $1\frac{1}{4}$ inch in diameter, with a rich orange blotch at the base.

Saxifraga Frederici-Augusti (Paul & Son).—A neat tufted plant, with small leaves and numerous long drooping spikes of pale yellow flowers. The early flowering and profuse characters of this Saxifraga are its chief features.

Violet The Bride (J. Veitch & Sons).—A pure white flowered variety, very free, and of dwarf compact habit.

SCIENTIFIC COMMITTEE.—Dr. M. T. Masters, Vice-President, in the chair. Present—Messrs. Scott, O'Brien, Pascoe, Ridley, Murray, Smith, Dr. Lowe, Professor Church, and the Honorary Secretary, Rev. G. Henslow.

Hybrid Orchids.—Some cut flowers were forwarded by Mr. Veitch with the following observations:—"The two flowers of *Dendrobium micans* (hyb.) *Rehb.*, were each raised from a different cross. One from *D. lituiflorum* and the Assam form of *D. Wardianum*, and the other from *D. lituiflorum* and the Burmese form of *D. Wardianum*. The Assam *D. Wardianum*, as is well known among the cultivators of Orchids, has shorter and more slender stems, but more highly coloured flowers than the Burmese form, and it will be noticed that the last-named peculiarity is perpetuated in the hybrid. We may also add that the seedling from the Assam form has more slender stems than that from the Burmese form, which like its parent has the more robust stems and paler coloured flowers."

Hybrid Phalaenopsis.—Mr. Veitch also sent a supposed hybrid as being a possible cross between *P. grandiflora*, *Lindl.* (*P. amabilis*, *Bl.*), and *P. rosea*. The above specimens were entrusted to Mr. Ridley for examination and report.

Cattleya Trianae, abnormal forms.—Mr. O'Brien brought flowers of this plant received from the gardens of Mr. W. Furze, Roselands, Teddington. They were curious on account of their arising from different pseudo-bulbs, but all having the median sepal in a petaloid condition. In one flower all the parts were present; whereas in two others the petals were absent, but apparently partly "incorporated with the median sepal." Peculiarities also resided in the column. Dr. M. T. Masters undertook to examine and report upon them.

Strophanthus madagascariensis (Daruty).—This is a new species, named and sent by Dr. Daruty, of Mahéburg, Mauritius. The genus is African, of the order Apocynaceæ, or "Dogbanes," the name being derived from the cord-like appendages to the corolla. It is remarkable for the structure and poisonous properties of the seed. The latter somewhat resembles that of the Dandelion, but is larger, and has the silky hairs distributed down the greater part of the shaft. The natives crush the seeds, from which a red oily mass is obtained, with which they smear their arrow points. Several varieties or species are known, but more material is required for an accurate discrimination of them. As a drug, the active principle Strophanthin, is found in all parts of the pod as well as the seed, and is very powerfully toxic, one-fiftieth of a grain killing a large dog. It seems likely to prove to be a valuable remedy for deranged action of the heart. (See Christy's "New Com. Pl. and Drugs," No. 10, p. 7.)

Marraca, or *Mercurio-Vegetal root*.—Mr. T. Christy sent a specimen of this medicinal root of *Franciseca uniflora*, the bark of which contains the active principle Francisecine. The root is of a woody nature, tapering, and of a light brown colour externally, being of a cinnamon-brown within. From Dr. J. Hutchinson's experience it would appear to be a valuable new remedy for rheumatism, especially of a certain type.

Blue Daisy (?) from Tangier.—Dr. Lowe exhibited a drawing of a small plant, of some 2 to 3 inches high, received from Tangier. The question was raised as to its identity with the Blue Daisy found by Messrs. Hooker, Maw, and Ball on the Atlas Mountains. Dr. Masters undertook to investigate the matter and to report.

Scilla "Droppers".—Mr. Henslow mentioned as a result of a microscopic examination of the attachment of the bulbils, found growing on the inside of the tubular leaf-sheath of specimens exhibited by Dr. Lowe at a meeting of the Scientific Committee (see *Gardeners' Chronicle*, October 15th, 1887, p. 475), that there was a vascular union between the bulbil and the vertical cords of the sheath, consisting of a plexus of tracheids, which entered the base of the bulbil on the one hand, and communicated by arches to the cords of the sheath on the other. The bulbil, therefore, originated in the depth of the tissue of the sheath, so that the adventitious rootlets sometimes penetrated beneath the inner epidermis, which they ripped up; at other they pierced through the sheath to appear externally (see *Gardeners' Chronicle*, March 3rd, 1888, page 276, figs. 45, 46).

Pears, Cause of Unsymmetrical Growth.—Mr. Henslow explained the cause of so many Pears being unsymmetrical about their axis. This was only the case when the stalk was not vertical and the want of symmetry increased with its obliquity. He attributed the growth to the effort of the Pear to meet the strain imposed upon the stalk as the fruit increased in weight. The two forces to which it is subjected are gravitation, or the weight acting in a vertical direction, and the tension along the stalk. The resultant of these two forces tended to wrench the fruit from the latter at its point of insertion at the base of the Pear. To meet this strain, the fruit thickened in the opposite direction, so that the "hump" is always at the base and on the outer or opposite side of the fruit. The effect often extends over the whole of the outermost half of the Pear, so that a vertical plane at right angles to the one in which the stalk lies cuts the Pear into two very unequal portions. When the stalk hangs vertically, as is more usually the case in Apples and in

Oranges, there is little or no obliquity, so that the Pear grows symmetrically round all points of its axis, the radii of the circular transverse sections being all equal.

SELECT ORCHIDS FOR AMATEURS.

IN the following list a selection is given of the most useful, distinct, and easily grown Orchids with which amateurs might commence forming a collection. Brief cultural directions are given for each genus, with the characters of the plants, the time of flowering, the native countries, and the temperature best suited to them. They are in the latter respect divided into three groups. Those recommended for a warm house require a temperature ranging from 60° as a minimum in winter to 80° as a maximum in summer; the temperature of the intermediate house would similarly range from 55° to 75°, and that of the cool house from 45° to 65°, allowing a few degrees more than the highest named in hot weather with free ventilation, but in the cool and intermediate houses the temperature should not be permitted to fall below the minimum given in each case. For the warm house a slight fall in temperature will not be so injurious as the employment of excessive fire heat. The Orchids recommended are in the majority of cases the cheapest of their respective genera, except where some remarkable character renders them particularly worthy of culture. The names of the species or varieties are given in italics at the end of each paragraph.

ACINETA.—Strong-growing evergreen plants with short pseudo-bulbs and large leaves. Flowers large, showy, yellow, white, and purplish brown, spotted with rose or red, in drooping racemes from the base of the pseudo-bulbs. Mexico and Tropical America. Baskets. Warm house. March-July.—*Barkeri* and *Humboldtii*.

ADA.—An evergreen Orchid; free flowering and easily grown plant, with short ovoid pseudo-bulbs and narrow leaves. Flowers bright orange in erect racemes produced with the growths from the base of the pseudo-bulbs. *A. aurantiaca* is the only species in cultivation, and is a native of the Andes in Grenada, where it is found 8500 feet above sea level. Pots. Cool house. Winter.

AERIDES.—Evergreen plants with stems 1 to 3 feet or more high. Leaves narrow, distichous (two-ranked). Flowers small, fleshy, white and rose spotted with crimson or purple, occasionally fragrant; in racemes from the axils of the leaves. Tropical India, Manilla, Philippine Islands, Japan. Warm house. Pots; sphagnum and potsherds. Spring and summer.—*affine*, *crassifolium*, *Fieldingi*, *japonicum* (cool house), *nobile*, *odoratum*, *quinquevulnerum*, *sua-vissimum* and *virens*.

ANGRÆCUM.—Evergreen plants, with stems from a few inches to several feet high, and distichous leaves. Flowers white or cream coloured, mostly small, in long graceful racemes, but occasionally very large, as in *A. sesquipedale*, which has spurs exceeding a foot in length. Tropical West Africa and Madagascar. Warm house. Pots or baskets; sphagnum.—*citratum*, *eburneum*, *falcatum* (cool house), *Sanderianum*, *sesquipedale*.

ANGULO.—Deciduous plants, with large ovoid pseudo-bulbs and bold leaves. Flowers large, fleshy, and showy; single on scapes from the base of the growths; colour yellow and white. Peru and Colombia, at elevations in the Andes. Pots; peat. Cool house. Summer.—*Clowesi*, *uniflora*.

ANGECTOCHILUS.—Small evergreen plants with dwarf stems 1 to 6 inches high and extremely beautiful leaves; light and dark green, purple, or bronze of velvet-like texture, veined with gold and silver. India, Borneo, Java. Warm house. Rather difficult to grow, as the foliage is very delicate. They succeed best in shallow pans of peat, sphagnum, and sand, covered with a bell-glass, to be occasionally removed or elevated, and carefully watered. There are many species and varieties, but the following are the strongest—*Lowi* (*Dossinia marmorata*), *regale* (setaceum), *Petola* (*Maeodes Petola*).

ANSELLIA.—Evergreen plants. Stems 2 to 3 feet high. Leaves narrow, distichous. Flowers in panicles; yellow spotted brown. Tropical Africa. Pots; peat and leaf soil. Warm house. Winter.—*africana*.

ARUNDINA.—Evergreen plants. Stems slender, 2 to 6 feet high, clothed with narrow leaves. Flowers showy, rosy crimson, in terminal racemes. India. Pots; peat and loam. Warm house. Summer.—*bambusaefolia*.

BARKERIA.—Deciduous plants, with slender leafy spindle-

shaped stems. Flowers in terminal racemes, magenta, rose and white, and dark rose, very beautiful. Mexico and Guatemala. Somewhat difficult to grow, requiring a warm sunny and well ventilated position when growing, and a cool position for resting. Blocks. Winter—spring.—*cyclotella, elegans, Skinneri*.

BLETTIA.—Deciduous, with short thick pseudo-bulbs and long narrow leaves. Flowers in scapes a foot or more long, purplish rose or bright rose. China, Japan, West Indies, and New Grenada. Pots; loam, leaf soil, and sphagnum. Cool house. Winter and spring.—*hyacinthina, patula* (intermediate house), *Shepherdii, Sherattiana*.

BRASSAVOLA.—Evergreen plants, with thick linear Rush-like leaves, or thickened spindle-shaped pseudo-bulb-like stems. Flowers mostly singly in scapes from the base or terminal, sepals and petals greenish, lip large and white, deeply fringed in *B. Digbyana* and fragrant. Mexico, Central America, and West Indies. Warm or intermediate house. Blocks or baskets. Autumn and spring.—*acaulis, Digbyana, glauca*.

BRASSIA.—Evergreen, short ovoid dark pseudo-bulbs, and long narrow leaves. Flowers in racemes, yellowish green, yellow and spotted. Curious and distinct. Mexico, Brazil, New Grenada, West Indies. Pots; peat. Intermediate house. Summer.—*Lanceana, Lawrenceana, maculata major, verrucosa grandiflora*.

BROUGHTONIA.—Evergreen, with ovoid pseudo-bulbs and long narrow leaves. Flowers in terminal racemes, rich crimson. Jamaica, on exposed rocks. Block with moss. Warm house. Summer.—*sanguinea*.

BULBOPHYLLUM.—Mostly interesting for the strangely formed flowers, but of little horticultural value. India, Borneo, Java, Siam, &c. Blocks or baskets. Warm house.—*barbigicum, Lobbi, si un nse*.

BURLINGTONIA.—Evergreen, short ovoid pseudo-bulbs, broad leaves. Flowers in loose drooping or erect racemes from the base of the pseudo-bulbs, fragrant, white, flushed or streaked yellow or rosy purple. Demerara, Brazil. Baskets or pans. Sphagnum and potsherds. Warm house. Spring and summer.—*candida, decora, fragrans, venusta*.

CALANTHE.—Useful plants that can be culturally divided into two groups, one comprising *C. masuca* and *C. veratrifolia*, evergreen, with large pseudo-bulbs, broad leaves, and purplish or white flowers respectively; the other including *C. Veitchii* and *C. vestita*, which are great favourites, deciduous, with large conical pseudo-bulbs and long racemes of deep rose or white flowers. They all require pot culture and similar soil—namely, loam, leaf soil, and a little old manure; but the deciduous species require a well marked season of rest after flowering. They are widely distributed in the tropics of the old world, and require a place in a warm house when growing. The evergreen *Calanthes* are mostly summer flowering; the deciduous are winter flowering.

CATTLEYA.—Favourite and useful Orchids, evergreen, with pseudo-bulbs of various sizes, short and ovoid, or long and spindle shaped, with thick broad dark green leaves. Flowers mostly large and very handsome, several together in short racemes from the tops of the pseudo-bulbs, generally before the growth; sepals and petals white, mauve, or rose, with rich crimson and magenta lips, frequently fragrant; bright lemon yellow and very sweet in *C. citrina*. Pots or baskets, with blocks for *Acklandia*, *citrina* (which grows downwards), and *Walkeriana*. Brazil and Central America. Intermediate house. Plenty of light. In flower all the year, the following providing a succession and comprising the most showy. January to March, *Percivaliana* and *Trianae*; March to July, *Acklandia*, *citrina*, *gigas*, *intermedia*, *Mendeli*, *Mossiae*, *Skinneri*; July to September, *bicolor*, *crispa*, *Eldorado*, *Loddigesii*; September to December, *Dowiana aurca* and *maxima Warszewiczii*. There are numberless varieties of *Mendeli*, *Mossiae*, and *Trianae*, and these are all referred to the species *labiata*, the true autumn flowering form of which (*labiata vera*) is very scarce.

CHYSIS.—Deciduous, with thick spindle-shaped stems. Flowers in long racemes produced with the growth, handsome yellow and white streaked crimson. Venezuela, Mexico. Pots. Intermediate house. Spring and summer.—*aurca* and *bractescens*.

CŒLOGYNE.—Evergreen, globular or ovoid pseudo-bulbs and narrow leaves. Flowers in graceful racemes, white and yellow, or of strange brownish tints. India and Malaya. Pots. Intermediate house. February to May.—*crisata*, one of the most useful Orchids grown, *crisata Lemoniana*, *ocellata maxima*.

COLAX.—Dwarf evergreen Orchids, with small ovoid pseudo-bulbs. Flowers two or three in a raceme, white, marked with rich purple, very pretty. Brazil. Pots. Intermediate house.—*jugosus*.

COMPARETTIA.—Slender pseudo-bulbous evergreen Orchids, with crimson and rose-coloured flowers in graceful racemes. Peru and Central America. Baskets or blocks. Intermediate house.—*faleata*.—L. C.

(To be continued.)

PACKING FRUIT.

I HAD really no intention of replying to your correspondent, "R. W.'s" criticism on my paper on packing mixed fruits. However, after reading his reply to Mr. Treseder and "W. H." I thought perhaps it would be as well to answer him now, and set his mind at ease.

I wrote the paper in question at the request of a particular gardening friend, who is a constant reader of the Journal and a keen observer; and if I remember rightly I gave a plain statement of facts, describing the method I adopted in packing mixed fruits and the materials I used. I also stated that paper shavings and clean dry moss were recommended by some gardeners of experience for packing, but I neither recommended nor condemned them. I pointed out, however, that soft hay could be procured in sufficient quantity in most places, an advantage which could not be said in favour of good moss.

Your correspondent asks "why I prefer soft hay to paper shavings?" Well, to satisfy his curiosity, I will use his own words in answering the question, and say, Soft hay, such as is used here "is in my opinion preferable in all respects." It is convenient and easy to pack with, and the fruits packed in it travel in good condition to their destination. What more, I would like to ask, is required, whether the material used is dry moss, soft hay, or "R. W.'s" paper shavings? My paper dealt with packing mixed fruits (which your correspondent informs me "I spared no pains in describing"), but when packing Grapes by themselves I use the same material and a plain box without divisions of any kind in preference to "R. W.'s" favourite box with partitions of various sizes, "which he ventures to say will travel both by land and water if kept right side up. One side of the bunch at the journey's end will be looking almost as perfect as when they were cut from the Vines." We are here called on to accept "R. W.'s" ipse dixit as a settlement of the question. "R. W." writes:—"I also take exception to Mr. Pettigrew's mode of Peach packing. He recommends the use of two boxes, tin and wood. The former I do not find necessary. The box I use is made of wood divided in various sized divisions suitable for Peaches and Nectarines." Your correspondent makes a mistake in saying "I recommend the use of two boxes, tin and wood," in packing Peaches. I recommended nothing in the paper in question. I said the Peaches were packed in tin trays by themselves, which fitted neatly into a wooden box, and described the *modus operandi* of packing; but, as usual, your able critic finds a better plan, which I leave your readers to peruse.

In his concluding paragraph he remarks:—"I may also remark in the dispatch of fruit, should there be two or three boxes to be sent to the same address, I invariably find the fruit in better condition when tied together in one package than if travelling singly." Just so, "R. W.," I suppose the fruit is improved by travelling in bulk.—A. PETTIGREW, Cardiff.

THE PLÂS, TANYBWLCH, NORTH WALES.

TO the modern tourist in Wales the name Tanybwllch is one of the most familiar, thanks in no small degree to the wonderful Toy Railway between Portmadoc and Ffestiniog that was constructed some years ago for the conveyance of slates, &c., from and to the quarries at the latter named place, some of which bearing his name are the property of W. E. Oakeley, Esq., who is also owner and occupier of The Plâs.

The Toy Railway referred to is really a wonder, the permanent way having the appearance of an ordinary small tramway, such as is usual about coal and other works, the gauge being 2 feet only, the entire length of line being about 13 miles and rising in that distance 700 feet. The small engines that perform the journeys draw up this gradient fifty to sixty or perhaps even more empty slate waggons, besides goods trucks and passenger coaches, and are curiosities in the engineering world. They were designed by Sir Robert Fairlie, and are called "double bogie engines," with chimneys at each end, and are admirably adapted for such mountain work as they perform. It may be interesting to state that until their introduction horses were employed to draw the empty trucks up from the wharf at Portmadoc and were themselves carried down in the train, which was impelled downwards by its own gravitation. It is amusing to watch the train on its winding course, first appearing on the edge of a precipice and as fast disappearing again, only to reappear and play the same game of hide-and-seek the whole of its mountain track. The sharp curves give to the train in passing over them a most grotesque form. In one spot a horseshoe is very nearly described, and in another the letter S; indeed, a long train can in one spot perform the feat of describing two such letters at the same time. Looking out of the train as we approach Tanybwllch station we see the roof only of The Plâs house and stables immediately beneath us, so much so that the timid would instantly anxiously exclaim for the safety of the inhabitants.

Looking down the mountain side on leaving the station we see a beautiful lake several acres in extent almost surrounded by woodland, grand in all seasons, even in dreary winter. The Oak, which grows here natural, ever reluctant to cast its foliage, which though somewhat sombre, adds much to the general effect. It has been our privilege to enjoy the scene in various seasons; we can, however, only chronicle the fact that our measure of enjoyment was full to overflowing, and that our pen refuses to do more. The lake, though really artificial, made by Mr. Oakeley, was already formed by Nature, and only required a few yards of embankment, which has been made in such a manner, under the direction of Mr. Roberts, the much respected gardener, that we should not suspect any interference with Dame Nature's work. The water is supplied by mountain streams that never fail, and the overflow

again forms a series of waterfalls on its course through the grounds into the river in the plains below.

The carriage drive crosses this stream by a picturesque moss and Fern-covered bridge, ornamented by several sham arches, probably built early in the eighteenth century. Near by date 1727 is carved in the rock with the initials "E. G." and "J. M. N.," to which, however, we attach no superstitious meaning. Very near the entrance gate is situated the "Oakeley Arms Hotel," kept by Miss Rae, where the tourist is sure of good fare, but where we cannot linger but to mention a pair of Hollies, Gold and Silver, that annually confer upon the inventor of shears—well, not a blessing; their girths respectively at base being 3 feet 6 inches, and 4 feet 6 inches, and but for the misuse of the useful instrument referred to would have been noble specimens, probably in or near their second jubilee.

An old lady beaming with smiles, and crowned with the historical "beaver hat," trips it to open the gate for us, as we re-enter the drive, and to salute us with a hearty "Boreu Da"—Good Morning. We are very soon in the heart of the pleasure grounds, and surrounded on all

the hardier Palms; *Benthamia fragifera*, in splendid condition; Myrtles, growing like Privet; rich Bay trees here, there, and everywhere, some of which are 100 feet in circumference; Camellias in large quantities, annually bear loads of bloom, with no more trouble than Laurels or Rhododendrons; immense specimens of *Aucuba*, 60 feet and upwards in circumference; large wall spaces are covered with Magnolias, that flower most freely, and *Wistaria* blooming twice annually; and further, when we state that *Liliums*, *Dahlias*, and kindred subjects are wintered in the open ground, our readers will form some idea of the climate in this favoured spot, and imagine for themselves the wealth of vegetation here found.

Wending our way onwards we come upon a lovely spot, sheltered on all sides except from the sun, where luxuriates a grand piece of the seldom seen *Dimorphanthus mandshuricus*, and not far off are several plants of *Grevillea robusta*, which I fear, however, Mr. Roberts will not succeed in keeping long. A plant of *Berberidopsis nepalensis*, 48 feet in circumference, is a grand picture, as is also *Berberis Fortunei*, near to, and *Andromeda axillaris*. *Gynerium argenteum*, "Pampas Grass," crowded

FIG. 27.—THE PLÂS, TANYBWLCH, NORTH WALES.

hands by magnificent Conifers, which thrive here uncommonly well. *Cryptomeria japonica*, upwards of 50 feet high; *Cedrus atlantica*, about the same height; *Cupressus sempervirens striata*, nearly as tall, and numbers of very fine Irish Yews, and best Conifers in variety, all having the appearance of being perfectly at home. Some of the Silver Firs, which are represented by *Abies lasiocarpa*, *grandis*, *Nordmanniana*, &c., are perfect pictures, one huge specimen measuring, at 2 feet from the ground, 14 feet in girth. *Abies Douglasii* in various exposed positions demonstrates its adaptability for such situations to satisfaction. This is a favourite with Mr. Roberts for mountain work.

There are also scattered about many grand old Oaks, reminding us that the glory is not all of to-day, for with these we are face to face with ages past and to come, one of these near to measure, at 4 feet from the ground, 17 feet, and gazing upon its gigantic grandeur we felt glad that ships are built now of other material than English or "Welsh" Oak. Very fine Lime trees skirt the grounds where, on all hands, we find, attaining great heights the *Eucalyptus*, some nearly 40 feet, and would be much higher but for the strong winds that frequently carry off their leaders. The majority of these have been planted eight years, and some more than that, a fact that speaks well for the climate here, and when we add that hedges of *Fuchsias* thrive with *Chamaerops* and others of

with strong plumes, form a background to many of the herbaceous borders, which are a grand feature here, and upon which we might dwell at great length, but must for the present refrain, with but a reference to the splendid effect of *Sedum spectabile*, extensively used in these borders, and as edgings to the large shrubbery and other borders. Neither can we dwell upon the collection of *Rhododendrons* that comprises the very best hybrid varieties known, or the *Azaleas*, Ghent and *Mollis* varieties, equally fine, but following in our conductor's train we ascend on to the terraces immediately fronting the mansion, the front of which we find covered with *Clianthus puniceus*, *Aristolochia siphon*, *Myrtle*, *Magnolia*, &c., and at intervals on the terraces are stood Bays in tubs, and amongst them a pair of *Kalmia latifolia*, large and healthy looking. The view from here is exceedingly fine, and we would fain rest and enjoy it. Lord Lyttleton very near the same spot said, "With the woman one loves, one might pass an age in this vale and think it a day;" and in writing to a friend he said, "If you want to live long and renew your youth come and settle in this neighbourhood." Not long ago there died here an honest Welsh farmer who was 105 years of age. His youngest son was eighty-one years younger than his eldest, and eight hundred persons, his lineal descendants, attended his funeral."

We take a peep over the balustrade on to another terrace immediately

below—which is also a farewell glance—at a number of beds of large proportion that have been for several years a home for the most elaborate carpet bedding in the principality. The beds are now being turfed down, and carpet bedding entirely discarded, at least for the present. We must take the opportunity of paying tribute to Mr. Roberts for the very excellent manner in which he managed this department. His originality in design, and capital taste in detail, balance of colours, &c., would compare not unfavourably with the achievements of our London parks in these particulars.

In the glass departments general excellence prevails. Immense crops are the rule every year with Peaches, Nectarines, and indeed Grapes. Of the latter there is one young house especially in splendid condition, consisting chiefly of Hamburgs. A thousand Peaches is certainly a large number of good table-sized fruit to be the product of five trees, and amply bears out my statement as to heavy crops. The varieties grown are the old Royal George, Noblesse, Bellegarde, &c.; Pine Apple Nectarine is the favourite. The vineries afford a supply of another delicious fruit besides Grapes—namely, the *Passiflora edulis*, which is grown on the back walls, and which is deservedly popular here for dessert. Cut flowers being much in demand as in most establishments, we find Mr. Roberts resorting to many “artful dodges” for a supply. In one house recently used for tender bedding plants we find healthy Gardenias planted out, a safe resource for a few choice buds. Immense plants of double Ivy-leaved Pelargoniums on back walls, and coming outdoors we find in the kitchen gardens long ranges of earth pits, full of Violets, Marie Louise, Comte de Brazza, Victoria, and Odoratissima, literally masses of flower, though gathered daily. There are large quantities of Strawberries grown of the very best kinds, and among them Loxford Hall Seedling, a grand variety where it condescends to succeed as it does at The Plas. We will discuss the vegetables indoors, whither we are going, but not without a passing note on the long borders of Carnations of sorts that are also favourites and thrive like weeds. Directing our steps towards Mr. Roberts’ cosy cottage, through frames and Melon ground, we are favoured with the “outward and visible sign” of a Melon, that is to say the rind, the interior having just been discussed elsewhere, and we were assured that though cut three months it was quite as good as in the height of the season. I fancy I hear some old gardener remark, “Ah! it must have been ‘William Tillery!’” Gussed again. Here is another testimonial to the good old variety. Shortly afterwards we retrace our steps, after heartily thanking our host and hostess, but we find the path towards the station very steep, and we puff as hard as the “double bogie” that again bears us on our homeward journey.—BRADWEN.

THE BULB MITE.

HAVING read the article by “Observer” on page 152, I venture to add a few remarks upon Eucharises affected with the mite. I am fully convinced such a mite exists, not only on Eucharis, but also Vallotas, Pancratiums, and Amaryllises. Until recently I have, like others, discarded such plants as were affected with the mite, but often experience teaches us to modify our views and methods. A few months ago, in paying a visit to a previous situation, I asked if the Eucharises had recovered from the rough usage they experienced when under my charge. Some few plants were diseased, and were treated as follows. I turned every bulb out and scraped away every particle of the infested portion, then washed each bulb singly in warm water, afterwards soaking them in a strong solution of Fir tree oil for several seconds. I then placed them all on hot-water pipes to dry thoroughly, repotted several in a 12-inch pot, and conveyed them to a stove, merely placed on dry stages where moisture would readily evaporate. These were watered and kept rather dry for a considerable time. When a few weeks had elapsed signs of growth were promising, but I was not satisfied with their puny leaves. As soon as they had advanced a little I prepared quite a thickened mixture of lime, soot, and water, but added more lime than soot, and watered them thoroughly three times as they became dry. The surface remained undisturbed. After witnessing their vigorous and healthful appearance some time ago I fully believe the lime and soot exterminated the mite. From my observations of bulbous plants, and particularly of Eucharises, injudicious watering when the plants are in a low temperature encourages this pest greatly.—D. P., *Lockinge Gardens*.

THE discussion in your pages upon this subject has reminded me of a conversation I had with an old manager of a noted nursery in this county (Sussex) a few months ago. In passing through a house chiefly filled with fine Eucharises, he asked if I had ever seen the Eucharis mite, and replying that I had not he said, “I have, and my opinion is that it is caused by too much water.” The excellent condition of the plants in his charge was sufficient proof that they were in the hands of one who understood their wants. I am one of those, indicated by Mr. Haggart, who are expected to grow Eucharis without having an unlimited command of heat. For six of the twelve months they are chiefly under the shade of the Vines, and in the autumn and winter they have light quarters in a house used for Cucumbers in the early part of the year, but where the temperature often falls below 50° in the short days of winter. Though the plants do not bloom so regularly as they do where they have a good position assigned them all the year round, still the result is fairly satisfactory. Your correspondents, Mr. E. Beckett and Mr. A. Haggart, have proved that Eucharises can be well grown with less heat and moisture at the roots than is sometimes advised, and I

quite agree with the latter, that much mischief would soon be brought about by applying lots of water without, at the same time maintaining a high temperature.—A WORKING GARDENER.

HAVING a short time ago visited the well kept gardens at Aldenham House, Elstree, under the charge of Mr. Beckett, I can fully endorse the remarks recently made respecting the collection of Eucharis growing in that establishment. They are marvels of cultural skill. After so much discussion in the *Journal of Horticulture*, it is interesting to meet with a collection where there is no appearance of the mite (which has destroyed so many collections). I feel convinced that if all plants were treated in the same manner as those at Aldenham, we should soon hear less of the Eucharis mite.—C. B.

GARDENERS’ DIARIES.

I WILLINGLY send a few lines in support of what “J. H. L.” says on the above subject. When an under gardener I kept a diary for several years, and I can assure all young gardeners who wish to get on and gain knowledge of the profession that there is nothing will help him more towards that end than spending an hour or more of an evening writing down what has been done during the day in the various departments of the garden. Besides, if he does not happen to be a good hand at writing and spelling this will help him in becoming better at both. The young men in the bothy here are keeping diaries.—G. HILTON.

SELF-IMPROVEMENT.

I WAS delighted to read the article in the *Journal of Horticulture* of February 23rd, page 155, on the subject of self-improvement of gardeners, especially the last paragraph recommending the study of shorthand to young gardeners. I heartily support that recommendation, because I know from experience that shorthand or phonography is a useful adjunct to a gardener’s education, for by its aid he is enabled to record observations and make memoranda in a quicker and readier manner than in ordinary longhand writing. It is invaluable for keeping a diary, for making extracts from books, papers, and periodicals, the very habit of doing which is valuable exercise for the memory. One thing especially I have found it helpful in, and that is for recording any remarks, data, or observations on the labels used for pot plants or any other purpose. Take Chrysanthemums, for instance. The name of the variety could be written on one side of the label in longhand which everybody could read, and on the other side could be written in shorthand the date of potting, top-dressing, taking the buds, or any remarks which would be useful. The habit of doing this would be found an education of itself to young gardeners; they would often consult the labels and be surprised at the information they gave. There are many ways in which shorthand would be useful, not the least of which is correspondence with gardening friends who may have learnt the art. There are some people who think it is waste of time for a gardener to learn shorthand, but such have never acquired the art, and therefore cannot judge. I commend it to all young men engaged in gardening, feeling sure they would benefit by it.—E. D. S.

I MUST thank your correspondents for the advice which we have had from time to time in the *Journal*, and I for one will try and advance from being an illiterate under gardener to an educated gardener. I do not, however, think that we shall ever be able to attain to such high knowledge as some of your writers think we ought. For instance, we find “North Briton,” on page 171, advising us young men to learn French and Latin, whereas the majority of under gardeners have not mastered the English language. Many of us were called upon to earn our own livelihood at the age of twelve, and in two or three years, by steady advancement, we secured situations as under gardeners. Where are all these higher attainments to be reached? I confess that in our bothies hours are wasted which ought to be turned to better account. The time spent in card-playing, &c., might be better employed in improving our writing, spelling, grammar, and drawing, as well as keeping a diary of the work.—E. B.

IN the *Journal of Horticulture* of February 9th, “Experientia docet” referred to some gardeners holding good positions not being able to write an intelligible letter to their employers. I can fully endorse the statement. I know of one case in particular where the person, after having been resident for five years, could not write his own address correctly; who also sent parcels to his employer directed, “Per Parsle Posts;” who when writing (or rather trying to write) a label would do it in such a miserable form that even himself in five minutes after could not detect what letters his fancy ups, downs, and beyonds were meant to resemble. I have seen the same person label-writing with a catalogue lying before him, copying as anyone would have thought letter for letter; but no, his memory seemed to forsake him somewhere between the catalogue and the label, which would cause him to drop a letter altogether or put in some very doubtful substitute. The certificates his assistants received when they thought of changing were remarkable, and they were always ashamed to show them, thinking no doubt that others might be apt to judge the men by the master.

I have mentioned this case as it is the worst I know, but there are others who are very little better. It is disgraceful to see such men as those filling high positions in our midst, whilst well-educated and

thoroughly practical men have to stand aside for want of a fair field. I feel confident that if a Society were started on principles such as "Gamo" proposed in the issue of February 23rd, it would prove the most effectual way of removing all those who have been, as "Gamo" puts it, "pitchforked into good places." Then will be the time when thoroughly practical gardeners, with a fair amount of learning, whether self-taught or otherwise, will stand a better chance of recognition than now.

I trust some of our most able gardeners will take up and try and further the movement, and I am sure all with any interest in themselves and their profession will be only too glad to put their shoulder to the wheel.—TENTO.

CROPS THAT PAY.

RHUBARB.—During the past few years many have engaged in the culture of Rhubarb, but there is still room for others, and beginners need not despair that if they embark in this undertaking they will fail to find buyers for their produce. At the present time the demand is increasing, and the supply is not equal to it, consequently it realises moderately high prices early in the season. There is generally a scarcity just preceding the first pulling of the outdoor crop. This might be met without a large outlay on the part of different growers, or fresh ones. What is most needed is large quantities just preceding the first gathering of the outdoor crop. Every grower in the northern counties would do well to erect large sheds or houses, or cover the roots by some means, whereby they could supply a good quantity just before the other was ready. It is surprising how rapidly it comes forward with the slightest protection if covered early enough in the season. Cement and Apple barrels can often be had for next to nothing, or at the most the price of fire wood, and these are very suitable for the purpose; sheds with glass roofs are preferable, for the roots can be packed closely together. By carrying out any such plan it will be found that the ground devoted to this crop is doubly remunerative. The best returns are obtained by those who make provision for supplying it in a forced state only, and these growers have generally exhausted their stock before the time pointed out. Although the majority to be seen in our markets early in the year has a blanched appearance, there is no reason why it should be produced in this condition; the tide is changing, and ere long preference will be given to that produce which more closely resembles Rhubarb in a natural state—in fact, such produce will realise a better price now. One advantage is gained early in the season by growing it in the dark—namely, it attains the required length quicker than it is capable of doing when grown in the light.

Those who force Rhubarb to precede the outdoor crop should grow it as naturally as possible. They will discover that it will bring nearly as good a price, sometimes better than that forced early. Stock may be planted at once for another year's forcing. For this purpose we plant 2 feet apart each way, so that when they are once in active growth the foliage will smother any weeds that make their appearance. Large roots should not be planted, or those with large plump crowns. The last are objectionable for forcing purposes, for the simple reason that they flower, and numerous small crowns are then produced. Pieces with small crowns are the best, if they have the whole season before them in which to develop strong crowns. How is planting done to make this crop pay? Surely not by digging and planting, as that operation proceeds the same as performed in private gardens. No. The manure is spread upon the land if it requires manuring, but if this has been liberally applied for the preceding crop the Rhubarb has none. From this do not infer that it can be profitably grown on poor land, for such is not the case. Although Rhubarb will grow almost anywhere, it nevertheless pays for planting in well-worked and liberally manured soil. Sometimes it is planted on ground in which Lettuces have formed the early crop, followed by Veitch's Autumn Giant Cauliflower. Sometimes it is planted after late Potatoes, but very rarely, as it is better after Cauliflowers, Brussels Sprouts, or some crop where Lettuces or Potatoes have been taken from the same ground earlier in the season. Such crops take much out of the land, and a light dressing of manure then follows the removal of the last crop.

Rhubarb can be ploughed-in by placing the roots in every third furrow. The better plan is to plough the land whenever the weather is favourable and an opportunity presents itself, and then plant with the aid of a spade the same way as the land has been ploughed. In this case it is necessary for a man and a boy to work together. Those familiar with the planting of Turnips and other similar roots for seed as a field crop will readily understand how the work is carried out. Directly the plants show above ground the land is worked between them once to check small weeds. If this work is done by the aid of a horse the hoe must be used as well between the plants, which prevents the "headlands" being cropped for a time. Generally this work can be done in the case

of Rhubarb in time for a crop of Lettuces, Beet, White Turnips to draw when ready, and we have had a valuable crop of Swedes, just the size for shop purposes. When grown for this purpose alone the seed should not be sown too early, or on land that is too rich. However, this matter need not trouble those who live in the vicinity of towns, for large ones sell just as well as small ones, although for a different purpose. It generally happens that the larger they are the better they are likely to pay the grower, provided the quality is good.

SEAKALE.—Another crop that pays is Seakale in a forced state, if this may be regarded as a luxury; nevertheless it is in demand, and if more was produced more would be required, simply because it would be within the reach of a greater number of buyers, who at the present time are in the position only to look on and pass by. If it were half its present price, would it pay? Most decidedly it would, for it is not a crop that entails a large amount of labour in production. The cost of planting, manuring, lifting, and cleaning is less than that required in the culture of Potatoes. The preparation of the sets is only work for boys, and can be done during weather when most operations outside are at a standstill. Another advantage is that it can be planted before cropping generally commences, in fact it matters very little when it is planted provided the ground has been well worked and is fertile. I have planted from the end of January to the end of March with no striking difference in results. Towards the end of February is a good time, but so much depends upon the nature of the soil upon which it is planted. A stock is readily raised by sowing seed towards the close of March or early in April in shallow drills 15 inches apart, the young plants to be thinned to 6 inches apart. Fair crowns can be produced in one season from seed, but the plants must be given more room to develop. A one-year-old plant will frequently make two good sets or root cutting from which large crowns may be expected. The sets should be all one length, 6 inches, and be planted 18 inches from row to row, and about 15 inches apart in the row. If the land has been well worked they can be planted with a dibble, placed in a slightly slanting direction so that the soil is easily pressed to them with the foot. The most promising crowns only should be left, and when they are disbudded the ground may be worked to check weeds until their spreading foliage covers it. These are far preferable to seedlings.

All methods of forcing outside for market purposes have to give place to that of lifting the crowns and forcing them in sheds, under the stage of warm houses, rendered dark by shutters. Early in the season heat is essential, later it is not needed. The roots can be packed thickly together in ashes, leaf soil, sawdust, sand, garden soil, in fact anything. We prefer the second, or old Mushroom bed refuse, in which they root amazingly, and from which we fancy the best heads are produced. This is a matter, however, that might well exercise the attention of some private grower, who has nothing to lose by conducting a few experiments, but in the end gains enormously, by adding to his store of knowledge, and to that of others who cannot carry out such important work. Forcing when the season has advanced is simple, but the early practice is the most profitable, and that can only be had by pulling off the leaves of a portion of the stock in the end of September, or early the following month, digging up the roots, but not by conveying them at once to the quarters in which they are to be forced, as they are apt to be stubborn, like Rhubarb. After they are lifted leave them on the ground fully exposed, and allow them to become thoroughly frozen. This completes the season's work, and they are ready for the forcing house.

MINT.—I intended in this paper to treat of another "crop that pays." Its growth was the result of an advertisement in a daily paper announcing that at a certain restaurant lamb would be served amongst other things on a certain day. I could scarcely believe what I had read, for I had no idea the lambing season had commenced, and to realise that they would be fit for eating on a certain day surprised me not a little. So I concluded that if they had lamb mint sauce would be an indispensable accompaniment. I still have doubts about the lamb, but none about the Mint, for on the first market following the announcement I went early to see if Mint had found its way into the market. Some foreigner had anticipated this enterprising restaurant manager by forwarding three or four tiny bundles of Mint about 8 inches in length, beautifully blanched for 6 inches of its length, with a few pale sickly yellow-green leaves on the top. But there it was, and all who have any doubts about it will find Mint in our markets before the month of January has far advanced. But more on the Mint topic some other time.—MARKETER.

PLANTING ASPARAGUS.

MARCH is a good time for planting this vegetable. In preparing new beds see that the ground is well trenched to the depth of 4 feet where

the soil will admit of that depth. In trenching well mix with the soil from top to bottom a good quantity of the best old manure. Should the soil be of a light sandy nature it will be greatly improved for the Asparagus by adding a dressing of ground bones; if of a clayey texture, lime rubbish and road scrapings may be liberally added. After the ground has been prepared as advised the beds may be formed. These should be 5½ feet in width, with alleys of 3 feet between them. In such beds the plants can be placed 1 foot apart and 9 inches in the rows. The best for planting are those one year old from seed, which should be very carefully taken up with a fork, not a spade, exercising great care so as not to injure the roots in any way. They should be covered as soon as lifted with a mat, as the roots of the Asparagus soon feel the effects of the air. The fibres are very brittle, and great care should be taken not to break them, as they do not shoot out very quickly after being injured. Having the plants ready, stretch a line lengthways on the bed 9 inches from the edge, and proceed with a spade to cut out a trench 6 inches deep; then set a row of plants along the trench 9 inches apart, keeping the crowns 2 inches below the surface, placing some earth over them just to fix them in their place till the whole row is planted. After this is done rake back the earth into the trench evenly, and proceed to mark out the next trench in the same manner at 1 foot from the first row, and so on till four rows are planted. The bed should be lightly raked lengthways, taking off all big clods and stones, leaving the surface even and neat; then line out the edges in an exact manner, leaving an alley as above stated. Do not stand on the bed more than is necessary, as the soil must be kept as light as possible. If such a practice is carried out good Asparagus will be fit to cut in three years. Keep the bed at all times free from weeds, and abstain from sowing Lettuces, &c., on them.—AMATEUR.

RICHARDIAS.

MAY I venture a plea for the planting-out system of growing the *Richardia*? Like Mr. Record I have tried both ways, but unlike him I prefer the planting-out system. He says, "Some advise, and probably succeed, in growing them well by planting them out after flowering." I feel sure the probability if any rests with the pot culture. I think the majority of growers adhere to the planting-out system, and Mr. Record's experience is an exception. From an economical point of view it possesses a great advantage over the other systems, for after they are planted out they can be left to their own resources till the autumn; but we prefer to treat them well all the year through. Mr. Record finds they flower earlier, more freely, and produce better foliage; I am in a position to dispute all three points, for our plants began to flower in the middle of November. It is not possible for plants to flower more freely, and their foliage is all that can be desired, large, stout, and a beautiful dark colour. I heartily agree that there are few plants to surpass these for house decoration. We use them in quantity, both in large pots and small ones. I will give our culture for the past year.

Owing to pressure of work they were not planted out till the third week in June, but we prefer having them out in May. They were planted on rich ground that had received a good dressing of decayed manure previously. The plants were placed in rows, about 2 feet apart each way. The ground was trodden firmly round them, leaving a shallow basin round each one. They received a good watering when planted, and afterwards about every fortnight. Towards autumn, when growing vigorously, they were watered with the drainings from the manure heap. They were lifted on the 22nd of September, having been copiously watered the day before, and were crowded with healthy roots. Each plant was placed in as small a pot as possible, for we grow them specially for furnishing purposes. The smallest were placed in 6-inch pots, the others ranging up to No. 8's. For compost we used loam and Mushroom bed refuse in equal parts, with a good dressing of sheep manure rubbed through a fine sieve. The soil was rammed as firmly as possible. They were placed outside again, under a north wall, and syringed twice daily to keep them from flagging; not a single plant drooped. They were left here till the 29th of September, when we were obliged to house them for fear of frost. They were placed in a house with a night temperature of 45°, with a rise of 5° to 10° during the day. They were next removed to an early Peach house to retard them, for they were not wanted as early as expected; but we had a fine supply of spathes by November 18th, and they have been yielding quantities of spathes ever since. They will in all probability continue to do so till May, as they have done previously, and we have every reason to be satisfied both with their quantity and quality. I am surprised Mr. Record has kept his plants so successfully on the "Blue Ribbon" system. I doubt if many growers have done the same. The plants under notice have been heavily fed with Clay's Fertilizer, Wood's Universal Manure, liquid sheep manure, soot water, and drainings from the manure heap. They have a good watering every day, and the soil is bristling with roots on the surface. This will show that *Richardias* can be grown on the planting-out system as well as that advocated by your correspondent.—JAMES B. RIDING.

FILMY FERNS.

THE presentation to the Royal Gardens, Kew, by Mr. Stuart Forster of the whole collection of Filmy Ferns assembled together by his father, recalls to my mind such happy hours occasionally spent at 29, Upper Grosvenor Street, in the agreeable company of Mr. J. Cooper Forster, who honoured me with his friendship, and in that of his pet

plants, the culture of which formed his principal recreation, that I feel bound to refer to my now almost old note books and devote a few retrospective lines to these circumstances with which so much happiness remains connected that they cannot possibly be forgotten. To begin with, it is necessary to remind the reader that the love of Filmy Ferns was such with the late Mr. J. Cooper Forster that anyone sharing to any degree his kindly feelings towards that most interesting, though much neglected class of plants, always received the most cordial welcome at his hands. We have heard how his kindheartedness endeared him to all those connected with the surgical profession, of which he was one of the greatest ornaments. Tales without number are told every day showing how he could win the sympathy of the equally numberless patients under his treatment during his long stay at Guy's Hospital. The love of his students towards him is proverbial; his benevolent inclination was shown in many ways, and I may safely say that all charities organised with the object of alleviating the distress of either individuals or bodies met with a ready acceptance, which was in the majority of cases followed by a substantial acknowledgment. In fact, his kindly nature was such that the sufferings of a fellow creature, to whatever station in life he might belong, were sure to draw from him a feeling of sympathy and an attempt at relief. Cases without number are reported where his surgical skill was brought into requisition, and successful operations were by him performed, all free of charge, to many sufferers who had been abandoned by their own medical advisers. And in that respect the gardening confraternity held a prominent place, for many are there now in nurseries and gardens who can testify to his kind and generous treatment which saved their life after they had been completely given over. And this opportunity gives me the greatest satisfaction of paying a just tribute of admiration and gratitude towards the memory of such a learned and eminent member of society. His spare time he would devote to angling, a pastime for which he had a great predilection, and to the cultivation of his Ferns, for which his devotion was such that, from the time he began collecting them and until his death, he attended personally to their wants, and that with results in all respects complete, as must be admitted by all who have had the good fortune of seeing them at Upper Grosvenor Street, where their owner was particularly fond of imparting his own and dearly bought knowledge to his less experienced visitors.

His commencement, like that of all other beginners, were marked by sad mishaps, but being gifted with a very keen power of observation, and being particularly tenacious in the attainment of any object he had in view, Mr. J. Cooper Forster introduced in the culture of Filmy Ferns notions entirely new, diametrically opposed to those then in practice, and which at the time were very much ridiculed, although their general adoption in our days prove the soundness of these ideas, the principal one of which was the cultivation of Filmy Ferns under cool treatment. At the outset, in common with all other growers, and having only for examples cultivators who subjected their plants to stove temperature, he had a small heating apparatus of hot-water pipes supplied from the kitchen boiler and provided with a sort of evaporating tank or cistern introduced into the fernery in which West Indian species, it is true, such as *Trichomanes aneeps*, *T. auriculatum*, *T. Bancrofti*, *T. crispum*, the splendid *T. alatum*; the extremely curious *T. floribundum*, whose fronds have their pinnae beautifully fringed with hair-like receptacles; the erect growing and handsome *T. Kaulfussi*, whose narrow, rather hairy dull green fronds are borne on broadly winged hairy stalks; the superb *T. maximum* and others luxuriated; but on the other hand the more numerous series, that composed of the species native from New Zealand, Chili, and other temperate regions, in spite of all care and constant attention, were gradually dwindling away. It is then that Mr. J. Cooper Forster resolved to do away entirely with artificial heat, and to depend only on the influence of a cool, moist, and close atmosphere. The structure devoted to the Ferns being small, it was with the utmost difficulty that it could be heated to a given degree only, so the hot-water pipes were at last dispensed with altogether. From that time, if some of the West Indian kinds languished a little all the others began to grow apace; the vigour of the New Zealand and Chilian species under that new treatment was the astonishment of all interested in their cultivation; and the masses of *Trichomanes radicans* and its varieties, also those of *Hymenophyllum nitens*, *demissum*, *flexuosum*, and others from which he frequently detached handfuls of rhizomes to start some new beginner, showed that they, at least, thoroughly appreciated the change and enjoyed cool treatment. The delicately transparent and comb-like fronds of the Chilian *Hymenophyllum pectinatum*, and those of the superb Brazilian *H. Forsterianum*, which formerly were very sparsely produced and always had a stunted appearance, were now produced in great abundance; they were besides attaining large dimensions, showing a robust constitution, far surpassing all that had been expected from these species when they were first imported from their native habitats. The same remarks apply also to the charming West Indian *H. asplenioides*, which in its wild state is found hanging in masses from mossy rocks or trunks of trees; to the *H. caudiculatum*, a Chilian species of great beauty, with erect and curving, or pendent thrice-divided fronds which frequently attain 12 to 15 inches in length; to the small, dwarf-growing *H. Chilense*, from Southern Chili; to the extremely curious and charming *H. cruentum*, with broad undivided seaweed-like curving and beautifully veined fronds that, when old, are of a brownish rose colour, found in no other Filmy Fern; to the beautifully crisped and transparent *H. dichotomum*, which, like the preceding species, is also a native from Chili; and to the really charming West Indian *H. valvatum*, with ovate, attenuated, nearly smooth, dark green

fronds, everywhere beautifully undulated, are thrice divided, and attain from 6 to 10 inches in length.

All the New Zealand and Tasmanian species of *Hymenophyllum*, either glabrous or hairy, were there in their element, and perfect masses, which from little plants had there grown to huge dimensions, were to be admired of the pretty and comparatively dwarf *H. crispatum*, which in its native habitats clothes the trunks of Tree Ferns; of *H. demissum*, a handsome species whose dark glossy fronds attain 18 inches in length, and of its variety nitens, smaller in all its proportions and with more finely cut fronds of a lighter green; of *H. dilatatum*, one of the largest and most beautiful species of the genus, and which in New Zealand is found growing in moss and decaying vegetable matter, where its broad pale green fronds, much admired for their gracefully drooping segments, attain from 15 to 20 inches in length; of *H. flexuosum* and *H. pulcherrimum*, the latter of which, grown there in hanging baskets, formed perfect balls of hanging seaweed-like finely cut fronds; also of *H. scabrum*, *H. æruginosum*, and others too numerous to be detailed here. While among the *Trichomanes*, besides the European species popularly known as the Killarney Fern, *Trichomanes radicans*, which grows with thick rhizomes creeping on rocks in the south-west of Ireland and Madeira, we find that the cool treatment most benefited the South American *T. angustatum*, a very delicate-looking and beautiful creeping species with very narrow pinnules, and fronds 4 to 5 inches long borne on hair-like stalks; the *T. exsectum*, a species from Southern Chili, where it is found hanging from the roofs of dark caverns; its extremely delicate and membranaceous fronds, which are highly divided into narrow segments of a cheerful bright colour, reaching from 12 to 14 inches in length; the beautiful *Todea*-like *T. meifolium* from the mountains of Java; *T. pyxidiferum*, *T. venosum*, &c.

All the above-named species and many more were grown at Upper Grosvenor Street on the leads at the back of the dwelling house, and in the midst of London soot, fog, and of an atmosphere constantly impregnated with gas, where, one structure having become overcrowded by their exemplary growth, another one was erected, in which, however, no means of heating was introduced. There the Ferns luxuriated, and the *Trichomanes reniforme*, a New Zealand species, conspicuous by its large kidney-shaped fronds, which are quite as transparent as those of the most finely divided kinds, formed a glorious specimen about 2 feet in diameter, which, with its foliage produced in such abundance that each frond overlapped its immediate neighbour, was in itself a sight worth a special visit to this remarkable place, in which the constant amount of moisture necessary to the welfare of the Ferns was the greatest difficulty to contend with. This, however, was to a great extent overcome by the liberal use of sphagnum, which was placed between the pots and crammed under the stages and other places out of sight. By that means a comparatively moist atmosphere was constantly kept, but the temperature in winter frequently falling to 38°, and occasionally to 35°, caused the loss of a few of the West Indian species. For instance, the superb *Trichomanes maximum*, the stately *T. anceps*, the dwarf-growing *T. spicatum*, *T. Zollingerianum*, and a few others never supported the cool treatment, and their culture had to be abandoned. Mr. J. Cooper Forster being most earnest in the object he had in view made numerous and costly experiments, keeping careful records of their results, and when perfectly satisfied as to the hardihood of certain species, would then have it known among all lovers of these beautiful plants, which served equally to the decoration of the windows of his dining-room and staircase, where they were the admiration of every beholder. One of his most ardent wishes was to see Filmy Ferns grown in a more congenial position and temperature than they had hitherto been in Kew Gardens, and he exerted himself in their behalf to such an extent, that some five or six years ago a new place was built for them in the temperate Fern house, No. 3, where formerly they were only partitioned off near the western door, a case containing *Todeas* and *Trichomanes radicans*. In that cool house most of the Ferns, which for years had been simply kept alive under separate glass cases in the tropical Fern house, No. 2, have now been growing with a vigour which denotes the benefit which they have undoubtedly derived from the change. This cool treatment, besides being simpler in itself, possesses also the immense advantage of keeping the Ferns perfectly free from insects, whereas when kept in heat they are frequently attacked by thrips and other pests, which, by their depredations, completely disfigure and weaken them in a corresponding degree.

The comparative paucity of *Todeas* in this grand collection is due to Mr. J. Cooper Forster's antipathy to plants of acknowledged easy culture, as I have frequently heard him remark that "these grow with everybody, they are to other Filmy Ferns what the Indianrubber and the *Aspidistra* are to other decorative plants, and there is nothing to study or to learn from the behaviour of such plants." He preferred the species of cultivation reputed difficult, for the successful raising of which he had no rival. Such was the man who on March the 2nd, 1886, was suddenly taken from the field of his labours in science and horticulture, and whose loss is deeply regretted by all who were acquainted with him.

The Filmy Ferns were then removed to Binfield House, Bracknell, near Ascot, where his son, Mr. Stuart Forster, the present generous donor, had a house built specially for their reception, and where, besides the purer country air, they also enjoyed a more spacious accommodation, and altogether more comfort. The house, which is a lean-to, is sunk about 2 feet below the level of the exterior ground, and built in such a way as to have a constant supply of moisture, and, as by its judicious exposition the Ferns require but very little shading, they, of course, give but

very little trouble to their owner, yet since they have been there they have made such marked progress as Mr. J. Cooper Forster himself could never have anticipated. With the exception of the *Trichomanes reniforme* above referred to, all the Filmy Ferns are planted out in an artificial rockwork built of porous sandstone, and in such position not only have the Ferns benefited by the change, but their improvement in some cases is very noticeable, and it is to be hoped that their safe transfer will not in any way interfere with their welfare, and that their installation in the houses of Kew Gardens, where no doubt some suitable accommodation will be provided for them so as to keep the collection intact, as well as the deserving care which they will receive there, will help to render Filmy Ferns more popular with the generality of Fern growers, who will not fail to consider the presentation to the national establishment a most handsome and very valuable gift.—THEO.

CHRYSANTHEMUM PRINCESS OF TECK.

MR. PETTIGREW has thrown a bombshell into the ranks of Chrysanthemum growers. This is what I thought on reading the article on the above subject. What I did was to go straight to my cold pits (which, by the way, I had not seen the inside of for a week owing to the severe weather), and where I had about one hundred plants of Princess Teck stowed away for protection, to be planted out when favourable weather occurs. These plants I had intended to astonish the Chrysanthemum world with at the January Show of the National Society this year, having cut them down a month later than usual for that purpose; but my hopes were nipped in the bud, as were also my Princess Tecks, by the severe frosts in October, owing to the young shoots not being matured enough. They were taken into the house and tried, but I found the flowers that would open on them would not pay for the room they occupied. They were cut down and placed in the cold pit as above, but on reading Mr. Pettigrew's article my hopes re-awakened, but I am sorry to have to record there is at present not much sign of many shoots for cuttings, not to mention flowers. I should like Mr. Pettigrew to give us a more definite description of the plants he has mentioned, especially as they are in a trading establishment where flowers and plants are grown for profit. Had they been in a private establishment I should not have asked the question, as I should have concluded the smallest quantity of flowers in January and February would be acceptable, but in a nursery at that time of year the space is important. I would like Mr. Pettigrew or Mr. Crossling to tell us how many flowers there were on each plant, and what size were the largest of the flowers. The article as it stands would almost start one dreaming of two crops of flowers off the same plant in one season, a feat which I should think of all the Chrysanthemums the Princess Teck is the least likely to perform. I had myself this year several plants, such as *Curiosity* and *Comte de Germiny*, which threw up flower buds from the root, but the few small flowers they would have produced would not have paid for the trouble and room; and I also noticed this year more than any other the Princess Tecks that flowered with me in December threw out side shoots and small buds, but they also would not have paid for any further trouble. Is Mr. Pettigrew quite sure he has not made a mistake in the variety? *Sœur Melanie* would be more likely in my opinion to throw up suckers. In any case, I should say if the plants and flowers are in any way respectable it is a remarkable freak of Nature, and I as a grower of Chrysanthemums in a small way for profit, would be much obliged if either of the gentlemen would tell us candidly if these plants have given enough flowers to pay for the time and room. If they have not they can only be regarded as curiosities in a small way.—W. BROWN, *Florist, Richmond, Surrey.*

SINGLE CHRYSANTHEMUMS.

SINGLE Chrysanthemums are becoming popular, especially with those who are not bound by any of the rules, strictly confining their tastes to the florists' flowers. They are the easiest of cultivation of any Chrysanthemum that I am acquainted with, are comparatively dwarf in habit, and flower profusely. They can be grown in smaller pots and are much more useful for cutting and arranging in centre pieces for the dinner table or epergnes than the others, which are much too heavy. Some of the sorts, notably *Mrs. Langtry*, possess a most agreeable perfume when in flower, one or two plants in a house being sufficient to diffuse an agreeable odour, which is noticed the moment the house is entered. As yet they have not been seen much at exhibitions, for the reason that encouragement has not been given to them in the shape of prizes except in a few instances.

Chrysanthemum exhibitors do not, as a rule, grow the single varieties in the best way. Growing the plants in bush form and allowing plenty of flowers to develop is the best method. Cuttings should be inserted from the middle of January to the same time in February singly in small pots, or two or three cuttings in pots 3 inches in diameter, using sandy soil. Place the cuttings under handlights in a cool house, shading from bright sun. Sprinkle them occasionally to prevent

the leaves flagging; when roots are formed, which will be in about three weeks' time, gradually give more air, and pinch out the point of the leading shoot. Side branches will then form, and if small plants are required one topping of the shoot will be enough, while to have larger plants the side shoots when 4 inches long should be pinched also. Where the plants were struck singly in 2½-inch pots, as soon as roots are freely formed repot these into 4-inch pots, using a compost of two parts fibry loam, one part leaf soil, and one part of spent Mushroom bed manure, adding sharp silver sand freely. Where the plants were struck three in a pot they should be transferred singly into 3-inch pots, placing them where they can be kept rather close for a time until new roots are formed, and the plants will bear exposure without flagging, then remove them where more air can be given to induce a stocky growth. By removing the plants to a cold frame as soon as possible, giving an abundance of air in favourable weather, much may be done to prevent their being drawn up weakly. Repot again when the pots are filled with roots. Useful plants may be grown in 8-inch pots, but if an extra large size is needed 9-inch and even 10-inch pots may be employed. For the final potting add to the previously named soil some finely ground bones and a small quantity of soot. Charcoal will be of immense advantage if the soil is heavy, keeping the whole sweet and porous. The soil should be used in a rough condition, and be made quite firm at this last potting, as this prevents gross growth. Short, firm, well ripened shoots produce the best results; long spikes branching freely in a natural manner give better results than continually pinching the shoots up to the middle of June. For the smallest plants three or four branches are sufficient to retain from the first stopping, but in the larger size about eight are enough to produce large bushes. If three shoots are produced from the first topping a dozen will spring from the second; select from these the number required and tie them securely to stakes. At the natural break of the plants in August many more shoots will be produced than is required; these must be disbudded to the requisite number, about twenty-four on the largest, half that number on the smallest, and from these numerous side shoots will grow and bloom. After the central flowers are cut others are produced by the side shoots in succession. If the plants are housed in succession and some are temporarily protected from frost before they are placed in the houses the season will be much prolonged.

Stand the plants out of doors as soon as safe from frost, selecting an open sunny position, yet protected from north and east winds. Place the pots on a thick layer of coal ashes or boards to prevent the ingress of worms, supplying water to the roots carefully. Directly the pots are well filled with roots apply liquid manure about three times a week, increasing the strength and number of times as time goes on, until it may be given every time the plants need water. Syringe in the evenings after hot days. Allow all flower buds to develop, except where a few larger flowers are desired, then the centre bud on each shoot must be saved, removing all others; but for show purposes in a cut state it is better to cultivate a few plants specially. The bush plants previously noted must not be formally trained by placing a stake to each branch; or to secure two or three branches to one stake in a loose manner, which is all they really need, as they are generally of upright habit, and in many cases almost self-supporting.

Where exhibition is the primary object of growing single Chrysanthemums a different form must be adopted. The manner in which societies frame their classes for single Chrysanthemum cut blooms will guide the cultivator in the method the plants must be grown. If twelve bunches, three blooms to a bunch, be asked for, as is often the case, the plants should be grown by the "large bloom" method. Blooms skilfully grown and carefully set up for exhibition find many admirers. When twelve bunches, unlimited in size, are required the "bush" method is the best. If the former plan is decided upon the cuttings should be inserted singly in small pots without delay, using the soil of a sandy character. Select the best cuttings. Those stout and not in any way drawn weakly by overcrowding answer the best, because many of the varieties are naturally slender in habit of growth, and to produce the best results they must be grown as strongly as possible. Shift into larger pots as needful, never allowing them to become root-bound. Place the plants into cold frames as soon as possible, giving abundance of air as the plants become hardier and strong. Do not top the plants, but train up the leading shoot until it forms its first natural break, selecting three to six of the most promising growths. Secure these to stakes in the same manner as adopted for the large-flowered varieties. At the next break, should it occur during the first week in August, remove the flower buds then formed, and continue the growth of the shoots until the next break; then remove all growths, retaining the buds so formed to develop into the show blooms. Pots 8 inches in diameter are quite large enough, and give the same attention to the plants during the season as to the others grown for large bloom. I give a list of the varieties suitable for growing as bush plants, also for exhibition in a cut state. The first twelve named in the list are best suited for exhibition. I place them in this manner to avoid a repetition of names. Lady Churchill, brick red; Jane, white, having beautifully twisted long drooping florets; Mrs. Wills, white suffused with pink; America, blush, large; Helianthus, bronze yellow; Queen of Yellows, yellow; Crushed Strawberry, colour as its name implies; Patience, amaranth tipped white; White Perfection, white; Oriflamme, reddish brown; Mrs. Duke, pale lilac; Mrs. Langtry, pale pink; Lady Brooke, bright yellow, buttercup form; Meteor, dark; Oscar Wilde, dull brick red; Miss Gordon, light pink with long drooping florets; Miss Lulu Martin, small pink.—E. MOLYNEUX.

A GOOD INSECT DESTROYER.

LAST spring my employer sent me from London three tins of a powder called "Insect Death," a wonderful dust discovered and used by Mr. Rowland Ward, F.Z.A., with a request that I would try it upon some of my plants for the destruction of green fly and thrips. Since that time and up to the present I have repeatedly tried it, and have in every case found it most effectual; in fact within two hours after its application it has been difficult to find one insect alive. It is sold in tins at 1s. each holding something like a quarter of a pound. The tins have perforated tops with a sliding piece over that, so as to close the holes when not in use. It is essential that the powder should be kept dry, and should always be applied when the foliage of the plants is dry. I have tried it upon Rose trees both outdoors and in the houses, Cinerarias, Pelargoniums, and other softwooded plants, and it has proved invaluable. I also used it upon some Azaleas that were infested with thrips by dusting the leaves underneath as well as the tops, and it destroyed them. I therefore recommend not only gardeners to try it, but more particularly amateurs and Rose growers generally. Whatever its ingredients may be it has a pleasant smell, and therefore in no way disagreeable to use, and is easily and quickly applied. It is a saving, for it is much better to dust a few plants than to have to fumigate a whole house for their destruction. I have reason to think it will destroy mildew on Roses, for I treated half a dozen plants affected with that malady and they became clear of it, but before being quite sure I intend to make other trials. Mealy bug also soon shifts its quarters when it is applied to them, but I am not sure that it kills them without another trial. I had three tins, and have only used half of the dust, so one tin will last a long time. On all softwooded plants when the powder will hang well very little is needed, but for hardwooded plants and those with harder foliage a little more can be used. The powder is easily washed off with the syringe. Ought it not to be advertised? —THOMAS RECORD, *Folkington Manor*.

THE NEWCASTLE SHOW FRUIT.

I MUCH regret to find Tomatoes mentioned in the first prize collection, page 201, which is an error. I beg you will please to correct without delay, as I wish to be as correct as possible in this matter. I may be excused from replying to "One of the Judges" so long as he withholds his name, for I am in the same fix with anonymous writers as the schoolboy was with an egg. When asked to state the gender, answered, "He could not until hatched." So while my friends remain in embryo I shall remain mute. I notice in your correspondence you advocate the insertion of a clause in prize schedules that all "protests be lodged by a given time." If this is intended for me, I beg to remind you that an allusion is not a complaint, and I never intended my remarks on page 82 as such; but as "Old Hand" seemed somewhat alarmed at my position, and required further proof, I felt it necessary to assure him of my comfort and supply what he asked for, which I hope I have done to his satisfaction.—J. H. GOODACRE.

[The sentence including Tomatoes was printed exactly as it was written by our correspondent, who it seems does take a little notice of anonymous matter, and he is quite in error in supposing the reply on page 207 was intended for himself. It was an answer to a correspondent who was not interested in the above Show. We have communications from Mr. Hunter and another correspondent, for which space cannot be found this week.]

NEWTON'S PATENT GLAZING.

FROM time to time various systems of dry glazing have been brought before the public; but the best I have seen is the above, which has been advertised in the *Journal of Horticulture* for some time, and, in my opinion, only requires to be better known to be more generally adopted. I shall remark on facts (and they are stubborn things) which have come under my observation. Some eighteen months ago Mr. Newton had instructions to erect a greenhouse, 30 feet by 16 feet, three-quarter span, on his new principle, for W. Tindall Lucas, Esq., at his residence, The Foxholes, Ilitchin. Anyone with a knowledge of the locality will admit that it is one of the bleakest and most exposed in the neighbourhood—just such a place as a miller would like to place a windmill. It is not uncommon for pit lights to take flight during high winds. It was a bold venture to attempt such a system of glazing in the situation, and I think Mr. Lucas must have had some misgivings as to the practicability of it, for he had wood rafters fixed at intervals so as to be able to revert to the old system in case of failure; and another proof of a suspicious nature was that a portion of the roof was glazed on the old lines—viz., bedded in putty on the new patented bars, but the portion glazed dry has weathered the storms without any breakages whatever. Mr. Lucas speaks highly of the system, as also does the head gardener, Mr. Sheppard. The glazing bars are light in appearance, yet strong. The glass is fitted in so true, so that the roof appears wind-proof and waterproof, all moisture being conveyed away in the guttered part of the bar under the glass, as shown in the illustrated advertisement. Great credit is due to Mr. Newton for honesty of purpose in not placing his invention before the public before giving it a very severe trial. As the iron bars are galvanised no painting is required (at least, that is optional), so that the after cost is reduced to a minimum, and I am told the price is about the same as the old method of wood and

putty glazing. I am of opinion that when the Newton system becomes better known it will gain favour with nurserymen and trade growers, and it should be well adapted for moisture-loving plants, such as Orchids, also for propagating houses. I have always looked upon iron houses as liable to sudden variations of heat and cold, and when tightly glazed on the old plan with putty are subject to a good deal of breakage from expansion and contraction, but this difficulty seems to be overcome in dry glazing.

At Mr. Newton's residence there are two lean-to houses of about equal dimensions heated with hot water from the same boiler. The first, No. 1, is glazed in the old style with putty and paint, the sash-bars being wood; the other, No. 2, is glazed on the Newton system dry. The house, No. 1, has a brick end: the other, No. 2, glass, so that there is a greater surface of glass in No. 2, but the heating surface is greater in No. 1, yet the thermometer in No. 1 only stood 2° higher than in No. 2. It seemed rather remarkable that this house should retain its heat so well. This is a further proof that the heat does not escape as might be imagined between the bars and the glass. Mr. G. Sheppard, gardener at The Foxholes, says he finds no difficulty in keeping up a night temperature of 65°, and that speaks volumes for the system in such an exposed place, but the light in Mr. Newton's houses is very striking as compared with the old system, and the colouring in the foliage of the plants is more decided.—G. R. ALLIS, *Old Warden Park*

HARDY FRUIT GARDEN.

GRAFTING FRUIT TREES.—A long spell of cold weather has retarded the flow of sap in fruit trees generally, and the operation of grafting may yet be carried out with every prospect of success. It is the usual practice to cleanly cut off the stocks where they are to be grafted in January, but this, though advisable, is not absolutely essential, and it may be done just prior to grafting. There is much to be said in favour of grafting, and the younger gardeners especially ought to practise it extensively. For instance, what at present may be a comparatively worthless tree, the variety being of no value, may in the course of three or four years be completely changed in character by simply covering it with grafts of a superior variety. Grafting seedling fruits on a strong stock is the quickest way of testing their merits, and a vigorous or seedling stock of inferior variety will transmit much of its vigour to a naturally weakly scion.

APPLES.—Any strong standards of inferior varieties ought to have all the principal branches, or say those 3 inches or rather more in circumference, freely cut back, cleanly sawn off, each being then grafted. What is known as crown or rind grafting is the best in this case, two grafts being inserted in each small branch and three in the larger ones, and if firmly tied and properly clayed over not many failures will occur. All or nearly all should make good growth the same season, and if these branches are not pruned in any way a good fruiting tree will soon result. Strong young and well-ripened growths about 6 inches long saved at pruning time and kept plunged in the open ground are the best for grafting, these being dormant when used. Superior dessert varieties, such as Cox's Orange Pippin, Blenheim Pippin, Margil, Ribston Pippin, Adam's Pearmain, Braddick's Nonpareil, Court Perdu Plat, Lord Burghley, and Brownlee's Russet ought to be preferred. If culinary varieties are needed, some of the best are Lord Suffield, Stirling Castle, Keswick Codlin, English or Carlisle Codlin, Beauty of Kent, Kentish Fillbasket, Lemon Pippin, Wellington, French Crab, and Hanwell Souring.

PEARS.—Either standards or pyramids may be cut back and regrafted much as advised in the case of Apples, these coming into full bearing even more quickly than Apples. There are thousands of wall trees of Pears in this country not worthy of the space occupied, many of them being merely preserved owing to the complete manner in which they furnish the walls. Horizontally trained trees may have all the side branches sawn back to within 6 inches of the main stem, in each stump being inserted two good grafts of a superior variety. Only one, however, of these should be allowed to grow, and a good leading shoot being laid in from each reserved graft, no shortening back being resorted to, it is not long before the wall is again furnished with bearing wood. If it be preferred several varieties may be grafted on to each tree. Stunted branches or leaders on Pear trees are often an eyesore, these disfiguring what otherwise would have been a handsome tree. If the tree are lightly shortened back and grafted with a healthy scion, not necessarily of the same variety as the rest of the tree, the chances are a strong lead will again be available and the whole of the wall space soon covered. Either whip grafting or saddle grafting may be practised in this and all other instances when the stock and scion are of about equal girth. Pears worthy of extended culture are Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Superfin, Pitmaston Duchess, Marie Louise, Doyenné du Comice, Louise Bonne of Jersey, Easter Beurré, Glou Morceau, Winter Nelis, Josephine de Malines, Beurré d'Arenburg, Ollivier de Serres, Bergamotte Esperen, and Madame Millet. Grafted on the Quince Pears soon come into bearing order, but the best trees are to be had on the common Pear stock.

PLUMS may also be grafted now, the spawn or suckers thrown up from the roots of old trees frequently being preserved till strong enough to form stocks for choice Plums. All the Gages, Jefferson, Kirke's, Victoria, Coc's Golden Drop, and Blue Impératrice, are valuable varieties.

CHERRIES, provided the scions were taken off early and thus prevented from starting into growth, are not difficult to graft. Old trees may be shortened back and re-grafted, or seedling wild Cherry stocks may be headed down and grafted. Good dessert varieties are Knight's Early Black, Elton, May Duke, Black Tartarian, Bigarreau Napoleon, and Morello. Peaches and Nectarines are generally increased by budding, but common Plum stocks may be headed down and grafted with them. In this case a short piece of two-year-old wood must be attached to the young growth to be grafted.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest-forced Trees.*—During the stoning process the temperature must be kept as equable as possible. Too high a night temperature is not favourable to the fruit, and cold draughts in the daytime are even more injurious. Continue the temperature at 60° to 65° at night, and 70° to 75° during the day. Thinning the fruit must be attended to betimes, it not being advisable to leave during the stoning period more than twice the number of fruits that are to be left for a crop. One fruit to a square foot of trellis covered with foliage is ample. Nectarines are often left much closer, which proportionally lessens their size, whereas to secure fine fruits they require the same space as Peaches. See that all the shoots are tied to the wires as they progress, stopping any gross shoots at a length of about 15 inches. If the pinching results in laterals stop them at the first leaf, and if extension is wanted the uppermost lateral may be trained in as a continuation. If the trees are in good order there will be little necessity for stopping the shoots, they being trained in their full length, allowing space for the development of the foliage in order to solidify the wood as made. Shoots retained to attract the sap to the fruit should be stopped to one leaf, they having previously had the first growth stopped at the second or third leaf.

Second Earliest-forced Trees.—Attend to dishudding, a shoot being taken from the base of the present year's bearing wood or last year's young wood, and one on a level with or beyond the fruit may be stopped at the second or third leaf. Upon extensions leave young shoots at 15 to 18 inches distance, the shoot from the extremity being trained as a continuation of the primary branch. The main shoots must be 12 inches apart. Commence tying early, as when the shoots are allowed to grow considerably they cannot be brought near to the wood they proceed from without danger of their breaking off. Overcrowding must be carefully guarded against; it is fatal to fine high coloured fruits and the formation and perfection of the wood for future crops. Thin the fruits by degrees, leaving those well placed upon the upper side of the trellis in sufficient quantity for a crop or a little more until the final thinning before stoning. In no case is it good practice to tax the trees with superfluous fruit after it is the size of marbles. Temperature 55° to 60° at night, 65° by day, increasing to 70° to 75°.

Houses Started at the Beginning of February.—In these the trees are in full flower, and some have set their fruits. Continue to fertilise the blossoms on late trees when the pollen is ripe, as we have not derived any aid from bees, which, owing to the cold weather, are "napping" longer than usual. When the blossom is all set recourse must be had to syringing in the morning and afternoon, having the foliage and young fruit dry before nightfall. Dishudding may be done gradually, commencing with the strongest shoots, also thinning the fruits after it is seen which takes the lead in swelling, removing the smallest first, but avoid large reductions of shoots or of fruit at one time. Temperature, 55° at night, 5° less on cold mornings; 55° to 60° by day, advancing to 65° or 70° from sun.

Houses Started Early in March.—The flowers are expanding, and we cease syringing directly the anthers show clear of the corolla, but damp the floors and border, admitting air freely in mild weather, fertilising the flowers on fine days. Maintain the night temperature at 45° to 50°, 55° by day artificially, and 65° from sun heat. Admit a little air constantly. Superfluous flowers on the under side or back of the shoots may be removed by drawing the hand down the growth.

Late Houses.—Replace the lights at once, the buds being well advanced in swelling, promising an abundant crop. Nothing conduces so much to a good set as turning on the heat for a short time in the early part of the day, to advance the temperature to 50°, and to permit of ventilation after the flowers expand, as if there be a prevalence of dull cold weather at that time, closing the ventilators for safety produces an atmosphere that converts the pollen into paste. Houses that have fixed roof lights must have the borders rendered thoroughly moist. If there be any trace of aphides fumigate thoroughly before the flowers expand.

MELONS.—Notwithstanding the cold weather early plants have made good growth, and are showing fruits upon the first laterals. To ensure the fruit setting it is necessary to afford a bottom heat of 80° to 85°, and sufficient moisture only in the soil to prevent the foliage flagging. This will arrest the growth, and in combination with a dry atmosphere—a circulation of warm air passing through the house—will favour the production of pollen. Fertilise the flowers every day, and stop the shoots one joint beyond the fruit. When the fruits commence swelling place warm soil against the sides of the ridges or hillocks. Supply water as required, avoiding a soddened condition of the soil, and to

assist the swelling afford liquid manure, maintaining a good moisture by sprinkling every available surface morning and evening, and syringe the plants lightly at closing time in bright weather. If a succession of fruit be required in the same house some of the plants should be deprived of the flowers if they appear on the first laterals, and stopping these at the third joint will cause the sub-laterals to appear and show fruit, which will be rather later and finer owing to the increased vigour of the plants.

Plants in pits and frames with the shoots trained over the surface will require to be treated in a similar manner to Cucumbers, detailed below, lining the beds and adding soil as the plants advance in growth. Train and regulate the shoots, removing every alternate lateral, and apply water only to maintain a steady growth. The soil should be well firmed so as to secure a sturdy short-jointed growth. As soon as the plants are ready they must be planted in beds properly prepared, and seedlings potted. Seed may be sown to raise plants for succession, also for pits or frames as they become cleared of Radishes or early Potatoes, about five weeks being required to secure strong plants.

CUCUMBERS.—*Pit and Frames Heated by Fermenting Materials.*—Beds that have been formed a few weeks will need good linings. Remove as much of the outside of the beds as can well be spared, and if the heat has not greatly declined it will suffice for the present if one half the bed be lined, deferring the other half until the heat is again declining. In any case let it be applied to the width of 2 feet, as thin linings are of little use, and soon require renewal. When the heat is up in the linings see that there is no accumulation of rank steam in the frame, especially when the sun is powerful, preventing it by ventilation. A good night covering will be necessary to maintain a temperature of 65° to 70° at night. Admit a little air at 75°, and permit the temperature to increase to 85° or 90°, closing at 80° to 85°, not, however, causing the temperature afterwards to exceed 90°. Add a little more soil as the roots spread themselves on the surface. Attend to training and pegging down the shoots, being careful not to overcrowd them. Stop the leading shoots a foot from the sides of the frame, and the laterals at one or two joints beyond the fruit. In watering avoid wetting the foliage as much as possible. Sow seed to obtain plants for growing in pits or frames that have been occupied by early Potatoes.

CHERRY HOUSE.—It will soon be seen whether the fertilising was effectual, as the Cherries will be swelling at the base of the decayed flowers, when syringing may be resumed, once a day at present, and twice a day when the weather is clear and warm. Fire heat will only be necessary to prevent the temperature falling below 40° at night, and to maintain 50° as a minimum by day. Ventilate at 50°, closing at the same, regulating the ventilation according to circumstances. If green aphides appear fumigate the house, having the foliage dry, and keep a strict look out for grubs. Stopping will soon require attention. Pinch out the points of the shoots when they have made 4 to 5 inches of growth, removing those shoots that are not required. Train extensions in their full length, also those for filling vacant space. Overcrowding must be carefully guarded against, it being prejudicial both to the present and future crops.

PINES.—Rooting potted suckers will be indicated by the growth of the foliage, but it is well to turn the plants out of the pots, or at least a portion of them, so as to ascertain the condition of the roots and the soil. The young roots which issue from suckers, or plants subjected to similar treatment are very tender and susceptible of injury from the effects of too much bottom heat, hence when the roots reach the sides of the pots 85° is ample, above which there is danger. When the bottom heat is excessive the pots may be raised, placing some loose tan under and around them, so as to allow the superabundant heat to pass away without injuring the roots. The plants must be carefully supplied with water.

Established plants will now make roots rapidly, therefore have soil ready for transferring them to the fruiting pots, as it is important that they be grown on without check by being either dry or rootbound. Sound fibrous loam in good sized lumps is the best material for potting, pressing it firmly round the balls of the plants, watering the plants with tepid water, and plunging them in a bottom heat of 90° to 95° until the roots have possession of the fresh soil, when 85° is more suitable.

Fruiting plants, and those that are at or near the flowering state should have a night temperature of 65° to 70°, and 75° by day, with 80° to 90° from sun heat, closing at 85°, well damping all available surfaces in the house at that time. Afford succession plants a bottom heat of about 85°, ventilating at 80°, and closing at 85°, lightly sprinkling the plants occasionally.

FIGS.—*Earliest Forced Trees in Pots.*—The earliest trees, or those started early in December, will be induced to swell their fruits by a top-dressing of rich material applied to the surface of the soil, and if a layer of turves has been placed around the rim of the pots, as before advised, space is afforded for the top-dressings. Do not give heavy dressings of rich compost all at once, but apply it little and often; apply also liquid manure, 1 oz. of the soluble artificial manures to a gallon of water, but give it in such quantity as to pass through the pots. Driblets do no good. Maintain a genial atmosphere by syringing twice a day when the weather is bright, but avoid keeping the foliage constantly wet, as would be the case by syringing vigorously in dull weather. Damp the paths, walls and bed, keeping the evaporation troughs charged with liquid manure, and to check red spider paint the hot-water pipes with sulphur. Admit a little air at 70°, increasing it with sun heat up to 85°, which ought not to be exceeded, closing at 80°. The night temperature which

still range from 60° to 65°, 55° in the morning in very severe weather is safer than the higher temperature, advancing 10° by artificial means in the daytime. Avoid crowding, stopping or tying the shoots as growth advances, as the fruit to have flavour and colour must, when ripening have full exposure to light combined with a circulation of warm dry air.

PLANT HOUSES.

Nepenthes.—Transfer into larger baskets all *Nepenthes* that are crowded with roots. Do not disturb the old ball further than is necessary to remove the drainage from the base. A good layer of crocks should be placed over the bottom of the basket, and then the space must be filled in with fibry peat and lumps of charcoal. Press light soil of this nature as firmly as possible, and place living sphagnum moss on the surface. Any plants that have grown tall and ceased to produce pitchers may be cut back close to the base, and be allowed to break again into growth before they are potted or placed into larger baskets. When subjected to good management they do not need severe pruning for several years. By a regular and judicious system of pinching back they are constantly making young growths, which produce large pitchers. Cuttings strike freely if inserted in small pots amongst sand and sphagnum moss, and then plunged in the propagating frame, where a brisk heat is maintained. The cuttings should consist of two joints, and require to be kept close, moist, and shaded from the sun after insertion until they are rooted.

Crotons.—Now the plants have commenced growth cuttings will root readily. To root large heads successfully without losing their foliage take them off where the wood is soft; if taken where the wood is hard and ripened, they generally lose their foliage, and are a long time before they root satisfactorily. However large the heads may be, they can be successfully rooted provided the plants from which they are taken are growing and the wood is moderately soft. A temperature of 65°, a frame that can be kept close, and a brisk bottom heat are needed. Plants from which the heads have been taken may be retained if stock is needed; these will produce strong growths, and in a short time yield good heads. Do not take them in too small a state, or instead of large bold foliage at the base they will have small leaves, which destroy their appearance for many purposes. Plants that have filled small pots with roots and are needed for decoration may have an application of artificial manure to the surface of the soil. Place into 5 and 6-inch pots young stock that was rooted in autumn and wintered in 3-inch pots. Larger plants may also be potted. Use for a compost rich fibry loam, one-seventh of decayed manure, one 6-inch potful of soot to each barrowful of soil, and the same quantity of bone meal, with a liberal addition of sand. Grow these plants in a warm atmosphere, close to the glass and fully exposed to light.

Dracæna Goldieana.—Plants that have grown too tall may be shortened and their tops rooted. In taking them off be careful to cut them where the wood is moderately soft. If the wood is firm they are three or four months before they are well rooted, and often lose their lower leaves, which detracts materially from the beauty of the plants. When the base of the wood is soft they root quickly and freely without losing a single leaf. Good heads may be inserted in 5-inch pots with a little sand for the base of the stem to rest upon. Plunge the pots under handlights, and cover the rim of the pot and surface of the soil with the plunging material, then no water will be needed before they are rooted, provided they are dewed with the syringe occasionally and the plunging material kept moist. *D. gracilis* and *D. Lindenii* can be successfully rooted in the same way. If increase of stock is needed keep the old plants in brisk heat, and if carefully watered at their roots they will soon break into growth. The side shoots can be taken and rooted in small pots. It is surprising what a number of young plants can be raised by this method in the course of a season.

PRACTICAL BEE-KEEPING.—No. 31.

THE end comes at last. With a few additional words of advice and warning this series of papers comes to a close. Most points of importance to the bee-keeper have been touched upon, although many of course have been passed by in silence. A bee-keeper who has read each paper and appreciated its meaning, will, I hope, be able at any rate to grasp something more than the elements of practical apiculture. If this is impossible, then my labour has been but lost, and the kindness of the Editor in allowing me so much of his valuable space has been thrown away. If one bee-keeper has learnt something which he did not know before, it is at least a satisfaction, while if the majority of the readers of this Journal are led to reconsider the position they have taken up, owing perhaps to advice given in more advanced papers, and to return to the paths of simplicity, a good work has been performed.

Spring is quickly approaching after two dreary months of winter

Frost and snow and keen east winds have kept the bees at home, and have therefore done good service to the bee-keeper. Unless it is absolutely necessary, or it is wished to do so for mere experiment, bees should not be disturbed in January, February, and March, although towards the end of the latter month an examination may be made of all stocks if the weather is sufficiently fine to allow of manipulation. If it has been decided to gently stimulate the bees in the latter part of this present month, in order to have them sufficiently populous to take advantage of the May honey or to throw early swarms, this may be done, as I have already pointed out, with safety, provided a constant supply of food is given and means are taken to prevent the escape of heat. If the internal heat of the stock is allowed to escape, the progress of the stock is retarded and not quickened, the aim of the bee-keeper thus being frustrated through his own carelessness. In all probability this will be an early spring, and it is possible that we may escape the infliction of late frosts, notwithstanding the old saying, "As many in March, as many in May." It does not at all follow that because of the long—and as I write, still unended—winter, that stocks will be later in swarming than usual. Six weeks of mild warm weather, when bees are able to fly freely, and almost all day long, will make a wondrous change. Now is the time to obtain all the requisite appliances for the coming season. Everything should be obtained at once, and immediately prepared, so as to be ready for use when required. The unexpected generally happens, so we must always be prepared to meet an emergency. It must also be decided whether to work for sections or extracted honey, or for both, and preparations must accordingly be made, while if an increase is desired, steps must be taken to have a supply of queens and hives—the one to head the swarming stocks, the others to hold the coming swarms. Whatever we do let it be done well. An ill-made section rack, which gives way under the weight of sealed sections just as it is being lifted off the stock, and precipitates 20 lbs. of honey with a crash on to the top bars of the stock, is likely to give a vivid impression of the result of bad workmanship, especially if the accident happens at the end of the season, when honey has ceased to come in freely, and thousands of eager bees are on the outlook for unprotected stores.

Throughout the season, from year's end to year's end, let us remember, and act upon, our knowledge, that all uncalled for interference is not only not advisable, but absolutely injurious. In the middle of the honey flow it causes a cessation of work, in the autumn it gives rise to robbing; later still, and in the early months of spring, it disturbs the necessary quiet and chills the bees, making them restless and more eager to leave the hive than they would have been had they been left to their own resources. When necessary to do so let every stock be carefully examined, because the evil then feared, and which by such examination is or may be asserted, is greater than the loss occasioned by such an examination.

Let every stock be well supplied with food and strong in bees, headed by a good queen in autumn, and success in spring is practically assured. Keep every stock strong and healthy, and by every possible means avoid the infection of "foul brood." If disease appears attempt without delay to eradicate it, and if the attempt fails sacrifice your stocks rather than waste time and money when by the expenditure of the same time, and by having the bees to take advantage of the honey flow, your extra expense and loss might easily to a great extent have been recouped. Keep strict and careful accounts, and enter up each item as soon as possible, and then at the end of every year a balance can be struck; and if in any year the balance is unfavourable there is something wrong in the management, unless the weather has been more than usually unpropitious.—FELIX.

DIRECT INTRODUCTION OF QUEENS.

I HAVE read with much interest "A Hallamshire Bee-keeper's" article on queen introduction (page 161). There are few writers who give details so instructive to the subject on hand as "Hallamshire Bee-

keeper" does, and experience makes his remarks all the more valuable. But like him I am anxious to let it be known who the persons are that have "benefited us with the great discoveries and inventions which add to our everyday comforts." I suppose matters concerning bees are not excepted? This is the point I wish to explain. "Hallamshire Bee-keeper" and "Felix" speak of the different systems of introducing queens under the name of Mr. J. E. Pond, S. Simmins, Alley, and "A Hallamshire Bee-keeper." If there is anything new the last named is the only one entitled to the honour. But I am afraid the novelty will only be found in the clever way he details his experience. Who, then, are entitled to the honours regarding queen introduction? That is easily answered. The pioneers of this Journal are entitled to all that is valuable concerning queen introduction. Mr. T. W. Woodbury, "A Renfrewshire Bee-keeper," "A Stewarton Bee-keeper," as well as myself, all took part in the subject more than a quarter of a century ago, and direct introduction, although sometimes successful, was condemned, and everything mentioned by "A Hallamshire Bee-keeper" either appeared in the pages of the *Cottage Gardener*, or by private letters interchanged by the above named. Most of these letters are still preserved, and a quotation from one of Mr. Woodbury's may be relied upon as the only safe method to attempt the introduction of an alien queen. He says, "The only safe method is to deprive the bees of the power of raising a successor to the one deposed," which was also my experience. I still advise all bee-keepers to adopt the same plan. I have so often found pleasure in reading "Hallamshire Bee-keeper's" sensible remarks, and beginners should follow his instructions. It is, however, singular that the most of his remarks are similar to those of "A Renfrewshire Bee-keeper" (for which see back numbers), as the different systems of queen introduction direct and otherwise. The aptitude of bees to raise queen cells when an alien queen is introduced occurs too often to allow of any remissness whatever on the part of the bee-keeper, and I can endorse all that "Hallamshire Bee-keeper" says on that point. As "Felix" remarked, "It does not matter who was the first to make a valuable discovery, it was enough if the bee-keepers had the advantage." But on the other hand, is it just to allow those to have the honour who did nothing but appropriate the ideas of others? There still is much of that dishonourable practice, which all the more induces me to stand up for the rights of this Journal and its pioneers in bee subjects.

PROGRESSIVE BEES.

A copy of the *British Bee Journal* was sent me lately as containing something interesting for me. Among other things I observed that the subject of appropriating old ideas was causing animosity amongst some. But what was most interesting was the remark that "Young bees were nursed, fed, brushed down, and led out for their first flight by the adult bees." Such actions I have never seen, nor have I observed that any of the old naturalists mention such a thing. In fact, my experience as well as theirs is exactly opposite. My observations proved that with plenty of food young bees in the cells were attentively waited upon, but immediately they began to break the seals of their cells they had to fight their own battle, making the best of their way out of their cells, performing their own toilet as well as being their own nurses. What say the Darwinians? or can Dr. Walker throw light on the subject? We have not experienced such things, but perhaps like man the bee is progressing.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Dahlias and Hardy Plants.*

TO CORRESPONDENTS

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (W. K.).—The address you require is, we think, Mr. W. Collins, 6, Martine Terrace, Martindale Road, Balham, London, S.W.

The Eucharis Mite (*G. C.*).—The information you desire will be published in an early issue of the Journal.

Beetles in Tomato House (*A. A. B.*).—The examples sent appear to be, as you surmised, one of the click or skip-jack beetles, the larvæ of which, as "wireworms," are so frequently destructive, this particular species being *Agriotes* or *Elatér obscurus*. It is not the common species to which the name wireworm more specially applies, yet also injurious, as you have found it to be, though its occurrence on this Tomato is somewhat unusual. Trapping the larvæ or grubs is certainly a good plan of thinning their numbers; also the destruction of the mature insect. The mischief done by this group of insects is intensified by the fact that, though small, they live and feed in the larval stage for two, or even three, years. Though the usual time for the beetles to emerge is July or August, a portion of a brood will occasionally be found in spring, their development being hastened by a warm summer and autumn preceding.

Dissolved Bone Manure (*H. H.*).—This is excellent for Roses, fruit trees, and all kinds of kitchen garden crops, also for flower beds and borders that are more or less impoverished. It may be applied now in quantities varying from 2 ozs. to 4 ozs. per square yard, according to the poorness or otherwise of the soil, and the condition of the Roses on trees to which it may be applied, obviously those that may be healthy and strong not requiring half so much as others that may be very much the reverse. It is a very safe manure, and the good it does is exactly in proportion to the judgment that is exercised in its application on the lines indicated. Bones can be dissolved in an earthenware jar without wood ashes by pouring sulphuric acid on them till they boil. This plan is usually adopted when a large quantity is collected, and in disposing of a few at a time as they are had from the kitchen they will not be offensive if covered with wood ashes as often as the bones are collected. You can, however, try the acid, then adopt the method most suitable to your case.

Gumming Flowers (*Idem*).—The petals of Pelargoniums are sealed by placing one drop in the centre of each flower of a strong solution of gum arabic that can be had from a chemist's. If you desire to make a quantity place 8 ozs. of the gum in 5½ pints of soft water, and allow it to stand two or three days to dissolve, then strain through a piece of muslin. The gumming process can be done quickly by having the solution in small tins, such as ladies use in oiling their sewing machines.

Pruning Clematis and Passiflora (*E. W.*).—Your Clematis does not appear to have made much growth, and the soil must either be poor or have been very dry last summer. Shorten the stem about one-fourth or a little more—that is, if there are buds on it, as there should be, and spread a layer of manure 3 inches thick on the soil over the roots, covering the ground 2 feet from the stem in all directions, and give water copiously once a week in hot weather. If the ground is dry and poor now give a good soaking with liquid manure, soot water being excellent. Allow the mulching to remain and decay. The main growths of the Passiflora should be trained a foot apart or thereabouts, the side growths from them, if any, being cut back within an inch of the base, and the soft green ends of the leading shoots may be cut off. Fruits of the common Passion Flower, *Passiflora cœrulca*, are not eaten, but those of *P. edulis* are, and esteemed for their sub-acid flavour. This species requires to be grown under glass.

Damp Conservatory (*S., Surrey*).—Imperfect ventilation, a low temperature, and overwatering are the causes of the mildew and damping off among the plants of your conservatory. A temperature of 50° by fire heat, or higher by sun heat, opening the roof sashes early and regularly on fine days, and careful attention to watering, will soon set matters right at this season of the year. On wet or windy days do not open the ventilators, but insure circulation of the air by gentle fire heat. Your proposal to apply liquid manure to young climbers to induce them to bear flowers is wrong. It is probably owing to excessive vigour that they have been flowerless hitherto; as the growth spreads it will become less rampant, and then you will have flowers. It is the want of light and a low temperature which causes the young growth of the *Lantana* to be discoloured, spotted, and withered. Remove it and the *Raphis flabelliformis*, which is also suffering from lowness of temperature, to a warm house where the temperature ranges from 50° upwards, till the season's growth is fully developed, and then use them again for the decoration of rooms or cool houses.

Shrubs for Slope in Exposed Situation (*Woodlands*).—If you require something that will afford an evergreen covering, few things afford it better than *Hypericum calycinum*, which grows about a foot high, and has large bright yellow flowers in summer. *Berberis Darwini* also does fairly well, and *Mahonia aquifolium*, both evergreen, and with yellow flowers in spring. *Vinca major elegantissima* is also suitable. *Daphne Fioniana* is also suitable for banks, and *Cotonaster microphylla*. *Genista albus durus*, *G. multiflora luteus*, and *G. præcox* are dwarf, very free-flowering, and good. Double Gorse is particularly desirable, and *Veronica Traversi*. If you require anything to appear above the dwarfier plants there is nothing to surpass Hollies, both green and variegated. As you reside near Leeds it would be worth while noting the kinds that succeed on Woodhouse Moor. In deciduous shrubs the Golden and Silver variegated Elders are very desirable. Variegated Dogwood (*Cornus sibirica variegata*), *Lonicera tatarica*, and var. *alba flora*, *Hypericum hircinum*, Lilac in variety, and Ribes vars.

Roman Hyacinths (*Regular Subscriber*).—When the Roman

Hyacinths that have flowered have been thoroughly hardened and the weather is genial, say towards the end of the present month, you may plant them outside. In doing so they should be planted in patches so that they can be protected while in flower with handlights or a frame. The Roman Hyacinth flowers when planted outside too early to insure the flowers being any good for cutting without protection. Rain and early frosts are certain to spoil them, in fact this is the case in the majority of seasons. When February proves mild they often flower outside early in March, and generally before the close of the month. For years we have been in the habit of having a valuable supply of their pure white flowers for nearly a month after those grown inside were over. This was accomplished by planting on a sunny border in patches about 18 inches square, so that they could be covered at intervals of a few weeks with handlights after the growth appeared above ground, the last clumps being covered directly the colour of the flower was visible. Requiring a late supply no longer we lifted the whole stock and forced them. When lifting them we were surprised at the size some of the bulbs had attained and the increase in their number that had taken place. The spikes were equal to any we have seen from the first quality imported bulbs. Rather than plant a few weeks hence we should prefer to keep the bulbs well watered until they ripen their foliage, then shake the soil from them, and dry them in the sun. Then plant them in July, where they are intended to flower. This is the course we have adopted successfully.

Peach Buds Falling (*A. B.*).—There are various causes for Peaches and Nectarines casting their bloom buds. The evil sometimes arises from over-development of the buds, as in the case of trees that are subjected year after year to early forcing, to imperfect formation of the buds, due mostly to insufficient supplies of water and aliment, too much wood, or crowding, overcropping, and attacks of red spider. The buds often fall from a deficiency of moisture at the roots during the season of rest, but of all the causes the most fertile is that of undue excitement and its concomitant checks during the resting period. We do not think the buds falling is in your case due to the cold draughts through the house, but incline to the opinion that the trees have not been duly supplied with water and liquid manure during growth, and the foliage not kept free from insects, also that the trees are kept in too changeable an atmosphere, and too dry whilst at rest. Sometimes the buds fall through a careless application or an overdose of an insecticide. The only way to escape buds falling is to attend carefully to the cultural requirements of the trees. We have not lost any buds of consequence for many years by simply lifting trees that exhibited that tendency, lifting being, with otherwise good management, an almost certain preventive, and it is equally important that the trees be exposed to the full influence of the atmosphere by removing the roof lights so soon as the buds are formed and the leaves give indications of falling in the case of trees that do not ripen their fruit before August, but very early forced trees require the lights removed so as to prevent premature development of the buds. The removing of the roof lights insures a season of complete rest instead of the alternating fluctuations and depressions, which are often sudden, attending trees kept under a fixed roof.

Protests at Shows (*G. C.*).—"Exhibitor," to whose letter we replied last week, did not mention your name, nor the name of any person. He stated a case on the general subject of protests from exhibitors who feel themselves entitled to ask for a re-examination of certain classes in which they conceive an error has been made, and we had no hesitation in expressing our opinion on the subject on page 207. To that opinion we adhere. If judges make a mistake they have a right to have an opportunity of rectifying it, and are glad to do this when they perceive that justice demands it. When any error arises through the conditions of the schedule having been departed from, it is for the officials of the show, with or without consulting the judges, to take cognisance of the matter; but even in such cases the protests ought to be placed before them in writing immediately a supposed infringement is observed, and that is as soon as the awards are made. Any exhibitor, whether he is a member of a committee or not, can enter a protest if he desires to do so, but he should take care to have good grounds for his action, and to state them clearly and promptly in writing to the secretary, in order that the matter can be there and then investigated. You say you were not an exhibitor at a particular show to which you assume allusion was made. In that case the duty of protesting, if a protest was called for, obviously rested on someone else. Whatever is unsatisfactory at past shows should undoubtedly be considered in committee, with the view to its avoidance in the future; but the deliberations should be conducted in a temperate manner, and in a spirit devoid of recrimination in respect to past action. We refer to no person individually in these remarks, but they are of general application. We find that even Mr. Goodacre was not entirely free from the suspicion that the remarks on lodging protests were intended for him. He was not in the mind of "Exhibitor" when writing, nor in ours when answering last week, nor, we repeat, was your name before us.

Wintering Gloxinias and Amaryllises (*J. E.*).—The lowest temperature in which we have wintered the tubers and bulbs is about 45°, occasionally it may have been lower, but more often a few degrees higher; but we do not state that as the "lowest" endurable temperature and possibly Amaryllises if quite dry would endure greater cold. We prefer a temperature of about 50° for Gloxinias when resting. Amaryllis seed may be sown now in brisk heat. Under the best of culture and most suitable structures a few seedlings may flower in two years, that is when planted out in a warm bed in a very light house, but the majority are three and four years before flowering.

The reason of this is the failure of the Turnip crop upon so many farms last year, and we repeatedly hear it said that after all Turnips cannot be so necessary for ewes as was supposed; and we are even told that Turnips may have been the cause of much of the heavy loss in past years. Those of our readers who have followed our teaching during the last few years will remember how persistently we have warned them against folding upon Turnips before the lambing, nor have we been content with a mere warning, but we have shown how we and others have suffered heavy losses from their premature use. Even so late as last year we lost about a score of ewes from the disobedience of one of our shepherds, who was not sufficiently under the master's eye for a thorough check to be kept upon his doings. His dismissal will, we hope, tend to enforce attention to our orders in future. We may here mention in passing how frequently we experience a feeling of envy against those farmers whose land lies well together, so that they can see all that is necessary once or twice daily. We have a tenant who farms a thousand acres of land, most of which he sees twice every day, but two of the farms we have in hand are nearly fifty miles apart, and the others are so scattered that we cannot see as much of any of them as we should like. Depend upon it, if farming is to be successful there must be constant and close supervision of every detail of the work done at all seasons of the year.

Returning now to the lambing, we quote from a daily contemporary the following important statement:—"From every quarter we hear that there have been fewer losses of ewes, as well as a smaller proportion of abortions and still-born lambs than usual, and this is universally attributed to the inability of flockmasters to feed their in-lamb ewes on any Turnips this season. Some theorists are, parrot-like, repeating the hackneyed phrase that farmers are learning a serviceable lesson this year by making the discovery that in-lamb ewes should have few roots; but the experienced and intelligent among them learnt it long since. Owing to the great losses of ewes and lambs in the winter of 1876-7 Mr. Henry Woods of Merton sent out 500 circulars to the leading flockmasters of the kingdom to ascertain by unmistakable figures how their experience differed. In one case, from the county of Norfolk, he found that in a flock of 590 ewes there had been 130 abortions and 105 deaths of ewes, while in another flock of 344 from the same county not a single abortion or death was experienced. One Warwickshire flock of 340 suffered 98 abortions and 36 deaths, while another of 729 in the same county chronicled only four abortions and seven deaths. The greatest exemption from losses was probably that of a large flock of 1206 in Kent, in which there were no abortions and only five deaths. Mr. Woods, in making known the results, said, "I have taken fifty cases where the feeding and results are most satisfactory, and fifty other cases just the reverse. The fifty good cases comprise 25,281 ewes, and in that number the cases of abortion only amounted to 126, and the deaths from all causes, up to the end of April, to be 222. The fifty unsatisfactory cases comprise 21,682 ewes. Of these twenty-two do not report the actual number of abortions, contenting themselves with acknowledging heavy losses, but the remaining twenty-eight alone give the startling number of 1884. In ten the owners, while admitting great loss of ewes, are absolutely silent as to numbers, yet the remaining forty give a total of 1255 deaths."

Although these facts were thoroughly made public at the time, and farmers have repeatedly gone through worse seasons of scarcity for roots than the present one, in which they have invariably suffered less from deaths amongst the sheep than when Turnips are plentiful, the bulk of them still proceed in the beaten track of pursuing costly culture and allowing their flocks to feed *ad libitum* on Turnips when they are plentiful. Even in the present season we have seen ewes and lambs out on Swedes half covered with snow, the ewes greedily eating the half-frozen roots, the lambs standing about in the mire caused by trampling the snow into the soft soil beneath it. Worse still, if possible, is it to see the pregnant ewes in other folds out upon Turnips with a sea of mud around them,

where they cannot lie down, and into which they sink at every step, so that mere movement causes a severe strain upon the entire frame. Under such conditions is matter for wonder that losses of both ewes and lambs are numerous?

WORK ON THE HOME FARM.

Frost and snow have left us, and we have March wind and sunshine to dry up the land, so that by the time this note is printed we hope to be in the full swing of sowing the spring corn. First of all come spring Tares for the sheep, then Peas and Beans, followed by Barley and Oats. Clovers and Grasses will either be sown with the corn, or, as many wisely prefer, it will be sown when the corn is well above the surface, in order that the growth of such forage plants may be sufficiently retarded to keep it from growing so much as to prove a hindrance to the corn harvest.

Glad indeed are we to find so many farmers coming to us for advice about the use of chemical manures with their spring corn. In every case they have been told not to expect good results unless other points of culture have full attention, for manure alone will not improve a crop if the land be wet or very foul. Where pasture was under snow throughout February, and a week or more of the present month, the manure was not applied. No time should be lost in using it once, for if it is not used while there is a probability of rain the results will be the reverse of satisfactory. As much as possible of the manure is drilled with the corn, so that the moist soil may render it soluble by the time the young plant requires assistance. In plants, just as in animals, we like to promote vigorous growth from the first, and we can only hope to do this by having an ample store of fertility in the soil at the time of sowing. In some recent experiments the plan of withholding nitrogenous manures till the plant is in full growth has been tried with not very satisfactory results, for the simple reason that readily as such manures dissolve they cannot do so without moisture. To withhold them till late in spring involves so much risk of having little or no rain for such a purpose that we decidedly prefer sowing with the drill or before it, so as to ensure the manure being sufficiently blended with the soil to cause it to dissolve. In the excelsior drill we have an implement which sows seed and manure at the same time in a simple and expeditious manner.

AGRICULTURAL BALANCE SHEET.

PLEASE permit me to thank most heartily the author of your agricultural article on page 185 for his very courteous reply to my request *re* the above subject. I had not the slightest idea of in any way doubting his veracity when writing my note. If the wording suggested this it was not intentional. What prompted me to write just then was an observation made to me (when mentioning your correspondent's note to him) by an experienced land agent—viz., that it was easier to write articles on scientific farming than to produce a balance at the bank after paying all the expenses of such farming. The cause of the said agent making this remark was in reference to a note in the *Yorkshire Post* penned by the writer of this, which note I herewith forward for your inspection. You will see that part of the substance of my note in the *Post* was a repetition of some of your able coadjutor's remarks in your column. Had I personally doubted his veracity I do not think I should have repeated his sayings, which I practically did. As a further proof of my not doing this, I may remark in conclusion that for some time past I have had a wish that circumstances would only have allowed me to send a strong active lad of mine for a year or two as a worker under his tuition. This cannot be, though.—C. J. H.

[The letter referred to, and a very good one it is, is of the nature indicated by "C. J. H."]

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

REMARKS.

4th.—Fair, with a good deal of sun, but cold wind.
 5th.—Cloudy early and at times in the afternoon, otherwise fine.
 6th.—Fine, but at times cloudy, especially in the afternoon.
 7th.—Beautiful morning, but generally cloudy in the afternoon.
 8th.—Stormy from S.W., dull and damp.
 9th.—Rain in the small hours; dull day with occasional showers.
 10th.—Dull and drizzly till 10 A.M., then finer with a little sun, and bright afternoon.
 Sudden change of temperature in the middle of the week, so that the weekly means are very near the average for the season; and with the higher temperature came some very acceptable rain.—G. J. SYMONS.

NEW LAWNS.

SOME lawns are so uneven in surface, so full of weeds, such as Daisies, Plantains, Dandelions, and coarse grasses, that they give much trouble in keeping, and are never satisfactory. More time, labour, and expense are often incurred in patching and mending such lawns than would be necessary to form a new one that with ordinary care would be all that could be desired.

Imperfect drainage is the cause of many unsatisfactory lawns. Drainage acts beneficially through freeing the soil of superfluous water, rendering it not only drier but warmer. All water lodging within 3 feet of the surface is injurious, and should be prevented by a proper system of drainage. Sandy or gravelly subsoils need the drains farther apart than clay subsoils, 8 yards apart being taken as the maximum distance for the former, and 4 yards as a minimum distance for the latter. Where the subsoil is excessively porous the lawn often becomes browned in summer, and to attempt drainage in such cases is unnecessary, indeed it would be better to bring in clayey marl and good soil.

We need not enter on a description of the work the formation of new lawns entails in connection with the erection of a mansion, whether on an old or new site, farther than to point out that it is done sometimes in a most improper manner. All work that necessitates moving the soil or placing it deeper than is necessary in performing the operations of digging or trenching should be done sufficiently early to allow of its settling down before an attempt is made to prepare the surface for sowing seeds or turfing. The soil, whatever it may be, must be well dug, making it all alike—not a few inches deep in some places to burn and brown the grass in hot weather, with deeper, better soil in others to show in drought amid the general brownness as green oases in a desert. Stir the ground as deeply as the good soil allows, and if the pan below be of a stubborn nature it must be broken up with a pick. If the soil be thin there is greater need to keep it at the surface, and the best plan is to mix the good soil uniformly, as in turning a manure or rubbish heap with enough of the surface soil to form a good tilth. Very light soil may have clay marl mixed with it; a hundred loads per acre can be spread on the surface during frost, and afterwards be dug in evenly, or a similar quantity of chalk can be employed to make it more retentive of moisture. Heavy soils may have ashes, lime rubbish, sand, and road scrapings mixed with them as deeply as the soil is stirred, which will make them more porous, drier, warmer, and more favourable to an early and late growth. If the soil be very stiff throw it up in ridges so that it fall in spring readily into that even surface which is essential for a proper bed for turf or seeds. All digging, trenching, or mixing should be done some little time before turfing or seeding to allow the soil settling. Spare no effort whilst digging or trenching in removing any Couch, Bindweed, Docks, Dandelions, or other weeds.

Where the ground is "in good heart" manure may not be required, but poor soils should have a liberal dressing. Twenty cart-loads per acre of good manure will be sufficient for poor soils, and it should only be pointed in or mixed with the top 6 inches of soil. Soil that only needs moderate enrichment will have the want supplied by a dozen loads per acre. Where manure cannot be obtained recourse must be had to artificials, in respect of which I can only reiterate what was stated of them for old lawns—viz., that they are excellent. If the soil be deficient in lime give a

supply, as it is essential for the finer descriptions of Grasses, particularly of the Fescue Grasses, Clover, and Lotus, using it in a maximum quantity of 160 bushels per acre, and a minimum of 80 bushels. Apply it in autumn or in spring. If the ground must be manured do so after liming in autumn, or if lime is applied in spring omit the manure, reserving it for dressing in the following autumn or early spring.

From October to March, inclusive, is the best season to lay turf. It may be done at other times with perfect success when the weather is showery; but it is a very uncertain and extravagant method of securing a lawn. The moist showery weather of April and of September is sometimes better than the season indicated for laying turf; therefore, I shall only insist on moist mild weather being chosen. The turf must be taken from soil similar to that on which it is to be laid, and must be of the best possible character and free from weeds. I prefer the turf cut into squares of a foot every way as more convenient than the ordinary plan, leaving it grass side upward after every weed is carefully extracted. Lay the turf as soon as possible after cutting it on a firm and level surface, as even the best may have inequalities they must be rectified in laying. Beating after laying will certainly tend to reduce any irregularities, but the less there is for the beater in that respect the better; indeed, some turf is hammered after laying until the surface is a puddle. Nothing further is needed except a little fine soil (I prefer leaf soil or short manure) disposed evenly with the back of a wooden rake. After the first rain, as soon as the ground is in a state fit to walk upon, roll thoroughly, and the heavier the roller the better.

The best lawns are formed by sowing seeds, proper regard having been paid to preparing and cleaning the ground, and if in good working order firm it by treading, and rake it well, removing all stones and rough material. The tilth for Grass seeds should equal that of an Onion bed, but there is nothing so objectionable as a very close road-like surface. The Grasses will not become established so soon on that as where the surface is readily loosened by a rake. Sow the seed on a calm day, scattering the seeds evenly, and at once rake lightly to cover them from the birds. Roll the ground well and leave it until the Grasses are well developed, when a dressing of soot, 40 bushels to the acre during moist weather, will be most beneficial. Artificials may be given in lieu of soot, but if applied before seeding a second application will not be needed so soon, reserving it for moist weather after the first cutting. Do not be in a great hurry to cut the Grass, but switch it over occasionally with a scythe so as to remove any irregularities, but the more it is rolled when the ground is in a fit state the more the Grasses will spread.

The best time for sowing is perhaps the first moist weather in April and onwards, but the earlier it is done after the middle of April the better are the chances of a good turf being formed. Sometimes the ground is ready for seeding in late summer. In that case by all means sow in September; the seeds will germinate quickly and form quite a carpet before the weather is ordinarily severe. If the precaution be taken to dress the surface before winter with leaf soil or short manure, the twofold object of protection to the Grasses and enriching the soil will be effected.

I have tried compounding mixtures, procuring the Grasses separately, and attained a goodly measure of success, but I find there is little if anything gained thereby, as the various Grasses required for forming lawns differ but little in quantity and scarcely anything in kind for a light, medium, or heavy soil, therefore I am now content to procure a mixture of extra cleaned seeds of the finest dwarf evergreen Grasses for the purpose intended, making two distinctions only—viz., for garden lawns the finest Grasses and Clover, and for bowling greens, croquet grounds, lawn tennis grounds the finest Grass seeds only. If the lawn be an ordinary one occasionally used for tennis, it is easy to add to the mixture a few pounds of *Cynosurus cristatus* and *Festuca durius-*

cula; if very light, Suckling Clover and *Lotus corniculatus minor*, or even Yarrow if very sandy, and for shady places *Poa nemoralis sempervirens*. The chief thing is to procure clean fresh seeds and sow plenty of them. Parsimony in lawn-making is a certain verification of the adage, "penny wise and pound foolish." Three bushels of seed per acre is a proper quantity, but it is better to err on the side of too much rather than too little seed.—G. ABBEY.

ROYAL HORTICULTURAL SOCIETY.

THE NEW HALL—EXHIBITIONS.

It is scarcely necessary to say that this note has reference to the building hired by the Royal Horticultural Society for its committee meetings and shows during the ensuing summer. Mr. Smee says though the Hall may not be everything that could be wished, it is near the Army and Navy Stores, which large numbers of people frequent. It is a much finer building than its name of Drill Hall implies. Many, if not the majority of volunteer drill halls, are cold, bare, comfortless-looking, if not repellant structures, with gravelled floors, dirty walls, and corrugated iron roofs. The Hall in question is very different, and no objection can be taken to it in any of those respects. It is a well-finished imposing building, not devoid of architectural ornamentation—in fact as far as regards appearance it is not easy to see how any fault can be found with it.

It is a very large and lofty building, with galleries round, the roof being partly of wood—boarded—and partly of glass, the former perhaps predominating. On a bright day there will be light enough for a flower show, and the hall will probably not be "like a furnace" in summer; but on dull days it is questionable if the light will be all that could be desired; and in winter the building, which is not heated, will be too cold for plants and visitors.

It is not perhaps so large as the conservatory at South Kensington, yet there appears even more room in it for furnishing with exhibits, because a large amount of space is permanently occupied in the conservatory with Palms and other ornamental trees and plants. These have formed a splendid background to whatever may have been arranged on the tables in the wide central promenade. A show, therefore, in the hall cannot be made so attractive as in the conservatory, though with an adequate number of large plants the hall could, no doubt, be made to present a beautiful appearance; and if cultivators, both trade and amateurs, were to unite, and put forth anything like their best efforts, an exhibition would be produced worthy of the most exalted and extensive patronage that could be bestowed upon it.

When a great revival was attempted in 1875 such firms and exhibitors as Messrs. Veitch, Williams, Bull, Turner, A. Paul & Son, W. Paul, Lee, Osborne, Cutbush, Standish, Wills, Laing, Barr, Morse, Wimsett, with many other florists and private gentlemen, joined in producing a show gratuitously, and that will not be soon forgotten by those who witnessed it. Death has been active since then, and time has wrought many changes, yet if the same disposition exist now as then and united action be taken on the same lines a splendid exhibition would be the result, and one that ought to command wide attention. Will horticulturists, amateurs and professionals, join in friendly rivalry, as in the past? If a showing policy is to be carried out it must be carried out on a broad base and liberal lines if the multitude is to be attracted and "funds procured for the maintenance of the Chiswick Garden." Unless greater exertions are made in the future than in the immediate past the so-called "fortnightly shows" will be "lost" in the hall, the public cannot be impressed with the gatherings, and whatever of awakened interest may be created cannot perhaps be sustained.

But something more than shows appears to be required to make shows profitable. When Royalty has vouchsafed its patronage on some past occasions there has been no lack of followers. The shows have been crowded; but in the absence of some great personage they have been sparsely attended, and when prizes have been offered and the money paid there has been no profit, but the reverse, on the undertakings. Mr. Smee seems to base his calculation of the Westminster Shows strengthening the Royal Horticultural Society financially on the fact of £50 being taken as gate money in Finsbury Circus for the exhibition of a "few sickly plants" grown in the City. But did not a Royal Princess distribute the prizes to the humble growers on that occasion? and did not the people flock to see Her Royal Highness and the ceremony so gracefully performed? If that is so, and it was so on at least one occasion, the Finsbury result can be no criterion of the attendance at Westminster unless a member of the Royal Family attends there also. Is there any probability of that honour being conferred? If not the Finsbury example is deprived of its force.

Further, the promoters of the Finsbury Circus Show of sickly plants had a definite and to a very large extent charitable object in view—the encouragement of window gardening amongst the humble occupiers of dreary homes in the slums of the East End of London. This appealed directly to the sympathies of the kindly disposed who were willing and anxious to aid in the good work. The wonder is that under the circumstances not more than £50 was taken on the occasion.

As evidence of the influence of an appeal for charitable purposes affecting the takings at a flower show, perhaps another example may be worth adducing, and one which comes nearer home to the Royal Horticultural Society. This, moreover, affords, according to Mr. Smee's line of argument, stronger evidence in favour of shows at Chiswick being profitable than does the Finsbury case as presaging an inflow of wealth at Westminster. Since the sickly plant show was held in the east a healthy plant show was provided in the west. The district was then, and is now, much more sparsely populated than the other; indeed, it is considered by some persons to be so "far away" that "nobody will go." The Show now in question was held in the Royal Horticultural Society's Garden at Chiswick. Its cost was far greater than the eastern affair, and at the least ten times more money was provided for prizes, yet after all costs had been met, and all prize money paid, nearer £100 than £50 was handed to one of the London hospitals. Admitting the full influence of charity in both cases, and remembering there was the enormous weight of Royalty to draw money in the east and not in the west, Mr. Smee, with his great reasoning power and terse method of expression, could have no great difficulty in showing by induction that exhibitions at Chiswick would prove a source of revenue to the Royal Horticultural Society.

Considering all the circumstances of the case, and taking into account the teachings of past experience, the acting Committee (of which Mr. Smee is one of the most distinguished members, also a member of the Council, and one of the few gentlemen, therefore, on whom rests a double responsibility), will perhaps see the desirability of endeavouring to secure the patronage of persons of high official or popular rank to the shows that are to be held. If the first could be opened by the Lord Mayor, or by some gentleman of eminence and horticultural sympathies, as Mr. J. Chamberlain, the attention of the inhabitants of the great metropolis would be directed to the Society and its work more effectually than in any other manner, and the public would at once find their way to the hall in which their presence is desired. Much more than the £200, as suggested by Mr. Smee, might then be expected to be taken at the Westminster shows during the year. And, it may be observed, that much more will have to be taken before any material sum in the form of "gate money" is disposable for the maintenance of the Chiswick garden. The cost of shows that will be of sufficient importance to insure a large attendance of visitors can scarcely be expected to fall short of £100 during the season, and as the rent of the hall is £100, Mr. Smee's hoped-for takings are disposed of at once. If, however, an even balance, or nearly so, could be arrived at, and at the same time the shows should materially increase the number of Fellows, the hall would then not be a failure, but, on the contrary, the policy adopted would, as all hope, be a gratifying success.

Turning to Chiswick, Mr. Smee believes it will be advisable to have a few meetings in the summer in the gardens there. Many persons will be delighted to find that is a tenet in the belief of so influential a representative of the government of the Society. Chiswick has been woefully neglected for a long time. It was practically abandoned during the years of the general exhibitions at South Kensington, commencing with the Fisheries, and until now. Is it not a matter of common report that the gardens were not even visited by the President and Council during the whole of that time and longer? But a new spirit has arisen since the garden was seen to be in danger of slipping away; and the country has only to be convinced that the Royal Horticultural Society is determined to pursue its true functions largely through the agency of Chiswick to receive the support of hundreds of persons who have held aloof through want of confidence, or in other words because they felt there was nothing to support. The Society must be something more than the shadow of ornamental personages—it must be the substance of real horticultural work to merit the support of the horticultural community. The portals are opened wider now, and what is more, the Council is taking the public into its confidence by making known the official decisions on questions as they arise. That step can scarcely fail to meet with general approval, and eventually to bring an accession of Fellows as soon as it is perceived that real and earnest action is pursued on lines in accordance with their professional instincts. There is no doubt that a great wave of reaction has set in, the sleeping spirit of horticulture is awakened and only financial power is needed to float the Society to prosperity.

How can this be obtained? By City shows. Let us hope so. But cannot Chiswick itself attract visitors to a show of its own—a fruit blossom show in the spring? It would not cost a penny. Londoners want fresh air and spring beauty; railway companies want passengers; Chiswick wants patronage and the substance which follows. Cheap tickets are issued to “see the Chestnuts” at Hampton Court. Cannot arrangements be made for the issue of cheap tickets including admission to Chiswick during the fruit blossom period? When the stately pyramid Pears are draped in their silvery robe, Apple branches wreathed in rosy tinted blossom, and tender leaves are unfolding on the trees Chiswick is truly beautiful. A stroll round the garden then is highly delightful, and one which Londoners would greatly enjoy, if the attractiveness of the garden were made known to them and easy means of access provided. There is no more charming sight near London than Chiswick in the blossoming time; and it is conceivable that a system of shilling return tickets, giving admission to the gardens, could be arranged within a radius embracing an enormous population, and that railway companies and the Society might mutually benefit by such concerted action. The great obstacle in the way of London shows attracting largely is the difficulty in making their existence known when only of a day or two's duration; but a show extending over three weeks forces itself on notice, as the earlier visitors become advertisers, and each succeeding day brings greater numbers when there is something worth seeing and the weather is inviting. This is seldom bad for a week together, though it may be miserable on one or two days that may happen to have been fixed on for an event. The great International Horticultural Exhibition of 1866 would have been a great financial failure if it had been closed at the appointed time—just when its existence was becoming known—but by extending it over a few more days it proved a brilliant success. Would not a three-weeks fruit blossom show at Chiswick, open from 10 A.M. till sunset, bring many visitors and sensibly and favourably affect the Society's finances? Will Mr. Smee and his excellent coadjutors consider the matter? The idea may be fanciful, but the principle involved seems to at least possess the element of safety, for there appears nothing to lose in the venture, while there is the possibility of gaining a little, and it may be something substantial.—A FELLOW OF THE SOCIETY.

A PROVINCIAL VIEW.

The thanks of horticulturists are due to the *Journal of Horticulture* for discussing, on the basis of existing facts, the re-organisation schemes of the Royal Horticultural Society. Glossing over difficulties can do no good whatever. The retention of Chiswick and its development should have been the first consideration of those appointed to draw up a new scheme. If gardeners are to aid the Society in the future it must take a foremost position in all horticultural matters. At present it has a reputation in the provinces for spending money, and incurring expenditure, not on an actual, but an anticipated income. This is just what is being done under the new scheme. A departure would have been welcomed by provincial gardeners, and would have gained the support of many. I believe I could have induced at the least a dozen, and probably more, to join the Society who now await the issue of events.

There appears to be a prevailing impression that shows are the “backbone” of societies. It has been clearly shown that they have helped to weaken the Royal, and are not a source of remuneration to the majority of existing societies even in the provinces. In how many cases does the gate money cover the expenses of the shows? Very few indeed, and but for income from other sources nine societies out of every ten would have been bankrupt long ago. I hope that shows and showing will not be overdone, for I cannot bring my mind to conceive that the advancement of horticulture depends largely upon such institutions. If half the money now spent in shows was devoted to the training of young gardeners a greater and more lasting benefit would be conferred. If some scheme could be inaugurated by which they could be induced to study and make themselves more proficient, good of a substantial nature would be accomplished. If the Royal had its headquarters at Chiswick and there matured a policy for the future, including a scheme bearing upon the above suggestion, it would have gained the help and sympathy of the majority of young as well as head gardeners. Many, I am convinced, that take a deep interest in gardening would readily have responded to an invitation to help. Even now I believe hundreds will be excluded from contributing to the Society's support by not lowering the fee to 5s. These could have been called members, and the degree of Associate and Fellow conferred afterwards according to the standard of proficiency attained. If such honours could be had by working for them and winning, an enormous stimulus would be imparted to gardeners and deeper and wider interest invested in the Society.

I think the amount made out of Chiswick could be increased. But on this point those in the provinces are in a position to say but little, for they do not know exactly what is sold, or on what terms nurserymen, seedsmen, and others are allowed to send things there for trial. Whatever may have been the plan in the past, I think a fee should be charged all who send produce for trial, which would prevent anything of a “trumpery” nature finding a place there. Those that send should pay a marketable price for the seed, such as Potatoes, saved from

the stock sent for trial. In such a case the entrance fee might be deducted. Some such plan if properly conducted would allow trials to be carried out without entailing expense on the Society. I do not think persons sending new things for trial could reasonably complain of the plan, for they would not have more to pay than would be required for rent of land, labour and manure to grow the seed at home. Even if it did cost them a trifle more, if they succeeded in obtaining the Society's certificate the value of the articles would be enhanced.—ONE IN THE PROVINCES.

CERTIFICATES AND MEDALS.

Many amateurs and nurserymen express dissatisfaction at the manner in which the Floral Committee perform their duties, and I believe that numerous would-be exhibitors are deterred from sending their plants because there is so much uncertainty respecting the recognition they will receive. An amateur friend sent a new plant in flower to one of the meetings, and the Floral Committee passed it without a word of approval. The same plant was forwarded to a nurseryman who exhibited at the next meeting, and at once obtained a first-class certificate for it. So far from the plant having improved in the period between the two meetings it was not so fresh or satisfactory in several respects. This is only an example of many complaints which reflect upon the judgment of the Committee, and their awards are consequently losing the value and weight they ought to possess. The system adopted is also a peculiar one; for instance, a weedy plant common to many gardens was submitted to the Committee last year, three members voted, one against and two for a certificate, which was, therefore, awarded it, although in another case if ten voted for a certificate and eleven against a certificate it would lose it, though there would be five times as many in favour of the plant shown. There seems to be a strange inconsistency in this method, and the least that should be done would be to state how many vote for an award of this character.

The award of medals, though it may not rest entirely with the Floral Committee, is also carried out in an unsatisfactory manner. Presumably, one of the Society's objects is to encourage amateurs to exhibit as much as possible, yet the way they accomplish this was shown at the last Kensington meeting. Mr. Jacomb then contributed a group of *Odontoglossums*, comprising numerous fine varieties, and a vote of thanks was considered an adequate recognition, although medals are awarded with surprising liberality to collections of flowers purchased in Covent Garden Market or imported from the continental growers. The Society must indeed mend its ways before amateurs can be expected to join its ranks or aid in supporting its meetings.—A SURREY AMATEUR.

FLOWERS IN SEASON.

ALMOND blossom, Daffodils, Crocuses, Squills, and *Chionodoxa* in abundance. The silvery Willow “pussies,” “palms,” or catkins are now lovely, glistening like burnished silver, or like loose-strung pearls in the sunshine of March. Snowdrops are nearly over, but *G. plicatus* and late flowering vars. of *G. nivalis*, and the large blossomed *G. Elwesi*, are yet fresh and fair to see. A friend in England who makes quite a specialty of Snowdrops sent me fourteen distinct varieties, and several of these were new seedlings of his own raising. There are Snowdrops and Snowdrops now-a-days. A form of *G. Elwesi*, here has borne four flowers on a scape this year, and was a greatly admired curiosity. Some day we may obtain polyanthus varieties of Snowdrops and of Violets, just as we now have Polyanthus *Narcissi* and *Primroses*. What a lot of trouble they would save in picking and bunching. When I was a boy, set to pick Gooseberries day after day in a big old country garden, I pricked my knuckles so badly, and the smarting was so severe, that I often wished that Gooseberries (*vernacular rustique* “Goosegog”) grew in bunches like Grapes. But Snowdrops and Violets are so lovely as they are, that it will not matter much if the polyanthus varieties do not arrive in our own time.

A large mass of the *Chionodoxa Luciliae* has been much admired. It contains a hundred bulbs, and some *Scilla bifolia* amongst them. This is their fourth year, and their spikes are strong like Hyacinths, with six to fifteen flowers. *C. sardensis* is another perfect gem among the spring bulbs, its clear deep blue flowers with white centre being very admirable. Its stems and leaf bases are almost blood-coloured, and this adds a richness of effect to its blossoms which is lacking somewhat in *C. Luciliae*. I wish someone would tell us the origin of *C. sardensis* (? Sardinian, ? Sardis). My own impression is that it is simply a natural hybrid between *C. Luciliae* × *Scilla bifolia*. What lovely posies one may now have of outdoor flowers alone. A brown jug before me is filled with Willow wands covered with silvery “pussie.” A branch or two of Almond (in bud when gathered, but it has blossomed out most richly indoors), and a few pieces of green Broom, common Daffodils, and a handful of the fresh green shoots of Broom make quite a pretty vase.

All sorts of Daffodils are now coming into bloom rapidly, and the rain of Sunday last will work miracles in the garden. We have not had twenty-four hours' rain for a twelvemonth or more, and shrubs and trees were half starved, and in many cases suffering by the want of water. Now a few sunny days will work magic

amongst the flowers. *Tritoma media* is in full flower, even after 14° of frost laid low its spikes only a week or two ago. It is a most persistent and floriferous plant in mild localities near the sea. It is figured in "Bot. Mag.," t. 744, but it is very often misnamed *T. pumila* in gardens. The true *T. (Kniphofia) pumila* is distinctly different, and a more beautiful species I have never seen. It is figured in "Bot. Mag.," t. 764, and has more globular blossoms of a more vivid orange red colour. Can any wise man tell us where, whence, or from whom *T. pumila* (true), as illustrated in the "Botanical Magazine," can be obtained?

Iris stylosa has given us many flowers all through the winter, and I counted thirty fully open flowers in the sunshine of the other morning. Its soft lavender blooms are fragile and soon spoil in the wind and rain, but if you pick the flower buds as soon as they show colour, and place them in a glass of fresh water in a warm room, they open perfectly. Arranged with a few of their own grassy leaves no Orchid can be finer than the blooms of this gem from Algeria. The Greek form has larger, darker, and more boldly marked flowers, but does not seem so floriferous. The gem of this race is *I. stylosa alba*, with white flowers, but it is as yet as rare as it is beautiful. The little golden *Narcissus Cyclamineus* is quite hardy, and flowers much more strongly out of doors than in pots. *N. Johnstoni*, *N. bicolor lusitanica*, and other of the Portuguese species and varieties so generously introduced by A. W. Tait, Esq., of Oporto, are now lovely in a cold sunny frame. *N. moschatus* from Val d'Arras is lovely in pots, and the smallest and whitest of all the white Daffodils.

Everywhere there are signs and wonders of the annual resurrection in the garden. Swelling buds, upstarting growths, gleam of bud, and glance of glossy leafage, the grass attains a more tender green, and the *Celandine* appears here and there with the awaking Daisies of the lawn. Thrush and blackbird have begun the flutey overture, and all the feathered throng are getting ready for their great prima donna, the nightingale, she who loves the stillness of the early summer's night, and whose limelight is the silver moon.—F. W. BURBIDGE, *Dublin*.

GROWING MELONS IN FRAMES.

It was my intention to pen a few notes on the above subject, but seeing that so experienced a cultivator as Mr. Ward has given us most useful notes on Melons grown on the hotbed and cold-frame system, page 145, I shall confine myself to those grown in bricked frames.

The frames should first be cleared to the depth of 3 feet 6 inches or 4 feet in front and about 5 feet at the back, and the walls well whitewashed with quicklime and a little salt added. Take wires along the top of the frame, the same as in an ordinary Melon house, eyes being driven into the bearings 1 foot apart, and projecting from the wood about 6 inches; copper or galvanised wire may be used, or even strong string will form a good substitute for this purpose. From four to five wires will be found sufficient, the first one being kept near to the front; this will then give ample space for getting inside the frame at the back for syringing and other purposes.

About the end of March or beginning of April the seed should be sown in 60-sized pots, well drained, filling them with a compost of good loamy soil, a little leaf mould and sand added. Press the fingers on the top and fill the hole with sand, then insert two seeds. This is always best, as very often if only one is sown it ends in disappointment. The pots should then be placed in the warmest place possible, either over hot-water pipes, plunged in leaf mould in evaporating pans or boxes, or if this is not convenient they must be plunged in a hotbed. As soon as the seeds have germinated place the pots on a shelf near to the glass to prevent the young plants drawing and becoming weakly, a shelf in a stove or any house where a good heat is obtainable being suitable for this purpose. When the roots have reached the sides of the pots they should be still further encouraged by a shift into 5 or 6-inch pots, the soil for the purpose being made a little richer and heavier by adding a little Mushroom bed refuse and native guano, also using more loam.

A hotbed may now be made in the frame, it being 2 feet wide from the front wall and 18 inches high, composed of short stable manure, such as is used for Mushroom beds, with a few leaves to help to retain the heat for a greater length of time. Throw this material together in a heap for a day or two, turning it once or twice to allow some of the rank steam to escape. The outside should then be built up with whole turves and filled in with the following compost:—Half a load of good turfy loam, one half barrow-load each of leaf mould and Mushroom bed refuse, a little lime rubble, wood ashes, and charcoal. A sprinkling of soot and Clay's fertiliser, bonemeal, or native guano should also be used in it; the latter can be used with safety, and is also very cheap. The soil

should be made firm, and when the plants are well established after the last potting they may be stood on the soil a day or two before planting, which should be done with great care, choosing a warm day, and keep the frame close for a few days. It is always safest to leave a little mound of soil around the stems, which should be kept dry to protect them from canker. They can then be treated as recommended on page 4. By these means fruit may be obtained of as good flavour as when grown in houses. Great care must be given to syringing when grown under these conditions, as except on bright sunny days they will require little more than damping the floors and walls of the pit. An opportunity should be taken on all bright days to well syringe the plants in the morning as soon as the temperature rises, as they are very liable to decay in the growth caused by cold and excessive moisture. If this occurs the decayed parts must at once be well rubbed with a mixture of quicklime and soot until it is dried, or it will rapidly spread and most likely destroy the plants.—W. P. D.

STRELITZIA JUNCEA.

THE flowering of this superb *Strelitzia* is sufficiently rare in this country to demand some notice of the one that was recently in bloom at the Oxford Botanic Garden. Occupying a prominent position on the front stage of the Palm house it was for a time the chief object of admiration in the range, and as there were specimens of *S. humilis* in flower simultaneously it was the more particularly interesting. There are eight species catalogued by Loudon, all of them natives of the Cape of Good Hope, and the one under notice is figured in vol. vi. of the "Botanical Register," p. 516. The Oxford specimen, however, differs considerably with regard to intensity of colour with this, and may possibly have originated from seed, but on this point Mr. Baxter alone can speak with authority, and he unfortunately has ceased to be associated with the garden. Introduced by Sir Joseph Banks, when George III. was king, the most commonly cultivated species was named in compliment to his queen, of the house of Mecklenburg-Strelitz, and plant lovers are familiar with its uniquely formed and gorgeously coloured blossoms. *S. juncea* is still more remarkable and interesting. The foot-stalks being without leaves the plant at all times presents an uncommon appearance, as it grows to a height of about 4 feet, and the almost round, smooth, stout stalks are produced in a fan-like form. The flower-stalks are a little less in length, and are surmounted by sheaths from which emerge its phenomenal flowers. As these expand the bright orange coloured petals acquire a richness that the most brilliantly coloured blooms of *S. reginæ* do not surpass, and the colouring of the uctary, which is much larger than is the case in the other species, is of an intense indigo-shaded purple, and displays the most splendid and striking contrast conceivable.—S. P. E. S.

SPRING TREATMENT OF CALADIUMS.

ALL who have a warm pit or house should grow Caladiums. Their season may be said to extend from April to November. At first the foliage is very tender, but so soon as it is well developed the plants present a charming appearance and are not surpassed by any other fine-foliaged plant. When they die down in autumn the tubers are sometimes taken from the pots and shaken from the soil previous to being stored in sand, but more often they are allowed to remain in the pots, which are generally placed on their side under some stage or in the potting shed. If kept quite dry and in a temperature of not less than 55° or 60°, few tubers will be lost, but should damp reach them or the temperature fall too low some are sure to perish.

In some cases the pots containing the tubers are placed in heat at the time growth is commencing in spring, but I do not approve of this plan. The old soil is never favourable for the roots, and they do not make any satisfactory progress. But if the whole of the tubers are shaken from the old soil before being started into growth weakly and decaying ones can be removed, and only the best selected for potting. Caladiums multiply every year. If one large tuber was placed in a pot there might be half a dozen or more by the autumn, but few would care to continue growing the increased quantity every year. Now is the time to select them, and it is better to grow a few of the best than a large number of all sizes. If from one to four good tubers are placed into a 6-inch or 7-inch pot, and grown in these until the foliage is upwards of 1 foot in height, they may then be shifted into a larger size, and this potting is the only one they will require all the season. If good plants are desired in small pots for vase and other decorations, the tubers may be potted in some good soil the first time, and not disturbed again.

Caladiums root very freely; they delight in good drainage and a

rich firm soil. A mixture of three parts fibrous loam, one of half-decayed manure, and a liberal dash of sand suits them admirably. If plunged in a bottom heat of 70° or 75° they will start more rapidly into growth than without this assistance, but they will also grow well and robustly in a temperature of 65° or 70° without bottom heat. Supply water very sparingly until they have rooted into the new soil, and never allow them to suffer afterwards. Caladiums are the best of all plants to resist the attacks of insects. Indeed, they are hardly ever troubled by any pests, and this is greatly in their favour.—M. M.

ARTIFICIAL MANURES FOR PLANTS.

It is a matter of considerable satisfaction to me to find my remarks on the above subject criticised by Mr. W. Coombe, because I consider it a matter concerning which a great amount of useful information may be elicited by the friendly exchange of opinions that have been arrived at by close and constant observation, and if others may be induced to join in this discussion in the frank and practical manner that my critic has done, another good lesson may be added to those already learnt from the Journal. With the first two and a half lines of the article by Mr. Coombe I thoroughly agree; in fact, I am inclined to think that I believe in the views there expressed to a greater extent than does the writer himself, if I am to judge by his subsequent remarks. He begins by saying—"That artificial manures are of the utmost utility to plant growers there is no disputing, but in regard to their various qualities, composition, and action, there is a wide field for discussion." Now, he overlooked the inconsistency of his subsequent remarks, because a little further on he adds, "I am led to believe that many of the artificial manures are overcharged with ammonia-yielding substances;" then, still farther on, he says, "That if the manure applied in the first instance is a properly proportioned combination of the elements needed for the plant's support, no diminution of the plant's vigour will ensue even after a protracted application." If artificial manures contain, as he asserts, "too great a quantity of ammonia-yielding substances," they cannot, by his own showing, be of the utmost utility, simply because they do not possess a properly proportioned combination of the elements needed for the plant's support.

In another place he does not appear to believe that members of the vegetable kingdom are similar to those of the animal kingdom in the matter of sameness of food causing distaste, while towards the end of his article he says, "I sometimes think there is an analogy between plant and animal life, between the way we should treat a plant and the way we should treat ourselves." Yes, then I say give them a change of food, food that is varied in its chemical constituents according to the nature of the plants that are to receive it, the object for which they are intended, and the condition they are in at the time it is applied. If you want to induce a strong and vigorous growth, give them stimulants in which ammonia-yielding substances preponderate. If they show signs of becoming gross and unfruitful give them manures containing a larger percentage of potash and phosphates, which solidify and build up the woody tissues.

My opinion is that there are various reasons why plants do not thrive so well after one kind of stimulant has been continued for a time as they do when it is first applied. In the first place I do not believe that any one kind of manure, whether artificial or otherwise, contains all the constituents necessary for supplying the right kind of food for plants generally, and although a knowledge of chemistry may enable us to form various manures which are considered likely to supply the most suitable food, yet it is only by practical experience and close observation we can find out whether or not these anticipations are correct, and then how often is it that the results are different from what were expected. Another idea has occurred to me in thinking the matter over, and I wish to be clearly understood that I advance it only as a probable cause. It is this, that as earths, acids, alkalies, salts, &c., are formed by combinations of other substances, such as lime, potash, soda, carbonic acid, ammonia, &c., and these again when brought into contact with other substances in some cases unite and form an altogether different compound, is it then not probable that after several applications of the same food the soil in which the plants are growing must gradually become of a different nature from what it was when the first supply was given? Then is the time to supply something that will hasten the dissolution of the accumulated substances, and convert them into suitable plant food. A good illustration of this may be found in old kitchen gardens that have received heavy dressings of farmyard manure for years, till by their very richness they become distasteful to many crops. Give such land a good dressing of lime, and the results are surprising. But this must be followed up by liberal feeding again, or the rapid decomposition of vegetable matters which the lime has brought about would leave the soil in an exhausted condition.

There are two reasons for mixing Peruvian guano with Clay's fertilizer. Although a very valuable manure when used alone, it clogs the surface of the soil with a pasty sediment, but by mixing it with guano this sediment is very much lessened, and with an occasional rubbing of the surface soil with the hand before watering will keep it in a sweet and healthy condition, and it also has the effect of causing a greater amount of root action. Your correspondent says I am not much inclined to use nitrate of soda for pot plants. Now I consider its use very beneficial in certain cases when used as I described for plants that get into a sickly condition, and those that require something to hasten their

growth. Plants that no other kind of manure seemed to improve can often be brought into a healthy condition by this means, and if Mr. Coombe will try the effect of a few doses on plants of *Erica hyemalis* during the growing season, I think he will be convinced of its utility in their case, as it will cause a quick, vigorous, and healthy growth.—H. DUNKIN.

ONCIDIUM SPLENDIDUM.

UNTIL quite recently this handsome Orchid, which Sir Joseph Hooker described as "without doubt the finest *Oncidium* hitherto discovered," has been very scarce, and consequently valuable. Now, however, after a long search its native home has been re-found, and a large importation is offered for sale at Messrs. Protheroe & Morris's Rooms, Cheapside, on Friday this week. It is closely related to *O. tigrinum*, and several botanists describe it as a variety under that species, but it was allotted specific rank by the botanist, A. Richard, in an MS. description, and adopting this, Reichenbach and others also regard it as a species. The typical *O. tigrinum* was introduced in 1840, but it was fully thirty years after that before *O. splendidum* became generally known. It appears from the account given by M. Louis Van Houtte that it is a native of Guatemala, whence plants were first introduced by M. Herment of Caen. From him some were transferred to MM. Thibaut and Keteleer, thence to MM. Linden and Van Houtte, to Mr. B. S. Williams and others—in fact all the plants hitherto in cultivation are supposed to have been obtained from M. Herment's introductions. Attention was prominently called to the plant in

Fig. 23.—*Oncidium splendidum*.

England in 1870, in which year Lord Londesborough sent a group of Orchids to South Kensington on February the 16th. These Orchids were conveyed from Yorkshire to London under the care of Mr. Denning, and to insure their safety at such an unfavourable time of year a van was specially constructed and heated with hot water. Many beautiful plants were included in this group, but the special attraction was a fine plant of *Oncidium splendidum* bearing a grand panicle of twenty large flowers, and the first-class certificate awarded for it was never better merited.

A demand arose for this *Oncidium*, and many efforts were made to import it, but without success, *O. microchilum*, which closely resembles it in habit, frequently being mistaken for it when not in flower. After a long search, however, Messrs. Sander & Co. have succeeded in finding what is undoubtedly the true plant. *O. splendidum* differs from *O. tigrinum* in having larger flowers, broader sepals and petals, and a bolder lip, with a shorter neck. It is also much richer and brighter in colour, the sepals and petals undulated, yellow barred with rich reddish brown; the lip is bright yellow, of a very clear tint.

O. splendidum is not one of the easiest Orchids to grow, but several orchidists have proved that it can be had in very satisfactory condition. It requires the temperature of a *Cattleya* house, and should be placed on the sunny side, as the growths must be well ripened.

A single flower is represented natural size in fig. 28.

SELECT ORCHIDS FOR AMATEURS.

(Continued from page 218.)

CYMBIDIUM.—Evergreen strong-growing plants with long narrow dark green leaves and pseudo-bulbs. Flowers large, white, and handsome in few-flowered erect scapes (eburneum), or various tints of yellowish brown and red in long curving or drooping racemes (*Lowianum*). India, China, or Australia. Intermediate house. Pots, peat and loam. Chiefly winter or spring flowering.—*cburneum*, *Lowianum*, *Masteri*.

CYPRIPEDIUM.—All these popular Orchids are distinguished by their flowers possessing prominent slipper-like lips and a bold upper (dorsal) sepal. They can be classed in two groups. 1, Evergreen, epiphytal plants with dwarf stems without pseudo-bulbs. Leaves narrow, green, or beautifully marbled. Flowers usually singly or few-flowered scapes, white, yellowish, rose, crimson, variously streaked or spotted with green, crimson, maroon, brown, or purple. Native of the tropics in Asia and America, the group of species referred by some to the genus *Selenipedium* being confined to America. Warm house. Pots, peat and sphagnum. Flowering at all seasons, some like *C. insigne* being very useful for winter. 2, Deciduous terrestrial plants with tuberous roots, hardy or half-hardy, natives of temperate regions in America, Asia, and Europe. Pots, loam and leaf soil. Cool house, or damp position at the base of rockeries out of doors. Tropical epiphytes (warm house).—*Argus*, *barbatum*, *Bozalli*, *concolor*, *Dauthieri*, *Harrisianum*, *hirsutissimum*, *insigne*, *insigne* *Maulei*, *laevigatum* (Philippinense), *Lawrencianum*, *Lecanum*, *Lowi*, *niveum*, *Spicerianum*, *Stonei*, *villosum*. *Selenipedium* group.—*caricinum* (Pearcei), *caudatum*, *Roczli*, *Schlimi*, *Sedeni*, and several beautiful hybrids of great value, such as *calurum*, *cardinale*, *grande*, and *Schroederæ*. Temperate terrestrial species (cool house or frame), *guttatum*, *Trapeanum*, *japonicum*, *macranthum*, *spectabile*. Rockery, *Calceolus*, *pubescens*, and *spectabile*.

DENDROBIUM.—Numerous beautiful plants are included in this genus, having either long cylindrical stem-like pseudo-bulbs, with short leaves and racemes of flowers from the nodes or apex, or spindle-shaped pseudo-bulbs with larger leaves and long racemes from the apex. Flowers showy, often fragrant, yellow of various shades, white, tipped or blotched with crimson and maroon or rosy crimson, the lip frequently differently coloured from the sepal's and petals. Chiefly natives of India, with a few in Australia and Japan. Pots, shallow pans, or baskets, according to the strength of the plants; peat for the former and peat with sphagnum for the latter. Nearly all require a warm house in which to make their growth after their flowers have faded, and a period of rest in a cooler house. A few can be constantly grown in a cool house, the Australian species, *bigibbum* and *superbiens*, succeeding in an ordinary plant stove near the glass and exposed to the sun. Winter and spring flowering:—*Ainsworthi*, *chrysozum*, *heterocarpum* (aureum), *luteolum*, *nobile*, *Wardianum*. Spring and summer flowering:—*aggregatum*, *Bensoniæ*, *bigibbum*, *Brymerianum*, *chrysanthum*, *crassinode*, *Deari* (white), *densiflorum*, *Devonianum*, *Falconeri*, *fimbriatum oculatum*, *formosum giganteum*, *infundifulum* (cool), *Jamesianum* (cool), *lituiflorum*, *Picardi majus*, *primulinum giganteum*, *thyrsiflorum*, *tortile*.

DENDROCHILUM (*Platyclinis*).—Evergreen plants of elegant dwarf habit, with narrow grass-like leaves and small ovoid pseudo-bulbs. Flowers very small, of a yellowish tint, in long drooping racemes, and delightfully fragrant. Philippine Islands. Pots; peat and sphagnum. Intermediate house.—*filiforme* (flowers June to August); *glumaceum* (flowers February to April).

DISA.—Terrestrial Orchids, with slender leafy stems bearing several large handsome scarlet flowers at the apex. South Africa. Pots; peat and sphagnum; abundance of water during growth and shade. Cool house. Summer.—*grandiflora*.

EPIDENDRUM.—Four hundred very diverse species are included in this genus, but many are of little horticultural value. Pseudo-bulbs ovoid or spindle-shaped, or tall leafy stems terminating in racemes or panicles of durable flowers. The following are useful.—*bicornutum* (*Diacrium*); flowers white, dotted purple. April and May. Trinidad. Pots; peat. Warm house. *nemorale majus*; flowers pale rose with darker markings; handsome. Mexico. Pots. Intermediate house. *paniculatum*; flowers delicate mauve pink, fragrant. April. Peru. Pots. Cool house. *vitellinum majus*; flowers orange scarlet; very strong and useful. Pots. Summer and autumn.

GALEANDRA.—Deciduous; stems tall, slender, cylindrical and

leafy, the young growths terminating in racemes of flowers with large funnel-shaped lips. Tropical America. Pots. Warm house.—*Devoniana*; sepals and petals dark purple, lip white streaked purple.

GOODYERA.—Plants with pretty foliage, similar in habit to, but less delicate than the *Anæctochilus*. Found in Europe, Asia, and America. Warm or cool house. Pots; peat and sand.—*discolor* (*Hæmaria*); *macrantha* (cool); *pubescens* (cool).

GRAMMATOPHYLLUM.—Epiphytal Orchids of strong habit. Pots. Warm house.—*Ellisi*. Long quadrangular pseudo-bulbs; broad leaves; flowers in racemes from base, yellow streaked red. July and August. Madagascar.

HOULLETIA.—Epiphytal plants, with ovoid, ribbed, and furrowed pseudo-bulbs; broad leaves, and erect racemes from the base of curiously coloured flowers. Brazil, New Grenada, and Colombia. Pots. Cool house. *odoratissima*; flowers of a strange purplish tint with a fragrance resembling Violets.

IONOPSIS.—An epiphyte of delicate habit, small stem, with narrow leaves, and panicles of pale mauve flowers at different times of the year. A charming little plant. Tropical America. Block; sphagnum. Cool house.—*paniculata*.

(To be continued.)

ORCHIDS AT STREATHAM.

THE collection of Orchids possessed by R. H. Measures, Esq., The Woodlands, Streatham, has become widely celebrated for the rare and valuable plants it contains, as well as for the cultural skill displayed in their management. Combining an enthusiastic admiration of his favourites with an accurate knowledge of their characters and requirements, Mr. Measures has not been contented with merely acquiring so many hundreds or thousands of plants, but he has been careful to secure the most beautiful species, varieties, or hybrids in the principal genera, and to grow these in the best possible way. Selection, in fact, has been the rule rather than collection, and the result is that in the value and health of the plants this interesting suburban garden rivals some of the best establishments in England.

THE HOUSES.

The garden is of moderate size, but the most is made of the space at command, the portion near the house being chiefly occupied with the lawn, and the lower division, which is well open to the south and nearly quadrangular in form, is devoted to vegetables and fruit. On three sides—namely, on the north, east, and south, this space is bounded by the ranges of glass houses, the majority being span-roofed and running east and west. There are about forty houses altogether, but thirty fine structures are filled with Orchids, and much consideration has been given to these houses with a view to adapting them to the requirements of their occupants. In the first place they are very substantially built, yet light and spacious, the sides being in most cases glazed down to the shelves. In the wider houses there is either a central stage or a space with ornamental supports for large specimens like the *Cymbidiums*, which are represented by some wonderfully fine plants. There are also side shelves in all cases, and frequently bordered with *Pilea muscosa*, which thrives everywhere like a weed and has a very pleasing appearance. Upon the shelves a finely sifted shingle is used throughout in preference to any other material, though several kinds have been tried. This is found to retain sufficient moisture, it is much cleaner than most materials, affords little refuge for insect pests, and has a brighter appearance than anything else. Most of the side stages are double—that is, shingle is placed upon cement slabs supported by cross bars of T. iron, and the plants are arranged on open trellises a few inches above this. Ventilation is an important matter, and this is provided by means of a lantern-like ridge in several of the newer structures, so arranged the current of air admitted can be regulated to a nicety and is first directed upwards; beneath the stages there is also liberal provision in this respect, apertures in the walls being covered with perforated zinc, and closed by small shutters or glazed frames hinged on to iron rods in the centre, so that they can be readily opened or closed. Near the doors upon the side they open, the plants are protected from draughts by small glass partitions secured to the shelves and end of the house, a simple method of preventing much injury to delicate plants in severe weather. The supply of water has received careful attention, as the value of rain water is fully recognised; between eighty and ninety zinc tanks have consequently been provided to catch the rainfall on all the glass, and sufficient is stored in this way to provide for at least three rainless months. More attention to this matter would be advantageous in many establishments. The heating throughout is conducted in the same business-like manner, liberal supplies of piping being allowed in preference to smaller quantities to be highly heated, and they are coloured with a reddish composition of a special character, which is said to be preferable to anything else for the same purpose.

The occupants of the houses are very diversified, and comprise representatives of most of the best Orchids in cultivation, but specialties have been made of some genera or even species, and to them alone can these few notes be devoted, but at another time further details will be given respecting the general collection.

ODONTOGLOSSUM CITROSMUM.

Few Orchids are more generally admired than this, and in few establishments is it so well grown as at The Woodlands. About 150 plants are there included, and are grown in baskets arranged upon the side stages in a light house where an intermediate temperature is maintained. One of the special features in their culture is the long season of rest, for during the late autumn and winter they receive no water, in fact they generally have three months' dry treatment. As soon as the spikes are showing, as some are doing now, the supply of water is recommenced, and gradually increased as needed. That this treatment is appreciated is proved by the firm substantial pseudo-bulbs (many 4 inches deep by 3 inches wide), and the abundant flowers produced. The plants are brought on in three successive batches, but as many as 100 racemes have been expanded at one time for a period of two or three months, some of the racemes reaching 3½ feet in length, and carrying twenty to thirty-five flowers each. When suspended from the roof it can be imagined what an effect is produced by these beautiful delicately coloured and fragrant drooping flowers.

COOL HOUSE ORCHIDS.

Several houses are devoted to Odontoglossums, Masdevallias, and other plants requiring cool treatment. A most valuable collection of *O. crispum* varieties has been formed, comprising both spotted and pure white forms, the flowers of fine shape and excellent substance. *O. Pescatorei*, *O. Andersonianum*, *O. polyxanthum*, and scores of others also included. The Masdevallias are rich in choice varieties of the *Lindeni*, *Harryanum*, and *Veitchi* types, while the extraordinary *M. chimæra* seems very happy, having been in flower for a great time, and had thirty or forty of its strange flowers.

CYMBIDIUMS.

Rarely are houses in private establishments devoted to Cymbidiums, but it is also seldom that so many large specimens are seen in one place as in that under notice. *Cymbidium*, the majestic *Lowianum*, the handsome *C. eburneum*, the pretty *C. elegans*, and the strong *C. giganteum* are all represented by good plants, but there are five huge examples of the first-named in vases or on pedestals. The plants are 10 feet across from tip to tip of opposite leaves, in most vigorous condition, and they flower most profusely. One is now showing thirteen racemes, and they frequently have twenty flowers each. These plants are ornamental and graceful foliage plants, even when not in flower, but they need a spacious house to show themselves to advantage.

CYPRIPEDIUMS.

The Cyripediums hold a prominent place in Mr. Measures' favour, and his endeavour to form a collection of the finest species and all the most valuable hybrids has been singularly successful. Many of these are literally worth their weight in gold, and in the case of small pieces of very scarce forms the pots and peat might almost be included in the balance. But the mere fact of being rare is not sufficient. The plant must possess some distinct character or beauty of its own before it can be admitted to the company of the Cyripedium aristocracy. So we find that nearly every plant possesses some special charm, history or interest, and a long essay might be written upon them alone. The following list of those in flower at the present time will show what a hopeless task it is to attempt their description in one issue of the Journal.

Cyripediums in Flower February and March.—*Porphyreum*, *Spicerianum*, *vernixium*, *Measuresianum*, *Dayanum*, *Rowallianum*, *Williamsi*, *nitens*, *Dauthieri*, *callosum*, *callosum superbum*, *Argus*, *Petri*, *barbatum biflorum*, *barbatum Warneri*, *candidulum*, *concolor*, *calophyllum*, *Bullerianum*, *concinnum*, *cardinale*, *pluneurum*, *venustum*, *villosum*, *villosum aureum*, *marmorophyllum*, *chloroneurum*, *leucorrhodium*, *œnanthum superbum*, *euryandrum*, *Harrisianum elegans*, *Boxalli*, *Sallieri*, *Hartwegi*, and *elegans*.

Some of these are large plants and all are in wonderful health, the foliage of the marbled section being extremely beautiful. Particularly noticeable is this in the case of *C. coneolor* and its handsome variety *tonkinensis*, which have the surface of the leaves covered with a transparent crystalline epidermis, through which the exquisitely delicate markings have a charming appearance. These and many others of the Cyripediums are worth growing for their foliage alone. Besides those named as in flower there are numberless choice plants, amongst which is an admirable specimen of *C. Morganæ*, with most of the Veitchian hybrids as well as those from other raisers.

DENDROBIUM NOBILE OR HEATHFIELDIANUM.

Amongst several handsome varieties of *D. nobile* now flowering at Streatham one of the most remarkable is that named above, of which Mr. Measures has a strong plant with richly coloured flowers. The peculiar character of the variety (fig. 29) is in the petals being coloured precisely the same as the lip—namely, a rich velvety purple, the tint extending more than half the length. When the lip is bent back the flower appears to be in six divisions, the three outer (sepals) narrow and the three inner broader, and coloured (petals and lip) like regular flowers of the Lily and allied families. Last August, when visiting Newcastle-on-Tyne, I called at Heathfield House, Gateshead, the residence of Theodore Lange, Esq., and the gardener, Mr. Methven, gave the following information respecting the origin of the plant:—"It is said to have been raised at Heathfield from seed obtained by crossing *D. nobile*

with *D. Falconeri*, and the first plant flowered about 1881. In 1883 some plants were exchanged with Mr. Cookson of Wylam-on-Tyne, amongst them being one of the hybrid." This flowered at Oakwood in 1885, and was shown at South Kensington on March 10th of that year under the name of *D. nobilissimum*. Flowers were sent to Prof. Reichenbach, but through some misunderstanding he named it *D. nobile Cooksonianum*, but he has since substituted the title *Heathfieldianum* as being more appropriate. Last month both Sir Trevor Lawrence and Mr. H. M. Pollett exhibited plants at South Kensington for which certificates were awarded, and at the last meeting (March 13th) a very strong plant was shown by Mr. Perkins from the Greenland Gardens, Henley-on-Thames, when a cultural commendation was awarded for it. Another peculiar variety of somewhat similar style—*i.e.*, *D. nobile Tollianum*, has

Fig. 29.—*Dendrobium nobile Cooksonianum* or *Heathfieldianum*.

the colouring more confined to the margins of the petals. A variety of *D. nobile*, also in flower at The Woodlands, is named *Herbertianum*, and in the richness of its colour it is almost equal to the

LÆLIA ELEGANS.

A grand collection of *Lælias* and *Cattleyas* has been formed, and some four or five large houses are almost exclusively devoted to them. *Lælia elegans* is another Streatham specialty. Some fifty or sixty plants of the best varieties yet introduced are grown, including such named forms as *Cynanthus*, *myletha prasiata*, and *Measuresiana*. Some recently imported plants of *L. elegans* have flowered this season, and amongst them are several very beautiful forms. One of these was found by a collector in his wanderings, and was so much finer than any hitherto seen that he named it "King of the Woods." Shortly after, another still superior form was discovered, which was named "King of all the Woods;" and a third, "King of all the Kings." If my memory serves me rightly it is one of these that has received the name *Tautziana*—at least, I had the good fortune to see a flower of this, which, both in size and colour, surpassed any I have seen before. From tip to tip of the petals it measured 6¾ inches, the petals being dark rose in colour, and 1¼ inch in diameter, the sepals of a rosy bronze hue. The lip was very handsome, 2½ inches across, dark crimson and rich magenta. There is something peculiarly noble about *Lælia elegans* and its varieties, and it is not at all surprising that Mr. Measures is so proud of them.

CÆLOGYNE CRISTATA ALBA.

Cælogyne cristata, with its varieties *maxima*, *Lemoniana*, and the *Chatsworth* form, fill one house, and between 500 and 600 racemes have been expanded during the past and present months. Conspicuous amongst these, however, is a large specimen of the scarce and valuable *C. cristata alba*, which is probably the finest specimen in the kingdom. It has forty-seven growths, and has had thirty-two racemes of three to six pure white flowers each, which were only allowed to fully expand when they were cut off, as the strain was a heavy one upon the plant's resources. Some idea of the progress the plant has made can be gathered from the fact that two years ago it had only fourteen growths.

Much more remains to be said respecting the Woodlands Orchids; but it must be added that their condition throughout the whole collection proves the gardener, Mr. R. C. Fraser, to be not only a skilful cultivator, but one who takes a deep personal interest in the plants under his charge.—L. CASTLE.

LACHENALIAS.

I WAS very glad to see a few lines in favour of the more extended cultivation of the above in your issue of the 8th instant, and can fully endorse all your correspondent, "T. H.," says in their favour. I would,

however, strongly emphasise the value of *L. Nelsoni* above all others I know. Its fine robust habit, deep green leaves, and free-flowering qualities, added to its easy culture and freedom from insects, make it most invaluable. The strongest bulbs throw several spikes of bloom simultaneously. I have had as many as nine from one very strong bulb; each spike bears from nine to twenty-four bells. I have flowered *L. aurea* and *L. quadricolor*, and although very pretty in their way they seem to require more nursing with much less returns than *L. Nelsoni*.

I have grown for several years the following varieties:—*L. stolonifera*, *L. pustulata*, and *L. rubida*, but had not been able to flower them. I find the last named to be quite hardy. Having turned out a pot of bulbs last summer on a north border I see they have already pushed up about 2 inches, and that in spite of snow and frost. I have had *pendula* stand for one or two years under a south wall, and although it will live it will not thrive. I should think your correspondent, "T. H.," or any one who may have successfully flowered the varieties I have failed with, if they would kindly detail their method of culture in these columns I feel sure it would be of great interest to many besides—
T. WINKWORTH.

EVENTS OF THE WEEK.—Although the weather is not very suggestive of spring, the shows have commenced, and during the week from the 22nd to the 28th inst. four will be held. There is one at Shrewsbury to-day (Thursday), at the Crystal Palace on Saturday, and at Glasgow on Wednesday. The Royal Horticultural Society will hold their first meeting at the Drill Hall, James Street, Victoria Street, on Tuesday, the 27th inst., which, it may be added, is readily reached from Victoria or St. James' Park Stations on the District Railway, or by 'bus from the city. The Society's supporters should make a special effort to render the meeting an attractive one.

— THE WEATHER IN LONDON.—The day of our previous issue—Thursday the 15th inst.—was mild and spring-like; but since then a biting north-easterly wind has prevailed, with drizzling snow on most days, but not sufficient to cover the ground until Monday night, and there was a depth of about 3 inches on Tuesday morning.

— THE WEATHER IN THE NORTH.—"B. D." writes:—"The country from Aberdeen southwards was in the middle of last week visited by a snowstorm of great severity. Nowhere was the general depth very great, from 6 inches to a foot, but the drifting was unusually heavy. Everywhere country roads were, and in many places still are, blocked up, schools closed, and communication generally suspended. 6° frost occurred last night (18th), 12° and 17° on the two preceding. The present storm, except that the frost is not so intense, bears in its character and progress so far a great likeness to that which we had four days earlier last year."

— THE usual monthly dinner of the HORTICULTURAL CLUB took place on Tuesday the 13th inst. There was a large attendance of members, Mr. John Lee in the chair. Amongst those present were Dr. Hogg, the Rev. F. H. Gall, Messrs. Llewelyn, Crowley, Harry J. Veitch, Ball, H. J. Pearson, A. H. Pearson, J. L. Cousens, Geo. Paul, &c. The discussion was opened by Mr. T. D. T. Llewelyn, who gave an interesting account of Sikkim Rhododendrons in South Wales, and detailed many of the experiments which he is carrying out. As this was given from notes we are sorry to be unable to reproduce his most interesting remarks. A discussion took place afterwards, which was joined in by Dr. Hogg, Messrs. Paul, Veitch, Ball, and others.

— WE have received the report and balance-sheet of the UNITED HORTICULTURAL AND BENEFIT SOCIETY, and gladly record the expression of our belief that this excellent institution is in a safe, sound, and flourishing state. Members and funds are increasing, and the amount now invested in consols is £4000. Mr. W. Collins, 5, Martinhoe Terrace, Martindale Road, Balham, London, S.W., is the Secretary of the Society.

— A SUB-COMMITTEE of the GARDENERS' ORPHAN FUND, consisting of Messrs. Deal (chairman), Barron, Dean, Herbst, Richards, Roupell, Wright, and Wynne, was held on Friday night last for making arrangements for the first election of candidates and anniversary dinner

on July 13th, and their recommendations will be considered by the General Committee on Friday night, the 23rd inst. Applications of candidates for the benefit of the Fund should reach the Secretary on or before April 23rd.

— "E. J." sends us a few flowers of *NARCISSUS PALLIDUS PRÆCOX* to show the variation in size and colour. Some are as small as the minor variety of *N. pseudo-Narcissus*, while others approach the major forms in size. The colour ranges from nearly white to a clear yellow, the crown being much darker than the perianth in some cases. All are pretty, delicate, and valuable so early in the season.

— ON March 13th Mr. T. F. Rivers delivered a lecture on the ORCHARD HOUSE to the Birmingham and Midland Counties Gardeners' Mutual Improvement Association. A large audience was assembled, and the lecturer was warmly thanked at the close of his address. We shall publish the lecture referred to in an early issue.

— WE learn that Messrs. W. Paul & Son have a fine display of CAMELLIAS IN FLOWER AT WALTHAM CROSS this season, and they will be at their best in a few days.

— SPECIAL displays of HYACINTHS, TULIPS, AND FLORAL PLANTS are also provided by Messrs. J. Veitch & Sons, Chelsea, Cutbush and Son, Highgate, and by Mr. B. S. Williams at Upper Holloway.

— PRESENTATION TO MR. JOHN LAZENBY.—A correspondent sends the following paragraph—"At a meeting of the Ancient Society of York Florists, held at the "Golden Lion Hotel," Church Street, last week, Mr. John Lazenby, the Secretary, was the recipient of a very pleasing token of esteem and good will. Mr. G. Cowper, who presided, made the presentation in felicitous terms. He reviewed the long history of the Society, and alluded to the great services which Mr. Lazenby had rendered when its usefulness was very great. Mr. J. Robinson, Mr. G. Manton, Mr. J. Hume, Mr. Kirk, Mr. J. E. Wilkinson, and others added complimentary expressions to those uttered by the Chairman, after which the testimonial, consisting of a purse of gold, was handed to Mr. Lazenby, who suitably acknowledged this kindly recognition of his services. A vote of thanks to Mr. Rodwell and Mr. Burton, the Hon. Secretaries, and the presentation Committee, terminated a very gratifying incident."

— ACCOMPANYING the schedule of the NATIONAL AURICULA AND PRIMULA AND NATIONAL CARNATION AND PICOTEE SOCIETIES (SOUTHERN SECTIONS), we have received from Mr. J. Douglas the note appended:—"It has again been decided to hold the exhibitions in connection with the Royal Horticultural Society; owing, however, to the transition state of that Society, the Council are unable to vote the usual grant of £15 to each Society as heretofore. Under these altered conditions, the Committee trust that members and friends will try to make good this amount. By the kindness of a few friends an extra sum was collected last year as a Jubilee gift. It was under consideration to expend this sum in preparing cards for certificates on a new and original design, a sketch for which has been prepared by Mr. Alfred Slocombe; under the altered financial conditions, however, it has been decided to postpone the preparation of certificate cards. The Committee suggest that if each member of either Society would obtain another by personal solicitation, a great success for the ensuing year would be assured." The National Auricula Show will be held in the Drill Hall, James Street, Victoria Street, on April 24th; and the National Carnation Show on July 24th, in the same place.

— MR. C. PAGE, The Gardens, Fern Lodge, Bracknell, Berks, writes respecting GERMAN IRISES FOR FORCING, as follows:—"I doubt if many readers of the Journal are aware that these force readily. When calling on Mr. Lane, gardener to Miss J. D. Smith, King's Ride, Aseot, a short time ago, I was very much surprised to see several fine clumps in flower; also small pieces in 48 and 32-size pots, carrying four and five flowers. Mr. Lane informed me that they were lifted from the open ground about a month previous, potted at once, and stood in an early vinery. I do not think there are many flowers to equal them for specimen glasses, as their quaint shape and beautiful colours are then shown to advantage. I wonder they have not found favour with market growers."

— THE second exhibition of the BOLTON CHRYSANTHEMUM SOCIETY will be held in the Albert Hall, Bolton, on November 23rd and 24th this year. The result of the first show last year is a balance of

over £15 in favour of the Society, and this has induced them to increase the prizes and extend the classes. The Hon. Secretaries are Messrs. J. Sefton and J. Hicks.

— **CEMENT FOR GARDEN VASE.**—A correspondent thinks the following extracts from a London evening paper (the *Echo*) may be serviceable to "A. P.":—1, Isinglass 1 oz., distilled water 6 ozs.; boil to 3 ozs. and add 1½ oz. of rectified spirit; boil for a minute or two, strain, and add, while hot, first half an ounce of a milky emulsion of ammoniac, and then 5 drachms of tincture of mastic. This is a splendid cement. 2, Dissolve quarter ounce of best isinglass in 1 oz. of glacial acetic acid. Apply to the edges, letting each set for a few days before uniting the whole.

— **GARDENING APPOINTMENT.**—Mr. H. Rogers, gardener to Sidney Lawrence, Esq., Clapham Park, has been appointed to succeed Mr. Mill as gardener to Lord Rendlesham, Rendlesham Hall, Woodbridge, Suffolk.

— **THE MAIDENHEAD HORTICULTURAL SOCIETY** will hold their tenth annual Show in the grounds of Braywick Lodge on Thursday, August 15th, this year. The Hon. Secretary is Mr. O. King, Ray Park Cottage, Maidenhead.

— **MR. W. MOWBRAY**, gardener to the Earl of Leven and Melville, in sending us from Fulmer Gardens a number of *CINERARIA* blooms, writes:—"The plants are in 32-size pots, some of the heads of flowers being 20 inches across. They have been grown in a pit, not a house, and I hope the flowers will arrive in good order." The blooms are among the finest that have been sent to us, some of them exceeding 3 inches in diameter, with the florets overlapping to the extremities. The colours are also varied and good. Mr. Mowbray is to be complimented both on his culture of the plants and method of packing the flowers. A box, 2½ inches deep, was nearly filled with close wet moss and the blooms affixed in it. They arrived as fresh as when cut. When *Cineraria* flowers are placed in a box without any packing material, or are surrounded with dry cotton wool, they almost invariably arrive in a crushed and withered state. Mr. Mowbray is not a vendor of seed. Mr. J. A. Brown has also sent us some good blooms, but not equal to those above mentioned.

— **THE** schedule of the **KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY** for the present year gives the date of the twelfth Show as already announced (Nov. 6th and 7th). A fifth champion challenge vase, value 25 guineas, is offered under the same conditions as the previous ones, and the usual classes with liberal prizes are also provided. The balance-sheet for the past year shows a decrease in the receipts, owing chiefly to the unfavourable weather, but the expenses are moderate, though one item is rather alarming—namely, "Judges' fees, dinners, and refreshments, £15 11s. 11d.," which would appear as if the five Judges had very remarkable appetites or were regaled in a sumptuous manner. Probably, however, they receive some assistance in the latter portion of their duties. The Hon. Secretary is Mr. G. Woodgate, Warren House Gardens, Kingston Hill.

— **THE ANCIENT SOCIETY OF YORK FLORISTS** will hold their annual Exhibition of Chrysanthemums in the Fine Art Exhibition Building, York, on November 14th, 15th, and 16th of this year, and a comprehensive schedule has been drawn up, comprising two silver cups amongst the first prizes. Mr. John Lazenby, 8, Spurriergate, York, is the Secretary. It is surprising that the Committee should have so fixed their dates as to include the opening day (Nov. 16th) of the National Society's provincial Show at Sheffield, especially as the dates of the latter have been announced for a considerable time. Very little care seems to be exercised in some cases to avoid the clashing of shows, which is unfavourable to the success of all Societies within a short distance of each other.

FRUIT AT THE NEWCASTLE SHOW.

WHEN reading Mr. Goodacre's last contribution on the above subject, together with that from "One of the Judges," I was driven to the conclusion that someone must have played a practical joke upon Mr. Goodacre. I am surprised at his credulity in matters of this kind. All through this discussion he has taken care to exclude the fact that he was an absentee from the show, and was relying entirely upon information supplied to him by an irresponsible party. Twice I have pointedly challenged the truthfulness of his assertions. Instead of meeting my challenge in a fair and straightforward manner he persists in plunging deeper into the mire, and declared the first prize collection contained

"one dish or peck of Tomatoes [a statement corrected last week], one of unripe Citrons, six dishes of unripe Pears, seven dishes of unripe Apples (mostly culinary varieties), two dishes of unripe Plums." I unreservedly say there is no truth in these allegations. The same remark is applicable to his comments upon the Citrons, Apples, and Pears in the second prize collection. But perhaps Mr. Goodacre is not aware of the fact that some so-called "culinary varieties," such as Cellini, Lord Suffield, Maiden's Blush, and Peasegood's Nonesuch when grown under glass are indeed excellent dessert Apples. I believe that all those exhibited from Lambton Castle and Hutton Hall were orchard-house-grown fruit.

I am asked if I "can get a couple of conscientious, disinterested, practical gardeners to say in plain English that the awards were justly made and in accordance with the stipulated conditions of the schedule." I have no difficulty in so doing, and therefore name Mr. Lewis Castle and Mr. Edwin Molyneux; these gentlemen will in every way fulfil the desired conditions, and their opinion will command the confidence and respect of almost every reader of the *Journal of Horticulture*. They were both at the exhibition, and to my knowledge spent considerable time in thoroughly examining these Jubilee collections. Mr. Goodacre can appeal to them if he likes.

As Mr. Goodacre has not correctly quoted the stipulated conditions for the Jubilee prize, I herewith enclose the printed form as issued by the Society. If Mr. Goodacre is really in ignorance as to the names of the gentlemen who officiated as Judges he can easily obtain this information from the Secretary at Newcastle. Assuming that Messrs. Castle and Molyneux will act as referees, I would in addition to Mr. Goodacre's questions beg to submit the following:—

1st, Did Mr. Goodacre, as he alleges, exhibit in his collection eight distinct varieties of ripe Pears (see page 132)?

2nd, Did he exhibit a dish of ripe Doyenné d'Hiver!

3rd, Was one-half of his Gooseberries and Currants in a fit state to put on an exhibition table?—AN OLD HAND.

UNDER this heading a discussion has been going on for some time in the pages of the *Journal*. The collection of fruit from this garden has had a large share of attention and some condemnation from Mr. Goodacre. As a rule I do not take part in such discussions, especially where the attack is made by an interested and disappointed exhibitor. In all my exhibition career I have endeavoured to stage produce that could speak for itself and stand criticism, and when defeated, as I have been, and expect to be again, I have bowed to the decision of the judges without protest. I would have refrained from saying anything in this case, especially when having to speak as to the merits of one's own productions, which is better done by impartial persons, had it not been for the turn the discussion has taken and the remarks Mr. Goodacre has made, which exceed the bounds of fair criticism. As far as these remarks refer to the premier collection of fruit they are, to speak plainly, inaccurate and misleading, and though some of them have been refuted by "Old Hand," yet they are still reiterated by your correspondent. I feel I shall be doing a service to your readers in giving not only a flat and final denial to these assertions, but in placing some facts and particulars before them regarding the fruit in question.

Here is the sweeping assertion Mr. Goodacre makes, "Yet we find the first prize awarded to a collection not only deficient in the stipulated dishes, but containing at least one-third of unripe coarse fruits and some dishes that never would be fit for the table, as the following particulars will show—first, one dish or peck of Tomatoes." I had not one in my collection, and never showed such as a dish of fruit in my exhibition career. "Second, one of unripe Citrons." These were gathered, or rather allowed to fall into a net about three months before the Show, and were kept under bell-glasses in a cool fruit room, as my only fear was whether I could keep them, but they turned out a beautiful golden colour, of great size. Lemons were gathered in a similar fashion, and turned out perfectly ripe. The Pears were Beurré Diel, Durondeau, Beurré Giffard, Williams' Bon Chrétien, Brockworth Park, Pitmaston Duchess, Souvenir du Congrès, and Marie Louise. The first was grown in a Peach house started in January, and the six fruits weighed 117 ozs. The Apples were White Calville, Cellini, Worcester Pearmain, Lord Suffield, Jefferson, Ringer, Ribston Pippin, and Blenheim Pippin, "Plums," to use the words of your able reporter in the *Journal*, "were fine." Mr. Castle can also vouch for seeing the Citrons in our fruit room. Mr. Goodacre, in a former communication, mentioned my showing Warner's King, which is untrue. My collection was not deficient in a single dish, as mentioned in the schedule; nor short or above the quantity where stipulated, and every dish was ripe and fit for the table. These are facts your readers can place against the assertions of our critic, who has the audacity to pass judgment upon a collection of fruit which he never saw.

My greatest difficulty was not in getting the fruit ripe but in keeping it, and for thirty days we had both Pears, Apples, Plums, &c., placed away in an underground ice-house, and I lost some dishes of early Pears. All the Pears, Apples, and Plums shown by me were grown under glass, the trees were brought into heat at various times from the month of January, and grown in temperatures varying from that of a cold pit to a Pine stove to suit the late and early varieties. I have under glass eighty-five varieties of Apples and sixty-seven of Pears in pots, besides an orchard house 324 feet long full of the finest varieties planted out and grown as cordons. Outdoor fruit cannot compete with the produce of such trees, especially at the end of August, when the Show was held. I could have placed twenty dishes each of Pears and

Apples ripe on the table at the time without a speck or spot. If Mr. Goodacre intended frightening us northerners he ought to have brought something different from the samples he sent, which will long be remembered by the gardeners at the Jubilee Exhibition. After all, I think Mr. Goodacre has been very fortunate, for had any flaw or error been found in either the first or second collection sufficient to disqualify them, we have it on the authority of "One of the Judges" that his collection would have remained where it was—third. Mr. McIndoe showed a remarkably fine collection, and I should not have quarrelled with him had he been placed equal, although he agreed that the Judges were right.—J. HUNTER, *Lambton Gardens*.

PERHAPS I may state in a few lines how the controversy initiated by Mr. Goodacre strikes an outsider who is unacquainted with any one of the exhibitors, judges, or even attendants at the above Show. If the schedule stated that the dishes of fruit were to consist of ripe fruit and a certain number of dishes of each kind, then I say if the fruit was not all ripe and the number of dishes of each variety as per schedule in the competing exhibits, no prize should be awarded to any exhibitor who failed in either of these respects. If the rules of a schedule are not adhered to what is the good of any rules? I have not yet seen it fairly proved that any one of the three exhibits consisted of all ripe fruit and the numbers of dishes as per schedule.

I must add I sympathise with Mr. Goodacre in his complaint of contributions on controversial subjects not being signed by the writer's proper name. If a man has the courage of his own opinions and attacks another let him sign his name in proper English fashion.—H. S. EASTY.

PEACH TREES CASTING THEIR BUDS.

PEACH trees casting their buds is rather more prevalent this year than usual, especially in early houses and with large-flowered varieties, such as Hale's Early, Barrington, and Grosse Mignonne. I am inclined to accept Mr. Barker's theory as the correct one, and the remedies he advocates are the most feasible that I have yet heard. I have endeavoured to discover the cause, and have observed that the long time our early Peaches remain dormant during the hottest period of the whole year dries up the buds rather than ripens them. For instances last year we had a Grosse Mignonne, from which all the fruit was gathered by the end of May; and although the tree was well attended to it was leafless by the middle of August. The buds began falling in October, and by pruning time some of the wood had scarcely a bud left. This wood, as might be expected, was nearly as hard as ebony to cut; the centre was the colour of mahogany, while the bark was very thin, but quite healthy. This tree is now swelling as good a crop of fruits as we can desire. Any excessive fluctuations of temperature after the buds commence swelling will cause them to fall as with unbeated houses in the spring.

I have noticed where trees once lose their buds they are more or less liable to continue doing so, especially if left in the same position, and sometimes I think the stock has something to do with it. I have only seen one instance that I remember of outside trees casting buds, and this was a standard Walburton Admirable, a parently in perfect health. But whether they shed their buds or not, it is a step in the right direction to lift the trees and add a little fresh loam to the roots; but when is the best time to do this? I have lifted trees in June with fair success. By keeping the house close, densely shaded, and heavily syringed for two or three weeks, and gradually admitting air and sun, by the end of a month they are all right, and any little top growth they make may be removed from time to time.

I also believe it is an advantage to thin the buds when they begin swelling, especially the large-bloomed sorts. In very light soils I believe a little salt may be used with advantage, but this must be done constantly and after the fruit has stoned. But a long chapter might be written upon Peach culture, and views exchanged with advantage.—J. H. GOODACRE.

Is it not possible that in the case of early Peach trees losing their buds in showers at the time the trees commence growth, they may have been injured by excessive heat, say the hot scorching sun together with a dry parching atmosphere? I incline to think that the mischief is done at some time previous to starting them into growth or during their resting period. With early forced trees this evil is most marked, the buds being more or less in an advanced stage of development during the hottest part of summer, and probably the most forward may be the first to suffer. We never had better bloom than that of this year. The earliest trees were covered with strong flowers, and at the time of starting scarcely a single bud fell. I may say that in addition to our usual practice last year—viz., supplying the roots with abundance of water and giving the trees a daily bath—during the intense heat we never allowed the house to become parchingly dry, the evaporation pans too were kept filled, and this practice will be extensively carried out with us for the future. I may further state that although the same trees the previous season seem to be in better condition, the shoots browned and better ripened, we lost many buds, and on cutting several in halves I found the centre to be quite black as if they had been damaged for some months previous, and not unlike a burn.—H. MARKHAM, *Mereworth Castle*.

PLEASE permit me to record my success in securing a good set of fruit on Peach trees after three seasons of failure. Different treatment has been given to the trees every season. Some have been lifted and

planted in fresh soil, others root-pruned, putting back the old soil but well beaten to make it firm; others were top-dressed with strong manure. The buds fell from all alike. In previous seasons I only used fire heat to keep out frost, because plants were wintered in the house, but this year they have set their fruit well owing to the fact that fire heat was employed continually from the time the buds were seen to be swelling. The trees were well syringed twice a day until the flowers expanded. After they were set the syringe was again employed and fire heat kept at 55°.—DAVID JONES, *Hartsheath, Mold*.

RECLAIMING SANDBANKS.

COULD you find room in the Journal for this note in reference to reclaiming sandbanks? The plant referred to as *Ammophila arundinacea* is identical with Mr. Moorman's plant. It is also known under the names of *Psamma arenaria* and *Arundo arenaria*; its English name is Sea Mat Grass. Local English names, as a rule, are very misleading, but Mr. Moorman's name is rather appropriate, for the spiked paucile somewhat resemble an ear of Wheat, and its running roots, hence Bindwheat. It is known in the neighbourhood of Southport as Star Grass, and I have seen notices cautioning persons against pulling this Grass. The leaves are not round as they appear to be, but are involute—that is, the edges of the leaves are rolled inwards, thus giving them a Rush-like appearance. The plants are commonly planted about Southport, as I have seen years ago, and London in "Encyclopædia of Plants," says it has a strong creeping root with many tubers at the joints the size of a pea. It is planted and encouraged on the coast of Norfolk to aid in fixing the sand against the action of the wind and tide, which it effects in a surprising manner. The Marrum, as it is called, is considered of so much importance that there are severe laws to prohibit its being destroyed. Mats are made of it, and it is used as thatch.

I should think that Mr. Moorman's informant about its having been imported from Holland must have been wrong, for I do not believe that there is a sandy coast of any extent in Britain where this plant does not grow. For I have seen it in its glory all along the Welsh coast from Chester to Aberystwyth, and northerly from Liverpool into Westmoreland, and I daresay following right into Scotland, for I have seen it abundantly on the sands of Barry, near Dundee; then, again, on the east coast at Hartlepool, Hull, and I am informed that it grows abundantly on the Lincolnshire coast; then we come on the Norfolk coast before mentioned, and if a native of Italy, and introduced into Britain by a local farmer, it certainly must have been a long time ago.

There are also other plants that act the same way, but probably in a less degree, such as *Carex arenaria* and *Elymus arenarius*. The *Elymus arenarius* is a beautiful Grass, rising to a height of 3 or 4 feet, with broad glaucous leaves, thus giving it a noble appearance. The *Ammophila* in general appearance is very much like *Lycium spartium*, the Esparto, or Spanish Grass, so extensively used in the manufacture of paper. Its qualities are, I am informed, superior to common rags. It is imported by thousands of tons annually, and I see no reason why the *Ammophila* should not answer the same purpose.—JAMES PERCIVAL.

THE following extract from Lindley and Moore's "Treasury of Botany" will, perhaps, be interesting to Mr. J. W. Moorman. "*Ammophila*, a genus of Grasses of the tribe Arundineæ, inhabiting the sandy seashores of the coasts of Europe and North America, and extensively cultivated in many places, as in the eastern counties of England and in Holland, for preserving the sandbanks which prevent the inroads of the sea. It is the widely creeping and matted rhizomes which serve to bind together the sandbanks on which it grows. The only species, *A. arundinacea*, or *Psamma arenaria*, is variously called Maram, Marram, Sea-weed, or Sea-Matweed." I do not think there can be any doubt as to the identity of the plant used by Mr. Muir and that observed on the Sussex coast.—T. S.

THE Grass which grows on the sand near Rye is *Ammophila arenaria* or *Psamma arenaria*, as it is called in Hooker, but I rather imagine by the reference to a Rush-like Grass, and by the local name of Bindwheat, that *Triticum junceum*, which almost invariably grows with and amongst it, is confused with it. It is, however, the root of *Ammophila* which binds the sand together, and when it is stated that the roots exceed 20 feet in length its binding power will be conceived. As he states, it is a native of the South of Europe and north coast of Africa. It has been extensively planted in Norfolk, the Hebrides, round Calais, Egypt, &c. It is very doubtful when it was introduced into England, but it was well known in Queen Elizabeth's reign, when an Act of Parliament was passed to prevent people destroying it. It is stated that the town of Hull owes its preservation from being washed away to this plant being planted on the shores there.—J. R. NEVE, *Cumpton, Glos.*

BEAUMONTIA GRANDIFLORA.

OLD inhabitants of British gardens are occasionally brought into notice at the meetings of the Royal Horticultural Society, and they are often quite as welcome as novelties, and sometimes much more beautiful. *Beaumontia grandiflora* must be ranked as one of these, for though it has been grown in England for about seventy years it is seldom seen in modern gardens. Within the past two years attention has been twice called to it at Kensington. On April 27th, 1886, Mr. Ruffett of Pan-

shanger Gardens, Hertford, exhibited specimens, for which a first-class certificate was awarded by the Floral Committee; and March 13th this year Mr. J. Anning, Digswell House Gardens, Welwyn, Herts, sent well-

which it has passed, and it is included in the same family, the Apocynaceae. It is of strong growth, but of climbing habit, and is usually trained to the walls of a stove or warm conservatory, where it has

FIG. 30—BEAUMONTIA GRANDIFLORA.

grown examples of the same plant, for which a cultural commendation was adjudged. From the latter specimen our engraving (fig. 30) was prepared.

Beaumontia grandiflora is a relative of the genus *Echites*, under

plenty of space. The leaves are somewhat like those of *Luculia gratissima*, but rather thicker, and dark green, 6 or 8 inches long by 3 or 4 inches in breadth. The flowers are borne in terminal or axillary corymbs; the corollas being about 6 inches long and 4 inches broad at

the mouth, funnel-shaped, with five broad lobes, pure white, and possessing a strong fragrance. The plant is a native of Cbittagong in India, and sent by Dr. Wallich in 1818 to Messrs. Whitley of Fulham, with whom it flowered 1825, and it was figured in the "Botanical Register" for that year. A compost of good turfy loam, leaf soil, and plenty of sand suits it, and the temperature of a warm conservatory is even better adapted for it than an ordinary stove.

VALUABLE BOTANICAL AND GARDENING BOOKS.

It may interest some of your readers to know the price realised for certain works on botany and gardening at the recent sale of the Aylesford Library by Messrs. Christie, Manson, & Woods. Andrew's Engravings of Heaths, 4 vols., folio, calf gilt, £13 15s. Besleri Hortus Eystettensis, 3 vols., £5 5s. Bute, Earl of, Botanical Tables, 9 vols., £60. Candler & Booth's Camellias, 1 vol., £4. Brunfelsii Herbarium, 2 vols. in 1, 27s. Clusii Exoticorum lib. x., Rariorum Plantarum Historia, 2 vols., 32s. Edwards' Botanical Register, 33 vols. and appendix, calf, £35. Dethicke's Gardeners' Labyrinth, 1 vol., £10. Curtis's Flora Londinensis, £13 10s. Curtis's Monograph of the Genus Camellia, £3 15s. De Tussae Flore des Antilles, 4 vols., £41. Duhamel du Monceau Traité des Arbres et Arbustes, &c., 7 vols., £49. Duhamel du Monceau Traité des Arbres Fruitières, &c., 6 vols., £47. The Grete Herball, 1526, £8 8s. Herbaria Vulgare, 1522, and Plantarum Effigies, 2 vols., £5. Hooker's British Jungermannia, £9 10s. Horticultural Society's Transactions, 10 vols., 78s. Hortus Ericæus Woburnensis and two others, 24s. Knight Pomona Herefordiensis, 29s. Hoiland, Mrs., Description of White-Knights, £2 15. Noisette et Gautier Jardin Fruitier, 45s. Repton's Fragments on Landscape Gardening, £4 15s. Repton's Sketches and Hints on Gardening, £2 4s. Redouté Les Liliacées, 8 vols., morocco, £47. Redouté Les Roses, morocco, £23. Redouté Choix des Belles Fleurs, morocco, 1 vol., £12 10s. Redouté Histoire de Plantes Grasses, morocco, 2 vols., £10 5s. Scott Perfite Platform of a Hoppe Garden, and Maseall, the Arte of Planting and Grafting, 1 vol., £7 15s. Watson's Dendrologia Britannica, 2 vols., £5 15s. This class of books seems rising in value. I have several of them and others in my library, purchased a few years ago, at much lower prices than those recently realised.—WILLIAM PAUL, *Waltham Cross, Herts.*

PROTECTING FRUIT BLOSSOM.

THE articles of "A Kitchen Gardener" are always read with interest, and these few remarks are not intended to be a criticism on his seasonable notes on the above subject, but merely supplementary. Although considerable differences of opinion exist as to the necessity of protecting fruit trees while in bloom, it is generally conceded that in exposed situations is more beneficial than otherwise. The greatest difficulty is how to protect them effectively without exceeding the cost of production, for any system which does so will not long commend itself to the owners of gardens. Now that fruit-growing is so extensively conducted, there are doubtless many methods in operation to save the blossom from frosts, and if those in charge would publish the systems which they have found most successful, in the manner "A Kitchen Gardener" has done, much good would doubtless result. I have proved from experience that the same practice does not succeed equally well in all localities.

A portion of the wall space here chiefly covered with Peaches and Apricots was nearly always a failure as regards a crop of fruit, although ordinary precautions with nets, as recommended by "A Kitchen Gardener," were taken to protect the blossom, and yet a few miles off the same kind of protection was as satisfactory in its results, as noted by your correspondent. A glass protector proved effectual for most of the Peaches, and the difficulty regarding the other trees was met by a mode of protection which may be of service to some others similarly situated. The seathing effects of east winds are very noticeable on walls where there are no buttresses projecting to break their force, or where there is no plantation sufficiently high, as in our case. To lessen their violence two 9-inch boards braced together are placed close to the wall, jutting out at right angles from it, and fastened by means of two screw nails to an iron stay about two-thirds up the wall—this proving quite sufficient to steady it. These temporary shelters are placed about 30 feet apart and connected at the top furthest from the wall by a half-inch rod of iron, the rods being flattened at the ends, and a hole made to fit a hook which is screwed into the boards; this forming a continuous length as far as required. To keep the rod from swaying or bending downwards, brackets to support it are fixed into the wall in distances of about 10 feet from each other. Along the top of the wall is stretched a wire, and then all is ready for the coping, which consists of branches of Yew or any other shrub, between 3 and 4 feet in length. We find Yew the most suitable, being less liable to be caught by the wind than larger leaved varieties, besides being more cleanly. The branches are spread thinly along, barely touching each other, the thick end being tied to the wire on the wall, and the other end fastened to the rod which it overhangs. The effect of this protection is very marked. Instead of a crop of Apricots once in eight years there has been a fair crop each year since it has been used; and on the Peach trees—not inside the protector—where blistered leaves were once prevalent scarcely one is seen now. No ill results from the shade of the branches is anywhere noticeable, the trees being all as healthy as before it was used, and when the work is finished its appearance is not at all unpleasing.

When all danger of frost is over, the protecting branches are taken down, and the iron rods unbooked and stowed away overhead in the barrow-shed. The boards generally remain a fortnight longer to break the force of the wind on the young growth, then they are taken down and put away in the same place until required the next season. The cost of material is but trifling when its durability is taken into consideration, and the time taken to erect and remove again merely nominal.—M. D.

THE CULTURE OF FREESIAS.

I AM pleased to see that the few remarks by me on the value of the Freesia have found so able a supporter as "J. H. E." He, however, seems somewhat incredulous in regard to my statement respecting their powers of reproduction, and gives me credit for more than ordinary success. This, however, I cannot admit, having seen equally good results obtained by other growers who followed a similar line of culture to that described. To verify my statement by one instance, I obtained from a grower, who had potted what he required, a few medium-sized bulbs. These were placed in half a dozen 32-size pots, flowered well, and the following season, after potting, filled eighteen pots of the same size. I had remaining both a larger stock and a better sample than that with which I commenced the previous year. Respecting the time of potting I may say that this seems important, and I recommend June or July. They can be thoroughly ripened by that time, and the bulbs will be found one mass of fleshy white roots by the end of September, which must surely give them a great advantage over those still in a dormant state. The bulb merchant's catalogue will form but a poor guide to the proper time for potting other bulbs besides the Freesia. The early ripened must wait for the late.—J. C. A.

YOUR correspondent, "J. H. E.," page 199, doubts if the Freesia will treble its produce of flowering bulbs in one year. I can fully endorse what appeared in a previous number on this subject, as I have been growing them for several years, and find that under good cultivation it is by no means an uncommon occurrence.—FOREMAN.

A SHORT time back a contributor to the subject of Freesia growing stated he had flowered them within twelve months of sowing seed. If you think the following worth a note you might insert it in your Journal. I sowed seed of Freesia on August 22nd, 1887, and have now (March 10th) flowers on some of the plants produced. Is the Freesia a recently discovered plant, or is it a new name for an old plant?—E. T. COSSOM, *Gardener to the Right Hon. H. Campbell-Bannerman, M.P., Hinton, Kent.*

[Freesia refracta alba has been prominently before the public for about ten years, as it was certificated by the Royal Horticultural Society in 1878.]

PROPAGATING TREE CARNATIONS.

AT all times of the year from January to December the flowers of Carnations are always welcome. Those who require exceptionally large plants and early autumn blooms should strike cuttings in the autumn, while the majority who need these flowers when Chrysanthemums are past will do well to push on with their propagation at once. The best cuttings which can be had for present propagation are those produced from the main flowering stems, the young shoots which upon some form so readily in the axils of the leaves, in a cool temperature, say from 45° to 50°. They are best when about 3 inches long, and should be detached from the parent plant with a heel. Such cuttings as these will need little preparation before being inserted, or at the most it may be only necessary to remove the lower pair of small leaves. The kind of soil well suited for them at this stage is equal parts of loam and leaf soil, the latter thoroughly decomposed, and the whole made very sandy but not very wet. Where there is abundant room at disposal and a gentle bottom heat of from 60° to 70° there need not be much trouble in raising a good stock of these useful winter flowers. I am much in favour of inserting the cuttings singly in very small pots, for this reason—Carnations do not all root at one time, even though the cuttings may be in as nearly as possible the same condition when inserted, and to leave them in the cutting frame till all are rooted means making those first rooted weak and sickly, while to take them out is only done at the sacrifice of those not rooted. Another advantage accruing from the single-pot method is that the operator is saved the trouble of potting them when rooted, as when this is done from store pots every care is requisite to prevent their threadlike roots being torn off.

Depending entirely upon the weather, I do not water my cuttings for from four days to a week after insertion, and then give sufficient to penetrate the whole of the soil. The pots are plunged two-thirds their depth in cocoa fibre refuse, and the frame kept close till they receive the first watering, when the lights are left off a sufficient time to allow of the tops (cuttings) becoming quite dry. Dewing or sprinkling them from time to time is deadly to them, and should be carefully avoided. Aphides are often very injurious to the cuttings. As a precautionary measure I have in readiness a weak solution of quassia and soft soap, into which the cuttings are dipped before being inserted, afterwards allowing them to dry thoroughly before being placed in the pots. Whether green fly be in existence or not, this is by no means time lost, but should they exist even in small numbers, it will be time saved,

especially when we consider their much more rapid increase in the warmer and closer atmosphere of the cutting frame.—J. H. E.

ROSE SHOWS IN 1888.

- June 28th.—Brockham and Ryde.
- June 30th.—Eltham and Reigate.
- July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
- „ 4th.—Croydon, Hitchin and Richmond.
- „ 5th.—Bath, Farningham, and Norwich.
- „ 6th.—Sutton.
- „ 7th.—Crystal Palace (National Rose Society).
- „ 10th.—Ipswich.
- „ 11th.—Ealing and Tunbridge Wells.
- „ 12th.—Winchester.
- „ 14th.—New Brighton.
- „ 17th.—Leek and Ulverstone.
- „ 18th.—Birkenhead.
- „ 19th.—Helensburgh.
- „ 20th.—Darlington (National Rose Society).
- „ 21st.—Manchester.

There are still a few fixtures which I shall be glad to have, and which I hope will reach me in time for insertion in my next list, which will appear early next month.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

THE GLOUCESTERSHIRE ROSE SOCIETY.

A LARGE and influential meeting of ladies and gentlemen of the city and county was held at Gloucester on Saturday, the 17th inst., for the purpose of starting a Rose Society for the county, the result of the meeting being the formation of the above Society, which promises to be exceedingly well supported. Mrs. Gambier Parry of Highnam Court, Gloucester, was unanimously elected President, and several ladies and gentlemen of the city and county consented to act as patrons and patronesses. An influential Committee was appointed, and the Rev. T. Holbron, Sandhurst Vicarage, Gloucester, and the Rev. F. R. Burnside, Chipping Campden, were elected Hon. Secretaries. Mr. Hatherley, manager of the National Provincial Bank, Gloucester, was appointed Treasurer. The first Show of this new Society will be held in the Corn Exchange, Gloucester (a room admirably suited in every way for a Rose show) on Thursday, July 12th. The Committee hope to be able to frame a liberal schedule, which will be issued by the end of April or the beginning of May.

SOLUTION FOR PREVENTING MILDEW ON ROSES.

“A. B., *Ayrshire*,” should dissolve half a pound of soft soap in a gallon of hot water, then add half a pound of flowers of sulphur, which must be thoroughly mixed previous to adding the petroleum, about 8 ozs. of which will be sufficient. He will then have a mixture sufficient to use with ten or twelve gallons of water, and if used in a tepid state all the better. The above will be sufficient to syringe a good sized Rose house with.

MARÉCHAL NIEL ROSE.

YOUR correspondent, “N.,” does not admit my plants of the above are forced, at any rate they are assisted. I cut the first flowers on February 19th, and have cut several since. I have three plants of Maréchal Niel in an unheated house, and they are only just commencing growth. I have had no mildew on those plants referred to last week; but I freely admit I have had plenty of trouble with it on other varieties; but by the use of the mixture referred to in the preceding note I am able to keep it well in check.—W. W., *East Yorks.*

MY ROSES IN 1887.

I HAVE already (some months ago) given in the Journal my view of the Rose season as regarded its general aspect, and shall, as far as possible, avoid all generalising, and refer only to my own garden. But what a season it was! how perplexing and worrying to all owners of a garden the long spell of cold weather, in which everything seemed to stand still! and then the long-continued drought, when day after day blazing sun, drying winds, and dewless nights added to their difficulties, and when watering was the principal work to be thought of and done. With many, however, this was an impossibility; gardens had to go without, for there was little enough for domestic uses. Happily I am not on a “dry and thirsty land.” We are on the chalk formation, and have an abundance of springs about us in all directions. This advantage, however, I think, somewhat interferes with the earliness of my garden. My position is sheltered and well exposed to the sun, but yet we are always late here. I believe this is to be accounted for solely by the low temperature of the soil, occasionally as I imagine by the number of our springs; but at any rate, during such a season as the last, “we have the pull” over those who are earlier but drier.

I have made no alteration in the kinds of Roses I cultivate, I mean as to stocks. Much has been said and written about standards, notably

by Mr. George Paul in the “Rosarians’ Year Book,” while in a contemporary I see a well-known writer, “D. T. F.,” writing on the “Return of the Standards.” This is a consummation most devoutly not to be desired. I do not believe in the superiority of the blooms to be had as maidens from these, for I believe that equally good can be obtained from the seedling Briar; and one must never forget that one who, considering the quantity of plants that he grew was, I consider, our chief amateur grower in past days, always grew his Roses on the Manetti, and always exhibited from cut-backs, I mean Mr. R. N. G. Baker of Exeter. Sometimes it is said the staying power of Roses thus grown is greater, but have we not the authority of “D. T. F.” himself that the box of Roses which he exhibited at Norwich were of such surpassing beauty as to excite his wonder and admiration, even after their long journey from Exeter across London to Norwich? Moreover, those who are weak enough to think of reinstating standards must be prepared for a collapse when the first severe frost comes. I shall never forget the splendid piece of standard Roses which I saw with old Margottin at Bourg la Reine, or the pride with which Jules showed them to us, and yet not one of them ever came to the market—they were all cut off by frost. There are a few cases in which standard Roses may be tolerated, but only a few. I have seen scores of weeping Roses, and a few will not be out of place in the back row of a Rose border; but I have no hesitation in saying that, whether for beauty or utility, the less the general amateur has to do with them the better.

As far as my own garden was concerned the season for the Hybrid Perpetuals was a short but a merry one. My beds were a blaze of colour and beauty for about ten days, and then all was over; but not so with the Teas for a month. Although I have, comparatively speaking, few plants, I had a succession of lovely blooms, those on the wall first giving me their blooms, and then those in the beds. The hot weather did not seem to improve them, and although the autumn was cold and cheerless, yet I had a succession of good blooms. I may say, too, that preceding all these my Maréchal Niel, still nominally in a pot, gave me about 350 blooms, not of large size or deep colouring, but still very pretty useful blooms. I see as yet no signs of canker, but am hopeful it may continue for a little while longer. The difficulty is to give it space to grow, and as I cannot permit it to fill up the house a quantity will have to be cut out. I have made some little alteration on my wall, having taken away a plant of Perle de Lyon, which rarely opened its bloom, and have placed in its stead one of a pretty and comparatively unknown Rose which I saw with Mr. George Bunyard at his celebrated nurseries at Maidstone, Claire Carnot. It somewhat reminds one of Celine Forestier, is of the same lovely yellow colour, but a better Rose; it is like it, too, as a Noisette of good habit. I have another Tea, Madame Jules Margottin, which is not satisfactory, and this I have also displaced and put in its stead another Rose which Mr. Bunyard highly recommended, Emilie Dupuy; it is of the Gloire de Dijon race, but he describes it as very good, and a bloom I saw of it made me think it would be an acquisition. I have also a strong inclination to disestablish Belle Lyonnaise; true it grows well and flowers freely, but the flowers are very apt to come split and quartered, and I think one may dispense with such Roses nowadays. I have also added some new ones to my small lot—Earl of Dufferin, Lady Helen Stewart, Miss Ethel Brownlow, Sir Rowland Hill, Duchess of Leeds, Princess Beatrice, Victor Hugo, Madame Joseph Desbois, Madame Desiré, Raoul Galliard, and also two Roses, one of which I never saw or heard of till I saw it in Messrs. Cooling’s of Bath, and of its origin, where raised, or by whom sent out the catalogues reveal nothing—Countess of Limerick: it is a perfectly shaped Tea Rose, white, with a faint tinge of pink. The other is Laurette. This I have known for years; it was always exhibited by Capt. Knight and Mr. W. H. Wakeley at our East Kent shows, but I never saw it anywhere else till I found it also with Messrs. Cooling’s. I do not know when or by whom it was sent out, but it is a very pretty Rose, white, with faint pink edging, somewhat of what may be called a refined Homère. Of these Roses I shall have, if spared, to report by-and-by. I have during the past year added another bed of Teas, a small one, for they are so very satisfactory and bloom on to so late a period that one can hardly have too many. So thinks my friend Mr. Alex. Hill Gray, but we cannot all build “fortifications” as he has done. I do not, however, think that those Rose growers are wise who talk of discarding nearly all their H.P. and substituting Teas. This is running into extremes. We cannot do without the brilliant colouring of the H.P.’s, however much we may admire the refined delicacy of the Teas.

Who grows the Austrian Yellow single Briar? One of the most beautiful sights in the way of Rose trees was a bush of this in a cottage garden in my parish, a shower of lovely gold-coloured blossoms, and yet wanting to get it for my own garden I had some difficulty in finding it. The Austrian Copper I could get, but not the Yellow. At last I found it, and I hope that I have got it true. Of other single Roses what I have not bloomed before were Paul’s Single White and Single Crimson. I have planted these for a pillar, and think the White exceedingly pretty and well suited for this purpose. I do not think so well of the Crimson.

Of the Polyantha Roses we have to note a very pleasing addition in Perle d’Or and Mignonette: they are useful both in the garden and as pot Roses. Some of the latter exhibited by Messrs. Paul & Son last year in pots were greatly admired. The former is an exceedingly pretty little Rose, nankeen yellow, with orange centre, not unlike the colouring of William Allen Richardson when well coloured; it is very dwarf and interesting. One would hardly have expected that a cross of Tea blood with the rampant single-flowered Japanese Rose would have

produced such pretty little dwarf hushes and flowers. Yet another cross is announced, Madame Geo. Bruant, said to be a hybrid between *R. rugosa* and *Somhreuil*. I should say, from the bloom obligingly sent me by Messrs. Cooling & Son of Bath, that *Rugosa* has not much, if at all, participated in it; it is very pretty and most deliciously sweet scented, but knowing nothing of its parentage I should have said it was a pure Tea. I have not as yet grown it, and probably we shall know something more of it as the season advances.

It was a trying season for new planted Roses, and therefore some of the "species" which I tried to grow did not make much headway. *Berberifolia Hardii* is clearly not hardy in this part of England, although I have little doubt of it in S. Wales or Cornwall. What it might do on a wall, or under a shelter of a wall, I know not, but it was placed in the sunny part of the rockery, and there succumbed to frost. Others, such as *myriacantha*, *pimpinellifolia*, and *laevigata*, are now established, and I hope will make progress next season.

It would be useful to go through the list of those Roses which have done well and pleased me this year. Some of the older varieties quite hold their own, and notwithstanding the lavish praises which are bestowed on new varieties, it will be some time before many of the older varieties are beaten out of the field. They are praised for a season or two, and then disappear in the background. Have such flowers as *Marie Baumann*, *Duke of Edinburgh*, *Souvenir d'Elise*, *Catherine Mermet*, or *Comtesse de Nadaillac* yet been surpassed? but hybridisers are not discouraged, nor, indeed, should they be. There is something yet to be done, we do not so much want monstrous Roses, as Roses of good substance and distinct colouring. If we get size with these well and good, but let not great size be the hybridiser's chief effort.

In this part of England (Kent) we have had an exceptionally severe time, not for the intensity of the frost, but the depth of the snow. There are no signs of pushing huds, and pruning must be late, but let us hope we may be spared those bitter north-easters in May, for we have had enough of them already, and then, I think, we might look forward to a really good Rose year.—D., Deal.

CHRYSANTHEMUM SHOWS.

WE have received notices of the following fixtures for the Shows of 1888:—

National Chrysanthemum Society, Metropolitan Shows, September 12th and 13th; November 7th and 8th; and January 9th and 10th, 1889.

Provincial Show at Sheffield, November 16th and 17th.

Kingston-on-Thames, November 6th and 7th.

Portsmouth, November 7th, 8th, and 9th.

Teddington, November 8th and 9th.

Crystal Palace, November 9th and 10th.

Ascot, November 13th.

Southend, November 13th.

Devizes, November 13th.

Brighton, November 13th and 14th.

Putney, November 13th and 14th.

Winchester, November 13th and 14th.

Bournemouth, November 14th.

York, November 14th, 15th and 16th.

Market Harborough, November 14th and 15th.

Brixton, November 15th.

Reading, November 15th.

Pembroke, November 15th.

Lindfield (Sussex), November 15th and 16th.

Sheffield and West Riding, November 16th and 17th.

Liverpool, November 20th and 21st.

Birmingham, November 21st and 22nd.

Hull, November 22nd and 23rd.

Pontefract, November 23rd.

A NEW DEPARTURE IN CHRYSANTHEMUMS.

IN the first number of the American "Garden and Forest" a distinct variety is figured in photogravure under the name of Mrs. Alpheus Hardy. It is a large, broad floretted, Japanese variety, having spine-like glandular hairs on the backs of its incurving florets. Its appearance is quite unique. It has the asperity of a star fish, and the curled-in look or appearance of *Anastatica heirochuntica*, or *Rose of Jericho*, when in its dried up or sunburnt phase of existence. It was sent to Mrs. A. Hardy direct from Japan by a student of the Flowery Land, whom she had befriended when he was on a visit to the United States. A Japanese botanist who saw the flower at Cambridge, Mass., said he had never seen a variety like it in Japan. The spines or glandular hairs are about the eighth of an inch long, and curved like the letter f, their apices being tipped by a globular mass of gum or resin. When the Delaux's and Boucharlets of sunny France get hold of this variety it is likely to become the progenitor of a new race of Japanese flowers.—F. W. B.

CHRYSANTHEMUMS FOR BORDERS.

A LONG succession of Chrysanthemums can be had in the flower borders as well as in shrubberies. Very frequently old pot plants are saved and either divided and planted or placed out intact. The former practice is preferable of the two, but still better results attend planting out newly struck cuttings. The latter take most readily to their fresh quarters, and the three or four strong branching growths these form are ample. Dibble the cuttings thinly in ordinary Pelargonium boxes or large pans of fine sandy soil, water them through a fine-rose pot, set in gentle heat, keep them rather close and shaded from sunshine till rooted. When struck pinch out the tops and strike these if needed, and when breaking afresh transfer to a cold frame or pit to harden off. By the middle of May capital bushy plants will be ready for the open ground, no potting being necessary. The dwarf early-flowering varieties may be planted in mixed borders, three plants in a group, while those that flower later, and which it is intended to either lift or protect, may be planted 18 inches apart in rows 2 feet apart. All should have well manured freely worked soil to grow in, and if duly staked will succeed surprisingly well. The following Chrysanthemums for the open ground may be selected:—*La Petite Marie*, both yellow and white varieties, very dwarf, early, and compact; *Mrs. Cullingford*, white and good; *Fiberta*, yellow, of branching free-flowering habit and early; *Frederick Pélé*, crimson, early and very free; *Madame Piccol*, rosy purple, free-flowering, and early; *St. Mary*, white, branching, and good; *Pompon Toulousain*, reddish orange, very free; and *Flora*, rich yellow. These should commence flowering in July and last till frosts cripple them. *Madame C. Desgrange*, sulphur white, of sturdy habit, one of the best; *G. Wermig*, a yellow sport from the last named; *Alexander Dufour*, violet, of medium height, and very effective; *La Vierge*, pure white, and valuable; *L'Isle des Plaisirs*, bright crimson, dwarf, and good; *Sœur Melanie*, white, sturdy, and very free, one of the best; and *Mandarin*, creamy white, flower grandly in October, and all are suitable for lifting. These give finer and less formal flowers than do the summer-flowering varieties. *James Salter*, lilac, a tall, early, and very free-flowering Japanese variety; and *Lady Selborne*, a beautiful, pure white sport from the latter, frequent, flower grandly in the open, and transplant readily. *Mrs. Rundle*, *Mrs. Dixon*, and *Mrs. Glenny*, struck and grown as just advised, will, if the autumn be mild, yield a wonderful profusion of flowers, and the old variety *Julie Lagravère* also does well under similar treatment. The later-flowering Japanese, as well as the large-flowering incurved and reflexed varieties, seldom pay for garden culture, but nearly all the Pompons may safely be given a trial.—W. I. M.

ROYAL BOTANIC SOCIETY.

MARCH 21ST.

THE first Spring Show of the season was held in the Corridor and Conservatory in the Botanic Gardens, Regent's Park, on Wednesday last. Exhibits were numerous, and there was a brilliant display of flowering plants, the beauty of which was considerably heightened by a bright sunny morning.

BULBS.—Hyacinths as usual contributed largely to the Show, Mr. Douglas winning first honours for twelve plants of the following varieties:—*King of the Blues*, *Czar Peter*, *Koh-i-Noor*, *La Grandesse*, *Vuurhaak*, *Solfaterre*, *Lord Derby*, *Princess Amelia*, and *Princess Mary* of Cambridge, all having substantial spikes and bells. Messrs. Eason and Scott were second and third respectively. In the nurserymen's class Messrs. H. Williams & Sons took the lead with good specimens; Mr. H. R. Wright being second. Mr. Douglas staged the best twelve Tulips in the amateurs' class with well-developed flowers of *Proserpine*, *Ophir d'Or*, *Keizerskroon*, and *Joost Van Vondel*. Messrs. Scott and Clements followed in the order named. In the nurserymen's class Messrs. Wright and Williams were the exhibitors, and were awarded first and second honours.

Mr. J. Douglas was first with twelve *Amaryllises*, very strong, several with two scapes and four flowers each. Messrs. Paul & Son, Cheshunt, were second, the plants also being strong, but the flowers were smaller.

Messrs. H. Williams & Sons, Finchley, were first with six pots of *Lily of the Valley*, well flowered. Mr. J. R. Chard, Stoke Newington, was a close second with grand specimens, and Mr. R. Scott, gardener to Miss Foster, Regent's Park, was third. Crocuses were well shown by Messrs. Scott, Douglas, and Clements, who gained the prizes in that order. Chinese *Primulas* from Messrs. H. Williams & Sons, W. Kemp, and H. R. Wright winning similar awards.

For twelve pots of bulbous plants, Messrs. Paul & Son were first, showing freely flowered specimens of *Iris reticulata* and *Krelagei*, *Scilla siberica*, *Chionodoxas Luciliae* and *sardensis*, *Leucojum carpathicum*, *Galanthus Sharlocki*, and *Bulbocodium vernum*. The same firm was first with six Roses in pots, the fragrant dark crimson H.P. *Comtesse de Camande* being very notable. Messrs. Douglas and Eason were the winners with six *Deutzias*, the first having his usual large specimens.

Azaleas were not very satisfactorily shown, but Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, had the best six in the amateurs' class, dwarf, fairly well flowered plants. The second and third prize plants were of little merit, and one half-dozen ought not to have been exhibited.

Mr. T. S. Ware, Tottenham, had an interesting collection of hardy plants in the open class, *Daffodils*, *Dielytras*, *Primulas*, &c., and was awarded the first prize. The first-prize collection of hardy *Primulas* from Mr. Douglas comprised pretty examples of the white *villosa nivea*,

villosa hybrida, *marginata*, *spectabile*, *pubescens*, and several *Auriculas*. Mr. J. Clements, gardener to L. H. Hicks, Esq., Springfield House, Muswell Hill, was second, showing *floribunda*, *rosca*, *obeonica*, *verticillata*, and *erosa*. Messrs. John May and Odell were the trade exhibitors of *Cyclamens*, and Mr. D. Phillips, Slough, and Mr. J. Clements the amateurs, the first in each class having much the finest plants. Messrs. Wright, Williams, and Douglas had good collections of *Polyanthus Nareissi*.

MISCELLANEOUS.—The non-competing groups were very extensive and beautiful, the following being the principal exhibits. Mr. B. S. Williams, Upper Holloway, Hyacinths, Tulips, Narcissi, Amaryllises, and Azaleas, a very handsome group (large silver medal). Messrs. H. Williams & Sons, Finchley, Hyacinths, Tulips, Daffodils, Lilies of the Valley, &c. (large silver medal). Messrs. J. Veitch & Sons, Chelsea, a group of excellent Hyacinths in all the best varieties (large bronze medal). Mr. J. James, Slough, a collection of extremely fine *Cinerarias* (large bronze medal). Messrs. Paul & Son, a large group of Roses in pots (large bronze medal). Messrs. W. Cutbush & Son, Highgate, a large and tasteful group of Hyacinths (large bronze medal). Mr. T. S. Ware, Tottenham, Daffodils and *Anemone fulgens* (certificate). Mr. J. Odell, Hillingdon, a group of *Cyclamens* (certificate). Messrs. Paul & Son, Cheshunt, a collection of hardy plants. Messrs. Barr & Son, Covent Garden, a collection of Daffodils (certificate). Messrs. H. Lane & Son, Berkhamsted, a collection of *Azalea mollis* varieties (large bronze medal).

Botanical certificates were awarded for the following:—

Trillium discolor atratum (Veitch & Sons).—A peculiar variety with marbled leaves or bracts, and dark maroon flowers.

Dendrobium nobile Cooksonianum (Mr. Perkins, gardener to the Right Hon. W. H. Smith, Greenlands, Henley-on-Thames).—A fine plant of this variety with eight flowering growths with ten to sixteen flowers each. The variety is described and figured on page 237.

Saxifraga Frederici-Augusta (Paul & Son).—A dwarf tufted species previously certificated at South Kensington and described last week.

Floricultural certificates were awarded for the following:

Rose Lady Alice (Paul & Son).—A Hybrid Perpetual Rose, a light coloured form of *Lady Mary Fitzwilliam*, very delicately tinted and very beautiful in the half opened state.

Cineraria Favourite (J. James).—A single variety with large blooms of great substance, the florets broad and thick, rich rosy crimson at the tips, and pure white at the base.

Cineraria Maria (J. James).—Single, blooms large, pure white, with a purple centre.

Cineraria Irene (J. James).—Single, an intensely deep purple, florets broad, with a narrow white band at the base.

A few new Hyacinths were shown by Messrs. Veitch & Sons, and though no certificates were awarded they are worthy of note. *Sybil* is a single variety with purplish mauve flowers in a compact spike, and it is something in the style of *Harlequin*, but rather darker. *Symmetry* is also a single variety, salmon red with a darker vein in the centre of each lobe of the corolla. *Criterion*, single, pale lemon yellow, a delicate colour and rather pretty. *Star of Hillegom*, double or semi-double, pale blush white, large bells and massive spike. The best of the Hyacinths in the general collections were *Queen of the Blues*, *Czar Peter*, blue; *Ida*, yellow; *Mont Blanc*, white; *General Pelissier*, red; *Masterpiece*, very dark blue; *Charles Dickens*, pink; *General Havelock*, dark blue; *Countess of Rosebery*, rose; *Electra*, pale blue; *La Joyeuse*, pink; *Koh-i-noor*, semi-double, rose; *Madame Van der Hoop*, white, fine; *Prince Albert Victor*, red; *Vuurbaak* and *Linnaeus*, bright red; *Grand Maitre*, blue, large; *King of the Blacks*, dark blue; *Snowball*, white; *La Franchise*, creamy; *Garibaldi*, red; *Roi des Belges*, bright red. These are all single except where otherwise stated. Of Tulips, *Vermilion Brilliant*, *Standard Royal*, scarlet and white; *Ophir d'Or*, bright yellow; *White Joost Van Vondel*, and *Canary Bird*, pale yellow, were the best.

KITCHEN GARDEN.

PARSNIPS.—Parasnip seed is sometimes sown in February, and very often early in March, but seed sown now in suitable weather will produce as fine roots by October as any sown previously. It is a good time to sow the main crop. Give them deep friable soil, free from anything that would cause the roots to fork. Break the soil up well on the surface previous to sowing, open drills 18 inches apart and 3 inches deep, and sow thinly. Cover with the surrounding soil, and tread it firmly.

EARLY CARROTS.—The French Horn and Short English Horn should be sown now. Where ground was prepared for them some time ago by forking in soot, sand, or lime to prevent grubs doing harm do not fork again, but run the Dutch hoe through the surface when the soil is dry, and sow on the same day. A south border is the best position for them. The drills need only be 1 foot apart and 2 inches deep. Separate the seed well, and avoid thick sowing. A little sand may be placed over the seed before the soil is placed back in the drills, and roll the surface when the soil is so dry as not to stick to the roller.

THE FIRST TURNIPS.—These are always acceptable, but they are very apt to fail if the seed is sown too early. We have sown in February and the early part of March, and the plants all "bolted," but the seed sown now will produce plants that will form roots in May, and that is as early as Turnips are obtainable in most districts. Let the soil be made very rich near the surface; they will not do much good in poor soil, and a sunny spot suits them admirably. Early Milan is the best for a first crop, and as the roots from this early sowing will not gain any great size much space may be economised by sowing the seed broadcast in a small bed. Many scores of roots may be secured from a bed 4 or 5 yards in length and 4 feet in width, but if in rows in such a small space the return would not be great. Sow thinly and cover slightly.

AUTUMN-SOWN ONIONS.—Onions have not grown much since September. They are short and healthy, and in good trim to avoid seeding prematurely. Thin the plants in the rows to a distance of 5 inches apart, then tread along the side of those remaining, and plant those drawn up elsewhere, giving them very rich ground exposed to the sun, and if placed in rows 10 inches apart and 4 inches between the plants, part of them may be drawn for use in May and June, and plenty allowed to remain to form large bulbs in July and August.

SPRING ONIONS.—The term applies to all Onions sown in spring, and all seed must be sown without delay. Do not make up the old-fashioned cumbersome bed, but apply plenty of manure and soot to a strong quarter of soil; dig or fork it well in, and then open drills all over it at a distance of 10 inches or 1 foot apart, and sow the seed. Two inches is a good depth to sow, and if a little genial soil can be placed over the seed it will be an advantage. As soon as the seed is covered tread each row firmly, then rake the surface and roll it well. Firm soil always induces the plants to bulb early and well. Pig manure is excellent for Onions.

KIDNEY POTATOES.—These are earlier than any of the round sorts, and should always be planted for a first crop. Like other tender vegetables, Potatoes, if planted too early, are apt to be cut down by late frosts, but those planted during the last week in March are not very likely to suffer. We are now wheeling some manure on a vacant south border, spreading it out and digging it in, and as digging goes on the Potatoes are planted. The rows are 20 inches apart, and the sets are placed 1 foot asunder. The varieties are all of the Ashleaf type, and as these do not make very large top growths, the distance named suits them. Where the manure was dug in some time ago, drills 6 inches deep may now be opened and the sets placed in. Heavy soil does not suit early Potatoes, but light land, if well manured, is admirable. It is a mistake to plant early Potatoes in cold sunless positions.

MAIN CROP PEAS.—Prepare for sowing Peas. Throw out trenches for every row, make them 1 foot deep and not less than this in width. Put a layer of good manure in the bottom and fork it over. Throw a little soil over this when forking is finished, tread the whole firmly down, and then sow the seed. Do not sow in a narrow strip but all over the bottom of the trench, and cover the seed with 4 inches of soil. This arrangement will keep them down from the drought they may experience in July, and while surface-sown Peas would be suffering for want of moisture, these would be as green and fresh as possible.

RADISH.—The early ones in the frames are now ready. They are useful little roots and beautifully crisp. Do not sow again in frames, but place two or three short rows in on a border or any warm corner.

BROAD BEANS.—These have not suffered by the severe weather. Those sown in January are healthy, but several more rows should be sown, and if placed in like the Peas excellent crops will be the result. Two rows, 10 yards or 12 yards in length, will furnish many dishes.

SMALL SEEDS.—Manure and fork over a friable piece of soil, open drills in it at a distance of 10 inches or 1 foot apart, and then sow quantities of Cabbage, Cauliflowers, Leeks, Lettuce, and Brussels Sprouts; cover them with some good soil, and in a month or so hence they will be ready for transplanting to their bearing quarters.

SPINACH.—The winter Spinach has kept better than we ever saw it. The weeds have been drawn out of the rows, a little soot sprinkled between them, and plenty of leaves will soon be forthcoming to keep up a supply until the spring sowings are ready. A good sowing of the round-seeded Spinach should now be made. Give it a rich surface soil, and keep the drills 1 foot apart.

FRUIT FORCING.

VINES.—*Earliest House.*—The fermenting materials have been removed before the berries begin colouring, retaining however, about a couple of inches thickness as a mulch, and giving the inside borders a thorough soaking with tepid liquid manure. After the Grapes commence colouring ventilate as freely as possible, and gradually reduce the atmospheric moisture. The temperature should be well maintained in the daytime, 70° to 75°, with 10° to 15° rise from sun heat, allowing the temperature to fall through the night to 65° or even 60°.

Vines in Flower.—Keep up a steady circulation of warm rather dry air where Vines are in bloom, maintaining a temperature of 70° to 75° for Muscats, and 5° less for Black Hamburgs, allowing an advance of 10° to 15° from sun heat. All shy-setting varieties should be artificially impregnated, dusting the bunches carefully with a camel's-hair brush, apply pollen from the free-setting varieties to the stigmas of the shy setting sorts. We find it is a good plan to brush over the bunches of the latter first and then apply the pollen with another brush, the brush in both cases being used lightly.

Disbudding.—Do not attempt this until the bunches appear in the points of the shoots, and then it must not be done in a hurry nor a large reduction made at a time, but proceed gradually and rationally so as to give as little check as possible. Retain no more growths than will have

full exposure to light, as crowding the foliage is one of the greatest evils in Vine culture.

Stopping.—It is a safe plan to allow the shoots with fruit to extend three or four leaves beyond the bunches before taking out their points. The laterals from the leaves below the bunches may be rubbed off, or they should be pinched at the first joint, but those above the fruit may be allowed to extend until the available space is fairly furnished, then pinch them and keep them within bounds afterwards by pinching to each joint of growth as made.

Thinning.—A very important operation is this both as regards the bunches and berries. Remove all duplicate bunches before they flower, as it is hardly likely one bunch will set well and the others indifferently. Free-setting varieties may have the berries thinned as soon as they are fairly out of flower, but Muscats and other shy setters should not be thinned until it is seen which berries have been properly fertilised. It is difficult to give precise instructions for thinning, as the berries vary considerably in size in different varieties, and even different individuals of the same variety. Every berry should have room to swell without becoming wedged, and yet leave sufficient berries to ensure the bunch retaining its form when cut.

Watering, Feeding, Mulching.—Vines from the time they are started until the fruit ripens must not lack moisture at the roots. It is extremely difficult to state how often the borders will need watering through the borders being so variable in dimensions, in depth, and in their formation. A narrow border will need watering twice as often as one double the width, assuming the Vines to be equally extended and cropped, and a border of loose material will require water much more frequently than one formed of firm retentive material, consequently the cultivator must be guided by the state of the Vines in relation to their rooting area. The proper plan is to examine the border, and when water is necessary give a thorough supply. Surface dressings of the approved advertised artificials, and supplies of liquid manure may be given. The borders having been dressed at the usual season—i.e., whilst the Vines are at rest, a dressing after the Grapes are set about the completion of the stoning process will help considerably, the material as regards inside borders being at once washed in, or a good soaking with liquid manure at those times and when the fruit commences to colour will assure the berries swelling to a good size. In the case of Vines restricted to narrow borders higher feeding will be necessary, according liquid manure whenever there is need of moisture. Supply a mulching 2 or 3 inches thick of rather lumpy manure, the best being stable manure freed of the straw.

Late Vines.—Syringe Vines that have commenced growth several times a day, endeavouring to secure an even break by closing with a moist atmosphere at 75°, employing fire heat as may be necessary to secure a minimum of 55°. Vigorous young canes do not break evenly. To prevent a rush of sap to the upper part they should be brought into a horizontal position until all the eyes have started, when the canes may be brought up to the wires.

Young Vines.—Those planted last year and cut back to the bottom of the rafter or trellis at the winter pruning must be encouraged by gentle fire heat, so as to allow time for their making and perfecting a good growth. The laterals must have their points pinched out at the first leaf up to a height of 6 feet up the canes, which will cause the buds in the axils of the principal leaves of the canes to form fruit buds and become plump for next season's fruiting, but above that height may be allowed to grow.

Planting Young Vines.—It will require to be done early in April, and where provision has been made for inside and outside borders the Vines should be planted in the former, which will be sufficient for the first year, indeed a 4 to 6 feet width is quite ample in the first instance. The Vines, if cut-backs of last year, may be shaken out and placed in position either before or after they have grown to the extent of a couple of inches, the roots being disentangled and spread out evenly in the border, covering them about 3 inches deep, and watering moderately to settle the soil about them. Vines of the present year's raising will not need to be planted out for some time yet. They are preferably raised in squares of turf, and may be planted when the roots are protruding through the sides, or if in pots they should be turned out before they become root-bound. They will require to have a temperature at planting out suitable to Vines in growth—viz., 65° at night and 70° to 75° by day, with an advance of 10° to 15° with sun, but Vines of last year should be allowed to start unaided, syringing them two or three times a day according to the weather.

Vines for Early Fruiting in Pots.—Cut-backs of last year's raising should receive their final shift. The pots (12 inches in diameter) should be cleaned and efficiently drained, potting firmly in turfy loam, with about a tenth old mortar rubbish and a twentieth of crushed bones. Bottom heat is not necessary, but if they are plunged in it, it should not exceed 80° to 85°, and they must not remain in that so long that the roots enter the plunging material. Keep the house rather close, and if the weather be bright shade for a few days. It is essential that the canes be trained near the glass to insure the solidification of the growth. Pinch the laterals at the first joint, and subsequent growths treat similarly, stopping the lead at about 8 feet.

PLANT HOUSES.

Epacris.—Some of the earliest plants that flowered and have well started into growth may be repotted if they need it into a slightly larger size. The pots used should be carefully drained, and the soil, good peat and sand, pressed firmly round the old ball. Do not bury the

collar of the plant, and disturb the ball no further than is necessary in removing the old drainage from the base. After potting place the plants in a temperature of 50°, and stand them on some moisture-holding material. Syringe the plants twice a day when fine, but water the roots with great care. Plants that have flowered should be cut close back, and be placed in the temperature advised above until they break into fresh growth. Be careful not to crowd those in flower in the conservatory. More harm results to these plants while in such structures from the exclusion of light to the lower part of the plant and careless watering than from any other cause. Keep those required for late flowering as cool as possible, they will be better in a structure with a northern aspect.

Softwooded Ericas.—*E. hyemalis* and others that flowered early may be repotted without delay in the compost advised for Epacris. If they have commenced growth they are better in a perfectly cool house. They may be kept rather close for two or three weeks after repotting. If they were well pruned back after flowering the shoots may be tied out towards the rim of the pot. This not only keeps them well furnished at the base, but allows more room to the shoots to properly develop themselves. Stand them where they will have moisture at the base. These will bear the syringe without injury on fine days. Give abundance of air to *E. autumnalis*, and be careful not to syringe or to allow the air in which they are growing to become stagnant or overcharged with moisture, or they are certain to be attacked with mildew. If mildew appears dew the plants with the syringe and dust the affected parts with sulphur. Keep young stock as cool as possible. Give them plenty of air whenever the weather will allow of this being done. They may be transferred from 3 to 5-inch pots as opportunities offer. The sooner they are done the better, so that they will become established before drying influences surround them.

Hardwooded Varieties.—All young plants that it is intended to grow on should be repotted if they need it. If good sized plants are needed as quickly as possible it is a mistake to allow them to become root-bound before placing them into larger pots. Use good peat with plenty of coarse sand and a little charcoal in lumps, according to the size of the plants. After potting draw any shoots that are taking the lead towards the rim of the pots, which will give the weaker ones a chance and render the work of training afterwards easier. Keep the plants close when drying winds prevail, and be careful that the base upon which they stand be kept moist. Until they are rooting in the new soil bright sunshine may be shaded from them for a few hours during the middle of the day. If they can be stood in a position where shading is not needed all the better. Staking and tying established plants should be brought to a close as rapidly as possible. In tying regulate the growths so that the bloom will be as even as possible over the plants. Keep them perfectly cool, and give air abundantly.

FLOWER GARDEN.

Methods of Propagating Bedding Plants.—Where there are plenty of gentle hotbeds and well heated propagating frames various softwooded plants may be rapidly increased without much difficulty, but these are not by any means generally available. The cuttings require a good bottom heat, and to be kept close and shaded, or they are slow and uncertain in striking root. A well managed Cucumber or Melon frame is most suitable for propagating purposes. Failing any of these conveniences, any number of Iresine, Ageratum, Heliotrope, Verbena, Alternanthera, Abutilon, and Coleus cuttings may be quickly rooted in pans of sand and water set on hot-water pipes. They may be dibbled in as thickly as they will stand in the sand, the water being then poured in and kept renewed constantly. Plenty of roots are soon formed, and the tiny plants may be boxed or potted off as safely as those from cutting pots, taking care, however, to use rather fine and previously warmed soil. Leaves and tops of Echeverias and Sempervivums and Mesembryanthemums must not be kept close and hot, or the majority of them will decay. All these root most surely in sandy soil and set on a sunny shelf or staging in a warm house.

Plants to be Propagated.—Stoeky plants of *Lobelia speciosa*, or selections of the same, divide readily, nearly every little piece being already provided with roots. These may first be dibbled out thickly in boxes and set in gentle heat, and subsequently will develop into fine stoeky plants if bedded out in frames. The herbaceous *Lobelia* stored in pots or boxes are increased by division, plenty of suckers being thrown up from the old crowns. *Salvia patens* to be started and propagated similarly to Dahlias. The long fleshy roots of *Verbena venosa*, which have been kept plump in boxes of soil, may be cut into short lengths, two joints to each being sufficient, dibbled thickly into boxes of fine soil, and set in heat to strike. Every little piece will form a plant, the subsequent treatment being the same as that given the ordinary bedding Verbenas. Store plants of *Polemonium caeruleum variegatum* will now be forming fresh growth. These may be turned out of the pots and divided into as many plants as there are crowns. Pot them singly and keep in cold frames. *Centaurea candidissima* and *ragusina* after they have grown in heat for a time will yield a lot of cuttings. Every short side shoot may be taken off, dibbled thinly in well-drained pot or pans filled with sandy soil, and set on a shelf in forcing house. Shade from bright sunshine only, and water carefully. *Cineraria maritima* and varieties may be propagated in a similar manner or from seed. Tops of *Gazania splendens* will root in heat, but autumn-struck plants are the least trouble. The same remarks apply to the shrubby *Calecolarias*. Tops of Zonal and variegated *Pelargoniums* root most surely when dibbled thinly in well drained 6-inch pots filled with sandy

soil, these being set on the front staging of ainery not far from the hot-water pipes, and given water very sparingly for a time.

Seeds to be Sown.—Antirrhinums and Pentstemons ought to be sown at once on the surface of pans filled with fine sandy soil and only lightly covered. Set on a gentle hotbed, covered with a square of glass, shaded from bright sunshine, and never allowed to become dry, the seed will soon germinate, and strong plants that will flower this season be eventually obtained. If the first sowing of dwarf Lobelias has failed there is yet time to try again, and Tuberous Begonias sown at this time will flower in the autumn. Golden Feather Pyrethrum ought to be sown in pans, or a box of fine soil, and set on a gentle hotbed. If many small plants are required for carpet bedding, sow the seed in a single or double light frame set on a mild hotbed, thousands of plants requiring no pricking out being thus obtained. Ageratum and Petunias may yet be sown, seedlings of these growing rapidly. Where there are hot sunny banks or borders to be covered, single Petunias should largely be raised for these. Perilla nankinensis may shortly be sown, and also variegated Maize. A few pots of Mignonette and Sweet Peas should also be sown and placed in gentle heat, these duly hardened off and planted out being a long way in advance of any raised in the open. Asters, Stocks, Zinnias, Phlox Drummondii, Dianthus, Helichrysums, and ornamental Grasses germinate most surely in boxes or pans of fine good soil in heat, the plants being eventually pricked off in other boxes, or in frames. The Grasses may also be sown in the open where they are to grow; Ricinuses and Marigolds need not to be sown yet.

THE BEE-KEEPER.

FERTILE QUEEN INTRODUCTION.

THE art of queen introduction may be explained by considering the subject under two heads or cases—*a*, A stock of bees queenless; *b*, A queen subjectless. A stock of bees may become queenless naturally or accidentally, or may be made so artificially. Among the former cases a queen leaves the hive and is then subject to the dangers of being destroyed by birds, insects, or reptiles, or it may miss its way or may not be hived, &c. It may die of old age or disease, or may become a prey to some parasite. The weather, the time of year, or a lack of drones may be against the successful union of the sexes, and so make the queen useless and worthless—merging into so-called fertile workers.

Amongst the reasons for artificially deposing the queen may be mentioned the desire for a queen of greater prolificness, bees of greater amiability or other qualities, or of a different race.

When bees discover that they are queenless (either artificially or naturally so made) they at once set upon the work of raising a queen from any worker larvæ not more than three days old, provided virgin queens are not being raised. If they are rendered queenless while eggs or larvæ less than three days old are in the hive, and they begin to raise queens or build queen cells upon those, it is difficult to queen them, but still this is possible. The queen cells should be allowed to develop until a day or two before the queens are likely to hatch, and should then all be cut out—*i.e.*, the queen cells, and the place brushed over with carbolic acid solution except one cell, upon which the alien queen might be eaged after the larvæ or nymph has been destroyed. The queen may be liberated at dusk the next day. This deceives the bees so far as we are able, and causes them to believe their own endeavours have been successful.

There are objections to eages of all kinds—*e.g.*, the queen is confined, and so valuable time for egg-laying is lost; but this must be sacrificed for safety by this plan of introduction. There is an alternative method for those who object to cages, but which from very careful experiments I cannot do otherwise than condemn; in fact, I have not had a single success by it, nor have I known one by any of my friends who are keen and careful observers. It has been denominated "Pond's," sometimes "Simmins'," method; at present I have not time to describe it. I will, however, say, as "Felix" has just been treating on the subject and giving instructions for doing "Pond's" or "Simmins'" plan, that last year I experimented with a great number of queens on "Simmins'" (?) system, and in no instance did I find the queen missing on the third day, though fully half were on the tenth day; therefore the system seems a very valuable one for queen dealers, as they can guarantee safe introduc-

tion, telling their customers to look on the third day to be sure, and yet prepare to send them another on the fourteenth, by which time she will be lost in some unaccountable manner.

Often these queens will drop a few eggs, and through some peculiar instinct of the bees these eggs are often, if not always, selected to rear the fresh queens from; therefore if the apiarist is busy, and does not happen to frequently examine the hive, taking things for granted, he will have a hybridised daughter reigning, and think she is the one he introduced, if he had not marked her. I might also say I have several times, upon the ninth day, found the poor queen upon an outside comb in a starving condition quite alone. Upon microscopic examination, in a few cases, a very poor condition of the ovaries has presented itself, through neglect by the subjects, although in other cases neither neglect nor disease could be traced. Moreover, I have for some years, upon quite a number of occasions, tried the "Hallamshire law," and having tried this at various periods of the year, I can truly say, provided the instructions are faithfully carried out, a "fertile" queen presented, &c., I have never found this method fail, and I have staked some expensive and pet queens on it. I do not, however, like the idea of withdrawing all the new laid eggs and unsealed brood, which is so very necessary, but "the shortest way across is the longest way round." Nevertheless the Hallamshire law is based on natural lines, while the other cannot be reconciled at all, except that we might consider the alien undergoes such a state of subjection, or fright, and hunger, that she is glad to set to board and lodging, but this we can plainly see drives her into such a gone-back egg-laying condition, that she is, sooner or later, rendered quite unfitted for her motherly duties.

I have been very successful by a method that can be used at any time of the year—I allude to the method of shaking the bees off their combs in order to get them into the condition of a swarm. This exposes brood to the atmosphere unless performed in a manipulating house, but of course eggs could perhaps be fixed in some other hive in the apiary in the case of this method, as also in the Hallamshire law.

With regard to the "Hallamshire law" and the reason why bees prefer eggs or larvæ to raise their own queens rather than accept a strange or alien queen. I have often thought that the force of habit is too often either not recognised or overlooked in dealing with bees. All my experiments in faithfully trying Simmins' proposed method of queen introduction have resulted in the desired queen being "put out of the way" when means of raising a successor were present in the hive, for the bees have invariably raised a queen after their own will. I have carefully marked a few of those queens and have watched the proceedings of the bees most attentively; in fact, I believe Burnens could not have been more attentive, and the finale has each time been the same when eggs or larvæ have been in the hive at the time of introduction. As I have already stated, immediately the cluster is broken to withdraw the queen to substitute an alien the colony is disorganised. I might say I have never placed another queen on the identical spot the original queen was parading at the same moment of removing it. There is no doubt about the bees sometimes suffering the queen to remain within the hive apparently uninjured for a period of time when ushered in upon the Simmins' or Pond's system. This period I have not found to exceed nine or ten days; the poor insect gradually moving from comb to comb to the outside of the cluster, there to perish and be carried out of the hive, though sometimes it is highly probable it may leave the hive alive through lack of homage. I have observed the bees carrying the deceased queen out, and I have seen the queen take refuge from one hive to another. It may be interesting for me to relate that I have on these occasions found alien queens so acting in this latter manner, and that in each case, although the queen entered another hive, a few bees seemed to accompany, but their courage or love seem to falter as they clustered on the handle of a garden spade, on a post, and on a pea stick on each occasion respectively. In each case the alien was balled on the

floorboard, and no doubt would soon have been despatched had I not rescued them. As they receive so little homage they thus quickly present the appearance of non-laying queens and are nearly as capable of flight, as no partly or wholly digested food is offered them (the food bees feed the queen with being about the same as they feed to the brood.)

But why is she superseded? It is no use saying dethroned, as she never had the honour of reigning. Of course I am now speaking about alien queens, and if she was in a stimulated condition eggs would be deposited or dropped, and while there is an egg in the hive (whether queen cells are present or not) the bees will try to develop it into a queen, so that if the first started cells were on the old brood the new queen might destroy them as soon as they become nymphs. Then if she left the hive in disgust or because she got no homage, why of course a daughter of hers takes her place.

I have found by repeated experiments that as soon as a queen is taken out of a seam of bees, operations are commenced to raise a mother bee, and by even placing the queen on to another frame these operations will be commenced. Sometimes she will then be crushed to death. By means of the so-called dummies a number of queen cells may be started and completed in the same time, providing each cluster is separated. I do not mean cork packed or great thick dummies, but perforated zinc. The main point being to place the queen on to a different frame after a few eggs are laid in a few cells. But why is she not destroyed on the new frame? Simply because the whole family is working in natural harmony or habit. It is the habit for the queen to move from frame to frame; but mark well, it is not the habit of the queen to do so until the whole of her business is transacted upon that particular frame, hence the break appearing it is the habit of the bees to perform the operations of raising a new queen. During the summer so many of the brood cells become clogged with stores that the queen wanders from comb to comb, which causes the same thing to be done, hence the swarming fever. The queen gradually becomes of a non-laying appearance and quite capable of flight, owing to the want of the necessary amount of feeding and attention she should have to keep up her former state, and leaves the hive as an insect a little removed above the habit of a worker. If this is not so, for why do they do it? Moreover, no attention is paid to an alien, as it is not her, or the custom, fashion, or habit for queens to be carried from one hive to another.

Now, suppose there are no eggs in the hive, how can the bees raise a queen? They cannot do it. Place a frame containing a few eggs into the hive. Why do the bees recognise this gift? It is their habit to obtain all they can, which we all know perfectly well; and as I have already stated it is their habit to raise a successor from the egg. They therefore gladly commence operations upon this frame of eggs. The same conditions as above being present—i.e., in a disorganised state.

Now, suppose the whole of their eggs and means of raising a new queen are withdrawn, or more naturally their queen dies in a state of nature perhaps there is at no time of the year a hive without eggs in a normal state. If this death happen at a time when fertilisation cannot be obtained the hive died out, or else should a fertile queen, say at mating or swarming time, fly to this hive, the habit is (we challenge anyone to contradict this) that this queen is accepted. Hence the Hallamshire law is on natural and correct lines. I have no hesitation in saying from my own experiments that if the law is truly and faithfully tried it will invariably succeed, excepting those few persons who believe and state their own way is best, and who omit or cannot discern some of the particulars and conditions of the Hallamshire law.—T. BONNER CHAMBERS, F.L.S., *Tref Eglwys Caerows, Mont.*

TRADE CATALOGUE RECEIVED.

Rawlings Bros., Old-Church, Romford, Essex. — *Catalogue of Dahlias.*

••• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Shorthand (G. H.).—The work to which you refer can be obtained by ordering through any bookseller in your locality.

Oncidium undulatum (H. S.).—Many thanks for flowers and list, but they arrived too late for a note this week. They shall have a paragraph next week.

Stove Climbers (T. S.).—Four good plants for training up the roof of a stove are *Stephanotis floribunda*, *Allamanda Hendersoni*, *Dipladenia Brearleyana*, and *Bougainvillea glabra*.

Chrysanthemums (R. Crossling).—We have received the blooms, which will be referred to when your letter is published. It is too late for this week. Your experience is interesting and the results of it satisfactory.

Repotting Orchids (S. J. A.).—Letters arriving on Wednesday cannot be satisfactorily answered in the current issue. Do not disturb the plants at present. Information will be given in time to be of service to you.

The Eucharis Mite (M. C.).—The bulbs are undoubtedly infested with the mite, and are in an extremely bad condition. The prospect of their recovery is very small, but we shall publish something further on this subject shortly. No doubt low temperature and excessive moisture often cause a very unhealthy condition in these and other heat-loving plants.

Abutilons (E. M.).—The dark coloured seedling is a very good one, and well worthy of preservation, but we have seen others quite as dark in colour. If you exhibited well grown plants of the seedling and parent they might receive some notice from the Floral Committee, but you had better write to Mr. A. F. Barron, Royal Horticultural Society, Chiswick, who will advise you where they should be sent. There is a meeting on the 27th inst.

Piping for Heating Greenhouse (A. B. C.).—You give no particulars regarding the form or size of the house, which makes a considerable difference in the piping required, and the heating is also considerably influenced by the arrangement of the pipes, also by external surroundings. To heat 2600 cubic feet of air, and maintain it at a greenhouse temperature in all weathers, you would require about 80 feet of 4-inch pipes. N.B.—Your second letter arrived too late for this week.

Megarrhiza californica (Regular Subscriber).—The plant is of little horticultural value, but is interesting to a certain extent botanically, chiefly for the enormous root it produces, from which character it derives its generic name and also the popular title Californian Big-Root. It is of trailing or climbing habit, not unlike the common Bryony, with lobed leaves, inconspicuous flowers, and roundish fruits covered with soft spiny projections. The seeds should be raised under glass, but the plants can be left out of doors if protected in winter.

Insects on Peach (Shillingstone).—As your specimens travelled to us in a cold drying wind they reached us in a shrivelled condition. It is preferable to enclose such small insects in a glass tube or tin box, with a little bit of damp moss. The insects appear to be a species of Psylla or Chermes, a pest resembling the Coecus or scale insect in its habits, but of somewhat larger size. There are several kinds not unfrequent in houses, and they are readily killed by tobacco in the form of fumigation or wash. Some have strongly recommended for their destruction a wash containing softsoap and sulphur, applied moderately warm.

Cucumbers and Tomatoes (Cambridge).—We have seen excellent crops of Cucumbers and Tomatoes grown in the same house; but not when the latter were much shaded by the former. The plants must have both light and air, or they will not bear good crops. Cucumbers are equally well grown with "little or no ventilation," and with sufficient to enable Tomatoes to prosper; but we are not certain that a person who had been accustomed to either routine exclusively would succeed equally well the first season with the opposite. He might or might not, so much depending on individual aptitude. Perhaps you will proceed the most safely by not materially lowering the temperature for the

Cucumbers, as they proved the more profitable, and let the Tomatoes take their chance, as, if they produce half a crop, this added to a full crop of Cucumbers, would leave you a gainer; but if you by a compromise materially reduce the Cucumber crop, and fail—as you may do—to have a full crop of Tomatoes, you would perhaps lose by the enterprise. Excellent crops of Cucumbers may be had from plants in tubs 2 feet square; but Tomatoes do not require nearly so much room. It appears you will have one house as liberty in the autumn. Tomatoes grown in pots plunged in the garden would probably set good crops of fruit that might nearly ripen outdoors, and would finish in the house if the plants were removed to it after the Cucumbers ceased to be profitable. See an article on the subject on page 167, in our issue of the 1st inst.

Vines and Plants (J. E.).—We are not able to state “the highest temperature to which Vines may be safely exposed during winter and early spring and yet remain in a state of rest,” as much of necessity must depend on the hygrometrical state of the atmosphere. With a dry air they will rest for a long time in a temperature between 45° and 50°, but a very dry air is not suitable for several plants, and we do not advise amateurs to run as near the danger line as possible. Ask a nurseryman to supply you with “planting canes,” and those of the right size will be sent for that purpose, and treat them as advised last week, planting when they start growth if the border and house are ready for them. The easiest way of raising Lobelias and Petunias is to sow seed in August in a frame, or even outdoors with the pots or boxes shaded from bright sun and protected from heavy rains, wintering the plants either in small pots or transplanted in boxes, on a shelf in a cool house, a vinery at rest answering very well. Half-hardy annuals, such as Stocks, Asters, and various others, may be sown in April, as the temperature of the house must then be warm and genial for the Vines that will have started into growth. Thousands of such plants are spoiled every year by raising them too soon, or keeping them too long in warm houses before they can be placed in cool frames or the open air. Your warm case will no doubt be useful, but if seedlings or rooted cuttings are kept too long in it they will spoil, and a second cooler frame in the house would be very useful for their reception in preparing them for full exposure. Apply the fertiliser at the rate of from 2 ozs. to twice that quantity to the square yard, according to the nature of the soil, as obviously that which is poor needs more than that which is fertile. It may be applied in the same ratio to the soil of Vines in pots when they need extra support, commencing with the smaller dressing, increasing the supply as the advancing growths deprive the soil of its fertility. No rigid rules can be laid down equally applicable under all circumstances, and the action of cultivators must be guided by intelligence.

Gardenias Unhealthy (A. Black).—It is very difficult to say exactly what is wrong with your plants from the very limited information afforded us. We can find no trace of insects upon the roots sent, but mealy bug has infested the foliage. If you syringed them towards the close of the year with a strong insecticide the evil may in part be traced to that source. Some years ago we saw a number of Gardenias that had been syringed with a strong solution of petroleum, precaution not having been taken to prevent its entering the soil; the result was that it destroyed the whole of the fibres, consequently the growth was at once arrested. The plants were being forced in a high temperature, and they soon afterwards looked as if they had been grown in semi-darkness. The roots of Gardenias occasionally have a knotted appearance, and this is usually the most conspicuous when the roots have been subjected to extremes of temperature. Too high a temperature in the soil would bring about the swollen condition of the roots, while top growth would be checked. Other causes will also result disastrously. For instance, too liberal supplies of cold water. This is very liable to happen when Gardenias are planted out, especially if they have a good depth of soil in which to root. Evils arising from this cause would scarcely be perceptible during the summer, but generally show before the winter is over. Excessive applications of liquid manure will also destroy the roots. In this case soot water would do no good, but, on the contrary, add to the evil. We presume the peat used was good, but we have known failure arise by a too free use of samples of inferior quality. If the loam contains too great a per-centage of lime Gardenias will not thrive, and we have seen the growth very similar to that sent. You had better shake all the soil from the roots of the plants and pot them in as small size as it is possible to place them in, using plenty of sand in the compost. Start them into growth in a close moist temperature of about 65° at night, with a slight rise by fire heat in the day, allowing the temperature to rise as high as it may from sun heat. Syringe liberally, but apply water sparingly to the roots. If practicable, plunge the pots in a bottom heat of 75°, and cover the surface of the soil and rim of the pot with the plunging material. When they are rooting freely, if you think it desirable, you can prune them as closely as you desire for producing dwarf well-furnished plants.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (B).—1, *Sericographis Ghiesbreghtiana*; 2, Cannot be determined from a crushed and flowerless fragment, but it resembles a strong shoot of *Fuchsia procumbens*. (A. A.).—1, *Diplacus glutinosus*; 3, *Eurya latifolia*; 4, *Begonia fuchsoides*. The Ferns cannot be named without

spores. (B. R. T.).—Your specimens are excellent ones, and we name them with pleasure. 1, *Davallia canariensis*; 2, *Adiantum Williamsi*; 3, *Asplenium eicutarium*; 4, *Trichomanes radicans*; 5, *Selaginella Wildenovi*. (E. R. W.).—The flower suffered considerably in transit, but it is probably *Aspasia lunata*. It is not rare, nor is it very common, but a variety known as *superba* is far superior to it, and consequently more valuable.

COVENT GARDEN MARKET.—MARCH 21ST.

Trade has been very dull during the past week, and will continue so till the Easter holidays are over, the only demand being for good well kept Apples.

FRUIT.

RESULTS—FORMULÆ OF MANURES FOR CROPS.

THAT the last three years have been unfavourable to the progress of agriculture all will agree, but that they have been unfavourable in much more than a general sense may not be so apparent to an ordinary observer, yet there can be no doubt that

such seasons of drought as we have lately had tend materially to curtail the yield of several of our most important farm crops. Attempts, therefore, at improved methods of culture have in several instances only met with partial success. Results have, however, been sufficiently remarkable to encourage those of us who have been engaged in such important work to persevere, and in so turn the lessons of adversity to account as to insure a full measure of success in the future.

Only a few years ago did Lord Salisbury recommend farmers to "manure their land with brains," or, in other words, to use their wits, and see if they could not so alter and improve their practice in the selection and application of manures as to combine economy with efficiency in a better manner than had hitherto obtained among them. Quite recently another noble lord, who had read some of our notes on the use of chemical manures, owned to us, that while not having such entire faith in them as we had, he was free to admit their high value, and to own how wasteful and extravagant the manufacture of farmyard manure was, and how much of the goodness of every muck heap was known "to steam away, and stream away," in the form of liquid manure running down the roadside, and of volatile gases lost in the air.

It is not sufficient, however, to point this out to the ordinary farmer and to tell him we have a cheap and efficient substitute for his costly manure heap. He requires tangible proof in the form of a heavy crop and profitable balance-sheet, and it was to afford such proof that various associations have been formed in so many parts of the country. Of work so done, none which has come under our notice is more thorough and exhaustive than that of Messrs. F. J. Cooke, G. Taylor, and B. B. Sapwell on their farms under the auspices of the Norfolk Chamber of Agriculture. In a summary of results in the report of the experiments of last year they say, "We may pretty safely claim to have shown that the best and most economical artificial manure for Barley upon a good deal of light soil in Norfolk, from which Turnips have been drawn, is 2 cwt. superphosphate, half to 1 cwt. muriate of potash, and 1 to 2 cwt. of nitrate of soda per acre; or three-quarters to 1½ cwt. sulphate of ammonia in place of the nitrate of soda when its market value is lower per unit of nitrogen. The same dressing is applicable to Barley after a previous white straw crop when such is taken. Where a part only of the Turnips have been so lightly folded with sheep as to suggest further assistance for the Barley, or a heavier folding is made very early in the year, nitrate of soda only, up to 1 cwt. per acre, will probably be the most suitable application. A complete manure for Swedes, and an economical one upon the kind of land mentioned, is 2 to 4 cwt. superphosphate, 1 cwt. sulphate of ammonia, and half cwt. muriate of potash per acre, or with five to six loads of good rotten muck the superphosphate alone would be sufficient. A mixture of bone flour with the superphosphate—half cwt. of the former to 4 cwt. of the latter—will insure better distribution (a matter of very great importance) if nothing else.

For Mangolds we have, so far, found the most economical dressing to be 2 cwt. nitrate of soda, half to be applied at time of drilling seed, and half as a top-dressing after singling the plants, with 3 cwt. common salt—or instead of the salt 1 cwt. muriate of potash—the mixture to be used with, or without, five to ten loads of rotten muck per acre. Without the dung in a good season, 4 cwt. nitrate of soda per acre, sown as before, might be justified in the return, the Mangold being a very gross feeder. As hundreds of pounds are annually spent upon superphosphate for this root, and we have not found it to be wanted upon well-farmed light land, the information on this one point alone should be worth much more than our outlay.

A dressing of 1 cwt. muriate of potash, where it pays at all, will pay well upon Clover or Sainfoin, especially when applied at time of sowing the seed; but there are probably few well farmed soils upon which it is of much service for these crops, and therefore great caution should be exercised in using it.

To an expression of some hesitation in thus offering formulæ based upon the results of two years' experimental investigation, they very wisely add, "We are sure they will be more accurate guides than the chance mixtures of the manufacturer as labelled for special crops, which are for the most part compounded on no principle at all, unless it be one of profit to the vendor." This is entirely in accord with our repeated advice, that all manures should be procured separately and mixed at the farm. Common sense shows such advice to be sound, yet it has been termed "an unwarrantable aspersion on the honesty of manure traders," who, by the way, are generally most positive in their assurances of the virtues of their mixtures. Surely we have a right to be equally positive in only spending money upon manures of our own selection for farms.

(To be continued.)

WORK ON THE HOME FARM.

Work on the land has been much hindered by broken weather, and very little corn sowing has been done at the time of writing this note. This has proved a serious matter where a large staff of labourers is maintained, as the outlay involved in finding work for them is by no means desirable now that every item of expenditure has to be watched so narrowly. But where the chemical manures have been applied to winter corn and pasture good work has been done, for the manure has been dissolved and washed in, and we may now feel certain of a full crop of hay and brisk robust growth in the corn. If when the spring corn can be sown not a day is lost in doing it, germination and growth are certain to follow so quickly that the late sowing may prove advantageous rather than otherwise. Well will it be, therefore, not to press forward the sowing before the land is dry enough to admit of a fine deep tilth being had to thoroughly cover the seed. On light land some sowing has been done, and light land farmers certainly are favoured in being able to work upon the land so soon after the rain is over. The exercise of a little patience will, we hope, enable heavy land farmers to get in the seed in time to ensure a good plant, and with a favourable spring we feel hopeful all will come right. Farmers, however, more than other men have need to be hopeful, patient, and persevering, for however carefully and well their plans may be made they are still very much at the mercy of the weather.

Never was there a year when a forward spring would have been a greater boon to flockmasters than the present one, for many of them are at their wit's end what to do to procure food for the sheep. No Turnips, no Mangold, no grass, a short supply of straw and hay, what are we to do? This is the cry of many a farmer, especially on light land; certainly to purchase food now for the flock is a ruinous proceeding, and yet how many are doing so! Glad are we to be able to report a successful lambing season, and that the lambs are making satisfactory progress. They are now folded upon Turnips with a frequent change for a few hours upon pasture, and although the Swede tops have suffered from frost, white Turnip tops have not done so, and the lambs are able to run forward upon them. Chaff and crushed Oats are given in troughs to the ewes, and the lambs have what lamb food they can consume in a given time, as we altogether object to having any stale or sour food in the troughs. We have only lost one lamb from a stoppage by wool balls, and cautioned the shepherd to remove all loose wool from the ewes' udders to prevent the lambs getting it in their mouths by mistake as they are so apt to do.

REMARKS.

11th.—A violent westerly gale all day, with frequent rain.
12th.—Dull and damp early; cloudy day.
13th.—Cloudy and cold, with one or two slight falls of snow and sleet; heavy fall of snow after 7 P.M.
14th.—Morning generally dull and showery, but with one or two breaks of sunshine; afternoon generally bright till a thunderstorm from 5.5 P.M. to 5.55 P.M.; showery evening.
15th.—Rain early, and dull and damp till 10 A.M., then bright and beautiful.
16th.—Rain in small hours; a little snow at 7.50 A.M.; dull, damp day, with slight showers of fine snow and rain.
17th.—Fine at times, but with frequent sprinkles of snow.
With the exception of one day, a week of unpleasant winter weather, with frequent rain and snow, and very little sunshine. Range of temperature considerable, but the mean nearly up to the average.—G. J. SYMONS.

WATERING.

IF asked to mention the one most important point in the cultivation of plants in pots, I should unhesitatingly say it is watering. It is all-important that the application of water to plants be thoroughly understood, for without a proper knowledge of their requirements in this respect, no amount of attention to other particulars can make their cultivation a success. In too many instances the watering, or a great portion of it, is left to inexperienced hands, and frequently the consequences are too apparent. It cannot be too strongly impressed upon the minds of young men that a thorough knowledge of this very important point in plant culture is absolutely essential to success, and consequently that they cannot pay too much attention to it. The requirements of different plants must be studied, and also the nature of the soil employed in potting, particularly the loam, which varies so much in different localities; so much, in fact, that a change of situations is frequently almost equivalent to beginning to learn afresh the art of watering. In some very heavy soils it is absolutely necessary to let it reach a state of dryness before applying water, that in less retentive soils would be dangerous. Thus it is mistakes are frequently made by young men, after being accustomed to a light soil, having to deal with a heavy one, or *vice versa*.

We frequently read of certain plants said to require an abundance of water, and I always think such statements misleading, especially to inexperienced persons, for few plants require water until the soil is nearly dry. By dry, I mean when there is not sufficient moisture left to prevent the plants flagging, which no plant when growing should ever do; but in heavy soils the nearer they approach that state the better for the plants—at least most plants. There are some exceptions, and amongst them I may mention Ferns during active growth when the pots are filled with roots. Then, with some strong-growing species it is almost impossible to give too much water, and to allow them to get as dry as some plants require to be would insure a check, and probably disfigurement of the fronds, which would be apparent throughout the remainder of the season. A plant of *Nephrolepis davallioides* furcans we had here last summer, quite 8 feet in diameter, in a 14-inch pot, was supplied with water four times on every hot day, treatment it plainly indicated it liked. Some growers advocate keeping Ferns dry during winter, but I am convinced it is a mistake to do so; others say that because they receive most water in winter when growing in their natural homes, it is proof conclusive they should be kept wetter at this season when grown in pots, but it is as easy to err on the wet side as by keeping them too dry. They should be allowed to get drier than when growing freely, but not so much as to cause them to flag, for that is decidedly injurious to Ferns at any time of the year.

Anthuriums are plants that may safely be said to require an abundance of water, for when potted in suitable material they delight in an almost unlimited amount of moisture both at the roots and in the atmosphere. A compost we find suits these plants well is one-half good peat fibre, the small shaken out, and one-half charcoal and broken crocks, with a surfacing of living sphagnum.

Going to the other extreme, it may with equal certainty be said that Hedaromas, Leschenaultias, Pimeleas, *Dracophyllum gracile*, and Heaths—especially the hardwooded, slow-growing varieties of the aristata section—with other hardwooded greenhouse plants of

a like nature, require more careful attention in this respect than any other kind of plants generally grown. If a *Pelargonium* or a *Fuchsia* becomes so dry that it flags, or if it is kept too wet for a time, it will recover, although injury has certainly been done it; but subject any of the above-mentioned plants to such treatment and they are worth but little after; for even if they do not die outright they are ever after miserable-looking objects. It is greatly to be regretted that those good old plants should have been allowed to go out of cultivation as they have, for they are second to no class of plants for beauty when in flower, not even excepting Orchids, with all due respect to those lovely flowers. At the same time they require a greater amount of skill to grow them to perfection, thus rendering good examples doubly valuable in the eyes of the cultivator. But I fear their day is past, principally because of the great demand for cut flowers in most establishments at the present time, for supplying which they are not so well suited as the softwooded, free-flowering plants. Even among these there is a great difference in the amount of water they require, or, rather, in how dry they may be allowed to get before water is applied. Take, for instance, the Heaths. The softwooded varieties, such as *hyemalis*, *Wilmoreana*, *Cavendishiana*, or *Eweriana superba*, must never be allowed to get so dry as some other varieties with shorter harder wood absolutely require to be kept, or their growth will be seriously checked.

Azuleas also suffer very much if carelessly watered. I am inclined to think the loss of leaves so frequently noticed in the winter is mainly owing to their getting dry during some period of their growth; not necessarily at or near the time the leaves fall, but probably some time before.

Mignonette is very impatient of too much water at the roots. If wintered in a cold house where in severe frosts the temperature is allowed to fall to 35° at night, very little water is required from November to February. Our plants of this were kept in a cold frame—matted to keep out frost—this winter, and are now growing freely on a shelf in a cool house.

Too much water is often the cause of *Primulas* decaying at the "collar," though some who lose their plants in this way do not care to acknowledge it. There are few plants that require more careful watering than *Primulas*, particularly the double varieties that are propagated annually from cuttings, and being rather more tender than the singles are more liable to damp off.

Strawberries in pots, more especially such as are forced very early, will soon show only too plainly the results of negligent watering. The majority of ill-formed fruits (ill-formed through being imperfectly set) are the result either of allowing them to get too dry or keeping them too wet when in flower. Examining them frequently and giving water only to such as absolutely need it is the only way to ensure a good set of perfectly formed fruits, all other conditions being favourable. Another time of the year when Strawberries are apt to be over-watered is after they are shifted from the small pots they are layered in into their largest size. If the balls of soil are wet when potting is done, as they should be, and they can be stood in a shady place and freely syringed every evening, this will generally suffice until about a fortnight after, when they may be removed to more exposed quarters and given a thorough soaking.

It is after being newly potted that plants usually receive most injury, and then it is necessary to exercise the greatest possible care, for if given too much water the new soil becomes sodden and sour before the roots have established themselves in it, whilst on the other hand there is great danger of the ball of old soil becoming so dry that the water given will not penetrate it, the consequence being great injury to the plants, and in many cases death. It is a good plan to frequently syringe newly potted plants, and so prevent their requiring water for as long a time as possible. In the case of plants that must not be syringed, such as Heaths, they should be kept shaded, and the staging and pots syringed to keep a moist

atmosphere until they have somewhat recovered from the check all plants unavoidably sustain in the operation of potting. Hedgeromas are particularly liable to die after repotting, and without any apparent reason, but I believe it to be due to imperfect watering. The behaviour of this genus is very unaccountable, the most experienced plantmen losing them at times, and being quite unable to give any reason for their dying.

The addition of charcoal to potting compost is a practice that cannot be too highly recommended, for it not only keeps the soil open and porous, but also acts as a storehouse for food for the roots, and should be freely used when possible for all plants. In the absence of charcoal broken crocks may be used, and will be found an excellent substitute; but no matter how good and suitable the soil, no plant can thrive if not properly supplied with water.—
C. L., *Br'stol.*

ROYAL HORTICULTURAL SOCIETY.

I WAS glad to see the remarks of your correspondent, "A Surrey Amateur," on the unsatisfactory awards made by the Floral Committee. Had I not been unfortunately laid up for the past month I should have brought under the notice of the Council the case of *Dendrobium Cooksoni*, which I remember well was exhibited by Mr. Cookson about two years ago, when it was not thought worthy of recognition. I notice in your issue last week that this Orchid has since been discovered to be a hybrid between *D. nobile* and *Falsoneri*, raised at Heathfield House, Gateshead, and was received by Mr. Cookson in exchange. I hope as soon as the new by-laws have been settled by the Council that the question of the advisability of splitting up the Floral Committee into sections with a chairman for each section will be discussed. I hope to see at least an Orchid committee tried, who should not only award first-class certificates for plants of horticultural merit, but they should also grant a botanical certificate to all new plants when exhibited for the first time, and that the functions of the nomenclature committee should be revived, and should again become a prominent feature of the R.H.S. meetings. I hope horticulturists throughout the country will freely express their views on this subject, either in the horticultural press or to me personally. I should like to see definite rules laid down for the guidance of every committee, and that they should send a report to the Council after each meeting of the plants and fruit which they have had under their consideration, and their reasons for giving or withholding certificates and medals.

To your correspondent, "One in the Provinces," I hope hereafter a plan may be devised by which gardeners who become associate members shall on election receive a diploma, and I trust that the day is not far distant when candidates for the diploma will be required to give some satisfactory proof that they are worthy of election; but I must urge upon all who value the advancement of horticulture throughout the British islands to actively support the Society, not only by exhibiting the wonders of their gardens, but also by becoming members of the Society. Unless the Council is supported and funds forthcoming they will not be in a position to make Chiswick the success that I for one should like to see. At the present time the Council is more or less crippled by want of active support. Many things require to be altered. For this year at least all measures must be of a tentative character. Let horticulturists say what they want and support the Council with funds, so that they may be able to carry their wishes into effect.

It is my impression, in answer to "A Fellow of the Society," that there were two or three exhibitions in the gardens of Finsbury Circus. At one at least Royalty no doubt did give away the prizes, but I think the Rector of Bishopsgate gave them on other occasions. I believe the reason that these exhibitions were given up was not for want of funds, but because certain inhabitants of the Circus objected to them on account of the damage that was done to the croquet and tennis lawns. If my memory serves me right I think that the entrance was either 1d. or 2d. after six o'clock. I believe 3000 or 4000 persons attended each Show. I did trust arrangements could have been made last autumn with the Treasurer of Finsbury Circus by which shows of the R.H.S. might have occasionally been held in the gardens, but unfortunately nothing came of the negotiations. The suggestion about opening the garden at Chiswick when the fruit trees are in flower is worth consideration, but I am afraid that it will not prove so attractive to the public as your correspondent thinks. I think we shall have to advertise the meetings in some popular manner. I have met Fellows of the Society who were not even aware of the day on which the fortnightly Shows are held. I fear that I have trespassed on your space in endeavouring as briefly as possible to show that the Council are

not unmindful of the consideration of matters, while they hope to be able to place the Society again in the proud position of the first horticultural society of the world—A. H. SMEE.

[In this hope we join, and bespeak for the Society the support of those amateurs and professional gardeners who are in a position to become Fellows or Associates under the new regulations. See pp. 215-216 of our issue of the 15th inst.]

EUCCHARIS CULTURE.

OF late there have been in the pages of the Journal numerous notes on the Eucharis and its cultivation. As this deservedly favourite flower is grown in almost every garden under almost every possible condition, so must the experience, and consequently opinion, of each individual grower, necessarily differ somewhat from that of others; hence an interesting controversy, which if conducted amicably can have no other than a happy result, for these records of the experience of practical men are valuable in that they show the good results that may be obtained from widely different methods of treatment.

In my note book I have a few facts appropriate to the subject and of interest to gardeners, which are as follows:—In a garden which I often visit there are several pots of *Eucharis grandiflora*, which are the healthiest and best I have seen. They are growing in a loamy compost in 12 and 16-inch pots, which are so full of bulbs that they are literally crowding each other out. They are well furnished with dark green leathery leaves, some of which measure upwards of 2 feet from base of petiole to apex of blade, and 8 or 9 inches across the latter. They bloom profusely twice, and sometimes thrice a year. They have not been potted for five or six years, and being very much rootbound require and receive liberal supplies of water. They also each occasionally receive a haunful of dry sifted manure from the fowl house. During the winter they are kept in a temperature ranging from 50° to 65°, and throughout the summer months they have no artificial heat whatever. In a great measure they are left to take care of themselves, and they appear to do it very well indeed.

Undoubtedly the Eucharis in course of time, to some extent, adapts itself to the conditions by which it is surrounded—in a word, it makes the best of its opportunities, and thus affords to mankind generally a very salutary lesson. This remark applies to all cultivated plants, whether temperate or tropical, indigenous or exotic.

Apparently some gardeners, in their zeal to grow a plant well, fail to grow it at all. They seem, if one may judge by the way in which they treat the subject, to be imbued with the idea that growing a plant is an operation analogous to making a fire, requiring much personal attention and much fussing and poking about. As a matter of fact, plants are not at all so obstinate as these people would lead anyone to understand. They require neither force nor persuasion, but simply permission to grow—that is to say, they are only too happy to do their own growing, if no insuperable obstacles are placed in their way. It is the work of the cultivator to find out what these obstacles are, and to remove them. When he has done this the plants will grow and thrive without the aid of any exterior assistance.—G. B.

FERTILISATION OF EARLY PEACHES.

IN a recent number of the Journal a correspondent finds he can dispense with artificial fertilisation for his Peaches. I wish I could record a similar experience, for we could avoid a very tedious operation. But I think if artificial means were used more generally for the early houses we should hear far less about light crops. I am afraid the majority of gardeners could not leave the front ventilators open and still command a night temperature of 50° or 55°. During sunny weather the blooms may set well by merely tapping the trees, for the pollen is then light and dry, consequently it will fall well; but I fear sunny days early in January are more imaginary than real. I have used a camel-hair brush and a rabbit's tail for several years now, and have never seen a light crop follow, but I have seen many failures in the early houses where the tapping system alone had been used. I think it far safer to insure a crop than trust to mere chance. No doubt much depends on the house where the trees are grown in, also the position, for it is an easy matter to keep a light buoyant atmosphere in some houses, while in others during dull weather it is nearly impossible.

Again, the varieties grown must be taken into consideration. The small-flowered varieties, such as Royal George, generally speaking, bear abundance of pollen, while those of the Barrington, or large-flowered section, do not bear nearly so much. It would be interesting to hear if many of your correspondents can trust to the system advocated by "S. T. C.," I fear not. It may be the same

as the Grape-fertilisation question advanced by Mr. S. Castle, who finds artificial fertilisation necessary at West Lynn, though he never had to resort to such means before. Even with carefully fertilising the blooms I cannot echo "S. T. C.'s" words, that he has not noticed a single flower in the early houses that has proved unfertile.—JAMES B. RIDING.

CELOSIA PYRAMIDALIS COCCINEA.

THIS is a very effective plant, the scarlet plumes being most telling when intermixed with other plants having flowers of lighter shades of colour. It may be had in flower all the year round by sowing a pinch of seed early in February, and again in August, in a pan properly crocked and filled to within an inch of the rim with light soil. This should be made firm with the hand before sowing the seed, which must then be covered lightly with fine sandy soil, and watered before being placed in heat to germinate. As soon as the little plants appear, the pan should be placed near the glass, and as soon as the plants are large enough they may be pricked out, 2 inches apart, in well-drained boxes or pans, containing a mixture of three parts of light sandy loam and one of leaf soil, and sifted manure from an old hotbed, with a sprinkling of sharp sand added. These can afterwards be lifted with plenty of soil adhering to their roots, to be potted into 4½-inch pots before they are crowded in the boxes or pans. From this time grow them in heat near the glass until they show flower, keeping them well supplied with water at the roots and over the foliage, otherwise the leaves of the plants become a prey to red spider. If larger plants than can be grown in the 4½-inch pots are desired, some of them should be shifted into 6-inch pots, afterwards transferring the desired number into 7½-inch pots, using the loam in a rougher state for the last two shifts. As the plants increase in size and the weather becomes warmer, admit more air to the plants, and if a slight sprinkling of Beeson's manure be applied over the soil once or twice a week during the growing period before giving water at the roots, it will be advantageous.—H. W. W.

MODE OF SUPPLYING BOTTOM HEAT TO MELONS AND CUCUMBERS.

It is surprising with what tenacity we cling to customs which have nothing to recommend them except that they are "time-honoured." They may have been well adapted for the purposes they were intended to serve when first brought to notice, but have since become quite unsuitable, because of the changes that have taken place in surrounding circumstances or methods of procedure suggested themselves. I cannot help thinking that gardeners have in many cases been working on the wrong principles in their mode of supplying bottom heat for such plants as Cucumbers and Melons that are grown during the winter and early spring months. Before the age when hot-water pipes were brought into general use for supplying bottom and top heat in glass houses the greater part of these plants were grown in dung frames, and the use of fermenting materials for creating the bottom heat was no doubt the best means that could be devised under the existing circumstances. With the advent of hot-water pipes fermenting materials were really no longer necessary for supplying bottom heat, yet in many instances we still find manure and leaves used for that purpose as well as pipes, with the disadvantage that there is no means provided for keeping the heat as regular as was the case with the dung bed, the linings then being frequently renewed kept the mass heating materials at a fairly even temperature. Houses have been built and beds constructed with hot-water pipes for supplying bottom heat. These pipes in some cases are sunk as much as 3 feet from the surface of the bed, and over them manure and leaves are placed and pressed down firmly. This material is then covered with soil, and mounds are formed, on which the plants are in due time set. The strong bottom heat from the fermenting material causes them to make extremely rapid growth for some weeks, but young shoots grown under such conditions are not so short-jointed or so firm in texture as it is desirable they should be, and in the case of Melons not likely to withstand an attack of canker should it once appear. After the plants have grown thus rapidly for a time the bottom heat gradually declines, and as the hot-water pipes cannot be expected to supply a steady heat to such a body of materials there is from that time but little, if any, more bottom than top heat. This state of affairs is often reached just at the time the plants are swelling their fruits and require a brisk heat to enable them to do so quickly, and the want of it causes a check to the fruits, resulting in the skins becoming hard and tough.

The question arises, If hot-water pipes can be depended on for supplying a steady bottom heat why is the manure used at all when the pipes are at command? It entails a great amount of unneces-

sary labour, and I have come to the conclusion does more harm than good, because it starts the plants into a sappy growth, and often leaves them in a stunted condition. We have discarded the use of fermenting materials in Cucumber and Melon houses altogether, but as the pipes are placed rather low in the bed large pieces of wood are placed over these in such a way as to leave plenty of open spaces between, so that the heat from the pipes may circulate amongst them and reach the soil above. A few spruce branches are placed over the wood, and these are covered with straw to prevent the soil from falling through among the wood, and thereby choking up the passages through which it was intended the heat should circulate. When this is completed there is room for a depth of soil from 1 foot to 15 inches, which we find is sufficient for all purposes. The bottom heat can be regulated at will by the valves attached to the pipes, and a steady and continuous heat is kept up throughout. The plants grown in this way do not make such rapid growth at first, but the shoots are firm and short-jointed, and the leaves thick and leathery. With plants answering the above description Melon growers can look forward with confidence to the results. The same mode of supplying bottom heat we also find very satisfactory for winter Cucumbers, as even fermenting materials are used it is almost impossible to keep up a steady bottom heat unless the plants are grown in pots and fresh materials placed around them at intervals, but we consider the planting-out system decidedly preferable to growing them in pots. Were we constructing new houses for growing Cucumbers and Melons the beds would be made only 18 inches deep from the top of the hot-water pipes, over here would be placed a layer of wood and straw, with the soil added in the usual way. I am inclined to think the plants are grown in this way very little would be heard about the attacks of mildew on Cucumbers in winter. I believe in nine cases out of ten this is caused in the first place by defective bottom heat. Another great advantage under this system is that as there is no sinking of the bed the young shoots can be trained in their proper positions from the first without fear of their being cut by the tying materials, which sometimes happens when manure is placed in the beds, and which often sinks more than was anticipated, causes a great tension between the roots and shoots, and unless noticed in time must result in some of the shoots being cut through or the plants being lifted bodily from the soil.—H. DUNKIN.

TUBEROUS BEGONIAS IN POTS.

HAVING been fairly successful with tuberous Begonias in pots both for exhibition and home use, a few notes at this time of the year may be of service to some persons who are desirous of cultivating this popular greenhouse plant. Many persons fail to grow Begonias well through starting the tubers in too much heat. A steady free growth made in a cool temperature is more conducive to healthy foliage, free growth, and abundance of flowers into the autumn from the same plants. A specimen from 5 feet to 6 feet in diameter of a single-flowered variety—Emperor, for instance, is very handsome during July and August. The large-flowered varieties of the present day do not grow into such large plants as do some of the older and smaller flowered sorts. Perhaps it is as well that they do not, as much space would be needed to house many plants of that size.

The present is a good time to start the tubers into growth. Presuming them to be one, two, or three years old, some perhaps more. We winter ours in sand in the Mushroom house, scarcely ever losing any. One potting of the tubers of the sizes named is enough, nothing is gained by successional shifts during growth. The main point is to know from previous years' growth the habit the plants have, vigorous, medium, and so on, and pot accordingly. For the information of those who do not know, I would say that a tuber 3 inches in diameter should have a 7-inch pot; a 5-inch tuber, which would produce twelve or fourteen growths, should have a 12-inch pot, and so on, according to the size. A plant of the last named size will require abundant supplies of water during the season of growth, and its branches will be what is known as "top heavy" if a suitable pot is not allowed for such a plant.

The compost should be made up with the following materials:—Two parts fibry loam, one part leaf soil, half a part the materials of a spent Mushroom bed, one-quarter part of charcoal broken into about 1 inch pieces, and a free admixture of sand according to the nature of the loam, heavy or light. To each bushel of this compost add a 4-inch potful of finely ground bones. Drain the pots freely. Over the drainage place the roughest parts of the compost, ramming the soil firmly into the pots. Use soil in a rough state, preserving all the fibre of the loam, and cover the tuber about half an inch deep; allowing a good space for water, as copious supplies will be needed during growth. Place the plants in a house having a temperature of about 50°. A vinery just started suits them well,

as the moisture required for the Vines suits the Begonias. No water will be needed for a time until growth commences, only preventing the soil becoming dust dry in the pots. When the growths are 3 inches long remove the plants to the greenhouse, as the heat of the vinery by that time will be too much for the Begonias, and give them a place as near the glass as possible. In fine weather syringe the plants in the afternoon of each day and give water to the roots as required, increasing the supply as growth proceeds. When the pots are filled with roots alternate supplies of weak liquid manure is of immense advantage. Drainings from the farmyard are as good as anything. Do not pinch the points of the shoots, but allow them to grow away freely. Tie out the branches as growth proceeds, allowing space for a free development of their leaves.—E. M.

ORCHIDS IN FLOWER AT CAMBERWELL.

WE have been obliged with the following list of Orchids flowering in Mr. R. I. Measures' collection, Cambridge Lodge, during the present month, a large proportion of which are still in flower.

Cœlogyne cristata varieties—*alba*, *Trentham* var., *Chatsworth* var., *Lemoniana*.

Vandas—*tricolor*, *tricolor insignis* and *tricolor superba*, and *cristata*.

Cypripediums—*insigne*, *insigne sylhetense*, *insigne Forstermanni*, *Lindleyanum*, *paudinum*, *Boxalli*, *Harrisianum*, *villosum*, *villosum Warneri*, *villosum aureum*, *villosum nanum*, *Argus*, *Dauthieri*, *Dauthieri superba*, *Sedeni*, *Sedeni porphyreum*, *barbatum*, *barbatum pulcherrimum*, *chlonoreurum*, *Brayeanum*, *Williamsi*, *Warneri*, *Wernixium*, *Amesianum*, *Haynaldianum*, *Hartwegi*, *Sedeni candidulum*, *callosum*, *Roezli*, *longifolium*, *eurandrum*, and *Spicerianum*.

Trichopilias *suavis* and *suavis alba*.

Lælia præstans.

Masdevallias—*ignea*, *Chelsoni*, *Shuttleworthi*, and *Shuttleworthi xanthocorys*.

Dendrochilum glumaceum.

Rodriguezia planicaulis.

Cœlogyne elata.

Cattleyas—*amethystoglossa*, *Trianæ* (150 flowers), *chocoensis* and *bogotensis*.

Dendrobiums—*Leechianum*, *Domini*, *nobile*, *Ainsworthi*, *Wardianum*, *crassinode*, *crassinode Barberianum*.

Oncidium undulatum.

Restrepia antennifera.

Phalænopsis Schilleriana.

Lælia harpophylla.

Odontoglossums—*Roezli*, *Roezli album*, *cristatum*, *Rossi majus*, *Wallisi*, *odoratum*, *gloriosum*, *Andersonianum*, *Alexandræ*, *Wilckeanum*, *Halli leucoglossum*, and *triumphans*.

ORCHIDS AT LEEDS.

T. A. Titley, Esq., Oakley House, Gledhow, near Leeds, may be congratulated on being the fortunate possessor of the most extensive and complete collection of Orchids in this district, and their remarkably healthy appearance is highly creditable to his efficient head gardener, Mr. Massey. Six span-roofed structures are devoted to their culture, and although not lofty and imposing ones, are admirably adapted for the purpose, the stages being well filled, and from the roof are suspended some hundreds of all the best varieties of this beautiful and interesting class of plants.

It is not my intention in these few notes to particularise the many new and rare pieces of extraordinary value, but shall confine my remarks to the general collection. The *Cattleyas* are magnificent, a fine specimen of *C. Mendelli* being noticeable, 3 feet in diameter, on which I counted eleven sheaths. *C. Trianæ* and *C. Percivalliana* are represented by forty grand masses now in flower, amongst which are some beautiful varieties with large blooms and excellent colours. There are also good plants of *C. Mossiæ*, *C. crispa*, *C. lab'a'a*, *C. Dowiana*, *C. Warneri*, and *C. Bowringiana*. *Lælias* are numerous and exceedingly well grown, including *L. purpurata*, *L. præstans*, *L. anceps alba*, *L. albida*, *L. majalis*, and *L. harpophylla*. The *Odontoglossum* houses contain some hundreds of strong healthy plants, several in flower, amongst which are some remark-

ably good varieties of *O. crispum* and *O. Rossi majus*. Of *O. vexillarium* there are some fine plants remarkably well grown, also *O. Halli*, *O. gloriosum*, *O. citrosmum*, and *O. Roezli*. *Dendrobiums* are represented by well-grown specimens 2 to 3 feet in diameter, including *D. densiflorum*, *D. nobile*, *D. Wardianum*, *D. thyrsoflorum*, *D. Falconeri*, *D. Findleyanum*, and *D. crassinode*. Of *Lycaste Skinneri* there are fifty vigorous plants in bloom. A fine plant of *Lycaste lanipes* has forty-eight flowers. *Cœlogyne cristata* is in grand masses exceedingly well flowered. Several fine specimens of *Cypripedium villosum* and *Lowi* are flowering, also *C. Spicerianum*, *C. Hookeri*, *C. Stonei*, and *C. Veitchi* with others too numerous to mention. Although Orchids are the special feature at Oakley House, other departments are by no means neglected. Stove, greenhouse, and conservatory are stocked with healthy plants. In the greenhouse is a fine specimen of *Lapageria alba* covering a greater portion of the roof. Cleanliness and good order prevail throughout, the grounds and kitchen garden being in excellent condition.—L. T.

CULTURE OF DECIDUOUS CALANTHES.

As the season for potting these will very soon be here a few remarks on their culture may be acceptable to some of your readers. As soon as the young growths commence growing, and before any roots are formed, is the time to pot them. The soil used should consist of rough fibrous loam and peat in equal quantities, with some sharp silver sand and charcoal broken fine mixed with it. Some people recommend dried cowdung, but I do not think it necessary if the plants are well fed later on. In potting I prefer placing a single pseudo-bulb in a large 48-size pot, but of course two or three in a large 32-size will do equally as well if desired. After potting the plants should be quite firm in the pots, but the soil must not be pressed too hard in the pots, as in that case the roots will not grow readily. Place the plants in a house with a minimum night temperature of 60°, rising 5° as the season advances. Great care must be taken that the plants are not overwatered at first, as that, besides causing the first roots to damp, makes the soil sour for their successors; but after the pots are well filled with roots copious supplies will be necessary, with the addition of weak liquid manure. As the leaves turn yellow the supply of water must be gradually lessened, and when they are quite dead it must be withheld altogether. The flower spikes commence growth after the leaves are dead, and are supplied with nourishment from the pseudo-bulb. Consequently it matters little how dry the soil is at that period.—EN AVANT.

SELECT ORCHIDS FOR AMATEURS.

(Continued from page 236.)

LÆLIA.—Handsome and useful evergreen pseudo-bulbous Orchids, similar in habit to the *Cattleyas*, and closely related to them. They are distinguished botanically by possessing eight pollinia in two series, *Cattleyas* having four pollinia in one series. In some the pseudo-bulbs are ovoid and short, but in most they are long, spindle-shaped, or slender, crowned with thick dark green leaves. Flowers in racemes, some small (*albida*), but chiefly large and richly coloured, shades of crimson and purple preponderating in contrast with white (*purpurata*). *Lælias acuminata*, *albida*, *anceps*, *autumnalis* and *majalis* are natives of Mexico, the others are chiefly Brazilian. All require an intermediate temperature and pots, except where otherwise stated. Autumn and winter flowering—*acuminata*, *albida* (cool) *anceps* (many varieties) *autumnalis*, and *Perrini*. Spring and summer flowering.—*elegans*, *harpophylla* (bright orange), *purpurata*, many fine varieties.

LEPTOTES.—A dwarf evergreen Orchid, small pseudo-bulbs, and narrow, thick, quill-like leaves. Flowers singly, white and purple. Brazil. Pots. Intermediate house. Winter.—*bicolor*.

LIMATODES.—Terrestrial plants related to *Calanthe*. Flowers in racemes, pale or dark rose, very pretty. Trop. Asia. Pots. Peat, leaf soil, and sand. Warm house. Winter.—*rosea*.

LYCASTE.—Pseudo-bulbs somewhat conical. Leaves broad and ribbed. Flowers singly from the base, massive, wax-like, durable, white, rose, or crimson, or buff yellowish and purplish. Trop. America. Cool house. Pots, peat. Winter and spring.—*aromatica* *Deppei*, *Harrisoniæ*, and *Skinneri* many varieties, very useful.

MASDEVALLIA.—Evergreen plants without pseudo-bulbs, narrow leaves, flowers singly, white, yellow, scarlet, rose, crimson, and magenta, with brown, almost black, and strange tints in the *Chimara* section. Peru and New Grenada. Pots, peat and sphagnum. Cool house, except *bella*, *Chimara*, and *Wallisi*, which must be grown in baskets suspended from the roof and are better in a slightly warmer house.—*amabilis*, *bella*, *Chimara*, *Davisi*, *Harryana*, *ignea*, *Lindeni*, *polysticta*, *Shuttleworthi*, *tovensis*, *Veitchiana*, and *Wallisi*. Some of them are always in flower.

MAXILLARIA.—Evergreen, with pseudo-bulbs and stem. Flowers

singly, white and purple or white and yellow. Peru. Cool house. Pots. Autumn.—*grandiflora, venusta*.

MESOSPIDIUM.—Evergreen plant with short pseudo-bulbs, and drooping racemes of small rosy flowers. Peru. Cool house, suspended in baskets. Autumn.—*sanguineum*.

MILTONIA.—Evergreen, small pseudo-bulbs. Flowers singly or two to six on a scape, yellow and brown or white and purple. Brazil. Pots.—*Clowesi*, intermediate; *spectabilis* and *Moretiana*, cool house.

MORODES.—Deciduous epiphytal Orchids, with peculiar flowers, white or yellowish, spotted brown. Mexico and tropical America. Pots. Intermediate house. They require a marked resting period.—*luxatum eburneum, pardinum*.

NANODES.—Epiphytal, dwarf, very interesting, and distinct. Flowers with yellowish sepals and petals, and large purplish deeply fringed lip. South American Andes. Cool house. Basket.—*Meduse*.

ODONTOGLOSSUM.—Evergreen Orchids with ovoid or flattened pseudo-bulbs, narrow leaves, and racemes of handsome flowers, white, yellow or rose tinted, spotted and barred with brown. New Grenada and Mexico. Pots. Cool house. Flowering at all seasons, especially winter and spring. Very useful, easily grown, and popular plants.—*Andersonianum, blandum, Cervantesi, cirrhosum, citrosimum*, basket, very little water in winter, flower summer; *cordatum, crispum* (Alexandra), *Edwardi*, purple, violet fragrance; *gloriosum, grande, Halli, Inseayi leopardinum, maculatum, odoratum, Oerstedti majus, Pescatorei, pulchellum*, very fragrant; *Rossi majus, Sanderianum, triumphans, Uro-Skinnersi*. The following require an intermediate house and flower from spring to autumn:—*Phalænopsis, Roezli*, and *vezillarium*.

ONCIDIUM.—Greatly varied evergreen Orchids, with pseudo-bulbs and panicles of showy flowers, principally shades of yellow marked with brown and red. Tropical America. Intermediate house. Pots or baskets, a few on blocks.—*ampliatum majus*, spring and summer; *cheiroporum*, autumn; *concolor*, spring and summer, cool house, basket; *crispum*, block; *cuttatum*, spring, cool house; *dasystyle*, winter, cool house; *flexuosum, Forbesi*, autumn, block, cool house; *Jonesianum*, autumn; *macranthum*, spring and summer, cool house; *Marshallianum*, basket, cool house; *ornithorhynchum*, autumn and winter, basket; *papilio majus* (Butterfly Orchid), basket; *sarcodes*, spring; *sphacelatum, tigrinum, varicosum Rogersi*, winter.

ORCHIS.—Tuberous terrestrial Orchids. Leaves often spotted, dense spikes of small rose and purple flowers. Pots; loam, leaf soil. Cool house, greenhouse, or outdoors. Spring and summer.—*foliosa, maculata superba*.

PAPHINIA.—Small pseudo-bulbous plants, plicate leaves, drooping racemes of strangely coloured flowers. West Indies and tropical America. Pots. Warm house.—*cristata*.

PERISTERIA.—A strong-growing Orchid with large pseudo-bulbs and broad leaves. Flowers in tall racemes, wax-like, white. Trop. America. Pots, loam and leaf soil. Intermediate house. Summer. Requires a good rest after growth.—*elata* (the Dove Plant).

PHAIUS.—Terrestrial Orchids of strong growth, with bold leaves and flowers in racemes, white, yellow, brown, and rosy crimson. Widely distributed in the tropics. Intermediate house. Pots; loam, leaf soil, and manure. Winter and spring. Need a resting period.—*grandifolius*.

PHALÆNOPSIS (Moth Orchids).—Most graceful and beautiful plants, requiring care in culture. Epiphytes without pseudo-bulbs, having broad green or marbled leaves and panicles of handsome white and rosy crimson flowers. India and Malaya. Warm house. Need a regular supply of moisture. Baskets, sphagnum. Winter and spring.—*amabilis, grandiflora, Schilleriana* and *Stuartiana*.

PILUMNA.—Small epiphytes, with pseudo-bulbs and drooping or erect racemes, white, fragrant. Central America. Cool house. Pots. Winter.—*fragrans, nobilis*.

PLEIONE (Indian Crocuses).—Charming little deciduous Orchids with small pseudo-bulbs and bright green leaves. Flowers produced before the leaves, mauve, rose, and crimson. Winter and spring. Himalayas at 4000 to 10,000 feet elevation. Intermediate house. Pots or pans; peat, loam, and sphagnum.—*humilis, lagenaria, maculata præcox, Wallichiana*.

PROMENEA.—Epiphytal Orchids with small pseudo-bulbs and drooping racemes of flowers, yellow, spotted crimson. Brazil. Intermediate house. Pots; peat. Summer.—*citrina*.

RESTREPIA.—Epiphytal, stems in tufts, few leaves, and small flowers beautifully streaked and dotted, very peculiar and interesting. Trop. America. Cool house. Pots.—*antennifera*.

SACCOLABIUM.—Evergreen plants in the style of *Aerides*, with stems and distichous leaves. Flowers small in dense racemes from the axils of the leaves, white, spotted rosy purple or crimson, fragrant and very beautiful. Tropical India and Malaya. Warm

house. Baskets. Spring and summer.—*ampullaceum, Blumei, giganteum, guttatum*.

SCHOMBURGHIA.—Tall spindle-shaped pseudo-bulbs, and long racemes of rose and white flowers spotted brown. Tropical America. Intermediate house. Baskets or pots. Summer.—*tibicinis*.

SCUTICARIA.—Epiphytal, with drooping quill-like leaves 2 to 4 feet long. Flowers large, yellow spotted with brown. Tropical America. Intermediate house. Baskets.—*teeli*.

SOBRALIA.—Terrestrial, strong-growing, slender stems and plicate leaves. Flowers large, showy; crimson and purple; several from the apex of each stem. Tropical America. Intermediate house. Pots; peat. Summer.—*macrantha*.

SOPHRONITIS.—Evergreen, with small pseudo-bulbs, and dark green leaves. Flowers singly, or a few together, produced freely. Brazil. Cool house. Baskets or blocks. Spring.—*grandiflora*, one of the most useful Orchids grown, flowers scarlet; *violacea*, purplish.

STANHOPEA.—Epiphytes, with ovoid pseudo-bulbs and dark green leaves. Flowers in drooping racemes, produced from base of plants, wax-like, very showy, of short duration, white or yellow spotted and blotched with crimson, orange, and reddish brown. Tropical America. Warm house. Baskets. Summer. Require a good resting period.—*grandiflora, insignis, oculata, tigrina, Wardiana*.

THUNIA.—Deciduous; stems in tufts, terminating in flowers, white, marked with yellow or streaked with crimson. Himalayas. Warm house. Pots; peat and sphagnum. Good rest needed.—*alba, Bensonia, Marshalliana*.

TRICHOCENTRUM.—Epiphytes, with small pseudo-bulbs, leaves and flowers, the latter brown and purple. Brazil. Intermediate house. Baskets.—*albo-purpureum*.

TRICHOPILIA.—Evergreen; ovoid pseudo-bulbs, with thick leaves. Scapes from the base; flowers with large funnel-shaped lip, shades of crimson and purple. Tropical America. Intermediate house. Pots. Spring and summer.—*coccinea, suavis, tortilis*.

UROPEDIUM.—A peculiar plant, much like a *Cypripedium* without the pouch and lip. Very interesting. New Grenada. Warm house. Pots; peat, loam, and sand. May.—*Lindenii*.

VANDA.—Handsome plants, with stems like *Aerides*, and distichous leaves. Flowers in small racemes; blue, white, or yellow, spotted with brown, lip often crimson. Tropical India and Malaya. Warm house. Pots; peat and sphagnum. Flowers at different times.—*cærulea* (blue), *Parishi, suavis, teres, tricolor*.

VANILLA.—Tropical Orchids, with long climbing leafy stems, chiefly interesting for the long pod-like fragrant fruits. Warm house. Pots; peat and sphagnum.—*aromatica*.

ZYGOPETALUM.—Useful evergreen epiphytes; pseudo-bulbs, and terminal racemes of brown, purple, and greenish flowers. Intermediate house. Pots. Winter.—*crinitum, Mackayi, maxillare*.—L. CASTLE.

AURICULAS—A HINT TO BEGINNERS.

THE advantage of having Auriculas in a place where we can get among them at any time has been felt during the past week, when I have been able to overhaul between two and three hundred plants in my small house, while those in frames could not be touched for snow and frost. This overhauling has suggested to me one hint that beginners in the cultivation of this flower may find useful. I say nothing of top-dressing further than this, that the ambition of having bulky plants and large trusses will in time give place to a desire for a healthy stock and refinement of bloom, to neither of which rich top-dressing conduces. A slight addition of a simple mixture of loam, leaf mould, and sand will give a fresher look to the collection, and induce rooting at the collar; beyond this I do not use anything, and even this sparingly. One thing I strongly urge beginners to do at this season, the critical one in Auricula-growing, when many a plant may be lost or saved. Examine carefully the neck of the plant and the stem a little under the surface of the soil. Beyond a seeming tardiness in starting into growth, there may be little to indicate anything wrong. The Auricula disdains to make much show of its ailments, a source of danger to the inexperienced, and a plant may be almost hopelessly gone before such a one detects symptoms quite patent to the practised eye. Should a thin white streak at the collar be observed, or a darkish speck, however small, be seen on the stem, proceed carefully to ascertain the cause. You may possibly discover more than you suspect or desire. With a sharp knife probe cautiously, and scrape away every particle of the brownish wasted bark or stem. Do not squeamishly fear to learn the whole truth, but clean out thoroughly. Then rub the wound liberally with powdered charcoal, add the above top-dressing, not too damp—I sometimes defer this for a

day or two—and you have likely saved the patient's life, if the surgery has given yourself pain. It may surprise you to find how soon, unless the heart of the plant be gone, new roots will be formed. This hint would at one time have been of much value to myself. Unpleasant surprises will be fewer as you come to love the flower as it deserves, and gain fuller knowledge of its habits, and I trust the result of your present investigation will be as gratifying as my own.—A NORTHERN AMATEUR.

TRITELEIA UNIFLORA IN POTS.

THESE bulbs are very useful for producing a quantity of white flowers in winter. Their dark green foliage and the number of flowers are always welcome in the dull days. We have many pots of them in a warm greenhouse. They commence flowering about Christmas, and continue until the end of March. The flowers are much liked in a cut state in the house, also for making wreaths and crosses, and they help to add to the beauty of the conservatory or greenhouse associated with other plants on the front stages. We place several bulbs in a 5-inch pot, the soil used being two parts good loam, one of decayed manure and old mortar rubbish. The bulbs are placed about an inch under the soil, which is pressed rather firmly. They should be potted in August. The pots are then placed in a cold pit until the end of October, when they can be removed to the house in which they are to flower. After they have filled their pots with roots liquid manure must be given twice a week. When the flowers have faded remove the plants from the greenhouse to a cold pit till the foliage is dead. The pots can then be placed under the shade of a north wall, or the bulbs may be planted out in such a place till August, when they can be taken up and repotted again.—GEO. PRICE.

CUTTING AND TASTING FRUIT AT SHOWS.

IN reference to this subject Mr. Goodacre at page 82 alludes to the dissatisfaction that was caused at the Crystal Palace early in September last year by the prize in the class for "any other black Grape" not named in the Company's schedule of prizes being awarded to good bunches of Lady Downe's in preference to what your correspondent terms "ordinary" Muscat Hamburgs, but which the majority of Grape growers present at the time considered neat well-finished bunches of that excellent Grape, and deserving first honours. If the "ordinary" character of the Muscat Hamburg is the production of medium-sized compact bunches consisting of well-coloured berries, then your correspondent's description of the exhibits referred to is quite correct. But the reason I have referred to this particular paragraph in Mr. Goodacre's letter is this—he says "Because I quite agree with the judges in this case I was advised to 'taste the difference,' but I did not do so, as I condemn the tasting system; it often disfigures exhibits," adding, "and I maintain that unless a man can judge with his eye he is not qualified to judge at all." I quite agree with your correspondent in his condemnation of the practice adopted at some shows of cutting and tasting all kinds of fruits, as in my opinion none but Melons should be tasted; but what I maintain is that Mr. Goodacre and every other practical fruit grower should know very well what the relative qualities (flavour included) of Lady Downe's and Muscat Hamburg Grapes are the first week in September, or at any other time of the year for that matter, without "tasting" them at the time. The same may be said in the case of judges who may consider it necessary to cut fruits of Royal George and Barrington Peach to enable them to decide the awards by flavour, the specimens of both being in every other respect equal. In short, all practical fruit growers, especially those who officiate as judges at shows, should be sufficiently well acquainted with the relative qualities of all our best and well-established varieties of Grapes, Peaches, Nectarines, Plums, Pears, and Apples, to be able to judge of the merits of examples of the respective kinds when set before them without having to taste them.—H. W. WARD.

THE ORCHARD HOUSE.

[A lecture delivered at Birmingham on the 13th Inst. by T. Francis Rivers, Esq]

THE cultivation of Peaches and Nectarines under glass, at one time almost a mystery of gardening, has, within the last few years, made an enormous stride; the horticultural exhibitions all over the country show that a very great development has taken place in spite of the obvious disadvantages of climate. The Peach, as everyone knows, is not indigenous. The habitat is generally assigned to Persia, and it is certain that Peaches are there very abundant and good. Travellers call them exquisite, and maintain that they are better than in England; this I take leave to doubt, animal food is generally so very indifferent in the East that fruit of any kind is welcomed. The climate of Persia, although very hot in summer, is very cold in winter, and this is exactly suited to the Peach, the tree is a rampant grower, and requires an intense and dry cold in winter to induce it to rest. You have, no doubt, seen how easily it is excited to growth by our damp and sometimes warm winters when out of doors. I make these remarks to show that the dry air of an orchard house conduces to the health and well-being of the tree. Until the abolition of the duty on glass, Peach-growing was carried on in

houses with moveable sashes glazed with 4-inch squares, and containing as much timber as glass, in a very few years these lights became dim and dingy, the glass itself was of very bad quality, and dust would accumulate in spite of the gardener's care. It is now difficult to understand how good fruit was produced at all under these conditions, and the abolition of the duty was a real relief to the gardener; to the nurseryman desirous that his sorts should be correctly named, it was invaluable, the most extensive nurseries had scarcely wall-room enough to grow the number of trees required for securing scions, and I am afraid there was therefore a good deal of confusion in the names of sorts. As these were limited the evil was, perhaps, not so very great.

About the year 1849, my father, recognising the great value of exactitude in nomenclature, and desiring to grow his own Peaches, constructed a rough glass shed with the new glass, departing entirely from the old system of sliding sashes. The shed was a lean-to, and built with fixed rafters 20 inches apart, with sliding shutters in the back and front. Of course he was told that the trees would burn, that the thorough draught would kill them, and other evils would occur, and he was rather nervous as to the result. Instead of losing his trees they flourished exceedingly, and he soon saw the importance of the dry air and brilliant sunshine. His expectations were more than realised, and he began to extend the culture, without, I think, being at all aware of the importance of the experiment on the future of fruit cultivation in England. After the rough shed, he took counsel with his garden architect, builder, and carpenter, who was at the same time a very intelligent labourer, and built a span-roof on the same principle of fixed rafters and large squares. The first shed was supported by larch poles sawn in half, larch being very cheap at that time, and the span-roof was built in the same fashion, but 20 feet wide, 12 feet in the centre to the ridge pole, and 5 feet high at the sides. This house, from the abundance of light and the thorough ventilation, the ventilators being deal planks on hinges, running the length of the house on both sides, was a still greater success, and began to attract the attention of those cultivators who were disconsolate from the repeated failures of the crops on walls. About this time the parish church was in debt for a considerable sum for restoration, which it was difficult to raise. The parish was then fortunate in having the services of a very energetic curate (the present rector of Fringford), who had watched the experiment with great interest, and who persuaded my father to publish the new system, and give the proceeds of the first edition to the parish. After some hesitation the book was published, and to the author's great astonishment quickly ran through a first edition, a large sum being placed to the credit of the church a year after its publication. It was therefore evident the idea was a happy one, it supplied a want which was felt by most fruit cultivators. No doubt many mistakes were made from want of knowledge, and I may say, because the system was expected to produce fruit without much care; moreover gardeners could not be practically acquainted with it, and it is difficult to learn from a manual, however simply written.

As the original houses were quickly filled with trees, more were required, and it became necessary to extend and somewhat embellish the first idea of a rough orchard house, and to devise a structure which should meet the claims of the kitchen garden and the ornamental fruit house. The next was a span-roof 14 feet at the ridge pole, 24 feet wide, and 100 feet long, and this size, I think, is the most convenient. The length, of course, depends upon the will of the builder, it may be half a mile if he likes. The points to be gained are complete ventilation, and as much sunshine as our climate will afford. A house 100 feet long, of the above width, built in the year 1855, has produced annually for the last twenty-eight years from 3500 to 4000 Peaches and Nectarines, a result which I venture to say would not be given by any wall built at the same cost—namely, £140, the original cost of the house, the harvest of fruit extending from the beginning of July to the first week in October. The work being carried on under shelter the gardener does not reap the plentiful crop of chilblains and the certain future of rheumatism consequent upon nailing and pruning wall trees in the inclement early springs of our climate. I do not, of course, say that the work is carried on without expense, but I maintain that this is amply compensated for by the increased and continual production of fruit, and the great pleasure afforded of the dry atmosphere throughout the winter and spring. I do not know a prettier sight than a well-arranged orchard house when the trees are beginning to show the pink tips of the blossoms, and during the brilliant display of the trees when on bloom, the climate is dry and is free from the moisture inseparable to a conservatory, the trees are one sheet of rose-coloured blooms, and the interest, unlike most flowering trees, is kept up until they have yielded their produce.

Since the permanent establishment of orchard house culture, the question of planted-out trees *versus* potted trees has been often agitated. For my own part, having given the planted-out trees a thorough trial—in fact, I have one house devoted to them—I am convinced that the potted trees are superior. There is great difficulty in restraining trees planted out. The Peach naturally grows very vigorously in a dry climate, and does not submit to root-pruning, in many places the soil is not suitable; but those who object to the constant labour of watering can pursue a modified system with the greatest advantage. This consists in the employment of perforated pots, the perforations, about an inch in diameter, being made about 4 inches from the rim of the pot and carried round; the pot being sunk in the border below the perforations during the summer, roots will push through these holes into the surrounding

soil, and in the autumn when the trees are repotted these roots can be cut off close to the pot without the slightest injury to the tree. For growing for market, when quantity and not quality is desired, and the soil is thoroughly well suited, it is possible that more fruit may be produced by planted-out trees; but of this I am quite sure, that more fruit will be ripe at the same time than it is possible for a private family to consume; it will be therefore necessary to find a ready market for the surplus.

I will, however, take both systems. When I speak of planted-out trees I do not mean trees trained to trellises, but trees planted with untrained heads like Apples, or orchard trees, and allowed to form round heads, the starting point of the branches being about 5 feet from the ground. This will give, in a house 14 feet high in the centre, about 6 feet of space for the head of the tree, which should always be kept about 2 feet or more below the glass. The tendency of the Peach is to excessive growth until checked by the production of fruit. It is therefore necessary to vigorously check those shoots which grow with superabundant vigour. To effect this without disturbing the balance of the tree, and causing a quantity of small shoots, the leaves should be removed from these strong-growing shoots, and a ring made round the bark; when the growth of the lower branches has been established these shoots may be removed altogether. The great point to be settled in pruning standard trees is that they should have flat heads, admitting air and sunshine. There is certain to be fruit enough, as the Peach will soon destroy itself by overbearing if allowed. Another great point in the culture of planted-out trees is that the soil in which they grow should be as hard as a barn door. When my trees were planted, now about thirty years since, this was stirred to the depth of about 2 feet; manure was mixed with it; it was finally trodden down, and so it has remained ever since. It is a hard calcareous clay, solid with the daily tramping of the workmen. Faggots of wood have been taken from the trees, which are roughly pruned as I have described, and which give annually large crops of fruit, and are apparently ready to go on for an indefinite time, as they are in perfect health and vigour. A surface dressing of manure is given to them annually in the spring, and they are dosed with water about once a week, as they get none from the sky. As they are in a house with pot trees they of course come in for the syringing.

Potted trees are, however, the trees for amateurs, the pots being above the surface are always absorbing the dry and warm air of the house, and the trees seem to appreciate this condition. Naturally more attention is required, but I fancy that Cucumbers and Melons require quite as much, and it always seems to me that more labour is wasted on these fruits than would suffice to produce a multitude of Peaches and Nectarines. However, both are necessities of the garden, and I cannot quarrel with them, but I am, as perhaps some may know, a member of the Fruit Committee of the Royal Horticultural Society, and it has been my lot for many days to sit at the meetings of the Committees, to judge of the merits of seedling Melons. In the early morning, nothing but Melon, good and bad, is rather trying to the digestion. My 100-foot house which I am now describing, and the proportions of which I think are best adapted for the supply of fruit for a large family, is now set out for the summer. This work is only just completed. The trees, although far from blooming, are showing their pink petals, it contains of Peaches and Nectarines alone 107 trees, thirty-one pyramids, from 8 to 10 feet high in 18-inch pots, ranged in three rows down the centre of the house, and seventy-six half-standards and bushes on both sides, ranged in two rows alternately, the pots being 3 feet apart. As the half-standards are about 5 feet high, the pots are partly sunk in the ground but not plunged, in order to give room for the heads of the trees. These trees are intended for permanent summer residents, and have, as I have said before, produced nearly 4000 fruit annually for the last twenty-five years, and will, I hope, do the same again this year and for some time yet. Now in addition, the house will hold and protect against frost an equal number of Pears, Plums, and Cherries, all of which can be removed to the open air about the end of May. Up to this time no difficulty will be felt in overcrowding, as the cultivation is identical, and the trees will not have made sufficient growth to incommode each other. I think the advantage of thus utilising an orchard-house will be at once seen, as sometimes there is a general wreck of outdoor fruits, and entire destitution can be thus escaped. I may here remark that the floor of the house is made gay with bulbs and Wallflowers up to the end of April. The effect thus given is very charming, but the introduction of Roses or any shrubs likely to introduce insects and pests must be absolutely and strictly forbidden.

(To be continued.)

FREESIAS.

FEW plants have become so popular in such a short time as Freesia refracta alba, and certainly no flower better deserves to be widely known. It is very beautiful, with a delightful scent. I have heard of a few failures with Freesias, but as a rule most persons who grow them succeed fairly well, and the success recorded by "R." goes to prove that their culture is very easy. I have grown a few pots for two seasons, and thought I had done fairly well, but I have not been able to get from twenty to thirty spikes out of eight bulbs. My bulbs, however, are much stronger the second year than they were the first, and I hope to do better in future. There is one important point in connection with Freesias—that is, the long period over which it seems possible to have them in flower. "R." had them in flower at the beginning of the year. I recently saw plants that looked promising to

flower about May. We have bloomed ours during March hitherto, but some were potted early in February; they are now starting freely, and if all goes on well they should flower about July or August. It is said Freesias can be had in flower from January to June, but it appears as if we might have them all the year with a little management, but this may not be desirable. In my opinion the winter months are the most suitable in which to have them in flower, and how charming they would be the Easter decoration. F. Leichtlini does not attract so much notice as F. refracta alba, but it is, according to my taste, little inferior. It is a stouter grower, the colour of the flowers creamy white with a tinge of orange red in the lower petals.—E. B.

TECOPHYLÆA CYANOCROCUS.

MESSRS. R. VEITCH & SON of Exeter exhibited plants of this beautiful Chilian bulbous plant at South Kensington early in March this year, and accompanying them were plants of a variety named Leichtlini (fig. 31). T. cyanocrocus has flowers of a brilliant blue colour, a rich and pure tint that is very rare amongst cultivated plants, and though of

Fig. 31.—Tecophylæa cyanocrocus Leichtlini.

small growth it is a favourite with many who have tried it. A light sandy loam suits it, and it requires to be grown in a cool house or frame. The variety Leichtlini requires similar treatment, and is distinguished by its flowers being white in the centre, edged with blue, and very fragrant. In some favoured districts these bulbs might be grown out of doors, but it is not a safe experiment in most places, and under any circumstances the flowers cannot develop so well as they do under glass.

PEACH TREES CASTING THEIR BUDS.

"J. W. W.," page 169, invites discussion on this subject. I have never had the least trouble with buds falling, and as I have had a full crop of Peaches for the last nine years, a few notes on the management may be of interest to "J. W. W." and other readers of the Journal. The early Peach house here is a lean-to due south, 36 feet long, with an inside border 12 feet wide. There are six trees in the house, three in front trained on a trellis, and three trained on wires to the back wall. To commence with, the house is closed the last week in November, and no fire heat is applied so long as the thermometer keeps at 50°. That temperature is maintained until the trees come in flower, and they are syringed twice every day until the beginning of January when the first flowers open. The temperature is then kept at 55° at night and 60° through the day, allowing 10° more with sun heat. Except when there is frost a little ventilation at the top is on night and day. After the Peaches are set the trees are syringed twice every day at 8 A.M., and a little before one o'clock to allow the foliage to be dried before night. From the time the Peaches are set until stoning is completed a night temperature of from 57° to 58° with 60° by fire heat is kept in the day. The border has a thorough drenching when the house is closed, and 240 gallons every four weeks after, until the

Peaches begin colouring. After the fruits are set I fumigate twice, then syringe twice daily until ripening commences. I give a mulehng in April of horse droppings and leaves, which is a great help in keeping the border moist. As a rule, every year I have three times as many Peaches to take off as I leave on; in fact, one year I took off three hundred and then left a heavy crop. My Peaches at the present time are nearly as large as marbles, and more than half will be taken off. The temperature will be kept from 58° to 60° at night until they have stoned, after that 5° higher with fire heat will not hurt when the trees are kept syringed twice daily until ripening commences.

After the crop is gathered I prune the trees at once, as I believe in having the wood as ripe as possible. I think pruning the trees greatly assists in ripening it, by admitting the sun and air among the foliage; the stems are untied, the top and front ventilators and door being thrown open. The trees are thoroughly drenched about 5 P.M. every evening with the garden engine, and twice a week a wineglassful of petroleum is added to each four gallons of water to make sure work of red spider. The border has its usual 240 gallons every four weeks until the leaves fall, then the trees are left to rest until the house is cleaned and closed for another season. I may also state I like a space of 4 inches between the shoots. How often we see Peach trees trained as thickly as possible, which I consider is a great mistake.—G. CLINGING, *Marden Park.*

— A SPECIAL general meeting of the ROYAL HORTICULTURAL SOCIETY will be held in the Council Room, No. 111, Victoria Street, S.W., on Tuesday the 10th of April, to take into consideration a code of new by-laws submitted by the Council for the future management of the Society.

— GHENT EXHIBITION.—Mr. Henry Pearson writes—"I have been in communication with the Manager of L. C. & D. R. Co. respecting the above, and have proposed to him the issuing of cheap circular tickets to enable horticulturists who wish to do so, to visit the bulb grounds of Holland after the Exhibition. He writes 'that his company hope to issue through tickets at a good reduction, fuller particulars will be given later on.'"

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mr. E. R. Cutler writes:—"I have the pleasure to inform you that the late Lord Northwick has, by his will, left a legacy of £100. free of duty, to this Institution, also that the Right Hon. Joseph Chamberlain, M.P., has appointed Wednesday, the 4th July next, for the anniversary dinner of the Institution, upon which occasion he will take the chair."

— THE WEATHER.—"D. B." writing from Scotland, remarks that, "The week ending 26th has been very variable and unpleasant. Generally cold E. and N.E. winds have prevailed, with occasional milder intervals. A rapid thaw on the 21st removed a great deal of the snow where not drifted. Frosts of 7° and 8° took place at the beginning of the week. A fall of snow last evening (25th) followed by 11° of frost makes everything as wintry looking as ever."

— MR. W. WENMAN, The Gardens, Hickleton Hall, Doncaster, writes:—"The weather still keeps very severe. Here in this part of Yorkshire we had 11° of frost on Saturday the 24th. On the 25th we had a fall of snow several inches deep, and on Monday we had 9° of frost. It will be a very late spring if we do not soon have more genial weather. Seed-sowing is at a standstill here." The weather in the south has been somewhat milder, but there has been much cold rain and a little snow. The soil is still in a very unfavourable condition for working or seed-sowing.

— THE GARDENERS' ORPHAN FUND.—The monthly meeting of the Committee was held on Friday night last. Present—Mr. G. Deal (Chairman), and Messrs. Barron, Bates, Cannell, Dean, Herbst, Laing, Roberts, Roupell, Wright, and Wynne, with Mr. G. Cummins, one of the provincial Secretaries. Since the last meeting the sum of £26 1s. 6d. has been received in donations, and £19 5s. as subscriptions, the number of new contributors being seventy-four. A total of £1503 3s. has been promised in the form of donations and subscriptions, of which £1192 10s. have been received. All amounts due should be transmitted to Mr. Barron at Chiswick as early as convenient, as it is desired to place as

many candidates as possible on the fund at the first annual meeting. This will take place at two o'clock on Friday, July 13th, at the Cannon Street Hotel, to be followed by a dinner at five o'clock, at which the President, Sir Julian Goldsmid, Bart., M.P., is expected to be present. This promises to be the great gathering of gardeners and horticulturists of the year, the room engaged being capable of accommodating about 500 persons. Further particulars relating to the event will be published. The following special Committees were appointed to take charge of the arrangements:—1, *Decorations—Flowers*, Messrs. Herbst, Bates, and Head. 2, *Dessert—Fruit*, Messrs. Roberts, Wright, and Laing. 3, *Music*, Messrs. Deal, Richards, and Turner. 4, *Tickets*, Messrs. Richards, Wright, and Wynne. 5, *Election*, Messrs. Deal, Roupell, and Dean. Samples of collecting boxes were examined, and a gross ordered for distribution. There are many applicants for these, and others can be sent to Mr. Barron. A complete list of subscribers was ordered to be printed. The position and prospects of the Fund are considered highly satisfactory, and the greater the support accorded the more extended will be the benefits to the orphan children of gardeners nominated for election.

— LITERARY IMMORALITY.—It has come to our knowledge that a contributor to the gardening press is in the habit of applying to vendors of garden requisites offering, for a consideration, to commend their wares (that he has not tried) in articles that he hopes to get inserted. The responsible heads of firms of high repute would seem to be parties to such literary immorality, and we shall not allow any articles to appear in our columns from the writer in question. He is not, we believe, on the staff of any of the gardening papers, though he has contributed to some of them, and very occasionally, though not very recently, to this Journal; but he is now informed that no matter what he may send us in the future it will be rejected.

— MESSRS. SUTTON & SONS send us a CINERARIA bloom so far above the average of the hundreds that reach us as to be worthy of mention. It was grown by Mr. T. Crosswell, gardener to W. M. Bullivant, Esq., Eden Park, Beekenhara. It exceeds 3 inches in diameter, is perfectly circular, the florets, of which there is a double row, overlapping to their extremities, and several of them are three-quarters of an inch in diameter. The colour is purplish crimson with a white centre, this however breaking into the colour a trifle, and in that detracting from the perfectness of the bloom. We are willing to notice any blooms equal or superior to this as encouragement to the raisers and growers, whoever they may be, and as an incentive to others to surpass them.

— TOMATOES AS BORDER PLANTS.—"J. G." writes—"In June last year I planted a border of my garden at St. Albans with twelve Tomato plants, a large red variety, from one of which I cut 20 lbs. weight of excellent fruit. I bestowed very little care on these plants beyond supporting them with stout stakes, and top-dressing them when they had set their fruit with Thomson's plant manure. Apart from the value of the crop, the plants presented a splendid appearance, loaded as they were with ripe fruit."

— BRITISH FERNS.—At a recent meeting of the Wakefield Paxton Society, Councillor Milnes, the newly elected President, was in the chair, Mr. H. Oxley occupied the vice-chair, and there was a good attendance of the members. Mr. T. Garnett, who has been appointed co-Secretary with Mr. G. W. Fallas, in the room of Mr. Herbert Chapman, resigned, read the minutes of the annual meeting held on the previous Saturday, and they were adopted. The President also mentioned that at a meeting of the Committee on the previous Wednesday evening it was unanimously resolved to present a student's microscope to Mr. Herbert Chapman as a slight recognition of his valuable services as one of the Honorary Secretaries for the past six years. Mr. I. Twigge, nurseryman, St. John's, read a very interesting paper on "Ferns and their Uses." About a quarter of a century ago Mr. Twigge, whilst residing in Derbyshire, collected and preserved about 800 specimens of British and Exotic Ferns, and he exhibited some of his specimens, and also a couple of pretty little baskets filled with young and healthy Ferns. Mr. Twigge said that August and September are the best times for collectors of Ferns to gather specimens for preserving, and they might be preserved between newspapers as well as by the use of blotting paper. Ferns stand unrivalled as pot plants, and as decorative plants they have no equal. Cut Ferns are now very extensively used in this country, and shiploads of them are sent to England every week

from abroad to supply the wants of the public. Ferns are very useful for growing in cases in dwellings, in hanging baskets in conservatories, and they are also suitable for rockeries. They are easily managed, and he was surprised they are not more extensively grown in this country, because a basket of Ferns will last for years with watering occasionally. Ferns grown in cases are extremely interesting, and afford much pleasure to those who wish to watch their growth. He knew of no better ornament for a home than a miniature fernery. The greatest enemy to Ferns is over-watering; many persons kill Ferns by over-kindness in this respect. Four times a year was quite often enough to water a Fern case. The best time to remove Ferns is February and March, and the best mode of propagating them is from spores. Ferns require a period of rest, particularly old plants, and they might be grown by the poorest amateur as well as by the wealthy in their conservatories and ferneries. A few questions were put to the essayist by Messrs. Alan Willis, G. Parkin, and G. Gill, and after these had been answered Mr. Garnett said he did not see why Ferns should not be cultivated for market purposes in Ireland, Isle of Man, Isle of Wight, and the Channel Islands, instead of importing them by shiploads every week from the Continent. A hearty vote of thanks was given to Mr. Twigge for his paper, and as he had devoted his attention chiefly to British Ferns he was requested to give a paper on Exotic Ferns.

— **CAMBRIDGE BOTANIC GARDENS.**—We understand that the estimates for the plant house (£2760) and research laboratory (£250) at the Botanic Gardens are accepted, Messrs. Boyd of Paisley being engaged for the former, Mr. Sindall for the latter. Sir Joseph Hooker, Mr. Thiselton Dyer, and several skilled horticulturists have inspected the plans, and they meet with general approval. The proposed Fern house, stove, and Orchid house have a combined area of 2660 square feet, as compared with 2290 square feet, the area of the corresponding present houses.

— **A CLUB FOR COVENT GARDEN MARKET.**—The Covent Garden Club was opened last Wednesday evening, March 21st, at the Covent Garden Hotel. The Club has been promoted chiefly for the accommodation of Covent Garden salesmen and growers and senders of produce from the country. Mr. W. Arthur Board is the Hon. Secretary.

— We learn that the **WILTS HORTICULTURAL SOCIETY** will hold the Summer Show on Thursday, August 23rd next, at Salisbury.

— **A CAMELLIA FREAK.**—A Boston Amateur writes, "I send a white Camellia bloom showing three centres in a single bud. I have a small plant of this with four more blooms fully out, each bud having two centres; also five buds beginning to open, and each bud seems to have at least two centres. Never having seen a plant like it before, and considering it uncommon, I have sent you a bloom. I have lost its name. I shall be pleased to hear from any of your readers if two or three centres to one bud is of common occurrence on white Camellias." The flower resembles candidissima.

— **THE BIRMINGHAM BOTANICAL AND HORTICULTURAL SOCIETY** announce a Rose Show to be held in the Botanic Gardens at Edgbaston on July 12th and 13th this year. Fifteen classes are provided for nurserymen, amateurs, and gardeners; a few are open. The prizes range from £5 for forty-eight blooms to £1 for twelve blooms, with second and third prizes of proportionate amounts. Schedules can be had from Mr. W. B. Latham.

— **AN Exhibition of Chrysanthemums and fruit** will be held by the **RUGBY AND DISTRICT FLORICULTURAL SOCIETY** on November 21st and 22nd in that town. Mr. W. Bryant, 28, North Street, is the Secretary.

— **A CORRESPONDENT** informs us that the **PRESTON SPRING SHOW**, held on Wednesday and Thursday last, "was a good one, and quite equal to any held at Preston before. Hyacinths generally were better than last year. The six Azaleas shown by J. B. Dixon, Esq., were praiseworthy specimens. The groups of miscellaneous plants by Messrs. Payne, Dixon, and Troughton had the most tasteful arrangements in the Show. Mr. Chas. Parker, Preston, was the most successful exhibitor of Orchids, also in the classes for cut flowers, bouquets, &c. Mr. Clark of Ribbleton Hall, among other exhibits, staged an excellent specimen plant of Mignonette. Mr. Frisby, gardener, Worden Hall, was the most successful in fine-foliage plants, also for twenty pots of miscellaneous

bulbs. Praise is also due to the last named for his excellent tray of vegetables for this season of the year. Mr. H. Wilding staged splendid Cyclamens, the best variety ever seen at Preston; he also gained the premier award for Primulas. Messrs. Dickson, Brown, & Tait staged the best Hyacinths, not for competition."

— **FRUIT AT THE NEWCASTLE SHOW.**—We have received a letter from Mr. J. H. Goodacre, in which he says he has "answered all the questions of 'Old Hand,' in some instances before they were asked;" also that "Mr. Hunter materially supports his arguments against the recognition of Tomatoes as dessert fruit, and coarse fruit generally." Another correspondent signing himself "A Young Hand," congratulates Mr. Goodacre on his courage in challenging the admissibility of fruits unsuitable for dessert tables, and doubts the advisability of providing classes in which only a few growers can compete, while the many are excluded. Mr. Goodacre is entitled to request the two "conscientious, independent, disinterested, and practical gardeners," whose names are published, to give their version of the awards, if he chooses to do so, and with that the controversy must cease. The decision of arbitrators is final, and we shall not allow their verdict to be criticised whatever it may be.

— **THE ENTERTAINMENT TO THE EMPLOYÉS OF THE ROYAL HORTICULTURAL SOCIETY.**—The Committee who have this matter in hand have arranged that the employés shall be invited to supper at the "Bolton Hotel," Bolton Garden, High Road, Chiswick, on Friday evening, April 6th, at 7 P.M. Mr. Harry J. Veitch has kindly promised to take the chair. Dinner tickets to visitors will be 5s. each. The hotel is five minutes' walk from Turnham Green Station. Those intending to be present should send their name to Mr. R. Dean, Ealing, the day previous.

HYACINTHS.

A MONTHLY meeting of the Notts Horticultural and Botanical Society was held at the Mechanics' Institute, Nottingham, recently, Mr. N. Pownall (Lenton Hall Gardens) in the chair. There were also present—Messrs. S. Thacker, Attenborough, Branstone, Baker, Kirk, Ralphs, Holmes, Edmunds, A. Page, E. Steward (Sec.), &c. A paper on the "Hyacinth" was read by Mr. Steward, who hoped that it would be the means of opening up a discussion on what, in his opinion, was really the great question for all gardeners and horticulturists in the present day—namely, how to "crop" their land so that it will pay the occupier and the owner. He should endeavour to show them that money could be made by growing bulbs and other flowering roots as well as it was done in the famous district in Holland. Mr. Steward then traced the history of the Hyacinth from its introduction from Greece in the year 1594. Since then Dutch growers had taken up the growth of this flower, the soil and situation of this district in Holland being particularly favourable for their development. The district in question was 1487 acres in extent, and it was estimated that the imports of bulbs to England annually reached £50,000, the bulb trade being a very extensive one. Few were aware of the amount expended in Hyacinths, bulbs, &c. The London parks required millions. Considering the present bad times their agricultural friends were passing through, he would suggest to them the advisability of turning their attention to the growing of bulbs, as he believed we had every variety of soil and climate suitable to their growth in the adjoining county of Lincoln. In fact, he knew of several growers in the neighbourhood of Spalding who raised many thousands of bulbs of various sorts for the trade in London and elsewhere, and he saw no reason why so much money should be sent into Holland, Germany, and other places for roots which could be grown as well, and in many cases superior, in our own country. Not long since he was shown a head of Snowdrops in one end of a barn near Peterborough, which consisted of about 250,000 roots. This heap was the result of about two acres growth, and had yielded a handsome profit to the owner by the flowers which had been gathered early in the spring, and yet that heap of roots was worth £180. If that was not a paying crop, he should like to know what was. Another item which he desired to mention was the growth of the Lily of Valley crowns. At the present time we imported something like 50,000,000 of this particular variety from Germany and Holland, at a cost of £25,000 per annum. All this money might just as well be saved and kept in our own country. Many thousands grown in Lincolnshire had been tried, and they had proved better in every respect than those grown abroad. He had had some of the finest Gladioli bulbs he had ever seen grown on poor sandy land near the Forest. He also mentioned in support of what could be done in England that there is a hundred acres of ground in Cornwall planted with Narcissus, and nearly the whole of the Seilly Islands are planted with the same flowers of various kinds for the supply of cut flowers for the London and midland markets. These flowers find a ready sale, and are extensively used for home and other decorations. They are without doubt some of the most useful of all cut flowers, on account of the long time they last after being cut.

A discussion followed. Specimens of Hyacinths and other flowers

were exhibited by Mr. James Booth, Chairman of the Society; Mr. R. Alford, Magdala Road, and others.

A cordial vote of thanks was awarded to Mr. Steward for his excellent essay.

SPRING FLOWERS.

THE following are some of the most prominent plants now in flower, the beauty of which cannot be too widely known.

ANEMONE BLANDA (Winter Windflower).—This must not be confounded with *A. apennina blanda*, which flowers some weeks later, and though a good plant, it cannot be compared with the first-named, either in size or general beauty, although in some respects it appears nearly allied. The flowers are sky-blue, about 2 inches across. It delights in peaty soil, or equal parts of peat and loam, and if a position sheltered from the blustering winds of March can be devoted to it, so much the better. In sheltered gardens this is a lovely plant, and if used as a belting to a bed of Rhododendrons or dwarf-growing American shrubs, it will afford most pleasing results. Every endeavour should be made to increase the stock of this plant, either by seeds or division. I prefer to sow the former as soon as ripe, and if all goes well the seeds will germinate in the following spring. The seedlings in turn should have every attention, and by the end of the growing season will have made good tubers, some of which will have flowered. Those who have had the opportunities to raise this plant in quantity from seeds will know how variable are the plants; and while these, so far as my experience of the plant is concerned, never surpass in beauty that of the original, yet many of them are nearly equal to it, and the worst well deserving every care.

ANEMONE FULGENS.—Another member of this genus, *Anemone fulgens*, is now striving to flower, and under the following circumstances. In the summer of last year the surplus of a large importation was planted, then, consequent upon their having been dry for a very lengthened period, somewhat shrivelled. At planting time the ground was dust dry, the result being that, apart from swelling considerably, the *Anemone* made no attempt to grow till the autumn rains began, when the ground was soon strewn with foliage, and towards the end of the year the flowers began to push forth. Could these have been protected from the severe weather of late there would have been a great show of bloom; as it was the bed has not been free from the brilliant scarlet flowers all the winter. I placed a few lights temporarily over them, which protected them from the winds that have damaged so many things of late. This goes to show that, however late these tubers are obtained, we are sure to secure a season of bloom from them, and should this come at the right time, so much the better. I have before planted some very much dried and shrivelled tubers late in spring, and had them in full flower in three months from planting. This is important, as showing what a succession of bloom a series of plantings may bring.

CHIONODOXAS, SCILLAS, PUSCHKINIAS.—Then comes the "Glory of the Snow," *Chionodoxa Lucilæ*, now glistening with its lovely flowers, so dwarf, so pleasing, while it is hardy and most enduring. I have a bed containing several thousands of its bulbs, planted about 2 inches deep, where they get froze hard as stone, coming through the soil as though nothing had happened, and expanding their blossoms in endless numbers. *Scilla bifolia* is just a day or two in advance of the last named, and its miniature sprays of blue are very pleasing. Both these plants and also *Chionodoxa sardensis* have been in flower in cold frames, and are now nearly past. Another beauty among early bulbs is *Puschkinia scilloides*. One cannot have too much of these things, so truly delightful are they. Here we have a white flower distinctly striped with blue, calculated to delight the most fastidious. It is an acquisition for the rockery or border in the early days of the year.

IRIS RETICULATA.—The intense violet purple of the delightfully fragrant flowers is always admired, and that deservedly, for no other spring bulbous plant can equal it. Choose a warm, sunny, and sheltered nook for this lovely gem, and plant it in very sandy loam. It is quite hardy, and should be in all collections of choice plants. There are several varieties of this plant, notably cyanea and Krelagei, the latter having light purple lilac flowers, quite distinct from all else. The seeds of these should be eagerly sought. All the forms of these netted Iris seed freely, and every care should be taken of them, and sow as soon as gathered. There is hardly a garden where this cannot be grown perfectly, for should the soil in the open ground be clayey, and consequently not suited to them, they may be grown admirably in pots in sandy loam sheltered by a cold frame or handlight.

HEPATICAS.—Another lovely group now in flower is formed by the Hepaticas, the innocent beauty of which cannot be overlooked. We find them represented by many shades of blue, lilac, and mauve, as well as red, pink, both single and double. Then we have

two very decided varieties in the single white and the old double blue. All these are peculiarly charming and full of interest in early spring, and should be largely grown by all who have room for a few of the most delightful of spring plants.

DAFFODILS.—Next we come into that multitudinous group of plants, the Daffodils and Narcissus, but these are later than usual.

Fig. 12.—*Narcissus incomparabilis albus expansus*.

Foremost amongst them, however, are the white Hoop Petticoat, *N. monophyllus*—so innocent and pretty are its satiny flowers—then the tiny little Trumpet Daffodil, *N. minimus*, just above the surface of the soil. This little one should have a spot where it can receive shelter from harsh winds and pelting rains, or its flowers are liable to be spoiled. Following this comes one of the most delightful of all, I mean *Narcissus pallidus præcox*, the soft yellow and sulphur of whose flowers are beyond description. I seem the more impressed of this fact as I annually see them develop into flower. There is much more in this lovely Pyrenean Daffodil than may appear at first sight, inasmuch as it opens up a

field for selecting some very distinct and pleasing varieties. In some there are six, seven, and ten segments respectively; in the one having the greater number the cup is bolder and more widely expanded, making a really grand flower. The hardiness of these plants is surprising. The buds are all ready for expanding, some on a south border being in flower, and having stood for several years undisturbed, are now exhibiting their great strength when established and fairly at home. They are planted in maiden loam, and were mulched last autumn early. During the autumn and winter season, when their roots are most active, they have been deluged with liquid manure, and this has evidently assisted them considerably. I believe in giving all the more robust Daffodils, and indeed many other plants too, that are established, a thorough soaking of liquid manure in this way, in preference to giving them crude manures of any kind, though this is not hurtful to many plants on certain soils.

Of innumerable other varieties now flowering under glass, or in early situations out of doors, the two following are especially worthy of note as types of large groups, namely—*N. incomparabilis albus expansus* (fig. 32), and *N. bicolor Empress* (fig. 33). The first has well formed flowers and open shallow crown, the perianth white, the latter yellow; the second has bold handsome flowers, the perianth white, the crown golden yellow, very similar to the celebrated *N. bicolor Horsefieldi*.

SNOWDROPS.—Snowdrops have been and still are very good, particularly *Galanthus Elwesi*, so large it seems against the old form *G. nivalis*, which still has its charms, and its purity and innocence when seen in a mass is not readily outdone; of course, *Elwes's Snowdrop* in similar quantity would make an astounding show, but there is much to be endured by its failing to grow readily from imported bulbs, which seem to be attacked by a sort of dry rot similar to that affecting Dog's Tooth Violets occasionally; this overcome, however, it will readily establish itself. In planting, I always use an abundance of sharp grit, in fact this seems very acceptable to almost any bulbs, particularly newly imported ones. The lovely *Crocus Imperati* must close the list of beautiful plants now in flower. It is fast becoming popular, which is a good sign, for it cannot be had in too great a quantity.—J. H. E.

ROYAL HORTICULTURAL SOCIETY.

MARCH 27TH.

MUCH interest had been excited amongst metropolitan horticulturists by the transference of this Society's Committee meetings and Shows to the new quarters at Westminster, and it was evident from the display produced that there was a general desire to render the experiment a success. The Drill Hall of the London Scottish Volunteers in James Street, Victoria Street, is a spacious and lofty building, a trifle dark in dull weather, like that of Tuesday last, but this is a defect which will probably not be noticed in brighter weather, in fact it may prove rather an advantage. There is ample room for a large exhibition, and the contributions on the opening day occupied considerable space, as besides the two long stages extending the whole length of the Hall, some groups were placed on the floor at the side, and some tables at both ends were similarly filled. Hyacinths, Daffodils, Cyclamens, Camellias, and Orchids were the leading features, but several miscellaneous collections of considerable interest were also staged, and added materially to the extent and beauty of the exhibition. London nurserymen came forward with great liberality, and amateurs' exhibits, though not so numerous, were varied and attractive in more than an ordinary degree.

By midday there was a large attendance of horticulturists, and the President, Sir Trevor Lawrence, Bart., M.P., in response to the request of several Fellows, made a brief but appropriate speech with reference to the Society's change of residence and prospects. He said that it had become impossible that the Society could remain at South Kensington any longer, as he understood the conservatory would be pulled down shortly. They had endeavoured to select as convenient and suitable a place for the meetings as possible, and he thought they had secured this in the Drill Hall, which was so well filled. The friends of the Society had contributed liberally to the opening show, and he hoped they would continue their assistance through the season, so that the public might be attracted. It was intended to forward the interest of practical horticulture in every way, and to press upon the Government the desirability of including horticulture in the new department for Agriculture and Forestry. He thought horticulturists could teach agriculturists something on profitable cultivation, and if the Royal Horticultural Society could take the leading part in this it would be engaged in a good work; and he concluded by stating that numbers of new Fellows had been elected, and they anticipated many more additions to their ranks, as without this it would be impossible to carry on the work of the Society.

COUNCIL MEETING.—At the Council meeting held in the afternoon it was decided to amend the privileges of Fellows paying 1 guinea, by permitting the ticket in future to be transferable.

A report in regard to the proposed Flower Shows in the City was discussed, and it was determined that two should be held, in May and November, if arrangements can be made for suitable positions.

A letter from Sir James Fergusson, Under Secretary of State for Foreign Affairs, to the President of the Royal Horticultural Society, was read, to the following effect:—That the Premier had directed him to lay before the Council of the Royal Horticultural Society a programme relative to an International Horticultural Exhibition to be held at Cologne in August, under the patronage of the Empress Augusta of Germany, and to ask if the Society would inform Lord Salisbury

Fig. 33.—*Narcissus bicolor Empress*.

whether they were willing to act as a Committee on behalf of any British horticulturists and others who may wish to take part in the Exhibition, and send a representative to Cologne. Also requesting the Royal Horticultural Society to give publicity to the proposed Exhibition, and stating that Lord Salisbury would cause the Committee for the Exhibition to be made acquainted with the steps taken by the Royal Horticultural Society if that body decide to take part in it.

It was resolved that Dr. Hogg and Dr. Masters be requested to act as representatives at the proposed Exhibition at Cologne, and that a reply be addressed to Sir James Fergusson to the effect that the Council agreed to comply with Lord Salisbury's wishes.

At general meeting of the Society held the same day, Dr. Masters,

F.R.S. in the chair, the following candidates were duly elected fellows :—W. H. Beaton, Mrs. A. Bevington, F. C. Capel, J. B. Concanon, Richard Cooke, E. H. Davitt, Chas. Dinham, J. Stewart Dismore, W. R. Foster, W. B. Hartland, Matthew Hodgson, Wm. Houghton, Thos. Jones, Wm. Langley, Gustav le Doux, Capt. Maxwell, W. H. Munro, Miss Pearce, J. Cater Price, Reginald Ryley, J. C. M. Veitch, Chas. F. Wintle, Hy. Yool.

FRUIT COMMITTEE.—Present—Harry J. Veitch, Esq., and subsequently Dr. Hogg, in the chair; and Messrs. John Lee, Phillip Crowley, G. T. Miles, W. Marshall, T. J. Saltmarsh, J. Woodbridge, Harrisou Weir, Charles Howe, Charles Ross, W. Warren, T. B. Hayward, G. W. Cummins, J. Cheal, R. D. Blackmore, W. Deming, J. Burnett, James Smith, J. Wright, J. Roberts, J. Willard, C. Norman, and Sidney Ford. As will be seen there was a large attendance of members, and several specimens were advanced for inspection. Herr Horvath, jun., sent bunches of three varieties of Grapes grown in the vineyards of Hungary—namely, Royal Muscadine, Chasselas Violet, and Beauty of Hungary, all small Grapes, and the berries were much shrivelled, but surprisingly luscious. A vote of thanks was awarded to the exhibitor. In striking contrast to the above were medium-sized bunches of Lady Downe's Grapes sent by Mr. G. Norman from Hatfield; the berries were medium-sized, beautifully finished, and as fresh and firm as in November. The bunches were cut early in January, and had been kept in a fruit-room since. A cultural commendation was unanimously accorded. Mr. Blair sent two bunches of Black Hamburg Grapes from Tretham Gardens, cut on January 18th; the berries were very large indeed, and only a little shrivelled, and the flavour was excellent. A commendation was worthily awarded both for good culture and good keeping.

W. Roupell, Esq., Harvey Lodge, Roupell Park, S.W., sent a collection of Apples grown in the suburbs of London. They were very fine, well meriting the vote of thanks that was accorded. Messrs. J. R. Pearson and Sons, Chilwell, sent further examples of their Newton Wonder Apple, which was found to maintain its character as a fine and good keeping variety. A seedling Apple was sent by Mr. W. Edwards, gardener to Lord Cadogan, Babraham Gardens, Cambs, medium-sized, firm, and no doubt a useful late sort, but apparently not sufficiently distinct for special notice. A dish of round, firm, good-sized Apples from Mr. Morell, exhibited by Messrs. Veitch, received careful attention. The variety was named Niton House, but was thought to resemble Stirling Castle too closely to warrant a certificate on this occasion. Mr. M. Dunn sent twelve varieties of Apples from Dalkeith. The first examined, named Cortis, was overripe; it is above medium size, and said to be the surest bearer in Aberdeenshire. Arniston, large, closely resembled Renette de Canada. Golden Pearmain was very large and good, but doubts were expressed as to its being correctly named. The same remarks as to nomenclature apply to fruits sent under the names of Herefordshire Pearmain and Winter Pearmain. Annat Scarlet was considered to be the Graham or Kentish Deux Ans, a serviceable variety. The large Hunthouse was sent as a good northern Apple, as it undoubtedly is, also fine fruits of Beauty of Wilts. A vote of thanks was accorded for the interesting northern consignment. Mr. Austin sent from Witley Court Gardens a late Pear which the Committee thought to be Merveille d'Hiver, or Marvel of Winter, but more specimens were required for satisfactory identification, as when one Pear is cut up and divided amongst twenty persons there is not much for each to examine.

Extensive and valuable collections of Apples, good in size, firm, well coloured, and correctly named, were staged by Messrs. James Veitch and Sons, Chelsea, and Messrs. J. Cheal & Sons, Crawley, Sussex, for which the thanks of the Committee were awarded with acclamation. The meeting was an excellent one for the time of year, a precursor, it is hoped, of others still better to follow.

FLORAL COMMITTEE.—Present—G. F. Wilson, Esq., in the chair; and Messrs. M. T. Masters, J. O'Brien, E. Hill, H. L. Lendy, H. M. Pollett, J. Dominy, H. Ballantine, C. Pilcher, G. Paul, R. Dean, T. Baiues, W. Holmes, W. Wildsmith, G. Duffield, W. Bates, H. Herbst, J. Laing, W. Wilks, Shirley Hibberd, B. Wynne, J. Walker, and W. Goldring.

A group of plants and flowers of exceptional interest was contributed from the Royal Gardens, Kew. Several good Acacias were shown from the rich collection in the temperate house, the most distinct being *A. cultriformis*, with silvery triangular phyllodes and spikes of yellow globular flowers; *A. verticillata*, with linear dark green leaves and pale yellow flowers, and the graceful *A. pubescens*. A flowering stem of a plant from Natal, which has been somewhat of a puzzle to botanists—viz., *Greyia Sutherlandi*, was shown, and it is peculiar in possessing both smooth and pubescent leaves on the same branches; the flowers are bright red in terminal clusters. *Sarcocolla usneoides* is a strange little leafless Orchid from India, having small yellow and brown spotted flowers with numerous twisting roots. A large flower head of *Brownia grandiceps* was very notable.

Flowers of the noble *Rhododendron argenteum*, the bright *R. barbatum*, and the red bell-like drooping *R. Thomsoni*, were included in the group. A distinct Japanese plant, *Azalea linearis*, has long linear hairy leaves and pink petals of exactly similar shape and size. Some *Philodendrons* comprised specimens of *P. erubescens* with a deep red spathe and white spadix, and *P. Simonsi*, which has a large spathe, bright red at the base, and white above, as also is the spadix. The white *Strelitzia Nicolai*; the white and drooping *Drimys Winteri* (Winter's Bark); the orange scarlet *Saraca indica* (*Jonesia Asoca*); *Haworthias*, *Arisæmas*, and several *Bromeliads* were also represented. Another group of large specimen *Hellebores*, bearing some hundreds of flowers, occupied a

position near the wall, and with the slender white-flowered *Cytisus filipes*, the bright green *Phyllanthus mimosioides*, and other plants, formed an important contribution. The *Hellebores* were chiefly *orientalis*, *colchicus*, and *guttatus*, and had been lifted from the open ground.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking (gardener, Mr. Bickerstaffe), contributed a choice group of new and rare Orchids, well-grown plants, and the majority flowering freely. Especially notable was *Cymbidium eburneum* with twenty fine ivory-white wax-like flowers. The three selected for certificates and described below—namely, *Spathoglottis Kimballiana*, *Dendrobium crassinode superbum*, and *D. splendidissimum grandiflorum*, were all remarkable plants. Besides these there were examples of *Angraecum Ellisi*, with long racemes of white flowers; *Epidendrum glumaceum*, pinkish and white, fragrant; *Trichoglottis fasciata*, with a leafy stem and neat flowers, white barred with brown, an old but seldom seen Orchid; *Odontoglossum Cervantesi roseum*, the flowers tinged with red, pretty; *Dendrobium Cambridgeanum*, bright gold, with a maroon blotched tip; *Masdevallia Lindenii superba*, very large and richly coloured flowers; *M. Carderi*, a peculiar little Orchid, with open, cup-like flowers, whitish dotted with brown, the reflexed tails lighter; *M. xanthocephala*, yellowish, small; *M. ignea*, a fine variety; *Cypripedium Measuresianum*, petals and lip of a glossy brown, the dorsal sepal streaked with green and brown; *Angraecum Leonis*, numerous racemes of white large-lipped flowers; *Cypripedium Swanianum superbum*, streaked with reddish purple on the dorsal sepal and lip; and an extremely large deep rosy red spathe of *Anthurium carneum*, 6 inches wide and 8 inches long.

A. H. Smee, Esq., The Grange, Wallington (gardener, Mr. Cummins), exhibited a group of Orchids, including several interesting plants. *Dendrobium macrophyllum giganteum* had a number of its large purplish mauve flowers, which possess such a strong and peculiar odour; a strong plant of the old but useful *Oncidium sarcodes* had a beautiful panicle of its brown and yellow flowers; the dull tinted *Phaius Wallichi* and several varieties of *Cattleya Trianae* were also shown. One of the latter was grown out of doors last year, and had rather small flowers; this season they are larger and of much richer colour in the lip. The variety *Emiliae* was notable for its fine shape and colour. *Dendrobium nobile*, *Masdevallia Shuttleworthii* and *triangularis*, with the bright orange scarlet *Lælia harpophylla*, *Odontoglossum Rossi*, and the fragrant *O. pulchellum* were also represented (bronze medal). H. M. Pollett, Esq., Fernside, Bickley, sent an uncommonly fine specimen of *Cœlogyne cristata alba* bearing about fifty pure white flowers. It was growing in a large basket and was in remarkably vigorous health. Gustav le Doux, Esq., East Moulsey, Surrey, showed a spike of *Dendrobium speciosum*, which had been forwarded from France; also a plant of *Cattleya Loddigesi* (vote of thanks). A cultural commendation was adjudged to W. C. Pickersgill, Esq., Blendon Hall, Bexley (gardener, Mr. Moore) for an extremely well flowered plant of *Lycaste Skinneri* with twenty-seven massive flowers.

A magnificent group of Hyacinths and other plants from Messrs. J. Veitch & Sons, Chelsea, deservedly secured for this firm a silver-gilt Banksian medal. Amongst the novelties the most noteworthy were the following:—A variegated form of *Rosa microphylla* with small leaves prettily streaked and dotted with white; fine specimens of *Boronia heterophylla* loaded with deep rosy red flowers were very handsome; *Trillium discolor atratum* has been previously certificated and described, but a cultural commendation was awarded for several plants of *Fritillaria Thompsoniana* (*Lilium roseum*), which has delicate blush-tinted flowers on erect stems. The group of Hyacinths comprised about 200 plants with massive spikes, representing all the best varieties in numerous distinct colours tastefully arranged. A new double variety named *Violet Gladiator* has dense spikes and reddish purple full flowers, something like a double form of *Harlequin* in colour. *Lord Salisbury* is another double variety, having taller and looser spikes, larger drooping bells of a similar tint, but with rather more mauve. Of the general collection the following varieties were notable for their clear, pure, or rich colours and fine spikes—*King of the Blues*, rich blue; *Masterpiece*, blue-black; *Mont Blanc*, pure white; *Chimney Sweep*, deep purplish blue; *La Joyeuse*, pink; *Countess of Rosebery*, deep red; *Obelisk*, yellow; *Harlequin*, reddish purple; *Madame Van der Hoop*, white; *Lord Derby*, pale blue; *Alba superbissima* and *Snowball*, white; *Distinction*, deep crimson red, black centre to the petals; *Criterion*, yellow; *Vuurbaak*, bright red; *The Sultan*, large spike, deep purple; *Sybil*, reddish purple; and *Star of Hillegom*, salmon red. Several fine baskets of *Lachenalia tricolor* with plants of *Rhododendron Early Gem*, were much admired.

Silver Banksian medals were awarded to the seven following exhibitors for important groups of plants and flowers. Mr. B. S. Williams, Upper Holloway, had a group of choice stove and greenhouse plants, including good specimens of *Diacaena Lindenii*, *Imantophyllum*, in numerous fine varieties, the white and fragrant *Toxicophlæa spectabilis*, with Ferns and other fine-foliage plants. Orchids were also a feature. *Odontoglossums Andersonianum* and *mirandum* were well represented; the peculiar *Phaius maculatus*, bearing yellow flowers and large green leaves spotted with white; *Cypripedium Boxalli*, *C. vernixium*, and others were shown, and a strong freely flowered specimen of the fragrant *Dendrochilum glumaceum* formed the corner of the group.

Messrs. J. Laing & Co., Forest Hill, staged a miscellaneous collection of flowering and fine-foliage plants, chief amongst which were several specimens of the pale yellow, free, and handsome *Acacia Drummondii*, with *Azaleas*, small useful *Ericas*, *Dracænas*, Ferns, and *Selaginellas*.

The Orchids comprised *Dendrobiums*, *Odontoglossums*, *Masdevallias*, and others similar to those noted at the Crystal Palace Show.

Cyclamens from Mr. C. Turner, Slough, formed an extensive and imposing group; some hundreds of well-grown plants were shown, representing a fine strain of seed and good varieties, the flowers large and very abundant. A box of handsome Tree Carnation flowers also came from the Slough Nursery (vote of thanks). Messrs. Lane & Son, Berkhamsted, had a large collection of Roses in pots arranged with *Deutzias*, and an extremely effective group. Amongst the Roses plants of *Général Jacqueminot*, *Princess Mary of Cambridge*, and *Countess of Rosebery* were noteworthy for the size and number of their blooms. Roses in pots, *Amaryllises* and *Lilacs* from Messrs. Paul & Son, Cheshunt, constituted an attractive group. The Roses were capital for such an early show, the plants healthy, and the blooms in several cases admirable. The best were *Comtesse de Camando*, *Avocat Duvivier*, *Celine Forestier*, *Dr. Andry*, and *Souvenir d'un Ami*, besides the graceful white *Parqueritte* and pink *Mignonette Polyantha* varieties. Plants of *Lady Alice*, the light coloured sport from *Lady Mary Fitzwilliam* (which it closely resembles), and the American Rose, *The Paritan*, were also shown and attracted much attention. The *Amaryllises* were distinguished by large brilliantly coloured flowers, and the fine white *Lilac, Marie Lemoine* (certificated) was remarkable for the size of its blooms even in comparison with *alba grandiflora* shown with it.

Camellias, contributed by Messrs. W. Paul & Son, Waltham Cross, were greatly admired. Twelve boxes of blooms were shown, and a fine selection of varieties included. These will be noted more fully in an early issue, but the following were prominent for their distinctness. *C. H. Hovey*, *Alba plena*, *Princess Charlotte*, *Corallina*, *Fimbriata*, *tricolor*, *Mathotiana*, *Bonomiana*, *Benneyi*, *Fatima*, and *Romaniensis*.

Daffodils and hardy flowers filled one side of a long table, but the collection from Mr. T. S. Ware, Hale Farm Nursery, Tottenham, amply merited the silver medal awarded. All the chief sections of *Daffodils* were represented, the pseudo-*Narcissus*, *incomparabilis*, and poetical types being in strong force, and comprising some exceedingly beautiful varieties. There were fine pans of the charming blue *Cibionodoxa Lueiliæ*, with the darker *C. sardensis*, *Grape Hyacinths* in variety, *Dielytras*, and numberless other choice plants. Messrs. Barr & Son, King Street, Covent Garden, exhibited a choice collection of *Daffodils* and hardy flowers similar to the above, but not quite so numerous (bronze medal), and Messrs. Collins Bros., 39, South Lambeth Road, S.W., had a group of *Narcissus obvallaris*, the golden *Tenby Daffodil*, and the delicately coloured *N. pallidus præcox* most effectively arranged in glasses (bronze medal). Mr. R. Drost, Richmond, sent large flowering branches of fine white *Lilac*.

Hæmanthus bicolor from Mr. W. Bull, Chelsea, was awarded a vote of thanks. It is very distinct, with red stamens and linear bluish tinted nearly white perianth divisions, the flowers being borne in a dense umbel, as with others of the genus. Similar recognitions were awarded to Messrs. F. Sander & Co., St. Albans, for *Masdevallia Sanderiana*, which has dark reddish-purple flowers, white in the centre and long yellow tails; and for Mr. Cookson's hybrid *Cypripediums*, *liniolare* and *pluneurum* (*venustum* × *villosum*), the latter having a dark lip and petals with a green striped dorsal sepal. Mr. C. Ross, Welford Park Gardens, Newbury, showed a plant of *Croton Rossi* (vote of thanks.) It is the result of a cross between *Weismanni* and *Veitchianus*, and has broad leaves, rich gold in the centre and green margins, very effective. Mr. Moggridge of Topsham was also accorded a vote of thanks for a seedling *Abutilon*, with very dark red and well-formed flowers. Mr. Troughton sent a plant of *Clivia miniata superba*, having a large truss of deep orange red flowers. A. S. Smith, Esq., Silvermere, Cobham (gardener, Mr. Quarterman), exhibited a plant of *Cœlogyne eristata* with two racemes to a pseudo-bulb, having six and eight flowers each. Mr. C. Herrin, Dropmore Gardens, Maidenhead, sent a box of fine *Camellia* bloom. Mr. Divers, Ketton Hall Gardens, Stamford, showed *Camellia* blooms and *Cianthus magnificus*, and Mr. C. Ford, Leonardslee Gardens, Horsham, was awarded a bronze medal for a beautiful collection of *Camellia* blooms.

CERTIFICATED PLANTS.

Spathoglottis Kimballiana (Sir Trevor Lawrence, Bart., M.P.).—A pretty terrestrial Orchid, with a scape over 2 feet long, having three expanded flowers and several buds at the apex. The flowers are 2½ inches in diameter, the sepals and petals oval, similar in size, shape, and colour, a bright shade of yellow; the lip is small dotted with red at the base. The leaves are long, narrow, and plicate.

Dendrobium crassinode superbum (Sir T. Lawrence).—A handsome variety with large flowers, the sepals, petals, and lip deeply tipped with rich rosy crimson.

Dendrobium splendidissimum grandiflorum (Sir T. Lawrence).—A hybrid between the same species as *D. splendidissimum*—namely, *D. aureum* and *D. nobile*, but from finer varieties. It is a grand *Dendrobium*, with broad sepals and petals tipped with crimson, the lip broad and open, intensely rich crimson in the centre. The plant shown had three flowering growths.

Phalænopsis John Seden (Baron Schröder).—One of the Chelsea hybrids, and bearing its raiser's name. It was obtained from a cross between *P. grandiflora* and *P. Luddemanniana*, and has plain green leaves with flowers 2 inches in diameter, white, freely dotted with purple, the lip three-lobed and tinged with reddish purple. It is the most distinct hybrid *Phalænopsis* yet obtained, and is very attractive.

Lilac Marie Lemoine (Paul & Son).—An extremely fine single white variety, the flowers seven-eighths of an inch in diameter, in large dense trusses. Very handsome.

Rose Gloire de Polyantha (Paul & Son).—An attractive and graceful variety of the polyantha type, with small neat blooms, deep rose, with white centre.

CRYSTAL PALACE SPRING SHOW.

MARCH 24TH.

THE first Sydenham Show of the present year was held on Saturday last, and, notwithstanding the unfavourable season, the display was a varied and satisfactory one. The Crystal Palace Company have provided a long series of important exhibitions for 1888, and the schedule is an unusually full one. The summer Show is fixed for May 12th (forty-five classes); the National Rose Society's Metropolitan Exhibition for July 7th (forty-seven classes); the National Co-operative Flower Show, August 18th, when £350 and ten medals will be offered. The Fruit Show takes place on September 7th and 8th (forty-seven classes); the National Dahlia Society's Show being fixed for the same date (twenty-two classes). A Hardy Fruit Show will be held October 11th to 13th, and a Chrysanthemum Show on November 9th and 10th. Numerous special prizes are also offered on each occasion, so that an interesting horticultural programme is provided under Mr. W. G. Head's direction.

At the spring Show the chief attractions are invariably the nurserymen's contributions, with the *Hyacinths*, *Tulips*, and *Polyanthus Narcissi* in competition, and on the occasion under notice these were the leading features. The amateurs' contributions of *Cinerarias* and bulbs were not of first-rate quality, but the season is undoubtedly to blame for many of the defects in these classes, as wherever attempts have been made to hasten the development of the plants the results were not quite satisfactory. In the open classes for bulbs Messrs. H. Williams and Son, Fortis Green, Finchley, and Mr. H. R. Wright, Turner Road, Lee, shared the prizes, the first-named leading with thirty-six *Hyacinths*, thirty-six *Tulips*, and twelve pots of *Lilies of the Valley*; Mr. Wright being second with *Hyacinths* and *Tulips*, and first with twenty-four pots of *Polyanthus Narcissi*. The Finchley *Hyacinths* comprised some good specimens of *Czar Peter*, *La Belle*, *The Sultan*, *Lord Derby*, *La Grandesse*, *Gigantea*, *King of the Blacks*, *Vuurbaak*, and *Lord Macaulay*. The best of the *Tulips* were *Proserpine*, *Rose Gris de Lin*, *Keisers Kroon*, *White Pottebakker*, *Vermillon Brillant*, *Van der Neer*, and *Joost Van Vondel*. The two collections of *Narcissi* were very close in merit, Mr. Wright's plants having fine spikes and flowers of *Her Majesty*, *Gloriosus*, *Laura*, *Queen of the Netherlands*, *Newton*, *White Perfection*, *Apollo*, and *Bazelman Major*. Mr. J. May, Twickenham, and Mr. J. Odell, Hillingdon, were first and second respectively with *Cyclamens*, and Messrs. Paul and Son, Cheshunt, were first with twelve *Amaryllises*, strong well-formed plants.

An extremely bright and tasteful group of miscellaneous plants gained Messrs. Laing & Son, Forest Hill, the premier award in the class, flowering and foliage plants being well proportioned. *Palms*, *Dracænas*, *Crotons*, *Aralias*, and *Ferns* were the chief of the latter, while amongst the flowering plants *Orchids* were prominent, especially *Cattleyas*, *Masdevallias*, and *Dendrobiums*; the peculiar *D. Brymerianum* was notable, also *D. crassinode*, *D. Wardianum*, and *D. densiflorum*. Small plants of *Erieas*, *Cyclamens*, *Azaleas*, and a neat margin of *Selaginellas* completed the group. *Azaleas* were shown by Mr. R. Wells, Sydenham, and Mr. C. Nunn, gardener to J. Soames, Esq., Maze Hill, Greenwich Park, but the plants were not quite up to exhibition style in either case.

In the amateurs' classes Mr. C. J. Salter, gardener to C. J. Southgate, Esq., Selborne, Streatham, was the leading exhibitor of twelve *Hyacinths*, showing capital plants of *Solfaterre*, *La Grandesse*, *Gigantea*, *Leopold II.*, *Leviathan*, *Czar Peter*, and *L'Innocence*. Some of the spikes were very fine. Mr. W. Kemp, gardener to H. Barry, Esq., Bushill House, Winchmore Hill, and Mr. T. N. Penfold, gardener to Rev. Canon Bridges, Beddington, were second and third, the last named being first with twelve *Tulips* and twelve *Narcissi*. Mr. C. J. Salter had six good *Amaryllises*, winning the first prize, *Cyclamens*, *Cinerarias*, and *Lilies of the Valley* being shown by several competitors. Mr. Phillips was placed first with twelve large *Cyclamens*, but many preferred Mr. Hibbert's second prize plants.

Special prizes were awarded as follows—To Mr. B. S. Williams, Upper Holloway, for a large and handsome group of bulbs and flowering plants; to Messrs. W. Paul & Son, Waltham Cross, for a choice collection of *Camellias*; to Mr. W. Hibbert, Kingston-on-Thames, for collection of *Cyclamen*; to Mr. W. Kemp, Winchmore Hill, N., for eighteen Chinese *Primulas*; to Messrs. Paul & Son, Cheshunt, for collection of alpine plants; to Mr. H. Wright, Lee, Kent, for collection of flowering plants; to Messrs. Barr & Son, Covent Garden, for collection of *Daffodils*, &c.; to Mr. T. S. Ware, Tottenham, for collection of herbaceous plants and *Daffodils*; to Messrs. H. Cannell & Sons, Swanley, for collection of winter-flowering *Begonias*, *Cinerarias*, and cut *Pelargoniums*; and to Mr. J. Odell, Hillingdon, Middlesex, for collection of 100 *Cyclamens*; Mr. H. Bennett, Shepperton, also had a box of *Rose* blooms, including several promising new varieties.

Certificates were awarded for the following:—

Rose Lady Alice (Paul & Son).—A Hybrid Perpetual of the *Lady Mary Fitzwilliam* type, previously described.

Narcissus Johnstoni (Barr & Son).—A pretty *Narcissus* with deflexed flowers, bright yellow, the crown long and straight.

Cyclamen persicum floribundum compactum (J. Odell).—A very strong but dwarf variety, with large flowers, white, tipped crimson.

Begonia semperflorens gigantea rosea (Cannell & Sons).—A vigorous-growing variety with large, deep, very red flowers in fine panicles.

BATH BULB SHOW.

MA CH 21ST AND 22ND.

A CAPITAL display of bulbs and various other flowering and fine-foliaged plants was again forthcoming, and being favoured with delightfully fine weather on the opening day another decided all-round success was scored.

HYACINTHS AND OTHER BULBS.—There was no appreciable change or advance made as far as quantity of exhibits was concerned, but neither the Hyacinths nor Tulips generally were quite so good as usual. In the open class for eighteen Hyacinths, distinct, Messrs. R. Veitch and Son, Exeter, repeated their last year's success, being first with a collection which included many sturdy spikes, carrying well developed flowers. The varieties shown were Queen of the Blues, Madame Van der Hoop, King of the Blues, Grandeur à Merveille, Lord Derby, Kohinoor, Marquis of Lorne, King of the Reds, Baron Von Tuyl, Primrose Perfection, Gigantea, Vuurbaak, Garrick, Lady Derby, Duke of Connaught, Czar Peter, President Lincoln, and General Pellissier. Messrs. G. Cooling & Son were second, and Mr. M. Cole, gardener to S. Tredwell, Esq., was third, and there were two other collections shown. The best twelve Hyacinths in pairs were shown by Mr. W. Taylor, gardener to S. P. Budd, Esq., who had Masterpiece, King of the Blues, Cardinal Wiseman, Due de Malakoff, King of the Yellows, and Lord Macaulay, compact and good. Mr. M. Cole was second. Messrs. R. Veitch & Son were again first in the open class for nine Hyacinths, followed by Mr. W. Taylor. In the next class for twelve Hyacinths, distinct, and confined to amateurs, the prizes were won by Mr. W. Taylor, Mr. S. Kerslake, gardener to the Rev. E. Handley, and Mr. G. Marsh, gardener to M. Dunlop, Esq., Clifton. In a corresponding class for six varieties Mr. W. Taylor was again first, Mr. A. Hawkins, gardener to T. Jolly, Esq., was second, and eight others competed. There were six competitors with twelve pots of Tulips, Mr. Taylor taking the lead with fresh and good examples of Murillo, Emperor of Austria, Grand Duke of Russia, Vermillon Brillant, Tournesol, Salvator Rosa, Proserpine, Velvet Gem, Joost Van Vondel, and Ophir d'Or. Mr. A. J. C. Biss was a good second, while Messrs. Taylor and J. E. Biss were the successful exhibitors of four pots. The best six pots of Polyanthus Narcissus were staged by Mr. C. H. Dutton, the varieties being Gloriosa, Soleil d'Or, and States General. Mr. J. Cannings, gardener to E. B. Titley, Esq., was second. Messrs. G. Cooling & Son were first with three excellent pots of Lily of the Valley, and Mr. J. E. Biss second. Mr. Dutton was first for Crocuses, and Messrs. M. Cole and A. Hawkins took the prizes for Amaryllises. A great number of Cyclamens were shown, but the majority were much drawn and the strain inferior.

FLOWERING AND FINE-FOLIAGED PLANTS.—The display of Orchids was much better than anticipated, and attracted great attention. With six plants the Rev. E. Handley was well first, these consisting of Cattleya Trianae with eleven richly coloured flowers; Odontoglossum cirrhosum with five good spikes; a freely flowered Dendrobium nobile; Odontoglossum Roezli roseum with eighteen spikes; Odontoglossum Roezli album with twelve good spikes; and Cattleya Trianae rosea, carrying ten fine blooms. Mr. F. Perry, gardener to H. C. Miles, Esq., Clifton, was second, his collection consisting of Lycaste Skinneri, Dendrobium Ainsworthi, Cypripedium villosum, Dendrobium nobile, Odontoglossum Pescatorei, and Odontoglossum Alexandrae. Mr. W. J. Mould, gardener to E. E. Bryant, Esq., was first for three plants these consisting of Cattleya amethystoglossa, Dendrobium Ainsworthi, and Cœlogyne cristata. Mr. R. B. Cator was second. The most beautifully flowered specimens were staged in the class for one Orchid. In this instance Mr. W. J. Mould was first with Phalaenopsis Schilleriana, having a grand branch bearing about fifty expanded flowers. The Rev. E. Handley was second, staging Dendrobium Wardianum with five pseudo-bulbs, carrying on an average twenty blooms each.

The class for six Roses in pots was also a good one, there being five well flowered trained plants. Mr. H. Kiff, gardener to R. B. Cator, Esq., was first, having freely flowered specimens of Madame de Sertot, Souvenir d'un Ami, Madame Willermoz, Celine Forestier, Rubens, and Anna Ollivier. Mr. H. Jones, gardener to C. Doherty, Esq., was second, and Mr. S. Kerslake third. Messrs. W. J. Mould, H. Jones, and A. Hanham, gardener to T. Jolly, Esq., were the principal prizewinners with trained Azaleas, and the two first-named were also successful with stove and greenhouse flowering plants and Ferns. Primulas were well shown by Messrs. W. J. Mould and W. Taylor; Cinerarias by M. Cole and A. J. C. Biss; table plants by F. Perry and A. J. C. Biss; and fine-foliaged plants by W. J. Mould and W. C. Drummond, who took the prizes in the order named in each instance. Mr. M. Cole was placed first for six pots of Violets, which included De Parme, Princess Maude de Savoie, New York, and King of the Violets.

GROUPS.—There were three classes for these, and the competition was keen in each instance. Messrs. G. Cooling & Son were well first for a group to occupy a space 12 feet by 6 feet, the arrangement being fairly light, and comprised Azalea mollis, Indian Azaleas, Ericas, Cattleyas, Odontoglossums, Cypripediums, and other Orchids, Palms, and Ferns. Mr. W. C. Drummond was a creditable second. Groups 9 feet by 6 feet were arranged by amateurs, and in this class Mr. W. J. Mould was easily first, and Mr. T. J. Tate second, the latter named having a very

densely packed arrangement. There is a great sameness about all the Bath groups, and it is to be hoped some of the exhibitors will on another occasion attempt something more novel and less formal. Five capital groups of Daffodils and Narcissi were arranged, these plants being very popular in Bath. Mr. S. Kerslake was first, and Mr. A. A. Walters second. A group of herbaceous plants in pots, staged by Mr. M. Cole was awarded the first prize, and fully deserved it.

CUT FLOWERS AND BOUQUETS.—Mr. H. Riff was first for twelve cut Roses, among these being a very fine Souvenir d'un Ami, and good Madame Willermoz, Madame de Watteville, Niphotos, A. K. Williams, Catherine Mermet, and La France. Mr. S. Kerslake was a good second, his best being Lady Mary Fitzwilliam, Madame J. Halpin, Grace Darling, Madame Lambard, and W. F. Bennett. Messrs. Cooling and Son also staged several good blooms. Mr. E. T. Hill was the only exhibitor of a vase for table decoration, and was rightly awarded the first prize. Only three hand bouquets were shown, but two of them were extra large, and much difference of opinion existed as to the decision arrived at by the Judges. The first prize was awarded to Mr. C. Winstone, Clifton, who had a bouquet wholly formed with Orchids; these measured 18 inches across, and were much too closely packed. Messrs. Perkins & Sons had a much more tastefully formed bouquet, the flowers used also being choice. This also was too weighty, but should yet have been first. Mr. Winstone was first, and Messrs. Perkins & Sons second in the class for ladies' sprays, and the same positions were held by these exhibitors with gentlemen's buttonhole bouquets. The majority of the latter were much too large. Mr. J. Cypher, Cheltenham, had a grand stand of Orchid blooms, not for competition, interspersed with Fern fronds. Conspicuous were Cattleya Trianae magnifica, C. Percivalliana, C. amethystoglossa, Dendrobium Jamesianum, D. Ainsworthi rosea, Odontoglossum Roezli in variety, Angreem sesquipedale, Cypripedium Harrissianum splendens, Odontoglossum Alexandrae, Cymbidium eburneum, and the Chatsworth variety of Cœlogyne cristata.

FRUIT AND VEGETABLES.—Few Pears and Apples were shown. With one dish of the former Mr. E. T. Hill was first, staging Beurré Rance in good condition, Mr. Leaney being second with Uvedale's St. Germain. A dish of well kept King of the Pippins won Mr. Leaney the first prize in the class for Apples, and Mr. W. Iggulden, Frome, was awarded the first prize for a good dish of Strawberries, the variety being the Princess of Prussia. Mr. M. Cole was first for Mushrooms, and Mr. A. J. C. Biss second. Mr. W. Evry first for Seakale, and Mr. W. Tylee second; and Mr. Evry first for Asparagus, the exhibits being good in each instance. Mr. W. Evry had the best six dishes of vegetables, these consisting of Kidney Beans Ne Plus Ultra, Asparagus, Mushrooms, Seakale, Brussels Sprouts, and Potatoes. Mr. W. Tylee was placed second; while the prizewinners with Cucumbers were Messrs. M. Cole and S. Kerslake.

ROSES AND THEIR RAISERS.

IT may interest "D., Deal," to have the dates and names of the raisers of the Roses he mentions on page 243, and which are as follows:—Laurette, Verdier, 1852. Emilie Dupuy, Levet, 1870. Claire Carnot, Guillot, 1873. Countess of Limerick, Nabonnand, 1877. The substitution of Emilie Dupuy for Belle Lyonnaise is one which might be generally recommended, for Belle Lyonnaise is sadly tender, and the flowers are easily spoiled by wet, whereas Emilie Dupuy is hardy, and opens fairly in late autumn.

I am glad to see that "D., Deal," continues to look after the single Roses, especially the beautiful Austrian Yellow and Copper. Here R. berberifolia Hardyi has survived the past two winters, both on the rockery and in the open, and flowers most freely.—T. W. GIRLLESTONE.

OIL AND SULPHUR AS A PREVENTIVE OF MILDEW ON ROSES.

AS some of your correspondents seem troubled with mildew I may state that I have found oil and sulphur applied to the hot-water pipes quite effectual in destroying mildew, and up to the present as a preventive. Some weeks ago we found the mildew making its appearance on pot Roses, and also on climbers trained to wires on the roof of our Rose house. I procured some linseed oil and flowers of sulphur, mixed to the thickness of paint, and applied to the return pipes with a paint brush. The mildew soon disappeared, and has not returned. I consider this preferable in every way to the solution mentioned on page 243, and I strongly recommend those having Roses affected with mildew to try it. It is easy of application, very effective, and only needs to be tried.

I may also state that I agree with your correspondents "N." and Mr. D. Gilmour, jun., in not admitting air to forced Roses. Our ventilators have not yet been opened, except on one or two occasions about an inch at the top, but in future under the same circumstances they will not be opened. On bright days we open the door which admits to the greenhouse adjoining, in which the ventilators are open.—GEO. HILTON.

ROSES ON THE MANETTI.

A CORRESPONDENT sends me a sketch of a Rose plant he has received with others, and asks, "How he is to plant it, or what is he to do with it?" My reply is, "Throw it away if it is on the Manetti." If we waste our time at all in planting Roses on this stock, we must, to plant them properly, bury the Manetti 2 inches below the surface. If we do so in this case, the roots will be so far from sun and air, that

Fig. 34.—Manetti budded too high.

Fig. 35.—As it should be budded.

failure will probably result. When such plants as these (fig. 34) are received from the nursery, by far the best course to adopt is to return them at once.

I give a sketch (fig. 35) of what a budded plant should be on any stock. This, I think, bears its own explanation with it without further words from me. I may say, however, that the stock might be cut a little closer without detriment.

Where fig. 34 happens to be on a Briar it should be treated as a small standard; at any rate this is the way that such a plant will answer best; in this way only can the roots be placed near enough to the surface.—D. GILMOUR, JUN.

UNDER GARDENERS.

In reply to "J. P. L.'s" remarks, I repeat that my opinion of under gardeners writing down those less fortunate than themselves is very poor. Your correspondent hastily accuses me of denouncing head gardeners. I spoke in praise of four, three I had served under, and only noted one exception. I am sorry for the discernment of "J. P. L." if he thinks this denouncing them all. When letter after letter appear written in a spirit of censure against under gardeners, it behoved me to take up their defence as a sympathiser with those who suffer wrong not of their own making. This brings me to the remarks on forgetting my position. I am of opinion that no individual should hold the future of his subordinates at his entire mercy, to give a character or to withhold one. In that I even propose to limit my own power, for I am master of my position, and my employer never intervenes between me and my men. I thank "A Foreman" for his remarks. I hope soon to hear he has joined the ranks of head gardeners, who know how to get the most work done and yet treat their men kindly.—HEAD GARDENER, *The Grove, Teddington.*

SELF-IMPROVEMENT.

I SEE in the Journal that young gardeners are recommended to learn shorthand. Several years ago I learnt enough of shorthand to be able to take down the greater part of the sermons in church on Sundays, but as I did not find it of any other use it gradually fell into the back-ground, and I do not think I could make use of it now without learning it afresh. There are many other subjects more useful than shorthand to gardeners. The following I consider the best in the order given:—Writing, spelling, English grammar, drawing, botany, agricultural chemistry, Latin and French. If the rudiments of the last four subjects only are learnt, they will be found very useful, but of course it will be much better if any or all of them can be thoroughly mastered. I find them all useful at times, with the exception of shorthand, and for that reason I recommend it to be last taken up.—J. L. B.

I HAVE read with much interest the correspondence under the heading of "Under Gardeners." I have been an under gardener for the last nine years, and confess I have been under more good masters than bad. Some head gardeners are very exacting in expecting the men under them to work overtime systematically and without any recompense. I am not against working an hour or two overtime on special occasions, but, on the contrary, am quite willing to do so, and I do not like to see young men leave off work as soon as the hour strikes as if they were wound up like the clock. I have always had pleasure in working in preparing for an exhibition, and had ample reward in visiting the show. My advice to my fellows is to do the best they can in their positions, and look forward to better days. Head gardeners

have bad times to contend against, restricting labour, and allowance should be made for this by subordinates.—SCOTCHMAN.

[A "Scotchman" requested us to correct his manuscript; we have done so freely, and now advise him to improve himself before he writes to the press again, and then to afford space between the lines for revision. At present we cannot congratulate him on the excellence of his work. A letter from "A. B." is not suitable for publication, and he must strive assiduously in improving his education if he aspires to the rank of a good representative British gardener.]

FRUIT PACKING.

MR. PETTIGREW'S reply to my criticism, contrary to his intention, is certainly courteous. Of course, I could not have been aware his paper on the above subject was written at the request of his particular gardening friend, who he states is a constant reader of the *Journal of Horticulture*, and a keen observer. No doubt the same distinction is equally applicable to a large number of readers, and this must be my only plea for intrusion. Mr. Pettigrew is evidently desirous that his plain statement of facts should be rightly understood. I must confess, as they have been stated, I have not comprehended them. For instance, Mr. Pettigrew states he can send Grapes hundreds of miles under pressure on all sides of packing materials, and at the journey's end they will be found as fresh as when cut from the Vines. The secret of this would be well worth knowing even by the keenest of observers; but possibly I may have mistaken the meaning of Grape packing, as Mr. Pettigrew says I have done respecting the use of two boxes in Peach packing. They may both be statements worth knowing to all constant readers, and especially to—R. W.

PRINCESS TECK IN SPRING.

IN reply to Mr. W. Brown (page 223) relative to late-blooming plants of the above Chrysanthemum mentioned by Mr. Pettigrew, I am glad to give any information I can. Your correspondent asks how many flowers were borne by each plant, and of what size were the largest blooms?

Fifty plants after blooming as usual were cut down with the general stock. But these plants, I am informed by the propagator, were struck from late-flowering plants of last spring, and were not more than eleven months old when I told Mr. Pettigrew they were struck with the general stock. Every year we have some plants of Princess Teck to throw up late bloom, but this season every plant threw a good head of growth, which has bloomed profusely, and the plants have averaged three dozen blooms each of the ordinary size of those usually produced in autumn and not disbudded. Up to this time they have made as good a display as in the autumn, in proportion to the number grown. The flowers are more variable than those of the same plants in the autumn, many of them being reflexed and almost Japanese in character. Whether I have obtained simply by selection (the Chrysanthemum being perhaps more given to sporting than any other florist flower) an approach to a perpetual flowering Chrysanthemum or not I cannot say, but certainly the side shoots are again breaking into buds at almost every point on plants not yet cleared of their bloom, just as a Marguerite would do.

In this district (South Wales) our greatest demand for white flowers is for grave decoration on "Flowering Sunday"—the Sunday before Easter, after which I do not expect to keep the plants, but I will certainly retain a few that anyone interested in their repeated blooming may see them. I send a handful of young growth taken from one plant (that has already yielded two crops of bloom—viz., in the autumn, and during February and March), with buds in all stages. I send only a few open blooms as they are wanted this week, as just mentioned.—R. CROSSLING, *Penarth Nurseries.*

[The blooms received are exactly as described by our correspondent, and the young growths are bearing a profusion of buds from the size of peas upwards, the florets of some just unfolding. There are eight of such buds branching from one stem, all fresh and healthy, and which would have expanded if left on the plants. The flowers are admirably adapted for wreaths.]

SUMMER FLOWERING CHRYSANTHEMUMS.

IN my opinion these are the most useful plants in the flower garden. They are hardy, and they are so easily managed that any novice may succeed with them. They flower freely in all situations. They grow well in towns under the direct influence of smoke, exposed to the sea breeze, under the shade of trees, and in positions where flowers generally do not succeed, and yet these Chrysanthemums prove gay and attractive under all circumstances. They begin flowering about the end of June, and continue to do so until frost destroys them. When we had our first plants of them we propagated them in heat in the spring, but when once the plants were established in the open we ceased to propagate indoors, and now allow the plants and roots to remain in

the soil all the winter, when they are lifted in April, divided into little pieces with a root attached to each, and replanted. This is our practice when we wish to increase them; if not, they are allowed to remain in the same position. Beginners will, however, require to buy a few plants, and I would advise this being done now, as many cuttings may be secured from the new plants before planting time. Immediately the plants are secured place them in moderate heat, and as soon as the growths are sufficiently large to form cuttings, take them off and root them in gentle heat. Placed out in May in the open they spread their sucker-like growths before the autumn, and these may be divided the following spring. Soil that will grow Pelargoniums will always produce fine Chrysanthemums of this class. Probably anyone not acquainted with these Chrysanthemums, seeing an isolated plant in flower might feel disappointed with it, as the flowers are not large, or anything like those huge blooms seen at shows, but when seen in a mass or in long rows they delight everybody. They may be used in the most artistic flower garden, the best kept pleasure grounds, or in the borders of any kitchen garden. The following are six useful varieties, named in the order of merit:—Madame C. Desgrange, white, yellow centre; Félicité, orange yellow; Lyon, deep rosy purple; Souvenir de M. Rampont, reddish; Nanum, silvery blush; and Frederick Pélé, deep crimson.—*J. MUIR, Margam, S. Wales.*

FRUIT FORCING.

FIGS.—Earliest-forced Trees in Pots.—The fruit will soon commence ripening, especially the small varieties, when the supply of water must be gradually reduced, and gradually withhold moisture from the atmosphere, keeping the top lights open constantly. Still continue to supply liquid manure to those trees on which the fruit is swelling, and syringe the trees at closing time, ventilating in favourable weather.

Early-forced Planted-out Trees.—Surface roots are of importance in the cultivation of fruit trees, especially those grown under glass with the roots inside. No fruit tree produces such roots so freely as the Fig if means are adopted to encourage them. A mulching of about 3 inches thickness of partially decayed manure will attract the roots to the surface and prove beneficial if kept moist. Liberal supplies of water or liquid manure will be necessary to assist in swelling the fruits satisfactorily. Continue to pinch out the points of the shoots and thin all crowded growths. No kind of fruit tree is more benefited than the Fig by the full rays of the sun; shading of any kind, even too much of their own foliage, is injurious. The temperature may now be increased to 60° to 65° at night, and in the daytime from 75° to 80° with sun heat. Attend to tying-in the shoots, allowing space for growth.

Raising Young Trees.—If it be desired to increase the stock cuttings may still be inserted, selecting shoots about 6 inches long, taking them off with a heel or portion of last year's wood attached. They strike readily in bottom heat. They are best inserted in 3-inch pots singly. When rooted shift without delay into 5-inch pots, and when they fill that size with roots transfer to 12-inch pots. Good drainage is necessary, and turfy loam with about a sixth of old mortar rubbish and a fifth of decayed manure forms a suitable compost, potting firmly.

PEACHES AND NECTARINES.—Earliest Forced Trees.—Do not hurry the trees during the stoning process, but continue the temperature at 60° to 65° at night, 70° to 75° by day with sun heat, and about 65° by day in dull weather, being careful to avoid sudden fluctuations or depressions. Tie the shoots to the trellis as they advance, and regulate the growths for future bearing so as not to have them too crowded, as by giving the shoots plenty of room the fruit is better exposed to sun and air, and the wood for another year is stouter and better ripened. Shoots disposed to grow more than 14 inches may have the joints pinched out, those remarks not applying to extensions. When the stoning process is over, which may be ascertained by testing a few fruits with a knife, the fruit will require regulating for the swelling-off period. Very vigorous trees may be allowed to carry a few more than those that are weakly, but on no account unnecessarily tax the trees with more fruit than can well be brought to maturity without prejudicing future crops. Weakly trees should be supplied with liquid manure, and the inside border in any case must be kept properly supplied with water, mulching the surface with partially decayed manure. This will secure more uniform moisture, and the fruit will swell to a good size. The temperature may be increased to 65° or 70° at night, and in the day to 70° or 75°, maintaining 85° or 90° through the day from sun heat; ventilate from 75°, and close early with plenty of atmospheric moisture. The very early varieties, such as Alexander, Waterloo, and Early Beatrice, will soon give indications of ripening, when syringing must cease, and the leaves that shade or overhang the fruit must be drawn aside, and the fruit raised on laths if necessary across the wires of the trellis so that its apex will be placed directly to the light.

Trees Started at the New Year.—The fruit has swelled very tardily, owing no doubt to the arctic weather that has prevailed for some weeks. Stoning will, however, soon commence, care being necessary to prevent sudden checks by injudicious ventilation, cold air in the day-

time and too high a temperature at night being fatal. Rest content with a night temperature of 60° to 65°, 5° less on cold nights, and 65° by day in dull weather, with 70° to 75° from sun heat.

Trees Started Early in February.—These are a full fortnight later than usual, but the set is very satisfactory so far. Syringe as soon as the fruit is set on all the trees, which will assist the trees to shed the remains of the blossoms, but avoid heavy syringing, an occasional one being what is needed until the foliage is more advanced. Allow a night temperature of 55° or 60° in mild weather, ventilating from 65°, permitting an advance from sun heat to 70° or 75°, but with full ventilation.

Disbudding.—This should be attended to early—as soon as the shoots can be displaced with the finger, and be followed up day by day until only the shoots required for future bearing or the extension of the trees are retained—viz., one from the base of the shoots now fruiting, and another on a level with or above the fruit; the latter, not being required for extension, should be stopped at a few joints of growth. In the case of trees not full grown it will be necessary to leave shoots about 15 inches distance apart, calculating from the base on last year's growth, to form the bearing shoots of next year, the terminals being trained in their full length as space permits. Closer training is often practised, resulting in weak overcrowded growth, not nearly so satisfactory as growth fully exposed to light and air.

Thinning the Fruits.—When fairly set thinning should commence, removing the smallest first and those on the under side of the trellis, beginning with the weakest part of the trees, thinning proportionately more than on stronger wood, which from carrying more fruit will tend to the equalisation of the vigour of the tree. The fruit ought not ultimately to be left closer than one to every square foot of trellis covered with growth, but Nectarines being a smaller fruit may have one to every 9 inches square (81 square inches) of trellis covered by the trees. The first thinning should commence not later than the fruit is the size of horse beans, the second when the size of marbles, when very few more should be left than is required for the crop, looking over again when the fruit is the size of walnuts, and very few indeed over the intended crop should be left, though there should always be a margin for casualties.

Syringing.—Syringe all trees not in flower, twice when the weather is bright, so as to keep them free from red spider. The afternoon syringing should be done at closing time, so as to have the foliage nearly dry before night. If the trees have water hanging from the edges of the leaves in the morning, as sometimes occurs with very vigorous trees, omit the afternoon syringing.

Heeling-in the Shoots.—This should commence early, as it requires to be done carefully so as not to bring the shoots down too sharply, yet it is necessary that it be done; indeed, it is of the utmost importance where symmetrical training is considered, and in securing the growths to the trellis that space must be left for the swelling of the shoots.

Trees Started Early in March.—Syringing must cease when the anthers show clear of the petals, but a genial condition of the atmosphere should be secured by damping available surfaces in the morning and early afternoon. Prevent a vitiated atmosphere by leaving a little air on constantly by the top ventilators. The night temperature should be 50°, falling 5° or more through the night in severe weather, 50° to 55° by day, and 65° from sun heat. The inside border must not lack moisture.

Latest Houses.—The trees have the blossoms opening, and as they are very abundant thin them well, particularly on the under side of the shoots. Failing bees (which are the best fertilisers) shake the trees daily from the first pollen ripening until the last of the blossom needs attention, selecting the early part of fine days where artificial impregnation is resorted to, and it is a capital plan to dust every blossom when the pollen is ripe with a camel's-hair brush, a feather, or some other light substance. Any trees deficient of pollen should have some taken from those that afford it plentifully, as the small-flowered varieties usually do. The temperature should be maintained at 40° to 45° at night, 50° to 55° by day, in all cases accompanied by slight ventilation at the top of the house, which must be increased when the temperature reaches 50°, and full at 65°.

Unheated Houses.—The buds are, despite the weather and the lights being off until the middle of March, swelling rapidly. Observe 50° for ventilating, and do not allow an advance above 65° without full ventilation both top and bottom, and close the house at 65° when there is a prospect of frost at night, but leaving on a little air to allow of moisture escaping. In mild weather leave the ventilation on when the temperature is over 50°. As there is a superabundance of blossom buds remove those on the under side of the trellis.

PLANT HOUSES.

Azaleas.—Ghent and mollis varieties of Azaleas as they cease flowering should be protected in a cool house or in frames until the weather is sufficiently genial to plant them outside. If turned out of warm houses and planted at once the young growth they have formed is generally killed and the plants seriously injured. This treatment weakens them to such an extent that they are at least two years before they are again in a fit state for forcing. If well cared for and allowed to develop their growth in a cool house, and then plunged outside towards the end of May or early in the following month, they will set buds freely and be in the best possible condition for early forcing. The same treatment should be accorded such Rhododendrons as Early Gem, præcox, multiflorum, and others. They flower profusely every year when confined to

pot culture, and come into flower by the most gentle treatment long before they would if subjected to planting out after flowering. Any plants that have grown too tall or become bare at the base may be well cut back. Azaleas subjected to this treatment are best planted out directly they have been hardened, while Rhododendrons should be kept under glass for the next three months at least.

Deutzias.—Plants that have flowered may be well pruned provided they are in good health and in a luxuriant condition. If the plants are old, and their pots crowded with roots and incapable of making strong growth, the branches should be judiciously thinned only, merely removing flowering portions that have only a terminal growth upon them. Grow the plants for a time in a vinery or Peach house where the temperature does not exceed 55°. Young shoots strike freely in sandy soil in heat if they can be kept close and shaded from the sun. They may be rooted thickly together in pots or pans, and afterwards transplanted 2 or 3 inches apart in boxes, or in a frame, in which a slight hotbed has been made to give them a start. Admit air liberally to plants in cold frames that were cut back closely, but close early in the day while the sun is still on the frame to induce the plants to make an early growth.

Lilacs.—Prune plants closely of Charles X. that are grown in 8-inch pots directly they have flowered. Allow them to break into growth in cold frames, and then plunge them outside about the time advised for Azaleas. If the pots are thoroughly crammed with roots, give them a small shift at once in a mixture of loam, sand, and one-seventh of manure. Press the soil as firmly as possible.

Guellder Roses (Viburnum Opulus).—The young shoots root freely in heat, and if placed into 4-inch pots, and well cared for afterwards, they will make sturdy specimens before the close of the season. Plants raised by this means are useful in 5 and 6-inch pots for forcing at the end of the second and third season. The best method undoubtedly is to strike the cuttings in the open ground by inserting them in autumn and allowing them a season's growth before potting. But those who have not followed this plan should raise stock from young wood at the present time. Cut back closely plants that have flowered, and place them into pots slightly larger, using the soil advised for Lilacs. Allow them to break in cold frames, and then plunge the pots outside in a sunny position.

Prunus.—Cut back plants that have flowered. Allow them to make their growth in a Peach house or similar structure. Cuttings of *P. sinensis* fl. pl. root freely, while *P. triloba*, to flower it profusely, must be worked on the Plum stock.

THE BEE-KEEPER.

NOTES ON BEES.

THE WEATHER.

IN spite of the mildness experienced in January and the advanced state of vegetation at that time, the unfavourable February with its snows, keen frosts accompanied with cutting winds, has performed its work in a manner that will be disagreeable to many persons. Many plants that stood the lowest temperature of the year have succumbed to less severe but more protracted cold, and vegetation that was fresh and green at the beginning of February is now a mass of decay. Rain has been falling copiously, and it is to be hoped that a dearth of water has been averted, as seldom, if ever, at this season, have we seen the ground so dry and springs so low as at present. Those who are liable to suffer dearths of water should make some provision for storage. With all the rigours of an Arctic winter we have experienced, Nature has not been dormant, for while blackened vegetation above ground greets our eyes, underground life has been actively at work, and many flowers are peeping out.

OUTWARD INSPECTION OF HIVES.

Turning to our bees, how have they fared under the cold? A glance around our hives shows the safety of every one except a pure Syrian stock, which had succumbed after a gradual decrease in numbers throughout the winter, proving that they are ill adapted for a cold climate, and that in-and-in breeding impairs the constitution. After being satisfied with the state of the Syrian, the Carniolian wintered on one comb had my attention. My fears for its safety were not altogether groundless, as on the 26th February, when the thermometer stood at 25° Fahr., the bees flew as if swarming, humming loudly for twenty-four hours as if they had lost their queen. It is safe, however, and breeding has been in progress during the cold spell, as many young bees were on the wing. The

cause of the unexpected and untimely flight was, in my opinion, due to the necessity of the bees having a cleansing flight, and probably to feed a little, as the feeder has not been from it at any time since the bees were put into the hive on the 29th November. This hive was more restless than the others owing to its consuming more food to keep up the heat in their exposed state than those hives fully equipped for the winter's campaign.

The lessons it gives are—First, Bees ought to be kept in such a manner that the most severe cold will not lower the temperature below 50° Fahr. inside the hive, and to be kept at that, or even higher. How to effect these conditions I have frequently described. The second lesson is that no hive should be closed to confine the bees longer than a few hours when snow has newly fallen, because if bees require to fly they ought to have their liberty; confining them hastens their death within doors. A well managed and well furnished hive seldom requires any attention, and very seldom loses bees through flying in ungenial weather. The third lesson is to give bees every opportunity of flying out, as that lessens the risk of losing many bees when they fly out suddenly after a long confinement. Although the day this hive flew was so cold few bees were lost. Three weeks previous, the bees of this, as well as all others were working, and had aired themselves perfectly, and had their site marked and well on memory, consequently most of the bees ventured no farther than a few feet from their hive, returning in a few seconds.

Notwithstanding the severity of the weather during February, all my other hives have been breeding, and to a great extent, too. The one I joined the queen to at the end of January has thousands of young bees hatched which have shown themselves upon the alighting board—in fact, so far forward is this, as well as many of my other hives, that were it possible the honey flow would appear in three or four weeks from this date, most of them would be in a fit state to fill supers.

SYRIANS AND CARNIOLIANS.

The crossed Syrians are the most active and furthest advanced, but the Carniolians are also well forward. My nuclei are now much stronger in bees, and, as I predicted, are likely to be as forward by the middle of June as any—quite time enough for our district, and will not require any feeding whatever. I cannot vouch for that with the strong and furthest advanced. Every one is in full-sized hives, having room for every requirement of the bees except supering.

FERTILITY OF QUEENS.

I note what "A Hallamshire Bee-keeper" says at page 205 concerning the fertility of queens, and endorse his remarks. The wonder is that anyone would attempt to dispute the fact, and how anyone can adopt hives so much smaller than the bees require seems to me a greater wonder still. I know something about the subject in "A Hallamshire Bee-keeper's" other remarks, but my remarks thereon must be delayed till a future occasion.

THE STATE OF HIVES FOR EARLY DISTRICTS.

From the description of the two classes of hives it will be observed that I put no stress whatever upon the present strongest ones over my weaker lot, the latter being the ones most likely to turn out best from a commercial point of view. But in the sunny south, where honey is to be had in abundance by the 1st of April, and cease to be gathered in June, the usefulness of well advanced hives cannot be disputed. The first Stewarton super filled in the south of England was due to my instructions, and here, so far north, my hives are ready for work on the greatest emergency under the greatest glut of honey that is possible to be, on the 1st of April or even earlier. The whole instructions for effecting the above will be found in back numbers, youthful queens being the key and a principal element to success.

Writers upon bees have been telling us now is the time to crowd our bees on fewer combs, which does not sound like advanced bee-keeping, especially where bees are wanted in April. What advice would those writers give in the case of my own bees in their ad-

vanced state that cannot be contracted? Instead of being unable to fill 10 square feet of comb at the height of the season, several Syrian stocks have that space filled at present, and they were but nuelei in August. We want not only a strong hive of bees, but bee-keepers who know how to have full hives.

CARNIOLIANS THE BEST.

Taking everything into consideration, including the timidity of bee-keepers, I strongly advise the adoption of the Carniolian bee. They are undoubtedly the hardiest and most docile race of bees we possess, while their honey gathering propensities are good; besides, they frequent the receptacles of grease less, if at all, than any other variety, hence the purity of their comb. Bee-keepers going in for these bees should be careful to have queens from a reliable source, so that they are pure and come of a proper strain. Some dealers are not very particular in this matter, which I have good proof of. The pure Carniolian bee should be in shape not unlike the Ligurian, the whole of its pubescence of a light silvery grey, as well as the rings on its abdomen. There ought not to be any visible yellow band, although sometimes a rusty brown may be detected on the first ring of the belly, and when viewed against a window the two first bands appear slightly golden. Such, then, are the main features of this bee. Is it possible that imported queens can be other than pure? To settle the question on these, as well as the Ligurian bee, Mr. Frank Benton says, speaking of queens—"Some Carniolian queens are as yellow as Italians, yet they invariably produce workers and drones which are distinctively Carniolian." My own experience. "Yellow workers are not found in Carniolia, while black bees—natives, too, and not imported, exist in Italy," confirming the opinion of many that true mongrels were imported to this country as pure Italians, and the reason I discontinued keeping Italian bees. "I neither keep nor breed Italian queens, and the only drones in my apiary, or in this part of Carniolia, are Carniolians."

The above few quotations out of many with my remarks have been given because of many inquiries on the subject were prompted through an article written by "W. R." in another Journal, in which article he stated that "F. B." had Ligurians in his Carniolian apiary, a statement not in accordance with facts. It is to be hoped, however, that such strictures in regard to the best bee known will not deter bee-keepers from applying in the proper direction, and become possessed of these amiable and profitable bees, as they have long since proved themselves to be to—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUE RECEIVED.

Harrison & Sons, Leicester.—*Catalogue of Farm Seeds.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (T.K.).—A cheap work on Orchids is published at this office, price 1s., post free 1s. 2½d. (O.H.).—The "Chrysanthemum Annual for

1888" has just been issued, price 1s., post free 1s. 1d., from the publisher at this office. (W. Boddy).—We do not know the book you name, possibly your friend is mistaken.

Name of Violet (Violet).—The Violet is Belle de Chatenay, which is of another type—viz., of the odorata section; Count Brazza, White Neapolitan, is of the italica type, and the best white Violet, but it requires frame treatment in winter.

Madame Lambard Rose (Hayes).—Few Roses are more variable than this, and it is not unusual for a plant to produce blooms of different shades of colour. The example you send is one of the darkest we have seen, but whether plants raised from buds taken from the shoot would produce similarly dark blooms constantly can only be determined by experiment.

Tuberous Begonias (A. Newell).—You have done well in exhibiting these plants nine times and being awarded nine first prizes. We cannot enter into personal questions in connection with public controversy. Persons may entertain quite different views on a matter yet be equally honest in their convictions, and we have found after no slight experience that those who impute motives usually betray themselves.

Orchid Collections (Sheffield).—We are unable to comply with your request, as to publish the information in the form suggested would be the reverse of agreeable to most of the persons mentioned, and would inevitably lead to protests and disputation. A list of the leading growers is published in Mr. Lewis Castle's work on Orchids, and descriptions of leading collections have appeared from time to time in our columns.

Heating Greenhouse (A. B. C.).—The cubic contents of the house are about 2500 feet. To heat the house sufficiently for Pelargoniums, Azaleas, Cyclamen, &c., two rows of 4-inch pipes—i.e., a flow and return along one end and the front, will be sufficient to maintain in the severest weather a temperature of 40° to 45° at night and 45° to 50° by day—the proper temperature for a greenhouse during the winter months. It is not necessary to have the pipes all round the house, the back wall being in favour of the heating, a somewhat lessened quantity of piping being required than if it had been glass.

Improving Lawn (A. D.).—The mixture referred to could scarcely fail to do good if the soil is impoverished. It would be advisable to "comb" out much of the moss with a small iron rake having sharp teeth, and if the grass is thin it would be advisable to sow some lawn grass and white Clover seeds; then if a little sifted soil containing a liberal admixture of lime could be applied, the seeds would be protected from birds, and the lawn generally improved. The fertilisers may be applied in addition to the soil dressing, or without it, as may be most convenient to yourself.

Tuberose not Flowering (R. S.).—Judging from the specimen received we think the cause of the flower stem being blind is due to a check, probably when the plants were removed from the bottom heat, it not having been done gradually so as to avert a sudden cessation of nutriment, or it might have been occasioned by removing from the stove to the vinery, the former, we presume, being fully 5° warmer than the latter. Sometimes Tuberose go blind through the roots being lifted before the flower buds are fully formed in embryo, the growth not being completed, and though they throw up flower stems they rarely expand satisfactorily.

Weevils on Ferns (W. D.).—The beetle-like insect you have sent is the destructive Otiorynchus sulcatus. When numerous they do much damage, eating almost any kinds of plants, and they seem to have a special liking for Ferns. As they feed chiefly at night, that is the time to attack them, and if the plants are in pots they can be shaken violently over a white sheet for dislodging the enemy. They are easily seen on a white surface, and can be better prevented from escaping than if less visible on a brown mat. Solutions of tobacco and quassia water, not so strong as to injure the plants, have been recommended for rendering them distasteful to the weevils.

Potting Odontoglossum Alexandræ (W.).—The plants are usually potted at the end of August or during September, as the sun heat is then declining and there is less danger of their suffering. It could, however, be done now if the plants have flowered or are not too much advanced in growth. When plants are in full growth it is always inadvisable to repot them, as they are very readily checked and perhaps permanently injured. Any of your Odontoglossums still flowering or growing freely should be left until after summer, unless you like to sacrifice the flowers for the benefit of the plants, and if the latter are not strong this will be a good course to adopt, as bearing the flowers long is very weakening.

Hardy Bamboos (Somerset).—These will probably succeed well with you, but they should have a sheltered situation. Prepare the soil by digging deeply, incorporating a little leaf mould and old manure, and place the plants out in April. They will not need the tubs, indeed they will probably succeed better planted out if well supplied with water during the summer. You may add to those you possess (Bambusa Metake and B. Maximowiczii), B. falcata, also known as Arundinaria or Thalamocalamus, and B. viridi-glaucescens, both strong growing and distinct, especially the latter. Nageia japonica might be grown in warm situations in the West of England, but it is usually grown in a greenhouse. Write to Messrs. Veitch & Sons, Chelsea.

Peaches under Glass (S. R. W.).—As a rule the longer the petals remain fresh the better the fruit sets. You will have no difficulty in knowing when this is accomplished, as the flowers that fail to set soon

fall or shrivel. Your crops will probably have set by this time, and syringing may then be resumed. When this is done regularly and effectually in the way that has been frequently advised in our "Work for the Week" column, insects are usually kept in check. Strong fumigations are injurious to Peach trees, and a comparatively light volume of smoke on two or three consecutive nights is the safe plan to adopt when aphides appear. The greatest mistake that can be made is to allow them to become numerous before measures are adopted for their extirpation.

Top-dressing for Vine Borders (J. C).—No manure can be said to be the "best" for all soils and under all circumstances, and not one can make good certain defects in management. As you have used lime, that will effect a change in the soil's constituents, hastening the decay of the farmyard manure, and so liberating matter and rendering available as food what without the lime might remain inert or injurious from becoming sour; indeed the lime will form nitrate through acting on the organic matter, and that is valuable for other reasons than supplying the Vines with lime. Thomson's and other advertised manures are valuable, particularly those that contain potash and phosphorus. Chemical manures are peculiarly efficacious applied to soils containing inert substances.

Melon and Cucumber Houses (H. T. H.).—Beds 3 feet wide along each side a central path, afford ample room for soil for growing the plants in, and the path may be 3 feet wide also, though many are narrower, this being a question of individual preference. You can have the path as much wider as you wish (or beds either) if a greater extent of space is desired for the plants, which would cover the roof of a house 12 feet wide or more, as well as one 9 feet. Side lights are not necessary, and if the top four courses of bricks are single, and set in cement, a ledge is formed along the top of the 9-inch or lower part of the wall, on which the bottom row of pipes can rest, the top row being taken above it. We presume you have arranged for bottom heat. As you do not give the slightest indication of the time when the illustrations appeared, we are not able to say whether the numbers are in stock or not. Cannot you state the year in which those figures to which you refer were published? If you can give an approximate date we will try and find them for the purpose of answering your question more explicitly.

Vines from Cuttings—Planting Begonias (E. J.).—Naturally the cuttings with eyes or buds would grow more quickly and make good canes sooner than would cuttings from which "all" the eyes were removed. We have not before heard of this latter method of propagating Vines. As soon as you have as many as you require established and growing freely throw the others away. Not a few persons fail in their object by growing far more plants than they require, or for which they lack the requisite convenience for growing well. Tuberos Begonias are usually started into growth in boxes, or in a bed of good soil in a frame. Grown sturdily, and prepared for planting out after all danger of frost has passed, or when Dahlias can be safely entrusted in the open ground. This is generally towards the end of May or in June, according to districts and the weather. Many persons err by starting Begonias too soon, and growing them tall in a warm house before planting them in the beds. April is soon enough for starting the tubers in a cool house or frame from which frost is excluded. They root freely and transplant well when in a compost consisting largely of leaf soil.

Azalea mollis not Expanding (A Lady).—This is principally due to defective root action. In some cases the roots are cut to such an extent that they fail to absorb the necessary supply of food for insuring the development of the flowers, or even the retention of the buds. This is not, however, always due to the roots being cut off. If the plants are carefully examined when they are lifted from the ground, it will be observed that, although they have set buds freely, the roots have failed to take possession of the surrounding soil. When the plants are forced annually, some of them invariably get into that condition, and the result is that the flowers, if they do open, fall almost immediately. The evil complained of takes place more generally after warm seasons than moist showery ones. The flowers of some of the plants are often very far advanced in autumn; in fact, nearly ready for bursting. This is prevented by frost, and lifting. The consequence is the flowers fall through the severe check they have received. In some cases the falling of the flowers is due to imperfectly ripened wood. They are very similar in this respect to Camellias, and the flowers expand if the buds do not fall.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (W. Barkham).—No. 1, Lewis' Incomparable; No. 2, Not known. The insect is Oniscus armadillo, one of the woodlice, and is injurious to plants.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (T. R.).—1, Dendrobium nobile, similar in colour to D. nobile nobilium, but not such a finely shaped flower. 2, Dendrobium nobile variety in the style of coerulescens. 3, A poor variety of Cattleya Trianae. 4, Rhipsalis Cassytla. (W. S.).—1, Phalaenopsis amabilis. 2, Dendrobium luteolum. 3, Masdevallia Shuttleworthi.

RESULTS.

ERRONEOUS impressions of the action of chemical manures are still very prevalent, and it is generally found that the more ignorant a farmer is about a matter of such vital importance to him, the more positive is he in his assertions about it. We have been assured that such manures eventually so clog the pores of the soil that it becomes practically worthless; that they are so "forcing," that the use of them is persisted in for three or four years the soil is robbed of all its natural fertility; that they excite growth of abnormal vigour, which absorbs all the manurial constituents to be found in the soil, leaving it practically barren and unfit to produce another crop of any sort. Such postulates are all based upon mere assertion, proof of any weight never, being forthcoming in support of them, so that we may be told they are unworthy of

notice. Yet we cannot regard anything that is a hindrance to progress as a trifle to be ignored, and there is one very general error in particular to which we desire to call attention now.

If we were to ask, Is there a residue of any manure left in the soil after the crop for which it is used is harvested or cleared off the land? we should probably be told that there is when farmyard manure has been used, but that artificial manure, as it is termed, is either exhausted by the crop or washed out of the soil by heavy rains in winter. Well; but we do not always get heavy rains in winter, and if we do we are convinced that the proportion of loss in fertility is not nearly so great as is often supposed. In the Norfolk experiments last year upon Barley after Swedes, proof, clear and unmistakable, was afforded of the exact proportion of unexhausted manure in the soil. The Swedes were manured with 4 cwt. of bone flour, 1 cwt. of sulphate of ammonia, and 1 cwt. of gypsum per acre, and all the roots and tops were drawn from the land. Of thirteen trial plots, two had no manure, with the remarkable result of, in one case, a yield of thirty-six bushels of marketable corn per acre, weighing 56 lbs. per bushel, and with a market value of 33s. per quarter, and in the other, a slightly inferior yield of thirty-four bushels of head corn, weighing 54 lbs. per bushel, and worth 34s. per quarter.

In connection with this series of experiments we may mention here that where mineral manures, superphosphate and potash, were applied alone nothing was added to the yield over that of the unmanured plots, but the use of 1½ cwt. nitrate of soda gave 5 bushels extra per acre, at a cost of about 3s. 6d. per bushel. Muriate of potash with 1 cwt. nitrate of soda also gave 5 bushels extra per acre at a cost of about 4s. per bushel. Superphosphate with nitrate of soda gave 9 bushels extra per acre at the low cost of about 2s. per bushel. The highest increase was obtained by the use per acre of 2 cwt. nitrate of soda, 2 cwt. superphosphate, and 1 cwt. muriate of potash, which gave 14 bushels more Barley per acre than the unmanured plots. The soil of the field is light and of medium quality, nearly 2 feet of surface soil resting upon a substratum of reddish sand.

In another series of experiments upon Barley to test the value of unexhausted residue of manures applied in 1886 for Mangolds, it was found that the residue from 3 cwt. superphosphate, 4 cwt. fish guano, and 1 cwt. muriate of potash was fully as valuable as that from twenty loads of farmyard manure, the quantity of head corn upon the former plot being 43.87 bushels, while upon the latter it was exactly 43 bushels, and the market value of the corn from both plots was 33s. per quarter.

A common result of such experiments is more and more proof of the superiority of nitrate of soda to all other forms of nitrogen. In the Sussex experiments, in answer to the question, "Will not the application of nitrate of soda impoverish the soil and render it unfit for cultivation in future years?" it was shown by results from farmed-out land at Haywards Heath that without nitrogen, neither air nor water, neither the food in the soil nor the heat of the sun, could be utilised in producing a heavy crop, but so soon as nitrogen was supplied all these elements were healthfully utilised, and, being utilised, resulted in a profitable crop. The fact being that they are utilised, the farmer, if he is to farm rationally, will, in order to continue the process of profitable cropping, return a proportion of that profit to the soil in the form of more nitrogen (nitrate of soda), and he will also consider that in growing these heavy crops he has to add not only nitrogen, but part of those mineral ingredients—potash and phosphates—which former judicious treatment has utilised.

Probably it is inattention to this latter point that has given rise to the idea that nitrogen, one of the best plant fertilisers, exhausts or "scourges" the land. That belief is supported by irrelevant analogy with animals, in whom stimulants produce extraordinary results, to be followed only by corresponding depression. The analogy is made in forgetfulness of the fact that work by an animal means waste of tissue permissible to a certain degree,

when—if life is to continue—it must be followed by reparative processes; whereas growth by a plant means no waste, but merely a conversion into plant matter, chiefly of air and water, with but a minute proportion of the soil, which serves more as a medium for the ramification of the roots than for the provision of mineral food, most of which must be provided by manure.

The knowledge gained by us under the Sussex experiments by Professor Jamieson has enabled us to boldly grapple with the exhausted land of farms falling upon our hands year after year, for we know that such land requires no rest. He taught that the notion of rest was a bogie set up by ignorance; that perpetual cropping is rational farming, which must prove profitable if done intelligently; that towards this system advancing agriculture must tend, and by this system—the most profitable cultivation—the agriculture of the future will be characterised.

WORK ON THE HOME FARM.

Never were the resources of flockmasters put to a more severe test than they are this spring. To begin with, many of them were so badly off for food that heavy purchases have been made for several weeks, and with the growth of the lambs a proportionate additional outlay was unavoidable. A forward spring would therefore have been a great boon, but present prospects give promise of very little food upon pastures till May. Under such adverse conditions valuable lessons in flock management may be had at farms where there is a really intelligent system in force. We have in our rounds of late seized every opportunity of calling at different farms to see what is being done, to compare notes with our friends, and certainly to pick up crumbs of knowledge. In this way much that is interesting in practice, good and bad, comes under our notice, and the results of foresight and care, or the reverse, are before us. On one very large farm, where the practice is easy-going and about as careless as it can well be, we found the flock in sad plight, for the ewes were so low in condition that they had hardly enough strength to bring forth the lambs, and the lambs were small and weak. The mortality among both sheep and lambs was considerable, as many as fourteen ewes having been lost in one day. Pleasant indeed was it to turn from so sad an example of mismanagement to a really well cared for flock of some 300 ewes. Lambing was in full swing under most unfavourable conditions of weather, for it was blowing hard from the north-east, with the thermometer a little below freezing point, and snow was falling so fine and hard as to be almost blinding from the force with which it was driven before the bitter wind. Shelter of every kind had been turned to account for the sheep. The large sheep-yard, with its low thatched roof shedding running right round it, had occupants in every crib. Barns, cart and waggon lodges, were all filled with sheep, and even the waggons were made to afford shelter, by heaping straw upon them, drawing them into line, and putting high thatched hurdles along the windward side of them, so as not only to break off the wind but to afford comfortable quarters beneath the waggons for lambs and sheep. Ample supplies of chaff, roots, and corn were stored close by; the ewes were strong, healthy, well-conditioned animals, and the crop of lambs was satisfactory. Two hundred and fifty of the ewes had lambed in a fortnight, so that the lambing would only practically extend over a period of three weeks. On every hand we saw pleasing evidence of intelligence, energy, care, and thrift, and the farmer himself was as remarkable as his surroundings, as he walked about with us heedless of weather, a hale sturdy veteran of over threescore years and ten.

REMARKS.

18th.—Generally bright in afternoon, but bleak and cold throughout.
 19th.—Cold, bleak, and sunless. Slight snow began about 5 P.M., and by 9 P.M. was half an inch deep, and continued to fall.
 20th.—Snow early, and till 10 A.M., the depth at 9 A.M. being 2 inches; dull all day.
 21st.—Fine, bright and pleasant, and much warmer.
 22nd.—Sleet shower about 9 A.M.; wet morning; dull afternoon.
 23rd.—Wet from 1 A.M. to 7 A.M., and slightly foggy in the morning; dark with high fog from 10 A.M. to 1.30 A.M., and dull and damp all day.
 24th.—Cloudy morning; dark with high fog from 10 A.M. to 11 A.M., necessitating gas, then fine and bright; rain in the evening, and flakes of snow at 9.30 P.M.
 An unsettled windy week. Temperature about six degrees below the average, and four degrees below that of the preceding week. (G. J. SIMONS.)

CAMELLIAS.

CAMELLIAS have had a long term of popularity, and though perhaps the demand for collections of varieties has decreased somewhat in the past few years their utility is still widely recognised, and for decorative purposes the flowers are supplied to the florists and markets in far greater numbers than ever. Hardwooded plants have been neglected in favour of the more easily grown softwooded plants in many establishments where it has become a necessity that a large annual supply of flowers be unfailingly produced, but there is no reason why Camellias should be included amongst the uncertain plants to be avoided. With ordinary attention they are by no means difficult to grow. They are handsome as specimen plants whether in flower or not, as the glossy rich green foliage is at all times beautiful, and when large well established healthy specimens are obtained their wax-like symmetrical flowers can be cut by hundreds either for home use or for sale. There is a steady advance in the demand for Camellias, and few plants are more worthy of increased attention.

Before referring to the best varieties in cultivation at the present time, a glance at the long and gradually developed history of the Camellia in cultivation may not be without interest to some readers. The first published description of Camellia japonica of which we have any definite knowledge was that by the botanist Petiver, which appeared in 1702 with an illustration of the plant under the name of *Thea chinensis*, followed by Kämpfer's description ten years later. These notices attracted the attention of botanists and amateur patrons of horticulture, with the result that the plant was introduced probably both to the Continent and this country, but the exact date is not known. The single red Camellia is said to have been cultivated by Robert James Lord Petre before 1739, and the authority for this statement named in Aiton's "*Hortus Kewensis*" is Edward's "*Birds*," where it seems to be mentioned as *Rosa chinensis*. From that time until the publication of Thunberg's "*Flora Japonica*" in 1784, little appeared concerning the Camellia, and strangely enough it is not included in Phillip Miller's "*Gardener's Dictionary*," though it was subsequently published in Martyn's edition. Thunberg describes both *C. japonica* and the small-flowered *C. Sasanqua* (which is figured), and remarks respecting the former that many varieties are cultivated in Japan, single and double, white, red, and different colours. The first edition of Aiton's "*Hortus Kewensis*" was published in 1789, and *C. japonica* was then included in that collection, but no varieties are named. According to the particulars accompanying a figure of the Double White (*alba plena*) in Andrew's "*Botanists' Repository*" in 1799, this fine old variety, together with the double striped, was imported from China in 1793 by Capt. Connor to the garden of a Mr. T. Slater, and when the figure was taken the best plant was in Sir Joseph Banks' garden. It is worthy of remark that at the time named Camellias were grown in a hothouse, but cultivators soon found this was unsuited to the plants, and in a few years we read of some being placed out of doors. An excellent flower is represented in the plate, as well formed and full as the best of the present time. A good illustration was also given in the following year (1800) of the Double Striped, in 1802 one was published of the Double Red, which was introduced by Mr. R. Preston of Woodford in 1794, and "*The Botanical Magazine*" for 1796

(t. 42), included a plate of the Single Red Camellia, the first variety known in England.

At the commencement of the nineteenth century there were thus at least four recognised and named varieties in garden cultivation here, but though Martyn's edition of "*Miller's Dictionary*" was published in 1807 it only mentions the three species—*japonica*, *Sasanqua*, and *oleifera*—without referring to the varieties. The second edition of Aiton's "*Hortus Kewensis*" (1812), however, names ten varieties—the Single Red, Semi-double Red, Middlemist's Red, Myrtle-leaved Red, Anemone-flowered or Waratah, Pæony-flowered, Double-striped, Blush, Buff, and Double White. One of these—The Blush—better known as Lady Hume's Blush ("*Botanical Register*," t. 112), was introduced in 1806, and named in honour of Lady Amelia Hume, Wormleybury, Herts, and became a great favourite in all the early collections; it is, indeed, occasionally seen now in old gardens. The flower is somewhat star-shaped, with the petals overlapping each other in several series radiating from the centre, and not regularly imbricated, as in *alba plena* for example. It is of a delicate blush tint, distinct, and pretty, but for perfection of form cannot be compared with the more recent productions. *Anemoniflora* or the Waratah was introduced to the Royal Gardens, Kew, in the same year as the last named, and was figured in the "*Botanical Magazine*" (t. 1654) from a plant at Mr. Griffins' in South Lambeth. This also is a very distinct variety, the flowers having six broad guard petals and a dense tufted centre of small petals regularly arranged somewhat in the manner termed equitant by botanists, and the colour is a deep red. Some other varieties are found in collections under the name of the Waratah, but the general form is the same, the colour differs slightly, and the outer guard petals are more evenly filled up.

The Myrtle-leaved Camellia, a little-known slender-growing variety, reached Kew in 1808, and *C. Sasanqua* in 1811. The last-mentioned is an interesting plant, though it has not been concerned in the production of the present race of Camellias. It is noted and figured in Staunton's account of Macartney's Embassy to China, the following appearing in Stockdale's edition (1797):—"The petals of this plant, called by the Chinese Cha-whan, or Flower of Tea, from their resemblance to each other, and likewise because the flowers with those of the Arabian Jessamine are sometimes mixed amongst the Teas in order to increase their flavour. *Camellia Sasanqua*, which grows upon the tops and sides of mountains, is assiduously cultivated. It bears a nut from which is expressed an edible oil equal to the best imported from Florence." In a list of flowers used for imparting fragrance to Teas, published many years after by Mr. Robert Fortune, this Camellia is not mentioned, and it is probable that others of a more suitable character had been substituted. It may also be added that the concluding remarks of the quotation given seem to refer to *Camellia oleifera*, which was introduced by the Macartney Embassy, but subsequently lost, and re-introduced by Capt. Nesbitt in 1820.

The earliest English-raised seedlings from seed ripened in this country of which we can obtain any information are the one named Wiltoni, that is said to have been flowered by Mr. Knight in 1814, and the single white raised at Tooting about the same time; but as seeds are readily produced by some of the single and semi-double varieties, other horticulturists may have succeeded previously to the date named. Certainly in three or four years afterwards at least eight named seedlings were in commerce as the results of crossing the introduced varieties. Returning to the chronology of the imported varieties we find that in 1816 *C. maliflora*, a slender growing form of the *Sasanqua* type with double pink flowers, was sent to Mrs. Palmer's garden, Bromley, Kent, by Capt. Rawes, who, by the way, brought from China at the same time *Primula prænitens*, now such an important garden plant under the name of *P. sinensis*. According to another account the *Primula* was introduced with *Camellia reticulata* in 1820, but by the same Captain. In the same year, however, a much more beautiful

Camellia than *C. maliflora* made its appearance in Mr. Colville's Nursery, King's Road, Chelsea—*i.e.*, the Fringed White (*japonica fimbriata*). This handsome variety is still a favourite in numbers of gardens, the white petals being evenly and finely fringed. The Various-flowered Camellia was sent to Kew about the same time, but it is not known who introduced *fimbriata*.

Messrs. Chandler and Buckingham at Vauxhall in 1818 and subsequent years endeavoured systematically to improve the race of cultivated Camellias by crossing and the selection of seedlings. In 1819 they had obtained two very distinct varieties in *corallina* and *Chandleri*, both of which still retain a place in collections, a sufficient indication of their merit. *Chandleri* resulted from a cross between the *Waratah* and the *Double Striped*. A few years later the same firm issued their "*Camellia Britannica*," containing eight coloured plates of English-raised seedlings, comprised, in addition to the two named, *Aitonia*, *Altheæflora*, *insignis*, *florida*, *Anemoniflora alba*, and *Rosa-sinensis*. The Vauxhall nursery was then, and for many years subsequently, famed for its collection of Camellias, and very much of the public attention accorded to these plants was due to the efforts of Messrs. Chandler and Buckingham to popularise them, and also to their books, but especially the larger and beautifully illustrated work issued by Messrs. Alfred Chandler and W. B. Booth.

It has been already incidentally noted that a single white Camellia was raised at Tooting by Messrs. Rollisson & Sons in 1814, which, owing to its free seeding habit, became the parent of many fine double and coloured varieties. The plant, nevertheless, seems to have remained very scarce for some years, as at a meeting of the Society of Flora at Brussels, February 19th, 1825, a medal of honour was awarded to M. Vandermaclin for a specimen on account of its rarity. In 1824, Mr. Press, gardener to E. Gray, Esq., Hornsey, raised a number of seedlings from a cross between this variety and the semi-double red, several of which became great favourites. This was especially the case with Press's *Eclipse*, a double white with pink stripes, that for a number of years held a prominent place amongst the popular Camellias.

The introduction of varieties still continued, but two were added in 1820 and 1823 respectively, which were assigned the rank of species—namely, *C. reticulata* and *C. Kissi*, both very distinct and attractive. *C. reticulata* has somewhat the habit of *C. japonica* but less bushy, more straggling in style, with long tapering dark green leaves, and large semi-double rosy crimson flowers varied with a darker shade. It was introduced by Capt. Rawes at the time named. A plant flowered in 1826, and it was figured in the "*Botanical Register*" of the following year (t. 1078). A double variety of this was sent to England by Fortune a long time afterwards, and was figured in the "*Botanical Magazine*" in 1857 (t. 4976) from a specimen at Bank Grove, Kingston, 13 feet high with a spread of 16 feet, from which 2600 flower buds were removed and about 2000 allowed to remain. It is remarkable for its free flowering character, and the original plant now filling a frame in the Royal Horticultural Society's Garden at Chiswick annually produces an enormous number of flowers.

The fragrant Camellia *Kissi* was introduced from Nepal in 1823 by Mr. Samuel Brookes, Balls Pond, and it was thought at one time that a distinct race of fragrant Camellias might have been produced by its aid. If any experiments were undertaken in that direction they do not appear to have been very successful, for we find no records of any varieties so produced. The flowers are small, white, and pleasantly but not powerfully fragrant. *C. japonica imbricata* was imported for the London Horticultural Society by Mr. J. D. Parks in 1824, and flowered in 1827, when its large handsome effective crimson blooms immediately secured it a number of admirers, and has insured it a place in the best collections until the present day. Sweet's "*Hortus Britannicus*" was published in 1826, and in that four species are enumerated, twenty-seven imported varieties, and eight English seedlings. In the "*Horticultural Society's Transactions*" for 1830, Mr. William

Beattie Booth, A.L.S., Garden Clerk to the Society, contributed a descriptive list of the Camellias then known, naming twenty-five varieties, and the same writer furnished the descriptions for the admirable illustrations of Camellias by Mr. Alfred Chandler, issued between 1830 and 1832. This forms a valuable work in one volume, containing forty accurately drawn and coloured representations of the best Camellias known, and that it is still regarded as a creditable production can be judged from the fact that a copy was recently sold, as noted on page 242, for £4. From this time the advance of Camellias, both here, on the Continent, and in America, was rapid in the extreme, and to illustrate the demand for the flowers in New York, Loudon published a letter, dated January 10th, 1832, which stated that Pine Apples were selling for 3d. and 4d. each, while expanding buds of Camellias were sold at a dollar each, and a list of applicants was kept who were supplied in rotation as the buds expanded. Florists are not often troubled much in this way now.

Loudon's "*Hortus Britannicus*" for 1830 enumerates forty-seven varieties of *Camellia japonica*, while in the supplement for 1850 seventy-one more varieties are added, no less than sixty-three being seedlings, a good indication of the increasing attention they were receiving. It is remarkable, however, that Mr. C. McIntosh of Claremont Gardens estimated about 200 varieties were grown in England in 1838, and states that M. Parmentier of Enghien, Belgium, had 400 varieties. Whether these statements are correct or not, I have a catalogue of Camellias issued by M. Makoy of Liège before the year mentioned above, in which 290 varieties are named, ranging from 2 to 100 francs each, plants of the well known *C. tricolor* being priced at the latter amount. From this time we have been chiefly indebted to continental horticulturists for the new varieties, and especially to cultivators in Italy, where much attention has been paid to the improvement of the Camellia. Scores of novelties have been sent thence in the past twenty years, and the best have obtained a place in the select lists issued by English nurserymen, for no one now attempts to include all the varieties known. American horticulturists have contributed to the development of the Camellia, and an extremely distinct strong-growing variety named *Floyi* is believed to have been one of the earliest seedlings raised there, dating from about 1820, and it was included in Makoy's list already noted. More recently we are indebted to the late Mr. Hovey for several handsome varieties, one of which, *C. H. Hovey*, ranks as one of the best formed and brightest coloured Camellias in cultivation. Belgium has obtained the name as the Camellia-growing country, as there some millions are grown every year to meet a wide European demand, constituting, with the Azaleas, a large portion of the nursery trade. One of the Belgian nurserymen, M. Verschaffelt, also, some years ago, issued the finest illustrated monograph of Camellias yet published. It is entitled "*Nouvelle Iconographie des Camellias*," and it appeared during the years 1848 to 1860 in twelve volumes, with forty-eight plates each. The famous variety *C. Donckelaari* (fig. 37) is said to have been introduced by Van Siebold from Japan about 1833, being named in honour of M. Donckelaar of the Botanic Gardens, Louvain, and distributed by M. Jacob Makoy.

In Great Britain all the larger nurserymen devote some space to Camellias; Messrs. Veitch & Sons, Chelsea, and Mr. B. S. Williams, Upper Holloway, especially, but Messrs. W. Paul & Son, Waltham Cross, have made a specialty of the plant for many years, and some notes on their collection will be found on page 280. It is rather remarkable that of the hundreds of varieties raised or introduced only fifteen have been certificated by the Royal Horticultural Society, and several of these can by no means be considered as the best now obtainable, but may be worth recording in connection with these historical notes. The varieties that have been certificated are as follows:—*Contessa Lavinia Maggi* (Veitch), March 19th, 1862; *Napoleon III* (Lee), March 18th, 1863; *Filippo Parlatore* (Veitch), March 31st, 1863; *Reine des Beautés* (Standish), March 7th, 1865; and *reticulata flore pleno* from the

same exhibitor and on the same date; Amelia Lechi (Bull), March 20th, 1866; Triomphe de Loddi (Veitch), April 3rd, 1866; Princess Mary (Salter), April 17th, 1866; Lavinia Maggi rosea (Bull), April 16th, 1867; Kelvingtoniana (Baxter), January 19th, 1869; La Maestosa (Ball), February 16th, 1869; Princess Alexandra (Henderson), April 16th, 1873; C. M. Hovey and Mrs. A. M. Hovey (Hovey), March 25th, 1875; and Commendatore Betti (Williams), March 24th, 1885.

Though so many varieties have been obtained in different ways the old Double White still remains unsurpassed in symmetry of form, but in the past few years the single and semi-double varieties have come into favour as being lighter and more suitable for arranging with other flowers.—C.

VEGETABLES FOR EXHIBITION.

GLOBE ARTICHOKE.

A GOOD dish of fine succulent heads ought to be a strong point in every collection. They should either be grown well or not at all, as it is very certain the miserably dry heads are not appreciated by either a judge or cook. The ground for them ought either to be enriched to a depth of about 2 feet. Five or six years is quite long enough for plants to be grown on the same ground, and in our case a large space is given up to them, one or two rows being rooted up every spring and as many new rows planted. Old plants produce heads early in the summer. It is the young plants that usually produce the finest heads late in July and during August, or while most shows are held. Towards the end of March or early in April a few rooted suckers about 12 inches long may be placed in 6-inch pots, or larger if need be, and set on a gentle hotbed till well rooted, being hardened off and planted out before they become seriously root-bound; they will be the first to produce serviceable heads. Others taken off the old plants at the same time may be planted out at once for succession. Every pains should be taken to induce a quick and strong start. The Artichokes ought to be grouped in threes, the groups not less than 3 feet apart each way, being firmly fixed in the soil as deeply as possible without actually burying the heart of the plants, giving water when needed for promoting free growth. Before hot, and may be dry weather sets in, the ground about the plants should be heavily mulched with strawy manure, and occasional thorough soakings of water will greatly assist in the formation of fine heads for exhibition. Three strong growths are always ample for each group or old stool, and when they are drawn from for propagating purposes the three strongest and best placed suckers should be reserved and all the rest stripped off. At the same time remove much of the surface soil down to the roots, returning this after a liberal dressing of manure has been applied. Those that have been long on the ground may well receive a soaking of sewage or liquid manure in the spring and summer.

If seedling plants could be relied upon to come true to name, these would be found to produce the finest heads. Unfortunately it often happens that 50 per cent, or even a greater percentage, are little better than Cardoons, producing large branching flower stems and a great profusion of spiny but quite useless flower heads. Those with plenty of garden space, however, may feel disposed to raise a few seedlings, and will perhaps be rewarded with a few fine varieties. The seed may be sown early in April in patches 3 feet apart each way, and the seedlings eventually thinned to three plants in each instance. Seedlings raised in the open air arrive at a bearing stage rather late in the season, and those who want them early should sow seed in a pan of fine soil in March or April in gentle heat, and treat them for a time as half-hardy plants. The Green Globe is the best, being superior to the Purple Globe.

CELERY.

Unless Celery is extra well grown it is unwise to include it in a collection of vegetables shown either in July or August. In the neighbourhood of Sherborne, Dorsetshire, any quantity of grand Celery is seen at all the shows, one of the most successful growers being Mr. G. H. Copp, gardener at Holnest Park, Sherborne. To Mr. Copp I am indebted for several serviceable hints upon growing Celery for exhibition, and which he has not the slightest objection to being made public. For the earliest shows a vigorous-growing white variety should be grown, and on the whole I am of opinion that Wright's Grove White is the best. The seed should be sown late in January or in February, thinly, in a pan or pot, and set or plunged in gentle heat. As soon as the seedlings are large enough to handle they should be pricked off thinly in a pan or pans of good fine soil, and set on a shelf near the glass. Being properly attended to they soon become sturdy and well rooted, and ought then to be placed singly into 3-inch pots and returned to the shelf. Before they are

badly root-bound they must be shifted into 9-inch pots, a suitable compost consisting of loam and decayed manure in equal proportions, a good sprinkling of burnt clay or soil from a "smother" being added to keep the whole porous. All this can be done in an early vinery, and here the plants may remain until the Vines shade them too heavily, when they ought to be taken to a shelf in a cool house to harden prior to being set in the open air. By the middle of May the plants will be ready to stand in the front of a house.

For their final reception select a sheltered yet open place, say about 8 feet square. This will, when prepared, hold twenty-five plants, which number will in most cases be ample for the early shows. At each corner drive in a short stout stake, and one midway between them, to these being nailed a strong wide board. Next remove a depth of about 2 feet of the inside soil, and supply a compost similar to that in which the plants were last potted. In this the Celery should be planted the first week in June, being disposed 18 inches apart each way. They ought to be in a moist state at the roots when planted, and should have the soil trod very firmly about them, this being necessary in order to cause the growth of solid leafstalks, looseness of the root run being liable to encourage a "pipy" or hollow growth. From first to last Celery ought not to suffer by want of water, and when well established copious supplies of liquid manure should be given about twice a week. When growing strongly insert a stout stake to each plant, and tie the leaves lightly to these.

The blanching is the next consideration, and is a very simple proceeding compared with the other details. About five weeks before the Celery is wanted for exhibition, carefully wrap up the stems and much of the foliage in several folds of brown paper, so as to effectually exclude the light, and out of this the "sticks" turn in a perfectly blanched and beautifully clean condition. For the later shows Carter's Incomparable Crimson and Major Clarke's Solid Red are very suitable, and wonderfully fine samples of these and other red Celeries are frequently to be seen in the autumn hereabouts. The seed may be sown early in March, and the seedlings pricked off on a firm shallow bed of manure placed on a hard bottom, or exactly as the bulk of Celery is raised for ordinary purposes. Transplant with a good ball of soil and manure about the roots. They may well be grown in wide trenches prepared as advised for the earliest and given the same room, or be disposed 12 inches apart in a single trench. The other details are much the same as already given, the blanching also being carried out in much the same manner. Mr. Copp never thinks of blanching by earthing, but the late plants are enclosed in canvas, and bracken or dry litter is banked around them to prevent its being frozen. The fine Celery exhibited in the midlands by cottagers is usually grown on the surface of the ground, or only just deep enough to render watering an easy matter, and with the aid of soot water, sewage and occasional sprinklings of salt, wonderful growth is made. The blanching is always done with brown paper, or some substitute for it, and by no other means can such fine clean stalks be obtained. I have also seen very good Celery grown with the aid of 5-inch draining pipes. These are placed over the plants early, and effectually exclude the soil banked up around them from reaching the hearts, worms and grubs also being less liable to disfigure the stalks.

CARROTS.

A good dish of Carrots, although not exactly indispensable in a limited collection of vegetables, is yet frequently quite a feature in them, and I would always stage them if fairly large, of good form, richly coloured, and clean. Judging from what we meet with in the neighbourhood of London, the sandy peaty soil prevailing in some parts of Surrey just suits the Carrot. At any rate it is impossible to surpass the productions of Surrey gardeners and market growers. By good culture, however, it is possible to equal them, and that is all that is needed. It is the heavy clayey soils, such as prevail in the Weald of Kent and Sussex, and which we also have to contend with, that are the most unsuitable for Carrot culture. They will grow strongly enough in such soils, too much so, in fact, but land that binds badly, and which also cracks in all directions, produces more wedge-shaped ugly roots than we care to lift when searching for a good dish for exhibition. The land ought to be in such a free-working order as to admit of roots being drawn from it in almost any weather. This may be partially accomplished by early digging, the ground being then well pulverised by the action of frosts, wind, sunshine, and rain. Supposing the ground is dug late in the autumn in February, it may well receive a liberal dressing of any fine sandy soil, notably that sifted from a heap of old potting soil. Add to this a heap of burnt garden refuse, leaf soil, and spent tan, and again dig over the ground for further pulverisation. When the time arrives for seed-sowing, fork the ground so as to well mix that added with the now finely separated surface soil, and a good seed bed should be the result. On no account should heavy land be meddled with in

wet weather; better by far delay both digging and seed-sowing till more favourable weather is experienced. If a good sized plot, or enough ground for all the Carrots needed on the place, cannot be prepared in the manner described, it may yet be possible to take extra pains with enough for a few long or several short rows. Over-rich, or manure-lick land, will not grow good Carrots, these also being usually infested with the insects most injurious to the crop. Such ground may frequently be improved by bastard trenching or double digging, the shovellin s brought up and well mixed with the surface correcting this. Trenching, as a rule, is not necessary for the production of good Carrots, newly trenched land frequently having a tendency to grow them far too large. Supposing the ground has been manured and trenched for Potatoes, this would leave it in excellent condition for Carrots. Where the maggot is very troublesome, wood ashes should be freely dusted in the drills when the seed is sown, and surface dressings of soot are not thrown away.

For the early shows, or those held in May, June, or July, I prefer the Nantes Horn. Veitch's Model, also belonging to the Horn section, is also fine for exhibition. It is scarcely so long, but is thicker than the Nantes Horn. As a rule the best roots of these will be obtained from the beds sown on slight hotbeds early in the year and for a time covered with glass. These may be drawn from for several weeks, a few being left thinly over the bed to grow to their utmost, and very handsome and richly coloured they usually are. Very good roots of these varieties may be grown on a warm border. The drills for them should be drawn about 10 inches apart, and the plants gradually thinned out till they are left about 6 inches apart. For the August and later shows the New Intermediate or Veitch's Matchless is the best, this being a decided improvement in every way on the old James' Intermediate. The drills for this, and also the Long Surrey, should anyone prefer this for the late shows, ought to be 15 inches apart, and the thinning out must be commenced as soon as they have formed rough leaves. Finally they may be left about 8 inches asunder, a greater space only encouraging the production of coarse roots. I ought perhaps to add that I consider it unwise to sow the late varieties before the first week in April, and that a summer mulching of short grass from the mowing machine, leaf soil, cocoa-nut fibre, or fine peat, is preferable to anything in the shape of waterings given in dry weather.—EXHIBITOR.

ARTIFICIAL MANURES.

WITHOUT directly contradicting his previous assertions, Mr. H. Dunkin has unwittingly supported my opposition to his ideas when he advises "food that is varied in its chemical constituents according to the nature of the plant that is to receive it." Exactly so, and if he will only have the goodness to read carefully through my previous article he will find that the gist of my argument is to give only food constituted according to the nature of the plant; but your correspondent seems to think that this is a well nigh hopeless task, as he says "A knowledge of chemistry may enable us to form various manures which are likely to supply the most suitable food, yet it is only by practical experience and close observation we can find out whether these anticipations are correct." I must certainly oppose the use of the word "may" in the above quotation, and offer a substitute in the word "undoubtedly," as I consider a knowledge of even the rudiments of chemistry one of the chief items of every gardener's education; and as to "only practical experience and close observation," why I consider these two words (experience and observation) the whole foundation of successful gardening, coupled perhaps with the rather ugly word "failure," for is it not through failure that continued success often ensues?

"But how am I to find out the chemical constituents of plants?" some one says, or in other words, "analyse the ashes?" Possibly a difficulty may arise here, as everyone is not sufficiently advanced in the higher branches of chemistry to perform this delicate operation successfully. Still there are many ways of obtaining the necessary information, for who does not know that the Potato contains more than 50 per cent. of potash, and only about 4 per cent. of lime, while the Cabbage contains but 10 per cent. of potash, and nearly 25 per cent. of lime? and again, the Grape Vine contains them in nearly equal proportions. Granted that these are undisputed facts, cannot they be used to considerable advantage in the preparation of our compost and plant food? For instance, a cultivator ignorant of these facts treats his Vines to a course of Peruvian guano, or some other equally heavy ammonia-laden substance. No doubt he would continue applying it until, as your correspondent puts it, they show signs of becoming gross and unfruitful, when if he were made aware of the cause he would apply some other kind of manure, in the hope that it would contain "a something" the plants were in need of. Still we must think charitably, and hope that he would discover his error, and apply at once manures that he knew for certain contained a large percentage of potash and phosphates, which solidify and build up the woody tissue; but would it not be better practice to apply the solidifying agents in the first instance, and so forestall the gross and unfruitful state?

I am inclined to think after all the only difference between Mr. Dunkin's practice and what I advocate is, that while he prefers to give

the plant a strong stimulant to start it, and then waits for developments, afterwards giving it various compounds as fancy dictates, I prefer to give the plant its food in as complete a form so far as my slight knowledge of chemistry enables me to do so, and instead of inducing a gross unfruitful growth that I know the application of some compounds will cause, I prefer rather to use such as will build up a serviceable tissue from the beginning.

As to the charge of inconsistency, in my endeavours to be brief I inadvertently omitted a saving clause, and, as far as appearances go, must admit the imputation. What I should have said was, "That artificial manures if properly constituted to meet the requirements of the individual species of plants they are then of the utmost utility to the plant grower."

Again, as to my appearing to believe that members of the vegetable kingdom are not similar in some respects to those of the animal kingdom, I might have been more explicit. I intended the sentence, "But such I hold is not altogether the case," should refer to the distaste arising sometimes from other causes besides a long course of the same kind of food. Still I hold there is some analogy between plant life and animal life, and this is what I affirm. "That if the manure or food applied in the first instance is a properly proportioned combination of the elements needed for the plant's or animal's support no diminution of its vigour will ensue even after a protracted application." I may add that I believe both the loss of appetite in plants and animals is caused by unsuitable variety, an excess of one element and insufficiency of another, especially so in the latter, where food, and I may add drink also, that, to use your correspondent's words, is "varied in its chemical constituents," is a great destroyer of appetite. Though change of food undoubtedly in some instances improves the appetite, on homeopathic lines, I suppose that like cures like, yet it cannot be disputed that the plainer in reason both the animal as well as the vegetable is treated the sounder will be the constitution.

As to Mr. Dunkin's idea that earths, acids, alkalis, salts, &c., coming into contact with lime, potash, soda, carbonic acid, or ammonia, and these again coming into contact with other substances unite and form an altogether different compound, I should certainly agree with him. I think I comprehend his meaning, which I take to be that after charging the soil with various chemicals, useful and otherwise, the soil gets into a state known in garden parlance as sour, while the corresponding state in an animal would be called dyspepsical, then for the soil apply an agent in lime to disperse the accumulation of excessive food. However, such matters as renovating old kitchen gardens is a subject by itself for discussion, though I cannot let it pass without giving it as my opinion that instead of a good dressing of lime, which by Mr. Dunkin's own showing must be followed up by the same operation that has partly spoilt the soil—viz., heavy feeding with farmyard manure, I would prefer only a very moderate amount of lime, and with a judicious amount of trenching I should hope to make use of a large proportion of the excessive richness, instead of dispersing it into the air by means of heavy liming.

In reference to the use of nitrate of soda, I am well aware of its rapid action on vegetation, but as I said in my previous article, if these highly stimulating agents are not backed up by something substantial, the plants are apt to become debilitated after its influence is expended, and I do not for one moment dispute the effects produced by Mr. Dunkin on his *Erica hyemalis*. I have at several times had charge of plants bought in from the market grower, which at the time of purchase looked the picture of health, but they had evidently been treated to a strong stimulant, which eventually left them candidates for the rubbish heap. This, I believe, is the generally prevalent idea respecting the effect produced by nitrate of soda alone, and in only one instance do I know of its deviation from this rule, this being in a series of experiments with different kinds of manures, including bonemeal, native guano, muriate of potash, superphosphate, nitrate of soda, &c., on different portions of a pasture. The results were various, bonemeal giving the least, and the others in various proportions up to nitrate of soda, which gave effect first, and the rather strange part, this portion of the field showed improvement for the longer period than did any other part. Possibly as Mr. Dunkin is an advocate for nitrate of soda he may throw some light on to this rather peculiar case. I have some ideas as to the cause, but will defer them for a time.—M. COOMBE, *Ashton Court Gardens, Bristol.*

THIS subject merits the attention it has lately received in these pages. Cultivators who are so situated that they can readily procure quantities of stable or farmyard manure at all times are fortunate, but the majority of garden owners, especially amateurs, are seldom so favoured. I know many parts where natural manures cannot be bought in sufficient quantity, and all sorts of schemes are started to find fertilisers. Some of these may be useful, but most of them if not hurtful are next to worthless; and better results would be secured by using 1 cwt. of good artificial manure than half a ton, or indeed a ton, of all sorts of rubbish. I approve of converting all kinds of refuse into manure, but I cannot recommend much of it as a full substitute for stable manure. Many small gardens are well cultivated, and those who use most manure have the best produce as a rule, but I have heard many of them say that much of the manure they bought at 3s. 6d. per cart-load did little or no good excepting to assist in opening the soil, and the best growers now employ artificials. Really good artificial manures, such as are advertised, contain the very essence of plant life, and surely it is better to feed vegetation with that which it uses freely and to

advantage than to submit it to materials which it can barely exist on, or are absolutely injurious to the roots or branches. Here we have the command of a good cattle yard for making, but for all that we buy many hundredweights of artificial manure annually, as it is easily applied and excellent in its results. Artificial manures are admirably adapted for use by amateurs, as they can be conveniently stored away in a small space. Plants in greenhouses and conservatories may be surface dressed with them without interfering with the enjoyment of the flowers, and when converted into liquid manure a lady may apply them. They may be used with advantage in three ways: first as liquid, second as a surface-dressing, and third mixed amongst the soil used for potting or sowing or planting in, and if properly applied they will prove highly remunerative and satisfactory.—J. M.

THE ORCHARD HOUSE.

[A lecture delivered at Birmingham on the 13th inst., by T. Francis Rivers, Esq.]

(Continued from page 257.)

FOR gardens where there is not room enough for the 24 feet span the 14 feet will be found very productive and manageable. It will hold two rows on each side, and these should be half-standards and bushes. There will be the same convenience for sheltering trees until the summer, and in every respect, except in size, the houses are the same in management. There remains now to be considered the third form, which I am afraid has caused more disappointment than any other, and this because of its extreme simplicity and the obvious facility with which it can be erected. Walled gardens are plentiful enough, but crops of fruit from them are not so plentiful, and the often disappointed owner of such a wall, at the time of the publication of the "Orchard House," had a solution of the problem suddenly presented to him. What can be so easy as fixing rafters against a wall and covering it with glass? There is the front protection and the back wall, and the thing is done. It looks easy, and the house when finished is bright and pleasant. A very slight increase of the temperature outside raises the interior to an early summer heat, and it is a very agreeable lounge. Unfortunately, these hopes were often fallacious. The builder had forgotten the main point of the orchard house—viz., thorough ventilation. The angle formed at the base of the back wall and the area of the floor never secured or provided a complete circulation, consequently the air became stagnant, and the insect pests of all glass houses soon showed their ill-omened presence, this was very unfortunate for the system, as lean-to houses were so simple, with boarded sides and backs the ventilation of courses could be amply provided for, but people were often unwilling to break holes into brick walls. This difficulty is now, I am glad to say, easily removed, by the very simple plan of conveying air from the outside through 6-inch glazed drain pipes with open sockets at intervals of 6 feet. I was led to adopt this plan by the difficulty of ventilating the basement of a lean-to house, the experiment has succeeded perfectly, and possesses the great merit of economy. The drain pipes are not dear, and can be laid by any labourer at the trifling cost of excavation, no cement being required, a slab of slate or board will close the outer ventilator, and all ingress of air is at once stopped, the great convenience of ventilating thoroughly in windy weather will be soon appreciated by those who try this system. The lean-to orchard house 14 feet wide will take four rows of trees, two on each side of the centre path, the trees on the back row may be pyramids or half-standards, as there will be ample head room. It must be understood that in all these orchard houses the floors must not be paved, concreted, or flagged. It is absolutely necessary that the soil should be free for evaporation, the paths being gravelled. There is one very important point in the construction of orchard houses, and that is the supply of water, this cannot be dispensed with, and unless it can be easily and cheaply obtained it would be useless to spend money in building, as the work would be hopeless.

The question of soil must be considered very carefully by the orchard-house cultivator, as upon the quality which he uses will depend all, or much of his success. I think that I must consider myself fortunate that I have a soil in which the Peach fruits admirably, and this is a calcareous loam. Where it can be obtained there is nothing better. I prepare this for potting by throwing it in a ridge about nine months before using, mixing at the time of ridging about one-third of its bulk of good stable manure, and about a month before potting this soil should be placed in a dry shed, another third of well decayed manure being again mixed with it. If the soil is very tenacious, calcareous sand is an excellent material to use, for lessening this defect. The soil being prepared, the next operation is the potting, and this again, although apparently a very simple operation, requires some experience. My men, who are strong and hearty, and capable of hard hitting, ram the soil round the roots and in the pot with an instrument similar in size and weight to a policeman's truncheon, with all the vigour which a man can use when he has to work all day. One of the most fertile causes of failure in the early days of the orchard house, was the tendency to avoid this hard ramming on the supposition that the roots would not push their way through the soil, a notion completely erroneous.

The pots to be used for orchard house trees are by no means toys, being from 11 inches to 18 inches in diameter, according to the size and age of the tree. Good drainage must be provided, otherwise the soil will be sour; some large pieces of broken pots must therefore be placed at the bottom, the tree should not be too deeply potted, the upper roots being level with the rim. Young roots will always rise to the surface to feed, and will range round the side of the pot, showing the extraordinary attrac-

tion caused by the warm air of the house. Before I leave the subject I may here give the materials used for surface dressing, another important feature of pot culture. From long experience I have found the most efficient top-dressing, if it can be obtained, is horse manure free from straw, two-thirds, kiln dust (not the malt combings) one-third, spread this in a bed about 6 or 9 inches deep and saturate it with cesspool water, use it the day after mixing. This mixture, if repeated during the summer will be found in the autumn as full of small roots as a peat bed. In addition to this surface dressing, trees that are bearing a full crop should be watered with liquid manure from a tank as close to the house as possible, this tank being supplied with a bag of soot for soaking, some rusty iron, and horse manure without straw renewed at frequent intervals; the necessity of frequently supplying food by surface dressing and liquid manure is evident, the property of water being to carry off the salts necessary for the trees. While treating of water I may as well refer to the very important subject of giving water to the trees, and common sense will suggest the mode of action. There is no dew and no water from the sky, and the syringe must therefore supply the deficiency. This should be done morning and evening while the trees are in full growth. Trees out of doors, whether in bloom or not, are visited by showers during the spring, and are not harmed by the heavy drenchings they occasionally endure, therefore there is no reason to suppose that the same treatment will injure them under glass. August and September are usually dry months, and this will indicate the treatment. The roots must not be allowed to be dry, but they should not be kept in a puddle.

Another important branch of orchard house culture is the pruning, and this must be governed by the age and condition of the tree. If healthy and well grown, a tree that will ripen from four to five dozen fruit will produce blossoms enough for ten times this quantity. When pruning in winter this must be carefully borne in mind and the shoots reduced to a reasonable limit, care being taken to prune always to a triple or a leaf bud, which will provide the fruiting branch of the ensuing year. Many varieties of Peaches and Nectarines are apt to produce long, unfruitful shoots, as there are sorts of equal quality which will give fruit spurs in abundance. I should advise the cultivator to grow these and avoid the others; this is a point which will be soon understood by those who have the management of an extensive orchard house, and the study of these variations will soon become very interesting. The individuality of my trees is of real interest to the manager, and the knowledge of these peculiarities is of great value to the grower for market, as the sorts which furnish abundant fruit spurs and wood buds require less room than the stragglers; under the limited space of glass every inch of room is valuable. Pinching or nipping, a very old and necessary practice, must be done while the shoots are tender, the first, which is the most important, being performed at the fifth or seventh leaf from the base of the shoot; this is generally practicable early in May, and must be pursued at intervals of three weeks or a month during the early summer, the object being to equalise and regulate the growth of the tree.

I have hitherto confined my remarks to the cultivation of Peaches and Nectarines only, but our climate is not more liberal in the continuous production of other fruits. The Apricot perhaps is more difficult to grow than any other except in certain districts in England, where, as I understand, the line of demarcation is very rigidly drawn and ceases with the absence of lime in the soil. It is a native of the dry and cold climate of Armenia, hence the name "Armeniaca," although the cold of this country is severe and enduring in winter, the summers are very hot, and this knowledge must guide the treatment under glass. If placed in the same house with Peaches the Apricot must have a special compartment which can be ventilated freely as soon as the trees begin to show signs of developing their buds (as a rule they are easily excited), and then air must be freely given. In the soil an extra dose of lime must be added, and as soon as they are in flower give air day and night, except of course during severe frost. The season of fruit may be much prolonged by placing them out of doors. As with Peaches the harder the soil the better the Apricot flourishes, and although the remark may be made that these fruits are grafted on the Plum stock, which will grow in loose garden soils, yet it must be remembered that the elaboration of the singularly hard and solid stones of the Peach and Apricot is completed by the tree, the stock being merely the vehicle.

The next fruit of all others which requires glass is the Cherry, a native of a much warmer climate than either the Peach or Nectarine. My Cherry house, which has existed for some twenty-five years, is a span-roof, 60 feet long by 14 feet wide, and I may say affords even greater pleasure than the Peach house. It is not heated in any way, but the Early Rivers Cherry begins to ripen about the first week in June, and for three months from this time I am never without ripe Cherries. The protection from birds, and from the heavy summer rains which often spoil the finest crop, allows a development of flavour and size which is quite extraordinary, and also permits the retention of the fruit on the tree long after the time of ripening. The Cherry will hang like the Grape, for weeks without any loss of flavour or appearance. In all respects the cultivation is the same as the Peach, except that the ripe fruit will not bear the syringe.

The Plum comes next in order of orchard house fruit, and though comparatively hardy, the finer kinds are well worth culture under glass, but there is no necessity to retain them in the house after they have set their fruit and are in no danger from spring frost. To those who care to afford the expense a wire house like an aviary should be constructed to receive the trees destined for the open air. This will keep

birds from injuring the fruit and will be very useful in retarding Peaches, Nectarines, and Apricots, although Plums and Pears are, of course, the principal fruits to place in it. These should be plunged in a border specially prepared for them, the pots being covered with light manure and watered occasionally with liquid manure. The trees would pay for the protection, as they will never cease to bear.

(To be continued.)

BULBS IN HOLLAND.

A DECEMBER SHOW.

AMONG the many varieties of bulbous plants cultivated in Holland during recent years so much attention has not been paid to those which may be forced very early as might have been desirable. The aim has always been to have large flowers, and those are not always found among the earliest. For many purposes, however, early flowers are wanted, and there is now a tendency among growers to give more attention to them than before. In January last a show of flowering Hyacinths and Tulips was held in Overveen, near Haarlem, which succeeded fairly well. At the general meeting of the General Royal Union for the cultivation of flower roots, held on the 26th ult. at Haarlem, it was decided to hold a show of flowering bulbous and tuberous-rooted plants on December 24th, 25th, and 26th, 1888. The previous programme, which was discussed and enlarged at the said general meeting, contains forty classes—viz., for Hyacinths and Tulips in pots or glasses, for Crocus, Narcissus, Amaryllis, Orchids, Anthuriums, Cyclamens, and for miscellaneous bulbs and tubers for the open ground, as well as for glass houses, novelties included. As this exhibition is principally undertaken for the benefit of the trade and for study, there will be no medals or money prizes given, but certificates of the first, second, and third class. By this Exhibition the varieties fit for early forcing, not sufficiently known at present, can be put in advance and in consequence become more appreciated by growers.

THE TRADE IN CUT FLOWERS.

In July last year communications appeared in your Journal on this subject. The General Royal Union for the Cultivation of Flower Roots at Haarlem have resolved to do everything possible to stop the sale of cut flowers, considered so very injurious to the bulb trade, and the resolutions for this purpose were adopted at the sixty-eighth general meeting of the Society, which took place on January 30th last, and were confirmed at the sixty-ninth general meeting, held on the 26th ult. The results communicated of the operations of the Society showed that 2081 bulb-growers and tradesmen had signed the declaration not to sell any cut flowers of Hyacinths, Tulips, Narcissus, Ranunculus, and Anemones for trade, and not to deal with those who sell such flowers, or who refuse to sign such declaration. The number of such signatures increases daily. On the contrary, there were only 107 names on the list of those who refused to sign, and there is every probability that this number will yet decrease. From these facts it may be concluded that the measures taken have received general sympathy.—J. H. KRELAGE, *President of the General Royal Union for the Cultivation of Flower Roots.*

JUDGING FRUIT BY APPEARANCE.

SURELY Mr. Ward is mistaken in saying that you can judge of the quality of known varieties of Apples and Pears by sight alone. My own experience tells me that many well known varieties of both Apples and Pears may be of first rate quality or perfectly uneatable, or anything between the two, without there being the slightest apparent difference whatever between them. To name one instance, Beurré Bosc grown here on a wall sometimes ripens and is of fine quality, and sometimes is fit only for stewing, is never the same two seasons together in fact; yet it is always equally fine and well grown to look at. The same thing is more or less true of all other fruits. There is no such thing as perfect uniformity in quality even in Grapes, although they may come near it. So that if the object of judging fruit at shows be to promote quality in fruit and not sham and show, I do not see how it is to be done without tasting fruits; but it should be remembered that even then it is a most imperfect test of real merit, which can only (at least in the case of Apples and Pears) be found out by tasting them every two or three days during the whole time that they are in season.—C. W. STRICKLAND, *Hiltenly.*

NEWTON'S PATENT GLAZING.

IN the *Journal of Horticulture*, March 15th, page 224, I was very pleased to see the remarks by Mr. G. R. Allis on Newton's patent system of glazing. We have a house 32 feet by 12 feet, span-roofed, with partition erected by Mr. E. Newton, and I have seen none to equal it for lightness and strength. The heavy rains and wind of late have given it a very fair test, but not a drop of rain has been seen to come through owing to the small gutter in the galvanised iron sashbars. Neither can any draught be detected, which I have proved when the wind almost blew a hurricane. The temperature is all that can be desired; for instance, on March 21st, at 9.30 P.M. the temperature outside was 6° below freezing, and inside without any artificial heat it was 3° above freezing.—HENRY SHOEBRIDGE, JUN., *The Limes Gardens, Carleton, Surrey.*

TANKS IN ORCHID HOUSES.

IT was mentioned recently in some notes respecting Mr. R. H. Measures' collection of Orchids at Streatham that numerous "zinc" tanks were employed for retaining the rainfall. Mr. Measures states that they are nearly all galvanised iron and that he has a decided objection to zinc tanks. Upon several occasions when the water from an old zinc tank had been supplied to the Orchids in one of the houses, the foliage soon assumed an unhealthy appearance, especially the more delicate, such as Phalanopsis, but they quickly recovered when water from other tanks was given to them. It was carefully tested, and the evidence was so conclusive against the zinc tank that the water it contains is never supplied direct to the plant.—C.

SALES BY AUCTION.

AMATEURS in London probably do not require a word of warning respecting the auction sales of Orchids, but there may be others who like myself are unversed in the peculiarities of this business and to whom the following note may be useful. I recently visited an auction room with a friend who had a somewhat valuable Orchid for sale, and for which a substantial sum was expected. The bidding appeared to be brisk, and the amount offered rapidly rose to £12, and by the time the auctioneer had made a few remarks respecting what a bargain it was at the price the bidding had reached £16, at which price it was knocked down. Shortly afterwards I turned to congratulate my friend upon the good price obtained, when he informed me the plant was unsold, and that there were no bids above £10. Query, how was the amount raised to £16? Did the auctioneer bid or did he imagine that others did? Whatever the cause, the result was misleading.—AN ORCHID AMATEUR.

VANILLA.

THE following interesting particulars concerning the cultivation and fertilisation of the Vanilla are extracted from the "Kew Bulletin" for March. The illustration (fig. 36) is also from the same publication, Mr. Thistelton Dyer having obliged us with the use of the block.

The cultivation of Vanilla has been attempted in numerous tropical Colonies, but, with the sole exception of Mauritius and the Seychelles, it does not appear to have assumed an important position in any British Colony. This is due to a variety of circumstances. In some Colonies the climate may be unsuited to the successful growth of the plant, owing to seasons of extreme severity in droughts or heavy rains. In others the soil may be too retentive. In most of them, the need which exists for artificially fertilising the flowers of Vanilla, and the care necessary to properly cure the pods, have, no doubt, contributed to retard the cultivation. There are, however, no valid reasons why the cultivation of Vanilla in certain portions at least of the West Indian Colonies, of British Honduras, of the West African Settlements, of India, Ceylon, and the Straits Settlements should not be successfully pursued. With that view, plants of Manilla have been forwarded from Kew to certain Colonies where they did not previously exist, and it is proposed now to give very briefly the chief points bearing upon the industry.

The Vanilla plant is an Orchid of climbing habit, of which there are probably several species under cultivation. The more common plant appears to be *Vanilla planifolia*, Andr. (*V. claviculata*, Sw.). Other species under cultivation are *V. aromatica*, Sw. and *V. grandiflora*, Eich. The Botany of the plants yielding Vanilla requires to be carefully investigated. The specimens in the Kew herbarium in their present state throw little light on the subject. Hence, a good series of leaves, flowers, and fruits of plants yielding Vanilla, carefully dried or preserved in spirit, would be a valuable addition to the collections.

It appears that *Selenipedium Chica*, Rehb. f. (*Xenia Orchidacea*, vol. i., p. 3, t. 2) yields Vanilla on the Isthmus of Panama, which is described by Seeman ("Botany of Herald," p. 215), as follows:—

"The fruit of this plant is highly esteemed as an aromatic by the inhabitants of the Isthmus [Panama], and is used for all purposes for which real Vanilla is commonly used. It is termed 'Vanilla Chica,' or 'Little Vanilla,' because its fruit is very much smaller than that of any of the genus Vanilla found in the Isthmus."

Cultivation.—As regards starting a Vanilla plantation, it is important to bear in mind that the plants, being climbers, it is necessary to provide them with support of some kind, and generally, for this purpose, rough-barked trees, trellis-work, stone pillars, or stone walls are utilised. Living stems of rough-bark trees are probably the best supports of Vanilla. In Mauritius, the Seychelles, and Réunion, the stems of *Jatropha Curcas* are largely used. In addition to support, the Vanilla plants require a certain amount of shade. This, however, should not

exceed what is called half-shade (*demi-jour*). A certain amount of sun is, however, essential to the proper ripening of the pods. Whatever the support or nature of the shade may be, it is important to bear in mind that the Vanilla plants should be kept within easy reach of the cultivator, and not allowed to climb high up amongst the branches.

The ground around the support should be prepared by deep trenching to the depth of a foot or 18 inches. The drainage of a bed should be perfect. The most favourable soil consists of fine rich loam, mixed with equal parts of sand and leaf mould. Rich animal manure, or manure of any kind, is not a desirable addition. To renovate the soil at the end of the season, add some well-decayed vegetable mould or humus mixed with sand. Raise the bed about 6 inches above the surrounding surface, and support by means of stones or rockwork. Where obtainable, the cuttings should consist of portions of stems about 2 or 3 feet long, but all the better if 4 or 5 feet long. The leaves are first removed from the lower part, and three joints are laid under the soil and covered to a depth of 2 or 3 inches. The upper part of the stem is trained against the support in the position in which it is intended to grow. A single tree will carry several Vanilla plants, depending upon its size. The surface of the bed should be kept moist by being covered with leaves or "mulching," and, in very dry weather, it should be regularly watered.

Thus started, Vanilla cuttings readily take root, and the stem will grow and flourish. Depending upon the size of the cuttings, the plants begin to flower in the second year after planting. They do not, however, flower freely until the third and fourth years.

Fertilisation of the Flowers.—The first duty of the cultivator when the plants are in flower is to attend to the duty of fertilisation which, in countries where the Vanilla is not a native, will require to be done artificially. The flower of the Vanilla, as in most Orchids, is a very highly differentiated organ, the parts of which can be best studied by a reference to the engraving given on this page. In the wild state, the pollen is carried to the stigma of the Vanilla flower by means of the agency of insects. Where these particular insects are absent, their work must be performed by the cultivator, or no Vanilla pods will be produced.

It is recommended that the work of fertilisation should take place in the morning. It is advisable that all the flowers in a cluster be fertilised as they open; but of those that are successfully fertilised, only a certain number, depending on the age and strength of the Vine, should be allowed to remain. If too many pods are retained at first, the Vine is apt to be weakened, and the quality of the produce lowered.

The process of fertilisation will be better understood by a reference to the engraving given herewith. The only instrument necessary is a small piece of bamboo or sharpened stick the thickness of a lead pencil, about 4 or 5 inches long.

When the flower is opened, it will be noticed that there are three outer and three inner floral parts, which are sometimes designated the sepals and petals respectively. One of the latter is so much altered and so distinct in form and colour, that it is usually spoken of as the lip. Inside, and immediately hanging over the free part of the lip, is a process which is a continuation of the axis of the flower. This is called the column (see *b*, fig. 2). The end of the column enlarged, front view, is shown at fig. 4. At *a*, fig. 5, is represented the anther, containing the pollen masses, and at *b*, the stigma or viscid surface, on which the pollen must be placed in order to ensure the act of fertilisation. At fig. 6 is represented a section through the top of the column showing the position of the pollen masses *a*, and the stigma *b*. It will be noticed that the stigma is separated from the pollen masses by an upper lip projecting over the stigma. In the work of fertilisation it is necessary to lift up or tear away this lip, and transfer the pollen masses from the anther at *a* to the stigma at *b*, as shown in fig. 7. The mode of using the instrument is shown at figs. 2 and 3.

The work of fertilisation, when once understood, may be carried on with great rapidity. An expert person will, it is said, fertilise as many as a thousand flowers in one forenoon. The simplest mode is to seize the flower with the left hand between the thumb and middle finger, and support the column at the back with the forefinger. Then, with the sharpened instrument in the right hand, the hood at the top of the column is removed, so as to expose the anther and stigma. The upper lip of the stigma is

FIG. 3.—FERTILISATION OF VANILLA FLOWER (DELTEIL).

- EXPLANATION OF PLATE.—FIG. 1.—Portion of stem of Vanilla plant, with leaf, aerial root, and cluster of flowers; *a*, front view of Vanilla flower; *b*, side view; *c*, aerial root, with root hairs.
- FIG. 2.—Single flower of Vanilla, exhibiting the first stage in the process of artificial fertilisation. The operator, provided with a finely pointed piece of bamboo, divides the lip or labellum medially, so that the central lobe is separated from the two side lobes. This exposes the column and organs of fecundation. The instrument is represented as placed against the column, ready to press upwards the anther *a*, and bring the pollinia in contact with the stigma *b*.
- FIG. 3.—Single flower of Vanilla, exhibiting the second stage in the process of artificial fertilisation; *b* shows position of column exposed by division of the lip [the middle lobe of lip is pulled forward and curled upon itself to show the position of the column; the side lobes of lip, separated as shown in fig. 2, are represented at back of the column]; *a*, the position of pollen masses, taken from the anther and placed on the stigma.
- FIG. 4.—Enlarged front view of top of the column; *a*, the anther.
- FIG. 5.—Enlarged side view of top of the column; *a*, the anther; *b*, the stigma, or viscid surface on which the pollen must be placed to ensure fertilisation.
- FIG. 6.—Enlarged section through top of the column; *a*, one of the pollen masses *in situ*; *b*, the stigmatic cavity.
- FIG. 7.—Enlarged section through top of the column; *a*, the pollen masses, having been transferred from *a*, fig. 6, are now represented in contact with the stigmatic surface. [Although diagrammatically shown, these figures give a tolerably good idea of what is actually necessary in order to produce fertilisation in a Vanilla flower.]

then pressed upwards, and the anthers brought down and placed in contact with stigmatic surface, as shown in figs. 3 and 7. The explanations given to the figures in the engraving will clearly show the operations here described. When the flowers have been fertilised they will begin to wither about the third day. By the end of the first month the fruit attains nearly its full size, although it is not fully developed until it is six or seven months old.

Curing the Pods.—The pods are left on the Vine until they begin to show a slight yellow tinge at one end. They are then gathered from day to day, care being taken not to injure those not yet fit to gather. When the day's gathering is completed, the pods are placed in a basket, and, according to one method of preparation, they are plunged for about half a minute in very hot, but not actually boiling, water. Directly after this operation the pods are spread out on mats to drain. For the next six or eight days they are exposed on woollen cloths or blankets in the sun, while each night they are kept in a closed box, where they undergo a certain amount of fermentation. When they have become soft and brown, the pods are placed to dry in the shade, they are carefully and regularly pressed between the fingers, slightly anointed with oil, and rendered supple and lustrous. When quite cured, the pods are of a rich dark chocolate colour, pliable in texture and perfectly free from moisture. The whole process of curing extends over several weeks.

In packing for the market, the pods are sorted according to length, and put up in packets of fifty pods each; they are tied in the middle, and also near each end. These packets are then carefully put up in closely fitting tin boxes. When Vanilla pods are in good condition, they become covered with an efflorescence of needle-like crystals of Vanillic acid. The interior of the bean is then soft, unctuous, and balsamic.

Those who wish to carefully study the various modes of growing and curing Vanilla, cannot do better than consult "Vanilla, its Cultivation in India," by J. E. O'Connor, Calcutta, 1881; and "La Vanille, sa Culture et sa Préparation," par A. Delteil. Paris, Challamel aîné, 2, Rue Jacob, 1884.

Vanilla plants have been frequently grown and fruited in this country at Kew, at Sion House, and other establishments. In 1878, some bunches at Sion House contained as many as fifteen pods, each of which measured 9 inches in length.

Mr. Piessé gives the following interesting information respecting the use of Vanilla pods for perfumery purposes:—

"In order to obtain the perfume or essence, $\frac{1}{2}$ lb. of such pods are cut up small, and put into one gallon of pure alcohol, of a strength known as 60° over proof, giving the whole a shake up daily. The ingredients must remain together for, say, four weeks, at which time all that is worth extracting will be found in the spirit, which may then be strained off quite clear and bright. It is then suitable as a flavouring agent, or, when blended with other scents, it makes delicious perfumery. Those sold under the titles of Clematis, Heliotrope, Wall-flower, &c., mostly contain about one-half in bulk of Vanilla extract. About two centuries ago, Vanilla may be said to have been unknown in this country; it is, however, stated that Morgan, an apothecary, showed to Queen Elizabeth a sample, but he knew nothing more about it than that 'it was brought from abroad by some Spanish merchants.' At the present time the total annual average crop of all the varieties of Vanilla from the several countries which produce it may be estimated at 80,000 lbs., representing a value of not less than £150,000."

EVENTS OF THE WEEK.—The second meeting of the Royal Horticultural Society in their new quarters, the Drill Hall, James' Street, Victoria Street, will be held on Tuesday next, April 10th. Upon the same day a general meeting of Fellows will be held in the offices to consider the new by-laws proposed by the Fellows' Committee. Towards the end of that week numbers of British horticulturists will be making their way to Belgium, the Ghent Quinquennial Horticultural Exhibition opening on the 15th inst.

— **AMARYLLISES AT CHELSEA.**—The extensive collection of Amaryllises in Messrs. Veitch & Sons' Nursery, Chelsea, is now open to visitors, and a fine display of brilliant flowers will be provided for several weeks.

— **THE WEATHER.**—"B. D." writes from Scotland—"The weather in the beginning of the week ending April 2nd was disagreeable in the extreme. Snow, hail, and sleet fell on the 27th and 28th ult., the latter being in the afternoon and evening one of the wildest days of

the winter. A strong gale blew from the N.E., and the snowdrift was in some districts even more severe than in the preceding storm. Frosts from 2° to 6° occurred in S. Perthshire during the week. March closed with a bright, clear, though cold day, with a N.W. wind, and April continues in its first two days to be of the same character." In the south cold winds have prevailed with occasional showers, and bright sunny mornings.

— ON the eve of going to press we have seen an announcement of the death of PROFESSOR PLANCHON, of Montpellier, where he filled the Chair of Botany, in the sixty-ninth year of his age. He was well known throughout the horticultural and botanical world, was editor of Van Houtte's "Flore des Serres," and was commissioned by the French Government to proceed to America to investigate the ravages of the Phylloxera on the various species of native Vines. These he imported into France, and was instrumental in a great measure in having them substituted, both as permanent crops and as stocks on which to grow the European varieties. M. Planchon was also a frequent contributor to the scientific periodical literature of France. He was a correspondent of the Institute of France and of the Linnean Society of London, and was an honorary member of the Royal Horticultural Society.

— WE are informed that a fire broke out early on Tuesday morning in a large packing shed in the nursery of MESSRS. RICHARD SMITH AND SONS, Worcester, and a workman in the nursery named Thomas Parker, a young man aged twenty-two, was found dead in the building. It is supposed that, being out late, instead of disturbing his landlady he went into the building to sleep, and that on lighting a match he dropped it and the dry moss caught fire, resulting in his suffocation, as he was very slightly burnt.

— A CORRESPONDENT sends us the following note on RIPE PEACHES IN MARCH:—"On March 26th Mr. T. King, the well-known gardener at Devizes Castle, gathered a capital dish of Peaches from a tree of Early Alexander planted in a mixed Peach house. Last year he was a few days later in gathering, and the fruit sold readily at 5s. each. In all probability a still better price will be realised this year, as they will be sent to Covent Garden Market for Easter week. The house was closed on November 15th, and seeing what a long and very cold winter it has been, Mr. King's achievement is highly creditable. It is, in fact, very doubtful if anyone has, previous to this year, been successful in gathering ripe Peaches from planted-out trees so early in the season. It would appear that the Peach season now extends over a period of seven months, or from April to October inclusive."

— A LATE Honorary Secretary of the Ludlow Horticultural Society sends us the following note on AZALEAS AT DOWNTON HALL:—"On the 27th ult. I was favoured by a kind invitation to visit the Downton Hall Gardens, near Ludlow, to inspect Sir Charles Rouse Boughton's collection of Azaleas, and venture to send you a few remarks on what I saw. The collection was well worth the visit, and comprised Alba; Bernhard Andreasalba; Charmer, red, a mass of bloom; Criterion, pink, a 5 feet mass of colour, and no leaf to be seen; Iveryana, John Veitch, Dr. Livingstone, Madame Glover, pure white, a beauty; Raphael, good; Roi Leopold, 6 feet high by 4 feet in diameter; much special care and attention seemed to be given to this plant; Sigismund Rucker; Stella, I would give the first prize here; Mrs. Wright, Flag of Truce, Her Majesty, Madame Marie Lefebvre, and Due de Nassau. The arrangement of the above, with Roses in full bloom, Heaths, and other plants, made the visit on a snowy day a treat indeed."

—"B." asks, "If it is generally known that MRS. SINKINS PINK is one of the best of forcing plants, not only on account of the ease with which it produces flowers, but more especially on account of the great size, fullness and purity of its blooms?"

— THIS correspondent also remarks:—"I fell in with an old fashioned plant last autumn which I had not seen for nearly twenty years. It is called ROCHEA FALCATA, a very striking succulent with a large corymb of small glowing blossoms dotted with a regiment of golden anthers. Everybody had to inquire about it. Some to insinuate a desire to possess so desirable a plant, others to boldly inquire as to the possibility of sparing a cutting. So you see, who read, that Rochea is worth growing." It is belted out every summer in Battersea Park, and flowers freely.

— CRICKETS IN GREENHOUSE.—“W. C.” writes to know if any reader of the Journal can recommend anything to destroy crickets and cockroaches.

— ROYAL PARKS AND GARDENS.—A return recently presented to Parliament gives the following particulars of the Royal Parks, &c. Battersea Park covers an area of 199 acres, and is devoted to the public, except about two acres reserved for frame ground to propagate plants. Bushy Park contains 994 acres, but from a large portion of this the public are excluded. No less than 104 acres are kept as meadow land for hay, and fifty-five acres timber, and these 159 acres produce £91 per annum. Then there is a reservation of seventy-five acres for the Royal paddocks, thirty-six acres for enclosures for deer, and the total reservation amounts to about 320 acres. Greenwich Park contains 185 acres, almost all devoted to the public; and Hampton Court Park, with an area of 752 acres, is wholly unreserved, and the same may be said of Hampton Court Green (seventeen acres), and Hampton Court Enclosure Gardens (forty-two acres). Hyde Park, with 360 acres, is also practically unreserved, and the public have equal freedom in Kennington Park (nineteen acres), Kensington Gardens (274 acres), Kew Gardens (248 acres), and Regent's Park (472 acres), the largest reservation in Regent's Park being thirty-one acres for the Zoological Gardens. Other portions also are let, bringing in a total revenue of £2344 18s. 10d., to which £358 0s. 9d. is contributed by the Zoological Society. There are also four contributions to the revenue—Baptist College and grounds, £213 8s. 9d.; St. Dunstan's Villa and grounds, £250 16s. 7d.; St John's Lodge and grounds, £234 2s. 3d.; Botanical Society's Gardens, £360; and South Villa and grounds, £333. There are also some smaller tenancies, which make up the total. Richmond Old Deer Park, containing 363 acres, is not open to the public, and produces a revenue of £972. Richmond and Petersham Parks cover 2470 acres, and from these the following reservations are made:—Plantations, 142 acres; mowing grounds, 104 acres; deer paddocks, 137 acres; ranger's meadow, twenty acres; arable and for growing roots for deer, eighteen acres. There are several minor areas from which the public are excluded, and the revenue per annum is set down at £400 for the sale of timber, and £100 for feeding cattle. St. James's Park (ninety-three acres) and Victoria Park (212 acres) are unreserved, but from Windsor Green Park, which covers 5300 acres, 1395 acres must be deducted from which the public are excluded. The revenue of this park is also nil. Windsor Home Park consists of seventy-three acres, with no restrictions to the public. Other parks in the kingdom are mentioned, the largest being Phoenix Park, Dublin, which covers 1752 acres, and of which area 421 acres are reserved for the Viceregal Lodge and other Government purposes.

— MR. W. J. MURPHY, Clonmel, writes:—“Would some of your readers who succeed with the DOUBLE DAFFODIL, ALBA PLENA ODOBATA, kindly say with what method of culture and under what circumstances, such as indoors or planted out, position, soil, &c.? I have tried and been disappointed with it repeatedly. Dutch bulbs, seemingly sound and planted in pots in a cold frame last September, are only in several cases now commencing growth. In other years they did similarly, or decayed. Those planted in a warm south border never flowered either. One bulb this year in a pot promised to be an exception, but has turned out a monstrosity—seemingly a dwarf form of the great double yellow Spanish Daffodil. It is only 8 inches high, with blooms very large and reflexed. I am sending it to Mr. F. W. Burbidge to examine.”

— THE same correspondent observes:—“I should like to ask how those beautiful and useful plants ANEMONE CORONARIA have fared with your readers so far. Here excellent strains, produced by a rigid process of selection of seeds, were grown in specially prepared beds in numbers of gardens. I have seen many others lately, and all seem, like the lines in my own borders, badly ‘burned and battered.’ I was very proud of two beds filled with plants raised from the celebrated ‘St. Brigid’ strain; but though they have fairly borne the alternate frosts, thaws, and sunshine, I blame the snow for doing most mischief amongst them. Cold does not seem to do as much injury to either blooms or foliage as thawing snow or sleet, with sunshine. At present the temperature of the soil seems lower than last January. To make certain of a profusion of blooms in the autumn I intend remaking two beds, using fresh loam from the farm, and sowing a selected strain of Anemone seed mixed

with the ‘St. Brigid’ strain. Some half moist sand rubbed with the woolly seed hastens vegetation. I never transplant seedlings.”

— REPLYING to Mr. T. Winkworth's inquiries respecting LACHENALIAS, “T. H.” remarks:—“I am unable to give him the information required, as I have never grown all of the varieties mentioned on page 233. Although I have frequently met with them in other gardens, I never thought them worthy of recommendation, as they generally throw up weakly flower spikes, and it is very rare for some of them to flower at all. The foliage is very pretty in some of the varieties, but not sufficiently to render them worth growing. I only recommend those varieties I was well acquainted with and that were easy to grow, and anyone following the simple instructions given could not possibly fail. I was pleased to see your correspondent enlarge all that was said in favour of these plants, and I appreciate the compliment.”

ROYAL HORTICULTURAL SOCIETY.

MARCH 27TH.

SCIENTIFIC COMMITTEE.—The meeting was held on this occasion in the committee-room of the Drill Hall—a room not very convenient of access, and suffering from the very great objection that the library is in another building. When the large room at Victoria Street is completed doubtless the meetings will be held therein. The difficulty then will consist in the necessity of removing the plants from the Drill Hall for the purpose of examination, and, moreover, at a time when it is particularly desirable to link together, rather than dissociate the several Committees. It is unfortunate that they should have to meet in separate buildings, but when there is a choice of evils the least must be the one selected. On the present occasion the Committee was represented by Sir Joseph D. Hooker, K.C.S.I., Chairman; Messrs. McLachlan, F.R.S., James O'Brien, Professor Church, Mr. F. Pascoe, Dr. Lowe, Mr. Albert Michael, G. F. Wilson, F.R.S., H. N. Ridley, British Museum; Professor Scott, School of Science; Professor Boulger, Dr. Masters, F.R.S., and Rev. George Henslow, Secretary.

The Blue Daisy.—Dr. Masters reported that the plant exhibited from Tangier at a previous meeting by Dr. Lowe was *Bellis annua*. Sir Joseph Hooker mentioned that it was common in the neighbourhood of Tangier, and that it was different from the plant found on the Atlas Mountain (*Bellis cœrulescens*).

Dispersal of the Seed in Pinus insignis.—Dr. Masters, alluding to the great differences that exist in the species of *Pinus*, as to the time at which the constituent scales of the cone separate in order to liberate the seed, showed a series of cones of *Pinus insignis*, the oldest of which bore the date 1864. In this all the scales were widely separate. The most recent cones dated from 1877, and in them the scales were not at all separated. Between these two extremes cones were shown exhibiting almost every intermediate stage of separation. It is to be remarked that the separation begins generally just above the centre of the pendulous cone on the side furthest away from the branch, at the place where the obliquity of the cone, due to the free exposure to light and air, and the absence of obstacles afforded by the branch was greatest, and that it follows a spiral course towards the base of the cone. The scales separate in successive spiral coils, till, at length, all except a few at the base and apex respectively, and which are probably sterile, are separated one from the other.

Semi-double and other Orchids.—Dr. Masters referred to various specimens submitted to him for examination. Among them were the following:—

Semi-double flowers of Cœlogyne flaccida.—These were obtained from M. Sallier, through the courtesy of M. Schneider. The conditions varied slightly in different flowers, but the most noteworthy case was one in which there were three sepals, three equal petals resembling the sepals in form, a column and two lips; these latter organs, therefore, representing two stamens of the outer whorl.

Cattleya Trianae.—Three flowers were brought to the Committee at a former meeting by Mr. O'Brien.

In (1) the two lateral sepals were present and also two petals, one median, occupying the place of the absent sepal, and one opposite to it forming the lip.

This flower, then, afforded an illustration of a tendency towards a dimerous and decussate arrangement of the parts of the flower, such as is frequently seen in malformed Orchids.

In (2) the dorsal or median sepal was also wanting, its place being occupied as in No. 1 by a petal, so that of the two lateral petals one was dislocated from a lateral to a median position, while the other was adherent to the column. The other parts were normal. It would appear in this case as if, for some reason or other, that the median sepal was not developed; 2, that the axis of the flower underwent a twist of 45°, so as to displace the petal and transpose it into the position of the sepal; 3, at the same time that this unusual growth was taking place on one side of the flower development was partially arrested on the other (the concavity of the helix), so that the petal remained in union with the column.

The third flower was normal in all respects, except that the median sepal had the appearance of a lateral petal. The case was one, therefore, of petalody of the sepal.

(4) A fourth flower of the same species, forwarded by Mr. Marcus H. Voss, was remarkable for the absence of one of the side sepals without other change. Here, again, was another illustration of the tendency to a dimerous condition, there being two sepals (in this case placed obliquely), but one of them forming a pair with the lip, and two lateral petals.

Phaius grandifolius, *Peloria*.—Sir Trevor Lawrence obligingly sent a flower of this species with two sepals placed right and left, and two median petals, each lip-like in character, and provided with a spur. The column was straight, the anther imperfect and incumbent. This flower then again illustrated the dimerous condition as to number of parts and the peloric condition as to the form of the petals.

Odontoglossum crispum, *Synanthy*, &c.—Mr. B. S. Williams forwarded a raceme of this plant which showed a tendency to branch or become paniculate. The branch, however, instead of becoming detached remained in union with the main axis, producing somewhat of a fasciated condition. As a result of this union it happened that sometimes the flowers were scattered, while in other cases a node of the main axis was placed side by side with the branch, so that two flowers belonging to different axes were brought into contact, and not only this, but in some cases there was actual synanthy or union of two flowers. In one of these flowers there were four sepals in decussate pairs, from petals also in decussate pairs, and two lips placed opposite to two columns. There were thus twelve parts present instead of fourteen, two sepals being missing, presumably one of the lateral sepals of each of the two flowers being suppressed at the point of contact. In many cases of synanthy the suppression of parts takes place to a much greater extent, but then it is relatively uncommon to see synanthy between two flowers belonging to different branch systems.

Malformed Fuchsia.—Baron von Mueller kindly sent a flower, in which the ovarian cavity is absent, the flower-stalk ending in a club-shaped expansion, from which are given off two stalked leaves, while the scars between their bases indicate the existence of others which have fallen off. The sepals are represented by two coloured segments, both stalked. One of the sepals is three-lobed, the central lobe oblong lanceolate and coloured like the sepals (pinkish-white), the lateral lobes shorter, broader, and coloured like the petals (purple). The second sepal is divided above the middle into two oblong petaloid lobes. Then follow three obovate stalked petals. The stamens are absent, but there is a shallow disc surrounding the base of the ovary. This latter organ is superior, one-celled, with three parietal placentas, and surmounted by three styles, coherent all the way up, with the exception of the distorted stigmas.

Proliferation, &c., in a Fuchsia.—From Mr. Douglas came an extraordinary flower. In this case the ovary was present, but there was no flower-tube above it. In place of that the ovary was surmounted by a tuft of sepals, petals, and stamens, forming an entangled mass, some of the parts being leafy, others petaloid, others staminoid, with others presenting various intermediate characteristics. The flower had partly fallen to pieces before it was examined, but the presence of four leafy sepals, as many leafy petals, and then a number of parts, the exact relative position of which could not be determined, and which presented the intermediate characters before mentioned, were observed. Within these sprang a second flower with a curved calyx-tube giving off four sepals and as many petals. The stamens were increased in number, some nearly perfect, others represented by long filaments terminating in spoon-shaped petaline laminae. The ovary of this flower was superior, but very imperfect, and surmounted by a style divided into two stigmatic lobes. A section across the ovary of the flower showed a double series of vascular bundles, the outer belonging to the flower-stalk, the inner to the carpels embedded in its substance. It would seem, then, that the complicated arrangements of this flower may be referred to dialysis, metamorphy, and displacement of various organs associated with median floral proliferation, or the production of a secondary flower from the centre of the first in the position occupied by the style in a normal flower.

Anthurium Chamberlaini.—Dr. Masters exhibited a drawing of a magnificent new Anthurium, which had appeared accidentally with an importation of *Cattleya Gaskelliana*, in the garden of the Right Hon. J. Chamberlain. The heart-shaped leaves are of gigantic size, and the large boat-shaped spathe is of the richest crimson colour. Mr. Cooper (gardener to Mr. Chamberlain) speaks in high terms of this plant as a decorative plant.

Eucalyptus urnigera.—Dr. Masters showed specimens of this Tasmanian species in flower and fruit. It had been received from Whittinghame Gardens, Prestonkirk, near Edinburgh, and not far from the sea. The tree was perfectly hardy.

Daffodil with Crested Corona.—Rev. E. C. Gabbett sent through Dr. Masters two flowers of a curious Daffodil from plants growing on his lawn in Co. Limerick. The "firill," or outgrowth, is produced from the outer surface of the corona, which has thus a very peculiar appearance, of which we hope shortly to give an illustration. Mr. Gabbett reports that six blooms were so affected, and that in former years, when the weather was more propitious, the frilling was more pronounced. Mr. Gabbett had observed this peculiarity for four or five years.

Fringed Cyclamen.—Mr. O'Brien showed a flower of this variety in which the petals produced a crest-like outgrowth from the upper surface of the petals. But in this instance there was the additional peculiarity that the petals were not reflexed as usual, but formed a belt-shaped corolla. Dr. Masters adverted to the anatomical peculiarities of these

flowers, which were referred to Dr. Scott for further examination as to their structural details.

Douglasia larigata.—Mr. G. F. Wilson alluded to this plant as having been shown before the Floral Committee as a charming dwarf alpine plant exhibited from the Royal Gardens, Kew, and proposed that it should receive a botanical certificate, which was agreed to. It is a low growing plant with tufted leaves and lilac flowers, like those of an Androsace, but larger and with the tube of the corolla longer than the calyx, and with only two seeds to the capsule. The species are natives of North-western America, the first known species having been collected by Douglas not far from the sources of the Columbia River, and named in his honour by Dr. Lindley.

Hybrid Phalaenopsis.—Mr. Ridley reported on the *Phalaenopsis* shown at the last meeting as a cross between *P. amabilis* and *P. rosea*, but stated that he was unable to detect any trace of *P. rosea* in it. Mr. O'Brien remarked that the influence of the cross was sometimes observable in the vegetation of the plant, even when it was not conspicuous in the flower.

Acacia armata.—Mr. Pascoe reported upon some leaves of *Acacia armata*, from the surface of which a brownish outgrowth proceeded. This was ascertained not to be of fungus origin, and it was considered probable that it might be the work of a Coccoeus. Mr. O'Brien alluded to the formation of similar excrecences as a consequence of insect or aphid punctures.

Euchresta Horsfieldi.—Mr. Christy sent some seeds of this plant, not unlike roasted coffee. The natives of Java use them as a tonic and to arrest the spitting of blood. The shrub is the only known species, and grows in the mountain districts of Java and Formosa. Dr. Horsfield says the natives use the seeds an antidote to any poison, and Leschenault says the powdered fruits mixed with food prevents diseases. Mixed with Lemon juice they are also applied externally to wounds.

Cola Chocolate.—Mr. Christy sent samples of chocolate made from the seeds of *Cola acuminata*, and which he had ascertained to be useful in certain forms of indigestion.

Bamboo Cane.—Rev. G. Henslow exhibited a box which had contained seeds sent from Japan. Professor Church stated that the form of some of the Italian drug-pots of the fifteenth and sixteenth centuries appeared to have been modelled from the Bamboo vases.

Araucaria imbricata Timber.—Mr. Ford, gardener, Leonardlee, exhibited slabs of wood cut from a tree of this species, and which at 6 feet from the ground girthed 26 inches, and the tree being 35 feet in height. The wood was yellow, soft, evenly grained, and, judging by the distance between the rings, quickly grown.

Plants Exhibited.—From Mr. Ware came specimens of the elegant *Leucojum trichophyllum*. Sir Trevor Lawrence sent *Masdevallia Carderi*, a species remarkable for its deep and broad cup-like flower-tube. To this, as also to *Trichoglottis fasciata*, and the *Douglasia* before mentioned, botanical certificates were awarded.

CAMELLIAS AT WALTHAM CROSS.

MESSRS. W. PAUL & SON'S nursery at Waltham Cross is widely famed for its Roses, which provide the visitor in June and July with a wonderful floral feast, but the establishment is scarcely less noted for its Camellias, and these are at their best during March and early April. A spacious span-roof house, 130 feet long, 36 feet wide, and 14 feet high, is there devoted to large and small specimens of all sizes, and the best varieties, to suit all requirements and tastes. There are healthy little plants in 48-size pots and tree-like specimens in tubs 3 or 4 feet across; there are varieties of all imaginable tints from the purest white or delicate blush to the richest crimson and brightest fiery red, the flowers ranging as widely in form, from the most exact symmetrical imbrication of wax-like petals to the great bold flowers of the semi-doubles of the Donckelaari type. Beautiful and useful as small healthy Camellias in pots invariably are, all the characters of these plants cannot be seen until they reach the size of specimens 10 or 12 feet high, when, either planted out or in tubs, they annually load themselves with their handsome flowers. About 100 such specimens are arranged in the central bed of the house already mentioned, and most of these are compact bushes 3 to 6 feet in diameter, ornaments for any large conservatory, as their rich glossy green foliage renders them attractive even when not flowering. The free growth made, the abundance of flowers produced, and their general satisfactory condition, prove how carefully their culture is studied; there is no other secret. A soil of substantial loam, plenty of water when growth is being made, both at the roots and on the foliage, and a thorough ripening, are the chief items of the practice, and the results are vigorous health with flowers to be gathered by bushels. The smaller parts in various stages are numbered by thousands, and all alike can be characterised by one word—excellent.

Over 220 varieties are represented in Messrs. Paul & Son's collection, and from these the following fifty are selected as the most distinct and of the best habit, a few of these being marked with an asterisk to indicate the most useful for small collections. Adamo, white flaked with rose; Adelina Benvenuti, pale pink spotted and striped crimson, very free; *Alba plena, the old double, unsurpassed as a white variety; Auguste Delfosse, crimson striped white; Angustina superba, bright pink, handsome; Baron de Vriére, excellent shape, delicate blush striped white; Beali, crimson; Beali rosea; Beauty of Hornsey, deep rose, streaked white; Belle Jeannette, crimson, banded white; Benneyi, bright red, white streaks; Bonomiana, white streaked with crimson; Candidissima, white, delicate; *C. H. Hovey, one of the best varieties,

rich crimson, excellent form ; *C. M. Hovey, bright, nearly scarlet ; *Commendatore Betti, very large, broad petals, rose pink, free, good habit ; Conspicua, semi-double pink ; Contessa de Hainaut, exquisite

Donckelaari, semi-double, crimson flaked with white, large flowers, free and handsome variety (fig. 37). This makes a fine specimen for a conservatory. Chandleri elegans, clear rose, large flowers ; Fatima, an

FIG. 37.—CAMELLIA DONCKELAARI.

delicate blush tint, and fine shape ; Contessa Woronzoff, rosy pink, good form ; Corallina, bright deep red, tufted centre, useful, free ; Countess of Derby, white striped with pink, very beautiful ; Countess of Orkney, a pretty cupped flower, white, streaked rose ; Cup of Beauty, somewhat variable, but handsome, blush tinted, or sometimes nearly white.

early, dark red variety ; *fimbriata, white with fringed petals ; imbricata, bright rosy red, an excellent variety, free and of good habit ; Lavinia Maggi, white striped with pink ; *L'Avenir, rose with lighter margins and stripes ; Leopoldo Benucci, pink, white centre ; Livia Boromeo, similar colour ; Lucrezia Gazzarrini, pink striped white ; Madame

Cachet, white, with faint pink streaks, pointed petals; Madame de Strelakoff, blush, large handsome flowers, round petals; Marchioness of Exeter, brilliant rose, good shape; Maria Nicolais, crimson, neat flower; *Mathotiana, very dark crimson, large bold flowers; M. d'Offroy, soft pink, charming symmetrical flowers; *Ninfa Egeria, white with dark and beautiful foliage, flowers well formed; Prince Albert, white, streaked pink, handsome; Princess Charlotte, white, with faint pink tinge; Princess Clothilde, semi-double, white streaked pink; Princesse Rospigliosa, pink, small but free, light centre; *Rafia, very rich dark crimson; Reine des Fleurs, dark red; *Reticulata, semi-double, bright rose, graceful habit, free; *Romanicensis, white mottled crimson; *Souvenir d'Emile Defresne, red striped with white, free; *Targioni, very delicate pale pink, tipped white; and tricolor imbricata, white streaked with red and rose, well formed flower, free.

Considerable difference is observed in the time at which the varieties flower, but the following six are some of the earliest, and the succeeding six are late varieties. *Early Varieties*.—Alba plena, imbricata, L'Avvenir, Donck-laari, Princess Charlotte, and Fatima. *Late Varieties*.—Countess of Derby, Belle Jeannette, Cup of Beauty, Leeana superba, Contessa de Hainaut, and C. M. Hovey. With plants of these and the midseason varieties in different stages, the Camellia season can now be prolonged over a much longer period than formerly, a constant supply of flowers can be had for at least three months.

THE LIVERPOOL SHOW.

MARCH 28TH.

THE elements seem to have decreed that the Exhibition should not prove a success financially, as was the case last week. Snow commenced falling early in the morning, accompanied with a strong piercingly cold wind, then rain followed, and continued more or less during the day. Yet the large number of exhibits in St. George's Hall made one of the finest displays that has been brought together since the Society has been in existence. There was a falling off in some of the classes, while the additional interest afforded by others more than counterbalanced any deficiency. The falling off was most conspicuous in the Hyacinth and Polyanthus Narcissus classes, but this may and doubtless is due to the postponement of the Exhibition from an earlier date.

Stove and Greenhouse Plants.—Fox six stove and greenhouse plants Mr. J. Jellicoe, gardener to F. H. Gossage, Esq., Camp Hill, Woolton, took the lead with fine plants of Pritchardia pacifica, Latania borbonica, Croton Queen Victoria, Rhododendron fragrantissima, 3 feet through and covered with bloom, Azalea indica, and a Chorozema Lawrenceanum. Mr. A. Crosbie, gardener to B. Hall, Esq., was a good second; Mr. A. R. Cox, gardener to W. H. Watts, Esq., securing the remaining award. For one foliage plant, Mr. A. Crosbie was accorded the premier position with a large specimen of Asparagus plumosus in grand condition, being fully 5 feet high and 4 feet through. In the corresponding class for one flowering plant, Mr. J. Harrison, gardener to Mrs. W. G. Bateson, took the lead with Phaius grandifolius with about twenty spikes fully 5 feet high. For one greenhouse plant in flower, Mr. A. Crosbie was again successful with Imantophyllum miniatum coccineum with fifteen or sixteen fully expanded trusses, most of them being 8 or 9 inches across.

Hyacinths.—On the whole these were not so good or staged in such large numbers as has been the case at previous shows held by the Society. In the class for eighteen distinct varieties, Mr. C. Waring, gardener to Mrs. J. Sikin, Princess Park, Liverpool, was well ahead with strong plants of the leading varieties. Mr. J. Kelly, gardener to R. Singlehurst, Esq., Endfield House, Aigburth, was second. The flowers were much smaller, and the foliage considerably drawn. Mr. T. Stephenson, gardener to R. Cornelius, Esq., Aigburth, third with an uneven collection. In the class for twelve, Mr. A. Cox took the lead with praiseworthy examples. The remaining exhibits in this class were uneven, and merit no further comment. No less than seven competitors staged in the class for six plants, Mr. C. Copple, gardener to T. S. Rogerson, Esq., securing the foremost place with good examples of King of the Blues, Fabiola, La Grandesse, Lord Derby, Grandeur à Merveille, and Kool-i-noor; Mr. T. Wilson, gardener to O. H. Williams, Esq., Fulwood Park, Aigburth, was a good second; and Mr. C. Waring third. For six pots, three bulbs in each, not less than three varieties, Mr. T. Stephenson was first with well-grown plants, followed closely by Mr. P. Barber, gardener to A. Barnsley, Esq., St. Michaels Hamlet; third Mr. James Kelly. Seven collections were staged. Mr. C. Waring was the only exhibitor in the class for twelve Hyacinths in glasses, and the examples staged were very good. They well merited the first prize awarded them; many of the flowers were superior to those shown in pots, and the foliage dwarf, considering they had been grown in water.

Narcissus.—These were poorly represented, only two collections being staged for the prizes offered for six pots. Mr. P. Barber took the lead, and Mr. J. Loundes, gardener to S. S. Parker, Esq., obtained the second award. It is a pity that prizes are not more generally offered to encourage the culture of border varieties in pots, which for effectiveness surpass the Polyanthus varieties.

Tulips.—We have seen on past occasions a greater display, but the quality throughout has not been as generally good as on this occasion. It is gratifying to say that there was scarcely a poor example in any of the collections. In the class for twelve pots (single) of six varieties Mr. A. Collins, gardener to S. Smith, Esq., Princess Park, took the lead, followed by Mr. Barber and Mr. T. Stephenson. For six pots Mr. A. R. Cox took the foremost position with dwarf well grown plants. Messrs.

C. Copple and J. Loundes were second and third respectively. For ten pots of double fine varieties Mr. T. Stephenson gained first honours; Mr. John Bounds, gardener to A. L. Jones, Esq., Aigburth, second; and Mr. W. Bustard, gardener to J. Lewis, Esq., third. For six pots Mr. Barber was first, Mr. J. Loundes second, and Mr. C. Copple third.

Crocuses were particularly good, being shown in 8-inch pots. Six competitors staged for the three prizes offered. The prizewinners were Mr. Barber; Mr. J. Watson, gardener to F. Tobin, Esq., Aigburth; and Mr. W. Bustard in the order named.

Lachenalias were not numerous, only two lots being staged for the three prizes offered. Mr. T. Winkworth, gardener to R. Brocklebank, Esq., Childwall Hall, was well first with L. Nelsoni, the 5 and 6-inch pots having from ten to twelve spikes each. Mr. W. Bustard was second with the less showy tricolor, but the specimens staged were very creditable.

Primulas were represented by several collections, but none were of a noteworthy character except those staged by Mr. A. R. Cox. These were dwarf and well flowered; in fact, the plants were very fresh and the flowers of large size and substance.

Cinerarias were considerably above the average, in fact they were not only better but more numerous than they have before been at the Association's Show. The first prize collection, staged by Mr. T. Stephenson, were all that could be desired. The plants were dwarf with good heads of particularly large well-shaped flowers. Mrs. Watts and Mr. W. Porter gained the second and third awards, while Mr. Warrington, gardener to T. Bright, Esq., was deservedly awarded an extra prize.

Lily of the Valley.—No class in the schedule was better filled, or the prizes more keenly contested for, than the three offered for six pots of these flowers. Mr. J. Jellicoe was placed first. The second and third prize exhibits as well as many others were specially good, but we omitted to take down the names of the various competitors.

Azaleas.—On the whole these were better than they have been for some years. Mr. Jellicoe was the chief prizewinner with well flowered examples of Fielding's White, Souvenir de Prince Albert, Reine de Pays Bas, Charles Van Echaute, Alba variegata, and Roseum; Mr. W. Wilson, gardener to H. Cunningham, Esq., Gorse Cop, Gateacre, was a good second, and Mr. W. Bustard third with uneven specimens. Azalea mollis was particularly good, many of the plants being large and most profusely flowered. For four plants Mr. J. Bounds was first with plants 3 feet through them, and full of flower; Mr. J. Loundes was a good second, and Mr. A. R. Cox third. For one plant the prizewinners were Messrs. J. Jellicoe, J. Bounds, gardener to A. L. Jones, Esq., and C. Waring.

Ferns were not largely shown, but those staged were good. Mr. T. Gowen, Linton Lodge, Mossley Hill, was well first for four exotic varieties with a large fine plant of Goniophlebium subauriculatum; Adiantum assimile, 3 feet 6 inches through; Dicksonia squarrosa, with a stem 3 feet, and Dicksonia antarctica. Mr. A. R. Cox was second with fresh well-grown plants, and Mr. W. Bustard third. For one plant R. Brocklehurst, Esq., was placed first, and Mr. T. Stephenson second. For one Tree Fern Mr. Jellicoe took the lead, followed by Mr. J. Bounds, both showing healthy well-grown plants.

Palms and Cycads.—Only two classes were provided for these, and six lots were staged in the two classes. The plants were fresh and healthy and of a moderately large size. In the class for three Mr. A. Crosbie gained the first position, followed by Mr. T. Gowen and Mr. A. Gowen, gardener to W. C. Clark, Esq., Sefton Park. For one plant Mr. J. Agnew was first with Kentia Belmoreana, a fine healthy young plant; Mr. A. Crosbie was second with Cycas revoluta, and Mr. J. Bounds third.

Foreed Plants.—Three good collections were shown. Mr. A. Crosbie was placed first for six plants with Clematis Madame van Houtte very fine, Rose Climbing Jules Margottin, large plants of Rhododendron Purity, and Deutzia gracilis were very fine. Mr. W. Bustard was second, and Mr. J. Bounds secured the remaining prize.

Table Plants.—These were shown in the usual style, and were very attractive down the centre of one of the tables. The plants in every instance were small, neat, and light. For six plants Mr. J. Agnew, gardener to Mrs. Watts, was first, his collection comprising Draecana gracilis, D. Sydneii, Croton interruptus aureus, Pandanus Veitchi, and Thrinax grandiceps. Mr. C. Evans, gardener to W. Maxwell, Esq., was a good second, and Mr. Jellicoe third. For three plants Mr. G. Park, gardener to Lieutenant-Colonel F. Warrington, Wigau, was first.

Roses.—On the whole Roses were much better than they have been before at any of the Association's spring shows. For four plants Mr. A. Crosbie took the lead with Adam, Souvenir d'un Ami, Due de Magenta, and Isabella Sprunt. Mr. A. Lewis was second, and Mr. W. Bustard third. For one plant Mr. Crosbie was again first with Souvenir d'un Ami; Mr. W. Bustard second with Maréchal Niel, and Mr. J. Loundes third.

Hardy Rhododendrons.—The effectiveness of the Exhibition was materially increased by the Rhododendrons. With four plants Mr. W. Bustard won first honours, showing moderately large plants, followed by Mr. Kelly and Mr. J. Stephenson. Mr. J. Agnew led with hardy herbaceous and bulbous plants.

Orchids.—Now that so many of these plants are grown in the neighbourhood, this portion of the schedule might with advantage be extended. For four plants Mr. J. Edwards, gardener to A. Tate, Esq., was placed first with Odontoglossum radiatum, having four good spikes, Cattleya Mendelli, with three fine flowers, Cypripedium villosum, a fine pan with fifty or sixty flowers, and the old Maxillaria Harrisoni with about

twenty flowers. Mr. J. Poyntz, gardener to R. Young, Esq., was second with *Cattleya Trianae* having six flowers, *Dendrobium crassinode* with six or seven large pseudo-bulbs flowering profusely, a fine variety, and *Dendrobium nobile Wallichianum* with about a dozen well-flowered growths. Mr. A. R. Cox was third, and had good examples of *Cymbidium Lowianum* and *Phalenopsis Schilleriana*. For one plant Mr. Jellico was first with a fine specimen of *Dendrobium Jamesianum* bearing many flowers. Mr. J. Harrison, gardener to Mrs. W. G. Bateson, was second with *Phaius grandifolius*; third, Mr. J. Bounds, and an extra prize was awarded to Mr. Poyntz.

Groups.—In the class for a group of miscellaneous plants arranged for effect, to occupy a space of 60 square feet, Mr. A. R. Cox and Mr. J. Jellico were rivals for the first position. Both staged light, neat, and effective groups. Mr. Cox was successful; his arrangement was better finished near the edge. This exhibit was a little over 4 yards long and nearly 3 wide, with a plant of *Cocos Wedd-Ilia* raised in the centre, *Crotons* about 3 feet high at each corner, with two *Aralias* on each side of the *Cocos*. The groundwork was composed of *Adiantum cuneatum*, dotted with *Primulas*, *Cyclamens*, *Tulips*, *H. acinths*, a *Coleus* or two, and *Masdevallias*. Mr. Jellico's group had two *Dracenas* raised above the groundwork, and if it had been better finished at the margin would probably have secured the first position. Mr. J. Kelly was third, four competitors staging for the three prizes offered.

Cut Flowers.—In the open class for one bouquet Mr. G. Cashel of the Liverpool Horticultural Company secured the chief award, followed by Messrs. Fishlock Brothers, St. John's Market. The latter was the best shape, while the former secured the position by its choice flowers. In the corresponding class Mr. J. Mercer, Higher Bebbington, was first, Mr. J. W. Sandback, Birkenhead, second, and Mr. J. Agnew third. A class was provided for six *Roses*, cut blooms, and several competitors entered. Mr. J. Downham, gardener to E. H. Harrison, Esq., Eastham, was placed first with large magnificent flowers of *Gloire de Dijon*, *Maréchal Niel*, *Duke of Edinburgh*, *Etoile de Lyon*, *Madame Lambard*, and *Rubens*. Mr. J. Bounds was second with really good blooms, and Mr. Thos. Wilson third. For a box of stove and greenhouse cut flowers Mr. A. R. Cox was placed first, Mr. Bounds second, and Mr. J. Jellico third.

Fruit to some extent was a new feature, although *Grapes* have been staged on past occasions. With two bunches of *Grapes* Mr. G. Park was first for good examples of *Alicante*, and Mr. Elsworthy, gardener to A. R. Gladstone, Esq., was second with the same variety, well kept. Mr. J. Smeatbam was third. Mr. Elsworthy also contributed four bunches (not for competition) of *Alicante*, *White Tokay*, and *Gros Guillaume*. The bunches were not large, but very fresh and plump. Mr. Hannagan, Hooton Hall, also staged a collection of fine *Apples*, and a certificate of merit was awarded.

Miscellaneous exhibits.—The tables of flowering and fine-foliage plants from local nurserymen have never been so effective. Messrs. R. P. Ker & Sons staged a quantity of the newer forms of *Azalea indica*, some of which were noted last year. Conspicuous amongst them was the following, exhibited at Liverpool:—*Sacountala*, double white, very good, much after the style of *Deutsche Perle*; *M. de Kneef*, single white with large pure well-shaped flowers; and *General Postmaster Stephen*, very dark, after the style of *Flambeau*. Mr. J. Davies, Waver-tree, contributed a beautiful group of *Hyacinths*, *Narcissus border* and *Polyanthus* varieties, *Amaryllises*, *Azaleas indica* and *mollis*, as well as a general assortment of other flowering plants. The Liverpool Horticultural Company had a similar table of plants in which *Orchids* were freely employed. They also contributed a number of wreaths, crosses, and bouquets. Messrs. Fishlock Brothers also staged a similar exhibit, including a number of the most lovely sprays suitable for ladies. Mr. J. Brambam displayed outside the Hall his heating apparatus, and Mr. Bethel his folding boxes, while Messrs. W. Wood & Sons had on view their samples of peat and loam. All who took part in the arrangements of this exhibition deserve the highest congratulations. The staggers had a very arduous duty to perform, for the hall was occupied the night previous, and the staging and other arrangements could not be attended to until the morning of the show. This was bad for all, more especially as the weather could not have been worse. The only regret is that it was not so largely patronised by the public as such an elaborate exhibition deserves to be.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY.

THE *Hyacinth* and *Spring Show* of this Society was held in the City Hall on Wednesday, the 28th of March. The weather was of the most unfavourable description, sleet, cold winds and hard frost (7°) preventing many competitors risking their valuable plants. Fortunately several of the largest collections were staged on the day preceding the Show, otherwise it would have been a comparative failure. The well known firm of Messrs. Austin & M'Aslan, Buchanan Street, contributed largely to the success of the Exhibition, having a splendid bank of flowering shrubs, containing many fine varieties of hybrid *Rhododendrons* and *Azaleas*, *A. mollis* being in some instances particularly good. An uncommon sight at this season was a plant of *Laburnum* in full flower. Messrs. Smith & Simons filled two tables, each 12 by 6, *Azaleas* and stove plants remarkably well grown and tastefully arranged; while from the Island of Bute Messrs. Dobbie & Co. brought a very choice assortment of border *Narcissi*, good specimens of *N. bicolor Empress*, *N. Horsefieldi*, *N. Princess*, and the pretty small white *N.*

albicans, these attracted much attention, as did also a very pretty one named *Mary Anderson*. Mrs. M'Kenzie, 65A, St. Vincent Street, sent five large choice bouquets, which were highly commended.

R. Brooman White, Esq., Arddarroch, Garelochhead, sent a choice collection of *Orchids* in flower, many of them for the first time, as they are his own importation, the plants of *Dendrobium nobile* being much finer in colour than we usually see. A very fine form of *D. Dalhouseanum* was prominent, *D. superbiens* had two fine spikes, several hybrid *Odontoglossums* and a particularly good *O. Rossi majus*—a most interesting collection, such as has not been seen in Glasgow for many years. The condition in which these plants were staged after such a long journey reflected much credit on Mr. White's gardener, Mr. W. Kidd. Mr. Jas. Bryson, nurseryman, Helensburgh, sent, as usual, a grand collection of *Roses*, cut blooms *Maréchal Niel* in large quantities, and pretty floral designs, a large anchor of *Maréchal Niel* *Roses* being greatly admired. *Banksian*, *Tea*, and hybrids were also largely represented, the whole forming one of the most interesting features of the Exhibition. Mr. George Russell, gardener to Mr. J. B. Mirreles, Redlands, Hillhead, exhibited a choice collection of flowers of seedling *Rhododendrons*.

In the class open to all for the best *Tree Fern* Mr. Geo. Meston, gardener to W. Carsewell, Esq., Murcia House, Pollokshields, had first and Mr. John Campbell, Govan, second. For one hand bouquet Mr. Raeside, Yorkhill Gardens, was first; Mr. Geo. Bambridge second; and Mr. Geo. Neil, Greenhead, St. Newmills, third. Mr. Donald McBean, gardener to J. C. Cunningham, Esq., of Craigends, had the best dish of *Mushrooms*. In the class for nurserymen only the prize for twelve table plants was gained by Mr. John Sutherland, Victoria Nursery, Lenzie, and were models of what table plants should be. Mr. Sutherland was also first for three hardy *Rhododendrons*. For a table of bulbs 12 feet by 6 feet Mr. Peter McKenzie, 65, St. Vincent, was awarded first prize for an admirable collection. Mr. McKenzie was also first for eighteen *Hyacinths* with fine even spikes, and Mr. John Sutherland was a good second.

Gardeners' and Amateurs' Class.—Table of plants 12 feet by 6 feet. The first prize was gained by Mr. Geo. Meston, and although he had no opposition, his table well deserved the award. Mr. Thos. Hogg, gardener to John Gordon, Esq., of Aitkenhead, was the most successful competitor in the plant class, and his plants were never shown in better condition. He was awarded first for six stove or greenhouse plants in flower, distinct varieties, and for three stove or greenhouse plants, comprising a magnificent specimen of *Rhododendron Countess of Haddington*, densely flowered, *Azalea Duchesse de Nassau*, and a good *Cœlogyne*. Mr. Geo. Meston was second. With three specimen *Orchids* Mr. Hogg was first, having splendid plants of *Cypripedium insigne* 3 feet through and splendidly bloomed, *Cœlogyne cristata*, and *Dendrobium Wardianum*. Mr. Geo. Neil was second. The best three specimen *Azaleas*, and three *Azaleas* in 8-inch pots, were shown by Mr. Hogg; second, Mr. Wm. Cowan, Killellan, Campbeltown; and third, Mr. Geo. Irvine, Italian Villa, Pollokshields. Mr. Hogg also led with three greenhouse *Rhododendrons*, six *Cyclamens*, and three *Amaryllises*. He exhibited some blooms of seedling *Azaleas* obtained from *graudis* crossed with *Apollyon*, the result being very satisfactory, all the blooms of good shape and substance, large, and fine colours, ranging from pure white to deep crimson. The chief prize for three hardy *Rhododendrons* was gained by Mr. Wm. Cowan. For one specimen *Mignonette*, Mr. Wm. Dickson, Chanting Hall, Hamilton, was first, and Mr. Walter Rae, Woodville, Biggar, second. With six table plants, Mr. Alex. Raeside, Mr. A. Montgomery, Rozelle, Partick, and Mr. Agnew, Ascog, were the prizetakers in the order named. For three *Cinerarias*, Mr. J. Lyon, gardener to J. W. Moore, Esq., Greenlaw, Blantyre, had first, Mr. Thos. Hogg second, and Mr. Jas. Bell, gardener to Miss Lyon, Stonelaw Tower, Rutherglen, third. Four Chinese *Primulas* were shown by Mr. Wm. Halliday, Cordale Gardens, Renton, Mr. Hugh Millar, gardener to A. Russell, Esq., Auchentraith, Bothwell, and Mr. Chas. F. Carnegie, Gartshore House Gardens, Kirkintilloch. The prizes for twelve *Hyacinths* were gained by Mr. Donald McBean, Mr. Carnegie, and Mr. Geo. Irvine. Messrs. Hugh Millar, Geo. Irvine, and Chas. F. Carnegie were placed in the order named with six double *Hyacinths*. For six *Hyacinths*, Mr. Carnegie was first, Mr. Geo. Irvine second, and Mr. D. McBean third. Three pot *Hyacinths*, three in each pot, Mr. Hugh Millar had first, and Mr. Robt. Millar, gardener to Mrs. Clark, Netherhill, Paisley, was second. For the best arranged and most meritorious basket of spring flowering plants, Mr. James Millar, Castle-milk gardens, was deservedly first, Mr. Henry Dixon, Knightswood, second, and Mr. A. Raeside third.

Tulips were plentiful and shown in capital condition. Mr. Heron, Pollok Gardens, Pollokshaws, the successful competitor of former years, was again to the front, securing the first position with four pots of *Tulips*, three pots of single *Tulips*, and four pots of *Polyanthus Narcissi*; Mr. Hogg being second in both classes, and Messrs. Raeside and Millar third. For four pots *Crocus*, Mr. Millar had first prize and Mr. Wm. McIntosh second. Six *Alpines* in pots not to exceed 6 inches, Mr. John Mecklam, Cameron Place, Bridge of Weir, had first; Mr. John Nicoll, Carriagehill, Paisley, second; and Mr. Wm. Watson, Bellsbank, Rutherglen, third. For three pots *Spirea japonica*, Messrs. Geo. Meston was first, Wm. Cowan second, and Wm. Halliday third, were the prizetakers. Two pots or pans *Lily of the Valley*, pots not to exceed 9 inches, were shown by Mr. Wm. Cowan, Mr. Heron, and Mr. Dixon in that order. For three pots not exceeding 6 inches, Mr. Cowan was again first, Messrs. Heron and Dixon following. With two pots of *Primula obconica* Mr. A. Walker, Gallowat Place, Rutherglen, had the first place;

Mr. D. McDonald, Dalmuir House, Drymen, second; and Mr. Watson third. With six blooms Camellias, distinct varieties, Mr. D. Waddell, Southpark, Rothesay, was first, showing splendid blooms; Mr. Thos. Hogg, a close second; and Mr. Wm. Semple, gardener, Castle Semple, Lochwinnoch, a good third. For six trusses Rhododendrons, Messrs. Hogg and Millar were respectively first and second.

In the class open to amateurs only there was a good display, many of the exhibits comparing very favourably with the professionals, notably the Hyacinths, the most successful competitors with these being Messrs. Henry Dixon, Knightswood, and Wm. McIntosh, 2, Firpark Terrace, Dennistoun. A very interesting class was the one open to ladies only, for one Hyacinth grown entirely in water. Miss M. Hutchieson, 32, Carriagehill, Paisley, was first, Miss M. R. McIntosh, 2, Firpark Terrace, Dennistoun, second, and Miss M. Sharpe, 21, Heriot Street, third. Two pots Dutch bulbs in bloom, first was gained by Miss M. R. McIntosh, Miss M. Hutchieson second, and Miss Jessie B. Taylor, Craigie Knowe, Barrhead, third. For three Hyacinths grown entirely in water Miss M. R. McIntosh was again placed first, Miss Lizzie Sharpe second, and Miss Janet J. Sutherland, Victoria Nursery, Lenzie, third.

The arrangements of the Show, which were entirely satisfactory, were as usual carried out under the superintendence of Mr. Frane Gibb Dougall, the energetic Secretary of the Society.—KELVIN.

MARIE BERTON AND JAMES SPRUNT.

THE former of these is the most beautiful of all the Gloire de Dijon race, and deserves much more general cultivation. It has the same free growth as its parent, the young shoots and foliage are of a handsome dark red colour, and the large pale yellow blooms very attractive in appearance. In strong contrast in size and colour is the also little known Bengal Rose, James Sprunt, a climbing sport from the old Cramoisie-Supérieure (Agrippina), the flowers of which are of rich velvety crimson, and fuller and larger than the parent sort.—W. WESTON TURNOR.

THE PAST WINTER—CLOSE PRUNING.

THE time for pruning our Roses is now at hand, and I made the first cut last week. I am agreeably surprised to find that the Roses here, at the altitude of 1000 feet above the level of the sea, or thereabouts, have suffered very little, and I think our prospects are decidedly rosy. Favoured with fair average weather, we may hope to have fine Roses in due time. After former winters, I have often noticed that Baroness Rothschild (the Baroness herself, and none of the new and not too satisfactory imitations) has been killed quite brown and dead at the base of the shoots; this season, so far, I have noticed nothing of this. In fact, I have not seen any dead wood on any of the Roses. That I am pruning harder and closer than ever goes without saying, as I get more and more proof of its advantages the older I grow. Here is a fresh instance: A standard of Niphotos in a pot had the head broken off short; nothing remained but to cut it back to a mere stump, but lo! shortly appeared a new strong shoot about as thick as a lead pencil, which grew to 2 feet long, and then branching at the top into four distinct branches, produced twelve blooms, the first of which was, vulgarly speaking, a "whacker!" My mental memo. on the occasion was "Cut all standards in pots (and out of pots, too) back to a single eye in future." I wintered a quantity of Teas in pots in open frames, simply packing dead leaves round them and strewing them loosely over the branches. The frost has, of course, killed the exposed part of the shoots back, but under the leaves I find all alive and the buds plump and swelling. I did intend to place lights over these plants, but omitted to do so, and I think the result is even more satisfactory to me, and the plants stronger than if I had done so, besides the saving of labour opening and shutting the frames during the winter and early spring.

MERVEILLE DE LYON.

Are Rose growers going mad, or why is it that this best of Roses goes a begging? To my thinking there can be nothing finer at a Rose show than a large box of these blooms, all alone, none of another colour put in to kill the purity and beauty of the best white Rose we have. On a vacant piece of ground here it is my fixed intention to have a perfect sea of this variety. The plot holds 5000. When completed and in full bloom I think it will be worth seeing.

HER MAJESTY.

Many are the questions asked as to the pruning of this Rose. I have a hundred of them planted out in poor soil, unmanured, and these I am only cutting down to about a foot long. This, I think, is the best plan to follow until we have more experience of the growth of it as a cutback. It is possible that being so near a relation to Baroness Rothschild, it may, like that Rose, answer under close pruning. On second thoughts, I will, as an experiment, cut one row of the plants hard, and communicate the result in due time.—D. GILMOUR, JUN.

MANETTI STANDARDS.

RELATIVE to Mr. Gilmour's note on page 265, a gentleman purchased three dozen Roses from a continental nursery a few years ago, probably because they were somewhat cheaper than home-grown plants. They were almost exactly similar to the example figured to be avoided on the page quoted, some having longer and some shorter stems. They grew fairly well, or some of them did, the first year, but subsequently one after another dwindled and died, in spite of special efforts to prevent it. In the same bed other Roses worked low, with some raised from cuttings, grew luxuriantly year after year. Roses worked on Briars with clear stems grow admirably in the same garden, but the stilted Manettis refused to thrive.—THE GARDENER.

LEEDS PAXTON SOCIETY.

THE second annual dinner in connection with the above Society was held on Wednesday, the 28th prox., at the Grand Restaurant, Boar Lane. Over 100 members and friends sat down to an excellent repast. Mr. Joseph Smith, President of the Society, was in the chair, and the vice-chair was occupied by Mr. J. W. Frankland (Vice-President). The tables were tastefully decorated with flowers furnished by various members of the Society, and these were greatly admired. After the usual loyal and local toasts had been duly honoured, the Hon. Secretary, Mr. William Appleby, was called upon to read the report, which showed that the Society consisted of five honorary and 117 ordinary members. During the year twenty-three essays on different gardening subjects had been read at the Society's meetings, and these had given rise to much useful discussion, and the Executive had hopes of securing the attendance of those who had hitherto held aloof, inasmuch as the advantages accruing from membership establish a strong claim upon every lover of horticulture in the district. The Committee had already formed the nucleus of what it was hoped will soon become an extensive and useful library, and steps will shortly be taken to as far as possible enlist the sympathies and co-operation of employers of gardeners in order to make the Society still further a source of mutual advantage. The average attendance of members had been thirty-seven, which was deemed fairly satisfactory. A donation of £5 had been sent to the Gardeners' Orphan Fund. The statement of accounts showed a balance of £12 17s. 7½d. to the credit of the Society. The report was formally adopted.

In responding to the toast of the "Leeds Paxton Society," which was proposed by Mr. H. Chapman (Wakefield), the President remarked that he believed the Society could now claim to be thoroughly established, and he had good grounds for believing that the ensuing year would show a large increase in the number of members. He promised on behalf of the Executive that every available means should be taken of making the objects of the Society a source of profit and usefulness to its members. "Kindred Societies" was proposed by Mr. Newman, who spoke of the great advantages to be derived by a commingling of members of different societies, and gave a cordial welcome to the delegates present. Messrs. Hale (Wakefield) and Edcolmb (Rotham) responded. "The Yorkshire Association of Horticultural Societies" was proposed by Mr. Wood, who remarked that as the Association's meetings were held at Leeds this year, they (the Paxton Society of Leeds) were desirous of signalling the present year by making the Association more practically useful than had hitherto been done, and he hoped that those societies not at present in the Association would shortly become so. Mr. Proctor (Morley Paxton Society) replied. Mr. M. Ramsden proposed "The Officers of the Society." He said the Society owed much of its prosperity to the well-directed efforts of its managers. Messrs. Frankland and Appleby responded.

"The Essayists" were proposed in eulogistic terms by Mr. Hancock, who spoke of the great pleasure he had derived from the reading of essays, and he considered this the most important part of the Society's work. Mr. Barnes returned thanks. Amongst those taking part in the evening's proceedings were also included Messrs. Kay and Featherstone (Leeds), Collier (Bradford), and Holland (Sheffield). A party of glee singers contributed largely to the enjoyment of those present, and the Society is to be congratulated upon the very satisfactory arrangements made by the indefatigable Secretary.

EARLY SWEET PEAS.

ALL growers are partial to plants that will grow well without much attention, remain quite free from insects, and give an abundance of showy or fragrant flowers, and as possessing the above characters the Sweet Pea is of especial value. As a rule it is only grown out of doors. The seed is sown in the open in April or May, the flowers are produced in June or July amongst hosts of others, when they are not half so much valued as they would be in May or earlier. Attractive sweet-smelling flowers are not numerous in that month, and if Sweet Peas were grown to blossom from May onwards they would be most valuable. As a rule we have them in bloom in April and always in May. Our plants are now 1 foot high, but seed sown now would have flowers before May was over and long before those out of doors expanded. We place from twelve to eighteen seeds in some good soil in 3-inch pots. They are placed in a heated pit, and the plants grow as soon and freely as the culinary Peas. When about 3 inches high they are given more air, and as soon as the pots are filled with roots they are transferred into 8-inch pots, and it is in these they are flowered. They succeed best in rich soil, well drained, and as soon as they are growing freely they are placed in a position

where they are well exposed to the light and air. This may be in a pit or greenhouse, or if the weather is genial in April in a cool frame. When the growths become so long as to be inclined to fall over they should be supported by a few tall twigs, and supplied with plenty of water at the roots. Insects will never trouble them, and as soon as they gain a height of 18 inches they will begin to show flower, and then the best position is the greenhouse or conservatory, as the soft green of the foliage, the bright hues of the flowers, and their delicious fragrance gain them general favour. If the flowers are allowed to form seed the supply will soon cease, but if they are cut before they wither a long succession will be produced.—A KITCHEN GARDENER.

THE EUCHARIS BULB MITE.

FOR the past three years we have had a few bulbs of Eucharis decay through the autumn and winter months, and in each instance I have found this little insect on the decayed bulbs and in the soil adhering thereto. It appears to me the mite attacks the bulbs when the soil in which they are growing in remains wet for several days together. I think an average temperature of 50° during the dull months of the year is anything but a good one for the Eucharis. This is the temperature our plants are in during the period named above. To prevent the soil becoming too wet we have to water the plants very carefully, and by adhering strictly to this, I think we prevent the insects attacking more

Fig. 3.

A.—Eucharis bulb, natural size, showing mites.
 B.—Mite enlarged fifty diameters; the male and female are the same size, they differ a little underneath. Body colourless, legs very pale rose, with two brown spots on body.
 C.—Hypopial form, enlarged fifty diameters.
 D.—Suckers from underneath ditto, enlarged 150 diameters.

of our plants than they do at present. By what I have noticed for some time, I am of opinion that drought is detrimental to the mite. I do not wish anyone to think that we keep our Eucharises on the verge of flagging to prevent the bulbs being attacked by the mite. Our aim is to keep the soil in which these plants are growing neither wet nor dry. Nothing will prevent the roots of the Eucharis decaying if the soil is allowed to become dust dry, and is then saturated directly after. With these notes I am forwarding a few decayed bulbs, with the insects on them, for the Editor's inspection.—E.

RHIZOGLYPHUS ROBINI.

APROPOS of the Eucharis mite and its brethren of that group, I have to remark, first that they furnish one of the most perplexing problems in insect life, and their study is quite a specialty, to which some naturalists, chiefly continental, have given a large amount of time with only small positive result. The creatures are found to occur in two forms, so peculiarly distinct that it is thought by some the one is a parasite by which the other is attacked and devoured; while others argue that the insect is all one species throughout, but undergoes a curious transformation. On the whole, our latest evidence favours the

latter view, but there is this complexity, that though for some time it was supposed the hypopoid harder-skinned form was the final outcome of the Rhizoglyphus, instances have been discovered where it was just the reverse, the Hypopus becoming a Rhizoglyphus. The most feasible conjecture is that under certain atmospheric conditions the changes are modified by Nature, and the supposed hardier Hypopus type appears when the Rhizoglyphus would be liable to extinction. All this is exceeding curious, but probably not interesting to the majority of gardeners. We are still in the dark on the important point, how these insects, seemingly very sluggish, manage to transfer themselves or their progeny from bulb to bulb.

M. Claparède says that the female of R. Robini has, when adult, a peculiarly thick and clumsy third pair of legs. The habits of the two are similar, but this species has been detected also upon the roots of the Potato and Dahlia; R. echinopus may frequent these too, though as yet the fact has not been recorded. R. echinopus (also called Hypopus Dujardini) was, it is thought, first observed by Boisduval, who called it Aearus Hyacinthi, on the supposition that it had a special liking for Hyacinths. The continental authors remark that persons who had to handle infested bulbs complained of irritation of the skin caused by the mites migrating to the human body; this does not appear to have been noticed by our gardeners. It is probable that the autumn is the season when they propagate.—J. R. S. CLIFFORD.

ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 21st ult., at the Institution of Civil Engineers, 25, Great George Street, Westminster, Dr. W. Mareet, F.R.S., President, in the chair.

Dr. G. E. Scholefield and Col. W. S. Young were elected Fellows of the Society.

The President, Dr. Mareet, delivered an address on "Atmospheric Electricity." He first alluded to Franklin's experiments in America in 1752, who succeeded in obtaining the electricity of a storm-cloud by conducting it along the string of a kite sent into the cloud. De Romas in Europe repeated the experiment, and having placed a wire within the twine his kite was attached to, obtained sparks of 9 or 10 feet in length. The characters of the two kinds of electricities were next described—the vitreous or positive, which was produced by rubbing glass; and the resinous or negative, obtained by rubbing sealing wax or another resinous substance; and it was shown by bringing suspended balls of pith within the influence of these electricities, that electricities of different kinds attract each other, and those of the same kind repel each other. De Saussure's and Volta's electroscopes were next described, pith balls being used in the former, and blades of straw in the latter, for testing the pressure of electricity. With the object of measuring the force of electricity, Sir W. Thomson's electrometer was mentioned, in which the electricity is collected from the air by means of an insulated cistern, letting out water drop by drop, each drop becoming covered with electricity from the atmosphere, which runs into the cistern, where it is stored up, and made to act upon that portion of the instrument which records its degree or amount. The atmosphere is always more or less electrical, or, in other words, possessed of electrical tension, and this is nearly always positive, while the earth exhibits electrical characters of a negative kind.

The effects of atmospheric electricity were classed by Dr. Mareet under three heads—1, Lightning in thunderstorms; 2, The formation of hail; 3, The formation of the aurora borealis and australis. He explained how clouds acquired their electrical activity by remarking that clouds forming in a blue sky, by a local condensation of moisture, became charged with positive electricity from the atmosphere; while heavy dark clouds rising from below nearer to the earth were filled with terrestrial negative electricity, and the two systems of clouds attracting each other would discharge their electricity, giving rise to flashes of lightning. In some cases a storm-cloud charged with positive electricity would approach the earth, attracting the terrestrial negative electricity, and when within a certain distance shoot out a lightning which would apparently strike the earth; but it would just as well have struck the cloud, only there was nothing in the cloud to sustain any damage, while on the earth there were many objects a lightning would destroy, to say nothing of its effects upon animal life. Thunder is the noise produced by the air rushing in to fill up the vacuum made by the heat of the lightning flash. There may be sheet lightnings, zig-zag or forked lightnings, and globular lightnings. The latter are particularly interesting from their assuming a spherical form. Illustrations were given of objects struck by lightning, the most remarkable being, perhaps, the clothes of a working man, which were torn into shreds, while the man himself was not seriously injured.

Dr. Mareet next proceeded to show a flash of lightning, which he produced by throwing on a white screen the image of an electric spark 2 or 3 inches in length, enlarged by means of the lens of an optical lantern; forked lightning, 6 or 8 feet in length, with its irregular zig-zag course, was most clearly demonstrated. After alluding to the protecting

power of lightning conductors and their construction, Dr. Marceet explained the formation of hail and of waterspouts, and exhibited an instrument by Prof. Colladon of Geneva for showing the formation of waterspouts. He concluded his address with a few remarks on the aurora borealis and australis, the formation of which was illustrated by De la Rive's experiment, which consisted of successive discharges of electric sparks through a partial vacuum while under the influence of a powerful magnet; electric sheets of light were seen assuming the form of hands and possessed of a certain rotating motion.

Mr. G. J. Symons, F.R.S., read a short communication on "The Non-existence of Thunderbolts," briefly described the history of several so-called thunderbolts, the specimens obtained being of an amusing character, thus clearly showing that they were of a terrestrial and not a celestial nature.

In connection with this meeting a most interesting exhibition of instruments was arranged in the rooms of the Institution of Civil Engineers. The Exhibition was devoted chiefly to instruments connected with atmospheric electricity. There are various forms of electrometers, including those formerly in use at the Greenwich and Kew Observatories. Numerous patterns of lightning conductors were exhibited, together with models of churches, houses, chimney-shafts, and ships, showing the various methods of protection. The Postal Department showed a number of lightning protectors used for telegraph purposes. Many objects damaged by lightning were exhibited, including lightning conductors, telegraph apparatus, portions of rafters, trees, &c., also the clothes of a man torn off his body by lightning. An interesting collection of meteorites and some alleged thunderbolts were shown, the latter being of an amusing character. There were also several new meteorological instruments exhibited, which had been brought out during the past twelve months.

One of the special features of the Exhibition was a most valuable and interesting collection of over fifty photographs of lightning flashes. Many of these were taken during the great thunderstorm which occurred in London on August 17th last year, while others were taken in various parts of the world. The Exhibition also included a large number of photographs of damage by lightning, and photographs of clouds and meteorological instruments, as well as records of atmospheric electricity.

CHRYSANTHEMUM BELLE PAULE.

I WAS much struck upon entering a conservatory on March 27th to find plants of this variety bearing flowers. They were, of course, pale in colour as well as being small, but still they were useful, and I was told some that had been cut a short time previously were much better. The plants had been both late struck and pinched late as well, thereby making late growth. This is only another instance showing what an adaptable plant is the Chrysanthemum.—S.

NATIONAL SOCIETY'S EXHIBITIONS.

I STRONGLY advise the National Society to issue their schedule of prizes with the least possible delay, so that intending exhibitors will know what to prepare. I noted some time since in the Journal a list of the sections which was intended to be included in the Society's official catalogue. It is proposed to define and make a class for Japanese reflexed varieties. This being so, it is but natural to suppose the intention is to encourage that section by offering prizes for them at the metropolitan and provincial shows. I trust the leaders of the Society will take this gentle reminder that there are many persons who are anxious to know the programme for the coming season, so that proper arrangements may be made conducive to the welfare of the Society as well as simplifying the work of exhibitors generally.—A POSSIBLE EXHIBITOR.

FERTILISATION OF EARLY PEACHES.

I MUST agree with your correspondent, Mr. James B. Riding, that it is not a safe plan to trust altogether to the tapping system in the case of early forced Peaches. We do not commence forcing here until February, and then we use a camel-hair brush. We have a splendid set of both Peaches and Nectarines in our first house by the above means, and later ones promise well.

I should like to hear from any of your correspondents who practise the syringing system mentioned by "S. T. C." I am not venturesome enough to try it myself. With reference to tapping the trees I fail to see how it can answer, except in the case of trees on the back wall and trees grown on wires near to the glass. To practise tapping trees grown as ours are—viz., on the half-moon trellis, would result in the pollen dropping on the ground. Taking everything into consideration, I think the camel-hair brush the best and safest method to be adopted.—G. HILTON.

HARDY FRUIT GARDEN.

FIGS.—In the south and south-western counties Figs frequently produce profitable crops, and many more trees might be grown with advantage. A hot sunny corner, formed by the junction of a south with a west wall, will be found the best position for the trees, but many a high sunny end wall of outhouses, and indeed various blank spaces on south walls, might well be utilised for Fig culture. A rich soil is altogether unsuitable, this causing a rank unfruitful growth, and which is far from being hardy. The site should be well drained, and, if it can be spared, replace the ordinary soil with turfy loam and old mortar rubbish, the latter, for which chalk is a good substitute, being added at the rate of one bushel to three bushels of loam. A wide border is not to be recommended, the most prolific trees being those planted in a comparatively narrow border with a hard pathway or carriage road in front of it. The roots invariably find their way into the hard roads, and this poorness and firmness of root run induces the requisite short-jointed growth. Brown Turkey and White Marseilles are the most prolific on the open walls. Brunswick is quite as hardy as these, and a fine variety, but as a rule is a shy bearer. Preference should be given to trees grown with a clear stem, and as these are generally supplied in pots, planting ought always to be deferred till all danger of severe frosts is past. The branches should be laid in fan-shaped, no shortening back being resorted to unless more branches are needed for laying the foundation of the tree. The leading branches being trained thinly laterals will start freely from these, and which, if well thinned out, those reserved being laid in right and left, will ripen properly and fruit the following season. Young trees ought not to be very freely pruned, as plenty of young branches are usually forthcoming for laying in wherever there is space to be filled, these being of a more fruitful character than those obtained by pruning.

PRUNING ESTABLISHED FIG TREES.—In most districts it is necessary to protect the trees, and more especially the points of the young wood, this being done either with Russian mats, thatched hurdles, or branches of Spruce Fir. Last March exceptionally severe frosts were experienced in some of the southern counties, and those trees uncovered and pruned early were much injured in consequence. The first week in April is quite soon enough to uncover the trees. As before stated, a too free use of the knife is unwise, and on the other hand, unless some pruning is annually done the centre of the trees soon becomes bare, the outside branches or points only being fruitful. Supposing the main branches are thinly trained and well furnished with lateral growth, one-half of these ought to be cut back to near their starting point, this inducing the formation of several young growths. One of these being laid in and the remainder early removed, a considerable number of short fruitful branches will be obtained. The following spring the remainder of the old laterals may be similarly shortened back. In this manner half the lateral growth will be pruned every season, and a constant supply of fruitful wood maintained. As a rule Fig trees are informally trained, and where this is the case all the pruning necessary consists of thinning-out the wood, those long branches that have reached the limit being sawn or cut back to near the main stem. A few being thus cut back every year, young bearing wood will be always well distributed about the tree. This training ought always to be practised, and on no account should the short-jointed young growths be shortened, as these produce the fruit.

PROTECTING PEAR TREES.—Those on walls especially, and which are remarkably well set with buds, fully repay for any trouble taken with them in the way of temporary protection. It is unwise to wait till the flowers are open before the protection is given, as a severe frost will cripple those in a bud state. Many Pears are of such value as to merit wooden coping, hoards, rods, and curtains, these being so contrived as to be easily opened or closed. The next best coverings are doubled or trebled fish nets, these being fastened to the top of the wall and kept clear of the trees with the aid of long poles let into the ground 2 feet from the wall, and fastened to staples or spike nails near the coping. If the nets are hung over the trees early they will moderate the effects of sharp frosts, and also preserve the buds from the birds. Very large pyramids are not easily protected, but those on the Quince stock or miniature trees are not so difficult to cover. About five long and strong poles are needed for each tree, these being let into the ground at equal distances apart, and made to meet over the centre of the tree. They ought to be quite clear of the principal portion of the branches, and securely fastened at the top. The protecting material may be either doubled or trebled fish netting, cotton netting, frigi domo, or garden mats. The three first-named may frequently be left over the trees for several days, or during the prevalence of cold frosty winds, but the mats are too heavy, and if left on in the daytime will weaken the bloom. Cordons trained near garden walks are easily protected. All that is necessary in this case is to fix a single line of rods or stakes directly over and about 12 inches clear of the trees, the protecting material being thrown over this and fastened to pegs in the ground on each side.

CROOKED ORCHARD TREES.—A ride through many rural districts will bring into view numerous young fruit trees, and which, whether in orchards or singly, are in a very unsatisfactory state. Not one in twenty are properly staked, and the consequence is a number of trees with very crooked stems, and which will not greatly improve as they gain in strength. All young trees ought to be kept carefully staked and well protected from cattle. This leads to the formation of clean straight stems, these in their turn being conducive to the growth of large healthy fruitful heads. Either one stout stake or three moderately strong ones ought to be placed to each tree directly they are planted, this in addition to keeping the stems straight also preventing wind waving them and consequent injury to the roots. If strong rope yarn or tar twine is used for tying purposes the trees must be first bandaged, or the bark will soon be badly cut.

FRUIT FORCING.

MELONS.—Plants swelling their fruits in the early house will require to have supports placed for them. Half-inch deal boards, 6 or 7 inches square, with a hole through each corner, and suspended by four pieces of string or copper wire from the trellis in a slanting direction to prevent water lodging, may be employed for the purpose. Pieces of slate with holes drilled in the corners are preferable to wooden supports, and glass would be still better. Remove all flowers from such plants; also superfluous growths, stopping and tying as necessary. See that the plants do not suffer through insufficient supplies of water, affording weak liquid manure occasionally. The evaporation troughs should be filled with liquid manure, and a good atmospheric moisture secured by damping early in the morning and afternoon, syringing the plants lightly about 3 P.M. on bright afternoons. Later plants will be showing fruit, and, unless abundant, remove the first blossoms, it being important that the female blossoms be nearly of one stage of growth. Maintain a somewhat higher temperature and dryer atmosphere during the setting, only affording as much moisture as will prevent flagging. Stop the shoots at one joint beyond the fruit, but employ the knife as little as possible during the setting period. In pits and frames a good bottom heat must still be maintained, observing the conditions previously given during setting. When the fruits are set they should be placed on a piece of slate. Look out for canker at the collar, placing a little quicklime around the stem as a preventive.

CUCUMBERS.—Those that have been bearing through the winter will need to be renovated at the roots, removing with a hand fork as much of the exhausted soil as is possible without much injury to the roots, and fill with rich lumpy compost pressed down firmly. Stopping, training, and cutting out the old growths must be followed up, and abundant waterings given as necessary. Assist plants in full bearing with copious supplies of weak liquid manure, and earth the roots occasionally. Damp the floors and other available surfaces before 8 A.M. and about 3 P.M., the foliage being syringed lightly on fine afternoons, and keep the evaporation troughs filled with weak guano water or other form of liquid manure. There ought not to be any further delay in having the blinds in readiness, so that they may be employed for an hour or two at midday, when the sun is brightest. Shading is most needed after a period of dull weather, to prevent flagging. Worms may be expelled by lime water.

VINES.—*Early Forced Vines.*—Although Vines in pots afford creditable crops of early Grapes, better results are often had by planting the Vines out in beds or borders such as are employed for Cucumbers. A span or lean-to house answers perfectly, having borders 3 to 4 feet wide and about 2 feet deep, so as to admit of 6 to 9 inches of drainage, and 15 to 18 inches depth of soil. The Vines being raised from eyes or cut-backs will need to be forwarded in another structure until the Grapes are cut. These being ripe in March or early April will be off by the close of April or early May. The Vines that have fruited are cleared out, fresh soil is placed in the borders or beds, and the Vines that are to fruit the following year are planted at 27 to 30 inches apart. If they have made considerable progress, but are not root-bound, they may be turned out with the ball entire, firming the soil well about them, and watering well. If in small pots they should be disentangled and the roots spread out. Turfy loam with an admixture of about a tenth of old mortar rubbish forms a suitable compost, adding about a quart of some approved fertiliser to every bushel of soil. Manure can readily be given as a mulch or in liquid form. The canes being trained near the glass will make short-jointed wood. Almost any amount of vigour can be had by encouraging the laterals, but not allowing them to interfere with the principal leaves; indeed under good treatment they will make canes like walking sticks, with eyes like nuts, and being as much under control as Vines in pots they can be matured so as to be ready for starting by late October or early November. By this plan the root action is considerably extended as compared with Vines in pots. The Vines are taken up after fruiting, as is the case with early fruited pot Vines, treating them as annuals. Cut-backs are very much the best for treating in this way.

Grapes Ripening.—The fruit swells considerably after commencing to colour. In order to ensure a full swelling of the berries inside borders should have a thorough watering and mulching early on a fine day, ventilating freely to allow excessive moisture to escape. A full crop of early Grapes is a great strain on the energies of the Vines, and through it in early forcing perfection in colour is not always obtainable, much may be done by a liberal and constant supply of warm dry air combined with a moderately low night temperature, but the temperature must be well maintained by day—70° to 75° from fire heat, and 80° to 85° with sun heat. When hard forcing is practised red spider usually

makes its appearance, and should be destroyed by painting the pipes with a mixture of sulphur and skim milk. Care, however, must be taken not to use too much, or it will act injuriously upon the skin of the berries and spoil their appearance.

Succession Houses.—Attend to thinning the bunches and berries. Stop and remove laterals, especially where there is not room for extension, as to allow them to extend considerably, or so as to necessitate large reduction of foliage at one time, results in a check, very often inducing shanking at a later period. See that the borders have plenty of water, and weakly Vines will be benefited by tepid liquid manure. Vines swelling their fruit should have a moist atmosphere, damping available surfaces two or three times a day, and if liquid manure be used at the latest damping it will improve the Vines and act as a check to red spider. An ounce of the ammonia manures to a gallon of water is suitable. Syringing the Vines must not be practised after the Grapes are set.

Late Vines.—Disbud and tie out these as they require it. Close the houses early in the afternoon with sun beat, and maintain plenty of atmospheric moisture by frequently damping available surfaces. They are now making rapid progress.

Young Vines.—Those planted last spring will now be breaking naturally, and when the buds have grown about half an inch a little fire heat will prove beneficial, especially on cold days. Remove all buds except one at each break, retaining the strongest, and crop lightly, but supernumeraries may be weighted with as much fruit as there is prospect of their bringing to maturity.

PINES.—Plants started into fruit early in the year are fast approaching the flowering period, and will be benefited by an occasional sprinkling overhead at the time the house is closed, but when in flower they must not be so treated. The foliage being as yet tender, it will be desirable in the case of houses with large panes of glass to afford a slight shading for an hour or two in the hottest part of the day for a few weeks until the foliage becomes inured to the sun's influence. When the flowering is over the fruit will advance rapidly if the roots are in good condition, and plentiful supplies of weak liquid manure will be requisite. Attend to ventilating early in the morning, commencing when the temperature is at 80°, and closing at 85° with sun heat. Keep the atmosphere moist when the house is closed, the bottom heat steady at 80° to 90°, the night temperature 70°, and 75° by day artificially. As soon as the suckers appear remove all except one to each plant.

SPRING WORK.

THE busy time of the bee-keeper's year is now fast approaching. The fast lengthening days betoken the near approach of flower-lad fields and honey-yielding blossoms. It is now that full and complete preparation for the long-expected honey flow must be made—if a great part of the work has not already been done during the past dreary months when the frost-locked earth has forbidden outdoor labour in the field or garden. Sections should at once be purchased, and after being carefully fitted with the best super foundation, these may be arranged in crates, and stored away ready for instant use when the stocks grow strong and honey is freely coming in. Boxes of frames must also have our care if we desire to obtain our surplus in a liquid form instead of in the pure white comb. The combs in use last year have, of course, been carefully preserved, and will be simply invaluable some six weeks hence, because while equally as useful as new built combs, they are more able to withstand the strain put upon the cells when the honey is dragged out by the extractor now in general use.

If there are no frames of ready built combs available, then full sheets of foundation may with advantage be used, and if "wired foundation" is used the combs will have more strength, and will be therefore less liable to break out from the frames when being extracted from at the close of the season. If it is preferred, "wired frames" may be used instead of the "wired foundation" with much the same result. It is not absolutely necessary to use the wire at all, for good foundations may be used alone, and the combs need not be destroyed by the extractor provided that the bee-keeper carefully regulates the pace, and does what he can to minimise the risk of breakage. In the hands of a novice the extractor does, however, woeful mischief in many cases where the combs are new and therefore easily broken.

It occurs to me that many have asked as to the pace at which

an "extractor" should be worked. There is no fixed rule, but the frames should never be made to revolve faster than is absolutely necessary for throwing out the honey. The pace should be kept slow at first, and gradually increased until the honey is heard to freely "spit" against the sides of the barrel, when no further advance in speed should be made until the cells on both sides of the comb are comparatively empty. The fuller the comb the greater the strain. This is an important point to remember. It is also unwise to entirely empty one side of a comb before turning it and taking some honey from the cells on the opposite side. The frames must also be placed close to the outside of the cages and against the wire. There is a tendency to draw the centre of the comb towards the outside, and therefore unless the comb presses close to the wire frame this gradual drawing out will break up the centre of the comb. These points are far more important when using new combs, because an old comb will stand far greater wear and tear without any real damage.

The simplest honey extractor is the best. If an increase in the number of stocks is desired preparations must at once be made for receiving the swarms when they come, otherwise there will be a considerable waste in fitting up hives some fine day, when half a dozen stocks send forth their clouds of emigrants when they are least expected to issue.

Many bee-keepers are no doubt beginning to feel anxious as to the state of their stocks. At the time of writing no thorough examination has yet been possible, but if we may hazard a guess founded on observations made on fine warm days some weeks ago we should say that on the whole the winter has been preservative of bee life. The weather has been not of the severest type perhaps, but sufficiently hard to prevent frequent flights, and yet occasionally days have occurred most opportunely when every stock was able to take a cleansing flight with safety. Experiments have been made in wintering stocks on the cold and warm systems, but it is at present, on account of the severe weather, impossible to give the results in either case. At the earliest possible opportunity every stock must be examined, and if necessary feeding must be at once commenced. In fact, even now, if a stock is known to be short of store, warm syrup must be administered or a piece of candy laid upon the tops of the frames; but unless there is a great doubt of the sufficiency of the food supply no stock should be disturbed at all until warm weather invites us to make a thorough examination. This done, the necessary steps should at once be taken to remedy any actual or possible mischief; and then, after wrapping every stock up as warmly as possible, no future disturbance should be necessary for a considerable period, unless it is intended to stimulate the stocks by feeding gently but continuously until the natural supply takes the place of the artificial. Other things being equal, the stock least often opened will be the most prosperous.

We may perhaps be allowed to wish the bee-keepers of the world a good harvest, and we may, at any rate, comfort those who are somewhat despondent as to the weather we are likely to experience during the coming season by reiterating what has been said in the past, and is no less true in the present, that unless the season is exceptionally bad honey will be obtained by the man who manages his bees upon practical principles and knows when to do a thing, and also has the knowledge when to leave well alone.—
FELIX.

QUEEN INTRODUCTION—THE HALLAMSHIRE LAW.

"A LANARKSHIRE BEE-KEEPER," page 227, thinks I am not entitled to all the honour in connection with the above, and considers the late Mr. T. W. Woodbury was the author, and quotes him as follows:—"The only safe method is to deprive the bees of the power of raising a successor to the one deposed."

Now, with all due deference to our friend, and respect to the memory of Mr. Woodbury, I must beg to point out that the above is not the "Hallamshire law," it is only part of it; there is also one other condition—viz., the bees must have had time to realise the fact that, in addition to being queenless, they are hopelessly without means of rearing a successor; and they do not arrive at this stage, when in possession of

combs, under thirty hours. But to be on the safe side I have fixed the minimum in the law at forty-eight hours.

I have never claimed to be the first to successfully enthrone queens in accordance with the "law;" the honour of this belongs to M. de Reaumur. He was also the first recorded person who introduced an alien queen to strange bees. Like many other observers, he deduced wrong conclusions from his experiments. Huber relates these cases, and criticises them under date 30th August, 1791, in such a way, one would think he knew all about the "law."

The late Mr. Woodbury was probably the next person who really took the subject up in earnest, and no doubt many times succeeded when the bees had been deprived of the means of rearing a successor long enough. But there is no evidence that he ever grasped the importance of this condition; if he had, he would not have failed to impress it on everyone. As it was, he and his pupils thought that all that was, or should be, necessary, was to deprive the bees of the power of raising a successor to the one deposed, when they would accept another as soon as they had discovered their loss. Thus the matter was left; then came the cages to gradually let the bees become acquainted with their new mother. Then it was noted by some that when the bees were old and had been long queenless, the cages were very unsafe, some going so far as to assert that such bees could not be re-queened.

I think I have now made it clear that the "law" has unconsciously been used to introduce alien queens for upwards of 100 years. What I claim as my discovery is the "law," just as Newton discovered the law of gravitation. When a bee-keeper has it firmly engrained on his mind he will find many ways to apply it. Moreover, it is the only means by which a queen will be accepted by the bees as the mother of the hive at the moment of her introduction.—A HALLAMSHIRE BEE-KEEPER.

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (*J. G. H., New Jersey*).—We have no copy of "Blaine's Canine Pathology" in our library, and have failed on inquiry to ascertain where the work can be obtained. We mention the title in case any of our readers can give you the desired information, with the price of the volume.

Chrysanthemum Sport (*N. J. S.*).—It is simply a reversion to Queen of England, the variety from which Empress of India originally sported.

Kew Gardens (*G. W. H.*).—Write to the Curator, Royal Gardens, Kew, stating what you desire, when the necessary forms will be sent to be filled and returned.

Liquid Manure (*A. M.*).—We do not use boiling water in preparing liquid manure, as it would facilitate the escape of ammonia, which it is desirable to retain.

Insecticide (*J. P.*).—We should exceed our duty by complying with your request. It is for vendors themselves to advertise their wares if they think good to do so. Nor are we justified in publishing the full addresses of correspondents who do not supply them for that purpose.

Vines from Cuttings (*F. J.*).—You stated quite clearly that all the eyes were cut out, but it appears you made a mistake. Select those plants that are making the strongest and best growths, taking up one only from each to produce a stout cane that will ripen early in the autumn, regardless of the method adopted in preparing the cuttings.

Consumption of Fuel (*J. H. S.*).—Your letter shall be answered in an early issue, and in order that our reply may be well founded we are having a comparison made of the quantity of fuel consumed in a garden in which the extent of piping is considerable, and the question of fuel a serious item from its being much more costly than in your district.

Double White Mignonette (*T. S.*).—The flowers you send are unusually fine, being white, large, double and sweet. It is a pity that

care is not taken to preserve the undoubtedly good character of the variety, which, as you present it, far exceeds any other so-called White Mignonette that has come under our notice. You have evidently exercised judgment in saving the seed, and skill in cultivating the plants.

Strawberries (F. W.).—We should choose the plants with the best crowns and the most fibrous roots, and if about three good crowns were attached to one rootstock we should not separate them; indeed, those taken up singly we should probably plant triangularly a few inches asunder, and the triplets at the ordinary distances assigned to single plants. By thinning the crowns and replanting old Strawberries in enriched soil excellent crops of fruit were obtained by the late Dr. Newington.

Peas in Trenches (F. J.).—Though a foot is a convenient and suitable width for a trench, it does not follow that it is necessary to sow the Peas all over a surface of that width, though there is no objection to the plan. You can, if you wish, make a level base 6 inches wide in the trench, and scatter the Peas all over it about an inch apart, these being new, heavy, and good. A narrow strip means a channel drawn with the corner of a hoe, and V-shaped, which is the reverse of good for sowing Peas in, though it answers very well for Onion seed.

Heating (J. R. G.).—We have not had experience with the boiler you name. If you can refer us to an advertisement of it in our columns we will endeavour to obtain information on the subject. The consumption of coal does not so much depend on the extent of piping to be heated as on the dimensions of the house and the temperature that has to be maintained. The setting of saddle boilers with the arrangement of the pipes are also important factors in the case. The weekly consumption of fuel you name appears excessive for maintaining a temperature suitable for greenhouse plants.

Tar on Hot-water Pipes (A Journal Reader).—We have no doubt that a serious mistake was made in coating the hot-water pipes with "coal tar varnish," though you do not appear to be responsible for it. The effluvia from coal tar is highly injurious to plants, and we have known serious consequences result from the use of tar even when it has not been applied to the hot-water pipes but only to the stages on which plants had been afterwards arranged. We are unable to point out any safe and easy method of removing the varnish, and suspect it will have to be scraped off, and the pipes washed with turpentine; but if any of our readers can state how the pipes can be best cleansed we will readily publish the information. A mixture of lampblack and linseed oil has been many times mentioned in this Journal as suitable for coating hot-water pipes in plant houses.

Peas Failing (A Young Gardener).—When peas are old some of them decay without germinating, others may germinate and attempt to grow, but perish in the attempt. We can distinguish old from new peas, but it is not easy to make the distinction clear on paper. Old wrinkled peas are much shrunk and have a dull dead appearance, lacking the freshness of life; smooth white peas assume a yellowish hue when old. Peas sometimes fail to grow freely when the soil is very cold and wet, the roots decaying, and we have known coal ashes injurious, these varying. Why not test the seed by sowing some in a pot in a greenhouse? A hotbed is scarcely a fair test, as we have known seeds to germinate freely and growth follow in a brisk moist heat that failed in the open ground. If you raise plants in pots now under glass, starting them in heat, then removing them to a lower temperature, and when ready and in good condition planting out, you may not be very late in gathering. They should be planted when the ground is in favourable condition, placing a compost consisting largely of leaf soil in contact with the roots to encourage their quick and free extension, at the same time protecting the tops from cutting winds with a few evergreen sprays or such other shelter as can be devised for the purpose.

Peach Trees Failing (W. J. W.).—Judging from your letter and the sample of leaves sent we fear your Peach and Nectarine trees are in a hopeless condition. When the leaves assume a silvery appearance the trees are liable to go off any time. They are decaying internally, and if you cut off the branches bearing the silvery leaves you will find that only a thin portion of the outer wood is alive. When in this condition it is only a question of time before the trees die. We should say your trees are poisoned, either from the soil being impregnated with salt or from the sulphurous acid from the adjoining works. If trees grow outside without showing signs of injury and decay, then you must turn to some other cause for the trees dying in the house. If they suffer only from the soil being impregnated with salt, then the difficulty can be overcome by a slight outlay in border preparation; but if death is caused by sulphurous acid there is but little hope of success, even if you renew the border and plant afresh. If salt is the cause, we advise you to remove the whole of the soil to a depth of 2 feet 3 inches, and thoroughly concrete the base, allowing the bottom to slope from the back to the drain in front. Six inches of good drainage will be ample, and this will leave 18 inches for soil. The soil should be secured from a distance, where you are certain it is free from salt. As you have a base of marl the bottom of the border should have been concreted in any case. We have seen trees fail repeatedly through their roots getting into the marl. They are then too far from the surface, too cold, and often too wet for the well-being of the trees. It is difficult for us to say what is actually the cause of failure in your case, but we think the most probable cause is the salt, or that and the sulphur combined. If you can send further particulars that may further enable us to help you, we shall be very glad to do so.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (W. S.).—It is *Deutzia crenata* flore pleno. (T. P.).—A variety of *Cœlogyne cristata*, but not so good as such forms as maxima or the Chatsworth variety. The shrivelling of the pseudo-bulbs is caused by the flowering.

COVENT GARDEN MARKET.—APRIL 4TH.

A very dull week. Prices of hothouse goods lower.

RESULTS.

RESIDUE FROM MANURES—ESSEX EXPERIMENTS.

WE were recently offered a manure bearing the somewhat singular title of Vitriolised Bones, with an assurance that it was a

perfect manure adapted for the particular requirements of a crop at the different stages of growth in this way. It consisted of fine bone dust, coarse particles of bone, and still large pieces of bone; the dust being absorbed by the plant when quite young, the coarse particles being next turned to account, and so on. The impression which the statement of the vendor was intended to convey to us evidently being that a crop would exhaust all the manurial constituents of such manure, and there would be no residue left for the benefit of the next crop. Now, this was so entirely in accord with the popular notion that artificial manure has nothing of a permanent or rather durable property belonging to it, that it would really seem to have had its origin with the dealers in manures. Whether bones treated with vitriol are sold as vitriolised bones or superphosphate they ought not to be used alone, but should be mixed in due proportion with other manures, as we have repeatedly explained.

The tendency of all recent experiments is to show that there is a residue in the soil from all manures after the crop to which they were applied was matured, and one of the lessons taught by such experiments is that land manured and cropped this year will require some manure, but a smaller quantity of it, next year. Another lesson of equal importance is that chemical manures are more economical and more efficient than farmyard manure, provided they are procured pure, carefully blended, and rightly applied. It is high time that the careless reckless use of mysterious compounds was ended, and that every farmer had sufficient scientific knowledge to enable him to treat the soil and his crops in the right way.

In the Essex field experiments of last year special attention was given to the residue question, and we find it stated in the report that "It was the general opinion of the Experiments Committee that it would be interesting to ascertain how far manures applied for the Mangold crop of 1886 might affect the succeeding corn crop. Accordingly the boundaries of the plots were carefully preserved, and a crop of Oats was sown in the spring of 1887 without the application of any manure whatever, either dung or artificials." The result showed clearly that there was sufficient residue to afford a fair corn crop on every plot, but some plots gave more than others. The largest crop, which gave 70 bushels of Oats and 1 ton 12½ cwt. of straw per acre, was from a plot which in the previous year gave 26 tons of Mangolds, and the manure for which was 12 tons of dung, 3 cwt. of superphosphate, and 2 cwt. nitrate of soda applied at seed time. The increase in the yield of Oats as compared with the plot that received dung alone was nearly 4¾ bushels of grain and 3 cwt. of straw per acre. Close to this came, with nearly 69 bushels of grain and 1 ton 12 cwt. of straw, another plot manured with a similar quantity of dung and superphosphate, and 1½ cwt. of sulphate of ammonia applied as a top-dressing in July. No special advantage could be claimed for this July application of ammonia, for a similar result was obtained upon another plot where the ammonia was applied early. The report adds that "Generally it may be said that the heavier dressings not only paid best in the Mangolds crop, but also gave good results in the succeeding Oat crop, the heavy crops of Mangolds being followed by heavy crops of Oats."

Soil so cropped with corn after roots might be regarded as practically exhausted, and it would require a full dressing of manure this year. Experience has shown that if a moderate quantity of nitrogenous and mineral manure had been sown with the Oats, not only would there have been from ten to twenty bushels more grain, and 8 or 9 cwt. more straw per acre, but the exhaustion would have been avoided, and a full dressing of manure could hardly have been necessary this year. No doubt in a very wet winter some loss of nitrogen stored in the soil does occur, and this should be taken into account in a calculation of quantities in spring. This one fact alone shows how difficult it is to prepare formulæ for general adoption. The influence of local circumstances cannot be ignored, but must be

taken fully into account if we would avoid the wasteful use of manures. For this reason, if for no other, we would urge every farmer to try and ascertain for himself the nature and requirements of the soil of his particular farm. One general rule we may very safely lay down is, that while there is a residue left in the soil from all manures, yet a certain quantity of manure may be applied to it profitably for every crop year by year.

WORK ON THE HOME FARM.

The ploughs have been kept going upon land where sheep have been folded upon Swales, in order to have it ready for Barley as soon as possible after the sheep folds were removed. There has been ample time for doing this, as it was impossible to sow any spring corn during March, snow or rain keeping the drills off the land throughout the month. On light land and mixed soil the land has been got ready for Mangolds—in many instances quite ready, the muck having been carted, spread in the rows, and the soil turned back over it so that the sowing of seed can follow on closely after Barley sowing, when we do get that long-delayed work done. The advantage of autumn culture will now be fully realised, for where the soil was clean immediately after harvest, and the ridging for roots was then done, the work now is light and easy. No doubt all seed will germinate quickly in the moist warm soil, and growth will be so free that we shall have to be on the alert with horse and hand hoes to keep down weeds. This work of keeping the land clean is so important that there should be no hesitation about the extra expenditure involved for labour. We have kept our weekly labour bills lower throughout the past winter than we have ever done before, and can now afford to employ as many extra men as we require. By all means keep down weeds, especially Charlock, and let the crops derive full benefit from the fertility of the soil. Can anything be more wasteful and extravagant than to expend heavy amounts for manures and then to suffer weeds to rob the soil of it? It is all very well to complain of low prices for farm produce. We cannot alter that, but we can effect much improvement in our practice upon the land. One of the most incessant grumblers we know had his Barley so infested with Thistles last year that the seed was blown all over the parish, and his lazy, thriftless habits will this year prove a curse to his neighbours as well as himself. Now this man wanted to hire another farm for his son 1st Michaelmas, but his bad practice was so notorious that although there were plenty of farms vacant he was unable to hire one of them. We have had applications for land under the Allotments Act in several parishes, and are quite willing to let any labourer have land who has sufficient energy and perseverance to cultivate it; but so far our experience of allotments has certainly been unsatisfactory.

OUR LETTER BOX.

Vetches (Inquirer).—When they are well above the surface and growing freely, apply by broadcast sowing in showery weather 2 cwt. nitrate of soda per acre. If the rainfall of your district is low and very uncertain, it would be better to drill the nitrate of soda in with the Vetch seed.

Renovating Pasture (T. R.).—The present is a very good time for sowing grass seeds in your field, and the most practical advice we can give you is to state the present condition of the pasture, the nature of the soil, and the acreage to be renovated, to a seedsman or firm who pays special attention to this subject, and you may rely on receiving the right quantity of a suitable mixture for effecting your purpose.

REMARKS.

25th.—Dull and damp morning; fair afternoon with some sunshine; rain and snow in evening and night.
 26th.—Snow and rain from 5 A.M. to 10 A.M.; dull morning with spots of rain, wet afternoon and night.
 27th.—Cloudy day, with a few flakes of snow at 4.30 P.M.
 28th.—Wet till 10.30 A.M., then generally fine and bright, but with one or two slight showers.
 29th.—Bright pleasant morning; fair till 2.30 P.M., then rain, and unsettled after.
 30th.—Fair, with occasional sunshine in morning; dull and showery after 3 P.M.
 31st.—Dull and damp early; fair day.
 A dull, damp week with very low barometer, snow and rain. Temperature rather higher than in the two previous weeks, but still below the average. March has been a wet month, the total yield of snow and rain being 3.34 which is more than twice as much as the two months of January and February. — G. J. SIMONS.

FRUIT CULTURE UNDER
GLASS.

MR. T. F. RIVERS' essay on the Orchard House, the concluding portion of which appears on another page, is much too valuable to be confined to even a large and intelligent Birmingham audience, and we have had pleasure in according the important contribution to gardening literature the wide circulation that it undoubtedly merits. The subject is treated exhaustively; indeed, no one but Mr. Rivers could have prepared such an essay, because no one else has had anything approaching an equal experience in the routine of fruit culture under glass as it is conducted at Sawbridgeworth. It is there the first orchard house was built plainly and inexpensively, and the large structures with boarded sides and glazed span-roofs, erected thirty years ago, still remain sound. There can be no doubt that a handsome profit has been derived from these simple yet serviceable erections by the sale of the fruit alone that has been raised in them, apart from the sale of trees; and it will be safe to say that if no trees were sold that this method of producing fruit of the first quality for market would be, as it has been, lucrative. Though the great majority who grow fruit do not do so as a means of income, but for home requirements and enjoyment, it is not the less satisfactory to know that the method adopted is well founded, and this can only be determined on commercial principles.

That the orchard house method of growing fruit, especially Peaches and Nectarines, as conducted at Sawbridgeworth is a distinct success cannot be doubted by any person competent to form an opinion on the subject after inspecting the work in operation. But facts are more conclusive than opinions, and it is a very hard fact that house is being added to house in this great emporium of trees and fruits, not for growing the former primarily for disposal as such, but chiefly for the crops they afford, though the trees themselves that have had a sojourn under glass are essentially better and more fruitful than those grown entirely in the open; indeed, those grown in pots on the Rivers' method are alone really suitable for orchard house culture. There is nothing grown to waste in these trees, for all growth that is not wanted is promptly suppressed, consequently all that remains is stout and hard, and at this season of the year covered with fine blossoms soon to be followed by far more fruit than the trees could perfect, however generously they might be treated. But new houses are being erected for fruit production primarily, and this would not be done if the practice were not remunerative. It is true Mr. Rivers is a gentleman of property, and can afford to indulge in luxuries, and perhaps does indulge in them. His Orange culture is possibly a source of enjoyment rather than of profit to him; at least, as regards the crops, for the sale of young trees may sweeten the luxury, and of these there is no doubt the finest stock in Europe; but in regard to Peach and Nectarine production in the houses erected and in the course of erection we see Mr. Rivers, as a man of business, observant of every detail, and watchful in every item of expenditure, studying simplicity and economy to the fullest extent consistently with efficiency, as closely as if his daily bread depended on the work. This is strictly and severely a business matter, and the under-glass culture of trees in pots for the sake of the fruit produced is being extended for the best of all reasons—because it pays.

Walls could be built for shelter and for providing warm

surfaces for fruit production, and Mr. Rivers would without doubt build them if he could rely on a good return for his outlay; but he cannot. Walls have been tried and found wanting. Their cost is too great and the returns from them too uncertain to warrant his indulging in such costly luxuries; and he prefers the shelter of orchard houses, whether as boundaries in lieu of walls or as independent structures in addition to them. The question of glazed boundaries to gardens is not new. It has been regarded as a fanciful notion; but it is very much more than that, and cannot be dismissed as visionary with a waive of the hand. A gentleman about to surround his garden with walls, after counting the cost and estimating probable results, changed his plans after inspecting glazed boundaries, and ascertaining the cost of erection and comparing it with their capacity for producing fruit under good management with constancy. But the best evidence in favour of glass *versus* bricks, or in addition to a limited extent of masonry, is found in the great fruit-growing establishment of Mr. Philip Ladds at Swanley. The proprietor desiring boundary protection on two sides of his land might have built walls and covered them with fruit trees, but instead of doing so he built span-roofed houses, one nearly 700 feet long; and the other upwards of 800 feet. These will give a good return for outlay and pay for themselves in a few years, but walls would not. Glazed boundaries are therefore not fanciful luxuries, but stern realities, and their extension is probably only a question of time.

Any visitor to Sawbridgeworth a week ago would have been satisfied both with the attractiveness and usefulness of orchard houses. One, well heated, 230 feet long, was wholly occupied by Peach and Nectarine trees in pots, except two rows of young Vines growing vigorously on the hot water pipes along the sides. The trees in the centre are models of culture. They vary in size, but are uniform as regards health and crops, every tree studded with fruit the size of walnuts, and it is not too much to say the contents are worth more than the building, though it is substantial and nearly new. The sight presented by that house at the present time is, so far as we know, unequalled. In other houses where forcing is not resorted to the trees were in flower—dwarfs, standards, and pyramids—several of the latter about 9 feet high, pictures of beauty. A single row of 4-inch pipes runs through most of the large houses, not for excluding frost in winter, but for drying the air in damp weather in autumn and spring. There is no trouble in any of these houses by the casting of the buds, whether the trees are planted out or not. Premature loss of leaves through the attacks of red spider in summer is one of the great causes of the evil, and is avoided. The use of the camel-hair brush is resorted to for insuring a full set of fruit, and the crops in these houses never fail. Not an aphid is to be seen, and no plants allowed in the structures that are likely to communicate insects. One was rendered sweet by masses of Wallflowers and Hyacinths, but Roses are excluded. Ants, which eat off the anthers of the blossoms, are baffled in a simple manner. The stems of the trees are encircled with 3-inch bands of chalk, this being rubbed on thickly, the particles are so loose that they fall as soon as touched by the feet of the little crawlers, and down they come as fast as they attempt the ascent.

Some houses are entirely unheated, and in them Pears, Plums, and Apples have set their crops, and the trees which are in pots will be plunged outdoors to ripen, or the majority of them, for there is not room under glass for half of them to perfect their growth, and overcrowding is fatal to success in orchard house management.

The walk through the Orange house is a delightful promenade, there being a wealth of fragrant blossom, and golden fruits in abundance of a quality far excelling that of the best imported Oranges. The Cherry house with its boarded sides is unheated, and the ventilators open for retarding the blossom. The finest of Cherries are produced in this simple structure yearly, and a supply

afforded during a period of two or three months. As a rule the means of affording a little heat should be provided in orchard houses, but when this is not done the safe course is to retard the expansion of blossom as long as possible. The opposite course has been adopted in some gardens and brought failure, and the houses condemned when the management was often at fault; but owners of houses for fruit culture should recognise the fact that they will always pay for piping, not for heating regularly for preserving plants that are out of place in orchard houses, but, in conjunction with good management, for insuring good crops of fruit. Mr. Rivers' essay is a simple record of practice, and his teachings intelligently followed, must bring success.

ROYAL HORTICULTURAL SOCIETY.

SECTIONAL COMMITTEES.

MR. A. H. SMEE, who contributes a generally excellent letter on page 352, suggests the desirability of dividing the Floral Committee into sections, in order that the merits of the different kinds of plants submitted may be better determined. That either the present Committee will have to be divided into sections, or sub-committees formed, bringing in outside talent, appears certain. It is a question if the present Floral Committee numbers sufficient specialists for forming separate contingents for adjudicating, say on Orchids, Auriculas, and kindred plants, Chrysanthemums, and other sections. Yet specialists are undoubtedly needed, and the few on a large general Committee may easily be outvoted by the many, who may be, and are, men of ability in some branch, but who fail to see the points of merit of certain plants before them. Mistakes have been made both with Orchids and Chrysanthemums that have not strengthened the Society, and which would not have been made by half a dozen men having special knowledge of those plants. At the end of the present year there will probably be more gardeners who are Fellows or Associates of the Society to choose from. Then will be the time for a general remodelling. Shifting about and altering in the middle of the season rarely proves satisfactory, but, on the contrary, indicates instability that does not beget public confidence. Since attention has been called to slight errors, particular care will doubtless be exercised not to increase the number; and as Mr. Smee says, "for this year all measures must be of a tentative character," it will, perhaps, be best to proceed to the end without any fundamental alteration. In the meantime, suggestions can be made and discussed, and methods devised, for effecting improvements of a permanent character. A not altogether unimportant matter to determine is this—If sectional committees are to be formed, by whom and in what manner are the members to be selected and elected?

SHOWS.

Mr. Smee still appears to be of opinion that shows will strengthen the Society, and seems to regret that one cannot be held in Finsbury Circus. An exhibition there might have proved a success or it might not. Every show that has been held has been hoped to bring strength to the Society, but the fact remains that most of them, taking small and large together, have had quite an opposite effect. There is a great risk connected with exhibitions, and the Society is scarcely in a position to incur such risk. Though I am strongly convinced that a year of rest, not from scientific, useful, and administrative work, but of cessation from showing, would have found the Society much stronger at the end of the season than it will be after a term of floral gaiety, I sincerely hope I may be wrong. If shows do not attract visitors in sufficient numbers to prevent loss to a society they fail in their immediate object, though it is conceivable they may to some extent have a stimulating effect in bringing new supporters—new Fellows. It is easy, however, to over-estimate that possibility, and the experience of the past is not encouraging.

But the plan of the future is to bring the shows to the people. The idea sounds well, but will the people "come in their thousands" to see them? That is the question. It is easy to take a horse to the water, but proverbially difficult to make him drink if he is not thirsty. I shall believe the public will crowd into the hall at Westminster when I see them, and not till then. An exhibition under canvas in Finsbury Circus or in the Temple Gardens might attract a throng of visitors, and probably would, subject to two contingencies, one of which is essentially uncertain, and the other problematical—namely, favourable weather, and some exalted personage to lead the way. One or two hundred pounds might be realised by the venture (and Mr. Smee in a former letter made a special point of "gate money"); but the same amount might be lost, and loss would certainly be incurred if the show days were remarkable, as has often been the case, for torrents of rain.

If it were proved that Shows brought an influx of Fellows, and that there would be no material additions without the said Shows, that would be a strong reason for holding them, even if the gate money did not quite equal the expenses; but the most recent experience does not support that proposition. Before the first Show was held at Westminster the glad tidings were freely circulated that more new Fellows had been proposed in a month than during the whole of the preceding year. The very fact that this was made known previous to the Show is conclusive evidence that the additions were not the result of it; and it shows, moreover, there are other ways of gaining subscribers than through the agency, often costly, of shows. Existing Fellows and members of the Committees have exerted themselves, and the guinea fellowship has opened a way by which many new supporters will enter. I have done a trifle in inviting some to come in, and hope to do more. But the truth must be told that some good men are hesitating lest if they subscribe, their money, to adopt their own phrase, which appears ready for use, will be "squandered." Now that the guinea ticket is made transferable, which is exactly what was wanted, I believe many gardeners would join if they felt an assurance the money would be devoted to strictly useful horticultural purposes, such as conducting experiments and trials at Chiswick, and publishing the results as speedily as practicable, and not a year or two after their interest has departed. I do not know whether the guinea transferable ticket admits to Chiswick or not, but that privilege would be as much appreciated by most persons as the entrée to shows, and more by some, while it would cost the Society nothing. Moreover, most persons appear to like being invested with a right if they do not often exercise it.

I fully believe the Council of the Society and the advising committee will consider fully and well every step that is taken, and that they will proceed on the most prudent lines they can devise. I am one of those who think they did not make the best start under the circumstances, but no one can hope more earnestly than myself that they will make a good finish at the end of the season, and commence under happy auspices another year. The maintenance of Chiswick is the ultimate desire of most, if not all, who are identified with the Society, and I trust support will not be withheld by any who can afford to give it in the cause of national horticulture.

Mr. Smee is afraid that opening the garden at Chiswick during the fruit-blossoming period to the public on payment of a small fee would not attract many visitors. Possibly not, but the point is this—there would be nothing to lose by the venture, while attention would be drawn to the Society in that form of "popular advertising;" and not only so, but if I had any choice in the matter I would prefer taking the Chiswick proceeds of three weeks to all the clear profit that will accrue during the year from the exhibitions held in Westminster.

The Apple congress that extended over some time attracted the public to Chiswick, and was more profitable than any show that has been since held, and it ought not to be impossible to draw patronage again that would be useful.—A FELLOW OF THE SOCIETY.

HALF-GUINEA SUBSCRIBERS.

PROVINCIAL gardeners have watched with interest, if in silence, the ways and means that have been adopted to strengthen the Society, though many have felt it beyond their reach. As gardeners represent horticulture the Society ought to represent them. Let it be Royal, but also a general Horticultural Society, then it will embrace all and not the few.

What are these half-guinea associates? They appear to be dreaded rather than encouraged. It has been recently said in a contemporary that "if you confer on the half-guinea man the same powers and privileges as on the guinea man, the latter personage will be extinguished, and on a critical vote a whole army of the least experience may carry the day against knowledge, judgment, and all that is called wisdom in human affairs." As that cannot be intended as an insult to gardeners, are we to understand it to mean that by paying another half-guinea knowledge, judgment, and wisdom are attained? Evidently there are more brains in one's pockets than some of us think. All honour to Mr. Smee. True to all that pertains to horticulture, I hope he will not forget the workers. The true principle of giving is not what a man gives, but what he has left.—B. L.

ENTERTAINMENT TO THE EMPLOYÉS OF THE ROYAL HORTICULTURAL SOCIETY.

THE entertainment recently proposed by Mr. R. Dean was held on Friday evening last at the Bolton Hotel, Chiswick. Harry J. Veitch, Esq., had kindly consented to take the chair, and was supported by Messrs. A. F. Barron, J. D. Dick, G. Deal, J. Roberts, H. Herbst, and Shirley Hibberd, Messrs. R. Dean and W. Richards taking the vice-chairs. The company was chiefly confined to the employés, and there were few visitors besides those named. An excellent supper was provided, and a

very entertaining programme of toasts and songs rendered the gathering an extremely agreeable one to all present. After the usual loyal toasts Mr. Herbst proposed "Success to the Royal Horticultural Society," which was responded to by Mr. G. Deal, whose remarks were to the effect that the Society is being placed on a better basis, and that the scheme for its popularisation is being steadily developed, giving a prospect of future success and even more good work than it has done in the past. Mr. Veitch proposed the health of the employés of the Society coupled with the names of Messrs. Barron and Diek, whom he highly complimented upon the efficient manner in which they had performed their respective duties during a long period of service. Mr. Barron in reply said, after thanking Mr. Veitch for his attendance, that he had always been favoured with a good staff of assistants, and none knew so well as himself how much they had helped him in many arduous duties.

The health of the Chairman was proposed by Mr. Shirley Hibberd in a felicitous speech, in which he referred to the gradual development of commercial horticulture of the present century and the important part Messrs. Veitch & Sons had taken in both practical and scientific departments, and the large number of plants they had introduced. He thought it augured well for the Royal Horticultural Society that they had secured the aid of such an earnest horticulturist and thorough business man as Mr. H. J. Veitch in the Society's Council for the present year, an observation that received the hearty endorsement of all present. Mr. Veitch in the course of his reply briefly traced the history of his firm from the time his great grandfather was engaged as gardener in Devonshire until he himself assumed the direction of the present business. The gradual development of the Exeter business, the fortunate employment of the Brothers Lobb as plant collectors, the migration to Chelsea, the improvement of several families of plants by hybridising and cross-breeding, such as the Orchids, the Tuberous Begonias, the Amaryllis, &c., were all referred to. Mr. Veitch thought that collecting new plants is played out, as, though there are many districts not fully explored, they are generally in the interior of countries difficult of access, and the plants obtained are subject to all kinds of dangers in transit. Recognising this some time ago they had turned their attention to hybridising plants already cultivated, and most of those present had had opportunities of judging the results attained. He concluded by adding that though, as in all commercial undertakings, £ s. d. must have the first consideration, this had not been the only moving power, but much had been accomplished by the deep personal interest taken in the work, both by members of the firm and their able assistants.

Shortly afterwards Mr. Veitch resigned the chair to Mr. Shirley Hibberd, who, being in excellent form, delighted the company with a comic song, and with several contributions from others an exceedingly successful entertainment was brought to a close. Messrs. R. Dean and W. Richards received the hearty thanks of all present, as the success attained was mainly due to their efforts.

FRUIT-GROWING IN TASMANIA.

As we are sending you some of our fruits, perhaps you would like to know a little about our gardens, especially as a few years hence you will hear a good deal more about us and see thousands of bushels of our fruit in your markets. Still your gardeners need not set their bristles up, as it will not affect them a bit, as our fruit will come in when theirs is all eaten. We are now only waiting for the ships to come with cool chambers and you shall see what fruit Tasmania can produce. Hitherto, with a few exceptions, fruit-growing has been carried on by small men, the largest gardens being eight or ten acres. But capitalists are now waking up to the fact that there is money to be made at it, and much larger orchards are being laid out. All English fruits, except Grapes, thrive splendidly. Our long sunny summers ripen and colour Apples and Pears to perfection, and moreover they keep well after gathering.

The Apricot and Peach are grown in the open orchard as standards. A good Apricot tree will yield several bushels of fruit in a good season. Our best gardens are quite equal to any in England I have seen. The trees are planted as yearlings, from 12 to 15 feet apart, the land being simply ploughed deeply before planting, then we cultivate and crop between the trees until they are six or seven years old, by which time they come into bearing. I have seen an average of a bushel per tree at six years old. We prune very hard at first, and keep our trees low, giving them a stem about a foot, then getting twelve or fourteen branches out of it, the favourite shape being the inverted umbrella with cordon branches from the stem. This form is adopted for Apples, Pears, Peaches, Apricots, Cherries, &c. We apply manure and cultivate as the trees come into bearing, digging or ploughing between them to preserve the moisture and keep the land from cracking.

The fruit grown includes a very fair collection. In Apples the Scarlet Nonpareil, Sturmer Pippin, French Crab, and Ribston Pippin have been perhaps most popular, but many others are grown. In Pears, Williams' Bon Chrétien, Winter Nelis, Vicar of Winkfield, Gansel's Bergamot, Easter Beurré, Beurré Diel, Uvedale's St. Germain, Achan, and a few others predominate. Hitherto we have grown only for the other colonies, and the growers have

obtained about an average of 1d. a lb., or 5s. a bushel, and have grown varieties which would keep and ship well.

Some of our gardens in a good season present a very pretty appearance, being simply covered with fruit. Our average crop is about 200 bushels an acre, but good gardens yield much more. A garden in the Huon district of ten acres and twelve years old turned off last year 3600 bushels, the year preceding 4600 bushels, and the year before again 3600 bushels, and the grower often gets 7s. or 8s. a bushel. This year has been very bad for Cherries, still we have had very fine fruit. I weighed some a few days ago which scaled forty-four to the pound. Raspberries in the best districts are very prolific, growing so high and strong that they have to be tied down to reach the fruit.

Our best fruit land is newly cleared bush land, the maiden soil and ashes made in burning off the timber giving the trees a splendid start. I have measured Plum or Apricot shoots 7 or 8 feet long. Three years ago I went into the bush and picked out a block of land. The Government sent a surveyor, who charged me £5 for surveying 100 acres. Then I had to pay about 1s. 6d. an acre for fourteen years, when the land becomes my own, or I secure my title at any time by paying up the £1 an acre. But to turn it into a flourishing orchard there is something to be done, as now it is covered with huge trees and thick scrub. The trees are magnificent timber, as good as English Oak; but no matter, I only hope it will burn well. One tree I measured 12 feet in diameter and about 300 feet high. Tree Ferns, too, which would astonish your gardeners; but the axe flies round to the tune of £2 10s. an acre, and down everything goes into an immense layer of at least 500 tons an acre. The hot summer sun now wilts and dries it, until, when ready, the fire stick is put in, and away goes the destroying, and to me, the clearing element. Now the land when turned up will grow anything—Potatoes as big as one's boots—Turnips, Cabbages, &c. The small stumps and roots are grubbed out, but the big fellows shall have Grape Vines planted around them, and they will not affect the fruit trees between them. But it will cost me £15 to £20 an acre before I get my trees well planted. Still, if my Potatoes, &c., turn out right, a great part of this will be returned in the first two years. My neighbour has four acres of Apple trees six years old and just coming into bearing, and a few weeks ago he refused £1000 for the orchard, coolly asking £2000. Our chief want is more rain, frost hurts us but very little. Your grand hothouse plants grow out of doors better than in the house. Will try to send you some samples of our fruits in a few weeks.—TOMAHAWK.

SUCCESSFUL BOUVARDIA CULTURE.

LAST autumn I had an opportunity of paying a short visit to Mr. Roberts at Gunnersbury Park, and Mr. Hudson at Gunnersbury House; and at both of the well managed gardens connected with these establishments a grand lot of Bouvardias were in full flower. On the whole they were the best lot of plants of this popular flower I have yet seen. Both the collections were totally dissimilar in character, Mr. Roberts' being a good instance of what can be done in one season, while the greater portion of Mr. Hudson's plants were large specimens two or more years old. Being a great admirer of Bouvardias, and well acquainted with their value in any place where superior cut flowers are required in quantity, I naturally asked for and obtained full particulars of the treatment given, and also permission to publish the same.

We will take each separately, and commence with the young plants as grown at Gunnersbury Park. Cuttings of young growth are taken not later than March, and these are struck in a close frame with brisk bottom heat. When well rooted all are topped, and when breaking afresh are potted singly into 2½-inch pots, and before they are much root-bound are shifted into 5-inch pots and still kept growing in gentle heat. Before the young shoots are far advanced they are carefully pegged down, this causing the plants to push up strong sucker-like growths from the buried stems. A final shift into 7-inch and 8-inch pots was next given, and during the hottest part of the summer all were set out in full sunshine. The compost used consisted of equal parts of turfy loam, leaf soil, and Wood's fertilising moss, and this evidently exactly suits the Bouvardia. Being housed before cold wet weather sets in they do not experience a check in any way, and commence flowering immediately. It is the fine branching central growths, and which vary from 2 feet to 4 feet in height, that give such excellent results. In addition to one grand terminal truss they produce side flowering branches throughout their length, a long succession of bloom being obtained during the winter. Fully 300 plants are thus freely grown, and these, arranged in a bank 33 feet by 8 feet, present an effect more easily imagined than described. They are given an intermediate temperature, and ought to be set not far from the glass. The very useful double white Alfred

Neuner and the pink President Garfield grow strongly and are quite as free flowering as the single varieties. In addition to these Mr. Roberts also grows large quantities of Dazzler, bright crimson; and Vreelandi, white; these being among the best single flowering varieties in cultivation.

Many of Mr. Hudson's plants were fully 2 feet through, well balanced, and crowded with flowers. They were growing in a neat pit, some in pots, others, if I remember rightly, planted out in a peaty compost. All would continue to be serviceable till mid-winter, after which time they would be partially dried off or rested, then cut back, those requiring it being potted, and all started in an early vinery. Those kept in pots are partially shaken out and repotted as soon as they break afresh, and all are duly stopped, this being necessary both to induce the formation of abundance of shoots, and also to prevent early flowering. Numbers of cuttings are struck each season, these being destined to take the place of the old ones when these fail. Early in June, and after the plants have been slightly hardened off, all are planted out in the open ground, where without much further trouble they form fairly strong healthy growth, which never fails to flower satisfactorily. They are potted up during the third week in September, and placed in gentle heat, where they soon recover from the temporary check given. The favourite single varieties are Humboldti, corymbiflora, Dazzler, Hogarth, and Vreelandi.

I ought, perhaps, to add that the soil at Gunnersbury House is of a light open character, which just suits the Bouvardia. Where the soil is of a heavy or clayey nature it is advisable to either plant the Bouvardia in cold pits in succession to Violets or forced vegetables, or to prepare an open site specially for them.—W. I. M.

VIOLETS.

THESE, I am afraid, are very often neglected. Like the ever-popular Lily of the Valley, when once planted in some out-of-the-way corner, there they are allowed to remain, and the flowers the poor plants are able to produce under such circumstances are gathered as a matter of course, and nothing better is looked for. But with the Violet as with many other plants, good cultivation is in no respect thrown away. They flower more profusely; the individual blooms are larger, the colour is better, and their season of longer continuance. Indeed the way to insure a small crop of poor-looking buds is insured by leaving them severely alone for three or four years.

If anyone who favours these lines with a glance should have a close turf of Violets which, notwithstanding the neglect they experience, never fail to produce their annual tribute. Supposing such a person, out of gratitude for the flowers yielded with such scant attention, should for once give the plants at least as much attention and as good treatment as that bestowed upon his Cabbage bed or his clump of gaudy Calceolarias, that surely would be no great return for the pleasure which this unassuming flower meekly offers year by year. But they do not even require so much as that. In our poorest soil they do well for two seasons, and in very strong soils I should imagine they would succeed even better. In any case, surely a biennial renewal of the plants, manuring and digging the ground, is not a very great tax on anyone's labour and means. The present time is very suitable for starting fresh plants. By examining the old rows and selecting the rooted runners a good number of young plants is secured. As our plants are grown year after year on the same ground—that is to say, in lines under the shelter of walls, we remove all the old plants and select the young ones at the same time. In digging, a good thickness of manure should be added, and if some of the exhausted soil is removed and fresh material supplied from the ground alongside, that will prove of much benefit. As the digging is proceeded with so is the planting. If the soil be dry water thoroughly, and in any case make the soil firm to the roots. A distance of 10 to 12 inches between the plants suits very well, and if they grow as they ought to do they will be close together by November, and at that time also will be producing flowers, continuing to do so for the following five months, weather permitting of course.

The old common variety pleases me best of all. It is the sweetest, deepest in shade—violet, in fact—and in the spring days is smothered with flowers. Unfortunately for its popularity the flowers are small. Some of the large sorts are too tender for our climate. The foliage goes with the first moderately severe frost, and the large flowers do not appear in any appreciable quantity until late in spring. Of the merits of the new Wellsiana I cannot speak from experience, but next to the common small odorata I like for other people's use the variety called The Czar. It stands the winters very well, and is always ready with flowers to open so long as frost keeps away. Double varieties do fairly well if allowed a very warm position at the foot of a south wall. A little dry

bracken to turn over the plants during severe frosts is of great utility in saving the buds. The best double is Marie Louise, a fine blue and the freest to open; and a fairly good companion with white flowers is Comte Brazza. We treat these somewhat differently from the singles, as the rooted offsets are taken off and established in frames, and then transplanted in April out of doors, either to the position they are to occupy when flowering or in some other warm spot. These do well with plenty of water, and appreciate good holding soil.—B.

CROPS THAT PAY.

MINT AND HORSERADISH.

MINT is in demand for at least eight months out of the twelve, in a green state, and none of the crop need be wasted, for it can be dried and easily disposed of in that condition. Few outside those who grow it for the market would regard it as very remunerative, yet few crops are capable of showing better returns. Early in the season—say during January—2s. a bunch can be had for it, 1s. 6d. during February, and it seldom falls below 1s. a bunch until it can be gathered outside. The markets, of course, fluctuate according to the supply, and the bunches increase in size as the season advances. The cultivation of this crop for the market, especially early in the season, is much better suited to the farmer than the market gardener. Whatever may be urged in favour of heat from hot-water pipes, and for our earliest supplies they are indispensable, but a little later in the season Mint is forced better on hot-beds. It is far less liable to be attacked by aphides than when forced under glass.

If plenty of decayed manure is mixed with the fresh litter the bed will be found to retain a steady heat for a long time, and this process does not do the manure so much harm as many think. A steady heat only is needed, not a violent one, and this can be readily regulated by the free admixture of plenty of decaying manure. If a bed is made 18 inches high and covered with a frame—one made of rough boards will do very well—all really needed are lights to fit close over the frame. On the surface of the manure a little ordinary garden soil may be spread, and on this the roots of Mint are packed closely together. These just covered with soil of the same nature, no attention is needed until they have commenced growth, air is then needed to prevent the shoots drawing weakly. When ready for use it should not be cut too low, then a valuable second crop from the roots will result. If the manure is not wanted after the second crop has been removed, a good watering will often start them vigorously again, and valuable roots for stock purposes are the result.

On some soils Mint will last for years and grow vigorously, but light soils must be heavily manured if it is to pay well. It should not remain on light soils more than two years, as if left too long on such soils, or planted in the same place year after year, it is liable to be attacked with a red fungoid growth which quickly spreads over the whole flat and arrests growth. I have lost the whole of my stock from the causes pointed out. It is a good plan to change the stock occasionally by obtaining fresh roots, or by striking the first growths early in the season. The last method necessitates handlights in which to root the cuttings. They strike freely, and in a season make some good roots. The quickest method of propagation is by cutting up the roots, and planting can be done at any time preceding growth—the earlier the better. The ground being manured and dug, shallow but rather wide drills 1 foot apart can be drawn out, and the portions of roots scattered evenly in them, and the soil drawn over them with a rake. A little weeding may be needed when they first appear, but they quickly spread and take possession of the ground. When large quantities are planted, the best of all methods is to plant on beds 4 feet wide, with alleys between them 15 inches wide. In this case the roots for planting can be laid on the surface of the beds, after making them even, and then covered with the soil.

HORSERADISH.—In some seasons Horseradish proves a very remunerative market crop. This season it has not generally done well, but those who have had it good have found a ready sale at a good price. Very rarely it realises less than 1s. a bundle of twelve sticks, and often 4d. and 6d. more for very fine samples. It does not entail a large amount of labour in production, but if a loose system of management is practised it tells enormously against the succeeding crop. Horseradish, like Rhubarb, will grow anywhere, but not that which finds a ready sale at a paying price. It requires well-worked soil heavily manured. The finest roots are produced by planting the sets vertically, but this method for the market will not pay, simply because the base of the set is 6 inches in the ground to commence with, and the roots descend into fertile ground to too great a depth. By this mode of planting they take too much lifting, and the land too much cleaning afterwards, for it is im-

possible to clear the ground of them—every bit will grow. The sets should not exceed 6 inches in length, and are best planted nearly horizontally. The end intended to form a crown should be a little higher than that from which roots are to form. Plant them on beds raised by placing the soil from the alleys on the top of them before planting is done. When planted on the surface of such beds, with the sets sufficiently deep only to keep them beneath the soil, lifting is rendered easy. If the soil was well broken up prior to planting they can be drawn out without breaking the fangs if loosened with a fork. This insures the ground being fairly free of them, which is very important, or double if not treble the labour that should be required will have to be spent on the crop that follows.

At lifting time the fangs are cut off to form sets for the following season, and these can be stored in a convenient position for preparation during bad weather. The marketable roots also undergo preparation, but the method adopted varies for different markets and by different growers. Some buyers purchase their stock and store it in cellars, and in this case it is best with the removal of any fibry roots that may have formed during the season, but tied in bundles in other respects as lifted. In this way it keeps best by those who have no soil in which to store it. In other cases it is washed and given the appearance of white Carrots by scouring it with sand. When this has to be done, however, rather stiff cocoanut scrubbing brushes are the best for the work. But my advice to intending growers is, Go to the market you intend to supply, and you will soon discern which method of preparation after lifting takes best. If they are sold without cleaning, try a few cleaned ones, and if they do not take so well discontinue the system.

The preparation of the sets before planting is important. The thicker the sets for planting the better will be the roots at lifting time. Very small sets do not attain sufficient size and strength in one season, and to have them tender they should not be of more than two years' growth—that is, one season's growth after planting. When the sets are cut into lengths, rub every fibre off with the exception of a quarter of an inch at the base. This must be carefully done to insure clean roots at lifting time. If allowed to root from any other position than the base of the set, the appearance is spoiled and the sticks are decreased in size. Very often two and three crowns will start, and these, like Seakale, should be removed and the strongest only left. Good Horseradish should be tender and resemble a white Carrot when cut in two.—MARKETER.

MY GLADIOLI IN 1887.

I MAY lay claim to being now the oldest amateur grower of this lovely autumn flower in the kingdom, an honour which I do not suppose many will envy me. For upwards of thirty years, at any rate, I have grown Gladioli. I have seen very great advancement in the flower in every respect. I have had my "ups and downs" in its culture, have passed through disastrous seasons which have made me also bankrupt in stock. I have also seen favourable seasons, but I never remember so favourable a season as that the doings of which, as far as my own garden is concerned, I now chronicle, and in looking back I have a black mark fixed against 1879; and taking all these things into account, it is clear to me that a dry season is the most suitable for it, just as it is for the Potato, and that for the same reason in both cases, that a dry season is not favourable for the development of the disease to which they are subject.

I write the word "disease" with some degree of satisfaction, because I think that the past season has satisfactorily settled the question as to the cause of losses which all growers of the *Gladiolus* have to mourn over. Two theories have been put forward to account for these losses besides that which attributes them to disease—exhaustion and degeneration. Now with regard to the former, Mr. Kelway, who is the largest grower in the kingdom, and who has always maintained this theory, writes to me, "Seasons govern results." I do not ask him whether he has given up his theory, but it is quite clear that if exhaustion is the cause of failure it must go on, no matter what the character of the season may be. As to degeneration, I cannot think that this theory will hold water in the face of the simple fact that I have had this year plants 5 and 6 feet in height from corms which have been four or five years old (I use this term popularly, although it is well known that the corm dies each year and a new one is formed above the old one); and to another fact, that varieties which came out twenty years ago can be had as good as they were when first brought out. Since the above was written I have examined some corms from France, direct from Fontainebleau, and some of them are as badly diseased as any I have ever seen.

One result of this past season will be, that wherever any culti-

vator has adopted some particular mode of culture he will attribute his success to that special culture, and ignore the effect of the season. Thus I see that one grower is so satisfied with the plan of starting them in pots that he intends to continue the practice, believing his success to be attributed to this, when probably it is owing to the character of the season. I have, amongst my many experiments with them, tried this more than once, but I never found any better results from it, and where the collection is large it entails a great deal of trouble.

I have been impressed with the notion during these last two or three years that it is a mistake to suppose that the *Gladiolus* likes a light soil, but that, on the contrary, a stiffer one suits it better, and that where the soil is calcareous they thrive best. Mr. Burrell of Cambridge holds this opinion very strongly, and last season confirmed my view. I had some planted in a part of my garden where the soil is stiffer and more calcareous, and some where the soil is lighter and full of decayed vegetable matter, and those in the former seem far ahead of the latter. I asked the question of Messrs. Souillard & Brunelet of Fontainebleau, my dear old friend Souchet's successors, and they inform me that the soil at Montreux where the greater portion of their culture is carried on, and which is also one of the most famous places for the Chasselas de Fontainebleau, is calcareous—that at Fontainebleau is sandy. They do not, any more than most of the tribe, like a "stodgy" tenacious soil, but they do like one that is tenacious and yet allows water to run off. I allowed last year my roots a large space between them, 12 inches, but on paying a visit to Mr. Campbell of Gourcock, N.B., I was surprised to find how very much closer his were planted, and as he is one of our most successful growers and exhibitors I have determined to plant closer this year, say 6 or 8 inches. I largely adopted the plan, last year, of cutting the corms in two, and indeed in some cases in three, and although there exists in some people's minds a prejudice against this plan, I can testify that some of the best blooms and corms were produced from such cut corms, and at the same time it doubles the grower's stock.

From letters I have had from Mons. Souillard this season I imagine that they have felt at Fontainebleau some of the same difficulties which we experienced in England this season. Only the other day he wrote to me to say that frost and snow were still with them, and that consequently planting was out of the question. Last year I planted mine at about the usual time—about the first week in March, but this year it will be quite if not more than a month later before the work is completed. I do not, however, think that that makes so much difference as might be supposed. In harvesting them last season I departed from my usual habit of taking them up in October, being moved thereto by Mr. Burrell of Cambridge, and delayed taking them up until late into November and early in December. This gives the corms a longer time to ripen, but at the same time it is somewhat more troublesome, as by that time the beds are tolerably saturated, and consequently more soil clings to the roots than when they are "lifted" in an earlier and drier time.

I had not so much opportunity of testing the new varieties sent out by the Fontainebleau firm last year as usual, and, unfortunately, circumstances prevented me from seeing the exhibitions at the Crystal Palace or at the Aquarium, where Mr. Burrell and Mr. Campbell of Gourcock showed so well, but am not sure whether they exhibited any of the novelties of 1886 or not. The following are descriptions of those of 1886.

FRA DIAVOLO.—This has a long and compact spike of large flowers of a lovely orange-red colour, flamed with reddish violet on the edges of the petals, and with a large pale yellow spot in the centre.

ENCHANTERESSE.—This I believe to be the best of the year. It is a large and compact spike of very large flowers, white with pale satiny lilac marking, violet-red stripe in two of the divisions, very tall.

MAGICIEN.—Plant of medium height, compact spike of large flowers, the edges of the petal slightly fringed; centre of flower passing into a pale rose.

MAGNIFICUS.—Tall plant, superb spike of very large flowers, round and open, cinnabar red, beautiful white spot in centre with violet border.

MINOS.—Tall plant, long spike with closely arranged flowers of salmon-rose, largely flamed, and variegated with cerise red, amaranth band and centre.

POLLUX.—Dwarf plant of rounded flowers, lovely carmine red, with brownish red stripe on border of the petals; beautiful white spot.

SIRIUS.—Long spike with flowers of a lovely rose, striped with carmine, with purple spot.

SPLENDENS.—Long spike well furnished with flowers of cinnabar red, with pale yellow spot on one or more of the divisions.

There is one great advantage which the *Gladiolus* possesses—the length of time during which it produces flowers, owing to the fact that there are four distinct periods at which certain varieties produce their blooms, some, as Shakespeare, producing theirs on or about July 26th, and others, like Phœbus, not blooming until quite late in October, and while this somewhat detracts from the appearance of the beds, as some are going out of bloom while others are coming on, yet the pleasure the flower gives to the grower is greatly added to by this fact, fresh beauties are daily expanding, and thus the interest is kept up. In drawing up the following list I have necessarily been guided by my own experience, and it is possible it may not agree with that of many growers, but as far as this locality is concerned it is correct. The four periods are from July 26th to August 10th; August 10th to 24th; the third from August 24th to September 10th; and the fourth from September 10th to the end of October. Let me take them in order.

1.

ALI, a curious flower, long spike, but imperfect shape, well arranged, pale rose, and heavy white striped with red.

AMALTHÉE.—Large flower, white ground, with violet stripes somewhat thin in texture.

ARCHDUCHESS MARIE CHRISTINE.—Large, white ground, deeply flaked with rose.

BELLADONNA.—White tinted with lilac, lower divisions lightly marked with carmine.

CARNATION.—A very pretty flaked flower, good spike.

DEMOTHÉNE.—Beautiful bright rose, very large, perfectly formed flowers.

HORACE VERNET.—Brilliant purplish red, good spike. Klusson marks this as a late variety; with me it is one of the earliest.

MABEL.—One of the most perfect flowers that we have; compact spike, ground colour white striped with bright carmine on the edge.

MADELEINE.—Very early flower, dwarf habit.

OPALE.—Large spike of good flowers, very delicate rose. I have never succeeded in growing it quite to my satisfaction.

PACTOLE.—Pretty yellow flowers, but somewhat uncertain.

SHAKESPEARE.—Very early and good, but sometimes blooms may be had of it later. I generally look for it about July 26th.

VICTOR JACQUEMINOT.—Salmon orange richly veined with scarlet; a bright flower.

2.

ANDRÉ LEROY.—Dark purplish red with white line on the petals.

BARONESS BURDETT COUTTS.—Lilac tinged with rose and purple; large and fine flower, but not stout enough.

BICOLORE.—Very distinct; top petals bright salmon; lower divisions white edged with rose.

CAMILLE.—Pale magenta lilac, flushed deeper colour; fine flower.

COLBERT.—Deep cherry red petals with white lines.

CRÉPUSCULE.—Creamy white, tinted lilac, large and fine spike.

DALILA.—A very lovely flower, bright rose with white lines and spot; very fine.

DR. FONTAN.—Pale rose, richly flamed with red, compact spike.

FLAMBOYANT.—Bright crimson scarlet, very large, bright and dazzling in colour.

HESPÉRIE.—Dark salmon striped, with a somewhat loose and flabby flower.

LEANDRE.—Bright lilac with large white blotch; a large flower of great solidity.

MASCARELLE.—A new flower of a very curious colouring, salmon rose; lower divisions yellow edged with rose; distinct.

L'UNIQUE VIOLET.—Dark lilac shaded violet; large and good.

NÉRÉIDE.—A very fine flower; compact spike, pale lilac rose, good spike.

ORIFLAMME.—Large straight spike, compact large flowers, orange rose, a little paler in the centre, the lower divisions lightly marked with gold yellow and lined with carmine.

OVIDE.—Purplish crimson, blotched and striped with white; a fine and striking flower.

ONDINE.—A very fine white flower.

PASQUIN.—Bright crimson scarlet, edge of petals suffused with slate colour; shape not good, too square.

PYGMALION.—Cherry red, blotched and striped with white.

TAMERLANE.—Very dark slaty red, blotched and striped with cream; requires shading, as it is apt to burn.

TOUR DU MONDE.—Dark cherry, shaded lilac, white blotches.

3.

AFRICAIN.—Slaty brown, flushed scarlet, white blotches, fine spike; a remarkable flower.

AURORE.—Clear orange, blotched and striped white.

ATLAS.—Pale porcelain, slightly tinted and striped violet; fine flower and spike.

CAMÉLÉON.—Lilac, striped white, pale orange blotch; fine and compact spike.

CAPRICE.—Pale ground, flushed purple.

CERVANTES.—Bright rose, tinted crimson, white lines, orange tinted lower petals.

CHLORIS.—White mottled, flushed carmine.

COLORADO.—Bright orange, shaded red, good shape, and very bright.

GALLIA.—Fine flower and good spike.

GRAND ROUGE.—Very like Meyerbeer, but larger, and blooms earlier.

JEANETTE.—Rose striped and flushed with carmine.

JUPITER.—Red flaked and spotted with dark maroon.

LACÉPÈDE.—Lilac rose, large, good flower.

MADAME DESPORTES.—A fine old flower; pure white, but not good in constitution.

M. ADOLPHE BRONGNIART.—Another old but very fine flower; flamed red on white ground.

MOUNT ETNA.—Velvety scarlet, blotched white; a very fine flower.

MURILLO.—Cherry rose, somewhat undersized, but a very pretty flower.

NEIGE ET FEU.—Good spike of medium sized flowers, bright cerise, with large white blotch.

RAYON D'OR.—Yellow with red stripes.

THÉRÈSE DE VILMORIN.—A new and novel flower, creamy white; good and compact spike.

4.

BENVENUTO.—Light orange red, white blotch.

GRAND LILAS.—Very large, fine flowers, beautiful shade of lilac.

LE VÉSUVÉ.—Brilliant scarlet red; a fine flower of good substance.

MATADOR.—Bright cherry red, striped and blotched darker colour; very fine.

MÉDICIS.—Long spike of large flowers.

PHœBUS.—A very brilliant flower, fiery red; the latest flower we have; very seldom exhibited.—D., Deal.

PEACH BUDS FALLING.

It is most perplexing to a cultivator when the Peach buds are falling and nothing can be done to prevent them. We have never had much cause to complain in this way, but always inclined to believe that the state of the roots, or a portion of them, has something to do with the evil indicated; and it may be that one tree will suffer while its fellow escapes. We freely admit that fire heat supplied unduly, sudden changes from warm to cold, injudicious watering, and a host of other causes may be instrumental in strewing peaches with strong and healthy looking blossoms. The few cases of which we have had experience were from some of the leading roots, only a few, getting through the drainage into inert sandy soil, and with these trees we had to give battle sharply to keep red spider at bay. We never had any mishap with early forced Peaches, say those which set in January, and this year after thinning all the flower buds to about an inch apart the set has been superabundant. We believe in keeping the shoots thin, and no more on the tree than are necessary—viz., one at the point of the fruit-bearing wood to draw up sap, and one at the base of the shoot to supply fruiting wood for next year. Moreover, it is always our practice to thin all wood buds not wanted as soon as they can be discerned, which is some time before the fruit buds open; the latter are thinned along with the immature wood buds. We maintain that by clearing off all these before they develop into growth the tree receives no check. This experiment we tried first when a lad, and have rigidly put into practice ever since.

Reverting to root-action, we may describe a case where bud-falling was considerable. The first season we were baffled. The roots, which filled the fine border to the surface, had every care, every necessity with top-dressing and moisture supplied, but half the buds fell notwithstanding. The following season matters were not improved. The foundation of the border inside was examined, and there a few strong roots were found that had gone through the drainage, which had been manipulated with much pains by a clever predecessor, and deep down among poor iron sand they had spread far and wide. They were immediately under the trunk of the tree, and it was useless to trace them with the view of saving them. They were cut clean off, and under the tree lime rubbish with stones was rammed. This was an effectual remedy, the trees doing far better without the strong roots than with them. Vines close by, very subject to red spider, were suffering from the same cause, and no watering could aid the roots.—M. T. C. H.

SOME USEFUL ORCHIDS AND THEIR TREATMENT.

THE following Orchids can be grown and flowered continually in one house where miscellaneous Ferns and flowering plants are always grown under the ordinary stove treatment.

CALANTHES.—These are foremost among Orchids in producing the largest amount of flowers during months of greatest scarcity. *C. Veitchi* and *C. vestita* are best grown in baskets suspended from the roof over the paths. The growths become more sturdy and matured in this way than in pots, and consequently the flower spikes much stronger. I have had flower spikes of *C. Veitchi* 6 feet long and with upwards of forty blooms, and when arranged white and red alternately they have a very pleasing effect. The best compost to grow them in consists of three parts fibry loam and one each of Orchid peat, sphagnum moss, dry cow manure and silver sand, with two of charcoal. The best kind of loam is from poor commons or hill sides, as the fibre, which is the only part needed, is more durable, and contains less soil than turf from cultivated pastures. The best cow manure is what has been used for mulching Vine borders in summer, which becomes thoroughly sweetened and friable. It should be removed in the autumn in a perfectly dry state, and kept so until required for use. *Calanthes* are benefited by liquid manure made from deer or sheep droppings, and it should be frequently given them when the roots are fully in action, and continued as long as the foliage remains green and healthy. As soon as the flower spikes are visible water must be gradually withheld, and this is of great importance, as the flower spikes will be weakened no matter how strong the pseudo-bulbs may be, if water is too suddenly withheld.

The evergreen species, *C. Masuca* and *C. veratrifolia*, require different treatment from those already named, which should be grown exclusively in loam, the same as that recommended for the deciduous *Calanthes*, only with this difference, the only part of it to be rejected is that which separates from the fibre when the turves are broken up. It should be in large pieces, mixed with lumps of charcoal, the pots being half filled with large hollow crocks, and the plants kept well above the pot and firmly packed with the well mixed turf and charcoal, but not rammed. The turf should be procured in sufficient time to have it mellowed before it is used, and the thickness of turf must be regulated by the depth of fibre. The plants, after potting, should have a good supply of water, which will be all they will require until the roots become active, when constant waterings are necessary, as they grow and flower all the year through, and if liquid manure be given them at the same time as recommended for the deciduous varieties, the substance and colour of leaf will be greatly improved, and a good winter supply of flowers insured. *C. Masuca* is rarely out of flower with me, but I have not had the same experience with *C. veratrifolia*, as the plant I have of the latter is from a small imported piece I have had a few years, and though it only occupies an 8-inch pot, it has just thrown up six strong flower spikes.

CYPRIPEDIUMS.—*C. Dominianum* is a great acquisition, and one of the most truly perpetual flowering plants I know. I have sometimes had six blooms on one stem. *C. caudatum*, which is one of the parents of *C. Dominianum*, resembles its progeny very closely in flower, but not in freedom of growth. *C. barbatum* grows freely and flowers profusely every spring, and solitary blooms in autumn, often two blooms, on a stem. I grow them exclusively in sphagnum moss and sand in pots filled within an inch or so of the top, crocks and charcoal, on which the plants should be raised above the rim of the pots with moss, and each growth packed around firmly with the same material, renewing it when needed, as they do not require periodical shiftings. The roots are fond of fastening on the rim of the pot, from which they do not like being removed.

CELOGYNE CRISTATA.—This both grows and flowers freely if kept near the glass. Peat in well drained pots suits it best.

DENDROBIUM.—*D. chrysanthum* and *D. fimbriatum* if kept quiet near the glass flower splendidly, producing blooms several years in succession from the same pseudo-bulbs grown in peat either in baskets or well-drained pots. Spring is the flowering period of both, though the former sometimes flower more than once a year.

PERISTERIA ELATA.—This is thought by some gardeners to be a shy plant, but it flowers with me every year. The large pseudo-bulbs, which are the size of small cocoanuts, produce flower spikes

6 feet long, and after the flowers commence to open they continue flowering up the spike for six weeks. Its peculiar spicy odour is more pleasing at a distance from the flowers than near to them. The best compost to grow them in is tough fibry peat and charcoal, the pots being three parts filled with large hollow crocks and filled nearly to the top with large lump of peat and charcoal, giving the plant as much elevation as possible, packing more large lumps of peat and charcoal around them, leaving the surface as open and porous as possible. After the potting is finished the whole surface should have a thick layer of sharp sand spread over it and well watered with a fine-rose pot, and no more water will be required for some time. The proper time for repotting, which should be done every year, is when the young pseudo-bulbs begin to emit roots, the plants being pulled out of the pots and the old soil shaken from them, the dead roots being cut off. Sponge the foliage and allow it to remain on the old pseudo-bulbs until they turn yellow, as all the time they remain green they are assisting the old pseudo-bulbs in the production of those which are to follow them. If too many old pseudo-bulbs should have accumulated for the size of the plant, only such as are shrivelled should be pulled off.

PHALANOPSIS.—*P. amabilis* and *P. grandiflora* grow and flower well, but the flowers of both are readily damaged in a humid atmosphere. *P. Schilleriana* is a great acquisition; it is superior in constitution to the former, the flowers are not so sensitive to damp, and are unrivalled in elegance both in form and colour. Wooden blocks or baskets seem the best to grow them.

SACCOLABIUM.—*S. guttatum* and its varieties grow and flower splendidly. I have pots made purposely for them, having as many apertures for ventilation cut in them as the pots will bear. When the plant roots are arranged around the pots it should be carefully filled to the top with clean hollow crocks, which may be covered with a thin layer of sphagnum moss, more for the sake of appearance than utility.

VANDA TRICOLOR, if grown in the same way recommended for *Saccolabium*, will have that desirable fine dark thick glossy growth which is too often painfully absent with *Vandas*, though most necessary in order to have them bloom twice a year as mine do.

ZYGOPETALUM MACKAYI is a useful and constant flowering Orchid, and at a season when much desired, best grown in pots well drained, using heavy plant peat and sharp sand and charcoal.

Doubtless there are other species that may be named, but none that I have tried can be so successfully grown in one house as those enumerated.—RD. WESTCOTT, *Raby Gardens*.

FREESIAS.

THE other day I saw some capital *Freesias* in the garden of the Misses Goodlad, Hill Place, Bishop's Waltham. There were nearly fifty pots of plants in different stages of growth, some coming into bloom, some in full flower, while others were past. The results clearly proved that for either conservatory or house decoration, where delicacy of colour and sweet perfume are valued, *Freesias* are most useful. Mr. Blake informs me that he prefers *Freesia Leichtlini*, in some respects, to *F. refracta alba*. The latter variety does not develop its flowers nearly so well, remaining more cup-shaped than *F. Leichtlini*, consequently the beauty of the flowers is not so easily seen. The latter also produces stronger spikes and individual flowers. Some of the bulbs he has had five years, and they are finer now than ever. They flower much better the second year after purchasing them. He grows about eight bulbs in a 5-inch pot. The flower spikes grow from 10 to 15 inches high, and produce twelve blooms on the strongest spikes. When flowering is past, which takes place in the conservatory, the plants are removed to a cooler house, gradually withholding water until the bulbs are ripened, when they are stood outside close together on a bed of ashes until the bulbs are repotted in the early part of September. The soil used is good loam and sand. They are then placed in a frame, where water will not be required if the soil was moist. When growth has fairly started they are removed to a cool vinery, securing a light airy position near to the glass. Water is most carefully supplied to the roots. In February they are placed in a vinery where the night temperature is kept at about 55°, and as the flower spikes develop the plants are removed to drier quarters, where the flowers last much longer.—E. MOLYNEUX.

CONSERVING HEAT.

THIS winter has been a very trying one, and to keep up the requisite temperature in a Cucumber house has been quite enough to worry the most equable. Last summer I purchased a slow combustion boiler, and I have found it answer admirably, for the heat has been on the average from 62° to 72° at six o'clock next morning after stoking at nine o'clock at night, and frequently the fire has not been out. I do not think in any case the heat has been lower than 62°, and in only two

or three cases has the fire gone out without burning, and I attribute the failure then to having let the body of fire get too low before stoking. My house is a sunken one, and the top lights not fitting closely I found the night temperature fall greatly when the wind was cold and strong, and to obviate this I hit upon a plan which may perhaps be very common, but which I have not seen elsewhere, and it proved very successful. I joined one end of an archangel mat to another, and they were thus long enough to go right over the house, and having heavily weighted with iron bars the ends on each side of the house they were kept securely in their places however high the wind might be. Four pairs of mats covered the house, were easily removeable, and considerably added to the temperature at little expense.—H. S. EASTY.

EVENTS OF THE WEEK.—The principal horticultural gatherings of the week will be the Ghent Quinquennial Show, which opens on Sunday next, the 15th inst., and continues open for eight days. It will no doubt attract many British horticulturists, either as exhibitors, members of the Jury, or visitors. On Wednesday, the 18th inst., the Royal Botanic Society will hold their second spring Exhibition in the Botanic Gardens, Regent's Park: and the Newcastle-on-Tyne Horticultural Society will hold their spring Show on the same day.

— **THE GHENT EXHIBITION.**—We have received the following note from Mr. Henry Pearson:—"The continental Manager of the L. C. and D. Railway writes me that through tickets will be issued for Ghent Show from London, via Dover, Ostend, Ghent, Brussels, and Rotterdam to Haarlem, returning via Flushing, Queenborough, to London, at £3 18s. first class, and £2 15s. second class. He sends no rates for return tickets to Ghent." It may be added that travellers, to whom a day in London is an object, can leave Liverpool Street Station, G.E.R., at 8 P.M., arriving at Antwerp the next morning, from which Ghent is about an hour distant by rail. Return tickets between London and Antwerp are—First class £2, and second class £1 4s.; single fare £1 6s. and 15s. respectively. We are informed by a Dutch bulb-grower that the Hyacinths are not in flower in Holland, being unusually late this year.

— **THE WEATHER.**—"B. D." writes from Perthshire—"April 2nd to 9th has been a week of beautiful weather. There has been frost every night from 1° to 9° last night, 8th. The days have been bright and sunshiny, and garden and farm work has been pushed forward." The weather in the south remains very cold, with slight frosts and light occasional showers. There has been no material interruption to work, but vegetation appears at a standstill.

— **LARGE CINERARIAS.**—We said on page 258 if any growers of blooms 3 inches or upwards in diameter, with florets three-quarters of an inch across and overlapping, they would merit and receive recognition. Mr. H. Cannell sends us examples of what he calls his "minia- tures." Some of these equal the dimensions above named, one bloom being 3½ inches across, and the florets of another exceed three-quarters of an inch in diameter. The colours are varied and rich. We observed in Mr. Rivers' greenhouse at Sawbridgeworth last week a plant with blooms 3½ inches in diameter and the florets seven-eighths of an inch across. Mr. Rivers does not sell seed.

— **MR. W. BULLIVANT,** Homewood, Eden Park, Beckenham, writes:—"I notice Messrs. Sutton & Sons sent you a bloom of *CINERARIA*, grown by my gardener, Mr. J. Creswell, and which you were good enough to notice in your Journal. It may be interesting to you and your readers to know that this *Cineraria* was grown in a 6-inch pot, and that there have been fifty-eight flowers on it, many—I should say a dozen—equal to the one you had, and I think some of more perfect colour, and none under 2½ inches across. I have the plant still in my greenhouse, but some of the flowers are not now at their best, and one spray, I am sorry to say, has been broken. I have at present grown by the same gardener a *Dendrobium densiflorum* in full flower, with six racemes, that I am told by two well known Orchid growers are by far the finest they have ever seen."

— "SPERO" writes:—"If any of your readers have tried *FLOWER POTS GLAZED ON THE OUTSIDE ONLY*, would they give their experience of them? I began by trying pots painted on the outside (two coats of Walter Carson's red paint). I liked the plan so much that I am growing plants largely in glazed ones. The gardener so far likes it, and under my instructions is growing two plants of the same kind in the same sized pots side by side. The plants in glazed pots do not require watering so often, and certainly look the best—so far."

— **DESTROYING CRICKETS AND COCKROACHES.**—"J. E. M." writes:—"Procure 1 lb. of treacle and a few jelly pots, then mix some of the treacle with water to the thickness of paint, and fill the jelly pots about a third part. Plunge the pots in fibre up to the top, so that the crickets or cockroaches can easily fall in. The pots ought to be placed wherever the crickets abound most, which is always where there is a warm dry heat. The smell of the treacle seems to have a great attraction for them, as in one night I have seen the pots with as many as the mixture would hold; and when they once get in there is not the slightest fear of their coming out."

— **THE CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION** concluded their winter session on the 4th inst. by a supper and entertainment at the Bolton Hotel, Chiswick, when about thirty members and visitors were present. The officials of the Association, Mr. J. Fraser, Mr. Sidney Summers, and Mr. J. Barry (Secretary) were present, and referred in appropriate terms to the work of the past season, the character of the papers read, and the interest taken in the general proceedings. Mr. G. Gordon, Mr. Bones, and Mr. Daniels, as proposers or responders to various toasts, also noted that satisfactory progress is being made, though a desire was expressed that members would attend the meetings more regularly as an encouragement to those who contribute papers. Several capital songs were sung by Messrs. Barry, Cook, Cannon, and others, and a very pleasant evening was spent.

— **WAKEFIELD PAXTON SOCIETY.**—The Committee of the above Society have unanimously decided to recognise the able services rendered to the Society by Mr. Herbert Chapman, who has acted as one of the Secretaries for a term of six years, by presenting him with a student's microscope. It was also resolved that an appeal be made to the members of the Society for subscriptions to defray the whole of the cost of this testimonial. The microscope will be presented to Mr. Chapman at the annual dinner, to be held shortly. The following is the programme of meetings for the first quarter, session from the present date, some having been held during March, at the Society's Rooms, "Saw Hotel," Westgate, each Saturday evening at eight o'clock:—April 14th, "The Fringe of Life," being an exposition of the lowliest forms of animals and plants, Mr. Henry Crowther, Manchester. April 21st, "Plants Suitable for Entrance Hall and Room Decoration," Mr. T. R. Preston. April 28th, "Garden Literature, Past and Present," Mr. W. K. Woodcock, Sheffield. Sale of Periodicals. May 2nd, "The Auricula," Rev. F. D. Horner, Kirkby Lonsdale. May 5th, "The Daphne," Mr. J. Smith, Leeds. May 12th, "Some Peculiarities of Climbing Plants," Mr. T. Garnett. May 19th, "The Peach and Nectarine," Mr. Atkin, Clayton West. May 26th, "The Tulip," exhibition and discussion. Sale of periodicals. The Hon. Secs. are Messrs. Geo. W. Fallas and T. Garnett.

— AN interesting experiment in **PLANTING WASTE SALINE** tracts in India has been carried out by Mr. Maries, Superintendent of the Gardens of the Maharajah of Durbhunga. "The results," says *Nature*, "have been communicated to the Agricultural Department, Bengal, and are contained in the last report of the Director. Mr. Maries says that six years ago, when he went to Durbhunga, he did not know what to do with patches of saline soil, on some of which not even weeds would grow. He dug the soil to a depth of 2 feet, and planted it thickly at the commencement of the rainy season with trees which had been grown in pots till they were about 3 feet high. In three years the ground was filled with roots, and to all appearances the salt had gone. When the trees were thinned out last year, leaving only the best, the ground was found to be in good condition. Similar experiments have been carried out in other places, and now Mr. Maries has splendid Plantains growing on soil which a few years ago would not even grow a weed. He employed various kinds of trees in his reclaiming operations, but he says that the best were the Inga Saman, or Rain Trees, and the *Albizia procera*. The former is valuable as producing an enormous quantity of surface-feeding roots, and these decaying yearly leave a rich vegetable deposit on the soil. The trees soon completely change the character of

the soil. The timber is excellent for fuel, and the trees bear lopping well. It is such an enormous water-absorber that it would most probably be very useful in swampy places as a fever preventive, like the Willow, which is planted in China around the villages in the Riee districts."

— A **WEeping RUSSIAN MULBERRY**.—An American paper gives an illustration from a photograph of a specimen seedling Russian Mulberry, raised by J. J. Measer, Reno County, Kansas, and remarks that "The tree, which is growing on its own roots, came up together with a large number of seedlings and attracted attention by its graceful drooping habit, which distinguished it from all others. When one year old it was transplanted and cut off close to the ground, and in its second year it was trained to a single stem. From that time till now—its fourth year—it has received but little care. Its fruit and general character are those of the common Russian Mulberry, and having survived a temperature of 20° to 22° below zero it may safely be termed 'hardy.' It is a rapid grower, bears almost any amount of pruning or cutting back, and makes a desirable lawn tree. To grow the Russian Mulberry in tree form the lower branches have to be cut off, else it will become shrubby, as grasshoppers and other insects feed upon the tips of the young shoots." In the engraving the tree closely resembles a Weeping Ash, the long slender branches drooping to the ground, totally different from the ordinary Mulberry.

— AT the ordinary meeting of the **ROYAL METEOROLOGICAL SOCIETY**, to be held at 25, Great George Street, Westminster, on Wednesday, the 18th instant, at 7 P.M., the following Papers will be read:—"Jordan's New Pattern Photographic Sunshine Recorder," by James B. Jordan. "On the Meteorology of South-Eastern China in 1886," by William Doberck, Ph.D., F.R.Met.Soc. "Lightning in Snowstorms," by Prof. A. S. Herschel, M.A., F.R.S. "Insolation," by Rupert T. Smith, M.Inst.C.E., F.R.Met.Soc.

— THE following **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS**, for March, 1888, have been received from Mr. Joseph Mallender:—Mean temperature of month, 37·7°. Maximum on the 9th, 57·6°; minimum on the 24th, 25·2°. Maximum in the sun on the 27th, 106·8°; minimum on the grass on the 24th, 15·1°. Mean temperature of the air at 9 A.M., 37·0°. Mean temperature of the soil 1 foot deep, 37·6°. Nights below 32°, in shade, nineteen; on grass, twenty-four. Total duration of sunshine in month, 71·5 hours, or 20 per cent. of possible duration; nine sunless days. Total rainfall, 2·48 inches. Rain fell on eighteen days. Average velocity of wind, 12·7 miles per hour. Velocity exceeded 400 miles on nine days, and fell short of 100 miles on one day. Approximate averages for March:—Mean temperature, 41·8; rainfall, 1·61 inch; sunshine (seven years) 104 hours. A very cold month with a good deal of snow. The mean temperature is lower than any previous year except 1883. Rather more rain than in any year since 1877, and the first month since January, 1887, that the fall has exceeded the average; less sun than any of the last seven years.

— THE **LATE MR. JOHN HOLLINGWORTH**.—"D., Deal," sends the following note:—"Amongst those who have succumbed to this terribly severe winter we have now to reckon my very dear and valued old friend, Mr. John Hollingworth, of Turkey Court, Maidstone, the doyen of Rose growers, and one of the most enthusiastic lovers of the flower that I ever knew, and, more than that, one of the tenderest hearted and most generous of men, one whom his native town will terribly miss, for his hand was ever open, and his most liberal gifts to his noble parish church testify to the love that he bore to the church of which he was a member, and the pride which he took in the splendid building which adorns his town. Some years ago I gave a short notice of my visit to his garden, and in it spoke of the two brothers so deeply attached to one another, and so ready in every good work. Since that time age had told upon him, or, as he said in a letter to me some time ago, "Old man has got a strong hold of me,"—and then, at last, somewhat suddenly the end came. How he will be missed by hundreds who were the recipients of his kindness no one knows, for the two brothers were men who, while not suffering a false modesty to withhold their names where it might be of use to do so, yet "did good by stealth." I often wonder whether Charles Dickens had them in his mind when he drew the character of the Cherryble Brothers, but there was much that often reminded me of them in my good friend. In his nephew, Colonel

Pitt, who will, I believe, ultimately succeed to Turkey Court, we have, I am glad to say, a thoroughly good rosarian, and one who will, I think, keep up the old traditions of the place."

— THE quarterly meeting of the **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY** was held on Monday evening last, April 9th, at the Caledonian Hotel, Robert Street, Adelphi Terrace, Strand. Mr. E. Berry in the chair. The Committee are glad to say that the number of members still continue to increase, twenty-four new members having been elected during the quarter, making a total of 250 benefit, and thirty honorary members, including two life members. The Committee earnestly hope that many more gardeners and persons connected with horticulture generally will avail themselves of the opportunity of joining this excellent Society. A copy of the rules will be sent to any address for six stamps on application to the Secretary, W. Collins, 5, Martinhoe Terrace, Martindale Road, Balham, S.W.

— THE death has been recently announced of **MR. AUGUSTUS MONGREDIEN**, which took place on March 30th, at Forest Hill, in his eighty-second year. He was the author of "Free Trade and English Commerce," and "History of the Free Trade Movement in England." He also published a number of works of a more general character, including "The Western Farmer of America," "England's Foreign Policy," and a treatise on "Trees and Shrubs for English Plantations." In 1878 Mr. Mongredien published a work in three volumes, entitled "Frank Allerton: an Autobiography." He established a nursery at Ascot, and an experimental farm at Bratton Clovelly, and engaged at one time rather extensively in the cultivation of the Ailantus, with a view to the promotion of silk production in this country, but was unsuccessful.

AMARYLLISES AT CHELSEA.

THE weather this season has been very unfavourable to the development of plants of all kinds under glass, and the flowering period of many has been greatly retarded. This has been the case with the Amaryllises in Messrs. J. Veitch & Sons' nursery, King's Road, Chelsea, which are fully a fortnight later than usual; but ample compensation for the delay will be derived by visitors during the present and following weeks. These plants invariably form one of the most brilliant of numberless attractions at the famous Chelsea nursery, and the wonderful progress made with them in recent years has been frequently recorded. Every season novelties of exceptional merit and distinct characters have been obtained, and the limits to the range of variation are evidently not yet reached. When taken in hand Amaryllises had small flowers with thin narrow petals and star-like shape, and the first efforts were directed to improving the form and increasing the size of the flowers. This was soon accomplished, and having secured a good foundation to work upon, the colours came in for consideration next with equally satisfactory results. Breaking away from the stereotyped shades, rich tints in crimson, scarlet, and rose have been secured, fading through delicate blush tints to white, and still further diversified by a charming reticulation in scarlet or crimson on a white ground, or relieved by bold bars of white through the centre of the petals. Grand massive flowers are now obtained that produce a magnificent display, the colours being almost dazzling, and the rich green foliage produced with them in many cases is valuable as a foil.

The span-roof house in which the Amaryllises are grown and flowered has been repeatedly described, but it may be mentioned that there is a wide centre bed and two narrow side beds. The former containing 1044 flowering bulbs in pots, and the latter some 2000 younger bulbs, some of which have, however, reached the flowering stage. Over 1500 spikes are borne by the bulbs in the centre, and as these have mostly three to four flowers each there is a total exceeding 4500 of these grand flowers either expanded or rapidly advancing. As Messrs. Veitch and Sons are equally as successful in the culture of these plants as in raising new varieties a few remarks on the system adopted may be useful. The bulbs raised from seed flower in about three years, though when planted out in beds they have been known to flower in nineteen months, but this is quite an exceptional occurrence. They are potted in the middle of January in a compost of good turfy loam, old cow manure, and silver sand, and the pots are plunged in a bed of old tan. The bulbs are a little more than half buried in the soil, pots being employed proportionate in size to that of the bulbs, but care is exercised to avoid employing too large pots. No water is supplied until about the end of February, when the flower spikes or growth are seen to be starting. A temperature of 55° to 60° is then maintained, and a little bottom heat is afforded by pipes under the bed. Growth advances in most cases with the flower spikes; in some instances, however, the latter develop fully before the foliage, and the flowers last about six weeks, and when they have been removed from the plants the growth is encouraged as much as possible; a layer of tan is placed over the bulbs, and the roots spread strongly into this both from the base and over the top of the pots. Free ventilation is afforded during the summer and autumn months with a little shade from the hottest sun, and from the middle of August until the end of February no water is supplied to the plants, the bulbs thus

being well ripened, a most important point in the cultivation of Amaryllises. In few gardens can houses be specially devoted to these plants, but they are not essential, as similar treatment can be afforded in other structures, and some are very successful with them in vineries.

All the varieties raised at Chelsea have distinctive merits, and any of those that have been named in the past four or five years are worth a place in the best collections, but the following novelties, nearly all flowering for the first time this year, are remarkable additions to the finest yet obtained, and will find many admirers.

Conqueror.—A superb variety with handsomely formed flowers, broad rounded petals, dark scarlet, with well defined star, the central white bars extending half way up the petals. One of the best.

Rodney.—Flower of good size and excellent shape, the petals nearly all of equal size, rounded scarlet, broad white central bar, and few veins. A very pretty variety.

Finette.—Medium size neat flower, even spreading petals, white, the three upper ones with a few scarlet veins in the centre and near the base, the lower central petal pure white.

Acquisition.—A grand variety, handsomely formed flowers, outer petals $3\frac{1}{2}$ inches across, flowers 8 inches in diameter; petals rounded, bright scarlet, with pure white central bars running to the apex in the outer ones and half way in the inner petals.

Ariel.—Very strong, large flowers, two spikes of four flowers each; light salmon scarlet, with darker veins and white central bar.

Chevalier.—An immense flower; petals $3\frac{1}{2}$ inches across, bright scarlet, pure colour. Very effective, bold variety.

Sims Reeves.—Medium size flower of remarkable colour, extremely rich dark crimson and dark veins, narrow white central bar; two spikes, one with four flowers expanded.

Vivian Grey.—Flower very large, $8\frac{1}{2}$ inches in diameter, broad flat petals, light clear scarlet. Handsome variety.

Hazledon.—An extremely distinct colour, quite a maroon purplish crimson, slight whitish tip; flower of medium size, neat form. A capital novelty.

Phadria.—Very large flower, broad round petals, white ground freely veined with scarlet, white central bars.

Chieftain.—A magnificent variety, flowers $8\frac{1}{2}$ inches across, open, bold, broad petals, excellent shape, rich reddish scarlet.

Franklin.—A grand flower in the style of Vivian Grey, but darker scarlet.

Terentian.—Large flower, dark scarlet shaded, greenish centre and bars, dark veins.

Catiline.—A delicately coloured fine flower, large, salmon red, a clear white central bar in each petal, well defined, and scarlet.

Mims.—A handsome variety, large well-formed flowers, broad rounded petals, light scarlet veins and edge, pure white bars and centre. A charming novelty.

Faust.—An exceedingly beautiful variety, very large flower, well expanded, petals nearly equal in size, bright scarlet crimson, veined towards the centre of the petals, in each of which there is a pure white well defined white bar, most distinct and bold.

Julius.—Flower well proportioned, reticulated scarlet on a white ground, white central bar in outer petals.

Kingwood.—Flower of medium size, neat in shape, scarlet with darker veins near white central bars.

Antipho.—Quite a novelty, white or blush tinted, speckled with purple from the base. This will probably originate a new race.

Princess Irene.—A well formed flower with broad petals, scarlet with white central bar.

Zephyr.—A distinct novelty; flowers open, broad petals, good shape, white with crimson veins, and light central bars. Two spikes of four flowers each.

Albertus.—Bright scarlet, white central bars, neat form.

Coneilla.—Dark scarlet, recurving petals, white centre. Showy.

Landseer.—Flowers of great size, rich scarlet to the centre. Very handsome.

Amongst the other varieties that have been described in previous years the following deserve prominent notice for their excellent qualities:—Empress of India, Her Majesty, Cato, Ptolemy, Sir Garnet Wolseley, Southey, Star of India, Bellona, Crown Princess of Germany, Hygiene, Lady Musgrave, and Othello—a very good selection to start with.

CUCUMBERS AND TOMATOES IN THE SAME HOUSE.

To those not thoroughly acquainted with them Cucumbers and Tomatoes show much of the same character in habit of growth. Cucumbers are often trained up wires in pits like Tomatoes, and it no doubt leads many to suppose that they may be grown in the same house, but this cannot be done satisfactorily, especially in the spring months. Cucumbers throughout March, April, and May delight in a good heat, 65° or 70° at least, a close atmosphere, and plenty of moisture. Tomatoes also like a similar temperature, but not a humid atmosphere or syringing. The deformity of many fruits may be traced to water having been placed on the flowers when open. Water at the roots they will take in abundance, but the less applied to the foliage and flowers the better. Cucumbers will succeed with very little ventilation, but Tomatoes can hardly have too much, and they are always most prolific where the air is freely admitted. We find early Tomatoes succeed admirably on the back shelves of vineries and Pine houses where the lights are opened, but in low close Cucumber pits they make very long-jointed wood and form few fruits. I would undertake to

obtain more fruits from two plants in pots on the back shelf of a vinery than from half a dozen plants in a Cucumber pit. If a pit is too large for Cucumbers run up a temporary division, grow the Cucumbers in the warmer and closer end and the Tomatoes in the other. I know the idea is tempting in span-roofed houses to have Cucumbers on one side and Tomatoes on the other, but the one or the other must suffer, and the division plan is the one to adopt. During the warm summer months, when Cucumbers will grow in airy pits, the Tomatoes may be their companions, and they will succeed, but it must be June, or July, before the same conditions will be found to suit them both.—J. M.

UTRICULARIA RHYTROPHYLLA.

THE Bladderworts are represented by a few species of really horticultural value, and amongst the most notable must be ranked the

Fig. 39.—*Utricularia rhytrophylla*.

recently introduced *Utricularia rhytrophylla* (fig. 39). The somewhat peculiar specific name is apparently derived from a Greek word referring to the long, narrow, strap-like leaves, but the chief character of the plant rests in the flowers. These are large, of a fine purplish hue, with an orange-coloured projection at the base of the broad rounded, lip-like portion, and are borne in slender graceful racemes from the base of the plant. It thrives well in small baskets of peat and sphagnum suspended from the roof of an intermediate Orchid house.

PACKING PEACHES.

HAVING tried nearly every method of packing Peaches for transit which we have seen advised we cling to an old system as the best, and frequently the parcels have been subjected to very rough treatment. Probably sending fruits by parcel post is the most severe test to which they can be submitted. Except Strawberries, forced and from the open

ground, we seldom risk tender wares through the post office. The method now adopted in transmitting Peaches, which has always proved satisfactory, and by a proper arrangement to have the packing material returned, little expense is incurred. Firstly, we have boxes of wood or tin in sizes which hold from a dozen to three dozen fruits, and about 2 inches deeper than good sized fruits. Over the bottom is placed a thin layer of fine paper shavings, moss, or hay, the latter silky and soft as wool, but the shavings being easily procurable they are the most often in use. On this a sheet of wadding is then pressed firmly with tissue paper spread evenly over all to prevent the fruit receiving any bad effects from it. Pieces of wadding about 2 inches wide are cut, also as long as will wrap round the largest Peaches. The pieces of wadding are neatly encased in tissue paper, forming bands which encircle each fruit (the tops and bottoms of the fruits are not covered), placed as tightly as the condition of the fruit will allow. A sheet of tissue paper is placed over the fruit, and another sheet of wadding over that. The lid fits evenly over all, so there is no shifting of the fruit, which is sent off before quite ripe. When the lid is removed with the wadding and the sheet of paper all the fruits are half exposed. They can be unpacked with great ease, or may remain in the box until they are used, just in the same manner as they are exhibited in baskets in fruiterers' windows for sale. The bottom layer of package we often allow to remain undisturbed for weeks. After each box is relieved of its load of fruit the strips of wadding remain inside, and are ready for future consignment. We have had lessons at Covent Garden on fruit-packing, and adhere more or less to our earliest tuition. We noticed on an obscure street in Liverpool a basket of Peaches for sale, packed as above described, which might have been a good lesson to some exhibitors we saw unpacking at a great show.—M. T. C. H.

JUDGING WELL-KNOWN FRUIT BY APPEARANCE.

SIR C. W. STRICKLAND is quite right in saying that the quality of known varieties of both Apples and Pears may be first-rate one year, and perhaps indifferent the following year. This is the experience of fruit growers generally when a bright and warm summer and autumn are followed by seasons the reverse of these, the fault being attributable to the climatic conditions under which the fruits were grown, and not to the apparent fickleness of admittedly good and well-tested varieties. If the inconstancy of the Beurré Bose Pear mentioned is not occasioned by the circumstances indicated, then to what cause must the fact of his fruit being sometimes of fine quality, and sometimes fit only for stewing be attributed, always assuming that the tree from which the fruit was gathered received the same cultural treatment? Sir C. W. Strickland says, "If the object of judging fruit at shows be to promote quality in fruit, and not sham and show, I do not see how it is to be done without tasting fruits." Has not the quality of all the best varieties of fruits shown in competition for prizes been determined years ago by eminent pomologists, the quality of some being settled, perhaps, in the manner indicated? Therefore, assuming that the gentlemen who make the awards are thoroughly acquainted with the quality—the established quality—of the several varieties which they have to judge, all they have to do is to give the prizes to the finest examples of properly ripened fruit, the process of cutting and hacking the fruit not being necessary. A survey of the fruit tents of a well-known west of England Show, where the disfigurement of Peaches, Apples, Pears, and Plums is tolerated by the Committee, and practised by the local judges on the plea of testing flavour is not agreeable to the exhibitors nor edifying to the public, and it is highly distasteful to gentlemen to whom the mutilated fruits belong. In conclusion, I may say that the quality of all fruits worthy of being cultivated in this country having been carefully settled, the object which show committees have in view in offering prizes to be competed for at their shows is to encourage the culture and staging of the finest ripe specimens of the respective high quality fruits, and the prizes being awarded to the largest and handsomest fruit, nobody need feel that these are produced at the expense of flavour.—H. W. WARD.

SIZE VERSUS QUALITY.

THE minority of cases where such handsome Lady Downe's are met with as were staged in the any other black Grape class at the Crystal Palace last September is far more important than a majority of such Muscat Hamburgs that were staged in the same class. Had they been competing for flavour alone, the results might have been different; but when better cultivation has to be considered, as it no doubt was in this instance, alters the ease materially, and makes the verdict, in my opinion, a correct one. I may save Mr. Ward trouble if I say that I have exhibited worse coloured Muscat Hambourgh as well as better, but the bunch and berry have been double the size, and the bunches quite as compact; therefore I consider the term "moderate" correctly applied in my note on page 82 when alluding to the Muscat Hambourgh at the Crystal Palace. I am curious to learn how these cutters and tasters of fruit manage the home dessert. I guess they have to trust the eye in common with the rest of us, and if they will only cultivate the eye, it can be made almost as reliable as the palate, and can be as safely trusted at shows as at home.—J. H. GOODACRE.

ACACIA CULTRIFORMIS.

SEVERAL of the Australian Acacias are little known in gardens, though they are useful and distinct plants for greenhouses, and mostly flower

profusely in the spring months. One of the rarer species—namely, *Acacia cultriformis* (fig. 40), was recently exhibited from the Royal Gardens, Kew, and is peculiarly distinct from most of those with which cultivators are familiar. It has flat, somewhat triangular, silvery white phyllodes, and racemes of small, globular, bright yellow flower-heads freely produced along the branches, and when a good sized specimen is in flower it has a very remarkable appearance. An example of this kind may be seen planted out in the Winter Garden at Kew, where an extremely large collection of Acacias is grown. In pots, plants of moderate size flower readily, requiring a compost of peat and sand, with the same care in the supply of water as is needed for hardwooded

Fig. 40.—*Acacia cultriformis*.

plants. During the past few weeks some of the florists' shops in Covent Garden Market have displayed bunches of *Acacia cultriformis* apparently obtained, with others now in demand, from continental growers.

OUR COMMON WHITE BUTTERFLIES.

FROM talks with gardeners, I find that some amount of ignorance, or at least confusion of ideas, prevails regarding the habits and economy of our two very familiar and abundant white butterflies. As the season is fast approaching when the first flights of these insects will be appearing, it may be of utility to outline the chief facts of their history. It should be premised that of all our British butterflies only these two can be accounted seriously destructive to cultivated plants. A few other species have been referred to as possibly injurious some seasons to certain plants, but they are seldom abundant, or else they usually prefer a different food. Others are now scarce, the black-veined white (*Pieris eratrægi*), for instance, still common upon Hawthorn on the Continent, and

which has occasionally visited the Apple. It was undoubtedly found around London during last century. For a good while it was supposed that the pretty little green-veined white (*P. napi*) laid its eggs on Cabbages, but Newman and other observers have proved that it seldom seeks these, preferring such wild Crucifers as the Hedge Garlic and Winter Cress.

In the month of March both the species under consideration—viz., the cabbage or large white (*Pieris Brassicæ*) and the garden or small white (*P. Rapæ*) are in the dormant condition of their chrysalis life. This endures from the autumn until spring without exception. I have never discovered caterpillars of either during the winter season on Brassicas or any plants, though I have often been shown ravages attributed to them; which turned out on examination to be the work of some *Noctua* caterpillars, hiding under the soil by day, or else the effect of numerous juvenile slugs. The chrysalids or pupæ of these butterflies being always exposed to the air through the colder months, on walls, fences, trunks of trees, and the like, are necessarily subject to atmospheric influences, but even hard frosts do not hurt them. They will chink against glass like little stones, and yet emerge in due time. Damp winters are possibly prejudicial. So far as my observations go, the insect-eating birds seldom devour these chrysalids. Parasitic foes largely help to reduce their numbers, specially one insect, a small fly, which having pierced a caterpillar deposits a host of eggs; the maggots feed up and form a cluster of tiny yellow cocoons after the chrysalis has been fastened to some object. These are frequently noticed, and sometimes supposed to be the caterpillar's "eggs." Another fly waits till the chrysalis state is entered and then covers the helpless insect with its tiny eggs, from which issue a hundred or more maggots. A good many of these chrysalids escape, of course, but they should be looked for and removed by the gardener whenever seen. It has been stated they are sometimes buried; this can rarely be the case. I have seldom found them even on low stems or stalks.

The first to appear on the wing is the small white (*P. Rapæ*), which might be, indeed, regarded as a pleasant pioneer of the spring, were it not that the progeny of this butterfly is so unwelcome a visitor to vegetables and flowers. Scarce near London for some years, owing to the building over market garden ground, which cut off its supply of food, it has again become a cockney insect since numerous churchyards and vacant plots have been brought into cultivation. Casuals which arrived found an abundance of Wall-flowers, Rockets, Nasturtiums, and the like, which attracted them nearly as much as culinary plants, and their numbers have increased since. (I have occasionally taken the caterpillar of this white off *Pelargoniums*, but it is not partial to that group of plants). The eggs are laid singly, as a rule, so are not easily detected upon the varieties of Cabbage, Mustard, and Turnips, the plants above mentioned, and others, during April. This caterpillar is distinguished from its larger relative by its greenish velvety appearance and its lack of black blotches. It has three yellow lines along the body, and this is studded with clubbed hairs resembling minute pins. From its liking to bury itself in hearted Cabbages it has been called the "heart worm." This is not the practice of *P. Brassicæ*, which is also more limited in its choice of food than *P. Rapæ*. This spring brood of *P. Rapæ* may be adult in three weeks or a month, perhaps sooner, should the weather be warm, and then follows another emergence of butterflies in or about July. To these succeed August and September caterpillars to produce the next year's insects. But some years there are doubtless more than the two broods, and probably, from April to the end of autumn, there is scarcely a day when one might not detect either the caterpillar or butterfly somewhere in the garden. Picking this pest from plants is tedious work, but it may be diminished by a variety of washes or dressings. Few applications, indeed, prove better than water alone, which, if used liberally, brings the caterpillars off their food, and sets up a disease which kills them.

On the whole, I consider the large white *P. Brassicæ* the more destructive insect of the two, although it comes out later, the butterflies of the first brood being usually on the wing in May. Their eggs are laid during that month on Cabbages of all kinds, now and then on Mustard or Turnip, and as a rule not singly, like those of *P. Rapæ*, but in small batches of ten to twenty. These hatch in about a fortnight, the caterpillars feed nearly a month with the next or summer brood, the change goes on more rapidly. They are of a bluish green marked with black, the skin is rather rough and hairy. If alarmed they bend head and tail, forming a half-circle, and fall to the ground, which the caterpillars of the small white never do. The dexterity with which they find their way back to the spot they have left is amusing. Another peculiarity in this species is that the caterpillars have a very disagreeable smell. Soon after midsummer we discover the chrysalis on walls and palings. The summer butterflies are, or seem to be, more abundant generally than the spring flight. The second batch of caterpillars

must be sometimes at least followed by a third, as I have taken quantities of them in October or a week or two later. Both these butterflies possess the peculiarity of making migrations in parties for long distances. There are undeniable instances of their coming over to us from the coast of France.—ENTOMOLOGIST.

ROYAL HORTICULTURAL SOCIETY.

APRIL 10TH.

THE supporters of this Society are evidently determined that the meetings of the Committees in the new quarters shall not diminish in interest, and efforts are being made both by amateurs and nurserymen to add to their attractions. The second gathering in the Drill Hall, James Street, Victoria Street, on Tuesday last was as effective and varied as could be wished; but it was unfortunate that the weather continued so cold and unseasonable, for it undoubtedly prevented many visitors attending. During a good portion of the afternoon the Hall had a somewhat deserted appearance, but brighter days and warmer weather will, it is hoped, bring larger attendance at subsequent meetings.

The exhibits on Tuesday were confined exclusively to plants and flowers; no fruits or vegetables were submitted to the consideration of the Fruit Committee, an exceedingly rare occurrence. A somewhat different arrangement was adopted this time, one broad table extending nearly the whole length of the Hall in the centre, with two other tables near the side walls, and one across the Hall at the end. This allowed ample space for inspecting the plants, and also had a rather better appearance. The central table was devoted to groups and novelties, Messrs. Veitch & Sons' *Amaryllises*, Mr. B. S. Williams' select stove and greenhouse plants, Messrs. Paul & Son's and H. Lane & Son's *Roses*, Mr. Pollett's choice *Odontoglossums*, a collection of interesting plants from Kew, and Mr. C. Turner's new *Carnations* constituting the leading features. Upon the side tables were displayed extensive collections of *Daffodils* in endless variety from Messrs. T. S. Ware, Barr & Son, and Collins Bros., with grand *Cinerarias* from Mr. J. James, Ferns from Mr. H. B. May, and *Cyclamens* from Mr. W. Clay. The end table was occupied with a group from Messrs. Rothschild, Gunnersbury Park, in which Mr. Roberts had a series of admirable plants of the exquisitely fragrant *Rhododendron Lady Alice Fitzwilliam*. Besides these were several special smaller exhibits that are mentioned in the following notes. Thirteen plants were found worthy of first-class certificates, including five handsome *Amaryllises*; three cultural commendations were awarded and eleven medals.

FLORAL COMMITTEE.—Present: Rev. W. Wilks in the chair, and Messrs. W. Goldring, W. Wildsmith, B. Wynn, H. Herbst, J. Fraser, G. Nicholas, W. H. Lowe, G. Duffield, C. T. Drury, R. Dean, W. Holmes, G. Paul, T. Baines, C. Noble, H. Ballantine, J. Dominy, A. M. Pollett, A. J. Lendy, J. O'Brien, E. Hill, Shirley Hibberd, J. Walker, and Dr. M. T. Masters.

The group of plants from the Royal Gardens, Kew, chiefly comprised *Narcissi* and *Primulas* in pots from the new hardy plant house, where such an interesting display is now provided. Very notable were plants of *Narcissus triandus* and its variety *albus*, the latter a charming *Narciss* for pot culture, with drooping creamy flowers having bell-like coronas. The small bright golden flowers of the graceful *N. rupicola*, and the still more slender *N. juncifolius*, received special attention. Of the *Primulas* the chief were the purplish *P. pubescens* and *P. viscosa*, together with the pretty white variety of the former, which is seen under so many names in gardens. *P. marginata cœrulea* with large pale purple flowers and white-edged leaves was also shown, and the yellow *P. Palinuri*. From the winter garden in the same establishment came large heads of the handsome *Rhododendron Falconeri*, having sulphur coloured, large, bell-shaped flowers, and *R. grande var. roseum*. A small plant of *Asystasia*, or *Maekaya*, bella from the greenhouse was bearing numbers of its lilac-veined flowers, and a group of similar small specimens in the house named is one of its most pleasing features at the present time. A large flower head of the old *Cineraria cruenta* with small mauve blooms was interesting in contrast with the Farnham Royal varieties on the opposite side of the Hall.

Messrs. Rothschild, Gunnersbury Park, Acton (gardener, Mr. Roberts), contributed a group of miscellaneous flowering plants and Ferns, with six even globular plants of *Rhododendron Lady Alice Fitzgerald*, well known as an excellent early-flowering variety, with large pure white flowers possessing a powerful and agreeable fragrance. A silver-gilt Banksian medal was awarded for this exhibit.

A tastefully arranged group of choice *Odontoglossums* and Ferns from H. M. Pollett, Esq., Fernside, Bickley (gardener, Mr. Parks), was worthily accorded a silver Banksian medal. The plants were all unusually healthy specimens, and the varieties, too, were some of the best, especially of such beautifully spotted types as *O. Ruckerianum* and *O. Andersonianum*, several of which had two racemes each. A remarkably vigorous specimen of *O. Wilckeanum* had five strong racemes. The beautiful *O. Sanderianum* was admirably represented by a plant with two long racemes of white-lipped flowers; *O. Schillerianum*, *O. scptrum*, and *O. prænitens* forming other noteworthy plants in the group. F. G. Tautz, Esq., Studley House, Hammersmith (gardener, Mr. Cowley), showed a plant of *Cypripedium Mastersianum*, a curious but not beautiful form, with a short broad green dorsal sepal and brown smooth petals and lips (vote of thanks.)

Mr. R. Ballantine, The Dell Gardens, Egham, showed a strong plant of *Cattleya Bluntii*, having four large pure white flowers, except a faint

tinge of yellow in the long lips (cultural commendation). This charming rare white *Cattleya* is regarded by some as a variety of *C. Mendeli*. It was introduced a considerable time ago by Messrs. Low & Co., named after the collector, Mr. Blunt, and first flowered by the late Mr. John Day at Tottenham, but was not certificated until shown by Messrs. Sander & Co. at the Orchid Conference, May 12th, 1883.

Lady Selborne, Blackmoor, Petersfield, sent well flowered stems of *Dendrobium nobile* (vote of thanks). Mr. F. Ross, Pendell Court Gardens, Bletchingley, showed large heads of the brilliant red *Brownia coccinea*, and flowering growths of the orange-coloured *Bignonia Tweediana* (certificated). W. Cobb, Esq., Silverdale, Sydenham (gardener. Mr. F. Cooper) sent a strong plant of a dark rosy coloured variety of *Odontoglossum vexillarium*, named *Fredericki*, having eight fine racemes (cultural commendation). Mr. Davidson, The Gardens, Iwerne Minster, Blandford, showed three trusses of *Imantophyllum*, said to have been "raised from seed gathered in South Africa eight years ago." The flowers were large and of good colour. W. Clay, Esq., Grove Road, Kingston, contributed a group of over 100 well grown *Cyclamens* (bronze Banksian medal); and W. Roupell, Esq., Harvey Lodge, Roupell Park, had a collection of seedling *Alpine Auriculas* (vote of thanks).

Chionanthus virginicus, from Messrs. Veitch & Sons, Chelsea, was represented by a number of plants 12 to 18 inches high in 32 and 24-size pots. They were compact little bushes worked on stout stems or roots, and bore numerous drooping panicles of white flowers with long linear white petals much resembling the Manna Ash, *Fraxinus Ornus*. It is related to the *Fraxinus*, being a member of the Olive family, and is sometimes popularly termed the Snow-flower (a literal translation of its Greek name). The tree is known and admired in some English gardens, but is rarely seen as a forced plant, though it is evidently well adapted for this treatment (cultural commendation). Messrs. Veitch & Sons also showed a basket of plants of the graceful and useful little shrub *Spiræa confusa*, which can be forced so readily and yields abundance of its pure white flowers in neat compact umbels. Flowers of *Iris reticulata* and several good *Daffodils* together with a group of *Amaryllises* were included in the Chelsea contribution.

A handsome group of Orchids and novelties from Mr. B. S. Williams, Upper Holloway, secured the award of a silver-gilt Banksian medal. Several fine *Amaryllises* were included in this group, one of which, Emperor Frederick, was awarded a first-class certificate, and others, such as Empress of India, one of the most useful varieties grown, had two spikes of four flowers each. Amongst the Orchids was the peculiar *Dendrobium Smillie*, which has white, pink, and green-tipped flowers clustered at the apex of stout leafless pseudo-bulbs (vote of thanks). Messrs. Paul & Son, Cheshunt, showed a large group of *Roses*, *Amaryllises* and other plants (silver-gilt Banksian medal). Messrs. H. Lane & Son, Berkhamsted, sent some well grown *Roses* in pots, securing a similar award, as also did Messrs. J. James & Son for their magnificent *Cinerarias*, which have been noted before this season.

The remarkably fine collection of choice *Daffodils* and hardy flowers from Mr. T. S. Ware, Tottenham, had their merits recognised by the award of a silver-gilt medal. A smaller group of *Daffodils* from Messrs. Barr & Son, Covent Garden, gained a silver medal, a similar honour being adjudged to Messrs. Collins Bros., & Gabriel, Waterloo Road, for a group of *Daffodils*, and a bronze medal was awarded to Mr. H. B. May, Edmonton, for a collection of Ferns.

Messrs. Parker & Son, Bristol, exhibited some extremely vigorous plants of *Mignonette*, Parker's variety, with large heads of flowers (cultural commendation). Messrs. Hugh Low & Co., Clapton, sent plants of *Boronia megastigma*, and two varieties named major and floribunda, but the differences were not very striking. Messrs. Backhouse & Son, York, exhibited specimens of *Alyssum pyrenaicum*, dwarf-tufted with numerous white flowers, and P. Allioni with small purplish flowers. Mr. T. Bunyard, Ashford, sent flowers of a late *Chrysanthemum* with deep red flat florets, something after King of the Crimson style.

CERTIFICATED PLANTS.

Amaryllises Conqueror, Finette, and Rodney (J. Veitch & Sons).—Certificates were awarded for these fine varieties, which are described on page 300, and also the following not there noted.

Amaryllis Miss Roberts (J. Veitch & Sons).—One of the best-shaped varieties yet raised, very smooth and even. The petals broad, rounded, nearly equal in size, with a central white bar, and veined with bright red on a light ground.

Amaryllis Emperor Frederick (B. S. Williams).—A bold effective variety; flowers of great size, petals very broad, of a brilliant scarlet colour. Strong in habit, the spike having four flowers.

Selaginella cuspidata crispa (B. S. Williams).—A neat tufted variety with fronds 3 or 4 inches long, finely divided, slightly crisped, and dark green. Excellent for pot culture.

Bignonia Tweediana (F. Ross).—A climbing plant, with opposite leaves, each having a pair of narrow green leaflets. Flowers rather suggestive of an *Allamanda*, with a tube 3 inches long, and a flat spreading limb 3 inches in diameter of a bright orange colour.

Carnation Purple King (C. Turner).—A tree variety of the Clove type, strong in habit, very free, with large full flowers powerfully fragrant, and of an extremely distinct rich purple hue. An excellent novelty.

Carnation Mrs. W. H. Grenfell (C. Turner).—Another Tree *Carnation*, a rival to *Miss Joliffe*, of good habit and most floriferous. The flowers are of moderate size, but capital form, and of a delicately beautiful salmon tint. A charming variety, certain to become a favourite.

Rosa polyantha grandiflora (Paul & Son).—This is regarded as an improvement on the old single white *R. polyantha*, and is a novelty of the present season. The flowers are 2½ inches in diameter, pure white with large petals; it is free and looks well in a pot trained in globular form.

Iris stylosa alba (T. S. Ware).—A pure white variety with large flowers of a well-known favourite *Iris*.

Cineraria Marie (James & Son).—One of the handsome Farnham Royal *Cinerarias*, pure white with a purple centre, florets very broad and of great substance.

SCIENTIFIC COMMITTEE.—Dr. M. T. Masters in the chair. Present Messrs. Maclachlan, Michael, O'Brien, Ridley, Professor Scott, and Rev. G. Henslow.

Narcissus, Fringed.—Professor Scott reported upon his examination of this monstrosity, and found that the orientation of the fibro-vascular cords was the same in the fringes as in the perianth leaves—*i.e.*, they are normal with the phloëm on the lower side, and the seylem on the upper, the fringes alternated with the perianth leaves giving the impression that they constituted another whorl, so that the tubular parts below the perianth leaves was probably of the nature of a receptacular tube.

Cyclamen, Fringed.—He also examined the specimens exhibited at the last meeting. The petals were not reflexed as in the usual state, but have crowded outgrowths on the inner surface. The cords were reversed on the outgrowths, the orientation of the tracheæ and phloëm being, therefore, just as they are in the corona of *Narcissus*. There was, however, no great regularity, the tracheæ very frequently being quite central.

Dr. Masters observed that similar appendages occur on the outside of *Gloxinias*, and in them the colour becomes reversed as well. Mr. Henslow called attention to the description of fibro-vascular cords as given by M. P. van Tieghem as being too diagrammatic; that where that author laid stress on the reversal of orientation in the anatomy of pistils; it was more general to find the tracheæ central, or else surrounded by phloëm in an irregular manner. This often occurs with the placental cords which supply the ovules.

Cattleya Trianae.—Mr. Smee exhibited a monstrous form, which was referred to Mr. Ridley for examination and report.

Hazel catkins.—Dr. Masters exhibited specimens bearing small clusters at the base of the male, as well as in the usual terminal position.

Cyclamen, with lacinate petals.—Mr. O'Brien exhibited a flower with petals cleft into several lobes, a result probably of some degree of impoverishment.

Quercus Skinneri, Acorns.—Mr. T. Christy sent specimens received from Mexico, for tanning purposes. They are remarkably large, being from 1 to 1½ inch in length, and three-quarters of an inch in diameter. They were introduced originally about thirty years ago.

Citharexylum latum.—He also forwarded seeds of this plant—also from Mexico. The "nestlets" are oval, plano-convex, and deeply grooved within. They are used for a beverage, which is said to be intermediate in flavour between chocolate and coffee. Certain species of *Lantana*, of the same order, *Verbenaceæ*, are used for tea; but whether either genus contains alkaloids allied to *Thobromine* or *caffeine* is not known.

GENERAL MEETING.—A general meeting of Fellows was held in the new offices, 111, Victoria Street, at 3 P.M., Sir Trevor Lawrence, Bart., M.P., in the chair, the following members of the Council being present:—Dr. Robert Hogg (who subsequently took the chair), W. T. Thiselton Dyer, Professor Michael Foster, A. H. Smee, H. J. Veitch, D. Morris, G. Paul, and the Rev. W. Wilks (Secretary). Sir Trevor Lawrence stated that the business of the meeting was the consideration of the new by-laws prepared by the sub-Committee of the Council and Fellows, and which were to provide for the admission of guinea Fellows and Associates, as well as making some material alterations in other matters. It was found necessary, however, that the new by-laws should be placed in lawyers' hands for revision and comparison with the conditions of the Charter, to avoid any illegality. In consequence of this only a small portion could be taken at the meeting—namely, that which had been passed by the lawyers, and which would enable them to elect the numerous persons nominated as Fellows. Considerable discussion took place respecting the advisability of postponing this matter until the Fellows had had time to examine the new proposals; but after the Secretary had carefully read the old and new by-laws clause by clause it was resolved that the latter be adopted up to the end of chapter 4, the whole of the eighteen clauses dealing with the election, subscriptions, and privileges of Fellows and Associates. The Secretary read the names of over 200 persons—*viz.*, 166 as one-guinea Fellows, thirty-two as two-guinea Fellows, and several four-guinea Fellows, and two Associates, all of whom were duly elected.

It was stated that the Society hopes to be able to arrange for a large exhibition, to be held in the Inner Temple Gardens on May 17th next, and the following Sub-Committee was appointed to make the necessary arrangements:—Messrs. W. Wilks (Chairman), Baines, Herbst, H. Turner, H. Williams, and Howard. The President had also communicated with the Corn Exchange authorities, and it was thought that an exhibition of autumn flowers and fruit might be held there at the end of September, with *Chrysanthemum* and fruit show at Chiswick in November.

At the Council meeting, the President reported the purport of an interview he had had with the First Lord of the Treasury on the subject

of joining horticulture to the proposed new Department of Agriculture, and also stated that he had received a letter from Lord Salisbury (which he read) to the effect that the powers of the new Department would cover the interests of horticulture. Dr. Hogg was requested to represent the Society at the proposed International Horticultural Exhibition at Cologne in August next, under the patronage of the Empress Augusta of Germany.

ROSE SHOWS IN 1888.

- June 28th.—Brockham and Ryde.
- June 30th.—Eltham and Reigate.
- July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
- „ 4th.—Croydon, Hitchin and Richmond.
- „ 5th.—Bath, Farningham, and Norwich.
- „ 6th.—Sutton.
- „ 7th.—Crystal Palace (National Rose Society).
- „ 10th.—Ipswich and Tunbridge Wells.
- „ 11th.—Ealing.
- „ 12th.—Birmingham, Carlton-in-Worksop, Oxford, and Winchester.
- „ 14th.—Gloucester* and New Brighton.
- „ 16th.—Newcastle-under-Lyne.
- „ 17th.—Lcek and Ulverstone.
- „ 18th.—Birkenhead.
- „ 19th.—Helensburgh.
- „ 20th.—Darlington (National Rose Society).
- „ 21st.—Manchester.
- „ 24th.—Tibshelf.

* The date of this Show is not yet definitely fixed.

In the above list the only exhibitions not held by the National Rose Society, or by Societies in affiliation with it, are those at Birmingham, Carlton-in-Worksop, Manchester, Newcastle-under-Lyne, Richmond, and Tunbridge Wells. In the case of Birmingham and Tunbridge Wells, where the shows extend over two days, the date of the first day's exhibition only is given. I propose issuing my next list of Rose fixtures early next month.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

PRUNING ROSES.

ANY Roses pruned in February with the idea of securing early blooms have had a bad time, and in addition to being much crippled will be later than those pruned late in March or early in April. We ought now to be through the worst of an unusually long winter, and the Rose pruning should be completed at once. There are a few simple rules to be observed in all cases. It is of importance that the heads of standards be freely thinned out, those with crowded centres rarely producing a good succession of fine flowers. They ought also to be kept within bounds, as if any strong shoots are allowed to extend unrestricted the head soon becomes lopsided. Irregular growths, then, should with old wood be cut back to a well-placed growth nearer the centre. This foreshortening, as it is termed, tends to keep up a supply of growth from n ar the centres, and preserves a neat floriferous head. Very gross shoots may well be cut cleanly out, and all useless spray ought also to be removed. Shoots near the size of a lead pencil are usually the best ripened, and these if shortened to a length of about 5 inches will produce plenty of blooms. Coarser than this to be left from 6 inches to 8 inches, and smaller from 2 inches to 4 inches in length. In every case cut close to an outside bud. It would be a great mistake to severely prune strong shoots, those resulting from this being still more gross and perhaps flowerless, while to lightly prune weak growth only leads to the formation of useless spray. These remarks are equally applicable to both Hybrid Perpetuals, and Teas, and Noisettes, Maréchal Niel excepted. Standards of the latter ought to be freely thinned out in order to cause the early formation of a few long shoots. Weakly growth also to be shortened, but long well-ripened shoots should be reserved to near their full length and loosely tied, this arching insuring the production of fine blooms at nearly every joint. Hard pruning will cause the Gloire de Dijon to form extra vigorous growths, and these will flower freely at every joint late in the summer.

DWARF ROSES.

These as usual have withstood the effects of the severe frost and cold winds much better than the standards, many of the latter having been killed outright. There are two methods of pruning these. Many, however, neglect them or imagine they require no pruning at all, but unless thickets of weakly growth and small flowers are preferred they must receive an annual pruning. Where they push up strong growths every season these may be shortened to about two-thirds of their length and pegged down all round the plant. All useless spray to be cut out and stiff upright medium-sized growths shortened back freely. Thus treated they will produce fine flowers all over the plant, a quantity of young shoots also being pushed up from the centre of the plant. These pegged-down growths to be cut clean away after they have done duty once, and

their place occupied by the young growths as before. The alternative system of pruning is much the same as advised in the case of standards, and bushes thus treated are frequently very serviceable and produce a long succession of bloom every season. Those on the Manetti stock ought always to have their stems buried, the Roses eventually becoming well rooted and independent of the stock. Manetti growths must not be mistaken for Rose shoots, and all that are detected ought to be cleanly cut out.—W. I. M.

ROSES IN POTS.

[A paper read by Mr. D. Gilmour, junr., at Walkley, Sheffield, on March 9th, 1888.]

IF we are to be anyway successful in the culture of Roses in pots, we must do as we have to do in other horticultural pursuits—that is to say, we must bring our reasoning powers into play. Depend upon it the man who thinks the most, who reasons the most, who, when he fails in anything, sets to work deliberately to find out the why and wherefore of his failure—I am coming to the most important part now—and who, when he does discover the cause of his failure, makes a mental never-to-be-forgotten note of it, and so avoids it in future, is the man who will be successful. It might be possible for one of the unthinking ones to go on all right in a beaten track for a time, but set him in a new place, give him a mental nut to crack, and behold what a dismal mess he makes of it. Do not suppose for a moment that I am an advocate for an amateur, or professional either, sitting over the fire or in his house, thinking, while there is work to be done in the greenhouse. There is no reason why a man should not think and work at the same time.

In growing a plant in a pot, we should remember that it occupies a very different position compared with one that is planted out and growing in a border. Where the roots of a plant can wander about in the soil the plant can pick and choose, as it were, what it will take up and what it will reject. In a pot this is different. Here the plant can only have what is contained in the pot, or what we administer to it; and remember it has to accept the whole of what we put there—it has to take up everything, and this is the reason why we may often, with impunity, pour over the roots of plants in the border strong liquid manures, which similarly applied would quickly destroy and kill the same plants if they were growing in pots.

I think the two greatest enemies to plants in pots are want of drainage and sour soil. Perhaps the one is the cause of the other. Many people do not see any necessity for drainage; they do not understand why careful gardeners put all those crocks in the bottom of a pot. In the same way the same people cannot see why farmers and gardeners go to the expense of putting in drains. Why do they do it? Because the question has been thought out by some of these people who think, and who, thinking and building experiments on one result after another, long ago discovered that plants will do no good if the soil in which they grow is kept too moist. I could go into this question scientifically and give you the results of some of these experiments relating to the why and the wherefore of draining, but shall ask you to take my word for this much, that drainage in pot plants is absolutely necessary. Even in cases where we use every effort to keep the drainage right the soil may become sour, and I have heard it said that the roots of plants will never have anything to do with any portion of the soil which has once become sour. There are several points, the neglect of which may lead to sour soil. I am leaving drainage out of the question now. One of the first or most likely causes is potting or repotting a plant into too large a pot; another is over-watering a plant, keeping the soil in an everlasting state of slop; still another is potting the plant in soil or compost which is too close and binding, and which does not allow the water to percolate through. There is one more point which I may mention as a reason why soil becomes sour, and it is this, that many amateurs and gardeners when they are not certain that a plant requires water press their fingers on the surface of the soil; the result is that the soil becomes like a cake. Now you may think this is rather inconsistent, as I shall shortly advise you in potting your plants to ram them as hard as a brick. My advice is sound for all that, and I can best illustrate it by taking as an example a newly metalled road over which a heavy roller has been passed. You will notice that though the stones are rolled down into a flat surface there are still many crevices between them; it is the everyday traffic that eventually consolidates the stones into one close, even surface. No matter how hard you press your soil down with the potting stick, there will still be cracks and hollows where the water can filter through. It is the constant small and light pressures of the fingers at a time when the soil is wet, more or less, and it is these pressures repeated again and again, that eventually consolidate the soil and make it impervious to water, and then very quickly afterwards sour. I do not think it by any means a waste of time to remove the surface soil from pot plants; indeed, I should prefer while I had the job in hand to go down until I saw the white roots showing. The old soil should be removed and fresh mixture or compost supplied. This may be done often.

I had better begin as I ought to have done at the first, and take the different parts under their proper heads. First, then, How shall we best form a collection of pot Roses? If we have the necessary cash at our disposal I should say, "Buy a collection ready made;" but even in that comfortable state of affairs and pockets there is another view to take of it—a man looks with very different eyes and feelings on his own children as compared with those of other people. The same thing applies to almost everything. And so a man takes a great deal more pleasure and pride in plants that he has formed and educated himself.

I will suppose, then, that we decide to make our own collection. For this purpose I recommend that fine open ground plants be procured from the nursery early in autumn. I say early, but we may defer getting them until after Christmas, even up to now (8th March) if we think proper. The plants should be potted without loss of time. Remember to ram them very hard, and this constitutes our first step. Our next step is to place the plants in a cold house. Plants newly potted should not have any heat at all during the first year, but should simply be allowed to commence growth at their own sweet will. I may say here that a number of plants which were so potted up about last Christmas, or a little later, and placed in a cold house, are now covered with good red shoots, and in some cases with foliage. It will save much trouble if these plants are plunged in leaf soil; so placed, they require very little attention in watering. As soon as the buds begin to swell the plants should be pruned back to good strong eyes, and they should be syringed in dry weather. They will bloom in course of time and grow strong, but some time about the end of June they should be put out of doors in a sunny situation. If they have made sufficient growth and have some good shoots on them I am in favour of stopping any further growth by letting the shoots become dry gradually at this period, but never allowing the roots to become dust dry. If this ripening is proposed the pots should not be plunged; but if we wish for larger plants, or that the growth should continue, we should plunge the pots and keep the roots moist. But if we intend our plants for early blooming the following spring we must ripen them in good time. The pots must be raised out of the ground and placed on a hard surface, while water is withheld as before advised. August is the latest date I should fix for this. The longer our plants remain outside the better. The cold nights, the dews, the breezes, and the sunshine will all help to ripen the wood and produce buds that will give us fine blooms. If hard weather sets in before Christmas the plants should have the shelter of a frame, or be placed under a wall or in some cosy place. They may come into heat almost any time after being thoroughly ripened, and be grown successfully. When I say heat I mean the ordinary temperature of an amateur's greenhouse. They may be pruned when brought in, and should not then have more water than is really required until the buds break and leaves begin to form. At this time the top soil should be taken off, using a pointed stick, and fresh soil added in its place. When the plants have bloomed all of them that require it should be carefully repotted, after which they may either be returned to the greenhouse for a fortnight, keeping the leaves as moist as possible, which enables the roots to get hold of the new soil, or they may be at once plunged outside as before.

In potting the plants at first let them be placed into pots as small as the roots will allow. If you err on the question of drainage, err on the side of too much rather than too little, the compost should be made up like this:—One part old sods or good turfy loam, half part of old manure, one-eighth part of leaf mould, one-eighth charcoal or sand. The compost should not be riddled but well mixed together. The pots must be well rammed. Any old thick roots should be removed or cut back, but all fibrous roots should be preserved. Some of the plants may make so much growth and so many roots that it may be necessary to repot them during the first season. In that case place them into pots the next size larger, taking care not to break the young roots. As a rule one repotting a year should be sufficient.

Pruning Roses in pots is rather a tough subject—I mean that it is a tough job to reconcile the teachings of the various masters of the art. My plan is a very simple one, and I adhere to this rule, “The more you remove from a Rose tree the finer the blooms will be.” In the case of H.P.'s, I advise that all the branches be cut back to, at most, three eyes or buds, and the result will be generally one or two strong shoots from each branch. This system will save an immense amount of tying work, bending shoots down, &c., and in my opinion give a better result. With the long and coarse-growing Teas, the Dijon section, and Maréchal Niel, this short-pruning system will not answer; these, blooming on laterals thrown out from last season's wood, must have some of the branches left long, simply removing the unripe and weak tops. But the dwarf-growing Teas flourish on the hard-pruning system, and give magnificent flowers, so I shorten my dwarf Teas back to about two eyes on each shoot. I have probably 200 standard Teas in pots; some of them this year were cut back hard, while others only had the weak and old wood taken out. In the one case I have strong vigorous shoots, grand foliage, and magnificent blooms; in the other I have weak foliage and small blooms. The moral is obvious.

For greenhouses the standard has many advantages, particularly for amateurs whose space is limited. The plants are lifted up so as not to interfere with smaller growing things; they get more light, and are neither so crowded themselves nor do they crowd other things as they do when grown as dwarfs and on the same level as everything else on the stages. Another advantage is, that after the first blooming the branches may be tied down like the ribs of an umbrella, and the result will be the bursting out of strong new breaks which generally carry the best blooms of the season.

I must go back again to the subject of watering, for although growing Roses in pots is made up of a number of small matters I really think that of watering is the most important; and I think it is the matter in which discretion is most called into play. If a plant is newly potted, or is without leaves, or if there is no growth going on, it stands to reason that a less quantity of water is wanted. Where a plant is in full growth, or where the pot is full of roots and the plant growing, we may give water freely. But I would far rather see a plant have too little water

than too much. The plant in the former case will give us notice of its wants by drooping its leaves, though it is not wise to allow matters to go so far. In the latter case we shall find the leaves turning yellow, but at this stage I should say the soil in the pot has become quite sour, and the mere withholding of water will not restore sweetness to it nor healthy growth to the plant. The infallible rule for all is the knuckle applied smartly to the side of the pot; if it ring out bell-like water is wanted, if it sounds dull and solid none is necessary. It is astonishing how much drying a pot Rose will stand. The roots may be dried until the shoots shrivel and the plant appears to the eye quite dead, but plunge it into a tub of water for twenty-four hours, and behold! the shoots plump and green and the buds again swelling.

I am afraid that, so far, most of my remarks will apply more to the Tea Roses than the H.P.'s. I certainly consider it a waste of time to grow these latter in pots, for various reasons. One is, because we can grow them better and with less attention in the open ground; another is, that when we take one crop of blooms from the H.P.'s we are not likely to get another for some time. Another reason is, that the Teas stand more knocking about—don't smile, let me finish—I mean that they do not want so much rest, and they may be made to bloom much more certainly at such times as Christmas for instance. Take the grand old Tea Rose Niphetos, or the almost equally useful and beautiful Caroline Kuster; one can get from four to six (may be more) crops of blooms from these Roses in one season. Where is the H.P. that will stand this sort of work? I know of none, and I do not think you do either. However, if we must have H.P.'s in the house, after they have bloomed once they are best outside, as they take up too much room and attention inside. If they make a good growth, equivalent to the spring growth of plants in the open, that is all that is necessary; this is the wood we want for blooms next season. If we dry them off small blooms will probably form during summer; these should be pinched off.

A few words on manures. These are only of advantage when the plant is capable, or in a fit state to absorb them. To give manure or stimulants to a weak or sickly plant is simply poison to it. Where a plant is growing in such a compost as I have described it needs very little until the roots have filled the pot. Then, if the flower buds are formed weak liquid manure may be administered, but give too little in preference to giving too much. Weak and often is better than strong and seldom. Feasts and famines are neither of them good for the human digestion, no more are they beneficial to plants. This liquid, whether it be made of horse or cow dung or sewage, and these are the usual materials employed, should not be stronger in colour than ale, if there are any abstainers here I don't mind saying ginger ale.

Where we do not, or cannot, repot our Roses, we may keep them strong and healthy for a long time by the use of stimulants and patent manures. These are bones, bone dust, dissolved bones, and other concentrated preparations. These should be put on the surface, or mixed with the soil we top-dress with, when the plant is in growth, not when it is at rest. I must say something about that curse of Roses—mildew. This is often the ruin of crops under glass. An attack may be brought on very quickly with forced Roses by simply opening a ventilator and letting the cold wind in for a few minutes. It cannot be so easily cured. When we can command hot pipes the remedy is simple. This is to paint said pipes with sulphur made into a paste, but do not have too much fire at the time you apply it. In cold houses we must prevent mildew. Keep it away, once it gets a footing in a house it is good-bye to blooms and leaves for some time. We must keep it away by using when we syringe a little softsoap at the rate of half an ounce to the gallon. The best way to prepare this is to mix 2 lbs. of softsoap with boiling water, adding at the same a wineglassful of petroleum, and making up the quantity with hot water to five gallons. If a little tobacco juice be added all the better, or rather all the worse, for the green fly. When we do syringe we must put half a pint of this delicious mixture into a large can of water. This recipe is pretty sure to be correct, because I had it from the “Gardeners' Year Book.”

In conclusion I will give a list of the very best varieties I know of for pot work:—Alfred Colomb, *Baroness Rothschild, Beauty of Waltham, Boule de Neige, Captain Christy, Charles Lefebvre, Dr. Andry, Dupuy Jamain, Edward Morren, Henri Schultheis, John Hopper, *La France, Madame Lacharme, Madame G. Luizet, Madame V. Verdier, *Marie Baumann, *Marquise de Castellane, *Merveille de Lyon, *Senateur Vaisse, and Souvenir de Malmaison. These are all H.P.'s except Malmaison. The best six are perhaps those marked *. Almost all the leading varieties of Teas give good results in pots. I will just name the very best—Anna Ollivier, The Bride, Catherine Mermet, Madame Charles, Madame Falcot, Madame Lambard, Madame Willermoz, Marie Van Houtte, Niphetos, Rubens, Souvenir d'Elise, Souvenir d'un Ami, and Sunset. Noisettes—Maréchal Niel, and Madame Caroline Kuster.

THE ORCHARD HOUSE.

[A lecture delivered at Birmingham on the 13th ult., by T. Francis Rivers, Esq.]

(Continued from page 276.)

PEAR trees under glass amply repay for cultivation, the protection from spring frosts rendering the crop a certainty. Grafted on the Quince stock the trees become very fruitful and dwarf, and are exceedingly easy to cultivate. After commencing to bear they grow very little and give all their energy to the fruit. I often think that their cultivation would be a considerable source of profit, but for this purpose none but large and late sorts should be used, such as the Doyenné du Comice, Marie Louise, Duchessed'Angoulême, Winter Nelis, Marie Benoist, and the Easter Beurré.

The grower would, I think, soon find customers among the connoisseurs in the country. The most inexpensive form of cultivation is, I think, that of using perforated pots and small pyramids, a rough glass shed, 100 feet by 24 feet, could be filled with trees about 18 inches apart, these may remain in under cover until about the end of May, or at all events until the danger of severe frost has passed, the young fruit of the Pear being very liable to injury when it is the size of a small Filbert. They should then be removed to a border specially prepared for them by draining and loosening the soil, and plunged up to the rim of the pot. As they will then be out of doors, they will not require so much attention in watering, but they must be kept fairly supplied, and when taken out of the house a mulching of manure must be placed over the pots. Liquid manure, as used for Peaches, should be given about once a week. Tom tits are very troublesome when the fruit has attained its full size, as before ripening they will pick a little piece of the flesh out near the stalk and leave the rest to decay. I am obliged to net the trees, but if expense is no object a wire house will amply repay the cultivator. During the summer the roots will push through the holes in the border, and thus gain strength enough to ripen large and fine flavoured fruits. At the end of October or in November all these roots may be cut off and the tree repotted; they can then be packed closely together, the pots protected from the weather with straw or dead leaves, and remain until the end of February, when they will be ready to put into the house for another season's crop. As it is a great strain on these little trees to bear continuously it is well to have an alternate supply, one bearing and the other out of doors and non-bearing. Very little pruning is required, the shoots should be pinched in May and June, after these months the fruit will absorb the vigour of the tree.

Apples grown under glass attain a flavour rarely equalled out of doors, especially the American sorts Washington and Melon, and the English Cox's Orange, the latter when kept entirely under glass is transformed, it becomes full of juice, and has the texture of flesh which we generally consider the attribute of the Pine Apple. The Washington is a sight to see, indeed I believe some were exhibited in a fruiterer's shop at Tunbridge Wells, for which he asked a guinea apiece. Grafted on the Paradise stock they are as dwarf and as fruitful as Pears, and may be grown in exactly the same manner, as, however, there is generally an Apple crop in England their cultivation under glass is not a matter of absolute necessity. If the glass shed used for protection has a row of hot-water pipes it may be used for Black Hamburgh Grapes, but the heat must not be applied to Pears. In my district Hamburgs will ripen without fire heat, but in the northern parts of England I do not think this is often the case. I only speak of Grape Vines for this glass shed; but the orchard house for Peaches, &c., must have the roof clear. Grapes may, however, be grown as small standards in pots, and are exceedingly ornamental. If the early but small Grapes are grown these little trees may be taken out of doors in August. The fruit will ripen in a fairly warm autumn, and so will Figs in pots, but the large leaves and vigorous growth almost banish them from an orchard house; if, however, a warm corner can be found for them they will give a good supply of fruit. The great secret of cultivation seems to consist in pinching the young shoots; unless this is done the tree will grow without fruit. The first shoot should be stopped at the fifth or sixth leaf, and the young fruits will immediately appear.

During the last few years, and mainly owing to the orchard house, a very great advance has been made in the season of ripening of Peaches and Nectarines. Under glass this now extends from the first week of July to the first week of October. I may here say, that although in the south of England artificial heat may not be absolutely necessary, it cannot be dispensed with in the cooler districts, and it is specially desirable during the early spring and the late autumn, a single pipe round the house being sufficient. With this help Peaches will ripen the first week of July, and a continual supply be kept up until the first first week in October by the following sorts, which are arranged in the order of ripening:—

JULY.		AUGUST.	
Alexander Peach		Early York Rivers Peach	
Waterloo "		Condor "	
Early Beatrice Peach		Early Alfred "	
" Louise "		Goshawk "	
" Rivers "		Lord Napier Nectarine	
" Hale's "		Early Grosse Mignonne Peach	
" Leopold "		Dr. Hogg "	
Advance Nectarine		Crimson Galande "	
		Magdala "	

SEPTEMBER.		NECTARINES.	
Grosse Mignonne		Goldoni	
English Galande		Stanwick Elrage	
Alexandra Noblesse		Rivers' Orange	
Royal George		Spenser	
Barrington		Pine Apple	
Nectarine		Humboldt	
Princess of Wales		Victoria	
Sea Eagle			
Lady Palmerston			
Golden Eagle			

This list is, of course, intended for pot cultivation, as the sorts are too numerous for trellis training. I have also confined myself to Peaches and Nectarines, as they are not perhaps quite so well known as Plums, Pears, and Cherries.

Although the orchard house was devoted expressly to the English dessert fruits, I propose to show that with some modification the system may be made available for a very luxurious purpose, although

not more difficult or expensive than Grape-growing, and that is the cultivation of the Orange. The Orange house was formerly a necessary appendage to great mansions, and usually a building of the most dreary character, the Oranges generally grown being small and bitter. Many years since a gentleman made my father a present of some Tangierine Orange trees, which were placed in the orchard house, and taken out of doors in the summer. This happened in one of our rarely hot seasons—that of 1858, I think—and the trees ripened their fruit as readily as Green Gage Plums. After this hot summer came the cold series, and as the Tobacco cultivators will find out to their cost one hot summer is not always followed by others. The impetus was, however, given, and my father and myself began to collect varieties of Oranges, Lemons, Shaddockes, and Limes, all of which I have proved can be as easily grown as Peaches or Grapes. The temperature of an Orange house in winter should be about 50°; in the summer heat it is necessary to give plenty of air. The house is a pleasant winter walk from October to March, almost cheating one into the belief that the promenader is transferred to Valencia without the damp and enervating climate. The fruit will last on the trees without any loss of flavour for six months, and may then be gathered and eaten. The soil which the Orange prefers is a ferruginous loam. In some parts of Italy, I understand the plantations are manured with beggars' rags, and it was once an article of belief that a sick Orange immediately recovered if a dead dog was buried at the roots. Cotton cake and scraps of leather are both good fertilisers. The great point to be urged is the necessity of a light, large, and lofty well ventilated house, not too lofty, because of the difficulty of keeping the trees free from scale, which, as all Orange planters know, is a direful evil. In my own house I sometimes use a wax taper in the corners of the branches, and the bark may be washed with petroleum. The leaves, however, must be sponged with warm water by a skilful and tender hand, as any bruise or rough handling soon brings about an injury. I have collected about fifty sorts of Oranges, Lemons, and Limes. These are very interesting from the great variation in size and flavour, and one soon learns to appreciate the difference. The Maltese Blood Orange, I think, hears away the palm, but the varieties of the St. Michaels are very good indeed, the best of them being the Sustain, next the Long and Silver, and also the sort usually grown for commerce. The Seville or Bitter Orange flowers more abundantly and more frequently than the St. Michaels; hence, if grown for the flowers alone it is likely to be more profitable. Although I am not prepared to say that as a commercial speculation Oranges grown in England can compete with Florida or Valencia, there does exist a considerable market for Orange flowers; the speculator must, however, avoid the season of Lent, when his wares are somewhat depreciated in value. Lemons and Limes may be grown on the back walls of vineries, and really make a very useful return, and will produce more abundantly than Oranges when trained. They also can flourish even when partially shaded. It seems almost extravagant to speak of Orange groves in England, but there is no real difficulty, and I am certain that if sanatoriums on a large scale are erected an Orange grove will form a most interesting and pleasant winter promenade.

The Tangierine Orange is almost hardy. It is dwarf and seldom grows to a greater height than 5 or 6 feet, and therefore when grown in tubs can be easily removed to the open air for the summer. Placed in a warm part of the garden, the fruit will ripen even in moderately warm summers, and if they do not the fruit will come to perfection when returned to the Orange house. Plucked fresh from the tree it is delicious, and is quite as good in England as in Lisbon.

This is, I fear, a dull lecture. It is impossible to avoid being technical in treating of technical matters, but I hope that I have been able to make my meaning clear. Although I am somewhat enthusiastic on this particular subject, I do not wish to lead anyone astray or to encourage an unjustifiable expense. Time, it is said, is the only real authority for a patent. As nearly forty years have passed since the first glimmerings of a new system of fruit cultivation, I may, I think, venture to hope that time has patented the orchard house.

ROYAL CALEDONIAN, EDINBURGH.

THE spring Exhibition held on the 4th and 5th inst. was, owing no doubt largely to the extreme severe weather experienced during the previous five or six weeks, hardly so full, especially of plants, as on some previous occasions. The prizes offered for a table of plants 20 feet by 5 feet brought only one competitor, Mr. Donaldson, gardener to H. E. Moss, Esq., Murrayfield, to whom the first prize was awarded. Messrs. R. B. Laird & Sons, West Coates, were in the same position in the class devoted to nurserymen; the main feature of the arrangement being some large Azaleas and Palms in a groundwork of small flowering plants and Ferns. Mr. Robertson Munro was the only exhibitor who set up a table of hardy spring flowering plants. With sixteen forced plants, Mr. McKinnon, Melville Castle, Lasswade, had first place, and Mr. McIntyre, The Glen, second. For four Azalea indica, Mr. John Patterson, Millbank, was first with large grandly flowered specimens. For two varieties Mr. McLennan, Restalrig House, had very good examples, to which first prize was awarded. Mr. Patterson was first also in the class for one plant. With six greenhouse plants the same exhibitor held first place, showing two fine Azaleas and a good Erica profusa, E. Victoria, and an Epaeris. In the class for four plants, Mr. Grossart, gardener to J. Buchanan, Esq., Oswald House, was first. Mr. Patterson was again in the first place with four Heaths.

With six Orchids Mr. Curror, gardener to Geo. Douglas, Esq., Eskbank, was first with grand pieces of *Cattleya Trianae*, *Dendrobium fimbriatum*, *oculatum*, *Wardianum*, *Devonianum*, and *nobile*. Mr. Grossart was second, having a very noteworthy plant of *Cymbidium Lowianum*. In the class for three plants Mr. McIntyre was first, and Mr. Patterson second, the names being reversed in the one plant class. A good piece of *Cypripedium hirsutissimum* was the premier plant. A few Orchids were exhibited by Mr. McIntyre, including a good specimen of *Dendrobium Leetchianum*, and two *Odontoglossums*.

Mr. Grossart had the best four foliage plants, Mr. D. Ramsay, gardener to J. T. Black, Esq., Gogar Park, being first in the corresponding class for two foliage plants. For eight foliage plants in 8-inch pots, Mr. McIntyre, gardener to Sir C. Tennant, The Glen, was first with nice clean plants, Mr. Grossart, the other exhibitor, being disqualified on account of a slight infringement of the conditions. The chief prizes for Ferns went to Mr. Forbes, gardener to P. Niel Fraser, Esq., Murrayfield, for four sorts; to Mr. Patterson for *Gleichenias*; to Mr. Plenderleith, Grange Loan, for *Adiantums*; and to Mr. Forbes for Filmy Ferns. In a strong competition Mr. Patterson came out first for six Roscs in pots; Mr. James Bald, Canaan Bank, second; and for three pots, Mr. W. Howie, Inch House, Liberton, was first. Mr. Bald had the best *Amaryllises*, very good plants. *Deutzias* were a large class, and Mr. McLennan had the best two, and Mr. D. Ramsay, Gogar, the best single specimens. Of *Cinerarias*, *Lily of the Valley*, *Mignonette*, &c., the competition was not so strong as we have noted in former years, but the quality was very good.

With Dutch bulbs there was a strong competition. For twenty-four Hyacinths open to nurserymen, Messrs. R. B. Laird & Sons were first with strong even heads; Messrs. A. Kerr & Sons, Kalemouth Nurseries, Roxburgh, second, with a less even, but good collection. In the gardeners' classes for twelve Hyacinths, Mr. H. Lime, Ridge Park, Lanark, was first with spike clean and well grown, but lacking in size; Mr. T. Scott, gardener to H. Davidson, Esq., Braedale, Lanark, second. For eight varieties, the first prize was without name. For six, Mr. Dunlop, South Bank, was first. Mr. Barnie, Jock's Lodge, Portobello, has the finest nine pots Tulips, and also the best garden *Narcissus*. The prize for six pots Tulips being awarded to those from Mr. J. Patterson, Willow Brae House. Mr. Grossart having the best *Polyanthus Narcissus*. The sorts were those shown in former years.

Amongst cut flowers Roses were the chief attraction, Mr. James Walker, Clarendon, Linlithgow, securing the first prize for twenty-four with very clean, not large, but even buds; Mr. W. Parlane, Rosslea, was a good second. For twelve Roses, Mr. J. Ramage, Wallhouse, was first. Mr. Peason, Beechwood, Corstorphine, had the best *Maréchal Niel*, twelve buds, smaller than those usually shown from the Beechwood Gardens. Mr. Grossart was the only exhibitor of twelve trusses stove or greenhouse plants, and had first prize, also first for cut Orchids; Mr. Cockburn, Coltbridge Hall, second. The best hand bouquet was from Mr. T. J. McDonald; Mrs. Ure, 144, Princess Street, having the best table bouquet; and Mr. R. Cockburn the best buttonhole bouquets.

The fruit was chiefly remarkable for the display of Apples, which were much finer in colour than is usually the case. Only three pairs of bunches of black Grapes were set up, Mr. Smith, Oxenford Castle, having the best *Lady Downe's*; Mr. McKinnon, Melville Castle, was second with *Alicante*. Mr. McKelvie, Broxmouth, Dunbar, had the best dish of Strawberries; Mr. Pirie, Selkirk, second. Mr. McKelvie was also first for dessert and kitchen Apples, twenty-four of each; Mr. Brunton, Gilmerton, second for dessert, and Mr. Potter, Seacliffe, for kitchen sorts. The best sorts were *Alfriston*, *Tower of Glamis*, *Kentish Fillingbasket*, *Yorkshire Greening*, *Blenheim Pippin*, *Wellington*, *Grange's Pippin*, *Sturmer Pippin*, *King of Pippins*, and *Flower of Kent*. A collection of seventy dishes from Mr. Brunton had a special prize awarded. Messrs. Brunton and Potter had the best collection of Pears in their respective classes. Mr. McIntyre, The Glen, was the only exhibitor of a Pine Apple, and had a first prize awarded to a fruit not quite ripened.

Vegetables were fairly represented. Mr. G. Potter, with a very good selection had the first place. Mr. Milne, Sunnybank, was first for collection of salads; Mr. Geo. Greig, Caigend Park, first for a good brace of Cucumbers. Extra good Mushrooms were shown by Mr. Gordon, Niddrie, first, and Mr. McLennan, Restalrig House, second.

In addition to the nurserymen's exhibits already noticed, Messrs. R. B. Laird & Sons were first for hardy and greenhouse *Rhododendrons*, four *Azalea indica*, six Palms, three *Crotons*, and three *Dracenas*, Tree Ferns, and *Coniferae* for table, besides table plants. Messrs. Ireland and Thomson were first for hardy *Rhododendrons*, twelve *Conifers*, and twelve forced plants; Mr. Bryson, Helensburgh, first for *Auriculas* and cut Roses.

Among the miscellaneous exhibits, Messrs. James Dickson & Sons, Hanover Street, contributed a table of decorative flowering plants, the Lawson Company a group of Japanese Maples in variety, Messrs. Ireland and Thomson a rich group of forced shrubs intermixed with ornamental *Coniferae*, also a table of stove and greenhouse plants, including some nice Orchids, *Azaleas*, &c. From Messrs. T. Methven & Sons came an attractive group of Ivies, and a large table bright with a charming variety of forced and other flowering plants.

The attendance of the public was very large and the takings satisfactory.

NATIONAL CHRYSANTHEMUM SOCIETY.

MAY I, on behalf of the above Society, acknowledge the gentle reminder of a "Possible Exhibitor" that it is desirable the schedules of prizes for the ensuing season should be issued as early as possible? I am sure the executive is fully alive to this necessity, and will each of them be equally pleased with myself to know that its issue is being somewhat eagerly looked forward to by the Chrysanthemum world generally. Although the season is rapidly advancing, not a single day has been lost in its preparation, but so much other matter is now included with the schedule that of necessity its issue must be delayed until all, or nearly all, the returns are to hand. I think I may promise, however, that it will be distributed in the course of the present week, and if "Possible Exhibitor" will favour me with his address I will take care that a copy be sent him immediately after I receive them from the printer, and venture to hope the announcements therein will induce your correspondent to adopt for the future the *nom de plume* of "An Exhibitor."

I should be glad to take this opportunity of referring to an interesting schedule I have received by the last mail. It is for a Chrysanthemum Show to be held in Melbourne on the 25th and 26th of this month by the Victoria Horticultural Improvement Society. No less than forty-seven classes are announced for Chrysanthemums, and success I believe is assured. I am pleased to note that the offer of certificates of the N.C. Society takes a prominent position in the schedule, and will be awarded to the premier classes for specimen plants and cut blooms respectively.

The following is a paragraph from the annual report of this Australasian Society, and is sufficiently interesting to justify my asking your permission to quote:—"With a view to assimilating the working of this Society to those of the old country, letters were forwarded to the Royal Horticultural Society, the National Chrysanthemum Society, the National Rose Society, the Scottish Horticultural Association, and the Royal Caledonian Horticultural Society. The three first-named replied, forwarding their rules, reports, schedules, &c. Your Committee were so favourably impressed with the working of the National Chrysanthemum Society that they have taken steps to affiliate this Society with it."

I may also just state that I have lately received an intimation from the Secretary, Mr. J. Kirtland, that one of their Committee, as a representative, is on his way to England with letters of introduction to myself, and to confer on Chrysanthemum matters generally.—WILLIAM HOLMES, *Honorary Secretary, Frampton Park Nurseries, Hackney.*

BRISTOL BULB SHOW.

APRIL 4TH AND 5TH.

No Show was held last season, and it is to be hoped that the resuscitation will have been attended with better success than on former occasions. Although not so large the competition in many instances being anything but keen, there was yet an excellent display, and which was seen to the best advantage in the commodious Drill Hall where it was held. Much of the effect was due to the fine exhibit of 200 Hyacinths in pots by Messrs. Garaway & Co., Durdham Downs Nurseries, Clifton, and a grand bank of fine-foliaged and other plants shown by Messrs. Parker & Sons, nurserymen, St. Michael's Hill, Bristol. The best among the generally excellent Hyacinths shown by the Messrs. Garaway were *Lord Derby*, *General Havelock*, *Laurens Koster*, *La Grandesse*, *Grandcur à Merveille*, *Koh-i-Noor*, *Queen of the Yellows*, *Prima Donna*, *Van Hooboken*, *Marchioness of Lorne*, *Primrose Perfection*, *Daylight*, *King of the Blues*, and *Heroine*. From Mr. T. A. S. Dorrien Smith, Scilly Isles (Mr. G. D. Vallance, gardener), came grand *Narcissus* and *Daffodil* blooms, a very complete named selection being sent.

The competition with Hyacinths in pots was, on the whole, fairly good, and creditable collections of well known varieties were shown. Mr. T. W. Gibson was first for twenty-four Hyacinths in eighteen varieties, and Mr. H. Cruger Miles (Mr. F. Perry, gardener) second, both having fresh even plants. The best twelve varieties were staged by Mr. M. Dunlop (Mr. G. Marsh, gardener), and the same exhibitor was first for twelve Hyacinths in six distinct varieties, and Mr. W. K. Waite second. Mr. H. Cruger Miles had the best twelve single varieties of Hyacinths, while Mr. T. W. Gibson was first and Mr. J. Walls second for six varieties. The most successful exhibitors of Tulips were Messrs. M. Dunlop, T. W. Gibson, and H. Cruger Miles, while Messrs. Dunlop and W. K. Wait had the best pots of *Polyanthus Narcissus*, and Mr. J. Howes received a first prize for *Amaryllis*.

Two capital bank of flowering and fine-foliage plants were arranged, Mr. H. Cruger Miles being placed first, but was very closely pressed by J. Derham, Esq. (Mr. W. Rye, gardener). Orchids were very freely used, especially by the first named exhibitor, and both groups were very effectively and lightly arranged. Mr. J. Derham was well first for

six fine-foliaged plants, the second prize going to Mr. W. Dobson, and the third to Mr. H. St. Vincent Ames (Mr. W. Bannister, gardener). The last named was the most successful with specimen Ferns, Mr. J. Derham also having a good exhibit, and was second. Azaleas were poorly shown, the first prizes in two instances being rightly withheld. The principal exhibitors of these were Messrs. H. C. Miles, J. Dole, and T. W. Gibson. Mr. J. Derham was first for four stove or greenhouse plants in flower, and Mr. H. C. Miles second. Table plants were well shown by H. St. V. Ames, who was first, and Mr. F. Tagart (Mr. E. Miller, gardener) was a good second. Mr. T. W. Gibson was well first for Roses in pots, and Mr. J. Dole second, and Mr. H. St. V. Ames had the best forced hardy plants. Mr. J. C. Wall (Mr. J. H. Vallance, gardener) was first for Lily of the Valley, and Mr. W. K. Wait second. Mr. J. Derham first for Primulas, and Mr. H. St. V. Ames second. Mr. H. C. Miles first for Cinerarias, and Mr. J. Dole second. Dr. W. C. Trotman first for Mignonette, and Mr. W. K. Wait second. Mr. J. C. Wall first for Gloxinias, and Mr. E. T. Hill second, and Mr. T. Tagart first for Violets in pots, and Mr. B. Hardwell second, the exhibits in each instance being highly creditable. Mr. T. Tagart was first for a specimen Orchid, and the best single flowering plant was shown by Mr. J. Derham.

With cut flowers, vases, wreaths, and bouquets the competition was much keener, and many of the exhibits were exceptionally good. Messrs. Perkins & Sons, Coventry, were most successful, being first for bouquets, with and without Orchids, and limited to 15 inches in diameter, for a wreath, and also for sprays for ladies and buttonhole bouquets, altogether a noteworthy achievement. Messrs. Garaway and Co. were also successful in these classes, their exhibits fully deserving the prizes awarded. Mr. C. Winstone, Clifton, was second for a bouquet, and Mr. M. Hookings was third in another class. The last named was first for a vase of choice flowers, and Mr. E. T. Hill second, the arrangement in each instance being light and tasteful. The best stand of twelve bunches of cut flowers came from Mr. H. C. Miles, choice Orchids being principally shown. Messrs. Cooling & Son, Bath, had a capital lot of cut Roses, and were placed first, the second prize going to Mr. T. W. Gibson.

The best collection of vegetables was shown by Mr. H. St. V. Ames, the Broccoli being particularly good, and Mr. E. T. Hill was second. Mr. J. C. Wall was first for a neat brace of Cucumbers, and Mr. M. Dunlop second, the first named also receiving an extra prize for Mushrooms. Mr. H. St. V. Ames was first for Apples, and Mr. E. T. Hill second, and with Pears Mr. J. Derham was first, and Mr. E. T. Hill second. Several lots of Grapes were shown, Mr. J. C. Wall being first for good Lady Downe's, and Mr. W. Iggulden, Frome, second with the same variety. The last named took the first prize for Strawberries with a fine dish of Vicomtesse Hericart de Thury; Captain Aleock (C. Saunders, gardener) being second with a good dish of Princess of Prussia.

KITCHEN GARDEN.

ASPARAGUS FROM SEED.—Asparagus seed can be purchased very cheaply, as it germinates freely, and half an ounce or 1 oz. will produce hundreds of roots. Early in April is a good time for sowing. In many cases it is sown in what may be termed a nursery bed, the roots being kept there for a year or two and then transplanted to their permanent quarters. Good plantations have been secured in this way. We have practised it often, but if a good bed is desired quickly the seed should be sown in the position the plants are to occupy. If only a bed is wanted select a good position, add a quantity of sand and manure to the soil, fork it well in, and then open drills 1 foot apart. Do not sow the seed all along them, but drop a few seeds in at a distance of 1 foot apart and cover them. Several young plants may appear; allow three or four of them to remain, and if undisturbed many good "sticks" may be cut from them the third year. Large plantations may be formed in the same way, but the rows may be kept 18 inches apart in their ease, and if the ground appears vacant between the rows when the plants are seen, a row of Spinach or Lettuces may be had between the rows of Asparagus.

TRANSPLANTING ASPARAGUS.—Roots of all ages may be transplanted. If an old bed is very thin of roots, lift the whole and plant a in close together. They will not bear so well the first year after shifting as they might do if left alone in the old place, but they will soon recover from the transplanting. Where young roots are close together in the seed beds lift them carefully and fill blanks in old beds or form new ones. They all delight in a rich open well-drained soil. Let the roots extend when placed in the ground without being twisted or cramped, and if planted 3 inches below the surface they will do well. We always transplant our Asparagus during moist weather, as a dry atmosphere checks the growth severely, and the sooner they are replanted after being taken up the better.

STIMULANTS FOR ASPARAGUS.—The desire always is to have Asparagus as large as possible, and everything is given to them that is

likely to increase the size of the heads. Where the plantations are large it is impossible to give them all liquid manure, but where the bed is only a small one liquid manure may be applied at this season with advantage. Guano water, soot water, and water from the cowshed or stable are all suitable, and if a little guano, salt, soot, or artificial manure is sprinkled round the crowns when it is raining the roots and stems will soon show the benefit. It is better to give them a little once a week for the next six weeks than to overdress them at once.

NEW SEAKALE PLANTATIONS.—Seed may be sown in the same way as advised for Asparagus, but it is only beginners in its culture that need to sow seed, as all who possess any plants can increase it and form new plantations more quickly than by seed-sowing. If the roots have been lifted and forced take them from the pots, boxes, or beds in which they are stored, cut each crown with a piece of root 3 inches long attached, and the remainder of the root may be cut into similar lengths. Keep all the roots with crowns attached together, and plant them in rows 2 feet apart and 15 inches between the plants. Give them rich deep soil, and merely leave the crown visible above the surface. These will bear a crop of Kale next spring, and if the roots that were cut into lengths are planted in the same way, but with 18 inches from row to row, and 1 foot from set to set, they will form excellent plants eighteen months hence. This is a good way of securing young healthy plants for a new Seakale plantation; Seakale which has been covered for forcing should now be exposed.

INCREASING RHUBARB.—This can be raised from seed, also roots may be divided and replanted. This is our favourite way of increasing Rhubarb. When the stools are very large they are cut down the middle with a spade. One part is allowed to remain undisturbed, but the other is lifted out of the ground and divided into two or three pieces, and each of these is planted. For a little while at first these will not grow so strongly as the part allowed to remain in the ground, but by the autumn they will be as strong as if they had never been disturbed, and a good new plantation may be secured in one year in this way.

JERUSALEM ARTICHOKEs.—These should be grown in every garden, as they are most useful in winter. When once they are introduced they readily take care of themselves; they are almost as difficult to eradicate as Horseradish. If allowed to grow for a year or two they become such a mass that the tubers do not gain any size, but they should be lifted every spring, a few of the best selected for planting again and the others kept in hand for use. Just now is the time to plant them. Keep the rows 2 feet apart, and 15 inches from tuber to tuber will allow the crop to develop freely. We have planted our Jerusalem Artichokes on the same ground for ten years, and they are as fine now as in the first season.

GLOBE ARTICHOKEs.—Globe Artichokes are more tender and more difficult to cook, but as much valued by some, though not cared for by others. They are, however, a high-class vegetable, and every professional gardener ought to grow them. They may be raised from seed sown in the open, and they are easily increased by dividing the plants. This should be done in April, and established plants should have the manure or protectors removed from their stems and a quantity of good manure forked in near their roots before they have advanced in growth to any extent.

FRUIT FORCING.

FIGs.—*Earliest Forced Trees in Pots.*—Early Violet and Early Prolific, though small, are desirable from affording fruit in advance of the large-fruited varieties. The fruit showing signs of ripening, watering must be gradually reduced and syringing must cease, but those swelling the fruit should be assisted with liquid manure twice a week, syringing the trees at closing time. A circulation of warm rather dry air should be secured when the fruit is ripening. A temperature of 60° to 65° at night, 70° to 75° by day, advancing to 80° or 85° from sun heat, is suitable.

Early Forced Planted-out Trees.—No other fruit tree produces surface roots so abundantly as the Fig, if measures be taken to encourage them by means of a mulch 3 or 4 inches thick of partially decayed manure given when the trees are fairly in growth. This, if kept in a moist state, will be full of active feeders by the time the trees need the most assistance in order to perfect the crop. Trees in borders of limited extent should be well supplied with water or liquid manure as necessary. Syringe twice a day. Ventilate freely in favourable weather, which will secure stout growth and leathery healthy foliage. No fruit is more benefited by the full rays of the sun than the Fig. Any kind of shading, whether by other plants or too much of their own foliage, is injurious and must be strictly guarded against by pinching out the young growths in the later houses and thinning out all the overcrowded shoots. The temperature should be maintained at 60° to 65° at night, 70° to 75° by day, advancing to 80° to 85° from sun heat.

Succession Houses.—Proceed with tying-in, thinning and regulating the terminal shoots, stopping the spurs at the fourth or fifth leaf, and the laterals from these at the first or second leaf. Mulch the borders with short manure if not already done. Maintain the night temperature at 55° to 60° at night, 65° by day artificially, 70° to 75° from sun heat, which ought not to be exceeded without full ventilation, as it is very important the growth be stout and the foliage have good substance. When the trees are in full leaf the night temperature should be maintained at 60° to 65°, and 70° by day, allowing it to rise to 80° or 85° from sun heat.

Unheated Houses.—The trees must now have the protection removed, eventually pruning the trees, thinning the least fruitful growths and the

old and bar, avoiding overpruning, as it is a common error in Fig culture, particularly in late houses in which the trees cannot have too much light. Allow the shoots for bearing to grow somewhat loosely with their points up to the light. Stopping must play an important part in cool houses. Pinch at the third or fourth joint on the young wood, which will assist the swelling of the fruit and induce the trees to break and produce short-jointed wood from the base of those shoots in bearing. Ventilate freely at and above 50°, advancing to 65° from sun heat. The border should have a thorough watering if dry, repeating as necessary to bring it into a thoroughly moist state, afterwards mulch with short manure.

PEACHES AND NECTARINES.—*Earliest Forced House.*—Continue syringing until the fruit commences to soften, as it will do during the late stages of ripening, and if syringing is persisted in it will cause the fruit to crack in the skin, and if only slightly it will give the fruit a very unpleasant mouldy flavour. It is very important therefore to have the trees quite clean by the time the syringing ceases, as it must when the fruit commences ripening. If there be the least trace of red spider apply an insecticide, repeating it so as to thoroughly free the trees of the pest. It is only the very early varieties that will be ripening, the others must be well syringed and have abundant supplies of water with good surface mulchings. Raise the fruits with the apex to the light, shortening or drawing the leaves aside so as to let the fruit have the full benefit of the light for colouring.

Second Early Forced House.—Trees started at the new year are not so advanced as usual, being much retarded by the prolonged cold. They are now stoning, and will need care in preventing checks from sudden fluctuation or depression of temperature, the night temperature being kept steady at 60° at night with 5° more on mild nights, whilst on cold nights it may fall to 55° in the morning, 65° by day artificially in dull weather, 70° to 75° on cloudy days, but with clear intervals, ventilating from 70° and freely above 75°. Attend to tying in the growths as they advance, and encourage no more than will be required for future bearing, the extension of the trees, and for the swelling of the current crop. See that there is no lack of moisture in the borders, affording liquid manure if the trees are heavily cropped and not making satisfactory growth, but avoid undue excitement to trees in full vigour, as any impulse given to growth during the stoning is apt to affect the process disastrously. Syringe twice a day, so as to keep the foliage clean.

Trees Started in February.—These have set too much fruit. When the fruits are the size of horse beans thin them well, removing the smallest and those on the under side of the shoots, leaving sufficient for the crop, those that are best situated for receiving air and light. Disbudding must not be neglected, and heeling-in the shoots required for next year's bearing can be carefully attended. Syringe twice a day, the second syringing at closing time or early in the afternoon, so as to have the foliage fairly dry before night, increasing the temperature to 55° or 60° at night, 60° to 65° by day, ventilating from the latter, and increasing it with the sun heat to 70° or 75°.

Trees Started in March.—Too many fruits are set in most cases, and where they have not it may be traced to over-luxuriance or to immaturity of wood and imperfect development of buds. An over-set is a source of great weakness, and not infrequently causes the incipient fruit to be cast in showers, leaving but a scant crop. There is no remedy but to well thin the flowers before they expand, not to disbud in quantity but gradually, and to thin the fruit so soon as it can be seen which is taking the lead. Syringe so as to assist the fruit in throwing off the remains of the blossom, and ventilate freely so as to insure stout thoroughly solidified growth. A temperature of 50° to 55° will be sufficient, not allowing an advance above 65° without free ventilation.

Late Houses.—Attend to fertilising the flowers. There ought not to be anything neglected that is likely to insure the perfect fertilisation of the blossom, as without it the fruit cannot attain perfection. Split stones and disaster in stoning are in a measure due to neglect of attention at flowering. Secure a temperature of 50° by day and ventilate freely, allowing an advance to 65° from sun heat. Leave a little air on constantly. As there is a superabundance of blossom thin it well—we have removed fully half this year in all the houses—all those on the underside of the trellis, and as there are some with half a dozen blossoms at a joint, and very many triple buds, all bloom, the necessity for thinning the blossom is great.

In unheated houses observe 50° as the point for admitting air, and 65° as a maximum from sun heat without full ventilation, but there must be no advance above it without a thorough circulation of air. There must be no deficiency of moisture at the roots.

PLANT HOUSES.

Cytisus.—Plants that have flowered should be cut back closely and returned to the greenhouse. It is a mistake to place them in heat for the purpose of inducing fresh growth. If they have been in a moderately warm structure while in flower, they should be placed for ten days or a fortnight after being pruned in the warmest portion of the greenhouse until they can be gradually hardened to cool treatment. They start into strong growth under these conditions, and are ready when genial weather arrives for placing in their summer quarters outside. The plants should stand upon some moisture-holding material, and be syringed once or twice daily according to the weather. When they have broken into growth they can be repotted if they need more root room. A suitable compost for them is good fibry loam, one-seventh of decayed manure, and a liberal addition of silver sand. Small shifts only are desirable, and the soil should be pressed firmly into the pots. Apply

water carefully until the roots are in full activity, when liberal supplies may be given.

Staphylea colchica.—Prune plants closely that have ceased flowering, or they will become bare at the base and lose their effectiveness for decorative purposes. When cut back and started, either in the greenhouse or cold frames, they make strong growths about 9 inches or 1 foot in length. These if well ripened by placing the plants in a sunny position outside after the weather is favourable will flower as well as imported plants. If the plants require more root room they may be potted directly they have broken into growth in the same compost as advised above. To increase the stock young plants can be raised by striking the growing shoots that are removed in pruning. These strike freely in the propagating frame in heat.

Liliums.—Plants of *L. longiflorum* and its variety *Harrisii* that have been flowered early for some years will now be developing their blooms. Be careful not to hurry them in this stage, or the flowers when they expand will be small and devoid of substance. Those that are only just forming their flowers must be carefully treated in this respect, or they will turn yellow and fall prematurely. Be careful never to allow them to become dry at the roots, at the same time the soil should not be saturated, for one evil is as bad as the other. The earliest of the old favourite *L. candidum* are developing their flower buds rapidly. Watch for aphides, which attack them at this stage of growth and soon mine the plants if not destroyed. The varieties of *lancifolium* that are required to flower as late as possible should be plunged in cold frames and abundance of air given whenever the weather will allow of this being done.

Roses.—Hybrid Perpetuals that have flowered should be placed in a cool structure until they are thoroughly hardened and the weather is sufficiently genial for placing them outside. Tea varieties if placed in a similar structure will practically rest for a time and then break again strongly into growth and produce better flowers than have been cut from them. It is surprising with what strength they start after they have enjoyed a slight rest in a cool structure.

THE BEE-KEEPER.

NOTES ON BEES.

THE CONSUMPTION OF STORES.

NOT only has this been excessive with my own strong stocks, but it appears to be general throughout the country. Both from correspondents at a distance, and verbal information from neighbours, the result is the same. Stocks have come back in weight as much as 30 lbs., and are on the point of starvation; nay, many record that they have discovered some dying, and but for aid in feeding would have been dead. In my own case, the only one that I have assisted is the nucleus of bees wintered on one comb, to which I have given a small super of sealed honey, heated well through before placing it over the cluster of bees. All the others being extra well supplied in autumn with honey, I feel quite at ease regarding their safety, as the 50 lbs., at least, of honey left with them in autumn cannot be consumed as yet. Nevertheless, as soon as the air becomes milder I shall feed all those having less than 12 lbs. of honey, and advise all bee-keepers to examine them on the first favourable opportunity, feeding all those having less than 12 lbs. of honey in store. It is better to ascertain their wants by weighing than opening the hives, preventing thereby the consequent cooling and attempt to rob by other bees. The only hives I have opened, or intend to until summer, are several very far advanced Syrians, and this examination took place early in February. Cold as the present spring has been, it is no exception to the rule that January is a safer month to manipulate, and to feed if required, than later on.

I should very much like to hear from those youthful bee-keepers who manage their hives on the brood-spreading and stimulating principle according to the printed directions in their guide. In a season like the present the slightest molestation of bees is very detrimental with hives in a normal state; when otherwise inspection should never be delayed.

The state of my apiary at the present is as follows: All are in full sized hives which admit of the internal economy of the hive being carried on without interruption, although there are 60 lbs. of honey. One half of my stocks are not only in full

sized hives, but are in full strength, capable of carrying in from 5 to 10 lbs. per day whenever the Gooseberries are in flower, which time cannot be far distant if the average of years is taken. It is quite common for bees at a distance of from three to four miles from here to increase in weight 40 to 50 lbs. in a week's time, from the Gooseberries alone.

Should the weather be favourable during April when the Gooseberries are in bloom, these forward stocks will carry in as much honey as will tide them over the greater part of the season, and be in the best condition for storing surplus honey from the White Clover. If they miss the Gooseberries, which they often do, then feeding heavily will be resorted to, and may turn out the least profitable half of my stock on that account. My other stocks, composed wholly of nuclei last autumn, are advancing steadily, although not so rapidly as the stronger stocks, but will not suffer to the same extent as the latter should the weather be unpropitious during April and May. Owing to this fact, and no expense necessary in feeding, they will be forward for the ingathering in June, which will make them the most profitable portion of my stocks.

It is a great mistake to suppose that bees should be manipulated or have a different position during the spring months from what they had during winter, and yet this is taught daily. The hive that is properly prepared in autumn so as to defend the bees from the rigours of an arctic winter, and having a young and fertile queen, all proving successful, require no other attention or alteration, because the bees will begin to breed at their own time, and continue in a more regular and continuous manner with less loss of bees than when brood nests are contracted, brood spread, seals of honeycomb broken, or stimulative feeding practised.—
A LANARKSHIRE BEE-KEEPER.

INTRODUCTION OF FERTILE QUEENS.

It was with the greatest pleasure and profit I read the truly scientific article by T. Bonner Chambers, Esq., F.L.S., page 247. His theories at once placed several matters I could hardly previously explain in a clear light. He speaks of what I have always referred to as "instinct," as "habit" or "custom," by which he leads us to first inquire what is the habit or custom of bees when placed in certain circumstances, and thus leads us to arrive at a correct theory.

Two distinct theories are propounded. First, that it is the invariable habit or custom of bees when they lose their queen to rear a successor from the egg or larvæ, and that being so, it is not natural, while in possession of such egg or larvæ, to receive a strange queen. This I very well know, though I never conceived it as a theory, nor should I ever have been able to put it in such clear or terse language as he does. For years I have tried experiments, introducing queens by means of cages; and though it has been asserted that old bees, or those long queenless, will not accept a strange queen under any circumstances, yet when offered under the conditions of my law she is invariably accepted. Strange to say, if instead of being dropped in amongst the bees she is caged on a comb in the midst of them for forty-eight hours, and the bees are old or have long been queenless, she will be at once balled when liberated and soon killed if not released. My experiments were directed to find out why this was so. I soon, however, found (I used the wire-mesh pipe-cover cage) that when I caged a Syrian queen amongst the old black native bees for six or eight days that one or more queen cells would be started, though no queen had been at liberty in the hive, nor was there any suspicion or possibility of any being in previous to the queen being caged. After they were sealed I removed the queen, when to my surprise Syrian queens hatched from them, thus proving conclusively that the egg or eggs had been dropped by the queen in the cage and carried by the bees to a cell to be developed. Had the queen laid them in the cells under the cage the bees could not have reached them. Thus it will be seen it was quite possible for them to procure the egg within the first forty-eight hours, or even twenty-four; and to be sure of finding it in one of the numerous cells, would require more patience than ever Job possessed. These queen cells have, I believe, been seen by others, but have always been treated by them as the produce of fertile workers; hence these were dubbed the "bee-keeper's pests," as no hive could be re-queened with them in, though as a matter of fact I have never found fertile workers to make any difference. It will be seen all these matters are made clear by the "Bonner Chambers" theory.

"A Lanarkshire Bee-keeper" has several times spoken of his safety cage, which fits on the top of the frames. I have an idea that its safety depends on the impossibility of any egg dropping out of the bottom, and not, as supposed, because the queen is safe from angry bees. If our friend, "A Lanarkshire Bee-keeper," will make his cage bottom of double wire cloth, pretty coarse so that eggs can drop through, and set it over a frame space, I venture to assert its safety will disappear. You see in his plan, as stated on pages 204-5, the bees have no means of rearing a successor, and not having been able to get an egg during the time the queen is caged they are exactly in the condition required by my law for safe introduction.

Mr. Bonner Chambers' second theory is, that when a queen leaves a comb before she has deposited an egg in each empty cell, the bees either think she is faulty or lost, and so begin constructing queen cells. Whether he is correct in this or not the future will decide, but in justice I must say this, that many times I have found queen cells that I could not account for, and I have grown so used to seeing them that I never conclude the queen is lost by their presence. Only as recently as Saturday, March 24th last, I found a sealed queen cell in a very strong stock; the reigning queen was laying, and seemed all right. As this cell excited my interest very much I carefully examined it and, from what I could make out, the queen previous to the last cold spell had deposited some eggs in the comb, and from some cause had left that comb for another one, as the sealed brood was very irregular. Then the cold coming the bees had contracted themselves from the comb ends, and being no passage through the combs, which have 1 square foot of surface, they might have been practically divided and so thought themselves queenless; or they might have started the cell solely because the eggs were in broken order. The cell in question had only just been sealed, as the queen had not changed from a larva to a nymph. I shall do my utmost to investigate this most important matter; from it we may learn why queens are so often superseded, and till it is firmly settled bee-keepers had better handle their brood combs as little as possible, as disturbing the queen will probably result in her being replaced by a daughter. I am sure all bee-keepers are under a deep obligation to Mr. Bonner Chambers for such an able article.—A HALLAMSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Webb & Brand, Saffron Walden.—*Catalogue of Hollyhocks.*
Thomas Painter, Smallwood, Stoke-on-Trent.—*Catalogue of Dahlias.*

TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (E. W.).—Perhaps the Rev. T. C. Bréhaut's work on modern pruning, published by Messrs. Longmans, might be useful to you. It can be obtained, if in print, through a bookseller.

Strawberry Plants (H. P. W.).—Possibly the plants may fruit in the autumn if they have proper cultural treatment, and the variety is *Viscontesse Héricart de Thury* or *Garibaldi*.

Wood Ashes and Bones (G. J. S.).—The bones are some months dissolving in wood ashes, the time depending on the size of the bones and the moisture of the ashes. The smaller the bones are broken the sooner they are softened, and the ashes must be constantly moist.

Peaches Setting (S. T. C.).—We have received the sample, which is as good as could be desired, but cannot insert your letter this week. We have observed that persons who particularly desire their letters to appear in the "next issue" are the latest in sending them, and thus defeat their object.

Heating (J. R. G.).—The boiler to which you refer is no doubt good when coke is largely or exclusively used as fuel, but if coal is used alone, or mainly, it is apt to "cake" in boilers of that type, steady and regular combustion not being assured except by frequent attention. There may be exceptions, but that is the rule.

Strawberries (Temple).—We suspect the atmosphere has been kept fully too moist, and perhaps the days were dull when the plants were flowering. The air should be dry enough for the liberation of the pollen, and it is a good plan to draw the hand lightly over the trusses, or rather draw them lightly through the hand, during the forenoon, for aiding its dispersion.

Scale on Pear Trees (W. S.).—The spurs are seriously infested with the oyster scale, *Aspidiotus ostreaformis*. It may be destroyed by applying methylated spirits well rubbed into every fissure with a brush, also by petroleum, but it is desirable to keep it from the buds. If you dissolve 4 ozs. of softsoap in a gallon of boiling water, stirring well in while hot a quart of petroleum, and apply this with a brush, it will destroy the scale. It is well to keep stirring the mixture as the application proceeds.

Strawberries—Vines (F. C.).—If the house is very light indeed the Strawberries would succeed either planted out or with the pots plunged in a moist medium, care being taken that the roots are not in the least dry when the work is done. We have seen heavy crops produced with the pots plunged, also when the plants have been turned out of them into good soil. Both methods are adopted where Strawberries are grown for market in very light pits. If your house is light enough, the plants, if good and well managed, will produce good crops of fruit. We are by no means certain you have done right in respect to the Vine border. Point the lime lightly in, make the border moderately firm, give a dressing of Thomson's Vine manure, and mulch to prevent the surface drying excessively, this causing the roots to go downwards, and often into ungenial soil. The condition of the Vines and the nature of the border have to be considered in the application of manure. If the border is inside the house examine it, not on the surface only, and if in the least dry apply sufficient tepid water for rendering it moist before applying manure or mulching.

Consumption of Fuel (J. H. S.).—The coal consumed in your garden during the past year appears at first sight to be very large; but after making a careful comparison of the fuel consumed in another garden, where economy has been exercised and the most approved systems of heating adopted, the quantity, as you will see, does not seem to be excessive. Coal, however good it may be, is not the most economical fuel that can be used for garden furnaces: for, however well the stoking may be done, there is a great loss by the escape of unconsumed gases, and this must take place to a very large extent at night after the fires are banked. According to various experiments this loss, in the ordinary methods of burning coal, amounts to 33 per cent., therefore 62 tons of oven coke would evolve as much heat as 100 tons of good average coal. Gas coke is considered 12½ per cent. inferior to this; therefore 74½ tons would be equal to the same quantity of coal (100 tons). This, then, puts a different aspect on the quantity of coal consumed in your garden. The 257 tons used would prove little if any better than 159 tons of oven coke, or nearly 192 tons of gas coke. This appears to be fully borne out by practical experience. In the garden to which reference has been made best steam nuts were used for fuel during the years 1873 to 1882 inclusive, and the average cost per year was £189 5s. 1d. During the years 1883 to 1886 inclusive the average cost for gas coke per year was £113 1s. 3d. The average quantity consumed during those years was 198 tons 9 cwts., and 2 qrs. The highest year was £124 18s. 10d.; quantity consumed, 210 tons, 5 cwts. 0 qrs. The lowest year was £99 9s. 5d.; consumed, 183 tons 11 cwts. 0 qrs. If we take the highest cost of the previous dates, when nuts were used, we at once see a striking difference—namely, £212 0s. 5d., while the lowest was £164 12s. 9d. The difference is great, but it goes to show that the figures given above have foundation in fact. There was no falling off in the quantity of heat during the years coke was consumed; on the contrary, the temperatures on the whole were higher, and maintained with greater certainty, with an additional house heated to a stove temperature during that period. The quantity of piping heated is 6500 feet, against 4780 in your case. Three boilers in each case were used; but in the one we have taken for comparison less fuel is consumed than is the case with you. This is readily accounted for. One of the boilers, a gold medal, heats 1500 feet of piping, for which two boilers—common saddles with brick flues—were formerly employed. The temperature of the house was raised 5° during the whole of the winter months, and the boiler now in use does its work with fully one-third less fuel. The other two boilers in use are set side by side, and work separately or conjointly as required. They are said to be capable of heating 20,000 feet of 4-inch piping. These are saddles, with ten 5-inch tubes running through each, which confines all the heat within the boilers; in fact, the smoke as well as the heat, after striking the back of the boiler, must travel through the lower five tubes to the front, and again through the top layer before an escape to the chimney can be effected. You appear to have plenty of boiler power—if the boilers are what we presume them to be—but if they are the old saddles with brick flues they are not the most economical that can be used, and their power is deficient. Too few pipes in any of the houses, which would entail overheating to keep the desired temperature, is the reverse of economy. But without doubt the lower temperature to which you are subjected during winter and spring would alone account for greater consumption of fuel than is the case in

the garden we have selected for comparison. You may not be fully aware how the external temperature affects the quantity of fuel consumed. To give an example, we will take the quarter ending March, 1883, and the consumption amounted to 71 tons 16 cwts. Again, the same quarter in 1886 the consumption was only 1 ton 1 cwt. less; while only 41 tons 1 cwt. was consumed during the same quarter of 1885; and the previous year was correspondingly low. To further show the effect of the external temperature, two quarters ending December may be noted. In 1884, 66 tons odd was used, while in 1886 only 49 tons odd. Your boilers appear to be exceptionally high and wide, and therefore we conclude they are not the common saddle boilers, but saddles with a number of tubes through them, and in addition flues at the sides the same as is necessary in setting the old saddle forms. These are good boilers, but not so economical as boilers in which all the heat is confined and exhausted before it can make any escape.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (J. H. W.).—The plant is a strong form of *Aloe ciliaris*. We shall be pleased to name the others for you, but it would be an advantage if you sent several together, and well-developed leaves would be sufficient with the most distinct.

COVENT GARDEN MARKET.—APRIL 11TH.

Business improving. Prices steady. Some new Grapes to hand, but unsaleable against good samples of old ones.

FRUIT.

ROOT CROPS.

MANGOLDS, Kohl Rabi, Swedes, and White Turnips are the root crops which are found upon most farms, and in addition to them Carrots and Parsnips are occasionally grown, but as the two latter crops are only used for horses and cows as an addition to the ordinary dietary they need not be taken into account for general purposes. Potatoes, too, are undoubtedly a profitable crop to grow for sale if the market be within a moderate distance of the farm, or where special facilities for speedy and cheap carriage exist, and on farms where there is a systematic process of cooking food for cattle or pigs Potatoes are very useful, but they should never be used uncooked, as our correspondents occasionally suggest.

The serious failure of many such crops from drought last year will probably lead to some curtailment of the space generally allotted them, and to improved culture. This certainly will be a step in the right direction, for we hardly need contend that if it is worth while growing roots at all it certainly answers to afford them the highest possible cultivation, and an acre of really fine roots is much more satisfactory and profitable than half a dozen acres of starveling roots. Repeatedly have we seen failures with Mangolds solely owing to a want of manure. To make a deep furrow or drill along which a very little farmyard manure is scattered—not enough, in fact, to cover the bottom, as we have often seen—to turn back the soil and sow the seed, is very poor practice indeed. The seedlings invariably come up puny and weak, and under the most favourable conditions of weather the crop is a poor one; but if drought sets in it is practically a failure. Such unsatisfactory results are so clearly a foregone conclusion that it is matter for wonder how anyone can allow himself to make such a deliberate bid for failure, and it is done repeatedly. Far better would it be to leave half of the land uncropped, and to cultivate the other half thoroughly.

Excellent crops of Mangolds may be grown without farmyard manure, but we prefer using it in combination with chemical manure, because, as we have so frequently explained, it contains so much moisture that once established in it the young plants are practically unaffected by drought. With the rows about 2 feet apart thirty cartloads of muck per acre spread thickly along the furrows is not too much, and before turning back the soil over the muck apply the Norfolk dressing of 3 cwt. of common salt and 1 cwt. nitrate of soda by scattering it upon the muck and soil. This dressing should suffice to produce an excellent crop of roots, and we hardly think the application of a second hundredweight per acre after the singling of the plants desirable, because the effect of this supplementary dressing must be speculative except in a wet summer. All things considered, we prefer our application of manures to be done as we have shown before the sowing, so as to have the soil well stored with fertility for the plant, and we certainly cannot suppose there is any risk of a loss of nitrogen before the roots are in full activity in the soil. We like to get this out of hand, and the singling and hoeing done as far as possible before haymaking begins. Sown now the plant is certain to be forward enough for our purpose, but land that is foul with roots and seeds of weeds will require the repeated use of both horse and hand hoes. Especial care must be taken to have the hand hoes going as soon as weeds are visible, for we have seen Charlock so rampant among Mangolds that it had to be pulled out by hand.

In Swede culture we prefer the Norfolk custom of sowing Swedes as soon as the land can be prepared after the Mangold sowing is done. Some roots may be spoiled by mildew, just as some

of the Mangolds bolt to seed from early sowing, but the per-centage of waste from such blemishes will be small, and there will be an ample amount of compensation in the superior bulk of the remainder of the crop. We may mention by the way that the bolting of Mangolds to seed may arise from seed saved from such "bolters," for which reason we prefer having our seed from a reliable source, even if we do pay a little more for it. The sowing of Swedes as a successional crop in alternate breadths with White Turnips often answers very well, and the plan has the additional merit of a variety of wholesome if not very nutritious food. A crop of late-sown White Turnips is always useful at this season of the year for the lambs. We have now a flock of ewes and lambs upon a piece of small but very sound roots altogether preferable to large tough woolly roots.

A certain breadth of Kohl Rabi is of especial value for autumn folding of land left under half-fallow. We saw excellent crops of it last year where Swedes were practically a failure, and it may be regarded as decidedly a more certain crop than Swedes. It requires very much the same cultural process as Mangolds, and the same manure, of which it is certainly worthy.

WORK ON THE HOME FARM.

April has brought with it the much-desired change of weather, and the corn drills have been kept going daily for the past week, and the Barley sowing will soon be over. All that we wanted was a few inches of the surface dry enough for drilling in the seed, and we gave orders that no deep stirring of the soil with duckfoot harrows, horse hoes, or cultivators should be done before the sowing, for every day is precious now, and the seed on the whole has been sown very well. Germination and growth will follow so quickly that we must be on the alert to get as forward as possible with all work on the land before the hoes are required for the corn. The Excelsior drills prove of especial service now, sowing the corn, manure and small seeds at one and the same time. This is certainly one of the best labour-saving appliances we have tried. It is light, yet very strong, and so simple in construction that we have really had no difficulty in getting our horsemen to understand and manage them at once. There are dial plates with indications by which the quantity of seed and manure sown is regulated to a nicety, and the land measurer attached to the drill shows the number of acres sown daily. We have long deplored the cost of drilling under the old system, which required three horses, two men, and a boy, but with new drill one man with a pair of horses can do the work expeditiously, and to our entire satisfaction. At first the horsemen said they should not be able to manage those straight rows with it upon which every drillman in East Anglia prides himself upon doing just a little better than anybody else, but we at once said the necessary degree of skill for this would soon be acquired, and at first we should be content if the whole of each field was sown.

We are sowing Sainfoin extensively this spring, some of the seed being home-saved, and other seed has been purchased at 24s. per sack of 4 bushels. Red Clover seed has fallen wonderfully in price since the season began, when 50s. per bushel could be had for pure bright seed, but it has now fallen below 30s. This seed, with Lucerne, mixed Grasses for temporary or permanent pasture, as well as Rye Grass, should now be sown without loss of time, for the soil is moist and is becoming warm, and in the best possible condition for the seed. To wait and have to encounter the possible risk through drought would certainly be wrong.

REMARKS.

1st.—A bright spring day.
2nd.—Slight shower in morning, otherwise fair till 3.30, then dull and showery; cold clear night.
3rd.—Generally bright, but with one or two slight hail and snow showers.
4th.—Bright early; dull morning, with frequent flakes of snow falling; fair afternoon.
5th.—Bright early; fair morning, with occasional flakes of snow; bright afternoon, cold night.
6th.—Bright and clear morning, cloudy afternoon with spots of rain.
7th.—Fine and generally bright day; rain in evening and night.
Much warm sunshine, but keen air and frost every night; a cold week, the average being rather below that due to January 1st.—G. J. SYM. NS.

FORCING STRAWBERRIES.

WE are now in the midst of the season for forced Strawberries, and a few remarks on the subject may be of service to those in need of advice. Unfortunately no general rules can be laid down, so much depending upon the facilities that each possesses for forcing. In any case it frequently takes two or three seasons to discover which varieties best suit the place, and to find the most suitable positions for them. As far as we are concerned no difficulty is experienced in producing ripe fruit by the middle of March, or when Strawberries cannot be bought for less than sixpence each, and this season not one plant in fifty has failed either to flower strongly or set a good crop. The earliest to ripen is a little known variety we have under the name of Princess of Prussia, this being a sure and heavy cropper and from a week to ten days in advance of Vicomtesse Hericart de Thury. The latter, however, is the better in point of colour and flavour and a better traveller. What makes the fruit still more valuable is the fact that it is of good flavour gathered direct from plants growing in a temperature and atmosphere suiting Pines, Beans, and Stephanotis. The favourite variety with my employers, however, is Sir Joseph Paxton; this ripens early in April, is of taking appearance, travels well, and is of good flavour. President for a succession and British Queen for the late supplies complete our list.

At one time our plants were started on the shelves in the early and successional Peach houses, being transferred to strong heat as soon as the crops were set. In these positions, where they naturally require abundance of water, they render the borders underneath very wet and sour, and we have now hit upon a better system in every way. In the first place the good old plan (which as a boy I did not like) is adopted of cleaning the pots, clearing off the rubbish and surface soil, and after the sides are well rammed a top-dressing of rich loamy soil is given. The requisite number, or say fifty plants, more or less according to the requirements of the establishment and the shelves to be filled, are plunged in a gentle hotbed of leaves not far from the glass in a heated pit. There they soon form fresh foliage, and the roots also being active fine trusses of bloom are thrown up. Plants are thus started every fortnight, and where it can be practised this will be found a sure, easy, and cleanly method.

Many succeed very well up to a certain point, but they fail to set the strongest or first flowers, and it is no unusual occurrence for the principal portion of early plants to be useless. The latter is most to be regretted, but I dislike losing the first strong flowers, as these only are followed by fine fruits. It is, however, possible to set every flower early in the season in a high temperature and a moist atmosphere, if only the precaution is taken to carefully fertilise each when fully expanded. This brings me to one of the most important factors in our success with Strawberries.

For various reasons it is advisable to dispose the Strawberry shelves as near a pathway as possible, there being no better position than against the comparatively low back walls of three-quarter span-roofed forcing houses, and if these are not sufficient, suspended shelves within easy distance of the pathways, as well as front benches over the front hot-water pipes are suitable. We rely on the back wall shelves principally, the plants being set on these just as they are opening the first flowers. There they are easily reached for the purpose of fertilising, and those in charge have no excuse

for neglecting to keep them well supplied with water. For effecting a good set I have tried syringing, tapping the trusses when dry, and the use of either a camel-hair brush, a piece of sponge, or the skin side of cotton wool, and prefer the sponge to any of the others. It is advisable towards midday to gently sponge each flower, this effectually lodging the pollen on the numerous tiny stigmas. This artificial method of fertilising may not be necessary after this month, nor at any time when plenty of air is admitted to the plants in full flower, but I hold it unwise to leave anything to chance, and never mind spending a little time in "sponging or setting" Strawberry flowers. In any case it obviates the necessity for keeping the plants in an airy house till a good set is effected.

Strawberries are sure fosterers of red spider and other pests in a less degree, hence the advisability of keeping them out of vineries and Peach houses as much as possible. It is better to be without a few dishes of early Strawberries than incur the risks of spreading red spider on the Vines and trees. High back shelves, although not the best places for Strawberries, are necessarily often utilised for their culture in pots, and it is in these positions where they require most water and very often get the worst attendance in this respect. Troughs that hold water are sometimes recommended for Strawberries, but although this may save the watering pot, it has a most prejudicial effect upon the quality of the fruits, these being nearly as sour as vinegar. Mr. Taylor when at Longleat used to stand all the pots on small squares of turf, and into this the roots soon found their way. Many are unable to procure thin turf suitable for this purpose, and in spite of Mr. Taylor's undoubted success with Strawberries in pots, I believe a good bed of fresh moss even preferable to turf. Our plants, being started in a genial hotbed, invariably send a number of roots through the drainage holes, and in order to preserve these we adopted the plan of covering the shelves intended for their reception with moss. The roots take readily to this, and I believe derive some support from the moisture and liquid manure that it holds. Turves will, if of a clayey nature, become sour, but not so the moss, nor does the soil become dry so quickly as when the plants are set on bare boards.

Whatever plan may be adopted it is unwise to leave many fruits on a plant, from six to nine on each, according to the varieties, being ample. The numerous small fruits ought to be removed early, and before the reserved fruits commence ripening all should be neatly propped up with Birch twigs. This greatly improves their appearance, saves the stems from being bent or crippled, and keeps the fruit clear of the soil or any dirty water or liquid manure that may be used. Much in every case depends upon those in charge of the houses, and when I can point to a good crop of fruit I never hesitate to give the foreman full credit for his share in the work. All head gardeners well know what a relief it is to have a man under them who never neglects the Strawberries and other plants in pots. The Strawberries occasionally require water twice in a day, liquid manure frequently, and syringing daily. Neglect of these details becomes only too apparent when the crops are swelling.—W. IGGULDEN.

[Six large fruits of Sir Joseph Paxton Strawberry accompanied this communication, four of which were extremely handsome and well developed; the other two were slightly deformed, and were sent to show the effects of imperfect fertilisation. Five fruits weighed about 4 ozs.]

LAST summer being an exceptionally dry one it was a difficult matter to procure Strawberry runners even for late summer plantations, while securing good ones for pot culture and forcing was quite out of the question, as none was produced until late in August; at least that was my experience in this dry chalky soil. Wishing to overcome the difficulty I decided to push on my plants that had been forced and try them again; therefore, in the beginning of June all the best of them had the soil shaken out, the

longest roots were shortened, and the plants placed at once into their largest pots, using two-thirds loam and the rest decomposed manure. They were potted firmly, and afterwards plunged in coal ashes until the pots were full of roots and the plants required more room, when they were treated in the usual way to secure good crowns and have them well ripened before storing away. My object in writing is to let you know that the plants have more than answered my expectations, for those that have just fruited have borne a much heavier crop than I could have had from maiden plants. The varieties are President, James Veitch, and Vicomtesse Hericart de Thury. I send a fair sample of the ripe fruit of each, also a specimen of the fruit as it set on the plants not thinned. If a similar difficulty should again occur in procuring runners those forced the previous season may with proper management be depended on for a crop a second season. I might mention that a short time after potting the plants produced some flowers, but these were carefully picked off.—THOMAS RECORD.

[The plant sent had seventy well set green fruits in different stages and a number of flowers to open. The ripe fruits were very handsome, and amply proved the success of the practice recommended.]

CROTONS AS DECORATIVE PLANTS.

THE present is a capital time to set about the increase of the stock and the preparation of the plants for summer and autumn use in the house, as at those times, where foliage plants are appreciated, nothing surpasses Crotons either for the dinner table or in the decoration of rooms. The varieties are now so numerous that no difficulty need be experienced in forming a good collection. The narrow-leaved drooping varieties are most preferred, but some of the upright, broad-leaved sorts are equally valuable for some positions. The brightest coloured varieties are much the best, as green or dull-coloured foliage plants can always be had. To keep up a stock of serviceable plants, cuttings should be struck in the autumn, using 2½-inch pots, in which the plants can be wintered in the stove, choosing a position near the glass, where they will not be drawn up weakly; nor should they long remain dry at the roots, or a loss of the lower leaves will take place, much to the disfigurement of the plants. This is a good time to give such plants their first shift from the cutting pots into those 4 inches in diameter, using a compost of equal parts peat and loam, a small quantity of leaves partly decayed, a dash of finely ground bones, some charcoal, and a plentiful addition of sharp silver sand. Some persons use no loam, but add sphagnum moss instead. To my mind this compost is much too porous; the loam adds solidity to the growth, and the foliage is retained much longer. In potting, press the soil about the roots firmly; growth then is more sturdy, and the leaves of a better colour. Replace the plants on the shelf close to the glass, where they can be exposed to the sun, as without it the foliage will not colour brightly. Where such a position is not available a capital makeshift can be adopted by drilling three holes in a triangular form into an ordinary saucer or feeder, just below the rim; to these holes place three wires, the length to be guided by the height of the plant. Inside the saucer place another one, but smaller; on this stand the plant, suspending the whole from a nail driven into the rafters of the roof. Crotons in this manner, particularly the drooping varieties, are not at all objectionable in appearance, while the position for their welfare is one of the best obtainable. Short, stout shoots taken off now, inserted singly in small pots of sandy soil, placed in a propagating frame over a brisk bottom heat, quickly form roots and grow into useful decorative plants by the autumn or end of the summer. It is a mistake to overpot Crotons; it is much better to use a substantial kind of compost, giving water freely to the roots, varying it occasionally with weak liquid manure, when the pots are well filled with roots. A lack of water during summer quickly renders the plants shabby by a loss of the lower leaves, and discolouration of many of the others.

To obtain plants for immediate use, well clothed with foliage, the process known as "ringing" must be employed, which is done in the following manner. Any plant with only one stem or more, which has been in constant use and lost its lower leaves, should have a ring cut around the stem about half an inch wide, removing the bark at that place at a distance of from 6 inches to 1 foot from the top. Around this incision wrap some moss, to which has been added some sand; tie the moss on tightly, and keep it moist by frequent syringings during the daytime. Roots will quickly form in the moss, and when they show through to the outside of the

moss cut off the shoots and place them into pots sufficiently large to contain the roots, moss and all. Place the plants in a propagating case, or under handlights, excluding air until new roots are formed in the soil, when it may be gradually admitted until free exposure will not harm them. If the syringe is used vigorously amongst Crotons, as it should be, mealy bug cannot increase.

The following are good varieties for decoration in a small state:—

Drooping varieties.—Picturatus, green, blotched with red; Sinitzinianus, golden blotched; nobilis, red; angustifolius and aureus, both belonging to the golden class; Johannis, long leaves, marked with yellow; Warreni, having long twisted red leaves; majesticus and interruptus, two older red-leaved sorts, still useful for their hardy qualities. Many more might be added, but these are all well-tried varieties.

Erect varieties.—Queen Victoria, Williamsi, and Hanburyanus are useful varieties, with red foliage; while the best yellow Crotons are Morti, Hawkeri, Disraeli, and variegatus.—S.

VEGETABLES FOR EXHIBITION.

ONIONS.

Tripolis.—These are usually included in the collections of vegetables shown in June, July, and frequently to the end of August. They are also the best to enter in the classes for the heaviest Onions. The seed ought to be sown late in August or the first week in September, on good well manured ground, and in drills 12 inches apart. If a few are wanted extra early the seed may be sown on a sheltered sunny border, those not disturbed at the thinning out time usually being the first to bulb. As a rule an open piece of ground is best, or it may be near where the Onion beds are eventually to be formed. If the plants are at all crowded they ought to be lightly thinned in the autumn, otherwise they should not be disturbed. The ground may be deeply dug or bastard trenched during the winter, plenty of solid manure being mixed with every spit, one end of this to be devoted to the Tripolis, and the remainder to the spring-sown Onions. As early in the year as the state of the soil permits dress with plenty of road grit, if procurable, and also a mixture of soot and common salt—one peck of the latter to three of soot—this being applied in moderation, a bushel being sufficient for every 16 square yards. Fork this well in without disturbing the manure underneath, and leave the ground loose. As early in March as it is possible to work on the ground without making it pasty, transplant the Onions. Do not drag them out of the soil, but prefer rather to ease them up with a fork so as to save as many roots as possible. A few may be left about 6 inches apart in the seed bed to mature, and the strongest of those lifted be replanted. Open wide flat drills 12 inches apart and 2 inches deep, arrange the plants 6 inches apart, spread out the roots, and cover firmly with the soil. Some of the plants invariably run to seed, and these may be drawn and used early, those left on the ground being all the better for the extra space given. White Naples is the earliest to bulb, and can be had good in June. Later on I prefer either the Giant White Madeira or Giant White Tripoli. Giant Rocca is the heaviest, and may be shown in the single classes, but is not so telling in a collection as the flat white-skinned varieties.

Spring-sown Onions.—I have already described a good method of preparing the ground, but omitted to add that, provided it is not done too soon, it cannot be made too firm for Onions generally. Loose deeply cultivated rich ground invariably encourages rank growth, large, late-maturing, thick-necked Onions being the result. Making the ground firm prevents this, and I have always observed the handsomest bulbs are produced on the ground dressed with road grit. The finest spring-sown Onions are obtained by sowing the seed early in February in pans or boxes of fine soil, setting these in heat until the seeds germinate. The seedlings should not be shaded in any way, and when about 5 inches high they may be gradually hardened, and finally planted out in rows 12 inches apart and 6 inches apart in the row. Although comparatively small when put out, they will yet be considerably in advance of any raised in the open ground, and will maintain the lead throughout. Fine bulbs can be obtained in this manner early enough for the August shows.

Those who are content to sow in the open ground only may do so as early in March as the weather permits. If a good seed bed cannot be had, nor the ground trampled during the first week in March, wait another week or two for better weather. The drills to be 12 inches apart and rather shallow, the seed being sown thinly, fixed with the foot, and then carefully covered. Keep the flat hoe going among all advancing crops of Onions, this keeping down the weeds, also preventing binding of the soil, followed by cracking and the rapid evaporation of moisture. Thin the plants early, leaving

them 5 inches or 6 inches apart. Some will soon take the lead, and if these promise to bulb well they will further be assisted by having the ground lightly loosened about them, and then treated to a sprinkling of either soot, guano, superphosphate of lime, or sulphate of ammonia. Only a very little should be given at a time, and that in dull weather, this either being washed in by the rains or by water applied through a fine-rose pot. Show bulbs ought to need no twisting down of the necks to hurry bulbing, but if wanted early this may be resorted to if necessary. In hot seasons a mulching of old tan, leaf soil, cocoa-nut fibre, or grass from the mowing machine, if given either after a soaking rain or a good watering, will do good. The less artificial watering necessary the better if handsome bulbs are looked for.

Banbury Improved is a good type of White Spanish Onion for spring sowing, Sandy Prize, Naseby Mammoth, and Giant Zittau also being good.—EXHIBITOR.

TACSONIA VAN VOLXEMI.

ONE of the most beautiful of all conservatory climbers is this Tacsonia, with brilliant crimson flowers on long thread-like footstalks. It is easily raised from seed sown in any light sandy soil, covered with some of the same compost, placed in heat, and watered. If the seed is good the young plants will appear within a fortnight or three weeks from the time of sowing. They should, as soon as large enough, be placed singly into 3-inch pots in a mixture of four parts fibry loam and one of leaf mould, with a sprinkling of sharp sand, returned to heat, watered, and shaded from sunshine until the roots have taken to the soil. Shift the plants into 6-inch pots before the roots become matted, and grow them until about 3 or 4 feet high, when they should be planted out in a well-drained border, training to the roof of a greenhouse or conservatory. The best compost is formed of three parts fibry loam and one of peat, with a good sprinkling of sand. Train the shoots underneath the roof. When well established thin them, but do not stop the shoots.—W. H. W.

IMPROVING OLD VINES.

PRACTICE under difficulties is often useful, and I am constrained to relate particulars of some Vines taken in hand last season with a view to their improvement. The house containing them is old fashioned. There is no lack of rafter, and the size of the panes of glass would disgust every cultivator of orchard house trees. The border is outside, and the roots are not very near the surface, for what reason I do not know, as the border is not sodden or poor. The house is heated by hot water, the rods being trained to wires in the usual manner, and there is ample ventilation.

The Vines had several rods each, some only a foot apart; some were old, others young, all spur-pruned, and produce few and poor Grapes. The Vines had been started with the New Year (1887), the rods being brought down horizontally along the front of the house, and the buds were breaking very irregularly. The border had the scantiest covering of protective material, which did not extend up to the house so as to cover the stems. The rods were tied in position, for I do not see the advantage of depressing rods (with canes it is another affair), and they were as I thought very much too close. There were the old rods, one to each rafter, and between those others of varied age, making the distance between a foot and 18 inches. The whole had been spur-pruned. I decided to take out fully half the rods. Grapes, however, being a consideration I was constrained to reserve the marked ones until the fruit appeared, as those shoots that showed fruit could be retained and the other rubbed off. I determined to keep the best of the rods, one to each rafter, which are about 2 feet 6 inches apart, and to cut away all the others, which were the youngest rods, as they were badly furnished with spurs. The Vines had been kept to one rod for many years, then canes had been run up to get better or more Grapes, or with a view to displacing the old rods, but how all came to be retained is left to the imagination. There they were in February, 1887.

Out came the doomed rods in due season after they had finished the few Grapes, and the canes taken up were remarkable for weakness and length, but though straw-like, there was an increase of strength as they advanced from the origin, and were short-jointed and ripened well. The Grapes, too, finished satisfactorily. In autumn there were old rods, and young canes of 6, 12, and 20 feet length. Perhaps I ought to state that the border had a good dressing of lime in the autumn. About two bushels unslaked was applied in little heaps on the border, slaked by sprinkling with water, spread over the border hot, and pointed in at once. Before frost the border was covered with litter, adding about 18 inches thickness of leaves, with some long litter over to keep the leaves in place when the Vines were started with the new year. Lime is of no use, say

some persons, and even Mr. S. Castle has doubts of the value of old mortar rubbish, but it is a fact that lime is present in most plants. Is the lime of no use when the roots come into the feeding ground it has prepared for them?

Now for the Vines. No 1, Black Hamburg. As the old rods were so puny in the shoots produced they were all cut away, and a cane taken up, which at first was no thicker than a quill, but gained strength as it advanced, the laterals assisting until it had a length of 20 feet and a thickness approaching that of the little finger. It was cut back to 6 feet, and had ten bunches of Grapes. No 2, Black Hamburg. Old rod left, spur-pruned—i.e., to two buds, no Grapes; cane very weak, cut hard back, no Grapes. No 3, Black Hamburg. Old rod retained, spur-pruned (in part), no fruit; pruned four to six buds (part), no fruit. Cane very weak, cut hard back; no fruit.

No 4, Grafted Vine. Black Hamburg stock, old rod reserved of the variety Alicante, ten spurs or their shoots pruned to two buds, showing five bunches, all other spur-shoots pruned to four to six eyes, giving eight bunches of fruit. The Black Hamburg cane was pruned to 7 feet, and is carrying nine bunches of Grapes.

No 5, Grafted Vine. Black Hamburg stock. Old rod retained of Mrs. Pince which, when spur-pruned, gave no fruit. Cane of Mrs. Pince, pruned to 4 feet 6 inches, showed six bunches. A Black Hamburg cane pruned to 6 feet furnished eight bunches, and another Hamburg cane pruned to 2 feet afford two bunches.

No 6, Grafted Vine. Black Hamburg stock. Old rod Mrs. Pince, spur-shoots pruned to two buds; no fruit; whilst those spur-shoots pruned to four to six buds present four bunches of Grapes. This Vine has the run of two rafters—i.e., double space, hence another old rod of Mrs. Pince was partly spur-pruned; no fruit; those pruned four to six buds have three bunches. Mrs. Pince cane, pruned to 4 feet 6 inches, had four bunches. A cane of Mrs. Pince, pruned to 2 feet 6 inches, has three bunches. A Black Hamburg cane pruned to 2 feet 6 inches carries three bunches.

No 7, Black Hamburg. Old rod pruned to two buds fruitless; pruned to four to six buds, three shows of fruit, which have twisted and curled into anything but Grapes. This Vine had no cane taken up in 1887. No 8, Young Vine. Black Hamburg. The old Vine collapsed, and the young one does not count, as it is only just planted, but the one shoot intended for the cane shows fruit.

It only remains to be stated that the treatment of the Vines is the usual one, but I have omitted to mention that the spouts were so arranged as to throw all the water from the roof on the border, which it is needless to say has been rectified. Perhaps I ought also to state that so bad was the border considered that a new one had been made for the young Vines in an adjoining vinery, which, so far as I can see, might as well have been left alone, as the roots may be 3 feet beneath the surface, but the Vines are fairly vigorous, and will no doubt push roots freely from the collar into the surface we have prepared for them with the lime and the protective mulching.

I shall only draw a few inferences. 1, The Grapes are all borne on the canes or semi-canecan. 2, Where the parts were many, as in case of the old rods, there is no fruit of value. 3, The want of fruit was the consequence of weakness, due to overcropping and overcrowding. 4, The weakness and sterility are most decided in the Black Hamburg. 5, Alicante and Mrs. Pince being strong growers and gross feeders, are most fruitful; in fact much easier of cultivation than thin-skinned Grapes. The Vines are making canes double the vigour of those of last year; indeed it is a question of roots, for the Vines are throwing out aerial roots, as they always do when the roots are not affording sufficient support. It is also worth note that the roots so excited are able to attack inorganic substances, thereby supplying its needs in that respect for the perfecting of its stones; in fact it is difficult to account for Vines otherwise acquiring phosphorus, sulphur, and lime.—G. ABBEY.

AMARYLLISES (HIPPEASTRUMS) AT CHELSEA.

THE annual display of these choice hothouse flowers referred to on page 299, marks the rapid progress made in their improvement during the last decade. Seedlings have been raised at Chelsea and elsewhere years before this; in fact, some of the best work performed by the celebrated Dean of Manchester (the Hon. and Rev. William Herbert) was the raising of cross-bred Hippeastrums. It is perhaps worthy of notice that one of the earliest of Dean Herbert's seedlings, Johnsoni or regiovittatum, is yet, or was quite recently, in cultivation. I am not sure whether this was not the first hybrid raised in England, first by a watchmaker of Prescot, in Lancashire, named Johnson, in 1799, and also by Herbert himself at Mitcham in 1811, and again at Highclere later. It was raised by crossing *H. reginae* with the pollen of *H. vittatum*, and Herbert's method of naming these hybrids was to link the two names

together. Thus *H. regio-vittatum* was Herbert's name for this early cross. Others named by him were *aulico-vittatum*, *Goweni-vittatum*, *striatifolio-vittatum*, *Griffini-Johnsoni*, *solandraefloro-Johnsoni*, &c., to the number of a score or more of these hybrids. Herbert's work was continued in different gardens for a period of thirty-four years, and at the time of his death a large collection of choice seedlings was left by him. A list of the principal varieties and species grown to hybridise from was given by a Mr. Carton (who served as gardener to him and also to his brother, the Earl of Carnarvon) in the first volume of "The Florist," page 239. They were *Hippeastrum reginae*, *H. equestre*, *H. solandraeflorum*, *H. striatum*, *H. miuiatum*, *H. rutilum*, *H. fulgidum*, *H. vittatum superbum*, *H. crocatum*, *H. psittacinum*, *H. calyptratium*, *H. stylosum*, *H. striatifolium*, *H. pulverulentum*, and *H. aulicum platypetalum*. Mr. Carton, after the death of Herbert, took charge of the gardens at Syon House, Isleworth, and writing in 1848 he stated that most of Herbert's beautiful hybrids were lost. They were not all lost, as I cultivated some of them years ago, but they had to be discarded in favour of the fine forms raised in Messrs. Veitch's nursery or imported by them from the Continent. The vigorous constitution of the varieties named there is doubtless owing to such fine varieties as Empress of India, while the infusion of the handsome species *H. Leopoldi* has given firm to the flowers. The best varieties of *H. pardinum* were also used with good effect. On looking over the collection a few days ago I was struck with the decided improvement made this year in the size, form, and colour of the flowers. For size, combined with form and rich colour, Chevalier is decidedly in advance of anything yet raised; the flowers are scarlet, with a greenish star, the petals 4 inches across, and 9 inches across the expansion of the flowers. Firebrand is very distinct in character from any other. Its parents might be Dr. Masters and Aekermannii pulcherrima, but it is superior to either of those in colour, which is a rich crimson, with dark maroon crimson at the base; good form. Acquisition is of a different type, light scarlet, mottled white, creamy bands, large flowers, of good form.

A score more besides these might be named and described, all of the very best quality. The strain has been so much improved that the production of high class seedlings is the rule, and ordinary forms the exception. Seasonable influence is an important factor in the development of these plants. It has been uphill work this year to bring them up to anything like the usual vigour, and the plants under the influence of London smoke must have felt the effects of the season more than those in the country. Of course as daylight increases the effects of this abnormal season will wear off, and any loss of strength sustained in the past will be made good in the bright days to come. We have been told that in some parts of England the Amaryllis can be grown well as a hardy border plant. Probably some of the South African species, or varieties raised from them, might succeed out of doors, but the best garden varieties have become inter-crossed with the tropical species from South America, and they are not sufficiently hardy to do any good even in a greenhouse temperature. We have been very successful with the culture of the tropical species, both with the named varieties and the raising of new varieties from seeds. For I never could settle down quietly to enjoy the fruits of other people's labour, but have always found a great fund of real enjoyment in anticipating the flowering of seedlings. It is now the time to hybridise them, and those intending to raise seedlings will not find the work very difficult. The organs of reproduction are very prominent, but to make sure that the variety from which the seeds are to be saved is not self-fertilised, the anthers should be removed before the flowers open, and two days after the flower opens the stigma spreads out into three divisions, and to the inner part of these the pollen must be applied. It, of course, requires some judgment and taste to select both the seed and pollen bearers. The seed bearer should possess a vigorous habit of plant combined with good form and quality in the flowers. The pollen bearer ought also to be of good quality and be possessed of clear and decided colours.

Those who are anxious to grow the Amaryllis should begin with the best varieties, especially if they intend to raise seedlings. It would be useless to start with what were considered the best five years ago, as the improvement in all respects has been much greater in that time than in the years preceding. We sow the seeds as soon as they are ripe in July or August. The young plants are quickly above ground, and form small bulbs by the end of the year, but they do not seem to have a resting period at all the first winter. The leaves remain quite green, and the plants themselves increase in size all the winter. Do not water them much, just enough to prevent the soil being dried. With good culture some of these small plants will produce flowering bulbs the following season, but the largest portion will not flower until they have made two seasons' growth. They do best placed in bottom heat and treated to a hothouse temperature.

The flowering plants have their season of growth after the flowers fade. The rapid production of leaf and flower from the bulbs seems to exhaust them so much that they shrink into much smaller proportions by the end of March, and a season of growth from April to the end of August is required to plump them again. During that period the process of development is very rapid, and any check to the growth would not be recovered from. The probable cause of an arrest of growth would be want of water at the roots, by an attempt to "dry them off" before their time. An attack of thrips or red spider might also do so. Both these pests are troublesome in hot weather. Syringing under the leaves will keep off red spider, and fumigating with tobacco smoke will annihilate the thrips. In September but little water is required; in October and the next two months none at all.

I report the bulbs in the first week of January. The potting soil should be moderately moist. Plunge the pots in a gentle bottom heat, but do not water them at the roots for a month at least. The temperature of the house for that time need not be more than 45° to 55° at night, with a slight rise by day. The bottom heat of about 80° brings them on gently, and the temperature seems to be what they like, for we have generally by the middle of March a mass of flower spikes crowded together, in many instances three from one plant. I have had seventeen flowers from one bulb. Two-year-old bulbs will give two spikes, with six to nine flowers. When the plants have once made good growth in the early months of the year, it is a grave error to lower the temperature for the purpose of keeping them back for an exhibition or anything else, it gives them a check which they do not like. It is also very easy to injure them with water applied either too freely to the roots or in the atmosphere.

An excess of atmospheric moisture in the house will frequently engender decay in the substance of the bulbs above ground, while the same process goes on at the base of the bulbs from too much applied to the soil. It is far better to err on the side of over-dryness.—J. DOUGLAS.

YOUR note on the Amaryllises at Messrs. Veitch's prompts me to say a few words on the method we adopt with our plants. In few private places can a house be devoted to their culture, and to attain success much contriving is required. We have a good number of bulbs, but, unfortunately, the variety is but small; however, for decoration we find the plants useful, also the flowers when cut. About the middle of January the bulbs are potted, shaking off most of the old soil without damaging the roots, placing them in various sized pots, avoiding large shifts, 6-inch pots being the largest used. The pots are well drained, using a compost of loam, a small portion of peat, the loam being of a heavy character, a small quantity of finely ground bones, some charcoal and sand. The pots are stood upon slates over the evaporating troughs and pipes in the Melon house, where they have a brisk bottom heat. No water is given until the roots commence growing, except an occasional syringing; afterwards water is supplied freely, and occasionally liquid manure is given. Towards the end of March the flower spikes appear. As soon as the flowers expand the plants are removed to cooler quarters, a vinery kept at about 55° by night, and 5° more during the day. The plants stay there a few days until hardened, when they are transferred to the conservatory as required.

After flowering the plants are placed on a shelf close to the glass in a vinery where the moist heat required for the Vines favours the growth of the Amaryllises. When growth is completed the plants have a similar position in a Peach house where the temperature is some degrees lower than the vinery. The shelf on which the plants stand being suspended under the back lights of the house, which is a three-quarter span, they do not require shading, but have abundance of light and air. Water is gradually withheld to ripen the bulbs thoroughly, but we never dry them so severely as to lose the foliage, as we find that, and keeping the soil too wet during the winter months, result in a loss of many of the thick fleshy roots.—E.

CAMELLIAS IN THE OPEN AIR.

THE Camellia is not common as an outdoor shrub. It is a favourite in the greenhouse and conservatory, and in the rare instances when it is found in the open it is always looked upon as a curiosity. This is particularly the case where they have been planted in suitable positions and treated so that they have developed into fine bushes. Here we have some Camellia bushes on the lawns 12 feet high and as much in diameter. We make no attempt at sheltering them in winter; they have withstood many severe frosts, and at the present time they certainly look as healthy and well as other much more common shrubs. At Singleton in this county some huge bushes may be seen, and when I saw them the other day they were about to afford a wonderful display. Ours are later, but they, too, will soon be fine. Although the rain sometimes blemishes the blooms this is no charge against them, as all open-air flowers are liable to suffer in the same way. When not in flower, but only displaying their glossy green leaves, they are as ornamental as any other green-leaved shrub, and I am sure if Camellias were generally planted in the open air they would afford their owners much satisfaction. To those with "no glass" they would prove highly valuable and interesting, as they would always be able to cut flowers in the open air in April and May. As a rule we secure our Camellia blooms from the open-air trees for the Church decoration on Easter Sunday, and they are amongst the most attractive flowers that can be gathered at that season. To some it may appear odd that they should bloom before Rhododendrons in the open, but such is the case, as although a few Rhododendrons may be in flower by the first week in April most of them are not out until after the Camellias. One reason why the latter do not succeed in the open is this. As a rule healthy young plants are never turned out, but old plants which have failed to do well under glass are planted in the open under the impression that anything is good enough to turn out. But I may say once for all that such plants are absolutely unsuitable for planting out. If strong clean healthy plants are transferred to the open they will probably grow as freely as if they had been kept under glass, and soon form as fine plants as they would have become in pots. The secret of success is a good beginning, and about the end of April or early in May is a good time to plant. The soil must be as good, and

they should be as well and carefully planted as if being grown under glass.—J. MUIR, *Margam*.

[A wonderful specimen of the old double Camellia is planted out in Baron Schröder's garden, The Dell, Egham. It is 15 feet high, 30 feet in diameter from tip to tip of the branches, and must be of great age. Protection is afforded in the winter by a kind of frame.]

ORCHIDS AT WILTON HOUSE, SOUTHAMPTON.

DURING the last few years the cultivation of Orchids has been largely extended in the gardens attached to Wilton House, the residence of J. Buchan, Esq., who is a thorough enthusiast with these plants. The collection consists of 4000 plants, all in capital condition, reflecting much credit on Mr. T. Osborne the gardener in charge. The houses are all substantially built and thoroughly adapted for the purpose required. The first, a warm house, is 40 feet long by 18 feet wide. The stages, which are covered with fine gravel, are edged with slate, the central paths are slate, the sides of the path being so constructed that they throw off a considerable amount of moisture when required. Capital tanks are constructed under the stages. In this house were very fine plants of *Cypripedium villosum*, 3 feet in diameter, in the best of health, growing in pans; at the time of my visit a short time since one had thirty blooms. The quaint old *C. hirsutissimum* was in capital condition, as also were *C. Sedeni*, *C. caudatum*, and *C. Lowi*. Numbers of seedlings of this family raised here by Mr. Osborne are very promising. Very notable are *Angræcum Leonis*, *Dendrobium Brymerianum*, *Calanthe vestita gigantea*, a fine variety; *C. Regneri*, *C. Veitchi superbum*, *Epidendrum prismatocarpum*, a fine plant with thirty leads; and *Dendrobiums Dallhousianum* and *albo-sanguineum*; also the deliciously fragrant *Dendrochilum glumaceum*. The next house of the same size as previously noted was filled principally with *Cattleyas* and *Lælias*, between 500 and 600 plants in all. A plant of *Cattleya amethystoglossa* was growing on a block in moss litter, where it had been for two years in the best of health. The flowers had been in perfection seven weeks, thus showing that moss litter is good for this variety. *C. Lawrenceana*, rich in colour; *Lælia flava*, deep yellow; *L. harpophylla*, terra cotta colour; *Oncidium sarcodes* in a pot suspended from the roof well flowered; and *Epidendrum Wallisi* were the most noteworthy plants. The next house is 30 feet long, and contains fifty-five plants of *Lycaste Skinneri*, with the same number of *Anguloa Clowesi* and *A. Ruckeri*. There is an exceptionally fine variety of *Lycaste Skinneri* alba, snowy white, of the finest form. Of *Dendrobium Jamesianum* there are several good specimens, together with *Miltonia euveata*, *Masdevallia chimæra*, *Zygopetalum crinitum*, and *Trichopilia suavis*. About fifteen healthy plants of *Cattleya citrina* were suspended from the roof flowering freely. A good stock of *Odontoglossum Harryanum* is flowering freely; *Cymbidium eburneum*, *Cœlogyne cristata alba*, and *Chysis bractesceus* promising well.

The cool house is nearly 100 feet long by 11 feet wide, built behind a north wall, and contains 1200 plants, all in excellent health. Noticeable were *Odontoglossum Alexandræ* and *O. Pescatorei*, some carrying forty blooms many shades of colour; *O. sceptrum*, a good variety with a strong spike; *O. cirrhosum*, *O. triumphans*, *O. Blunti*, *O. constrictum*, with twelve spikes; *O. luteo-purpureum*, five spikes and fifty-six flower buds; *O. Pescatorei*, with rich spots; *O. Sanderianum*, *O. gloriosum*, *O. Uro-Skinneri*, and many others equally promising. A collection of about one hundred plants of *Masdevallias Harryana*, *amabilis*, *ignea*, *Veitchi grandiflora*, and *tovarensis* are in the best of health. An intermediate house 20 feet long and 14 feet wide, having an east aspect, contained many fine plants. An extra good variety of *Cymbidium Lowianum*, has twenty-five flowers on each spike; *Oncidium leucochilum* has a fine spike and numerous flowers; *O. Marshallianum* is rich in colour; of *Cœlogyne cristata Lemoniana* there are about a dozen fine pans; with *Odontoglossum vexillarium* and *O. nævium majus*, the latter a fine piece of this scarce variety.

Suspended from the roof and growing in baskets in a disused Melon house, which is reached by descending several steps, into which air is admitted from the outside by means of drain pipes underneath the floor of the house, is a collection of *Phalenopsis Schilleriana*, *amabilis*, *Stuartiana*, *Sanderiana*, *Luddemanniana*, *violacea*, and *grandiflora*, all in rude health, although small, being

young plants. The treatment they receive appears to suit the plants exactly. The temperature is kept at 70° by night and about 85° by day.

In addition to the Orchids many other plants receive close attention. Grapes and Peaches promise well, a general collection of greenhouse plants is grown, double *Cinerarias* being worthy of note, while about 400 plants of *Chrysanthemums* grown for the production of large blooms looked as well as could be wished, comprising the leading new and old varieties.—VISITOR.

ORCHIDS AT BIRMINGHAM.

A PLAN of the large range of houses in the garden of the Right Hon. J. Chamberlain, Highbury, is given in Mr. Lewis's useful book, "Orchids." No. 9, as shown on the plan, is the Orchid show house, and at the present time it is very gay. A path runs down the centre, and above the rustic rockwork on each side are the stages with a carpet of *Selaginella* and small Ferns, with the Orchids elevated and lightly arranged. Among the most conspicuous is a fine variety of *Cattleya Lawrenceana* and a richly coloured form of *C. Trianae*, said to be nearly equal to the rare *C. T. Leeana*. Many others of this section are in bloom, ranging in colour from the one mentioned to nearly white, some known as the Popayan varieties having large open throats; several plants of *Cymbidium eburneum* and *C. Lowianum* with arching racemes of bloom, both with clean and graceful foliage, which assists in showing the flowers to the best advantage. The Chatsworth variety of *Cœlogyne cristata* is in full beauty, and among *Dendrobiums* are *D. crassinode Burberianum*, that sweet-scented *D. aureum*, *D. infundibulum*, *D. Jamesianum*, with specimens of *D. Wardianum* well flowered, *Odontoglossum Alexandræ*, *O. maculatum*, *O. Roezli*, and *O. Ruckerianum*, with various *Oncidiums* make a show that will last until succeeded by *Cattleya Mossiæ*, *C. Meudeli*, and others already well advanced in sheaths and spikes. A large mirror at the end of the house adds greatly to the effect.

The plants in bloom cannot all be placed in the show house, and many are seen in their growing quarters. A *Dendrobium* house recently erected, about 26 feet long and 14 feet wide, appears to answer the purpose admirably. A large piece of *D. macrophyllum giganteum* bore flowers 7 inches across. *D. chrysotoxum* is well furnished with spikes. *D. albo-sanguineum* is well grown, having growths 15 inches in length. *D. lituiflorum* and *D. trausparens* are flowering freely. The stages are of open trelliswork above a moist border of ashes, and are so arranged that they may be raised or lowered to suit the convenience of large or small plants.

The *Cypripediums* do well in the *Phalenopsis* house, a *C. Spicerianum* has ten growths, eight of them being produced in four years from two leads; *C. Lowi* is bearing three blooms on a spike, and the same answers the description of the chaste *C. niveum*; here also *Angræcum Leonis* and *A. Sanderianum*, together with *Aerides* and *Vandas*, are flowering freely.

There will soon be a display in the large *Odontoglossum* house, as the *O. Alexandræ* section are well furnished with spikes, the chief plants being in bloom are quantities of *O. Rossi majus*, *O. cirrhosum*, *O. pulchellum*, and *O. sceptrum*. Adjoining this is a span-roofed house devoted to *Lælia anceps*, *L. albida*, *Cattleya citrina*, all in large masses. *Sophronitis grandiflora*, grown on blocks of Tree Fern trunks, and *Oncidium Marshallianum* are flowering very freely, and are grown close to the glass; the spikes are dwarf and compact, bearing numerous large and bright yellow blooms. Some of the plants have been partly severed, causing them to break back from the old growths. In the corridor is a handsome specimen of *Arpophyllum giganteum*, which is mounted on a pedestal and surrounded with Ferns. It is 5 feet across, and carries eighteen large trusses of bloom. This is a graceful evergreen species too seldom met with in collections.

In a lean-to house facing south are remarkable plants of *Lælia autumnalis*, *L. furfuracea*, and *L. majalis*, *Odontoglossum Londesboroughianum*, and *Oncidium Rogersi*. These are growing almost touching the glass, and are never shaded. They are in pans and on blocks and rafts, and consequently take copious supplies of water. The foliage is thick and hard. Mr. Cooper considers this the only way to grow them satisfactorily. Under his treatment the pseudo-bulbs increase in size and number each year, and flower freely.—G. W. C.

NATIONAL AURICULA SOCIETY (SOUTHERN SECTION).

CIRCULARS have been issued to all the members of the Society informing them of the arrangements for the exhibition to be held in the Drill Hall of the London Scottish Volunteers, James Street, Westminster, on the 24th inst. I am writing this note on the 14th, and a few days ago the prospects of the northern exhibitors getting their plants in was problematical. Now things are much more pro-

missing for a good show. One of the leading northern exhibitors intends to be present, and I hope to hear that more will be able to say they will come south in a day or two. I hear the flowers have come in rapidly since the change in the weather. When vegetation has for long been in suspense by adverse weather it is astonishing how rapidly it moves with a favourable change. I hope members and visitors will not only attend in force themselves but will also bring their friends with them. An excellent luncheon will be provided at the "Hotel Windsor," quite close to the Drill Hall, at 1.30 P.M., tickets for which can be obtained from the Secretary or Chairman of Committee, the Rev. H. H. D'Ombraun, "Hotel Windsor," Victoria Street, Westminster; also from any member of the Committee. The Council of the Royal Horticultural Society have kindly placed the Drill Hall at the service of the Society, and Mr. Barron will receive the entries from exhibitors as usual. Other spring flowers besides Auriculas are likely to be exhibited, forming a really good spring show, and a large attendance of visitors would make things lively and pleasant all round.—JAMES DOUGLAS, *Hon. Sec.*

ARTIFICIAL MANURES FOR PLANTS.

I HAVE repeatedly noticed, when reading the various controversial subjects which are from time to time brought forward in the horticultural press, that one of the contending parties will assert that in some moment of weakness and bewilderment his opponent has put forward arguments that prove beyond dispute the correctness of the views they were intended to refute. This appears to be the course taken by Mr. M. Coombe in his latest contribution to this subject, but I think a few words may be given on the other side of the question.

I am quite prepared to uphold my previous statement that we should aim at giving plants as far as is practicable "Food that is varied in its chemical constituents according to the nature of the plants that are to receive it, the object for which they are intended, and the condition they are in at the time it is applied." Now I maintain that this cannot be done in so satisfactory a way by continually giving one kind of manure either in a liquid or solid form as by varying the food supplied according to the stage of the plant's growth. As my opponent is so emphatic in his opposition to my remark that "a knowledge of chemistry may enable us to form various manures which are likely to supply the most suitable food," I will offer no objection to his proposed substitution of the word "undoubtedly," as I am by no means opposed to the generally acknowledged fact that a knowledge of chemistry is extremely useful to both gardeners and farmers. What I wish to point out is, that it is not wise to place too much reliance on only a rudimentary knowledge of it; because, before we can carry out the theories of chemistry in a simple, sound, and practical way, much time must be spent in making experiments; minute calculations must be made to find out the component parts of soils, manures, plants, and the various gases they imbibe from the atmosphere. In the case of plants in pots, when we have so many differently constituted to deal with, it would be altogether too troublesome and expensive a method to have different manures for each, and I maintain that unless we do that we must depend to a very great extent upon what experience and observation teach us are applicable to plants generally; and I think I am on firm ground in asserting that the greatest part of successful gardening has been accomplished by giving plants and fruits a systematic change of manure.

Your correspondent shows us that the Potato contains 50 per cent. of potash and only 4 per cent. of lime, while the Grape Vine contains them in nearly equal proportions, and asks if these facts cannot be used to considerable advantage in the preparation of our composts and plant food. My answer is, Certainly they can, and I also add that gardeners have long since found out that farmyard manure (which is saturated with the urine of quadrupeds), and the refuse of the farm and garden converted into ashes, supply a large per-centage of potash, and form one of the best of all manures for Potatoes. It is also admitted by the majority of gardeners that Vines require a larger per-centage of lime than most other plants, and in the preparation of their composts for making Vine borders generally add a certain proportion in some form or other, unless they are satisfied that the soil already contains a sufficient quantity, which I think myself is rarely, if ever, the case.

But after knowing these facts I cannot agree that anyone would be wrong in treating his Vines to a course of Peruvian guano, as I consider it one of the best and most powerful of all fertilisers for Vines if applied at the right time and in proper quantities, but I think no successful grower would depend solely upon its use as a manure for them. Neither does it possess such a large per-centage of ammoniacal constituents as some people imagine. According to Dr. Ure guano consists of the following proportional constituents: Azotised organic matter, including urate of ammonia, and capable of affording from 8 to 17 per cent. of ammonia by slow decomposition in the soil, 50.0; water, 11.0; phosphate of lime, 25.0; ammonia, phosphate of magnesia, phosphate of ammonia, and oxalate of ammonia, containing from 4 to 9 per cent. of ammonia, 13.0, siliceous matter, 1.0. These figures show what a powerful and efficient fertiliser it is, and explain why we hear of failures resulting from its use, simply because it has been used too freely. Use it at the rate of 2 ozs. to a gallon of water, or sprinkle on a Vine border 5 ozs. per square yard, and water it well in. Apply it in this way to Vines that are carrying a heavy crop of fruit, just as the berries commence

swelling, give another application when colouring begins, and let the intermediate waterings be made with liquid from the stable, cow-shed, or the drainings from the manure heap, and then see if the results are not satisfactory, more so than they would be if liquid manure obtained from the other sources mentioned were only used.

The same course of manures will produce equally satisfactory results if used for Melons, Tomatoes, or Cucumbers, but care should be taken to always give the strongest manure when the strain upon the plant's energies is the greatest. This would certainly be giving the plants a "something," but it would contain food which experience and observation had taught us would produce good results. Much depends not only upon the kind of food given, but also at what stage in the plant's growth it is supplied. Were I to give large quantities of liquid manure to Melons before they had set their fruits, and to plants before the soil in the pots was filled with roots, I should cause the one to become gross and unfruitful, and the other to languish and decay.

I consider the most striking paragraph in Mr. Coombe's article is the one in which he defines the difference between the practice he advocates and my own, and by the way he put his case I should say he would make a grand "advocate" but a poor "judge;" he there says that I prefer to give the plant a strong stimulant to start it, then wait for development, afterwards giving it various compounds as fancy dictates. This is altogether misrepresenting what I wrote. I used these words: "If you want to induce a strong and vigorous growth give them stimulants in which ammonia-yielding substances preponderate." Now it often happens that this is exactly what we do wish to obtain. A quick and vigorous growth in Palms, Cannas, and fine-foliaged plants of many kinds is very desirable, and for these plants the largest and best growers of the day use stimulants abounding in ammoniacal constituents. In other cases where plants are in a stunted or unhealthy condition—as, like human beings, they sometimes will be through want of proper nourishment, or of attention at a critical time—for the plant the first consideration is to get it into active growth again, and experience teaches us that such manures as nitrate of soda applied in small quantities will have that effect. Is it, then, wrong to apply it to the plant any more than it would be wrong for the doctor to prescribe for the human being stimulating food consisting of a larger proportion of alcohol than he would consider desirable at ordinary times? In both cases when the object in view was attained the food given would be altered, not as fancy dictates, but such as experience proves to be right. From the time a boy first enters a garden with a view to learning the art, till he relinquishes the occupation he is—or ought to be—continually learning the various kinds of soils and manures most suitable for the individual requirements of plants. Is this to count for nothing but "fancy?" If so, I will only say that some of the finest horticultural productions have been grown on this system intelligently carried out.

In regard to the desirability of giving plants different kinds of manures in preference to keeping to one, I think there can be no disputing that the greater number of gardeners are in favour of the change. Observation teaches them that it produces the best results, arising, I believe, partly from the analogy there is between plant and animal life, and partly in consequence of the various stages of growth that vegetable life passes through. I turn to the writings of Mr. Molyneux. In his book on Chrysanthemums I find he says, "It is not wise to give the plants the same stimulants continually." The writings of other prominent cultivators of the day give advice in the same direction, and other well-known gardeners with whom I have come in contact say changes of manure are always appetising. These facts, coupled with the results of my own observations, lead inevitably to the conclusions I have given.

In commenting on my remarks about the treatment of soils in old kitchen gardens, Mr. M. Coombe says he should prefer a moderate amount of lime and a judicious amount of trenching. That no doubt would have the effect of utilising some of the excessive richness in the soil, but trenching is an expensive operation, that cannot always be carried out so much as is desirable. I think I can show that the application of lime would not "spoil the soil" to such an extent as he considers it would. The application of lime to such a soil as I described in my last article would have the effect of hastening the decomposition of animal and vegetable matters, and of imparting to the soil the power of retaining the moisture necessary for the growth of plants. It would simply present in a suitable form the food that was locked up in the soil, and the plants, by having such a stock of food open to them, would appropriate a far greater share than they would under ordinary circumstances; the crop would also show a corresponding improvement. That being so, it is reasonable to suppose that a dressing of manure would again be required.

Referring to the use of nitrate of soda, Mr. M. Coombe conveys to the general reader the impression that I have advocated the use of this stimulant to a greater extent than is the case. What I really pointed out was that a few doses had the effect of bringing sickly-looking plants into health again, and that when hard water had to be used for plants of Ericas and Epacrises, a little dissolved in the water given them would keep them in perfect health, and this anyone can prove for themselves. We all know that whatever plants market growers take in hand they grow well, because they make a specialty of them, and in order to bring them to such a state of perfection they require a course of very stimulating food. That the food given them is suitable the results show, but why they so often become candidates for the rubbish heap when they pass to the private grower I will at present leave an open question. It

cannot be solely because they have been highly stimulated, because those that are retained by the market growers to supply larger-sized plants the following year do not share the same fate; but I should not like to suggest in the case of Mr. Coombe that his treatment was unsuitable. If he will give me further particulars about the experiments he mentioned, with different kinds of manure applied to a pasture, telling us the time of the year these manures were applied, if all at the same time, and what kind of manure, if any, had been applied for a year previous, I will do my best to arrive at a correct solution of the problem he has given me.—H. DUNKIN, *The Gardens, Longford Castle, Salisbury.*

NOTES ON GLADIOLI.

GLADIOLUS DISEASE—IMMATURE CORMS.

WHEN your old time correspondent, "D., Deal," adopts any theory he keeps to it with delightful consistency. The Gladiolus disease is a case in point. At page 295 he brings it forward again "with some degree of satisfaction." It is needless of course to say that the Gladiolus is not subject to a disease, but though there is a disease which attacks the corms, your correspondent may rest assured that many growers are not troubled with it. In my own case I know hardly anything about it, but I do know that the great difficulty with many of the later-growing varieties is found in the shortness of our seasons and the inability of the plants to produce matured corms in the time they have to grow. Mr. Murphy, with a longer season, not only grows but flowers such a beautiful late variety as Duchess of Edinburgh, but here it only begins to show its spike when the season closes. Anyone who knows the Gladiolus will see at once the impossibility of growing this variety a second year, for the simple reason that the corm has had an insufficient period in which to grow and mature. Last year, owing to the exceptional season, very few immature corms were produced, and, as I noted in a previous communication, all the later varieties were well started in boxes before planting out, thus securing a longer season of growth. Mr. Kelway's dictum, that "seasons govern results," accords entirely with my experience. Some varieties I have grown for fourteen years, but they are early flowering, all the later ones dying through immaturity in the "bad" years. The last few years I have again worked up large numbers of some sorts, and if good seasons rule I expect no difficulty in continuing to do so.

HARVESTING THE CORMS.

With regard to the time of harvesting, I find it a safe rule to lift the earlier varieties directly the corms are finished. This will be seen by the foliage beginning to turn yellow. The danger of leaving these is to be found in rains, after a season of dryness, causing the corms to throw out roots. Late varieties are best left as long in the ground as possible, and I like to have some soil attached to the roots in the case of these.

CUTTING THE CORMS.

With regard to cutting the corms I quite agree with your correspondent. As instances of its very powerful tendency to cause growths to start, I have Encbanteresse with three growths, Thérèse de Vilmorin with four, and a large number of others with from three to five growths from one corm.

The following I do not see in the list of varieties given by "D., Deal." They are so fine that their omission is strange:—Dietateur (1886), Amitié, Eugène Souchet, Phidias, and Teresita. The following I should not care to go without, although not so good in some respects as the above:—Diamant, Le Phare, Orphée, Panorama, Sylvie, and Pénélope. Some of those in the list at page 296 do not succeed here; such are André Leroy, Colbert, L'Unique Violet, Jupiter, Madame Desportes, Murillo, and Grand Lilas.—B.

DEATH OF MR. J. WOODBRIDGE.

WITH deep regret we have to announce the death of Mr. John Woodbridge of Syon House Gardens, and the news will afford a painful surprise to his numerous horticultural friends. Mr. Woodbridge was attacked by a cold on April 7th, which resulted in congestion of the right lung; other complications arose, from which he was too weak to recover, and he succumbed on the morning of Friday, the 13th inst., in the fifty-seventh year of his age. The funeral takes place at 2 P.M. to-day (Thursday), at the Isleworth New Cemetery.

Mr. Woodbridge was widely known and respected; his career as a gardener has been varied and successful, and his unobtrusive kindness of manner won him many earnest friends. He was born in Amersham, Buckinghamshire, and commenced his gardening career at the Rectory of that town. A love of his calling was early developed, and his knowledge extended by periods of service as a young man in the gardens of the Marquis of Londonderry, Fulham; of Lord Chelsea, Putney Heath; and of the Hon. C. C. Cavendish, Latimer, Bucks. From the last-named garden he removed to that of Lord Boston, Hedsor, Maidenhead, and there, under Mr. Davis, gave considerable attention to fruit and Pine culture. Mr. Woodbridge subsequently passed some time at Gunnersbury Park and at Syon House; he was also engaged with Mr. Forest in laying out the Surrey Gardens, and in Messrs Garaway and May's nursery at Bristol.

His first appointment as head gardener was in the service of W. Tothill, Esq., Stoke Bishop, where he gained more than local fame as an exhibitor both of plants and fruits. Four years were afterwards spent at Kiddington Hall, Oxfordshire, and he was then appointed to the charge of the Orchid and Heath department in the Royal Gardens, Kew.

In July, 1870, he was engaged by the Duke of Northumberland as head gardener at Syon House, and so well were his services appreciated that he was promoted to the office of steward and agent in 1882. He there deservedly acquired the reputation of a careful thoroughly practical gardener, whose varied experience had rendered him conversant with all departments of horticulture, and he justly claimed to have gained some special knowledge in nearly every one of his situations.

During the past sixteen years Mr. Woodbridge was a member of the Fruit or Floral Committees of the Royal Horticultural Society; he was also a member of the Apple and Pear Congress Committees, and in February of the present year he was elected on the Council of the above Society. He was one of th

Fig. 41.—MR. JOHN WOODBRIDGE.

most earnest workers on behalf of the Gardeners' Orphan Fund, in which he took a deep interest, and at the time of his death was a member of the Executive Committee. He also frequently acted as a judge at metropolitan or provincial shows, and occasionally contributed to the horticultural papers.

A description of Syon House Gardens was recently given in this Journal (Feb. 23rd, 1888), and for the portrait of the late Mr. Woodbridge now published (fig. 41) we are indebted to the Editor of the *Gardeners' Magazine*.

VINCAS.

THESE pretty stove perennials are not so often seen in gardens now as they were twenty years ago, yet they flower freely from the points of the young growths during the summer months. They may be increased from seeds sown in a mixture of sifted sandy loam and leaf soil, covered lightly with the same compost, watered, and placed in heat, where, in due time, the young plants will appear. As soon as large enough they should be pricked out thinly in a pan, subsequently placing them singly into 3-inch pots, employing a mixture of three parts fibry loam and one of leaf mould with a little sharp sand. Return the plants to heat, giving

water to the roots, and shade from sunshine until the plants are established in fresh soil, when it should be discontinued. Pinch the young shoots a few times to cause them to branch. Propagation by cuttings inserted in heat is the method of procedure usually adopted. *Vinca rosea*, flowers rose, with dark centre; *V. alba*, pure white; *V. alba oculata*, white, with red eye.—W.

EVENTS OF THE WEEK.—Besides the usual sales there are few horticultural events arranged for the present week. On Tuesday next, however, the Royal Horticultural Society will hold their Committee meetings in the Drill Hall, James Street, Victoria Street, and the National Auricula and Primula Society's Southern Show will be held on the same day in same Hall, to be followed by a luncheon at the "Hotel Windsor" as noted on another page.

— **ROYAL HORTICULTURAL SOCIETY.**—The programme of arrangements for the meetings of the Scientific, Fruit, and Floral Committees for the present year. The Scientific Committee meet at 111, Victoria Street, and the other Committees hold their meetings in the Drill Hall, James Street, Victoria Street, on the following dates:—April 24th.—Auricula and Primula day, Azaleas, Daffodils, Orchids. May 8th.—Orchid day, Narcissus, Asparagus. May 22nd.—Calceolarias, pot Roses, cut hardy and ornamental shrubs. June 12th.—Cut Rhododendrons, hardy Azaleas, flowering shrubs, Ranunculus, Anemones, Iris. June 26th.—Begonias, Gloxinias, Pelargoniums, cut Clematis, Pæonies, Roses, Pinks. July 10th.—Roses, Lilies, Strawberries, Begonias, July 24th.—Carnation and Picotee day, Ferns and Selaginellas, Ivy-leaved and Zonal Pelargoniums. August 14th.—Hardy fruits, Phloxes, Pentstemons, border flowers and cut Clematis. August 28th.—Hollyhocks, Gladiolus, fruit of all kinds. September 11th.—Dahlias, Begonias, Asters, fruit of all kinds. September 25th.—Grapes, Tomatoes, autumn border flowers. October 9th.—Early Chrysanthemums, Apples, Pears, October 23rd.—Hardy fruits, Potatoes, Vegetables. November 13th.—Chrysanthemums, English Oranges. December 11th.—Hardy shrubs, berried plants, Ivies in pots, Primulas, Chrysanthemums, Poinsettias. The undermentioned special prizes are also offered for competition on July 10th by Messrs. John Laing & Sons, The Nurseries, Forest Hill—Six Tuberos Begonias, single, distinct, first prize 40s., second prize 30s., third prize 20s. Three Tuberos Begonias, double, distinct, first prize 20s., second prize 15s., third prize 10s. Open to amateurs and gentlemen's gardeners only. Schedules of the National Auricula and Primula Society's Show (April 24th) and the National Carnation and Picotee Society's Show (July 24th) are included, with lists of the members of Council, officers, and Committees.

— **A LIST OF NEW GARDEN PLANTS.**—The issue of the "Kew Bulletin" for April contains a descriptive list of new garden plants, recorded from 1st October, 1886, to 31st December, 1887, to which the following remarks are prefixed:—"The number of new garden plants annually described in various English and foreign periodicals renders it a matter of considerable difficulty to botanists and horticulturists to keep them in view. As long ago as 1860 a list of new garden plants was published in the "Gardeners' Year Book and Almanack," and this list was continued regularly until the "Year Book and Almanack" of 1886, which contained the new plants of the year 1885. The new plants up to October, 1886, were published by instalments in the columns of the *Journal of Horticulture* during the months of January to May, 1887, inclusive. Since that time no list of new plants has been published, and it is believed that it is no longer likely to be issued by private enterprise. As the publication of a list of new garden plants is of the greatest possible interest to botanical establishments everywhere, and as such a list would give information respecting many new plants grown at Kew, and distributed, in course of exchanges, to correspondents in all parts of the world, it has been determined to continue the list as one of the regular issues of the 'Kew Bulletin.' It is believed that such a publication will be of service to the horticultural world generally."

— IT is announced that an **ANGLO-DANISH EXHIBITION** will be opened at South Kensington on May 14th next by the Princess of Wales. The garden and conservatory recently occupied by the Royal Horticultural Society have been devoted to the purpose, and the Secretary is Capt. Bax, late Assistant Secretary to the Society just named. The surplus arising from the Exhibition is to be devoted to the benefit of the British Home for Incurables at Clapham.

— A **CORRESPONDENT** notes that "On the occasion of the visit of Lord Salisbury to North Wales recently he was the recipient of a **NOVEL BOUQUET**, over 3 feet in diameter, composed entirely of Primroses and Violets. It was designed and furnished by Messrs. F. & A. Dickson and Sons, The Queen's Nurserymen, Cbeater."

— **THE WEATHER.**—Our northern correspondent, "B. D.," says:—"There has been no frost during the week ending the 16th, the thermometer during the night only once being as low as 36°. Cold W. and N.W. winds prevailed during the first two days. Bright sunshine and occasional slight showers have marked the week, and yesterday (15th) a close genial rain fell heavily in afternoon and evening. This morning (16th) is mild and cloudy." In the south there has been a very agreeable change in the weather; a much higher temperature and occasional warm showers are hastening vegetation very rapidly. The shade temperature has varied from 50° to 65° in warm situations.

— A **SHEFFIELD** correspondent writes:—"Spring appears to be with us at last, and everywhere vegetation is starting into life. Grass is growing fast, Gooseberries and Hawthorns are bursting into leaf, Jargonelle Pear flowers will soon be bursting, and are very plentiful. There promises to be a fine display of blooms on hardy fruit trees generally, and as it will now necessarily be very late before opening we may fairly anticipate a good set and consequently a good fruit year."

— **MESSRS. J. CARTER & Co.**, High Holborn, send us some extremely fine **CINERARIA BLOOMS**, gathered from the 500 plants they now have in flower at Perry Hill. Some of these are 3 inches in diameter with florets three-quarters of an inch broad, of great substance, and surprisingly rich varied colours. We are also informed that this firm has been selected to supply grass seeds for the London parks under the control of the Metropolitan Board of Works.

— **GARDENING APPOINTMENT.**—Mr. C. W. Cbard, lately foreman at Clevedon, Maidenhead, succeeds Mr. H. Rogers as head gardener to Sidney Lawrence, Esq., Bygrove House, Clapham Park.

— **EUCHARISES AT CARDIFF CASTLE.**—A gardener writes—"About two years ago I regarded the Eucharises at Cardiff Castle as the best plants I had ever seen. Since then much has been said about them in these pages, and this made me rather anxious to see them once more, which I did the other day. I need hardly say I found them looking as well as ever, and if anything improving. They are grand specimens; many are growing in pots 20 inches in diameter, and the plants are 6 feet through. Eucharis culture is not generally well understood, and all who wish to succeed could not do better than follow Mr. Pettigrew's advice. There may be more than one way of growing Eucharises successfully, but I certainly give Mr. Pettigrew's system the preference. I might write much respecting the excellent crops of Grapes now well advanced, the Peach trees, the fruit trees in the open, and the fine-foliage plants under glass, but all these were noted recently."

— **BRITISH PRODUCTS EXHIBITION IN HAMBURG.**—Mr. G. A. Pogson, British Vice Consul, Colonnaden 104, Hamburg, sends us a circular on competition in trade, one clause of which states that he has, "after long and mature consideration, decided to establish a sample room of British products and manufactures at Hamburg, which will be divided into sections comprising articles of consumption, raw products, textile fabrics, manufactured goods, new inventions, &c. The samples will, when desirable, be exhibited in cases of uniform size—viz., 6 feet high, 3 feet broad, and 1 foot deep, which will be supplied at a nominal cost to the exhibitor. The annual fee for such space, which can be secured for one, three, or five years, has been fixed upon the scale of the German sample room at the Hamburg Exchange—viz., £7 10s., exclusive of insurance and cost of delivery. No trading of any kind will be undertaken, but where agents exist, their names and addresses will be legibly displayed on the cases, whilst the excellent telephonic communication of the town, combined with the contiguity of the business quarters to the sample room, which is close to the Exchange, will ensure

the almost immediate attendance of the agent when deemed of importance to exhibitors or inspectors of samples. A suitable staff of trained business assistants, proficient in foreign languages, will be attached, and a commercial library and other sources of information will enable them to supply buyers as well as exhibitors with useful and prompt information. A visitor's book will be kept for the benefit of firms displaying samples, and proper steps be taken to secure an inspection of the rooms by all buyers visiting Hamburg. Samples, which can be renewed at will, as well as price lists, descriptions, and circulars, will, when desired, be distributed to visitors without further charge to exhibitors."

— WE regret to learn that MR. W. STACEY, of the Nurseries Dunmow, Essex, died last week, after a painful illness of three weeks. Mr. Stacey was much respected in the district, and was also widely famed for the numerous beautiful Verbenas he raised, no less than eleven of which have received first-class certificates from the Royal Horticultural Society. The following were the names of those so honoured and the years they were shown:—Countess of Rosslyn and Lady of Lorne in 1873; *compacta*, *delicata*, *Fantastic* and *Mabel* in 1883; *Lord Brooke* and *striata* in 1884; *Distinction* and *Fairy Queen* in 1885, and *Lady C. Beresford* in 1886. Many others have also been raised that have become popular both for bedding and culture in pots.

— THE usual monthly dinner and conversazione of the HORTICULTURAL CLUB was recently held at the "Hotel Windsor," Victoria Street, Westminster, which is likely to be the future quarters of the Club, and was attended by a large number of members, amongst whom were the Rev. Wm. Wilks, Rev. F. H. Gall; Messrs. Crowley, H. J. Veitch, H. J. Pearson, C. E. Pearson, Geo. Paul, and James Walker. The arrangements were considered by all to be in every respect an improvement. In the evening an admirable paper was read by Mr. James Walker on Daffodils, and a discussion was entered upon afterwards, in which Mr. Wilks and others took part.

— FRUIT-GROWING IN HAMPSHIRE.—A meeting of those interested in the fruit-growing industries of South and West Hampshire was held, under the presidency of the Mayor, at Winchester last week. Lord Wolmer, M.P., was amongst those present. The object of the meeting was to consider the sale of fruit, and more particularly Strawberries, at Covent Garden. Mr. H. R. Lamport, who has been studying the district, pointed out that 850 tons of Strawberries left the neighbourhood in one season, which averaged £59 per ton in value. The railway charges were about 7½, and the commission in London 12½ to 15 and 20 per cent. One London firm turned over in one week 2000 tons, and the object of the meeting was to do the work of that firm, which must have realised a very large profit. It was decided, after a lengthy discussion, to form an association of growers to consider what steps should be adopted to obtain a better price for their produce. Lord Wolmer subsequently spoke on the subject of railway rates.

— A MONTHLY meeting of the NOTTS HORTICULTURAL AND BOTANICAL SOCIETY was held last week at the Nottingham Mechanics' Institute for the purpose of hearing a number of papers read on "The Duty of the Gardener to his Employer," for which three money prizes had been offered by Mr. S. Thacker. Mr. J. Booth presided, and among others present were Messrs. S. Thacker, J. S. Baldwin, F. Granger, J. W. Woodward, J. D. Pearson, J. Dixon, C. J. Mee, J. H. Walker, J. Bennett, H. Ralphs, J. Baker, J. Simpson, J. B. Hallam, N. H. Pownall, &c. Some fine Orchids were shown from Lord Newark's gardens at Holme Pierrepont (gardener, Mr. A. Parr); a basket of splendid Mushrooms was also sent from beds which had been in bearing all the winter. Mr. S. Thacker having made some remarks with reference to the exhibits, Mr. Woodward read the essays under their respective *noms de plume*. The prizes were awarded by ballot, the result being:—1st prize, 20s., "Excelsior," Mr. N. H. Pownall (gardener to Mr. F. Wright, Lenton Hall); 2nd, Mr. J. H. Walker (gardener to Mr. J. W. Lewis, Hardwicke House The Park, Nottingham); 3rd, Mr. S. T. Wright (Glewston Court Gardens, Hereford). Votes of thanks to the donor of the prizes and to Mr. Woodward for reading the papers concluded the meeting.

— "W. K. W." writes: "The large plant of RHODODENDRON VEITCHIANUM growing at Oakholme, Sheffield, the residence of Thos. Wilson, Esq., which has for some years past had more than a local reputation, and of which some notice has appeared in this Journal in previous years, is now in full beauty. It is carrying a total of 480 flowers, about

three-fourths of which are fully expanded. The flowers are each nearly 4 inches in diameter, stout and waxy in texture, handsomely fringed, agreeably perfumed, and pure white. The plant is trained over a stone wall, forming the back wall of a ridge-and-furrow-roofed lean-to greenhouse facing south, but is partly screened from direct sun heat by tall Camellias planted out in a bed occupying the whole centre of the house. The roots of the plant are confined to a very narrow border (less than a foot in width) running along the base of the wall and bounded by the flagged pathway. It receives a light top-dressing annually of lumpy peat and sand, and makes very luxuriant and strong growths. Many fine plants of the newer varieties of greenhouse Rhododendrons are now flowering finely at Oakholme and are all in robust health, but none can, I think, vie with *R. Veitchianum*. Mr. Hannah, the head gardener, has grown this plant from a cutting to its present size, and is justly proud of his work."

— CINERARIAS AND CALCEOLARIAS AT READING.—"J. B. C." writes:—"Cinerarias just now make a bright and effective show in Messrs. Sutton & Sons' nursery. In Sutton's Superb Mixed every care has been exercised in selecting the very best plants from which to save seed, the flowers being symmetrical in form, fine in size, of the richest and most varied colours, habit of growth robust. A strain having somewhat smaller flowers than the preceding, produces a large percentage of flowers true to the colours from which they are saved, comprising light blue, blue tipped, crimson, crimson tipped, purple, light rose, and white, the whites especially good and pure. A novelty was observed in a beautifully striped flower, the 'stripes' running longitudinally. Double-flowered Cinerarias were noteworthy, and producing abundantly their 'rosettes' of flowers so useful for button-holes, bouquets, and similar work. Of Calceolarias we noted grand plants, a few flowers 'peeping' here and there from the wonderfully healthy head of foliage. Auriculas, of which a particularly healthy and varied stock is grown in frames, were likewise showing flowers. Cyclamens and Primulas were just fading, but even at this late time enough was seen to show what an imposing floral spectacle they must have presented when in full flower."

PLANTING HARDY PERENNIALS.

ANNUALLY with the advent of April intending planters of choice hardy plants usually set about their work in earnest. If they have not made up their minds as to what they shall have no time should be lost in doing so, for by losing a showery April month for any such planting operations we are sacrificing time of the greatest value. To have the plants well established in the borders or beds before the dry weather sets in is no mean advantage to all concerned, for it avoids the uncertainty attending summer planting. It is very likely that during April and May more hardy plants are placed out than at any other period of the year. This is only natural, as many are just then commencing growth, the result being that they start readily and without any apparent check. It may therefore be worth while calling attention to some of the most showy and desirable, and in doing so I particularly desire to draw attention to one important particular—viz., the size and quality of plants most likely to succeed. Too often hardy plants are supplied in small pots, in which they have stood probably for a couple of years or more, with the result that they are miserably weak and stunted, with the ball of earth and roots as hard as stone; and should these come into the hands of the inexperienced and be planted with the hard ball undisturbed, the chances are very much in favour of partial or total failure. I am not entirely opposed to planting such as are established in pots, indeed some are very much benefited by this treatment, and make quicker headway in consequence, provided they are planted out as soon as the pots are fairly filled with roots. The majority can, however, be transplanted much better when good-sized pieces are secured, taken from the open ground. It would be very much to the advantage of purchasers of hardy plants to pay a proportionately higher price and insist on having strong plants from the ground. I will now briefly name some of the most important species and varieties, any or all of which may be planted when weather permits.

Achillea Ptarmica plena, 2½ feet high, flowers double, pure white, very abundant, excellent for cutting, and upon an equal footing may be placed *A. serrata* fl.-pl. *Achillea millefolium rosea*, 2½ feet high, rose coloured heads of flower, very free and useful for cutting.

Aconitum autumnale, dark blue, very attractive, 2 feet high, a valuable plant.

Alstroemeria aurca, 2 feet high, beautiful orange red, grand for cutting, suited to a warm sunny spot, impatient of being disturbed.

Anchusa italica, 3 feet, a very attractive free-flowering perennial, with intense blue flowers, not suited for cutting purposes.

Anemone japonica and varieties, all extremely useful and free-flowering autumn perennials, 3 feet high.

Antbericum liliastrum and the *majus* variety are very useful; flowers pure white and bell shaped, on erect spikes 1½ foot high.

Aquilegias in many varieties, all very beautiful and pleasing. The best are cœrulea, blue and white; californica, scarlet and yellow, 3 feet; chrysantha, golden yellow, 3 feet, one of the best; glandulosa, blue and white, a very telling plant, 1 foot high, and others.

Armerias, or Thrifts, are a very interesting group. The best are cephalotes rubra, alpina grandiflora, and plantaginea. The flowers are produced from grassy tufts of leaves on erect stems, from 1 foot to 1½ foot high, terminating with globose heads, thriving in any ordinary soil, and revelling near the sea coast.

Arnebia echioides is one of the gems among hardy plants that no garden should be without; it flowers continuously from May to September, grows about 1 foot high, and produces in endless quantity sulphur and yellow flowers, on which are some black spots, that disappear when the blossom has been expanded for a day or two, perfectly hardy, and succeeding well in any rich light loamy soil.

Asters or Michaelmas Daisies are very serviceable throughout summer and autumn. Very useful for cutting for harvest festivals, church decoration and the like. A few of the best are longifolius formosus, pinkish rose; cricoides, white, very elegant; bessarubicus, fine blue; novæ-angliæ, magenta; novæ-angliæ rubra, red; lævis, rich blue; lucidus, clear lavender blue. There are many more, but these are all good and showy.

Campanulas or Bell Flowers constitute a very important group, and no garden should be without a dozen of the best, such as carpatica and its variety alba, glomerata scariosa, persicifolia alba coronata, and persicifolia alba plena, grandis, and grandis alba, Hosti, nobilis, pulla, pumila, latifolia and Van Houttei. These would make a good assortment to commence with, all being good and showy.

Perennial Cornflowers, Centaurea montana, and varieties.—All of this group are daily becoming more popular; they are extremely useful and free flowering, specially attractive as cut flowers, and have the additional advantage of flowering twice in the same year, and being of an average height of 2 feet are suited to large or small gardens. The colours vary from white to pink, bright red, blue, and sulphur. They commence flowering in June. If the old stems are cut away when this flowering is completed they will produce a second crop in the late summer months quite equal to the first. In the case of old clumps divide and replant. They do much better if watering be attended to till re-established.

Chelone barbata coccinea, a brilliant perennial, with spikes of scarlet Pentstemon-like flowers, 3 feet high; the leaves are of a bright glossy green produced in spreading tufts.

Chrysanthemum maximum, showy perennial Marguerite; flowers pure white, 3 inches across, plant 2 feet high, very free flowering.

Coreopsis lanceolata.—The true type of this is comparatively scarce, that usually sold for it being, no doubt, seedling forms of C. auriculata. The true plant has been beautifully figured in the *Journal of Horticulture*, and both in form and general appearance far surpasses any other of its tribe; the colour is bright golden, height 2 feet, and flowers in the wildest profusion. It may be distinguished when not in flower by its slightly procumbent growth and distinctly lance-shaped leaves. That usually sold under the name has compact tufts of leaves, very much in the way of *Oenothera serotina* or Youngi.

Delphiniums.—These are all handsome plants of easy culture; their noble spikes are always admired, and when established no plants have a more majestic bearing. For association with Hollyhocks in the back row of the herbaceous border these are most fitting. Many fine forms may be raised from seeds, and if a good strain of the latter is obtainable it will prove most interesting. The best named varieties are really thus obtained, so that by careful selection a good assortment may soon be had. When planted in a deep rich loam and left for several years their massive flowering spikes are handsome in the extreme.

Dictamnus Fraxinella and albus are old-fashioned perennials, growing 2½ feet high, forming neat bushes, and producing handsome spikes of red and white flowers. Very attractive border plants.

Doronicum (Leopard's Bane).—Nothing is more effective among spring flowers than those expanding their flowers in April and continuing for weeks in succession. Their flowers may be described as related to the Marguerite, and of a bright golden, splendidly adapted for cutting or for pot culture for cool conservatory. The best are D. austriacum (2 feet high), and D. plantagineum excelsum (3 feet); the flowers of the last named are about 3 inches across; it is very handsome, though not so freely flowered as the first-named kind, nor yet so early. Both are grand for the border.

Echinacea (Rudbeckia) purpurea is one of the most distinct plants among perennials; the colour can hardly be called purple, as would be gathered from its specific name; it is rather a reddish claret with a magenta shade, and compares with no other plant of my acquaintance in this respect. At 100 yards distant this plant attracts attention; the effect is excellent when grouped. It flowers in August and September; flower bracts 3 inches and more across, produced in quick succession. The plant has a vigorous habit, and may be classed among the handsomest of all hardy herbaceous plants. Bees are extremely fond of it. As it is somewhat slow of increase at the root, endeavours should be made to secure seeds, and thus add to the existing stock. April and May is an excellent time to divide this plant, and by reason of its woody rootstock I find it a good plan to wash away all the soil previous to dividing them.

Erigeron speciosus, an attractive border perennial, growing 2½ feet high, the flowers are of a bluish mauve, about 2 inches across, and borne

in great profusion throughout summer and autumn; it is excellent in a cut state, lasting fully a fortnight, quite fresh, and invaluable.

Eryngium amethystinum.—This singularly beautiful plant is rapidly increasing in popularity. Few plants are more picturesque than this when in flower. It attains 3 feet high, having somewhat spiny leaves and cone-shaped flower heads of an amethystine blue, the same colour pervading the stems and bracts. The plant has a much-forked inflorescence, generally rigid; and when by hot sunshine it is all beautifully coloured it is effective in the extreme. Among cut flowers this lovely tint is quite unique.

Gaillardias.—In this group we have all that the richest colours and brilliancy could suggest, such as are not found in any other genus. There are crimson, orange, and gold to be found in happy combination in some flowers, intensified beyond description in many others, and toned down to clear primrose selfs in others; indeed, from a single packet of seed hardly two flowers will be alike, while all are beautiful. The plants are easily managed, and succeed well in good ordinary garden soils.—J. H. E.

(To be continued.)

BIGNONIA TWEEDIANA.

THE genus *Bignonia*, of which over 200 species have been described by botanists, contributes several beautiful climbing plants to our collections both in stoves and conservatories. Their chief fault is one that is not too common in cultivated plants—namely, an excessive luxuriance that can only be kept in due bounds by a liberal system of thinning or pruning. For large conservatories they are, however, very useful, and produce their showy flowers in great abundance. An old but beautiful member of the genus, *B. Tweediana*, was shown at a recent meeting of the Royal Horticultural Society from the Pendell Court gardens, when a first-class certificate was awarded for it. A small branch loaded with its large bright yellow *Allamanda*-like flowers, as shown at the meeting in question, is represented in fig. 42, which gives a good idea of its character. The flowers are 3 inches in diameter, with broad lobes, and tubers about the same length. The plant was introduced from Buenos Ayres by the Hon. W. F. Strangways in 1838, and gradually found its way into many of the larger collections of plants, but it is not very often seen at the present time. It thrives well planted out in a conservatory, a suitable compost consisting of fibrous loam, peat, or leaf soil and sand.

GHENT INTERNATIONAL SHOW.

APRIL 15TH TO 22ND.

GHENT, which is essentially a great emporium of plants, is, during the period indicated, the great centre of interest in the horticultural world. From all the countries of Europe horticulturists have congregated in the interesting old Flemish city; many by invitation as jurors appointed to co-operate in awarding the honours at the great Show; many in the capacity of visitors to inspect its treasures; some as exhibitors, and all as friends to the object in view—the representation of horticulture on a broad basis and in its highest form. As friends, too, all who by their presence gave their adherence to that object have been received by the courteous and hospitable Belgian people, who are identified with horticulture, commercially, or as patrons and supporters of it, as an element that knows no nationality, and which contributes powerfully to the sum of human happiness.

The Ghent Quinquennial Exhibitions are, as the term implies, held every five years. There is no uncertainty about them, for they come when the time comes and are prepared for accordingly. With such preparation, and under an organisation that appears as stable as it is complete, great expectations were created and great results are achieved. As indicating the extent of the preparations for the Exhibition it may be stated that the schedule embraces 370 classes, and nearly 800 medals are offered, about ninety of these being gold of 200 francs and 100 francs in value, the remaining medals, which are offered in the minor classes, and as first and second prizes in the more important competitions, being médailles de vermeil (silver-gilt) and médailles d'argent (silver). No money prizes appear to be granted except in one optional case, but objects of art equal or exceed in value the gold medals. Large gold medals are given by the King and Queen, the former for twenty-five specimen Palms, the latter for the largest and most meritorious collection of Orchids; by the English Van Houtte Memorial Committee for new Azaleas and forced shrubs in honour of the illustrious man whose name will never die; by the President and Secretary of the Society, the Comte de Kerchove de Denterghem, and Mr. Charles Leirens for collections of plants; by the brothers De Smet, in remembrance of their father, the late active and genial M. Louis de Smet, for 60 Azaleas; by the Members of the Council of Administration for 20 Imantophyllums; by Baron Henri de Ranst de Berchem for 30 *Cypripediums* in memory of the Comte de Gomer; and by the Federation of Belgian Horticultural Societies for forty grand specimen Azaleas, this prize consisting of a special gold medal and a work of art, or their value, 500 francs. The remaining prizes are offered by the Royal Agricultural and Horticultural Society of Ghent, supplemented by grants

from the Province of Flanders, the commercial and civic authorities of Ghent, and by the Government. It appears to be the custom of the latter to make a grant to any public object to which the commercial

Exhibition of the Royal Horticultural Society of Ghent, and it will be conceded that the whole system differs somewhat from that followed in England in connection with undertakings of a similar nature.

Fig. 42.—BIGNONIA TWEEDIANA.

and civic authorities subscribe, to the extent of one-third the amount—that is to say, should those authorities subscribe 20,000 francs towards a public park, statue, or horticultural exhibition, the Government would grant 10,000 francs, besides affording other facilities for assisting. Such is the provision made for the twelfth Quinquennial

There is a difference, too, in methods of detail in the working of exhibitions in the two countries. In England the plants are rushed into the building or tent on the morning of the show day as a rule, and are not always in position by the appointed time, and half a dozen, more or less, of judges race through the work of adjudication, feeling themselves

fortunate sometimes if they can complete their duties before being invaded by the public. There is no such hurry-scurry at a Ghent Quinquennial Show. Many plants, such as large Palms, were in their positions on Thursday, and practically all of them on Friday, ready to be judged on Saturday morning, this work being entrusted to upwards of a hundred jurors, representing different nations, who complete their duties before night. Then the work of arranging begins, and is continued till finished, the collections being disposed for spectacular effect. Imposing Palms tower almost to the roof of the casino; such plants are not seen in English shows, and afford relief to the truly magnificent Azaleas that are displayed in bold masses. Ornamental foliaged plants are disposed so as to enhance, if possible, the beauty of the *Imantophyllums*, *Anthuriums*, and other flowers, the whole representing a magnificently furnished garden. The chief building is about 250 feet long by 100 feet wide, but this does not suffice for the collections, other rooms from 60 to 100 feet long, besides a wooden building about 300 feet by 50, with a glazed roof, being crowded with collections. Several plants are also arranged in glass structures in the gardens. In the grounds Bays in tubs are remarkable for their size and deep green foliage, indicative of superior culture, such specimens we believe being unknown in England. Conifers are very good, but not more meritorious than the collections at our best home shows. Greenhouses and frames do not compare favourably with those of British manufacture either as regards workmanship or design. Many boilers and other garden requisites, with excellent examples of horticultural art literature, elaborate plans of parks and gardens, illustrations of training fruit trees, and sundry other items combine in forming a very diversified, interesting, beautiful, and extensive Exhibition.

The King, with the Crown Prince and Comte de Flandres, attended by Ministers of State and a military retinue, visited the Show on Saturday morning at ten o'clock—that is, before the Jurors commenced their duties and the exhibits were artistically arranged, still they were so far placed in position by great effort during the previous night as to render the effect highly imposing and worthy of Royal inspection. His Majesty arrived at the time of the roll call, or when those present of the 140 Jurors invited were called to answer to their names. The King was introduced to the Jury by the Comte Kerchove, and conversed in Flemish, French, German, and English with several individual Jurors, and was exceeding affable to all with whom he came in contact. The different exhibits were examined minutely by the Royal personages, who spent two or three hours in the Show, departing highly satisfied with their inspection. Before leaving the Casino His Majesty presented a gold medal to Professor Reichenbach in recognition of his services to botanical science, and especially as an orchidist of universal fame.

The Jury numbered 140 persons from Germany, England, Ireland, Austria, Belgium, Brazil, France, Italy, Holland, Russia, and Switzerland, the English representatives consisting of Messrs. Bause, Bull, Cannell, Harvey (Liverpool), Head, Hill (Tring), Hogg (Dr.), Iceton, Ker, Laing, Masters (Dr.), O'Brien, Protheroe, Richards, Sander, Shuttleworth, Turner, Veitch, Warner, Watson, Williams, Wright, and Moore (Glasnevin).

Some of the chief awards are as follow:—The Queen's gold medal for Orchids to M. A. Peeters, objects of art falling to MM. Ch. Vuylsteke and J. Bray, and gold medals to MM. Vervaeck, M. J. Hye-Leysen, Madame Block, and De Smet-Duvivier; M. Hye-Leysen also securing Baron de Ranst's gold medal for *Cypripediums*. M. A. Dallière secures the object of art for variegated foliage plants. M. Van Houtte receiving a gold medal for these, also similar honours for *Nepenthes*, Palms, New Holland plants, with the Veitch Memorial prize for new Azaleas, as well as the object of art offered by M. Charles Leirens for forty specimen plants in flower. M. P. Van Driessch-Leys winning the other prize (for forced shrubs) offered by the English Committee. Count Paul Heptinne and A. D'Haene have gold medals for *Aroids*, the first named and M. Jacob Makoy winning similar medals for *Bromeliaceous* plants. The King's medal for twenty-five Palms is taken by M. Ghellinck de Walle, who also secures the prize offered by the Federation of Belgian horticulturists, with an object of art for Azaleas, a similar honour going to M. Vuylsteke, and the De Smet Memorial prize is won by M. Vercauterin. M. Baumann wins high honours for *Rhododendrons*, as does M. Pynaert Van Geert, also for new plants, *Pernettyas* and various other exhibits. The object of art offered by the members of the Council of Administration for twenty *Imantophyllums* was awarded to M. B. Spae, MM. Boelens Brothers securing a gold medal in the same class, and M. Van Houtte a framed medal. Gold medals for *Camellias* were adjudged to MM. Louis Eehaute and E. de Coek; for *Hyacinths* to MM. Byvoet and Kersten; and premier prizes are won by M. A. Van Geert in many classes. Mr. B. S. Williams is granted a silver-gilt medal for his *Orchid Album*, Mr. Harry Veitch being awarded similar medals for his works on *Orchids* and *Conifers*. A silver-gilt medal is awarded to M. Dutry-Colson for garden tools and requisites. The new establishment of this firm, which is the largest of its kind in Belgium, was opened on the occasion of the Show, and attended by many visitors.

The Exhibition in the great hall was arranged after the judging by M. Jules Van Eechaute, son of M. Van Houtte's competent manager, and the young gardener must be complimented on doing so much and so well in the short time at his disposal. The Comte Kerchove de Denterghem gave his active superintendence throughout the Exhibition, to which there are 300 contributors.

No attempt will be made to give a detailed and formal report of the Show, but the prominent features will be referred to. Passing the Palm

groves and groups of Tree Ferns that overtop everything, and which are associated in the most picturesque and natural manner, we pause to admire the miscellaneous collection of fifty plants with which M. Louis Van Houtte wins the chief prize offered by the Comte de Kerchove. They comprise flowering and ornamental foliage plants of the best varieties, and both as regards superior cultivation and taste in arrangement it was unanimously conceded that a finer group of specimens, not one being faulty, was ever seen, and such a display could only be prepared in an establishment of the character of the world-famed Royal Nursery at Gendbrugge. As it is a question of giving the names of all or none the latter alternative is chosen; and possibly most readers if they were writers at two o'clock in the morning would adopt the same alternative. Mr. Ed. Vandenaabeele, Ghent, also staged a beautiful collection.

Indian Azaleas are seen at the Ghent Quinquennial finer probably than at any other Show in the world, at least we know no plants of the kind to equal them. They are truly magnificent, most of them being grown on stems 2 to 3 feet high with mushroom-shaped heads from 4 to 7 or more feet in diameter. It would be impossible for any bouquetist to pack the flowers more closely, and rarely are these seen with so much substance and more pure and brilliant in colour according to the varieties. Further, when the foliage is searched for amongst and beneath the blooms, it is found much stouter in texture than is commonly seen in English-grown plants.

The Belgian Azaleas appear to possess more inherent vigour than do our peat-grown plants at home, and there is no mistaking the efficacy of leaf mould when rightly prepared and combined with otherwise good attention in culture. The majority of Azaleas in England have a starved appearance in comparison with the robustness of the plants in Belgium. Not only are these planted out periodically in prepared beds and watered and syringed systematically, the same as if they were in pots, but the plants are not allowed to flower every year, but are accorded a season for recuperation after having produced so many and large flowers, which cannot but have an enervating effect. Possibly, if not probably, most of the specimens that are so grand now, and grand they undoubtedly are, were not permitted to flower last year; therefore it may be assumed that if the different varieties of Indian Azaleas are to be presented in the finest possible condition, the plants must not only be accorded more nourishment than is to be found in ordinary peat, but they must also be relieved from the stress of developing every year all the flowers that form, but a period of rest for reinvigoration must be from time to time afforded. Nor must some of the buds be removed while others are retained, as that would result in irregularity of growth, and no such uniformity of floriferousness combined with equal vigour could be expected as characterise the plants as they are represented at this Show. As several of the plants must be many years old it were useless enumerating the varieties, for most of the newer surpass them in merit, and it must suffice to say that the huge mounds of white, pink, rose, pink, lilac, purple, crimson, and scarlet, cannot fail to impress all who see them by their intrinsic beauty and the cultural skill that is stamped unmistakably on every plant in the Show.

Of the newer Azaleas the following are very good:—Comte de Paris (Van Houtte), red and white boldly flaked, one of the most distinct and beautiful in the Exhibition, and everybody should grow it; J. T. D. Llewelyn, peach, double, fine; Perfection de Gand (Vervaene), cerise, large and beautiful; Columba (Schulz), flaked like a Carnation; Vervaeniana, double, flesh pink, effective; Arlequin (Vervaene), distinct, somewhat like a pink and purple bizarre Carnation; Memoire de Van Houtte, purplish crimson, massive and fine; Comte C. de Kerchove de Denterghem, white, scarlet centre, striking; Roi d'Hollande, rich red; Madame Bertha Froebel, white, fringed; Madame Van Houtte, flesh pink; Mlle. Pharilde Mathilde (Vervaene), very large double white; D'ominique (Vervaene), deep orange scarlet; Baron N. Rothschild (Van Houtte), purple semi-double, fine; Madame Louise Vervaene, one of the best of the double whites; Candidissima (Vervaene) very smooth, an excellent single white companion.

Among the quite new varieties *Souvenir du Recteur Kiekx* has double dark rose flowers; *Prince Bandouin*, upper petals purple, lower rose, very large; *Bijou de Gand* (Vandercreyssen) white, richly flaked with purple, like *James Douglas Carnation*; *Bijou de Gand*, very double rosy crimson. All these are very fine indeed, and in time will be largely cultivated. M.M. Van Houtte, Vervaene De Kneef, Cuvelier, De Schryver, and Vandercreyssen are adjudged prizes for new varieties.

In the long wooden building previously referred to are floriferous banks of *Rhododendrons*, magnificent groups of Ghent and other hardy Azaleas, remarkably well grown and profusely flowered *Camellias*, such as the best British gardener would be proud to have grown, plants in 8-inch pots bearing from forty to fifty blooms, with proportionally increased numbers on larger plants, the leaves of all being glossy and rich.

Now we come to a group of the most useful and nearly hardy *Choisya ternata*, the specimens 18 inches high and through, like white bouquets. Standard and dwarf *Cytisuses* arrest attention, the former with stems 3 feet high and golden globular heads 3 feet in diameter, the dwarf plants being larger and symmetrical masses of yellow racemes. There are also good pyramids, the whole being highly effective. Splendid specimens of *Aspidistras*, 4 to 5 feet across; *Aralia Sieboldi variegata*, and vigorous *Indiarubber* plants, afford evidence of superior culture.

Agaves are in good variety and well grown, and worthy of a position amidst their floral surroundings. *Deutzias*, *Spiræas*, and *Migno-*

nette are about the same as these plants are seen in England. Roses not quite so good as at home, *Azalea mollis* ten times better; and we must not pass pyramids of *Acacia armata* from M. De Coster, 4 feet wide at the base and 7 feet high, close masses of soft yellow flowers, and, as specimens of culture, faultless.

Cinerarias are good and well grown, but not as regards varieties superior to the best English strains, at least regarded from the English standard of merit. By far the finest double *Cinerarias* are from Swanley, and Mr. Cannell also stages his fine pyramids of cut flowers of Zonal *Pelargoniums*, together with the *Pride of Penhurst* *Carnation* freely arranged in vases, and effective they are rising above the massive purple and crimson *Cinerarias*. *Kalmias* and *Andromedas* are well represented, some specimens of *A. japonica* very fine indeed.

Imantophyllums contribute powerfully to the brightness of the Exhibition, and they shine the more conspicuously in contrast with the Palms that at once form a background and a canopy to the several collections. No such display of the plants in question has ever been seen in England as is now under notice in the Great Hall of Harmony at Ghent. It is not suggested that distinctly marked improvements are conspicuous since the last exhibition five years ago, but those on view are good enough to satisfy the critical, and especially since the cultivation is so good, the foliage being as broad, stout, and deep green in colour as the trusses are large, and the flowers well formed and brilliant in colour. Among the more striking are *Baronne de Rothschild*, *Madame Freeman*, *Mr. Harry Veitch*, *Madame Donner*, *Lindeni*, a grand specimen from M. Charles de Vuylsteke; *F. Vervaene*, and *Madame Auguste Lemoine*.

Bromeliaceous plants are much more numerous and fine than are seen at the best home exhibitions, and when well grown, are not only handsome, but constantly so, for when the flowers fade the leaves remain, and these, with the character of the plants, are highly ornamental. One or two new varieties command much attention, notably *Vriesia hieroglyphica variegata*, which was awarded the first prize as a novelty in the section. In addition to the rich marbling of the leaves, each is banded on one side with white, and the contrast with the darker portions is most effective. It is doubtful whether the variety will be reproducible by seed, and if not its increase must of necessity be slow; but that as it may, the plant in question is one of the most striking novelties in the Exhibition. The plant to which the second prize is adjudged is remarkable by its massiveness and the red hue prevailing in its exceptionally broad leaves, which are 9 inches in diameter and about 2 feet long. It is exhibited by *Madame D. Bloek* of Brussels as an introduction from Brazil. *M. de la Devansaye* stages an interesting plant, the result of a cross between *V. Zahnii* and *V. splendens*, and named *V. magnifica*—a stately plant of considerable promise. Messrs. *Jacob Makoy & Co.* and *Count P. Heptinne* are very successful in this section.

Anthuriums.—These, chiefly *A. Schertzerianum*, are exhibited in large numbers, and as arranged in bold groups contribute greatly to the richness of the Exhibition. *M. de la Devansaye* offered a gold medal for seedlings, but this gentleman stages the most distinct that came under our notice, the spathes varying in size and shape and distinctly marbled. The gold medal for the finest collection is won by *M. De Smet-Duvivier*. *Gloxinias* are extremely fine for the time of year, and the medal for them is well won by *M. L. Delarue-Cardon*. *Tuberous Begonias* from *M. Jean De Kneef* were also exceptionally meritorious.

Amaryllises contribute materially to the effect of the Show, several collections being staged, but the great superiority of the *Veitchian* group of about a hundred plants could not be disputed. The flowers by their size, substance, and excellence of form created almost a sensation, and several of the plants will not find their way back to the home of their birth again. It is not too much to say that the Chelsea-raised seedlings exhibited by Messrs. *Veitch* are a generation, not of plants, but of men, in advance of the Belgian collections, and in these plants more distinctly, perhaps, than any others in the Show England leads the way. And, speaking of English plants, it may be stated that as Messrs. *Veitch* take the lead with *Amaryllises*, so does *Mr. B. S. Williams* with *Cyclamens*, for though there are other meritorious collections in the Show, the *Holloway* plants are clearly in the ascendant.

M. Alexis Dallière wins the chief medal for striped and marbled foliage plants, *Vriesia Leopoldi*, and *V. tessellata*, splendid, with *Aphelandra Louisa*, the narrow *Privet*-shaped leaves clearly veined with ivory white on a very dark ground. All the plants in the group represented superior cultivation. *M. Louis van Houtte* is a close second in this fine class. *Dracenas* are remarkable for high culture rather than great size, and never before were seen the green and golden *D. Lindeni* in such numbers and condition. *M.M. Vaneoppenolle* and *D'Haenc* well deserve their medals for these collections.

Orchids.—In no section has such a great advance been made in the five years that have elapsed since the last Show as in these. Then they were the weak point, now they are a strong feature. Not that they are large, as we have individual specimens much finer at home, but the Belgian exhibits are undeniably most attractive, the plants, as a rule, being in excellent health and profusely flowered. *M. L. De Smet-Duvivier* exhibited a truly charming assortment, with which it would be difficult to find fault, while the choicest varieties are included. Apart from these, an annex of the building is entirely filled with *Orchids*, these being artistically arranged on curving side stages, backed with mirrors disposed at acute angles, but it is doubtful if these contribute materially to the general effect. The stages are edged with neat wicker-work 6 inches high, which gives a neat finish to the rich banks of flowers. A central stage is also occupied with plants, and there are overflow collec-

tions (notably a very rich one, from *M. Hye-Leysen*, in which *Cypripedium grande* (*Veitch*) has "tails" $10\frac{1}{2}$ inches long) in an adjoining corridor, also in a glass structure in the grounds. To enumerate the varieties would fill a page, and as they are generally the same as are grown in England, and some of the plants are recognisable as having been seen there, it is the less necessary to particularise, and if a commencement is made of taking down names it might not be easy to know when and where to finish. A truss, however, of *Cattleya Trianae* variety from *M. Sidney Courtauld* is so distinct from all others that it cannot be passed in silence. The feature of the flower is that the deep colour of the lip is reproduced as a broad clear stripe up the centre of the petals and sepals, this being as distinct in its way as the band in some of the *Amaryllises*. This similarity led a jocular spectator to astonish an inexperienced friend by informing him it was the first cross yet obtained between the two genera, and he appeared to be delighted with the information.

Cypripediums are especially well grown, though the plants are not large, being mostly in 5 and 6-inch pots. *M. Hye-Leysen* stages a beautiful collection, which is awarded the premier prize, *C. Argus Mocnsi* being the most conspicuous flower in the group; but more conspicuous still is what some consider a sport staged by the same exhibitor from *C. Lawrenceanum*, the marbled foliage of which it retains, but the flower is totally dissimilar, the lip being soft greenish yellow, the colour running up in stripes three parts through the dorsal sepal on an ivory white ground. It is most chaste, and bears the varietal name of *Hyeaunum*.

M. Peeters, Brussels, wins the Queen's medal with a large and admirably grown collection of *Orchids*, which includes many superior forms, as *Laelia purpurata alba*, one of the best ever seen, *Cœlogyne cristata alba*, *Odontoglossum Ruckerianum superbum*, very fine; *Cypripedium Sallieri* and *C. Sedeni candidulum* very good. *Dendrobium Ainsworthi* is in excellent condition, as are all the plants, and the group is very beautiful.

Hyacinths are raised tier above tier to form steep banks of trusses, the pots embedded in and covered with moss. The growth is not so vigorous as the best English grown *Hyacinths*, though there are some massive trusses, the appearance of which might be improved by a little dressing for liberating some of the bells and disposing them evenly for rendering the trusses more symmetrical. *Tulips* are small, and would not take a third prize at a good show at home.

Forsythia suspensa, trained on an umbrella frame, several plants planted together and the stems encased in clay, this being sown with *Cress* seed to form a green stem, is one of the curiosities of the Show.

A dwarf white *Rhododendron*, *Rosalie Siedel*, ought not to be overlooked; it is very attractive and floriferous, being destitute of any central blotch of colour, only the top petal containing a few dark spots.

Mr. Brown, Richmond, scores a great triumph with his bouquets and table decorations, winning the two gold medals offered in the classes, with rich yet very light and tasteful examples of floral arrangement. When it is added that *Mr. Veitch* is granted a large gold medal, also the object of art offered by *Madame Versehaeffelt* in memory of her husband, for the splendid group of *Amaryllis*; that *Mr. B. S. Williams* secures the gold medal of 200 francs for *Cyclamens*; and that *Mr. Cannell* is awarded a silver medal for his exhibit above referred to, it will be conceded that the English contingent did well, as the gentlemen named were the only exhibitors from Britain. It is interesting to record that *Mr. Veitch* was surprised by being handed a gold medal that was granted in 1863, or twenty-five years ago, for new plants exhibited by his father; it was struck at the time but overlooked.

A most interesting feature in connection with the Exhibition is a fac-simile illustration of the first show held by the Society in a public house in 1809 (at least that is the date of the old Dutch newspapers that are laid on the tables), for the public house and its furniture are represented as well as the plants. At one end is the bar, with mugs, pewter pots, and glasses, and by their side is the tub for washing them. In the centre is a table with the brazier that was used for lighting the pipes of the old Dutch gardeners, these being also on the beam, near the ancient barometer, with the names of the smokers on some of them. There are two other small tables and cane chairs, with a candlestick fastened down to each of the tables for safety perhaps at critical moments, and on the other side of the room is the table of plants—the exhibition. There are between fifty and sixty of them, besides a small collection of *Hyacinths* and *Tulips*. The reproduction of this old show was a happy idea, and is admirably carried out, even to the sanding of the rough deal floor. The old man's name is over the door—*B. C. Lanekman, Hovenier*; (market gardener)—and each of his customers took a plant, these making the show. When the past and present are thus brought together the difference is astounding—the first show resembling a cottager's exhibition, the last being the greatest held in Europe during the present year.

The hospitality dispensed by the administration to the Jurors is remarkable. The luncheon on Saturday amounted to a banquet, attended by 200 to 300 persons, then followed a splendid reception at the *Hotel de Ville*, then as a grand finale a sumptuous banquet in the saloon of the Grand Theatre, followed by a special operatic performance in honour of the occasion. The *Comte de Kerchove de Denterghem* presided at the banquet, which was a splendid one, and his sprightly eloquence was received with enthusiastic applause. The city is *en fête*, and in every respect the gathering is a brilliant success.

The weather, which had been bitterly cold for a long time in Belgium, similar indeed to that which has prevailed in England, changed on Friday last, which was mild and bright, while Sunday was summer-like and

beautiful. The sea is now calm, and if it remains so, as does not appear unlikely, there is just time for English visitors who can find it convenient to do so, to inspect such a show as can only be seen in Ghent. We hear that some gentlemen are sending their gardeners, and they can leave London on Friday night, arriving in Ghent on Saturday in ample time to see the Exhibition before it closes at night, and there is much of interest to attract besides the Exhibition. The admission to the Exhibition on Saturday is 1 franc (tenpence). English visitors stay chiefly in the Hotels de la Poste, Royal, and Vienne, and though these are full now, there will be daily departures from to-day (Monday) onwards, making room for new arrivals.

THE LATE M. J. M. GONOD OF LYONS.

LYONS has to mourn the death of another of its principal rosarians in the person of M. J. M. Gonod, who died at Monplaisir, Lyons, on the 12th of March last, at the age of sixty-one years. It was only in November last that we lost M. F. Lacharme, at the greater age of seventy years. These men were two of the most distinguished Rose growers of the district; they were both raisers, and both large cultivators, but M. Lacharme was best known as a raiser of novelties, and M. Gonod as a general cultivator. When at Lyons, in June of last year, I spent a long morning with the former (an old friend), and an afternoon with the latter, and little thought that I was conversing with both for the last time. M. Lacharme communicated to me his intention of resigning the general cultivation of Roses this year, and confining himself exclusively to the raising of seedlings. On referring to my notebook I find I thought highly of two different seedling yellow Tea-scented Roses not then named, the one much in the way of Comtesse de Frigneuse, but apparently superior to it. I lingered long before a lofty wall running the whole length of his garden, and which was covered from top to bottom with glorious flowers grown expressly for bearing seed. This was truly a magnificent sight, and remains fresh in my memory. Turning to M. Gonod I find I thought well of his recent issue, Baronne de Fonvielle (Tea-scented), a very sweet coppery-yellow Rose splashed with lake. He had one piece of 50,000 dwarf Roses budded on the Dog Rose, and the growth and bloom surpassed everything I had previously seen at Lyons. I had known him before, and left him with the impression that I had been in company with an earnest, industrious, and clever man.—WM. PAUL, *Waltham Cross, Herts.*

ROSE HEDGES.

PARAGRAPHS have been going the round of the papers with regard to the employment of Roses as hedges on continental railways, and the *Daily Telegraph* recently gave the following interesting details:—"Excellent opportunities have been afforded to continental railway companies by the unusually heavy snowfalls of the past winter for testing the efficacy of the various means devised by experienced engineers for the protection of their 'permanent ways' against snowdrifts. Of all the results hitherto obtained by experiment in this direction the most satisfactory have been rendered by Rose hedges fringing either side of the railway line. The Rose tree exclusively utilised for these fences is that popularly known as the 'rosier de la Provence.' In Lower Hungary, where the iron road traverses long stretches of flat country, akin in conformation and aspect to the Russian steppes or to the prairies of Western America, hedges of Rose trees, thick and tall, cover both flanks of the snow-beset metals, and repel the fiercest onslaughts of their fleecy foe. On the State railways of the Banat, in the outlying regions of Magyarland, a section of the line nearly a mile and a half in length, which in former years invariably became blocked by the snow, has been kept clear during the abnormally heavy falls of the past winter by one of these double Rose hedges, averaging 6 feet 6 inches in height and about 3 feet in thickness. This stout bulwark—in summer time bisecting the dusky "puszta" with twin-streaks of gay green, aglow with rich colour and redolent of sweet fragrance—has successfully withstood the fury of the snow-laden tempests which have of late repeatedly swept over Eastern Europe, enwrapping thousands of square miles of territory in a cold white mantle, of such density and weight that whole villages and countless homesteads have vanished for the time being under its frozen folds.

"Although, no doubt, strictly practical considerations have suggested the planting of these avenues of Rose bushes which have been instrumental in keeping open an arterial line of communication between Central and Eastern Europe throughout some of the severest weather experienced for many a year past, the expedient adopted by the Hungarian Staatsbahn for protecting its traffic against interruption bears a romantic aspect that might well furnish a theme to poetical inspiration. It requires but little imaginative effort to picture to the mind's eye a summer's journey gladdened by the glory of Roses, shining to the right and left of a swiftly gliding steam chariot, while the surrounding atmosphere is fraught with faintly subtle scents which superinduce a soft languor in the fortunate traveller. Such sights and odours have hitherto been rarely allotted to tourists dependent upon

railway locomotion for their transport through strange countries. They may be found in the plains of Persia, where 'Roses are bright by the calm Bendemeer,' and in the Roumelian lowlands, adjoining the southern and eastern slopes of the rugged Balkan range. Between Tatar Bazar and Adrianople the horseman following the post-road on a sultry June day rides mile after mile through enormous Rose plantations blazing with scarlet and crimson, and giving out odours well nigh as overpowering as that of the attar distilled from their gorgeous blossoms. In those fields of queen flowers he may gaze his fill on 'the Damask Rose, whose rare mixture doth disclose beauties pencils cannot feign.' The uncounted millions of Roses grown in Roumelia are not merely turned to account by the Rose farmers for sale to the preparers of that powerful essence which, enclosed in long, slender, carefully stoppered bottles lettered with gold, is still so popular throughout the East, although it has quite gone out of fashion in this country. Many tons' weight of their leaves, gathered and packed whilst they are freshly fallen, are converted into Rose jam, one of the exquisite conserves which, under the generic name of 'dulchatz,' are so admirably confectioned in Turkey, Greece, and Roumania, and constitute a leading feature in the light but toothsome refectation offered to the casual visitor in every well-to-do Oriental household. Rose jam, considered as a sweetmeat, is far superior in flavour and savour to Rahat Lakoum, and to the somewhat cloying preparations of angelica for which Stamboul confectioners are justly famous. It is by no means sickly, or even insipid, as those delicacies unquestionably are, but is characterised by an after-taste no less brisk and refreshing than that of the Black Cherry 'dulchatz,' paragon of all Turkish sweets.

"There is but little hope that English railway lines will be hedged in by belts of Rose trees, with a view to guard them against the encroachments of the drifting snow, or in order to gratify the eyes and noses of British excursionists with infinite varieties of colour and faintly perfumed airs. It seems, however, that much might be done to render many of our iron roads—or at least their immediate surroundings—less monotonously hideous than they are at the present time. The bare slopes of embankments and cuttings alike might often be planted, tastefully, and not unprofitably, with trees and underwood. Where the track passes through a level district it might be enclosed with green hedges, sufficiently hardy and close in texture to stay the driving snow in winter time, and solacing to the traveller's gaze when dressed out in their summer garb of verdant leaves and wild flowers. Railways, it may be said by doctrinaires of the Gradgrind school are meant for use, not for ornament. Granted; but we would venture to observe that their decoration with flowers in no respect impairs their utility, whilst rendering them manifestly less unattractive than they would otherwise be. Englishmen who have travelled through Southern Germany, the Austrian Duchies, Bohemia, and the Tyrol will remember with pleasure the pretty gardens and shady groves attached to many of the humbler provincial stations in those countries; the trellised Vines and gracefully trained creepers, the gay beds and borders of hardy annuals, the devices in growing flowers of bright hues, the well-kept kitchen gardens on upward and downward inclines hard by the lines of rails, wherever the soil is of a sufficiently fertile character to permit of that class of cultivation."

BIRMINGHAM SPRING FLOWER SHOW.

THE eighth annual Exhibition of the Birmingham Chrysanthemum and Spring Flower Show Society was held in the Town Hall on the 11th and 12th inst., the entries being much in excess of previous years, and necessitated staging many plants in the galleries.

Orchids were well represented. In the class for twelve, Mr. Barnes, gardener to Mr. Charles Winn, Selly Oak, Birmingham, staged an excellent collection, which contained fine examples of *Odontoglossum Rossi rubellum*, *Cypripedium villosum superbum*, *Cœlogyne cristata Lemoniana*, and *Cypripedium caudatum*. Second, Mr. A. W. Wills, Wyldes Green, Birmingham, who had *Cypripedium lævigatum* and *Cymbidium Lowianum* especially good. Third, Mr. A. Powell, gardener to Mr. G. H. Kenrick, Edgbaston, having *Dendrobium formosum* and *Odontoglossum citrosimum* both good, also *O. citrosimum album* and *Phalænopsis Stuartiana*.

In the class for six Orchids, Mr. Cooper, gardener to the Right Hon. Joseph Chamberlain, M.P., staged superb plants, consisting of grandly flowered *Dendrobium Wardianum* and *Oncidium Marshalli*, *Cattleya Trianae delicata*, *Odontoglossum Alexandrae*, *Cœlogyne cristata*, and *Dendrobium elrysanthum*. Mr. Charles Winn took the second prize, and had good examples of *Cattleya Mendelli* and *C. Trianae formosa*. Besides these classes other Orchids were staged. Mr. Jinks, gardener to J. E. Wilson, Esq., Widdington, Edgbaston, had a magnificent *Dendrobium nobile*, nearly 4 feet through and densely flowered, a plant of *Phalænopsis Parishii* with quite thirty blooms, and other Orchids. Mr. C. Winn also set up a group, not for competition, in which were *Cypripedium Argus*, *Odontoglossum luteo-purpureum*, and some *Masdevallias*. In the class for three Orchids Mr. Cooper, Highbury, was first with *Dendrobium Wardianum*, *D. Jamesianum*, and *Cymbidium Lowianum*. Second, Mr. Charles Winn, and in this collection was a fine pan of *Odontoglossum Rossi majus*. Third, Mr. A. W. Wills.

Mr. Cooper staged, not for competition, a group of plants which included some of the new *Imantophyllums*, exhibited in Birmingham for the first time, of which Marie Reimers is one of the finest. Some good *Spiraeas* were shown, Mr. G. Showell taking the first prize. Excellent *Deutzias* took the first prize, shown by Mr. J. Crook, gardener to W.

Milward, Esq. Second, Mr. W. H. Dyer, gardener to Mrs. Marigold. One or two exhibitors sent grand plants of both Deutzias and Spireas in bud, but not open—a thorough waste of time and trouble to the exhibitor.

The three Ferns which took the first prize were most creditable to the grower, Mr. Caldecott, gardener to Mr. William Mathews, Edgbaston, comprising two excellent Gleichenias and a very fine *Toodea superba*. Three grand plants, and so healthy and well done. In the class for six stove and greenhouse plants Mr. A. Brassien, gardener to Sir Thomas Martineau, exhibited six excellent plants—viz., *Acacia armata*, *Rhynchospermum jasminoides*, *Dendrobium nobile*, *Erica Cavendishiana*, *Franciscea calycina*, and *Imantophyllum miniatum*, and Mr. Dyer was second. Mr. Crook took the first prize for six splendid specimen Azaleas, and Mr. Cooper was first for three Azaleas, exceedingly well-grown plants. The last named was also first for Roses in pots, grand in foliage and size of blooms, Tea varieties; and first for six hardy Rhododendrons. A striking feature of the Exhibition were three very fine *Cytisuses*, one a pyramid quite 6 feet high and 3 feet through at the base; the others, two grand standards, with stems 3 feet high and heads 3 feet by 3 feet, and all densely bloomed and admirably grown.

Messrs. Perkins & Son, Coventry, were first in the nurserymen's class for a tasteful bouquet, and Mr. H. Weiss first in the amateurs' class with a bouquet of considerable merit. In the class for twelve bunches of stove and greenhouse cut blooms, Mr. Marriott, Coventry, was well first; and in this exhibit were superb trusses of *Rhododendrons Maddeni alba* and *Princess Royal*, *Erica Victoria Regina*, *E. Holfordi*, *Aphelaxis macrantha purpurea*, *Darwinia fuchsoides*, and *Erica Cavendishiana*. Mr. Cooper was a good second, and his collection contained a very fine seedling *Amaryllis*, *Cattleya Trianae*, *Cymbidium eburneum*, and *Dendrobium Wardianum*.

Hyacinths in pots were well exhibited, and in many instances very good. In the class for eighteen Mr. J. Morgan was first (the prize in this class being given by Mr. T. B. Thomson, seedsman.) In the class for eighteen Hyacinths, Mr. F. Cooper, gardener to Charles Showell, Esq., was first. For twelve Hyacinths, Mr. W. H. Dyer was first, and also for six. Double and single Tulips were in great force, Mr. Dyer's first prize, six singles—viz., *Proserpine*, *White Pottehakker*, *Keisers Kroon*, *Duchess of Parma*, *Chrysolora*, and *Joost van Vondel*, were good, but in many other instances good culture was a characteristic. *Polyanthus Narcissi* and *Cinerarias* were also exhibited. There were capital table plants, the first prize going to Mr. A. W. Wills for light and elegant plants. The class for six pots of Lily of the Valley were well filled by well-grown and flowered plants. Mr. W. Brown, first; Mr. E. Cooper, second; and Mr. A. W. Wills, third. *Auriculas* were few, Mr. J. Crook and Mr. Spittle being the two exhibitors. Messrs. Pope & Son had six Gold-laced *Polyanthuses*, to which the first prize was awarded—viz., *Exile*, *Lancer*, *Prince Regent*, *William I.*, *Cheshire Favourite*, and a seedling of Mr. Hewitt's.

Amongst the honorary exhibits special praise must be given to Mr. Thos. Ware, Hale Farm Nurseries, and Messrs. Peter Barr & Son, King Street, Covent Garden, for grand hanks of cut *Narcissi* in great variety and tastefully displayed. In Mr. Ware's collection some of the most striking were *Emperor*, exceptionally large; *pallidus præcox*, *Golden Spire*, *Henry Irving*, *Horsefieldi*, several groups and very fine; *cernuus*, *Exquisite*, distinct and good; *Blondin*, *Rip Van Winkle*, a very curious, serrated, small double variety; *Capax fl. pleno*, a very distinct, small, double; *cernuus fl. pleno*, *sulphureus fl. pleno*, one of the finest of the doubles; and *spurius coronatus*, one of the finest of all. This collection numbered 260 bunches. Messrs. Peter Barr & Son's collection although not quite so large, contained many rare varieties. *Dr. Hogg* is a beautiful and distinct variety; *Horsefieldi*, incomparabilis *Beauty*, *Barri*, *Miriam Barlow*, are all fine; *Barri conspicua* is a noble flower, pale lemon, with orange and yellow cup; *Incomparabilis Sir Watkin* (the Welsh Peerless *Daffodil*), is a beautiful variety; *J. G. Baker* is another very distinct and beautiful variety; *Emperor*, *Leedsi*, *Duchess of Westminster*, *Incomparabilis Princess Mary*, and *maximus Golden Daffodil*, should be in all collections; and for a curiosity at once very distinct and pleasing *cyclamineus* must be named, it is very dwarf growing, and the calyx turns directly back, and the entire flower has an elongated tooth-like appearance. In front of this group were bunches of *Chionodoxa*, the double and single *An monoc fulgens*, and other spring flowers.

The local nurserymen came out strongly. Mr. W. Spinks, the manager of Hans Niemand's Nurseries, set up a most artistic group of plants, in which as a central object was a very fine *Ananassa sativa variegata*, set in a centre bed of *Asparagus plumosus nanus*, which Mr. Spinks propagates by division to keep it true. *Variegated Funkias* were used, also *Lycopods*, *Isolopis*, *Dracenas*, *Crotons*, *Palms*, *Erica ventricosa coccinea minor*, *Amaryllis*, &c.: it was a lovely group. The same firm had beautiful sprays in variety, in which *Bouvardia* and *Odontoglossum Alexandræ* were chiefly used. Mr. T. B. Thomson, nursery and seedsman, had a corresponding group of great beauty, with a background of *Palms*, and choice plants in flower and ornamental *Crotons*, *Dracenas*, &c., running through the group; and here again a pattern design was worked out, as in Mr. Spinks's group, by the use of *Muscari botryoides*, *Anemone fulgens*, *Narcissus Bulbocodium*, and other plants. This firm also set up a fine bank of *Hyacinths*, *Tulips*, and a fine strain of *Cinerarias*, and a large memorial anchor of great beauty, which was very much admired. Mr. Vertegans, Chad Valley, contributed alpine plants in miniature rockeries, and a handsome bouquet of *Narcissi*, as well as two baskets of this flower prettily arranged.

Messrs. R. Smith & Co., Worcester, contributed a charming display

of young plants of *Clematis* in small 48-sized pots, chiefly well bloomed, and what beautiful objects they are in this state for decorative work, also a goodly lot of berried *Aucubas*. Mr. Robert Sydenham, Tenby Street, set up a stand of *Hyacinths*, well grown plants, with long full spikes, of the leading varieties showing excellent culture, and Messrs. Perkius and Son, Coventry, sent a memorial wreath, a very fine one, a copy of one made by them by order of the Germania Club for the late Emperor of Germany's funeral. Mrs. Thewles, florist, New Street Station, contributed some lovely sprays, in which fine blooms of *Fancy Pansies* were used, and had a telling appearance. Horticultural accessories, such as rustic work and garden frames, were also exhibited.

A FRENCH ELECTION OF CHRYSANTHEMUMS.

A RECENT issue of the *Moniteur d'Horticulture* gives the results of an election of Chrysanthemums in France, in which 847 voters took part. The fifty varieties which obtained the highest number of votes were the following incurved and Japanese:—

No. of Votes.	No. of Votes.
731 Mme. C. Audiguier	389 Source d'Or
726 Triomphe de la rue des Châlets	383 Mdle. Lacroix
689 Gloire Rayonnante	382 M. Freeman
671 Erectum superhum	376 Marquise de Mun
653 Source d'Or	374 Aimée Ferrière
640 La Triomphante	368 Ratapoil
626 Richard Larios	363 Mdle. Cabrol
607 Margot	356 La Pureté
585 Marguerite Marrouch	351 Val d'Andorre
561 Yellow Dragon	349 Criterion
557 Empress of India	332 Hiver Fleuri
532 Fahian de Mediana	331 Mme. Boucharlat (Bouch)
498 Belle Paule	330 Edouard Audiguier
469 Don Quichotte	324 Jeanne Délaux
457 Queen of England	322 Cullingfordi
454 Jardin des Plantes	319 Dr. Besaucèle
448 Peter the Great	317 Bras Rouge
446 Timbale d'Argent	307 M. Moussillac
433 Jeanne d'Arc	301 L'Adorable
426 Empress Eugénie	293 Aurore Boréale (Delaux)
422 Comte de Germiny	289 Golden Eagle
407 Princess of Wales	286 L'Île des Plaisirs
405 Fair Maid of Guernsey	270 Ville de Toulouse
401 Rubrum striatum	269 Boule d'Or
391 Elaine	258 M. Theodore Bullier

Most of these are well known in Great Britain, but an election here would result very differently.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE schedule of the above Society for 1888 is just to hand, and in some measure is an exemplification of the rapid advance of this Society in recent years. It forms a substantial publication of sixty-eight pages, giving lists of patrons, officers, Committees, Fellows, members, and affiliated societies, the latter now numbering thirty-nine. The report for the preceding year and financial statement, together with lists, winners of medals and prizes at the metropolitan shows, and those of affiliated societies.

The schedules of the four exhibitions to be held by the Society this year give full particulars of all the classes and prizes offered. The first is that for early Chrysanthemums, Dahlias, and Gladioli, to be held on September 12th and 13th at the Royal Aquarium, Westminster, the Judges being for Chrysanthemums, Messrs. R. Dean and G. Gordon; for Dahlias, Messrs. Henshaw and Drain, sen. The chief metropolitan Show is fixed for November 7th and 8th; also at the Royal Aquarium, the Judges being for plants, Messrs. Donald and G. Prickett; for fruit and vegetables, Mr. A. F. Barron; for incurved blooms, Messrs. J. Douglas and G. Gordon; for Japanese blooms, Messrs. E. Molyneux and E. Beckett; and for miscellaneous blooms, Messrs. L. Castle and W. G. Head. A considerable amount is offered in money prizes besides gold, silver, and bronze medals as leading awards in several cases. The special class for Chrysanthemum and horticultural societies, in which a challenge trophy and £10 in money are offered for a collection of forty-eight blooms, twenty-four incurved in not less than eighteen varieties, and twenty-four Japanese distinct, is already exciting much interest. Classes for fruit and vegetables are provided as usual.

One of the events of the November season will be the Provincial Show of the National Society, to be held in conjunction with the annual Show of the Sheffield and West Riding Society in the Corn Exchange, Sheffield, on November 16th and 17th. The Judges selected are, for plants, Messrs. T. Garnett and G. Gordon; for incurved blooms, Messrs.

R. Dean and J. Wright; and for Japanese blooms, Messrs. L. Castle and J. Udale. Seventy-four classes are enumerated, a good proportion of which are open to all exhibitors. A class of special interest is that provided for the best representative collection of large-flowering Chrysanthemums, not more than twelve blooms of any section, the following or any part of them being included, Incurved, Japanese, reflexed, Japanese reflexed, large Anemone, and Japanese Anemone, the first two in distinct varieties, the other four in not less than six varieties each, or more than two blooms of any variety. The first prize is a cup value fifteen guineas and £10 in cash, with second and third prizes of £6 and £4. The other London Show will be held on January 9th and 10th, the Judges being Messrs. R. Dean and G. Gordon, Mr. W. Holmes acting as Referee at all the Society's London Exhibitions. The dates of the Floral Committee meetings, of which seven will be held at Westminster, are also given. Schedules can be obtained from the Hon. Secretary, Mr. William Holmes, Frampton Park Nursery, Hackney.

JAPANESE REFLEXED CHRYSANTHEMUMS.

THE Revision Committee (Messrs. Lewis Castle, George Gordon, and Harman Payne) appointed by the National Chrysanthemum Society to tabulate and arrange the returns for the new catalogue, have prepared the following list of Japanese reflexed as a guide to growers intending to compete in the new classes provided for these varieties.

It must be pointed out that the varieties named as Japanese reflexed are only excluded from the true reflexed class, they can be shown in all the Japanese classes as before. Nearly two-thirds of the thirty members of the Committee have named varieties they consider should be classed in the new section, and a total exceeding sixty varieties have been thus mentioned. The following twenty-four have obtained the highest number of votes, and will form the select list recommended by the Committee for exhibition. They are arranged in the order of merit as determined by the votes, and those that are also specially adapted for culture as specimen plants are indicated by an asterisk.

*Etaine, *Maiden's Blush, Triomphe du Nord, *Dr. Macary, La Triomphante, L'Adorable, Magdeleine Tezier, *M. Astorg, Amy Purze, Jeanne Délaux, Père Délaux, M. John Laing, *Val d'Andorre, *M. Henry Jacotot, *Flambcau, Gorgeous, *La Nympe, Criterion, *L'Africaine, *Roseum superbum, Phœbus, *Margot, *Wm. Holmes, and *Tendresse.

A few have advocated transferring Cullingfordi to the Japanese reflexed section, but the majority are in favour of its retention in the true reflexed class.

ROYAL BOTANIC SOCIETY.

APRIL 18TH.

THE Royal Botanic Society can hardly be said to be favoured in the matter of weather as a rule, and the occasion of their second spring Show was no exception. It is true that there were some glimpses of sunshine, but the greater part of the day was showery. The aspect of the corridor on a spring show day is familiar to many readers of this Journal, and on the present occasion there were fine banks of stove and greenhouse plants from Mr. B. S. Williams; Roses from Paul & Son of Cheshunt, Rumsey, &c., with Cyclamens, Daffodils, Cinerarias, Pelargoniums, and hardy plants from various exhibitors.

Alpine and Herbaceous Plants.—Alpines were an open class, with no restriction as to the number of plants to be shown. Mr. James Douglas, gardener to F. Whitbourn, Esq., Great Gearies, Ilford, and Messrs. Paul & Sons, The Old Nurseries, Cheshunt, being the only exhibitors. The former had fine pots of hardy Primulas, including villosa nivea, sikkimensis, viscosa major, and the charming rosea, Anemones, Hepaticas, Auriculas, Polyanthus, &c., and scored a deserved victory. There was greater variety in Messrs. Paul's second prize group, comprising the intensely rich Gentiana verna atro-cærulea, Saxifragas Burseriana and Sancta, Soldanella minima pallida, and some fine plants of Primula nivalis and Narcissi, amongst other interesting features. An interesting collection of hardy herbaceous plants was shown by Mr. T. S. Ware of Tottenham. The class was an open one, and there was no specified number to be shown. Large pans of the pure white Trillium grandiflorum, Iris reticulata, Androsace carnea, Anemone blanda, Iris pumila cærulea, light blue, with a variety of Primulas, &c., were the most admired features of his collection, which secured the first prize. No other was shown.

Roses in Pots.—Messrs. Paul of Cheshunt won with nine plants, their specimens being far ahead of the others shown. The beautiful blush Tea, Madame de St. Joseph, the creamy Innocente Pirola, and the soft rose Souvenir d'un Ami were finely shown; also Catherine Soupert and Leon Renault amongst the Perpetuals. Mr. W. Rumsay, Joyning's Nursery, Waltham Cross, followed, his specimens being neat and well flowered, notably Miss Hassard, Duchesse de Vallombrosa, and Catherine Soupert. No first prize was awarded in the class for six plants, the only exhibitor, Mr. P. Perry, gardener to W. G. Rowlett, Esq., The Woodland, Cheshunt, showing but moderate examples. The second prize was given.

Amaryllises.—Here Mr. Douglas was again to the fore. Twelve plants were asked for, and Monarch, Albert Victor, Hector, Rembrandt, and Juno were finely shown; other varieties represented being Enchantress, Empress of India, Jupiter, and Lady Hulse. Messrs. Paul and Son, Cheshunt, had fresh and richly coloured specimens, all seedlings, some of which will probably be heard of by-and-by, and secured a

ready second, the remaining prize falling to Mr. Butler, gardener to H. H. Gibbs, Esq., St. Dunstan's, Regent's Park, who showed creditably, but of course suffered by comparison with the great growers named.

Cinerarias and Pelargoniums.—Messrs. H. Cannell & Sons, Swanley, were the most successful with nine Cinerarias, the excellence of their strain being manifest in the larger size, shapeliness, and rich colour of the abundant flowers. Mr. Douglas's second prize plants were more freely flowered, but less meritorious from the florist's point of view; Mr. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, showing densely bloomed but small-flowered plants for third prize. The last-named was more successful with Pelargoniums, being adjudged the premier award for healthy specimens of unmistakable decorative value, Digby Grand, Duchess of Bedford, Duchess of Edinburgh, and Rosette being excellent. Mr. Kemp, gardener to H. Barry, Esq., Bushill House, Winchmore Hill, was fortunate in meeting no opposition for the second prize, his plants by no means doing him justice.

Azaleas.—Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park, was first for six plants in the amateurs' class, showing several well flowered but one or two weak plants, Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, being second. For the remaining group (shown by Mr. R. Butler), a certificate was recommended. Mr. C. Turner, The Royal Nurseries, Slough, was first in the corresponding class for nurserymen, having small but densely flowered specimens of Middle N. van Houtte, Madeleine, Roi d'Hollande, Apollo, Mrs. Turner, and Baron de Vrierc. Mr. Robert Wells, Longton Nursery, Sydenham, and Mr. Henry James, Castle Nursery, West Norwood, took the remaining prizes, but their specimens were not such as to call for comment.

Messrs. H. Lane & Sons, Berkhamsted, had the field to themselves in the class for twelve plants of Azalea mollis, and showing in their well-known style, were deservedly awarded the first prize. They also showed Rhododendrons in very fine condition, and were placed first, no others competing, though strong opposition would have been needed to defeat the Berkhamsted growers.

Auriculas and Polyanthus.—Mr. James Douglas followed up his successes in previous classes by a highly creditable victory in the class for twelve show Auriculas, distinct. The varieties shown were Sir W. Hewett, Neatness (a green-edged seedling), Ajax, Frank, Charles J. Perry, L'Abbé Liszt, Marmion, Conservative, Glory, Acme, and two unnamed seedlings, the one a fine purplish violet self after the character of C. J. Perry, the other a green-edged variety with very large pips and well worthy of a name. Mr. C. Turner, The Royal Nurseries, Slough, was second, his best flowers being Beauty (Traill), Colonel Champneys (Turner), and C. J. Perry (Turner). Mr. A. J. Sanders, gardener to Viscountess Chewton, Bookham Lodge, Cobham, took the remaining prize. Messrs. Turner and Douglas changed places with Alpines, the former being distinctly in advance of his old rival. Edith and Teunyson carried fine pips, and Diadem, Mrs. Thomson, and Symmetry were also well represented in the collection, which comprised several seedlings of promise. Mr. Douglas was first with Polyanthus; Mr. J. Odell, Goulds Green, Hillingdon, following.

Miscellaneous.—Mr. Turner was awarded a bronze medal for a beautiful box of cut Tree Carnations. Mr. J. Chambers showed two dozen pots of his fine double dark blue Violet Victoria, which were much admired. Messrs. Paul & Son, Cheshunt, showed a larger and very fine group of Roses in pots, for which a silver medal was recommended, and Mr. Rumsey received a small silver medal for an attractive group of the same popular plants. Messrs. Lane & Sons staged a splendid group of Rhododendrons, and were adjudged a large bronze medal. Daffodils were shown in immense variety by Messrs. Barr & Son, Covent Garden (small silver medal), T. S. Ware (large bronze medal), and Collins Bros. & Gabriel (bronze medal), and were, as might be expected, very much admired. Messrs. Cannell & Sons showed a collection of double Cinerarias, which ought to be more grown, Rawson's White Violet, Primula elatior platypetala plena, and Sempervivum cordatum, a distinct succulent with bronze-tipped leaves. Messrs. W. Cutbush and Sons, The Nurseries, Highgate, London, N., were represented by a group of Epacris. Mr. Odell received a large bronze medal for a fine group of Cyclamens, and a bronze medal was awarded to Mr. W. Hibbert, gardener to W. Clay, Esq., Kingston, for another attractive group of these favourite flowers.

A mixed group of flowering and foliage plants from Mr. W. Kemp was adjudged a bronze medal. Mr. B. S. Williams of the famous Holloway Nurseries staged a splendid group of indoor plants. It included the graceful Ferns Adiantum Williamsi and A. gracillimum, Cattleya Skinneri, Ada aurantiaca, Cyrtopodium Boxalli, and Oncidium undulatum and luridum, which were noteworthy amongst the Orchids, and a plant of Dendrobium infundibulum bearing a solitary flower, large, almost transparent, with an orange throat was also remarked. Glonera jasminiflora, a Brazilian plant with Bouvardia-like trusses of pure white flowers, and Arpophyllum giganteum with long spikes of rosy inflorescence, were noteworthy amongst more familiar plants. A silver medal was awarded to this fine group.

Plants Certificated.—Botanical certificates were awarded to the following—Puschkinia libanotica compacta, shown by Mr. Ware; Oncidium undulatum, Anthurium Schertzerianum atro-sanguineum (a very richly coloured form), Cordyline australis variegata, and Selaginella cuspidata crispa from Mr. B. S. Williams.

The following were awarded floricultural certificates:—Double Violet Victoria (Chambers), referred to above; double Cinerarias Rosina, Aspasia, rich violet blue; and Faust, rosy red (Cannell); Amaryllises Monarch and Albert Victor (Douglas); Aspasia, Exquisite, and

Thackeray, splendid flower, deep crimson (Jas. Veitch & Sons); Alpine Auriculas Marmion and Emperor Frederick (Douglas); Pedigree Rose Duchess of Rutland, soft pale rose, good form, and Polyantha Rose minutifolia alba, exceedingly free, flowers white, as large as a florin (Bennett); Cyclamens Lord Hillingdon and Dixon Hartland, conspicuously blotched (Odell); and Narcissus bicolor J. B. M. Camm, and Lecdsi, Duchess of Westminster (Barr).

FRUIT FORCING.

VINES.—*Planting Vines.*—This is the best time for planting young canes. We prefer the borders partly within and partly outside, planting the Vines inside the house. For very early forcing the borders are preferably inside, otherwise we do not advocate confining the roots in this way. The border should be concreted at the bottom; unless it has a substratum of gravel or other porous substance, rubble 1 foot thick must be placed on the concrete, and proper drains and outlets provided. Thirty inches depth of soil is ample. Turf 3 inches thick taken off loam friable rather than tenacious, broken up roughly and mixed with a tenth of old mortar rubbish, charcoal, and some crushed bones form a suitable compost, but well-drained and fertile garden soil will grow serviceable Grapes. The Vines were cut back in early winter, and have been kept in a cool house, the eyes now having grown 2 or 3 inches long. Turn them out of the pots, remove every particle of soil, carefully preserving the fibres. Spread the roots out straight and flat, the soil of the border having been brought to the required level, covering the roots to the depth of about 4 inches, working the soil well amongst them with the hand, and giving a good supply of water at a temperature of 90°, mulching with a little short litter. If the canes have not been shortened do not cut them now, but remove the buds from the upper portion down to where fresh growth is desired to issue, and cut away the dis-budded part when the Vines have made some leaves, as there is then no danger of bleeding. Six feet width of border will be sufficient to commence with. Sprinkle the Vines and house twice a day, but avoid sharp forcing. Temperatures of 55° at night, 65° by day artificially, and 70° to 75° with sun, are suitable. If the weather be bright and the panes of glass large, shade lightly from 10 A.M. to 2 P.M., when the house should be closed, damping all available surfaces. If the temperature run up to 85° or more it will be an advantage. When the Vines have started into growth give every encouragement, increasing the temperature to 60° to 65° at night, 70° to 75° by day, and 80° to 85° from sun heat.

Young Vines.—Those planted last year are breaking naturally, and may be assisted with gentle fire heat in cold weather. The canes will have been fully depressed so as to cause them to break regularly down to the basal buds, when they can be tied in position. Dishud, leaving the best shoots about 18 inches apart on both sides of the canes. Crop very lightly, one or two bunches being the maximum. Any extra Vines planted to fruit early and afterwards to be cut out, may carry a bunch on each; six to eight or more bunches according to the vigour of the Vines.

Early Forced Vines.—In the earliest house red spider may be expected. Paint the return hot-water pipes with sulphur mixed milk so as to form a thin pain. Give the border a thorough watering, mulching afterwards. This refers to the inside border. Apply the water early in the day, so that surplus moisture may pass off before closing time. Early Grapes do not always colour well, the defect arising from overcropping or continued hard forcing; it is only avoided by a constant supply of dry warm air and a low night temperature. Where Grapes are fully ripe a reduction in temperature is advisable, yet moderate moisture should be maintained for the benefit of the foliage. The moisture will not do the Grapes any harm provided the air is changed by free ventilation. Afford a temperature of 60°.

Succession Houses.—Attend to stopping and tying the shoots. Where the space is restricted stop the shoots two joints beyond the fruit, and as foliage is necessary leave the laterals on the shoots both above and below the bunch, or at least those from the two lowest eyes, and those level with and above the bunch. Pinch these at the first joint, especially those from the basal leaves, also those above unless there is space for extending the laterals, when they may be allowed to make two or three leaves, but no more growth must be encouraged than can have exposure to light and air. After the space is fairly furnished keep the growth closely pinched to one joint as made. Where there is more space stopping will not take place until growth has extended four or more joints beyond the fruit. The great evil is overcrowding, which deprives the foliage of the light and air, and restricting the growths is intended to avoid that.

Tying the side shoots into the places where they are to remain during the summer is an operation which commands much attention. It is a common practice to begin to tie down the shoots as soon as they are long enough to bend. This is not advisable unless as a precaution against

injury from frost, as the shoots at this stage are so tender that the slightest twist the wrong way breaks them. It is a better plan to defer tying down until the shoots are less sappy, which may be when the fruit is formed, but a better plan still is to dispose the rod that the shoots, instead of having to be brought down to a nearly horizontal position, will have a good incline upward, yet sufficiently outward or oblique to admit light to the basal leaves of the shoots. Afford Muscats in flower a free circulation of rather dry air, and a temperature of 80° to 85° or 90° by day, falling to 70° or 65° at night, raising the points of the bunches to the light, and liberate the pollen at midday by gently rapping the footstalks of the bunches. If there is a deficiency of pollen take it from those that afford it plentifully, as Black Hamburgs, and apply it to the shy-setting varieties with a camel-hair brush.

Where there is a large quantity of Grapes to be thinned commence as soon as they are out of bloom with the free-setting varieties, such as Black Hamburgs; and some, like Gros Colman, Gros Guillaume, Trebbiano, &c., may be thinned whilst they are flowering. Follow it up early and late, and on dull days. Surplus bunches may be removed holdly, as overcropping proves fatal to colour and finish. Crops swelling must have a liberal supply of heat and moisture, and the inside borders well supplied with water or liquid manure.

MELONS.—The fruits of the earliest plants are growing large, they must have the supports lowered. Frequently stop the laterals, or thin them where they are crowded. Supply water or liquid manure liberally to plants on which the fruit is swelling, but avoid excess of liquid manure, which may injure the roots, and the fruit in consequence will not finish satisfactorily. Plants coming into flower should only have water to prevent flagging, and a drier condition of the atmosphere is essential to a good set, especially so in the case of very vigorous plants. Attend regularly to the setting of the blossoms. Stop the shoots, however, one joint beyond the blossoms when impregnated, but after the fruit is set remove all superfluous growths. Avoid giving stimulants to plants until the fruit is swelling, when liquid manure may be afforded liberally, especially to plants carrying heavy crops, until they are well advanced towards ripening. Maintain a night temperature of 70°, 70° to 75° by day, and 85° or 90° with sun heat. Ventilate freely in favourable weather, closing early with plenty of sun heat, when the plants may be syringed lightly, except such as are in flower. Watch for canker at the collar, and rub it out with fresh slaked lime when it makes its appearance.

CUCUMBERS.—These have made good progress lately, and require attention in tying out the growth, stopping one or two joints beyond the fruit, removing bad leaves and exhausted growths so as to maintain a succession of healthy fruitful shoots. Water plants in houses abundantly, and with weak liquid manure about twice a week, syringing the foliage and walls daily about 3.30 P.M., when the house can be closed. Shade only to prevent flagging. Those plants in pits and frames will hardly need shading as yet, but they must not be allowed to flag. Use tepid water through a rose watering pot at about 3 P.M., closing the lights at the same time, but as the nights are yet cold, be careful that the foliage becomes dry before night. Close early, employing a good thick night covering. Maintain a good hottem heat by linings, renewing them as necessary. Preserve a night temperature of 70°, 70° to 75° by day artificially, 80° to 85° from sun heat, ventilating from 75°, being careful to avoid cold and drying currents of air, and close sufficiently early to run up to 90° or more with plenty of moisture in the house. Sprinkle available surfaces in the evening occasionally with liquid manure, or fresh horse knobs sprinkled on the surface of the bed will answer the twofold purpose of evolving ammonia to the benefit of the foliage, and supply nutriment to the soil, as well as encouraging surface roots. Pot ridge varieties, keeping these and other young plants near the glass.

FLOWER GARDEN.

Herbaceous Borders.—Very few plants in these are far advanced in growth, and it is not yet too late to lift and divide any that have developed into strong spreading clumps. The strong-growing gross-feeding Delphiniums, Phloxes, Potentillas, Pyrethrum uliginosum, Asters, Japanese Anemones, Geums, Helianthus, Hemerocallis, Tradescantias, and Rudbeckias, may be lifted, divided up with a fork and replanted in fresh well-manured soil, and be greatly improved thereby. Strong clumps of dwarf Pyrethrums may also be split up and replanted with advantage, but the majority of the more weakly growers ought not often be disturbed. The Flag Irises can be moved and divided readily now, and Narcissi may be transplanted prior to flowering better than when at rest, flowering next season quite as well as this. Carnations, Pinks, Pentstemons, Antirrhinums, Phloxes, Pansies, Pyrethrums, and all extra choice hardy plants wintered in pots under glass ought now to be sufficiently hardened off, and should therefore be planted out as soon as the weather permits. Mix plenty of leaf soil or short manure with the soil intended for choice, or they may not take readily to their fresh quarters. Now that nearly all the bulbous plants are well through the ground, the borders may have a quantity of short manure forked into the surface, this greatly benefiting the established plants as well as any annuals that may be sown or planted among them. If not already done sow a few seeds of Mignonette and Sweet Peas in 5-inch pots, these to be eventually planted in the mixed borders for an early supply of cut bloom.

Hardy Ferns.—Most of these can be transplanted when in full growth, but they are best divided just as active growth commences, or at the present time. It follows that now is also a good time for forming a new fernery. All thrive admirably in a rather shady position, but ought not

to be unduly shaded by trees. Those species with creeping or rhizomatous stems thrive best when in contact with large stones and old tree roots, but the *Athyriums*, *Lastreas*, *Polystichums*, *Scolopendriums*, many of the *Polypodiums*, and the *Osmundas* grow most vigorously in ordinary soil with or without stones. It is advisable, however, to mix plenty of peat or leaf soil or both, as well as lumps of sandstone with the soil for hardy Ferns generally, for the purpose of giving them a good start. Keep the commoner rank growers in the background as much as possible, or otherwise they will soon smother the choicer and more weakly growing species and varieties.

Lily of the Valley.—These pay for good cultivation. Starved and crowded together the spikes are poor and not very plentiful, but given good room and fairly rich soil fine crowns are formed and large spikes of bloom follow. Part or the whole of a bed may be lifted now, freely divided, and the crowns thinly replanted in well manured finely separated soil. A rather cool border suits them well, and the strongest of the crowns ought to be planted about 3 inches apart each way and just covered with soil. Finish off with a mulching of short manure or leaf soil, and a surfacing of the former may well be given to undisturbed beds. Replanting crowns does not interfere with their flowering the same season, and it eventually leads to the formation of good clumps or crowns for forcing.

THE BEE-KEEPER.

QUEEN INTRODUCTION.

"A HALLAMSHIRE BEE-KEEPER," at page 288, still holds to the opinion that the main point of safe queen introduction has never been grasped by any writer on bees.

Unlike your correspondent, I never read Huber nor Réaumur, nor indeed any bee book, for the first thirty years of my bee-keeping life, and but very few since then, the *Cottage Gardener*, now *Journal of Horticulture*, being my favourite paper, and the only one in which I found ideas worth treasuring. My only book of instruction has been the book of Nature. The great hindrance to the advance of bee husbandry is "unjust" criticism in certain quarters, and the unfair practice of pirating others' ideas, which naturally arouses jealousy. How much better would it be if all would draw honestly together!

That my friend has wrought out his ideas given in this Journal without the knowledge of what has been written on the subject I do not doubt, and but for his interposition to settle a point of importance in queen introduction would have been seized upon by someone. I cannot point to any particular number of this Journal containing the information, but I am certain it was given. Mr. J. Lowe contributed several long articles on the subject of bee commotion, on bees missing their queen, and although headed "New" it was well known to all advanced bee-keepers before that time. I know your correspondent is unconscious that anything has been previously written on the important point of bees missing their queen before another should be introduced; therefore his articles are just as valuable as if it had not appeared. If he turns to page 58 of my essay to the Highland and Agricultural Society he will see the following remark:—"The only safe method of joining queens is to allow sufficient time to elapse, so that the bees miss their queen." If I have forestalled all other writers in this I must be content, because I see looming in the distance what will or may outstrip me. "A. H. B.-K." has something more to add which will help to insure queens after their enthronement. Mr. T. Bonner Chambers, F.L.S., has already given us a chapter (*vide* pages 247, 248) not only able in detail, but really new—so far that it has never appeared in print at any time previously, although I have, without giving explanations of the reasons, stated the result. It is the most valuable article on queen introduction I have ever read.

It appears we are now on the eve of knowing more about the mysteries that have hitherto been veiled from us. Let us therefore continue in search of knowledge that will enable us to understand successes or failures, and enable us to know when to depose and when to introduce queens with safety in all the different complex phases.

It is perhaps superfluous to note here all the various phenomena that I have observed, further than that I have introduced queens under every known system, and have had success and failures with all of them. Many queens are lost by leaving the hive immediately they are placed into it from the top without previously caging her and closing the entrance, and this takes place in the dark as well as during the daylight. But the most common loss of queens is as described by Mr. T. B. Chambers at page 248, and it has puzzled me much to know the cause of such unnatural phenomena, which is not confined to recently introduced queens, but very often occurs with queens regnant from their birth. I have observed the seeming neglect of the queen as described, and have as often as six times in one season destroyed the royal cells being brought forward preparatory to the deposition of the queen, who receives rough treatment from her daughter subjects, and is at last killed by them, and not by the virgin queens. I cannot say these dethronements always take place because of impaired fertility, because several times have I rescued the reigning monarch, introducing her to another hive, and there she proved herself prolific. One I saved and presented to a neighbour after a determined attack had been made upon her life, and numerous royal cells had been raised by bees and destroyed by me. This queen was safely introduced, and lived for three years.

I am of opinion that the raising of royal cells is owing entirely to faulty combs, the queen not finding suitable cells to deposit her eggs incites the bees to depose her. It is different, however, with those queens recently introduced, and by which more queens are killed than by all the other modes of mishap, the lives of such queens being always in jeopardy after the bees begin to disregard her as their rightful queen. What is the cause of this continued determination? Here is a wide field for research on a topic of the greatest interest and importance to every bee-keeper.

By using the precautionary measures I have advocated so long both in this Journal and privately, the losses when introducing queens will be, as they have been, few in number, but it will be all the better if we can, by a combined effort, discover the real causes of the mysteries that present themselves in various forms under the same as well as different circumstances.—A LANARKSHIRE BEE-KEEPER.

TO CORRESPONDENTS

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Teddington Garden (Kiltiernan).—The particulars required will appear in the next issue of this Journal.

Orchard Houses (H. R. W.).—Your letter has been forwarded to Mr. Rivers, and the substance of his reply will be communicated to you. Plainly built structures of this character should not be expensive.

Late Chrysanthemums (W. D.).—The blooms sent are fair representatives of the variety, which is evidently a very useful one both for exhibition and decorative purposes.

Hellebores (F. I.).—The plants prefer a moist and rather shady situation, but any ordinary garden soil suits them, if not excessively

heavy. Most of the varieties of the *H. niger* type (Christmas Roses) are best planted in late autumn, but varieties of *H. orientalis* (Lenten Roses) can be planted in early spring.

Gloire de Dijon Rose Unsatisfactory (*T. J. W.*).—Though the soil was good when the Rose was planted, "seven or eight years ago," it has probably become impoverished now, and the failure may be due to that. Apply a good mulching of old decayed manure over the roots, or give occasional supplies of weak liquid manure. Ventilate the house freely in mild weather, and syringe the plants.

Soil of Vine Border (*A. C.*).—The soil is in a very unsatisfactory condition, and, judging by the appearance of the sample sent we should think the border is not thoroughly drained. However, the course you propose adopting is the best that can be followed this season; but you will probably find it advisable to overhaul and renew the border before it will be restored to a condition favourable to the Vines.

Slugs (*J. E.*).—Apply nitrate of soda to the ground at the rate of 1 lb. to 30 square yards, but before putting in the crops. We have no great difficulty with slugs, as we dress the ground with salt at the rate of 20 bushels per acre in March, or before cropping, and upon any appearance of the slugs we sprinkle the plants and soil about them with quicklime early in the morning or at dusk, repeating the sprinkling as the lime is washed away by rains, or the slugs continue their depredations.

Epiphyllums (*S. Mills*).—Repot them in spring after flowering; or, if they do not flower, in April. Provide good drainage, a compost of sandy fibrous loam and sandy peat in equal parts, with one-fourth of silver sand, pieces of charcoal, broken pots, and leaf soil or old dry cow dung. They are best grafted on *Pereskia* stocks. Grafting is easily performed by cutting the stock in a slanting direction and putting on a shoot of the *Epiphyllum*, securing it with a thorn of the *Pereskia*, tying with matting, and covering lightly with moss. It may be done in spring before growth, or after the growth is complete. Water the plants moderately, but when growing afford moisture, and in winter give water only to keep them fresh. Afford a light airy position, only when growing slight shade is preferable.

Thick-necked Onions (*B. E. W.*).—Various causes contribute to this deformity; one being spurious seed; another a wet, cold, or late situation; and another insects, only the latter evil results in a sort of bladder-like formation rather than a thick neck. In general, if good seed be obtained and sown sufficiently early on dry ground, and the season becomes moderately dry and fine, Onions of proper size and shape will be formed, either large or small as the character of the ground and their cultivation is attended to. But if the situation is damp their growth is prolonged too late in the season, and a number of thick-necked only half-ripened bulbs will be the result. In such places a good dressing of charcoal dust at the time of sowing will be beneficial, in addition to thorough drainage and as much road sand as can be had, or anything that will tend to make the ground drier and more porous.

Destroying Woodlice (*Subscriber*).—The most wholesale mode of riddance is to place some boiled Potato round the inside of the frame or pit on the surface, and cover with a little hay loosely. Do this as a bait for a couple of nights, and in the morning of the second night have some boiled water in a watering pot, and pour it through the spout on the hay around the sides of the pit or frame. This will not do any harm to the plants provided it is not used upon them, or even to their roots, unless used in excessive quantity. It may be necessary to repeat it in the course of a week, which the presence or otherwise of the pests will determine. Some baits formed by placing a boiled Potato wrapped loosely in a little hay in a small flower pot laying on its side near the haunts of the woodlice in the evening, and in the morning shaking the vermin into a bucket of scalding water from the hay in which they will be secreted after or still feeding on the Potato. This persisted in will eradicate them. A toad introduced will devour great numbers, and is an aid in the destruction of woodlice too seldom called into requisition.

Old Nonpareil Apple (*Clericus*).—It is generally allowed that the Nonpareil is originally from France. Switzer says, "It is no stranger in England; though it might have its origin from France, yet there are trees of them about the Ashtons in Oxfordshire of about a hundred years old, which (as they have it by tradition) was first brought out of France and planted by a Jesuit in Queen Mary or Queen Elizabeth's time." It is strange, however, that an Apple of such excellence, and held in such estimation as the Nonpareil has always been, should have received so little notice from almost all the early continental pomologists. It is not mentioned in the long list of the *Jardinier François* of 1653, nor even by De Quintinye, or the *Jardinier Solitaire*. Schabol enumerates it, but it is not noticed by Bretonnerie. It is first described by Duhamel and subsequently by Knoop. In the *Chartreux* catalogue it is said "Elle est forte estimée en Angleterre," but among the writers of our country Switzer is the first to notice it. It is not mentioned by Rea, Worlidge, or Ray, neither is it enumerated in the list of Leonard Meager. In America it is little esteemed. The Scarlet Nonpareil was discovered growing in the garden of a publican at Esher, Surrey, and was first cultivated by Grimwood of the Kensington Nursery.

Weevils in a Vinery (*G. Potts*).—The insect is a weevil, *Curculio* species, which is very injurious in a vinery. Spread a sheet beneath the Vine at night, and shake the Vine rod sharply, when the weevils will fall on the sheet, and may be destroyed. This repeated a few times will thin their numbers. We presume the Vines were stripped of their loose

bark, and afterwards dressed in the usual manner, the walls being whitewashed. Any holes in the wall should be stopped with cement. The tobacco juice from the manufacturer diluted with six times its bulk of water is useful, applying it through a rose watering pot; also the following:—4 ozs. quassia chips, hoiled ten minutes in a gallon of soft water, dissolving in it 4 ozs. softsoap. Wet the surface of the whole house with this two or three times, especially near the walls, just after dusk, and the following day damp the whole house with tepid water. Neither of the agents mentioned must be applied to the foliage of the Vines, but over any plants that will not be injured by the softsoap it may be syringed. We have also found sprinkling the floor of the house and border with guano, and then with water, useful; if the floors are wet, sprinkling with water afterwards is unnecessary. If the Vines are in tender leaf a little ventilation should be left on, as the ammonia evolved will scorch the leaves. Water well in the course of two or three days.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*B. R. T.*)—1, *Acacia armata*; 2, *Anemone fulgens*; 3, *Anemone nemorosa*; 4, *Asplenium Adiantum-nigrum*. (*W. O.*)—1, *Direa palustris*; 2, *Daphne Mezereum*; 3, *Daphne Mezereum album*; 4, *Daphne Laureola*; 5, *Selaginella Kraussiana*; 6, *Davallia canariensis*. (*R. W. M.*)—1, *Corydalis solida*; 2, *Chionodoxa Luehliæ*; 3, *Seilla siberica*.

COVENT GARDEN MARKET.—APRIL 18TH.

PRICES as last week, with the exception of Strawberries, which are easier. Business steady.

FRUIT.			
	s. d.	s. d.	
Apples, ½ sieve	2 6	to 4 6	Oranges, per 100
Nova Scotia and			Pears, dozen
Canada barrel	10 0	18 0	Pine Apples, English,
Cobs, 100 lbs.	45 0	0 0	per lb.
Grapes, per lb.	3 6	6 0	St. Michael Pine, each
Lemons, case	10 0	15 0	Strawberries, per lb.

VEGETABLES.			
	s. d.	s. d.	
Artichokes, dozen	1 0	to 2 0	Lettuce, dozen
Asparagus, bundle	8 0	0 0	Mushrooms, punnet
Beans, Kidney, per lb.	1 6	0 0	Mustard and Cress, punt.
Beet, Red, dozen	1 0	2 0	Onions, bunch
Broccoli, bundle	0 0	0 0	Parsley, dozen bunches
Brussels Sprouts, ½ sieve	3 6	4 0	Parsnips, dozen
Cabbage, dozen	1 6	0 0	Potatoes, per cwt.
Capiscums, per 100	1 6	2 0	" Kidney, per cwt.
Carrots, bunch	0 4	0 0	Rhubarb, bundle
Cauliflowers, dozen	3 0	4 0	Salsafy, bundle
Celery, bundle	1 6	2 0	Scorzouera, bundle
Coleworts, doz. bunches	2 0	4 0	Seakale, basket
Cucumbers, each	0 4	0 7	Shallots, per lb.
Eardive, dozen	1 6	2 0	Spinach, bushel
Herbs, bunch	0 2	0 0	Tomatoes, per lb.
Leeks, bunch	0 3	0 4	Turnips, bunch

FAULTS IN FARM MANAGEMENT.

"WHAT we want is higher prices for our farm produce," said a worthy old farmer at a meeting which was held to discuss the cause and possible remedy of the agricultural depression. Of course we do want higher prices, but how any sensible person can hope to get them passes our comprehension. To begin with, we may take it for granted that every sensible farmer knows the reason of the steady reduction in value of the produce of his land, and anyone to go on hoping and waiting for better prices is tantamount to owning himself a simpleton. Very wisely do Messrs. Sutton say in their recent Farm Seed Catalogue that "Agricultural prosperity or depression are not consequent upon good or bad seasons only, but that Indian and American railways, improved steamboats, and cheapened cablegrams have revolutionised the agricultural position. Farmers are settling down to the altered state of affairs, having become convinced that in the reduction of expenses is to be found the salvation of agriculture." Sound and wholesome advice is this, Messrs. Sutton, we grant, if taken with a grain or two of common sense, for we hold that even under the depression economy is only justifiable as applied to keeping under wasteful expenditure. We hardly need remind our readers how persistently we have striven to show that the best way to overcome difficulties arising from the agricultural depression was to get more out of the land, and in order to do this we were bound to see if the general practice of imparting the necessary elements of fertility to the soil to promote the fullest possible development of our crops was correct or otherwise. Well, we are free to own we found it very much "otherwise," and as we were able, step by step, to discover and set right faults in our own practice, so have we striven to assist our readers in doing so too.

Of faults arising from ignorance we may very safely cherish hopes of improvement, but what can we venture to say about those which are owing solely to carelessness? Take, for example, that important branch of agriculture included under the comprehensive term Dairy Farming. Surely we must term it carelessness upon the part of those having the management of the cows, or the dairy, if the milk, cream, butter, or cheese are not of the best? Why is it that the butter from a certain farm commands a higher price than any other butter in that particular district? Simply because it is the best. We know a certain farmer at the present time who is a shrewd man of business, and who is blessed with that "pearl above price," a good wife and clever manager, who is gradually taking the lead in supplying dairy produce to the inhabitants of a town where it is notorious that what is termed the milk business is overdone. But then no "sky blue" milk ever comes from his dairy; his milk is delivered to his customers in sealed bottles at the same price as other dealers sell it without such security, and the butter and cream are alike excellent. But success does not rest solely upon dairy management, for if the cows are not well bred, well fed, and well cared for in every way, the efforts of the best dairy woman in the world may be exerted in vain. We cannot, of course, go into details of management here, but we may insist upon the high importance of close attention to every detail as exercising an influence upon final results.

Turn now to corn-growing. How frequently are we told that Wheat-growing has ceased to be profitable in this country. May we not qualify this assertion, and say rather that careless practice in Wheat-growing is no longer possible, and that in order for it now to afford a margin of profit not one link in the chain of sound practice must be wanting? We have only to turn to the results of

sound practice last year for proof of this. Upon a mixed soil farm in our own hands we had a field of white chaff red Wheat, where the yield per acre was 7 quarters of marketable grain and 2 tons of straw. Now the best price obtained by us in open market before the end of last year for Wheat was 32s. per quarter, and for straw 50s. per ton, and it is therefore reasonable to take such prices as a basis in the calculation of possible results which we now make. Of grain we have 7 quarters at 32s., equal to £11 4s., and 2 tons of straw at 50s. equals to £5, or a total per acre of £16 4s. We are fully aware that this result is altogether above the average, but we are bound to insist that it is possible upon all really good Wheat land. Was there any reason to induce one to hold over much Wheat into the new year? Certainly we did not think so, for we had disposed of almost all our Wheat before last Christmas, and we know that 30s. or less per quarter has been the highest price since then. To retain Wheat in stack without an object is certainly wrong. Mice, rats, and rooks are after it all winter. It is true enough vermin may be held in check, but this is not always done, and we know at the present time three large Wheat stacks so badly infested by rats that there is a perceptible depression in the roof of one of them from the ravages of rats beneath it.

WORK ON THE HOME FARM.

So favourable has the weather been for work on the land that there has been practically no hindrance to the use of the corn drills from morn till dewy eve daily, and we were delighted to hear a light-land farmer whose occupation covers an area of nearly a thousand acres, say on the 11th instant that he had sown all the Barley and the greater part of the Mangold seed. Now this is quite as it should be, for we were all kept waiting week after week by winter in spring, and no time should be lost in sowing spring corn, Clover, Sainfoin, mixed seeds for alternate layers, Lucerne, seeds for permanent pasture, Mangolds, and Swedes. One word about Lucerne. We may usefully remind our readers that it is quite one of our best forage crops. We have now experienced three years of drought, of which trying period we hope last year was the climax, and throughout that time the best forage crop of all was clearly Lucerne. Nor is it difficult to see why it was the best, for it sends its roots down so deep into the soil as to be practically unaffected by drought. Under generous treatment it gives an early spring growth, and it gives successional growths continuously throughout the summer. It is eaten freely by horses, cows, and sheep, and may be made into excellent hay or silage, and it ought certainly to be grown much more extensively than it is. In a hot, dry summer the sight of pasture parched and browned by drought is a sad one, but Lucerne is never so affected, and the crop of succulent green food which it affords under such adverse conditions is invaluable. If a sowing of spring Tares has not been made no time should be lost in sowing sufficient for the requirements of sheep, horses, cows, and pigs, for they are all fond of it. We have frequently finished our lambs for market in folds upon Tares, and we hardly know whether to give preference to Tares or Sainfoin for such a purpose. Perhaps Tares should have the preference, because they may be grown upon all kinds of soil, but Sainfoin is not so amenable to general culture, yet where it can be had it is to be highly valued as affording two crops of great abundance every summer. The first may be eaten off or made into hay, and the second is always available for a supply of seed if it is required, and the plant may remain upon the land for three or four years.

REMARKS.

8th.—Frequent slight showers of soft hail in morning; fine afternoon and evening.
 9th.—Fine, and frequently bright day; showery in evening.
 10th.—Fine and bright early; shower of soft hail about 10.30 A.M., then generally dull.
 11th.—Dull and drizzly till 11 A.M., and cloudy till 2 P.M., then bright and fine.
 12th.—Dull and damp early; cloudy day.
 13th.—Bright and warm.
 14th.—Cloudy till noon, then bright.
 The two halves of the week have been markedly different. The first three days were colder than is usual in January, while the last two were such as are usual at the beginning of May. Sharp frosts on grass on 8th, 9th, and 10th.—G. J. SYMONS.

BELGIAN WORK AND WAYS.

AS has been seen by the sketch report of the Ghent Quinquennial Exhibition last week, somewhat different methods are adopted in the conduct of shows in Belgium from those in operation in this country. Horticultural exhibitions are presumably held every year in the thrifty little kingdom on the eastern side of the North Sea, but only once in five years is a great effort made to provide a show on a gigantic scale and of international character. The distinctive term, however, applies more forcibly to visitors who are invited to officiate as jurors than to exhibitors. It is true there are usually a few competitors from England, Holland, and France, but their exhibits bear no comparison in point of numbers with the representative horticulturists who share in granting the honours, and who receive such a warm and hospitable reception. It is not that the services of so many adjudicators are absolutely required for apportioning the medals, for less than forty competent men would do the work as well as the 140 who were summoned. The chief object of the managers of the shows in question appears to be to gain the co-operation of men who will spread the fame of Belgian horticulture over all the world. It is not easy to conceive how any better plan could be organised for achieving the object than the one in operation, and which experience has doubtlessly proved answers its purpose well.

"Do the Ghent Shows, which of necessity involve a heavy expenditure, pay?" asks the Secretary of a British horticultural Society. Without knowing anything whatever about the balance-sheet of the Society which organises the "Quinquennials," it may be suggested that if the Shows did not "pay" they would not be continued. But they have to be considered not as bringing grist to the mill of a Society, but as of far wider scope and significance—namely, attracting the attention of the world to the horticultural resources of the kingdom and expanding the great trade that is there established in plants. Horticulture is not so fully recognised as an industry in England as it is in Belgium, where official patronage is bestowed and effective aid rendered both by municipalities and the Government to the chief exhibitions. Grants are made by the State towards the promotion and extension of the industry in question, and also in the interests of agriculture, whereas in England whatever of advance may be made or improvements effected must be the result of individual enterprise. As an instance of State aid in the work of cultivation, any farmer in Belgium who is desirous of gaining information that may be of service to him has the right to summon to his assistance a Professor, or, as he is termed, an Agricultural Engineer, who is paid by the Government not only to initiate experiments on the land with chemical manures and various trial crops, but the manures and seeds are provided free of all cost to the applicants. This is a step in advance of a very practical nature, and as the plan is being put into action the results can scarcely fail to be of substantial benefit to the community in increasing the productiveness of the soil. In that way the nation will be undoubtedly enriched by the outlay that is invested in the work. So, too, is it enriched by the disbursements made in the cause of horticulture, as in the case of the great exhibitions that are periodically held in Ghent, which is the chief seat of horticulture of the kingdom, two or three hundred nurseries being established in the city and suburbs. The great gatherings cannot be held without a large sum of money being brought into the country and left there, while the sales effected in the nurseries are

very considerable. If not directly, then, not the less certainly, are the great shows profitable to the nation, and the outlay incurred in providing medals and banquets is regarded as a safe and sound investment.

As entertainers the Belgians are pre-eminent. There is of necessity and properly trade rivalry there as elsewhere, but when the time comes for dispensing hospitality and creating an impression all join in the object, and appear to vie with each other in striving for the success they deserve so well, and which they do not fail to secure. So striking and even brilliant were the receptions accorded on the occasion in question, that one of the British representatives, and not the least enterprising and successful, was troubled amidst the joyousness, because he felt that no adequate return could be made in this country of a similar nature, at least at the present time, but he hoped the time would come when the Royal Horticultural Society would be in a position to take the lead in a gathering that would be worthy of the nation.

It is to be noted that Belgian horticulturists possess besides the spirit of enterprise the virtue of patience. They have learned not only to labour, but to wait. Their policy is evidently to gain strength by an accumulation of resources. They do not make a number of small attempts and fail, but concentrate their energies on great efforts at wide intervals and command universal attention. State grants could not be obtained every year, as these are consequent on and governed by individual contributions. If the means at disposal were expended yearly the shows would be five times less in importance and not more than mediocre in character. In that case little would be heard of Belgian horticulture, for it would be essentially local instead of, as now, of world-wide celebrity. Great interest is manifested in Belgium in the Royal Horticultural Society of England, and some of the experienced continental workers delicately suggest that perhaps the English Society attempts too much, dividing its resources unduly and depriving itself of power. Perhaps our friends over the water, who do things so well, are not far wrong; anyway, that view of the position may be recorded, as it cannot possibly do harm if it does no good.

The contributions to the Belgian horticultural societies are not high. A guinea constitutes membership, though special donations are given for special purposes. Moreover, the societies do not stand alone, but are in almost every case amalgamated with musical societies. When each of these, harmonic and horticultural organisations, stood apart both were weak, but by association each became strong, or much stronger than before. Obviously it does not follow that a similar alliance is practicable in England, for it is probable that there are few, if any, harmonic societies corresponding with those established in the chief cities of the Continent; still, the circumstance must be narrated in a passing allusion to Belgian work and ways.

If we could emulate our friends in waiting and gathering strength, then unite our forces as they do, we could excel them in the magnitude and richness of our exhibitions, taking them in the aggregate, though in some of their productions they are in the ascendant; and we might then, as they do now, invite representatives of culture from various countries, and make London, for the time being, the centre of attraction in the horticultural world. We could, at least, give a hearty English welcome, and if it differed from that accorded in Ghent, would not, perhaps, on that account, be the less agreeable. One thing we could not very well do, since we have no State aid and State railways—gain a 50 per cent. reduction in fares for jurors travelling on the lines to and from the exhibition. That is a "way" they have in Belgium of showing courtesy to the friends who are officially invited to take part in great exhibitions like the Quinquennial at Ghent.

It is pleasant to observe not only continued, but evidently increased, prosperity in the horticultural industry of Belgium. The demand for plants of a decorative nature is greater than ever, and some kinds, notably Azaleas, Palms, and a few other

ornamental plants, appear to be grown more quickly and cheaply than in England. They are grown to be killed in the windows and halls of cities and towns, and they answer the purpose, room being constantly made for more; and so the demand continues, and the supply is commensurate with it. Wages are lower in Belgium than in England, and the hours of labour are longer there than here, while the activity of the men employed in the nurseries denote that they take no small interest in their work. Belgium is a hive of industry, and at the least ten times more men, women, and children, besides bullocks and dogs, are seen working on the land than can be found on a given area in this country, where the oxen chew their cud in laziness, and dogs are luxuries and not labourers.—A JUROR.

CULTURE OF THE DOUBLE VARIETIES OF PRIMULA SINENSIS.

[A Paper by W. H. Divers, Ketton Hall, Stamford, read at the Meeting of the Scottish Horticultural Association, May 7th, 1885]

I SELECTED this subject for my lecture for the following reasons. The double Primula is the most useful plant we have here for winter flowering, as by growing about 300 plants we can always rely on having plenty of white flowers from November to April. I think in a few years when its culture is better understood this plant will be largely grown by most persons who have a supply of flowers to maintain during the winter months. It does not require such a great amount of heat to flower it in perfection as the Eucharis, Gardenia, and other favourite white flowers. If liberally treated it gives a good succession of flowers which are useful for all ordinary purposes, and by carefully attending to a few chief points in its culture it may easily be grown in large quantities.

Before proceeding any further I may as well state that what is here mentioned refers altogether to the double Primula proper, and not to the semi-double varieties which are raised from seed. They may be useful for some purposes but are no favourites of mine, as I consider either the true doubles or the singles far prettier and more satisfactory in every way.

USES OF THE FLOWERS.—We use the old Double White or alba plena when cut for wreaths, vases, bouquets, buttonholes, and sprays, and the plants when in flower for dinner table, room, conservatory, and church decoration. The newer varieties should be mounted singly for buttonholes and bouquets, and are very pretty and useful for this purpose. They are, however, rather peculiar flowers to wire effectually. The best way is to take a piece of ordinary stem wire, turn a very small hook at one end with the pliers, push the other end down through the centre of the flower and pull it through far enough to be out of sight, wind a small piece of binding wire round the stem lightly, and all is complete. The old Double White is often most useful if wired in whole trusses; this is easily done by strengthening the main stem with a short wire and twisting some binding wire round the small stems of the bunch so as to draw all of them nearer together. They may also be wired singly in the same way as the newer varieties. The binding wire must be very gently placed around them.

PROPAGATION.—The chief reason this plant is not more extensively grown is because it has obtained a bad name with many on account of failures in propagating it, and if it is attempted to strike the cuttings in the same way one would proceed with Verbenas or Heliotropes, for instance, or even like Pelargoniums, failure is almost certain. It is too succulent in its nature to be struck the same way as most plants are treated; at the same time it will not strike under treatment given to ordinary succulent plants. The system I have found to answer best for propagating them may be described as a combination of the two, and by the plan I am about to describe 99 per cent. may be rooted. They require a place to themselves for propagating, a separate case in the propagating house, where such conveniences are at hand, or a propagating case fixed in a Melon or Cucumber house, or some house with a similar temperature, or failing either of these conveniences, a frame fixed on a hotbed is the next best obtainable, and that is probably within the reach of every gardener. The bottom heat should range between 70° and 75°, and may be derived from a heated chamber with plunging material on the top, or failing this, any kind of well-sweetened fermenting material will do which can be depended upon to maintain a steady temperature for four weeks. Cocoa-nut fibre, old tan, or sawdust should be spread on the top of the bed as a plunging material just deep enough to hold the pots.

I have seen it advised in gardening periodicals to strike the cuttings in August and grow the plants about fifteen months before flowering them. But this is a great mistake. There is no necessity to lose a whole season if the plants are struck early and liberally treated.

We have had plants of the old Double White struck here the first week in June 18 inches across in the following January, and bearing twenty-eight trusses of flowers in 6-inch pots. I mention this to show that plants may be grown in nine months large enough for all purposes.

The best time for propagating is at the end of April or early in May for those required to flower early in the winter, and the end of June is not too late if they are not wanted before the following February. The old plants should be induced to start growing freely before the cuttings are taken off by keeping them a little warmer, &c. The soil for propagating must consist of one-third leaf mould, two-thirds light sandy loam, and one-sixth of the whole good sharp sand. Take the cuttings with a portion of the old brown stem attached, cut off closely any leaves likely to decay soon, and the remains of the old dry leafstalks, using a very sharp knife, and being careful not to injure the bark on the stem of the cutting. Insert the cuttings as soon as possible after they are detached from the plant, and each one should have a small stake and a piece of matting run from the stake all round the leafstalks and tied, in order to steady it in its place. Give all a good watering before placing them in the propagating case, being careful not to wet the foliage more than is necessary, and as soon as the water has drained off place them in the frame. If this is a propagating case inside a house leave the lights off until all superfluous moisture has evaporated. If the frame is an ordinary one outside, of course this would not be advisable, but the light should be fixed for a time so as to allow a current of air to pass through. This must be stopped before the cuttings commence to flag. It is a good plan to lay a few lumps of charcoal among the cuttings. This helps to keep all sweet and absorbs some of the superfluous moisture.

Provision must be made to keep all sunshine from the cuttings until they are rooted. There are now two dangers to steer clear from. The first is having the atmosphere in the frame too dry and causing the cuttings to flag, which weakens them and delays their progress. The second is a stagnant atmosphere overcharged with moisture. Of the two the last is the greater evil, but the chief point to aim at in order to secure the greatest success is to keep a little ventilation on the case or frame without allowing the cuttings to flag. It is, however, safer to let them flag a little rather than to keep the air confined around them for any length of time, but much depends on the amount of moisture arising in the frame, and the air must be regulated accordingly. If this frame is fixed inside a propagating or other house the lid may often be left open after the ventilators are closed in the house in question, provided it has been well syringed and the sun is not shining directly on the case. During the night, and when the ventilators in the house are open, the lid of the frame should be tilted about a quarter of an inch whenever the cuttings will bear it without flagging, and very often it will be advisable to open the lid wide for an hour or two at six o'clock in the morning after it has been partially or wholly closed all night. But much of this matter of ventilating must be left to the judgment of the propagator. No two cases will require exactly the same treatment. Much depends on the form and character of the house itself, the position and proximity of the hot-water pipes and ventilators, &c., but a person with ordinary intelligence will soon be able to judge for himself. If the frame is an ordinary one outside on a hotbed a similar course must be pursued, only the lights will not require to be open wide as in the other case. Water should be supplied to the cuttings from the spout of a small watering pot when they require it, but in such a way as to avoid wetting the foliage, and on no account must the cuttings be syringed.

I will now briefly allude to another system of propagation which I have practised when circumstances have prevented the cuttings being inserted at the usual time. Prepare the old plants by taking off all partially decayed leaves and remains of leafstalks, &c. Insert the pots containing the plants to be operated upon inside of others one or two sizes larger. Fill the space between the pots with the coarser parts sifted out of the propagating soil, then place some of the soil recommended for cuttings under the branches of the old plant, slightly notch each branch and, if possible, peg it down on to the soil, then place some more of the soil around and over the stems sufficient to cover all the old portion securely, place the pots in a close frame for about four weeks, when the layers may be detached, potted singly, and treated as cuttings just struck. This is perhaps a safer system for beginners, and in most cases it may be advisable for inexperienced persons to retain some of the old plants for this system of propagation the first time they attempt to propagate these plants, to avoid losing their stock in case of a failure in striking, which sometimes happens with beginners; but a rule I consider cuttings by far the best, as they are ready before the shoots are long enough for layering, consequently they have a longer season to grow in and are also less trouble in other ways.

(To be continued.)

FACTS ABOUT GRAPES.

GROS COLMAN.

As far as appearance goes this is one of the noblest Grapes in cultivation, and it is almost needless to add it sells readily in consequence. It is also one of the best keepers, hanging or remaining plump when bottled longer than the Alicante, although it does not equal Lady Downe's in this respect. When well grown it is the finest black Grape, and the berries, besides being large, are firm and fleshy. Unfortunately, if eaten before March or April, the quality is very unpleasant, and not one in a thousand can honestly say they like the peculiar and what has been aptly termed Ivy-like flavour, which only long hanging seems to change. Mr. S. Castle of the West Lynn Vineyard usually succeeds remarkably well with the Gros Colman, and he first drew my attention to the fact that long keeping greatly improves its quality, the berries he kindly sent me last spring and also those we had at the time being much better than I had previously tasted. With us it thrives admirably at the shadiest end of a house of mixed varieties, no difficulty being experienced in securing plenty of bunches to select from, nor in effecting a good set. To do justice to it the rods ought to be fully 4 feet apart, and even this space scarcely admits of the proper development of the laterals. I hold that not less than three primary leaves, or those partially formed before the laterals are stopped, should be beyond each bunch, but it is useless to leave these if there is not room for them to grow out properly.

Plenty succeed with Gros Colman up to a certain point. The bunches may be large and the berries large and regular, but it is the finishing that tells the tale of wrong treatment somewhere. More often than not it is the premature loss of foliage that may safely be blamed for this failure. In other instances the foliage may be sound enough, and yet the berries remain nearer red than black in colour, this perhaps being the result either of overcropping or too much heat, or both together. I find that Gros Colman will not finish off properly nearly so many bunches, nor quite so great a weight of Grapes, as a Vine of Black Alicante of the same age and vigour. It is the weight that tries the Vines rather than the number of bunches, and when deciding how many bunches can safely be left on a rod the relative weights of each variety ought to be taken into consideration. Nor can any general rule as to the number of bunches each Vine should bear be laid down, so much depending upon the state of the border, the quantity of roots to be found near the surface, and the treatment given. With us Gros Colman retains its foliage admirably, but then ours is a renovated vinery with plenty of heavy wooden rafters and sashbars, this being very different to the modern structures, which have very much more glass surface exposed. Those houses constructed of iron and wood are very light and elegant in appearance, but they are the worst to manage. It is in these that red spider is most troublesome, the foliage also being more liable to burn. In such houses Gros Colman ought to be lightly shaded, this being accomplished either with the aid of doubled fish nets or by thin lime water lightly syringed over the roof as often as necessary. Gros Colman is one of the first to show colour in the berries; but when it is found the rest are much quicker in finishing, those in charge are apt to think something is wrong, and, speaking from experience, be tempted to put on more fire heat or give less air, as the case may be. No greater mistake can be made, as, if not hurried, being also kept well supplied with moisture and liquid manure at the roots, the colouring will go on all the while the foliage lasts, or say till November. The best bunches of Gros Colman I have yet seen were shown by Mr. Jennings, Farnborough Grange Gardens, at the last Reading Chrysanthemum Show. They were grand bunches and beautifully finished, and were not cut from overcropped or much-forced Vines.

LADY DOWNE'S.

If allowed to grow only one late black Grape this should be the variety. It is the very best for potting and keeping till new Grapes are available, added to which it is of good quality any time during the winter and spring months. As a rule the bunches are not large or showy, the majority ranging from 1 to 2 lbs. in weight, but the berries are of good size, very solid, crisp, and refreshing. A vigorous Vine is capable of perfecting a good bunch on nearly every uncrowded lateral, and if not given too much fire heat no difficulty will be experienced in properly finishing the crop. With us the berries are not large, but they are usually as black as they can well be. Unlike the Alicante, the best bunches are formed on the laterals from old wood rather than the young rods, and close pruning may safely be practised.

Others, beside myself, have doubtless found that the young rods rarely break evenly, many buds frequently refusing to move, others perhaps breaking weakly. It is those rods freely shortened at the winter pruning that are the most difficult to manage, these breaking strongly at the ends only. If a long straight rod is

desired, this can best be obtained by rapid extension. Planted in a good border a Vine ought to reach the end of a rafter 16 feet long in three seasons. Newly struck Vines usually make the best progress, and our plan is to stop these when about 6 feet long, no winter pruning being resorted to. The following summer they are stopped when the young cane is 7 feet long, and the third season finds them at the top of the house, the knife not having been used either season, with the exception, let me add, of the pruning necessary in the case of lateral growths. These summer-stopped unpruned rods invariably break evenly and well, especially if the points are well depressed or bent round prior to starting, and straight regularly furnished rods are the result. Those who leave an extra length of rod on young Vines must, however, remember that they are not yet capable of sustaining a bunch at nearly every lateral. A bunch on every third lateral is ample for at least four seasons, and if more are left the Vines may be seriously crippled for life.

There is one other serious defect in Lady Downe's that I ought to allude to—viz., its liability to scalding, more especially during the stoning process. The morning sun striking full on the cold berries is apt to damage all those most exposed. I cannot explain this matter in a scientific manner, but I can prevent it, and that, after all, is of the greatest consequence. It is at the ends of the houses where all varieties of Grapes are most liable to scalding, this being observable in the case of any exposed to either the morning or afternoon sunshine, oblique rays evidently being more powerful than those falling in a more vertical direction. Where scalding takes place it must be anticipated by temporarily shading both the roof and the ends of the vineries. When it is the morning sun that does the mischief, early ventilation must also be resorted to, and those houses with the ends facing westwards must not be closed till the sun has lost much of its power. Last season there were many complaints of serious scalding in the case of Muscats, Madresfield Court, and other Grapes, and nothing but judicious shading saved hundreds of bunches.

To our old friend, Mr. W. Taylor, Bath, belongs the credit of producing much the finest bunches of Lady Downe's I have yet seen, these taking first prize at Bath against any variety of black Grapes.—W. IGGULDEN.

DAFFODILS.

I AM watching the progress of some Daffodils which were sent me from Ireland about the middle of June last year. They had been lifted soon after flowering was well over, but before there was much decay of foliage. Some I placed in the border, some in the shrubbery, and though my garden soil is shallow and sandy, it has been cultivated and enriched with loam and well-decayed manure, and the clumps of bulbs have done well and are carrying abundance of buds. Only one sort has as yet perfectly expanded; a graceful flower; trumpet pale yellow, somewhat narrow in form, but boldly fringed; perianth white; divisions of perianth not very large, but graceful and star-shaped. Altogether these plants are very beautiful, and were greatly admired the other day, especially some I had planted in a sheltered place near some Box trees.

The heavy thunderstorms of Thursday (Primrose Day), and the copious but seasonable rains, sadly despoiled the golden robes of the ordinary Daffodils; no border plant looking more draggled and utterly suppressed than the once shining Daffodil gleaming in the sunshine, now literally extinguished in mire. I hope to tell you what the others are like shortly.—A. M. B., *Mid-Lincoln*.

AURICULAS.

THERE is nothing peculiar about the present Auricula season except that the flowering period is later than usual. They were held back up to the second week in April by continued cold weather. A change of wind set in about the end of the second week, and then a sudden change too took place in the appearance of the plants. They grew rapidly, and the trusses developed faster than I ever knew them to do. We have a collection in a cold frame, where they were merely protected with a mat on cold nights, and these are producing remarkably strong trusses and better developed pips than those grown in a house artificially heated. I fancy if we trusted entirely to growing our Auriculas in cold frames we should not have so much trouble to disestablish the Auricula aphis (*Trama Auriculæ*). This troublesome pest dislikes to be frozen in the pots.

The introduction of seedling Auriculas is a very slow process unless the variety happens to be free in producing offsets. This may or may not be the case. I have known a stock plant grow for six years and never produce an offset. In a case of this kind an inch or so may be cut from the base of the tap root and be planted

in a small pot of sandy soil, the cut portion to be left level with the surface soil. Buds will form, and ultimately plants will be produced from them. The plants may also be cut close to the surface when they have a long stem. Rootlets push out from the stem above the ground. Let the plants be cut close to the surface, and the top part will soon grow into as good or perhaps better specimen than it was before. It may be interesting to state that the first exhibition of the National Auricula Society (southern section) was held on the 24th April, 1877, at the Crystal Palace. Since that time forty-four first-class certificates have been awarded by the Society to show Auriculas, exclusive of the present year. They are as follows, and only those marked with an * have been sent out.

In 1877 no awards were made.

- 1878.—*Silvia (Douglas) grey edge.
 „ *Omega (Turner) white edge.
 1879.—Ringdove (Horner) self.
 „ Grey Friar (Llewelyn) grey edge.
 1880.—Cyclops (Horner) green edge.
 „ Orion (Horner) green edge.
 „ Thetis (Horner) grey edge.
 „ *Heroine (Horner) self.
 „ Rob Roy (Smith) exhibited by Mr. Dean, green.
 „ Rev. F. Tymons (Dean) green edge.
 „ *Conservative (Douglas) white edge.
 „ *Mrs. Dodwell (Simonite) white edge, sent out as Heatherbell.
 „ *Mrs. Douglas (Simonite) self.
 „ Lord Salisbury (Mellor) self.
 1881.—King of Greens (Barlow) green edge.
 „ *Mabel (Douglas) grey edge.
 „ Snowdrift (Horner) white edge.
 „ Erebus (—) self.
 1882.—Agamemnon (Horner) green edge.
 „ Luna (Horner) grey edge.
 „ Corona (Horner) self.
 „ Jumbo (Douglas) grey edge.
 „ *Mrs. Moore (Douglas) grey edge.
 „ *Duke of Albany (Douglas) self.
 „ George Rudd (Woodhead) grey edge.
 „ Mrs. Dodwell (Woodhead) white edge.
 „ *Brunette (Pohlman) self.
 1883.—Green Finch (Barlow) green edge.
 „ *Ajax (Horner) grey edge.

 1884.—Merlin (Horner) grey edge.
 „ Magpie (Horner) white edge.
 „ Mrs. Horner (Horner) self.
 1885.—*William Brockbank (Mellor) exhibited by Mr. Brockbank.
 1886.—No certificates awarded.
 1887.—Grayling (Horner) grey edge.
 „ Magpie (Horner) white edge.
 „ Amanda (Horner) white edge.
 „ Dulcie (Horner) self.
 „ Rubra (Horner) self.
 „ Edward Pohlman (Turner) green edge.
 „ James Douglas (Bolton) green edge.
 „ Samuel Barlow (Bolton) grey edge.
 „ Abbé Lizst (Douglas) green edge.
 „ Sir William Hewett (Douglas) self.

Having been frequently asked when this or that variety of the show Auriculas are to be sent out, the above list will supply the information sought. It also shows the work being done in raising seedling varieties, and gives some idea of the quality of the work, for it is not to be supposed that any of the above varieties would receive first-class certificates unless they had some qualities inherent to them not belonging to the older varieties. In fact, all the old Auriculas, with the exception of perhaps George Lightbody (Headley), Smiling Beauty (Heap), Lancashire Hero (Lancashire), and—but I cannot name another—must go out of cultivation in a few years. From the above list Horner's Greyhound is omitted. It has not yet received a certificate, but the year in which it was first exhibited it won premium as the best Auricula of any class. In the old-fashioned garden at Lowfields are numerous seedlings in all the classes as yet unknown to fame, but they will be brought into notice as soon as they have been proved equal to their first promise. Scores of good growers north and south are now raising seedlings, and the race is not always to the swift, nor the battle to the strong. The raisers of Smiling Beauty and Lancashire Hero were small growers, handloom weavers by trade, yet their names have long been cherished by Auricula growers and will not soon be forgotten. Considerable enthusiasm has been aroused in the south. New growers are being added every year, and we may hope that the

interest excited may be maintained, in order that these and other delightful old florists' flowers may not be lost to sight, and only be dear to us as memorials of the past.—JAS. DOUGLAS.

NOTES ON EARLY ENGLISH HORTICULTURE.

No. 1.

THE gardeners' pursuits and civilisation have gone in company over our world from its earliest recorded history until now, and the high culture of England at the present time has raised our horticulture to a position of importance beyond that it ever occupied before. We know that where savage life prevails gardens rarely exist; the ignorance, laziness, and brutality, as also the poverty, frequent amongst barbarous tribes, seem to forbid anything save agriculture of a rude kind, to which the men, or perhaps the women, are driven by necessity. Cultivation of flowers, fruit, and choice vegetables to please the palate, afford variety in diet, or gratify the fine sensibilities of the eye and nose, is not an employment likely to be followed by a degraded people. Even in a civilised land the art of gardening has its vicissitudes. Such has been the case with Britain. To take one instance, it is a fact that during the latter years of the reign of George III. horticulture made little progress, owing to the drain on the country's resources through long wars, and the great interruption to commerce which they caused. Recently I have been led to observe while in some metropolitan suburbs where much distress has prevailed, that many of the inhabitants are not showing their usual diligence in attending to their little gardens on the approach of spring. Some delay may have arisen from the ungenial weather, but there are those who have no heart for gardening because of the shadow of want which darkens their homes, and there is also a lack of means to purchase seeds or plants.

But leaving the present for the past, however, and not to dwell lengthily on antiquarian details, or recall the history of Adam and Eve, it is well, before writing about early English gardening, just to remind the reader that Egypt, the home of most primitive arts, was certainly the land where gardening was first extensively practised. The old Egyptians grew a variety of vegetables, and they had also gardens of herbs for flavouring purposes or medicine. They planted in avenues the Sycamore, Fig, or Mulberry, and other fruit trees; we have, moreover, evidence from their ancient monuments that they had for delectation gardens of flowers and shrubberies. Now the Phœnicians, the Sidonians probably also, who were great travellers in their day and had much to do with Egypt, visited England ages before the birth of Christ, but they do not appear to have imparted to our remote ancestors the art of gardening, or indeed any art. These early navigators came to this island simply as traders, and imparted no knowledge, as we may well suppose, to a wild people with whom they probably conversed by signs.

When Julius Cæsar landed in Britain he found on her shores a Celtic race which had attacked the original inhabitants, a dwarf race of Mongolian type, had conquered and killed many, driving the rest to the hills. These had no knowledge of plant cultivation, but they may have had flocks. Their successors, who fought so fiercely with the Roman legions, understood how to sow, tend, and gather in a crop of Wheat or other Grass. Nor were these ancestors of ours altogether as barbarous as the common representation makes them to have been. There were differences amongst them, and the tribes near the coast had made most progress. Old British barrows or burying places that have been explored show they possessed a variety of tools and weapons far superior to the primitive knives of flint. Capital knives, furnished even with sheaths, have been unearthed, made, not of iron usually, which was scarce, but of brass—*i.e.*, copper and tin mixed, resembling the brass of the Greeks. Here is one of the two earliest implements required for agriculture or gardening—*viz.*, an article by which plants could be cut. The other, a pick or spade of some primitive kind, the Britons had besides, we may be sure, though not now discoverable. They were acquainted with one means, at least, of improving a poor soil, for it is stated they used as manure on some fields of clay, a marl, either chalk, or chalk mixed with lime. But the corn was housed by them in places underground, without threshing it, and as long as it lasted they beat out of the ears day by day what they required. Rude fencing was placed about their crops to protect these from various enemies, and it is supposed they understood how to plant a quickset hedge, selecting shrubs prickly or thorny for this purpose.

Probably the Britons protected their orchards thus, for it is manifest that they planted Apple trees, from the various references to this fruit. The ancient name of Glastonbury is said to have been *Ynys Avella*, meaning an "Apple orchard." Whitaker thinks the Apple was first cultivated by the Hædri of Somersetshire, and

some suggest the Phœnicians introduced this tree from Greece. Not only did the Druids pay reverence to the Apple, but the old bards also esteemed the present of a branch of Apple blossom so fortunate an omen that it was their chosen reward for success in song. The fact was noticed that the parasitic Mistletoe grew on the Apple in preference to other trees, and as there was a special value attached to the plant when it was found upon the Oak, with the object of obtaining it there the Apples were set near Oak woods. They were ignorant of the method of producing Mistletoe plants by simply pressing the berries upon the bark of some suitable tree. The festival of this sacred shrub is reckoned to have been held about the 10th of March, the anniversary being kept as their New Year's Day also.

We have remarked that the Britons knew how to make hedges. Probably they often chose for this purpose the Yew and the Holly, the former on account of its dense growth, the latter because of its prickliness; both are indigenous species. The Yew was planted by them on spots where worship was performed, and the abundance of Yews in Wales, the last retreat of the ancient Britons, shows that it was regarded by them with reverence, or at least by their priests and bards. Probably the old name signifies "ever-living," and they used it as a symbol of immortality, even as the Greeks and Romans did the Cypress. And the tough wood of the Yew was found serviceable for weapons or implements. By some means the Britons acquired great faith in the medicinal qualities of Rue, and they grew this plant, having somehow obtained it from its habitat in the south of Europe. The Druids said it was only to be touched with the hand when young. When the greenish yellow flowers appeared it was to be carefully cut without grasping it. One virtue attributed by them to the Rue was a power to strengthen the sight, valuable therefore to the hunter or warrior. How they made use of it we cannot tell, but in later days people supposed that the Rue, or Herb of Grace, yielded its benefits to those who sniffed at the flowers and foliage. Heneæ has arisen a funny mistake, as some writers have called it a "nose-herb," meaning that its effects could be obtained through the nose. The supposition has been made that people made nosegays of it for the pleasure of smelling it, which would have been an odd fancy, as the odour is decidedly oppressive, almost disagreeable.

Of the Woad, a plant the Britons largely employed as a dye, they may have found an abundance growing wild, though in our day it is scarce. They understood how to obtain three distinct colours from this plant; and it is probable they sought in the spring, all round the southern coast, the wild Seakale (*Crambe maritima*), though they did not cultivate it, cutting off the young stalks close to the crown of the root, just as people do now.—J. R. S. C.

RIVINA HUMILIS.

THE clusters of rich scarlet berries which this greenhouse perennial produce so freely during the winter months render it a very useful and effective plant for furnishing purposes. It is of very easy culture. Seeds sown now in the ordinary way and placed in heat will soon germinate. Prick the seedlings out about 2 inches apart in a pan filled with light sandy soil, return them to heat, water and shade from sunshine until the roots have taken to the soil. Subsequently place the plants into 3-inch, and again in 4½-inch pots as soon as they require more room at the roots. Stopping the plants a few times to make them branch, and giving water at the roots when necessary, growing them on in a frame during the summer.—H. W.

FERTILISATION OF EARLY PEACHES.

YOUR correspondent, Mr. J. B. Riding, seems to question the good results of the practice which it is my duty to see carried out under the direction of the head gardener with whom I serve, and who tells me he has practised it for a number of years in different localities, and never yet failed to secure a good set of fruit. I had never before seen such simple means used in early houses, and was rather surprised on being told the course to be pursued. Now I can safely say, were I acting upon my own responsibility and having suitable structures with trees in good health (which is, without doubt, very essential to perfect fertilisation, whatever be the means applied), I should not hesitate in adopting the same treatment. It is, I believe, a recognised fact that small-flowered varieties usually set their fruit much more freely than large-flowered ones. It so happens that out of the seven trees in our early house five are large-flowered, and they set quite as freely as the others. The trees are in good condition, producing abundance of strong well-developed flowers, which made the house quite a sight at the time. The houses are constructed in accordance with the usual style of fruit houses—viz., lean-to's facing south, and stand in a light open position. We very rarely fail to have the temperature at 50° on a morning with a little ventilation at the front ventilators, difficult as it may appear to your correspondent, without having recourse to excessive firing.

With the head gardener's permission I have sent a shoot cut from one of the trees in a later house for the Editor's inspection, on which the fruit is set, but not thinned. This is, of course, no criterion as regards the early trees, still the same means are adopted for fertilising. I am thoroughly convinced that it is quite possible to get a first class set of fruit without resorting to such tedious operations as many do. Could Mr. Riding see the trees, I think he would also be convinced.—S. T. C.

[The example is highly satisfactory, out of twenty blossoms the setting of only two being doubtful.]

ORCHIDS AT MOUNT VIEW.

IN the *Odontoglossum* house at Mount View, Sheffield, the residence of D. Ward, Esq., J.P., there are not less than 150 strong spikes of *O. Alexandræ* and its varieties in a forward stage of development. One now flowering for the first time, and which had been imported and sold as *O. Alexandræ* of the ordinary type, is a beautiful and very distinct hybrid, apparently between that and *O. triumphans* or *luteo-purpureum*. In this house several plants of the small but pretty *O. Cærstedii* in 4-inch pans are covered with flowers, having about fifty on each plant, three from each pseudo-bulb, and in some cases two on one spike. About twenty plants of *Sophranitis grandiflora* in small pots are very bright and densely flowered. In a warmer house are fifty vigorous and strong plants of *O. vexillarium* throwing abundant flower spikes. On one plant in a 6-inch pot we counted nine spikes. Some plants of *Oncidium Marshallianum* in baskets were very showy in the same house with large branching spikes of about thirty flowers each.

In another large stove is a very beautiful display of flowers of *Cattleya citrina*, *C. intermedia amethystina*, a fine variety; *Dendrobium Wardianum*, a grand display from closely pruned plants, eighty flowers on a plant; *D. albo-sanguineum*, several plants flowering freely. In this house also are large numbers of plants of *Cattleya Mossiæ*, *C. Mendelli*, *C. gigas*, and *C. Skinneri*, with *Lælia purpurata*, all in vigorous health and throwing quite a forest of sheaths. In another cool house some twenty or more plants of *Oncidium concolor* are gay with abundant flowers, as also in still another warmer house are *Dendrobiums thyrsoflorum*, *Schröderi*, and *chrysotoxum*, with the singular and pretty *Utricularia montana* in baskets.

ODONTOGLOSSUM ROEZLI.

Such a display of this fine Orchid as is rarely seen is now provided in the *Phalenopsis* house at Mount View, Sheffield, the residence of D. Ward, Esq., J.P. The plants, which number thirty, are all in the most robust health and vigour, and are covered with numerous strong spikes of their large and beautiful flowers, amongst which there is considerable variation in form, colouring, and in size. Some varieties have more or less large and brightly coloured purple blotches at the base of each petal, whilst others are almost pure white throughout, except a light orange shading over the centre of the lip. We measured a flower of one of these latter varieties, and found it to be 4 inches in diameter and 2 inches across the lip. On the same plant the leaves measured 18 inches in length and 1¼ inch in breadth, the pseudo-bulb from which these leaves sprang being 3¼ inches in length, and carrying four flower spikes each with four flowers, this growth also being typical of those throughout the whole collection. A plant in a 6-inch pot was carrying eight flower spikes, and scarcely a spot or blemish is to be seen upon the foliage of any plant. We noticed also that new breaks were forming two, and in some cases three, from each flowering growth. Mr. Page (the head gardener) is one of the most skilful Orchid cultivators, as the large collection at Mount View by the vigour and fine condition of the plants abundantly testifies, but in nothing is his skill more strikingly exemplified than in his culture of *O. Roezli*, which he grows the year round in the *Phalenopsis* house.—W. K. W.

ORCHIDS AT BURFORD LODGE.

UNDER the management of Mr. W. Biekerstaffe, with an efficient staff of assistants, the Orchids in the collection of Sir Trevor Lawrence, Bart., M.P., still maintain their high character as one of the leading collections in this country. Order and cleanliness are at all times observable in the houses; in fact it would seem almost impossible to make improvement in that respect in any part of this well-kept garden. The floors, stages, pots and plants are all a

clean as constant washing will allow, but nevertheless some insects are so tenacious of life that even this will not eradicate them, although it keeps them in check. The little yellow thrips have perhaps caused more plants to go wrong where Orchids are grown than any other insect, and even here they are the source of much anxiety, as, for instance, a noble plant of *Lissochilus giganteus* is so subject to their attacks that it has only been by great perseverance that the present results have been obtained. The general appearance of the plant somewhat resembles a *Phaius*, and it has sent up a flower spike 8 feet in height, bearing fourteen fully expanded large blooms of a beautiful pale rose colour with as many more buds to open. Near to this in the large house are other rarities in bloom, including the lovely bright yellow *Spathoglottis Kimballiana*, which was certificated at the meeting of the Royal Horticultural Society on March 27th. It lasts a long time in perfection. *S. plicata* is also in bloom, and *Pescatorea Klabochiana*, *Acanthephippium bicolor*, *Catasetum Gnomus*, and *Phaius Blumei*.

The most useful appliance that has come under my notice for the destruction of thrips is Bloxham's fumigator. It is simple, and can be used without injuring any Orchid. By laying a plant on its side the smoke can be driven into the heart of the plant or any hiding place, and as the smoke passes through two perforated plates and a funnel it is quite cool before coming in contact with the foliage or flowers. An invention like this ought to be well advertised.

The specimen *Cypripediums* are very healthy, and those not flowering are growing freely. The rare *C. Stonei platytænium* is represented by a plant having several fine growths. In the Vanda house a group of *Phaius tuberculosa* occupy a shady and moist corner where they seem to thrive; they are growing on rafts placed in pots with a little peat and sphagnum. The curious *Trichoglottis fasciata* is flowering, and many plants of *Utricularia montana* in baskets are doing remarkably in a moist recess of this house.

*Epidendrum*s are well cared for, and although some are curious only, others like *E. Wallisi* possess great beauty, and *E. glumaceum* is fragrant like Violets. *Oncidium bifolium majus* grown in baskets is well flowered, and it is as beautiful as it is rare. *Habenaria militaris*, certificated last year and figured in the Journal, is represented by several plants. *Maxillaria Turneri* is bearing scores of rich cinnamon brown and crimson fragrant flowers. The *Masdevallia* house is very bright just now. *M. Harryana* in great variety makes a good show, also *M. Veitchi*, one named *gigantea* being of great size and superbly coloured. There are many choice seedlings of *Dendrobium*s and *Cypripedium*s; some have bloomed, and the others are being watched with interest.

The pleasure grounds, kitchen garden, fruit and plant houses at any time repay inspection. The *Anthurium*s are grand; many seedlings of various parentage and well-known species are producing hundreds of bright showy spathes. In a stove *Begonia*s of the *nitida* section, large plants of *Impatiens Hawkeri* and *I. alba*, with the violet-scented *Tinnæa æthiopica* and *Glonera jasminiflora* are among the flowering plants. *Asparagus decumbens* and wonderful strong plants of *Lapageria alba* and *L. rosea* are trained to the roof of the greenhouse. Mr. W. Bain, who has presided over this department so long, is well known as deserving great praise.

Annexed is a list of some of the Orchids recently noted in flower or expanding:—*Acanthephippium bicolor*, *Ansellia congoensis*, *Arpophyllum giganteum*, *Brassia Perrini*, *Calanthe nivalis*, *Camarotis purpurea*; *Cattleyas citrina*, *Lawrenceana*, *maxima*, *Mossiæ delicata*, *Schröderæ*, and *speciosissima*; *Catasetum Gnomus*; *Cypripediums Argus*, *Boxalli*, *Bullenianum*, *callosum*, *caudatum*, *ciliolæ*, *concolor*, *Dayanum*, *Druryi*, *grande*, *Harrisianum superbum*, *hirsutissimum*, *Lawrenceanum*, *leucorrhodum*, *Measuresianum*, *niveum*, *selligerum*, *Swanianum superbum*, *vernixium*, *vexillarium*, *Warneri*, and *Williamsianum*; and *Cymbidium Lowianum*.

*Dendrobium*s *aggregatum*, *barbatulum*, *chrysotoxum*, *crassinode superbum*, *Dalhousieanum*, *Devonianum*, *Falconeri giganteum*, *fimbriatum oculatum*, *Findleyanum*, *infundibulum*, *Jamesianum*, *Jenkinsii*, *lituiflorum*, *luteolum*, *macrophyllum*, *pulchellum*, *superbiens*, *Smillie*, *thyrsiflorum*, and *undulatum*; *Epidendrum*s *cinnabarinum*, *crassifolium*, *cnemidrophorum*, *glumaceum*, *nocturnum*, *Schomburgkii alba*, *Stamfordianum*, *Wallisii*, and *xanthina*; *Lælia cinnabarina* and *harpophylla*; *Leptotes bicolor*, *Lissochilus giganteus*, and *Lycaste flavescens*.

Masdevallias bella, *Chimæra*, *Chelsoni*, *Chestertoni*, *Harryana*, *igneæ*, *igneæ aurantiaca*, *igneæ Massangeana*, *Lindeni*, *ludibunda*, *pulvinaria*, *racemosa Crossi*, *radiosa*, *rosea*, *Shuttleworthii*, *Veitchiana*, *Wagneri*, and *xanthina*; *Maxillarias Harrisonii* and *Turneri*; *Odontoglossums Alexandræ*, *Cervantesii*, *Cervantesii decorum*, *cirrhosum*, *Edwardi*, *Harryanum*, *miniatum*, *nebulosum pardinum*, *Pescatorei*, *Phalænopsis pulchellum*, *Roezlii*, *Rossi majus*, *sceptrum*, *tentaculatum*, and *vexillarium triumphans*; *Oncidium*s *ampliatum*, *bifolium*, *concolor*, *incurvum*, *leucochilum*, *longifolium*,

macranthum, and *Marshallianum*; *Paphinia grandis*, *Pescatorea Klabochiana*, *Pholidota chinensis*, *Phaius Blumei* and *Wallichii*, *Phalænopsis amabilis*, *Pleione humilis*, *Pleurothallis ornata*, *Restrepia elegans*, *Schomburgkia crispa* and *tibicinis*, *Scuticaria Hadweni*, *Sophronitis grandiflora*, *Spathoglottis Kimballiana* and *plicata*, *Trichoglottis fasciata*, *Trichopilia lepida* and *suavis alba*; and *Vanda suavis*.—G. W. CUMMINS.

PLANTING HARDY PERENNIALS.

(Continued from page 322.)

WEATHER more suitable and seasonable for the above work could not possibly be selected than the present, therefore no time should be lost in procuring plants or dividing existing ones, or, in fact, performing any necessary work among hardy border plants.

Gentiana Andrewsii.—Taking into consideration that this species never expands the flower buds, this is one of the most showy of the group, and certainly one of the best of the herbaceous section. The flowers are produced in terminal and axillary clusters, and are of an intense indigo blue; it grows from 1½ to 2 feet high, delighting in deep rich loam in partial shade.

Gentiana asclepiadea.—An early autumn flowering species, coming into blossom with the Meadow Saffrons or Colchicum, and *Crocus speciosus*. It is 2 feet high, with somewhat slender stems and purple blue flowers. It is a good plant, and the white variety should always bear it company. Both are suited to moist partially shaded positions.

Gentiana acaulis and *verna*.—Both are beautiful among early spring plants, which nearly everyone may succeed with. The first named stands out alone for grandeur of blossom and colour combined, and no other of its tribe can in any way compare with this for effect when seen *en masse*. In the lovely Vernal *Gentian* and its varieties we find a charm peculiarly their own. Both succeed admirably in rich loamy soil, and should not be disturbed unnecessarily.

Geranium armenum.—A handsome perennial, 2 feet high, flowers purplish crimson in great profusion, a plant of sterling merit. *G. Endressii* has rosy pink blossoms, very pleasing and beautiful, grows 1 foot high. *G. ibericum* has bluish mauve flowers of considerable size, and attains 2½ feet high. Each of these produces flowers in great numbers, and continues in flower over a somewhat lengthened period.

Geum coccineum plenum.—The double scarlet *Geum* is a deservedly popular plant of pleasing habit. It may be classed as one of the best perennials in cultivation; it is excellent for grouping, and may be bedded with very good effect. The flowers are brilliant scarlet, double, and borne in great profusion from early in summer onward. This should be in all collections, for in many respects it is without a rival. It will grow in any ordinary soil.

Geum montanum.—This has golden yellow blossoms, and grows about 1 foot high, and is among the showiest of spring flowers.

Gypsophila paniculata.—Where something out of the ordinary is required for mingling with cut flowers the sprays of this unique plant are of great value. Its blossoms are whitish and individually small, hence its elegance when arranged in vases. It yields an abundant supply of much-branched flower stems, and is specially fitted for any floral arrangement. The plant is of bushy habit, growing nearly 2 feet high.

Helium pumilum.—A neat attractive plant, from 1½ to 2 feet high, covered with golden flowers, very useful for cutting.

Helium autumnale.—A much superior plant to the last, attaining 2½ feet to 3 feet high. The flowers are a beautiful soft canary, which so many admire. It flowers with great freedom from the middle of July for weeks in succession. An indispensable plant, either for the border or for cutting.

Heimerocallis (Day Lily).—This group may conveniently be divided into two sections, the species with narrow leaves and dwarf habit, and those of taller growth with broader bolder leaves. Another distinctive mark is that those contained in the last section produce flowers which last but one day, while those in the first group invariably continue for two days and then perish. In both cases the flowers are produced in great profusion, consequently those not aware of their characteristics would fail to note this, for they develop flowers almost daily in bright weather. Among the best are *flava*, *Thunbergi*, and *graminea*, each having golden trumpet-shaped flowers, those of the first being fragrant, and thus is also adapted for pot work. These belong to the dwarf narrow-leaved forms. Of the remainder *Kwanso fl.-pl.*, and *disticha fl.-pl.*, may be taken as the best, with flowers of a bronzy orange and bronzy yellow. The Day Lilies prefer a good loamy soil to make a good show in summer time.

Hepaticas.—These modest spring plants are not so fine this year as usual; they severely felt easterly winds recently, which played havoc with these Violets and many more which were not covered with snow, therefore they are lacking in their usual brightness; but in the full hope of a better future select a more sheltered spot, and plant at once to have them established ere the summer drought arrives. The singles provide the best display, and may be had in three decided colours of white, pink, and blue.

Hesperis matronalis alba plena (Double White Rocket).—An old fashioned perennial still popular. It is an easily cultivated plant growing 2 feet high, and producing massive branching spikes of white flowers. A good companion is the Double Purple. When well grown in rich garden soil both are very effective among early summer perennials.

Hollyhocks.—The grandeur of these is well known, and the fact.

that they are regaining their original popularity is welcome news. To insure success with these secure strong vigorous plants from the open ground, and free from disease, carefully avoiding those that are crippled in pots, and which have been coddled in heated structures. The strains of these flowers are so generally good that many of the seedlings are quite equal to the named varieties, and for border decoration.

Iberis corifolia (Perennial Candytuft).—A plant of shrubby habit, dwarf and bushy, covered in May and June with white flowers. Very attractive for rockery or border.

Iris germanica.—The genus *Iris* contributes a wealth of beauty both as regards diversity of colour, form, and time of flowering that cannot be equalled among perennials. In the group above named we have many superb plants, in colours varying from pure white and white suffused with the most delicate tint of satiny blue, to primrose yellow chrome, lavender, mauve, purple, dark blue, lilac, white with violet pencilling, and a host of other intermediate shades which almost defy description. All are perfectly hardy and robust, and delight in any fairly good soil, many being especially suited for towns and smoky districts; they flower in May, June, and July. Those who have never seen a choice collection can form but little idea of their great beauty, and should make a point of visiting some of the nurseries where these are grown extensively, and judge for themselves. Either in the border or for cutting they are most useful. If cut when the first flower expands and placed in water every blossom upon the spike will perfect itself, which is much in their favour, especially when this occupies some eight or ten days from the first bloom to the last. It is interesting to watch them develop and note the varying shades of their flowers.

Inula glandulosa.—I consider this all that could be desired in habit, vigour, and free flowering qualities. It is a true herbaceous perennial, flowering in midsummer. The leaves are ovate-lanceolate, thickly set with short hairs, and form a compact tuft close upon the ground. The flowers are pure gold, and are composed of numerous thread-like florets, which give the plant an extremely pleasing appearance. To give the reader a clearer idea of its beauty and grace, I cannot do better than compare its flowers to a single *Chrysanthemum* variety with blooms about 4 inches across. No collection of hardy plants can be complete without this. It prefers a strong loamy soil, and was introduced from the Caucasian and Georgian Alps in the early part of this century.

Lathyrus latifolius and *albus* (Everlasting Pea).—These are among our oldest acquaintances, forming huge bushes in country gardens where they have stood for years, annually to be covered with flowers which are very serviceable for cutting purposes. The pure white variety is especially serviceable for this purpose, and is a by no means common plant. Usually it is seen supported by a few rough stakes or tied to a trellis, while it is perhaps most effectively planted on the large rockery and allowed to trail at will. Thus placed and overhanging a huge boulder it produces an effect almost unique, and gives it a more natural appearance.

Liliums.—It is my intention at this time only to advance a word or two of caution respecting these. It is not a time to be planting them; this should be done in early autumn, and those who plant Lilies now, unless they are established in pots, will hardly expect them to do much good. Protect Lilies from spring frosts. All the forms of *L. speciosum*, *longiflorum*, and others are now several inches through the ground, and frosts will do them much harm unless they are protected in some way. This is easily accomplished when planted in clumps by placing a few boughs round them, or if in a bed a light awning or net will give them the required protection if placed on each evening.

Liatris.—A singularly interesting group of herbaceous perennials from North America. The several species are all of compact habit, and produce erect stiff spikes of rosy purple, purple, or pale purple flowers during summer and autumn. Any light loamy soil will grow them perfectly, and it may be remarked that they were apparently unaffected by the great drought of the past three summers. Bees are very fond of their flowers. All are perfectly hardy. Another peculiarity is they commence flowering from the top of the spike and continue flowering downwards. In most plants the reverse is the rule. *L. elegans*, *pycnostachya*, and *odoratissima* are perhaps the best of this family. — J. H. E.

(To be continued.)

CYCLAMENS AT RIPON.

THE best grown Cyclamens that I have seen of late years are grown by Mr. Wilson in Dr. Fremantle's garden, The Deanery, Ripon. Some are grown in 6-inch pots and others in 4-inch pots, the number and size of the blooms and corms being remarkable. I counted as many as 100 blooms on a plant in a 6-inch pot, and of a size and substance not often seen, at least in this neighbourhood. I think his practice differs somewhat from that adopted by most people, for after flowering he cuts off all the old foliage, gives them a fortnight's rest, then shakes out the plants and repots them. They are placed in a Melon or other pit where there is a good bottom heat until well rooted, and are then transferred to a shelf in a cool vinery near the glass, where they remain until they again come into flower.

The compost employed is one part each of loam, peat, leaf soil, and well decomposed cow manure, well mixed, and the plants are potted firmly. The result is a credit to the cultivator, plenty of the flowers are from 1½ to 2 inches in depth, and with stout stems.—K., *Bishopston*.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Rev. W. Wilks, Secretary, in the chair, 106 candidates were duly elected Fellows of the Society.

— IN answer to many inquiries from home and foreign correspondents, we have pleasure in announcing that Dr. HOGG has practically recovered from his indisposition while in Ghent.

— IN connection with the INTERNATIONAL EXHIBITION AT BRUSSELS, which will be opened in May this year, and continue until October, a series of horticultural shows will be held, of which a comprehensive schedule has just been issued. From May 5th to October 31st there will be a permanent exhibition of trees, shrubs, and flower garden plants in the grounds. On July 1st and 2nd an exhibition of cut Roses will take place; but the principal exhibition will be that fixed for August, 19th to 23rd, when 134 classes are provided with nearly 270 gold, silver-gilt, and silver medals as prizes. Sections will be devoted to new plants, Ferns, Cycads, Palms, Aroids, Bromeliads, Orchids, and numerous other plants; there are also sections for bouquets and floral decorations and fruit. An exhibition of fruit, vegetables and Dahlias will be held on September 30th and October 1st, and in addition from August 11th to 23rd there will be an international agricultural Exhibition.

— ANOTHER of the older British horticulturists has joined the majority—namely, MR. THOMAS CRIPPS, who died on the 17th inst. in his seventy-ninth year. Mr. Cripps founded the firm of Cripps & Son, Tunbridge Wells, more than half a century ago, and steadily developed a large business, the nursery having been noted chiefly in recent years for Clematises, shrubs, and trees. The first Fuchsia with white sepals—*Venus viatrix*—was sent out from this nursery in 1842 at a guinea per plant. It was purchased from the raiser, Mr. Gulliver, gardener to the Rev. S. Marriott, Horsmonden, Kent, and was believed to have been obtained from *Fuchsia gracilis*, which it resembled in foliage. The variety is still included in some nurserymen's lists, but is rarely seen in gardens, though very distinct.

— THE WEATHER.—“B. D.,” writing from Scotland, says:—“The first half of the week ending 23rd inst. was very showery, with a high temperature and little sunshine. On the 19th, after midday, a sharp thunderstorm occurred in South Perthshire. A fall of the thermometer immediately followed, and with a return of piercing N. and N.E. winds, the weather has since been bitterly cold.” In the south the weather has been very dull, with frequent heavy rain—a very unpleasant change from the previous week.

— REFERRING TO WRITING ON AND CLEANSING ZINC LABELS, a correspondent, “F. C. S.,” remarks:—“Chloroplatinic acid is good, but it is not always easy to obtain platinum. Copper salts (*e.g.*, the sulphate) do well if the label be previously washed in a dilute solution of acid, as by this means a chemically clean surface is obtained. I use a solution of about one part of hydrochloric acid to ten of water. I write this to suggest the advantage gained by cleaning the label, which should subsequently be washed in water.”

— IN a shady part of the Vanda house at Burford Lodge there is a very fine specimen of the LATTICE-LEAF PLANT (*OUVIRANDRA FENESTRALIS*). It is grown in a tub filled with clear water, and an occasional drip at regular intervals from a vessel above is sufficient to keep the water disturbed, which seems quite necessary to grow this interesting plant. Some of the leaves measure 15 inches in length without the stalk, and in width 5½ inches. Many seedlings are springing up.

— GLAZED FLOWER POTS.—We have received from the Cumnoek Pottery Company, Cumnoek, N.B., samples of the glazed flower pots prepared by them, and which were highly commended by our correspondent “Dun. Spiro Spero” on page 27 (January 12th) this year. They are thoroughly well made, of various sizes, the outer

surface only covered with a soft brownish glaze, that has a much more agreeable appearance than the ordinary red earthenware pots. The base of the pot is also slightly raised above the outside rim, so that there is no danger of the drainage being impeded. We have seen many excellent results obtained by cultivating plants in glazed pots, and Mr. David Thomson of Drumlanrig uses them almost exclusively now. The prices of the Cumnock pots can be ascertained from an advertisement on another page, and we have no hesitation in commending these productions to the notice of amateurs and gardeners.

— "K., *Bishopston*," writes—"I saw an article in the Journal some time since recommending *CROSSING VALLOTA PURPUREA* WITH *EUPHARIS AMAZONICA*, making the former the seed-bearing parent. I have done this and have some seedlings, but the only difference I can see at present is that some are much paler in the bulb and leaf than others, but as they become stronger they all have the characteristics of the Vallotas. Whether when they flower they will prove distinct remains to be seen. The first seed was sown in February, 1887."

— A BIRD SCARER.—"F. J." wishes to know if any of our readers have tried "*CLIVE'S BIRD OF PREY*," advertised in this Journal, and, if so, would they state the results?

— "G. W. C." sends the two following notes:—"The ornamental Fern house at Highbury, near Birmingham, is an interesting house, with Ferns, Palms, and Mosses growing well on and among the rockwork. In one corner is the new *ANTHURIUM CHAMBERLAINI*, with its roots clinging to the stones. It is one of the most handsome in the genus, bearing large leaves on stalks about 4 feet long, and the spathes are boat-shape, 8 or 9 inches long, 4 inches in width, and of the deepest crimson colour. This plant appeared with an importation of *Cattleya Gaskelliana*."

— "In the conservatory attached to the mansion at Highbury is a specimen of the *ABYSSINIAN BANANA*, *MUSA ENSETE*, the stem of which measures 6 feet 2 inches in circumference at 6 inches from the ground; it is fully 30 feet high, and the leaves 18 feet long. A large *Chamærops Fortunei*, *Phoenix reclinata*, and *Camellias* planted out fill the centre of the house. On the front stage well grown spring flowering plants are arranged, including most of the choice named *Clivias* or *Imantophyllums*. Mr. Chamberlain likes to see large masses of colour arranged separately, and there are large banks of *Tulips* here and groups of *Cinerarias* in another part of the house."

— UNDER the title of *THE ART OF PREPARING VEGETABLES FOR TABLE*, Messrs. Sutton & Sons, Reading, have produced a useful little book of sixty-eight pages, which has just been published by Hamilton & Adams, Paternoster Row. Fifty-two vegetables are referred to briefly, and concise instructions are given on the best modes of cooking and preparing them for table.

— MR. J. E. JEFFERIES, Oxford, sends us a photograph of a *POTATO MONSTROSITY*, the tuber represented having a peculiar palmate or five-lobed form. He also states that he has another with a link of an iron chain apparently passing through the tuber.

— *LIFTING AND REPLANTING OF VINES*.—"W. K. W." writes—"As an example of how little they are injured by this process if carefully and judiciously carried out we were a day or two since shown a house of *Black Hamburgs* which were lifted in September last and replanted in fresh compost, and which Vines are now in much more vigorous health and condition than they were previous to being lifted. They are also carrying a heavy crop of large bunches of *Grapes*, which are now (April 19th) just being thinned, showing that the Vines were not allowed a lengthened period of rest but were started early. The foliage also is plentiful and fine, the larger leaves being nearly 12 inches in diameter, almost a black green in colour, very stout and leathery. This house of *Grapes* is at Mount View, Sheffield, the residence of D. Ward, Esq., J.P., gardener Mr. Page."

— MESSRS. JAMES DICKSON & SONS, Chester, send us a box of blooms of *NARCISSUS SIR WATKIN*, a variety which, they say, is very grand with them this season. The flowers are very fine indeed.

— THE usual fortnightly meeting of the *WALKLEY (SHEFFIELD) AMATEUR FLORAL AND HORTICULTURAL SOCIETY* was held on Friday evening last at the Society's rooms (the Howard Hotel, Walkley), when an excellent paper was read by Mr. R. H. Laughton, Vice-President,

entitled "A Night with Canon Hole," and consisting of well-chosen extracts from that popular rosarian's "Book about Roses," interspersed with useful remarks and pleasing witticisms by the essayist, who on this occasion appeared to great advantage both as a writer and as a reader, and received much well-merited applause. A useful discussion followed, after which the usual thanks to the essayist was carried with acclamation. There was a large attendance of members, and the tables were well filled by a very fine display of flowering plants, Ferns, and cut flowers, comprising a very good specimen *Azalea* (*Princess Louise*) and cut *Roses* from Mr. F. Barnes, good *Azaleas* and a fine large specimen *Calla* from Mr. Cuckson, beautiful stands of *Tea Roses* and *Pelargonium* flowers from Duncan Gilmour, jun., Esq., and a fine collection of *Cinerarias* from Mr. Woodcock.

— *STATICE HOLFORDI*.—"This blue-flowered greenhouse perennial," says "H. W. W.," "is of easy culture. Cuttings of the young growths are taken from the base of the plant and inserted in 3-inch pots filled with a mixture of three parts loam and one of leaf mould, with a surfacing of silver sand. The pots are plunged in a gentle bottom heat, water to settle the soil about the base of the cutting, and keep them close until rooted. After this they should be grown in a more airy atmosphere near the glass, and be shifted into larger pots as they require more room for root-action, supplying the plants with moisture at the roots, and damp the foliage on bright afternoons to keep them free from the attacks of aphides and red spider."

— A CORRESPONDENT who desires information on *PRESERVING TURF* writes:—"I am compelled to remove about a quarter of an acre of turf which has been cut over three months. I wish to preserve it till November next, before I can lay the ground out owing to an extensive drainage scheme being carried out. Would any of your numerous readers give me their experience of how it would be best to keep it till then? If so, they would greatly oblige."

— *THE IRISH EXHIBITION IN LONDON*.—We are requested to publish the following:—"In addition to the already remarkable list of persons prominent in politics, religion, law, literature, and society, who have given their active support to this peaceful effort to benefit the sister kingdom, are the following—The Earl of Leitrim, who has joined the Executive Council, the Earl of Aberdeen, the Lord Mayor of Dublin, the Earl of Dufferin, the Lord Chancellor of Ireland, and Sir Algernon Borthwick, Bart., M.P. Many of the corporations in Ireland, including Dublin, Belfast, and Waterford, have officially taken up the subject and have strongly urged upon the trading community in their respective districts their conviction that Irish industries are likely to be substantially benefited by a comprehensive display in London of what Ireland's markets and manufactories can produce. A most significant fact, tending to show that one of the primary objects of the promoters is likely to be fully realised, occurred at the Mansion House in Dublin, at a meeting over which the Lord Mayor, Mr. Sexton, M.P., presided. Mr. Sexton said 'he believed the Exhibition would be a great success, and would promote what he was happy to call the daily improvement in the relations of the Irish people and their neighbours beyond the sea,' and he proposed the formation of a Committee to further the objects of the Exhibition. Several prominent men have offered considerable contributions towards the scheme, in the belief that no better means could be devised for advancing the best interests of Ireland. The date fixed for the opening at Olympia, Kensington, is the 4th of June, and the Exhibition, which covers 12 acres of ground, will remain open till the 27th of October." Lord Arthur Hill, M.P., is the Honorary Secretary.

— WE are informed that the *BARTON-ON-HUMBER AND DISTRICT CHRYSANTHEMUM SOCIETY'S SHOW* will be held on November 14th this year. Schedules may be had from the Hon. Sec., Mr. C. J. H. Crowder, Barton-on-Humber.

— "*SMALL plants of the half-hardy perennial shrub, VERONICA ANDERSONI VARIEGATA*," writes a correspondent, "are very useful, either as an edging to large beds of herbaceous or other plants, or as grown in 3-inch and 4½-inch pots for standing on the side stages of greenhouses and conservatories. It is readily propagated from cuttings of the young wood being placed in 4½-inch pots filled with sandy soil, watered, and placed in heat, afterwards potting them off singly in small pots and attending to them in the way of stopping and giving water at the roots when needful."

— "J. W. C." sends the following paragraph—"I wish to draw your attention to three good things for the garden—namely, GLAZED POTS, ANTHRACITE COAL, AND LETHORION CONES. My arguments in favour of glazed pots are—cleanliness, saving in labour in watering and scrubbing. Softwooded plants grow remarkably well in them with care after potting. The coal is the best, cleanest, and I think the cheapest I have used. The cones are good for small greenhouses, and especially suited for Orchids. We could not banish the yellow fly until we used the cones rather stronger than recommended, but they are rather expensive if used on a large scale."

ROYAL HORTICULTURAL SOCIETY.

APRIL 24TH.

THE combination of the National Auricula Show with the exhibits before the Fruit and Floral Committees of the Royal Horticultural Society produced the most extensive display yet held in the Drill Hall at Westminster. Four tables nearly the whole length of the hall, besides several at the ends, were crowded with plants, and the numerous persons who visited the hall during the afternoon were amply satisfied with the exhibition. The tables near the walls were devoted to the Daffodils. At the upper end of the hall were groups of fine Roses, the two central tables being occupied with Auriculas, Primulas, Amaryllises, double Cinerarias, Mignonette, Orchids, and Roses, the last-named having a fine appearance down the centre of the tables. Novelties were numerous, and fourteen were found worthy of certificates.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair, and Messrs. J. Wright, G. Norman, J. Cheal, John Lee, T. Saltmarsh, Philip Crowley, R. D. Blackmore, W. Marshall, Sidney Ford, T. F. Rivers, and W. Warren. At the commencement of the proceedings Mr. Veitch, in appropriate terms, referred to the great loss the Committee had sustained by the lamented death of Mr. J. Woodbridge, and proposed that an expression of condolence should be conveyed by the Committee, of which he was an effective member, to his widow in her great bereavement—a suggestion that was unanimously adopted.

E. E. Evans, Esq., Brinscombe Court, Strood, Gloucestershire, sent an Apple named Beauty of Brinscombe, a late-keeping variety, in use from February till June. It was supposed to have been raised by the father of the exhibitor, but the Committee thought it too closely resembled Besspool to be regarded as distinct. A seedling culinary Apple that had been previously before the Committee was sent by Mr. Neill, The Gardens, Wytheushawe, Northenden, near Manchester, a good looking conical Apple, but every fruit partially decayed in the centre; it was consequently passed by the Committee. Mr. J. C. Mundell sent a sample of the Moor Park Pippin Apple. It bears some resemblance to the Hollandbury, and is said to be a good keeper, and particularly attractive in spring by the beauty of its blossom. No special award was made. A. H. Smee, Esq. (Mr. G. Cummins, gardener) sent dishes of very fine fruit of Pears Madame Millet and Pius IX, but the quality was inferior. The former is occasionally very good, but proverbially uncertain, and Mr. Rivers remarked that the tree is the reverse of a good grower. Pius IX. is a very large Pear of no particular merit. Messrs. Saltmarsh, Chelmsford, sent a firm medium-sized Apple named Blanders Apple, a medium sized firm fruit, and the best late Apple on the table; also a dish of the Queen Apple, and the fruit, both in regard to appearance and quality, met with the approval of the Committee. The two dishes were sent to show the keeping qualities of the varieties. Mr. J. Lockie, The Gardens, Oakley Court, Windsor, sent specimens of his new Cucumber Lockie's Perfection, a straight dark green medium-sized fruit, resembling Veitch's Perfection. The Committee desired to see it again later in the season. Lullington's Variegated Broccoli, from the Society's Garden at Chiswick, was placed before the Committee. The leaves are white in the centre, edged with green and fringed, the heads being about the size of a breakfast cup. The samples were decidedly attractive, and a first-class certificate was awarded to the Broccoli as a distinct and ornamental variety.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. Shirley Hibberd, W. Wilks, W. Goldring, H. Herbst, W. Bates, W. H. Lowe, C. T. Drury, G. Paul, C. Noble, C. Pilcher, R. Dean, J. Dominy, H. M. Pollett, J. O'Brien, A. J. Lendy, B. Wynne, E. Hill, J. Walker, and Dr. Masters.

From the Royal Gardens, Kew, came an excellent collection of Primulas, hardy and other plants, including some remarkable rarities. The Primulas comprised twenty or thirty species and varieties, some of the best being Denyana and Escheri, small neat flowers, bright purple, the latter especially good; pubescens alba, rosea, obconica, denticulata, viscosa, Obristi, verticillata, and Palinuri. Other notable plants were the white-flowered Corydalis tuberosa, the wild type of Tulipa suaveolens, with scarlet flowers, found in Turkestan; a remarkable Saxifraga, S. latepetiolata, from Spain, having large divided leaves and small white flowers; the graceful Heuchera sanguinea, with small bright red bell-like flowers in spikes; the pretty Nareissus triandrus albus, often seen as calathenus, having creamy white drooping flowers; the diminutive but charming N. rupicola, with bright orange Jonquil-like flowers; and the American Dicentra canadensis, with elegant finely divided foliage and small white flowers. From the temperate and other houses in the same

establishment came grand flower-heads of Rhododendrons Aucklandi and R. Griffithi, also dense spikes of Echium callithyrsum, 9 inches long, the flowers blue, closely packed, with pink stamens. The extremely distinct Anemone Fannini, with broad peltate lobed leaves and large whitish flowers, together with long wreath-like flower-laden branches of the intensely rich crimson Bougainvillea spectabilis, which is too seldom seen in flower, attracted much attention. Many other interesting plants were included in this interesting exhibit, such as the large-flowered Pleurothallis insignis, the pretty pink Pinguicula grandiflora, and the brilliant Cereus Mallisoni.

A collection of Himalayan Rhododendron flowers from J. T. D. Llewelyn, Esq., Penllergare, formed a pleasing group, and amply justified the praise the exhibitor bestows upon these plants for the adornment of the garden. They had been all cut out of doors, and in such a late season as the present this was the more remarkable, as they were much more forward than many in the south of England. The deep red R. Thompsoni and a blush-tinted one named Campbelli were the finest, but barbatum, campanulatum, ochraceum, and others possessed considerable beauty. F. G. Tantz, Esq., Studley House, Hammersmith (gardener, Mr. Cowley), exhibited a group of Orchids, which included several fine examples of Oncidium Papilio majus (the Butterfly Orchid); a remarkably rich dark variety of Cypripedium Lawrencianum, named atro-rubrum; large handsome flowers of the distinct Odontoglossum Harryanum, the lip broad, pale yellow on the upper half, veined with crimson at the base; Cypripedium selligerum majus had three large highly coloured flowers; C. Hookerae majus, an unusually fine variety; C. grande, Cymbidium Lowianum, the curious brownish orange Oncidium Leitzi, with Cattleya Schroederæ, and C. Lawrenciana rosea were well represented. A. H. Smee, Esq., The Grange, Wallington (gardener, Mr. Cummins), contributed a fine collection of Masdevallias, comprising well grown plants of M. Shuttleworthi, the large dull reddish M. Trochilus, Houtteana, Estradae, xanthocorys, and a dark coloured and handsome variety of M. ignea.

H. Selte Leonard, Esq., Guildford, contributed an interesting collection of small alpine plants. Mr. S. Ford, Leonardslce Gardens, Horsham, was awarded a cultural commendation for long shoots of Passiflora princeps, crowded with bright reddish flowers. Mr. J. Crook, The Grange Gardens, Farnborough, sent a plant of Begonia glaucophylla in a basket to show its fitness for that mode of culture, the stems drooping and bearing salmon red-shaded flowers very freely. Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Rochampton, exhibited some very capitally grown Mignonette with long massive spikes of flowers (cultural commendation).

Messrs. J. Veitch & Sons, Chelsea, sent several new Azaleas, hybrids between the Ghent and mollis types, which we fully described and illustrated last year. They are most useful decorative plants, and well adapted for forcing. Belle de Gand, Perle, Etoile de Flandres, and Comte de Kerchove were the best of the varieties shown, and with them were some fine Pæonies, one of which was certificated. Mr. B. S. Williams, Upper Holloway, showed plants of Amaryllis Black Prince, a handsome rich dark scarlet variety of the Dr. Masters type (vote of thanks); Miltonia Tolliana, the flowers veined with crimson; Cattleya Mendeli grandiflora; Oncidium undulatum, with brown sepals, and recurving petals tipped with white, and veined with purple at the base; and Odontoglossum Rossi F. L. Ames, for which a certificate was awarded.

The groups of plants were numerous and beautiful, but we can only briefly refer to them this week. Messrs. Paul & Son, Cheshunt, contributed a magnificent group of Roses in pots (silver-gilt Banksian medal) and a collection of herbaceous plants (silver Banksian medal). Mr. Walker Whitton had a large and varied group of Daffodils (silver-gilt Banksian medal). Messrs. Barr & Son, King Street, Covent Garden, and Mr. T. S. Ware, Tottenham, showed fine collections of Daffodils similar to those we have repeatedly noticed from these firms this season; a silver medal was awarded to the former and a bronze medal to the latter. Messrs. Collins Brothers & Gabriel, Waterloo Bridge Road, were also awarded a silver medal for a group of Daffodils, and Messrs. H. Lane & Son, Berkhamsted, a bronze medal for a group of Roses. Mr. W. Rumsey, Waltham Cross, had a fine group of Roses in pots (silver medal). The contributions of these firms added greatly to the attraction of the Show.

Messrs. W. Paul & Son, Waltham Cross, exhibited a new bright red H.P. Rose, Meteor, and a delicate pink or blush H.P. variety named Madlle. Germaine Caillot, together with the white American Rose The Puritan. Messrs. Hart & Co., High Street, Guildford, showed a bold and effective Coleus named Hart's Conqueror. Mr. R. Clarke, Twickenham, contributed a group of excellent Cyclamens. Mr. Howard, Southgate, brought some fine Mignonette grown by Mr. Sweet. Mr. J. Chambers, Isleworth, sent plants of a white Viola named Snowflake, and the dark blue double Violet Victoria. The Civil Service Co-operative Stores exhibited two baskets and a bouquet of Daffodils. Messrs. Kelway & Sons, Langport, had a group of Amaryllises, mostly with medium-sized but well-formed flowers well varied in colours, also some double Cinerarias. Messrs. H. Cannell & Sons, Swanley, staged a handsome group of the floriferous Bæzonia Carrieri villosa, which appears to be of stronger habit than the ordinary Carrieri, compact, and having large flowers. Mignonette Cannell's Perfection was much admired, as also were the double Cinerarias from the same firm. A variety of Adiantum scutum, named roseum, was shown by Mr. H. B. May, the young fronds being of a reddish tint.

A novel and simple appliance for propagating softwooded plants was

shown by Messrs. T. Pascall & Sons, South Norwood. It is an earthenware trough constructed to fit over hot-water pipes. It is partly filled with water, and over this a perforated earthenware tray is placed. The compost intended for the cuttings is placed on the tray and the cuttings dibbled in. It was referred to Chiswick for trial.

CERTIFICATED PLANTS.

Rose May Rivers (Rivers).—This originated at Sawbridgeworth ten years ago as a sport from an old China Rose, Clara Sylvain, that is seldom seen now. May Rivers is a Tea Rose with large and deep blooms, the outer petals creamy white, centre clear lemon yellow. Though Mr. Rivers has grown this variety for so many years he has not before exhibited it, and the honour of a certificate was promptly accorded.

Rose Climbing Niphetos (Keynes, Williams & Co.).—A large plant of Climbing Niphetos Rose exhibited by Messrs. Keynes, Williams & Co., Salisbury, attracted considerable attention, as in addition to its free growth it was bearing fine blooms abundantly. Many visitors evidently regarded it as a most welcome acquisition.

Odontoglossum Ilumcanum (H. M. Pollett, Esq.).—A variety or hybrid of the O. Rossi type, with something of the O. maculatum colouring. The flowers are large, tinged with yellow, the lip broad, the petals spotted with brown, and the sepals heavily marked with a similar colour.

Angræsum arcuatum (H. J. Buchan).—A distinct species with rather small white flowers in short racemes, the sepals and petals very narrow, tapering recurving petals and sepals.

Odontoglossum crispum, *Charlesworth's variety* (J. Charlesworth).—An extremely beautiful variety with large well formed flowers, the petals broad and slightly fringed at the margin, the whole of the flower richly suffused with a rosy crimson hue and heavily blotched with reddish-brown. The plant was a strong one, and had a raceme of ten flowers. It is one of the best of the highly coloured forms that has been shown.

Pæony Comtesse d'Endort (Veitch & Sons).—One of the tree Pæonies with enormous globular flowers 8 and 9 inches in diameter, of a delicate salmon tint. With it was shown a much darker variety named Queen Elizabeth.

Primula Crimson Beauty (F. Crook).—A dwarf Primula, something of the P. pubescens type, with dark purplish crimson flowers and a white centre, very pretty.

Erythronium grandiflorum albiflorum (T. S. Ware).—A large Dog's-tooth Violet, with creamy white flowers and yellow stamens.

Cineraria Beatrice (Kelway).—A double variety, with neat globular flowers, white tipped pink.

Cineraria Queen Victoria (Kelway).—A double white variety, the flowers frequently tinged with pink.

Amaryllis Miss Ainslie (Kelway).—A neat variety, the flowers of medium size, but good shape, scarlet edged with white, and a white central bar. The plant had a scape of four flowers.

Cineraria Faust (Cannell).—A bright rose coloured double variety, the flowers full and handsome.

Cineraria Advance (Cannell).—Another double, rich purple, large, and good.

Cineraria Aspasia (Cannell).—Flowers double, rich, dark blue, fine in contrast with the lighter varieties.

Odontoglossum Rossi F. L. Ames (B. S. Williams).—A distinct addition to the O. Rossi group, with bold well formed flowers, sepals light brown, petals spotted brown, lip broad and white.

ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers, 25, Great George Street, Westminster, Dr. W. Marcet, F.R.S., President, in the chair.

Dr. E. Hale, B.A., V.C., Mr. R. Lawson, LL.D., F.S.S., and Mr. S. Walker were elected Fellows of the Society.

The following Papers were read:—

1. "Jordan's New Pattern Photographic Sunshine Recorder," by Mr. J. B. Jordan. The improvement in this instrument over the previous pattern of Sunshine Recorder consists in using two semi-cylindrical or D-shaped boxes, one to contain the morning and the other the afternoon chart. An aperture for admitting the beam of sunlight is placed in the centre of the rectangular side of each box, so that the length of the beam within the chamber is the radius of the cylindrical surface on which it is projected; its path therefore follows a straight line on the chart at all seasons of the year. The semi-cylinders are placed with their faces at an angle of 60° to each other. They are fixed on a flat triangular plate, which is hinged to a suitable stand, having levelling screws attached, and fitted with a graduated arc as a means of readily adjusting and fixing the cylinders to the proper vertical angle agreeing with the latitude of the station where used.

2. "On the Meteorology of South-Eastern China in 1886," by Dr. W. Doberck, F.R.Met.Soc. This paper gives the results of observations made at the custom-houses and lighthouses by officers of the Imperial Chinese Maritime Customs. In summer there is very little change of temperature with latitude. The temperature depends upon the distance from the nearest seacoast, and is greatest at stations farthest inland. The highest mean temperature occurred in July and

the lowest in January. The north-east monsoon blows from September to June, and the south monsoon during July and August; the latter does not blow with half the force of the former. Rainfall is greatest in Northern Formosa and least in Northern China. Along the east coasts of Formosa and Luzon the winter is the wet season, while in China July seems to be the wettest month of the year.

3. "Lightning in Snowstorms," by Prof. A. S. Herschel, F.R.S.

4. "Insolation," by Mr. Rupert T. Smith, F.R.Met.Soc.

GREYIA SUTHERLANDI.

A PLANT of *Greyia Sutherlandi* was flowering for some weeks early in the present season at the cool end of the succulent house in the Royal Gardens, Kew, and a specimen was shown at the Royal Horticultural Society's meeting on March 27th. Though it has been considered chiefly

Fig. 43.—GREYIA SUTHERLANDI.

interesting to botanists it is by no means devoid of horticultural merit, for the bright red flowers are produced in dense terminal clusters, and have a rich appearance. In this country specimens, which are not very numerous, seldom exceed a few feet in height, but in its native habitats, the rocks at Port Natal, it is said to attain the dimensions of a small tree, which when in flower has a very brilliant appearance. It is rather strange that amongst the numerous beautiful and distinct South African plants so admirably depicted by Miss Marianne North, this seems to have escaped attention—at least we do not remember seeing it represented in that lady's remarkable collection of paintings at Kew.

The leaves are somewhat fleshy and crenated at the margin. Some are quite smooth, and others densely pubescent, a peculiarity that has been repeatedly noted by several observers. The plant is now assigned to the family Sapindaceæ, but there was much uncertainty as to its

correct position until it flowered some years ago in the Chelsea Botanic Gardens, when it was determined by Sir Joseph Hooker.

GREVILLEA ROBUSTA.

SEEDS of this elegant-foliaged and most useful furnishing plant may be sown at once in a shallow pan filled to within an inch of the top with light sandy soil, covering the seed lightly, water through a fine rose, and then place in a hotbed with a square of glass over the pan and a covering of moss. The seedling plants will in due time appear, and by placing them singly into small 60-sized pots, returning them to heat for a few weeks, giving water at the roots, and shading the young plants from sunshine until the roots have taken to the soil, useful little specimens for furnishing purposes will be secured by next autumn.—SOUTH WILTS.

REVIEW OF BOOK.

Report of Observations of Injurious Insects and Common Farm Pests during 1887. By ELEANOR A. ORMEROD, F.R.M.S., &C. Simpkin, Marshall & Co.

IT has been rather ungraciously said that ladies make but poor scientific observers, because they are likely to display the feminine habit of "jumping to conclusions." Natural science in its various branches has of late years enrolled a large number of patient and enthusiastic lady students, who have already shown themselves able to rival the opposite sex, though their work may have made less noise in the world. Botany has been always a favourite study with the ladies, but entomology has not been successful in enrolling many, perhaps because the operation of killing specimens can hardly be avoided, and this is somewhat distasteful to the gentler sex. Amongst our few lady entomologists well deserved eminence must be given to Miss Ormerod, who has given a practical turn to her studies which merits the gratitude of gardeners and farmers. Her report of observations made last year, if it does not present any specially important features, epitomises excellently the facts noticed by her or reported by others which bear upon the loss and injury caused through insects.

Looking first at that portion of the Report which has most to do with horticulture, we find it sufficiently apparent that 1887 was not a year in which insects made themselves conspicuously troublesome. This is, however, quite obvious, and one is more impressed with the fact as we have recently had to hear much about the bulb mite and its allies, that mites of a variety of species are coming more to the front than formerly. This may not be because these insects are really commoner now than they have been in the past, possibly the explanation is that gardeners and naturalists are observing with more accuracy to what causes the decay and death of some plants is attributable. Miss Ormerod notes the complaints made by growers of the Black Currant, about the gall mite called *Phytoptus Ribis*, which pierces the leaf-buds in early spring. In Cheshire, a gardener reports that the Black Currants for miles round suffered severely, and in some instances the whole stock of trees was completely ruined, and fresh bushes, brought from a distance, shared the same fate. A grower in Clydesdale gives account of injuries equally serious, and suggests as probable that quantities of these mites descend to the soil later on, hence the advisableness of removing the surface where the bushes have been infested. If it be the case that many of the mites winter in the earth, to ascend the bushes at the time of budding-out, it would be well, Miss Ormerod says, to smear the stems and flower branches with the article called "Davidson's Composition," or some other sticky and deterrent material. The insect does not meddle with the Red or White Currant.

The slugworm of the Pear (*Tenthredo Cerasi*) was more abundant than usual, perhaps owing to the warm summer. It appeared to show a preference for trees trained on walls, but occurred also in Cherry orchards. It is now established as a fact that the pupation of this insect takes place in the earth, to which the grubs descend about September, burying themselves at a depth of from 1 to 4 inches, and emerging as flies in June or July. These little crown balls should therefore be looked for and destroyed, in the event of any caterpillars having escaped from the dusting or syringing which should be at once carried out when the species has been detected. In some parts of Middlesex, Kent, Herts, and Essex a good deal of damage was caused towards the end of summer to Cabbages, Kale, and green crops by caterpillars of the large white hutterfly (*Pieris Brassicæ*). Miss Ormerod infers from examination of various reports that the Turnip moth (*Agrotis segetum*) is gradually on the increase; many observers chronicle the injury they did to Swedes, especially during 1887. Though the insect is named from the Turnip, it has frequently been found at the roots of Celery, Spinach, Onions, Carrots, Potatoes, and even Oats. Except while young its proceedings are chiefly carried on underground, hence often unsuspected. Is their multiplication partly due to the diminution in number of those birds which seek caterpillars as their favourite food?

The Hessian fly was again discovered in many localities, but not to any notable extent. It appears to be now almost certain that it is seldom or never imported with foreign straw (as was supposed), because this straw is generally baked before it is used for the purpose of packing. Quantities of the granary weevil (*Calandra granaria*) have, however, for years past been brought to us with Russian and German Wheats. Recently in the neighbourhood of London this beetle has been found very mischievous with malt.

ROSA POLYANTHA GRANDIFLORA.

THE neat little double varieties of the polyantha type are becoming very popular, and new varieties are becoming quite frequent at the metropolitan shows and meetings. Messrs. Paul & Son of Cheshunt, however, recently exhibited a large single white variety named grandiflora, which the Floral Committee found worthy of a first class certifi-

Fig. 44.—ROSA POLYANTHA GRANDIFLORA.

cate on the 10th inst. It is regarded as an improvement upon the old single form of *R. polyantha*, and originated in France. The flowers are $2\frac{1}{2}$ inches in diameter, with broad rounded petals of good substance and pure white. They are produced freely, and the plant shown was trained in globular form, was a neat and attractive little specimen. To some tastes, however, such Roses as these look better in a more free and graceful style.

A ROSE SHOW IN BRUSSELS.

ARRANGEMENTS have been made for holding a Rose show at Brussels on July 1st and 2nd, in connection with the International Exhibition this year, and the schedule just issued is somewhat different from those we are accustomed to in this country. The prizes are all medals—gold, silver-gilt or silver, and the classes are in two sections, for amateurs and nurserymen respectively. Eight classes are devoted to amateurs, two of the principal being for 150 and 100 varieties of Roses each, with others for fifty and twenty-five varieties, and collections, the number not specified. Seven classes are appropriated to nurserymen similar to the

preeding, and one is open to all exhibitors—namely, that in which two medals are offered for the best seedling Rose not in commerce. Nurserymen often find a difficulty in making up their stands of seventy-two varieties, but it would puzzle many to exhibit a collection of 150 good blooms of distinct varieties on one day. British amateurs can seldom show in a larger class than for forty-eight varieties, and to make up a collection of 150 would tax the resources of the largest rosery. It may be remarked, however, that in the classes mentioned, "Roses of all kinds" are admissible, so that they would not be confined to the Hybrid Perpetuals and Teas, as is usual here in large classes.—S.

THE NATIONAL AURICULA SOCIETY. (SOUTHERN SECTION.)

APRIL 24TH.

CONTRARY to the expectations of some growers this Show, both in numbers of exhibitors and quality of flowers, was quite up to the average, and, as is remarked by a correspondent in another page, the recent spell of fine weather had assisted the plants surprisingly. The Show was crowded by visitors during a good portion of the afternoon, and it must be chronicled as the most successful of the gatherings yet held in the new quarters, the Drill Hall, James Street, Victoria Street. Two central tables were devoted mainly to the Auriculas, and that the display was representative not only of the south but the north may be judged from the fact that competitors entered from as far north as Warrington.

Numerous seedlings were shown, but only the three following from the Rev. F. D. Horner gained first prizes—namely, green-edge Monarch (Horner), grey-edge Irreproachable (Horner), and self Constance, a second prize being awarded for Mrs. James Tinsley (Bolton) in the self class, shown by the raiser. A first-class certificate was adjudged for—

Alpine Auricula Sir Trevor Lawrence (Barlow).—A beautiful variety with large even flowers, gold centre, and rich rosy crimson colour, shading to a light edge.

SHOW AURICULAS.—The greatest interest invariably centres in the class for twelve Auriculas, as it is in this that the leading growers test their strength, and, as the friendly rivalry is strong, it is naturally expected that there will be found the best plants and the finest varieties. Notwithstanding the unfavourable season, which might have been supposed to be much against the northern exhibitors, the Rev. F. D. Horner, Lowfields, Burton-in-Lonsdale, Kirkby Lonsdale, succeeded in obtaining the chief honours in the class with vigorous plants, fine trusses, and beautifully even, clean, well-developed flowers. The self varieties were especially noteworthy for their richness and fine quality, and nine out of the twelve varieties represented were raised by Mr. Horner. They were as follows—Laura, a fine truss with eight large pips; Hypatia, also strong, with the same number of pips; Heroine, remarkably handsome, with a grand truss of eleven pips; Ebony, extremely dark, with five pips; and Sapphire, charming, with a truss of twelve pips. All these are self varieties, and the last-named was well represented in several other collections. The edged varieties were George Lightbody (Headly), excellent, with five good pips; Magpie, five pips; Sea Gem, a pretty green-edge, with four pips; Kestrel, another beautiful green-edge, with five pips; Prince of Greens (Trail) with seven pips; and Edith Potts (Bolton), which was awarded the prize as the premier Auricula in the Show. It is an admirable green-edge variety, the plant bearing a fine truss of five pips. Second honours were accorded to F. Whitbourn, Esq., Great Gearies, Ilford (gardener, Mr. J. Douglas), whose collection was a capital one, more even than the first, with good trusses, but not quite such large flowers, though they were of excellent quality in several cases. The following seven varieties were raised by Mr. Douglas—namely, Mrs. Moore, seven pips; Mabel, seven pips; Abbé Liszt, eight large pips; Marmion, eight pips; Dignity, a fine self; Neatness, a green-edge, with eight good pips; and Sir W. Hewett, a self with eleven pips. The other varieties were Rev. F. D. Horner (Simonite), very strong truss with eleven pips; Sapphire (Horner), beautiful, nine pips; Reliance (Mellor), seven pips, not quite out; Smiling Beauty (Heap), nine pips; and Frank (Simonite), eight large pips. The third place was won by Mr. T. E. Henwood, Hamilton Road, Reading, who had healthy plants and neat but not large flowers, Conservative and Sapphire being his most notable varieties. Mr. W. Bolton, Warrington, was fourth, showing several fine selfs, amongst which a bright red seedling (Bolton) had large showy flowers. Sapphire and Mrs. Douglas were also well represented. S. Barlow, Esq., Stakehill House, Castleton, Manchester, was fifth with nearly all seedlings, comprising a good green-edge and some fine selfs. These sixty plants formed a most interesting class, and there was quite a little crowd of visitors and specialists criticising and praising the plants during the greater part of the afternoon.

In the smaller classes there were five and six competitors each, so that about seventy plants were staged in the three following. With six the Rev. F. D. Horner again secured the chief place, showing Prince of Greens, Heroine, Melainie (Horner), a rich dark self, Miranda, George Lightbody, and Neptune (Horner), a beautiful green edge. Mr. T. E. Henwood followed, showing good plants of Aeme, Sapphire, and John Simonite. Mr. Douglas was third, his examples of Smiling Beauty (eleven pips) and Ajax (nine pips) being unusually fine. J. T. D. Llewelyn, Esq., Penllergare, Mr. Bolton, and Mr. S. Barlow were fourth, fifth, and sixth respectively. Amongst the five competitors with four plants Mr. G. W. Wheelwright, Oxford Road, Reading, was first for creditable plants of Heroine, Reliance, George Lightbody, and Rev. F. D. Horner, followed by Mr. C. Phillips, Hamilton Road, Reading; Mr. W. L. Walker, Earley, Reading; Viscountess Chewton, Book-

ham Lodge, Cobham (gardener, Mr. A. J. Sanders); and Mr. J. Kew, London Road, Southend. For two plants Mr. Wheelwright was again first, staging Black Bess (Woodhead), a very dark and fine self, with nine pips, and Rev. F. D. Horner, having ten pips not fully expanded. Mr. C. Phillips was second, showing Otello (Netherwood) and Aeme; Mr. A. J. Sanders third for Aeme and Lady Sophia Dumaresque (Lightbody); Mr. L. Walker fourth with Aeme and Gipsy (Mellor), and Mr. H. Spurling, The Nest, Blackheath, fifth, with Aeme and C. J. Perry. It will thus be seen that four out of the five competitors exhibited Read's Aeme.

Single Specimens.—Some confusion occurred both in the staging and affixing the prize cards in these classes, but we have endeavoured to correct the awards from the revised official list. *Green-edge*.—Mr. Henwood first and fifth, with Prince of Greens; Mr. Phillips second and fourth, with Rev. F. D. Horner and Prince of Greens; Mr. Wheelwright third and eighth, with Lancashire Hero and Talisman; Mr. Douglas, sixth, with Lancashire Hero; and Mr. Bolton seventh, with Rev. F. D. Horner. *Grey-edge*.—Mr. Sanders first, with George Lightbody; Mr. Wheelwright second and fifth, with Lancashire Hero and Mrs. Moore; Mr. Douglas third and fourth, with Mabel; Mr. Bolton sixth and seventh, with Greyhound and Quicksilver; and Mr. Henwood eighth, with Richard Headley. *White-edge*.—Mr. Douglas first and second, with Conservative; Mr. Horner third and fourth, with Heatherbell and Pearl; Mr. Phillips fifth and seventh, Mr. Sanders sixth, and Mr. Henwood eighth, all with Aeme. *Selfs*.—Mr. Horner was first and second, with Heroine; Mr. Bolton third, with Sapphire; Mr. Wheelwright fourth and eighth, with C. J. Perry; Mr. Phillips fifth, with an unnamed variety; and Mr. Henwood sixth and seventh, with Negro and Duke of Albany.

Two groups of fifty Auriculas each, not less than twenty varieties, and including Alpines, were contributed by Mr. J. Douglas and Mr. C. Turner, Slough, who were awarded the first and second prizes in the order named. The plants from Great Gearies were strong healthy specimens, and represented some of the best varieties. Mr. Turner's plants were not quite so large, nor was the collection quite so diversified in appearance.

ALPINE AURICULAS.—Those who have not been educated to the refinements of the Show varieties of Auriculas can always appreciate the Alpines, which with their soft or rich tints and free habit of growth possess a much greater decorative value than the others. As a display the classes devoted to these were much more effective than the Show varieties on the opposite table, but they did not possess the same interest for some of the enthusiastic growers of the old school. Mr. C. Turner was as usual very strong in the Alpine classes, and both for twelve and six plants was easily first. The premier twelve contained John Laing, Ernest, C. Turner, Sir H. Darvill, Sunrise, Edith, Fred. Bates, Sensation (of a peculiarly deep velvety crimson shade), Lady H. Grosvenor, G. Wheelwright, Marguerite, and Lady H. Crewe. Most of these are varieties raised at Slough, and they formed a handsome, bright, and varied collection. Mr. Douglas was a good second, his plants were fine, but the varieties not quite so distinct. Mr. G. W. Wheelwright was third. Mr. Turner's leading six included Sunrise, Edith, Madonna, Reginald, Mr. Stafford, and Lady Crewe, of similar merit to the preceding; Messrs. Henwood, Douglas, Walker, and Wheelwright securing the remaining prizes in that order amongst eight competitors. The best four plants came from Mr. Henwood, bright and beautiful examples of Princess of Wales, Edith, Hotspur, and Mrs. Ball; Messrs. S. Barlow, Walker, Spurling, and Llewelyn following.

Single Specimens.—*Gold centre*.—Mr. C. Turner, first and third for Pallas and T. H. Henwood; Mr. Barlow second and fifth for Mrs. Meiklejohn and Diadem; and Mrs. Douglas fourth for Hebe. *White or cream centre*.—Mr. Barlow first with Susie Matthews, Mr. Douglas second with Queen Victoria, Mr. Henwood third with Lady Love, Mr. Wheelwright fourth with the same variety, and Mr. Turner fifth with Lady H. Crewe.

POLYANTHUSES.—The exhibitors of the beautiful old gold-laced Polyanthuses are never numerous, and attractive as the plants are they do not seem to find favour with an increasing number of growers. There are rarely more than three or four who compete for prizes, and on the present occasion Messrs. Barlow, Douglas, Llewelyn, and Dean shared the prizes between them. Mr. Barlow's plants were in good trim, especially his premier six, which included Exile, Lancer, Prince Regent, Sir Sydney Smith, Cheshire Favourite, and George IV., all well-known varieties. Mr. Douglas had similar varieties, but Red Rover was notable amongst them. The third place was taken by Mr. Llewelyn. For a trio of plants Mr. S. Barlow won first prize with Exile, Cheshire Favourite, and George IV.; Mr. Douglas was second, having the same varieties, except that Lancer replaced Exile; and Mr. R. Dean followed with seedlings of a rather promising character. In the single specimen class the variety George IV. secured first and second prizes for Mr. Douglas; William IV. and Lancer from Mr. Barlow were third and fourth, and Cheshire Favourite from Mr. Dean fifth.

FANCY VARIETIES AND PRIMULAS.—The several classes for these contained many garden plants of sterling value, especially amongst the hardy single and double Primroses and Polyanthuses. Fancy Auriculas were shown by Messrs. Barlow and Douglas, which were respectively first and second with twelve varieties. The Stakehill plants were mostly seedlings, the flowers being shades of yellow, buff, and brown, very peculiar but scarcely beautiful. The Ilford varieties included yellow and creamy white tints, one named Twilight, nearly white, bearing quite a ghostly appearance. Mr. R. Dean exhibited the best twelve Fancy Polyanthuses, and the same number of single Primroses,

all exceptionally good, seedlings of bright colours and strong habit. Messrs. Douglas and Paul & Son followed in these classes, the last named gaining first honours for six double Primroses, the Double Sulphur, White and Purple, with the pink and white Harlequin and the mauve Crousel plena being the best. Mr. Douglas and H. Selfe Leonnard, Esq., Hitherbury, St. Catherine's, Guildford, being second and third.

J. T. D. Lewelyn, Esq., was adjudged the chief award for twelve Primulas, the collection comprising excellent plants of rosea, denticulata, officinalis var. suaveolens, cortusoides, obconica, japonica, involuerata, the yellow Auricula, and a small flowered variety doubtfully named erosa. With half a dozen Primulas Mr. Barlow took the lead with capitally flowered plants of obconica, denticulata, floribunda, nivalis, rosea, and viscosa; Messrs. Paul & Son following closely.

There were several exhibits of Primulas that are noted in the report of the Floral Committee, but the non-competing exhibits under the Auricula Society were few. The most noteworthy were plants of a double yellow Auricula with undulated petals, giving the flowers a fringed appearance.

A luncheon was held in the afternoon at the "Hotel Windsor." There was a good attendance of members and friends, presided over by Sir Trevor Lawrence, Bart., M.P., supported by some members of the Council of the Royal Horticultural Society, the vice-chair being occupied by Mr. Samuel Barlow, the eminent northern florist, who was also supported by a portion of the Council.

CROPS THAT PAY.

ONIONS.—The season has been anything but favourable for autumn-sown Onions. It is true they have struggled to grow at different times, but have by sudden changes in the weather been repeatedly checked. The rows will be thinned and the thinnings transplanted on deeply dug well manured land 1 foot between the rows and about 4 inches between the plants. By planting in rows the ground is easily kept clean by freely working the hoe amongst them. Nothing promotes rapid growth more than constantly working the soil and strewing between the rows during showery weather a little nitrate of soda or sulphate of ammonia two or three times during the season. This should not be done before the bulbs commence swelling freely, or they are liable to run to seed. In planting only secure the roots in the soil; it is a great mistake to plant them too deeply, for they swell better when the greater portion of the bulb is above ground. The crop transplanted remains upon the ground and is ripened as early as possible, so that they can be disposed of before any of the spring-sown crop finds its way into the market or foreign produce is sent over. Hoe between the rows when the surface is dry, and a dressing of soot may be given with advantage during showery weather after they are once growing freely. These should not be severely thinned, for if a crop is to be ripened on the ground the final thinning must take place when they are large enough for bunching.

Our practice is to ripen only the transplanted crops and dispose of the others in a green state. This has proved the most remunerative course, as a profitable crop of white Turnips for bunching or Leeks can be taken from the same ground afterwards. Last summer was certainly an unfavourable one for Onions, and our crops were lighter than they have been for years; but the price has been good, and with good management they can be grown to pay.

Onions will follow almost any crop, but for years we have avoided sowing them on ground that has previously been occupied with any of the Brassica tribe. If this course is followed they are on most soils certain to be destroyed by grub. One of the worst practices is to plough or dig in the old stems of Cabbages or Broccoli. This may sound well scientifically considered, but while they doubtless return to the soil a certain amount of plant food that would otherwise be carried away, on the other hand they do more harm than good by providing food for the preservation of grubs and other insects to ravage the succeeding crop. My advice is burn them, for this is a certain method of destroying any insects that may be lurking about. Onions like deeply dug well manured soil, ground that has been turned up in early autumn being most suitable, for it invariably works well, and an excellent bed for the seed is the result. The manure is forked in if possible the same day as the seed is sown, and a good dressing of soot is applied at the same time as the manure. If a fine day is selected for the operation the surface dries quickly, and a roller is passed over it once or twice. Shallow drills 1 foot apart are drawn and the seed sown. The seed is covered by merely drawing the back of a large wooden rake over the drills. This leaves the drills visible, and the hoe can be first used directly they commence showing through. When the hoe is at work thus early it is surprising how much easier the ground is kept clean than is the case if the weeds are allowed to establish themselves before an attempt is made to eradicate them. The varieties grown were Bedfordshire Champion, Brown Globe, and James' Keeping, but the first only finds a place

now. Why? Because it produces on our land a heavier crop of larger produce than the last mentioned, and Brown Globe in some seasons produces too many "thick necks." Flat Onions, either for autumn or spring sowing, are useless for market purposes; they do not pay, they are too light in weight. Thinning is not practised to a large extent, and then if a few go off by grubs or mildew there is almost certain to be a crop. What are drawn are left until they are large enough to bunch and sell.

LEEKS.—Leeks pay very well as a second crop, and fortunately are not much trouble. They are a more certain crop than such Broccoli as Snow's, Osborn's, Veitch's Spring White, and others that turn in about the same time. Without considerable labour and expense in protecting the latter they are very liable to be killed by severe frosts, or to be rendered useless just as the heads appear. The last is generally their fate, and consequently they must, for all situated as I am, give place to crops that are certain to pay. My advice to each one is, Study the locality in which you reside and plant accordingly, for it is much better to dispense with the second crop than have three parts of a first crop in order to provide for a second that is an uncertainty. Leeks then are a sure crop, and the seed for the main crop is sown by the side of the Onions, only much thicker. Most plants are spoiled in their early stages by being sown too thickly or left too long before they are thinned, but Leeks seem to be an exception to this rule. They certainly draw up quickly, and attain a greater length before they are planted, which is a decided advantage.

To give some idea of our method of sowing, I may say 1½ oz. is enough for two rows 23 to 25 yards long each. The plantings from these are for winter and spring supplies, while those for use up to Christmas or for a time after are raised by sowing in boxes. These are dibbled out during showery weather, moderately thick on any spare patches of ground. This crop follows early Potatoes (sometimes Lettuces) that are planted 2 feet from row to row. After the Potatoes are dug moderately deep drills are drawn one foot apart. If the ground is dry the drills are soaked with water, but we avoid this operation if possible, it is too costly, and soon tells heavily against the crop. It is sometimes necessary. The Leeks are planted in these trenches with a dibble, the only care needed is to have the holes deep enough so that the roots go straight down, and do not bury the heart of the plant. These are placed in the row 7 inches apart. The drills made are filled by using the hoe amongst the plants. By this method of planting the greater portion is well blanched at lifting time without further trouble. These seldom attain the same size as those planted for lifting during the months of March, April, and as long as they can be kept. Two and three, according to their size, are placed in bunches, after the soil has been washed from their stem and roots, and twelve bunches are tied in a bundle. In spring, when they have attained a fair size, one practically forms a bunch; in fact, I have had no difficulty in selling them by the dozen. Those sown outside very frequently follow a crop of Cabbage, early Cauliflowers, or late Broccoli, with us generally the two first. These are planted the same as the others, only 2 inches farther apart, and the ground is dug, which is not done when planted after Potatoes.

Leeks will be doubly appreciated this spring, for green vegetables are scarce. Spring Cabbages are late, and in some instances have disappeared where the plants were small and weak at the approach of winter. Leeks keep a very long time in good condition if lifted now and laid in behind a north wall, a hedge, or anything that will answer the same purpose.

I promised to detail how to grow a late crop of Tomatoes, and for this purpose the seed should be sown at once. Further instructions shall be given in time to be of service.—MARKETER.

GLADIOLI NOTES.

THE TIME FOR PLANTING.—Although in a few respects my experience differs from that of "D., Deal," described on page 295, these few notes may be considered supplementary as with most of that article my results, extending over nearly twenty years, agree. Mr. Kelway was right in saying "seasons govern results," and this applies also to planting. The major portion of my corms, say 400, were planted in mid-February, as during January and up to that time here the weather was spring-like. Had I known what was coming I should have kept them out of the ground then. However, I now see many "spearing" through the beds, and though, owing to the low temperature of the soil, a few may have decayed, I am not sorry to have planted so early. The Gladiolus adapts itself to different treatment, so much so that those who plant now may have splendid spikes of bloom before frost next December. I was rather surprised to find that Mr. James Douglas likes to begin planting on the 1st of March and finishes about the 1st of May, at intervals of a fortnight, the object presumably being to have them blooming at different times over a more extended period. This seems unnecessary, as planted at the same time, one (say Shakspeare) will bloom in July or the beginning of August, and no amount of induce-

ment will make Duchess of Edinburgh, James McIntosh, or Phœbus expand their enormous blooms before the end of October; in deed, last year I had them flowering the first week in December.

SOIL.—“D., Deal,” formerly “gave a preference for Gladioli-growing to a good friable loam,” but more recently seems to think with Mr. Burrell of Cambridge that better results are attained where the soil is calcareous and stiffer. In Ireland, as far asunder as Saunder’s Nurseries of Cork, and Dickson of Newtownards, splendid spikes with twenty-two blooms each are freely grown on the former soil, and I certainly have better results with a deep rich sandy loam. I add the sand with the corms. I believe I am correct in stating neither Mr. Kelway of Langport, nor Mr. Campbell of Gourrock, N.B., grow on a calcareous soil, and your correspondent bears ample testimony to their success. I only grow as an amateur, and raise none from seed and little from spawn, yet my stock has steadily increased. I cannot justly complain therefore of disease, exhaustion, or degeneration.

ASPECT TO GROW IN.—Unquestionably a gentle southern slope, unshaded, and fully open to sun heat and to a maximum of ripening and maturing influence, is one of the great agencies that command success. The corms must be ripened, or failure will result. The ripening or maturation can only take place through the foliage. If anyone contests this let him try and grow a bed—all things else being equal—in a northern or shaded aspect, say at the back of a house, and note the result the second or third year. I ought to add that I assist the maturing process by taking my plants—those with the attached stems not quite withered—indoors at the end of November; surround the corms with moist river sand, and then let them slowly “dry out.” They come thus crisp, dry, and hard as bullets. I once spoke on this subject with Mr. F. W. Burbidge; he told me the champion gentleman grower of Ireland, J. F. Lombard, Esq., Rathmines, grows his under such circumstances on a warm southern slope.

VARIETIES.—I see your correspondent, in common with Mr. Campbell already referred to, divides the list of varieties given according to their time of blooming, into four classes, but where the same are named in both lists they do not always agree; for instance, Agrius, Carnation, Horace Vernet, &c., are early flowering with “D., Deal,” and later at Gourrock. The difference of latitude may, however, account for this. The time of planting, too, may affect the result. With many amateur and gardening friends we greatly admired the champion stand of upwards of one hundred different varieties staged by Messrs. Kelway at Kensington last August, and were then told those magnificent spikes were all English raised. Admitting this, have the French ever raised anything finer? I can bear personal testimony to the following English raised, and not included in the list given at page 296; I need not ask your space for description, as Messrs. Kelway’s, or any other grower’s catalogue, will give it, but all are distinct—Duchess of Edinburgh, James McIntosh, Pictum, Marquis of Lothian (sent out by Campbell, 1875), Brennus, Rev. H. H. and Mrs. D’Ombraun, Sir Stafford Northcote, Maria Lemoine (Lemoine), Mr. Thornton, Electra, Calliphon, Chambers (Dickson), Marcianus (fine), Appianus, Countess of Glentworth, Lady Bridport, Hankey (Dobree), Perry Rise (Carter), Egyptian King, and Anthony Waterer. A capital score, that all who can afford it should have, without including new varieties.—W. J. MURPHY, *Clonmel*.

THE “Notes on Gladioli” by your correspondent, “B.,” on page 319 will have astonished many who, as well as myself, have come to accept as inevitable the loss of a varying percentage of their corms annually. For a dozen years I have striven to attain the end “B.” seems to have reached, and have spared neither time nor trouble to do so. I think I have tried every recommendation I have read or heard of in the matter of soil, time, and mode of planting and after treatment, and I do not hesitate to claim a measure of success fairly comparable with that of other growers of the Gladiolus with whom I am, or have been, acquainted. Although among these are not a few in different parts of the country who have gained a reputation in the cultivation of this flower, I would seem to have an affinity for the unfortunate, as not one of them would say “I know hardly anything about” the disease to which the Gladiolus is subject, nor are they among the “many growers who are not troubled with it.” This last season I lost just about my usual proportion. My friend, Mr. Campbell of Gourrock, informs me that his loss fully exceeds his general average; another acquaintance that while he has not much cause to complain, two varieties that generally keep well with him have all but disappeared. By personal inspection of one large consignment from France, and by report from one of our leading houses on another, I know that imported corms are unsound to an unusual extent. Fortunate “B.,” whom I envy but cannot hope to emulate!

But what does the closing remark in the last of the three paragraphs mean? “Some, &c., do not succeed here.” It cannot be, surely, that in a locality so highly favoured the sorts specified do not grow and flower. Varieties as late as any of them seem to succeed, why not these? Is even the latest not amenable to the earlier starting in boxes or pots; or wherein are they refractory? Does Mabel or Ondine, or Orpheus or Opale, to mention no others, remain good for years with “B.?” I have had frequently to renew these, and I know other growers with whom they fail as frequently. Some varieties, although even among them failures occur, increase until one is able to give away surplus corms. I might mention, with others, Camille, Marquis of Lothian, Mrs. Finney, Talisman. As to Duchess of Edinburgh, of which “B.” says, “Anyone who knows the Gladiolus will see at once the impossibility of growing this variety a second year,” let me state my

experience. Six years ago I obtained one corm from Mr. Kelway. I have never bought or had another. The Duchess has flowered only twice with me, but it has increased until last year, when seven plants flowered splendidly. I have given away to friends at least three other corms, and one or two have decayed.

I cannot help inferring from this contribution by “B.,” as well as from another by him on pp. 188, 189, that he grows the Gladiolus mainly for garden decoration. Not to mention some of the varieties he seems to favour, I know no one who tries to do the noble flower justice who would allow, much less boast, of four or five stems from one corm. The term “growth” is used both for one stem and for all produced from one root. “Seventy-eight flowers were produced by one growth,” must mean at least three stems with their side spikelets. Tastes differ, but I would not consider my garden decorated by such Gladioli tufts or bushes, or allow any variety I have to grow and bloom in this random way. I cannot think the Gladiolus can be had in perfection when so treated, or many of our cares are expended in vain. What excellence might not “B.” attain! a grower with whom Mabel and Leander reach 6 or 7 feet in height, and who is all but exempt from that plague which so vexes others.

Of the newer sorts, Enchantress and Pasteur are two apparent acquisitions. As I saw both last autumn, the former, if it stretch enough in spike to allow the large flowers to clear each other sufficiently, is really good, and Pasteur is a smooth-edged flower of good form and pleasing colour. These seemed the best of the more recent additions that were then in flower at Cove Gardens.—A NORTHERN AMATEUR.

KEEPING GRAPES.

NOTHING new appears to have been discovered for many years past as to the method so well known of keeping Grapes late in the season, neither are there any suggestions as improvements on the practice of keeping the fruit late by the aid of bottles and water. We might go a little further, and state that no improvement has been made in the varieties for late keeping which have been so popular for nearly a quarter of a century. I have practised the water-and-bottle system for about twenty-five years to keep Grapes until May, and sometimes until June, and I have tried all varieties for general usefulness which I have seen recommended in horticultural literature, but still depend on Lady Downe’s Seedling, which is at the present time, the middle of April, as fresh in appearance, fine in colour, densely covered with bloom, and of as good flavour as they were last autumn. I have never yet been persuaded that the fruit deteriorates in flavour when well prepared in the previous season for keeping, and managed so that the waste of water from the bottles has been nil. Gros Colman is said by some to be rapidly taking the place of Lady Downe’s, but I do not think it ever will for private consumption, especially if proprietors’ palates have been long accustomed to fine flavour. For market purposes the larger varieties such as Gros Colman would probably command a more ready sale than Lady Downe’s. I have had no difficulty in keeping Gros Colman until April plump, fresh in berry and footstalk, and little changed in flavour, but I could not place it on a level as to flavour with Lady Downe’s.

Alicante, too is very useful for late supplies. The berries retain their bloom well to the end when kept late, but their tough skin renders them of secondary value for dessert. White Tokay has kept unusually well until April this season, though slightly limp in the skin, and had an imposing appearance to the last, the bright golden colour being always attractive in conjunction with the black varieties. Though we have kept, in addition to the above-named, others including Gros Maroc, one which I have never tasted of good quality at any time from numerous gardens, keeps fairly well, but the skin becomes like leather. Its appearance makes it an attractive variety in market, and there purchasers are often deceived when they find its good looks are not supported by good flavour. St. Peter’s, Gros Guillaume, and Black Morocco have been pitted against Lady Downe’s for late keeping, but it has outdistanced all comers, and horticulturists are deeply indebted to Mr. Thomson, Clovenfords, for reintroducing such a valuable variety when it appeared for some time to have been shelved.

Our means of keeping are a line of cupboards around the walls of our office with closely fitting doors, which answers well. Heat from hot-water pipes can be turned on at pleasure, but has been little needed during the past winter. We never found Grapes keep better than in a room at our disposal over stables, where Apples and Pears were kept in quantity, and there were no means of applying heat artificially.—M. T. C. H.

THE GHENT SHOW.

NEW PLANTS.—Reference to these was omitted from our report last week. They were not so numerous or so remarkable as one would have expected, and the classes, twelve in number, were poorly represented. In the principal class for twenty plants (flowering or non-flowering) there was but one collection, which was from M. L. Jacob-Makoy & Cie., Liège, who also showed in other classes for new plants most largely. The twenty plants consisted for the most part of fine-foliaged plants, the most noteworthy being Labisia Malouana, a Myrsinaceous plant, having large and rather broad leaves of a rich bronze green with a bright central band of silver. Another bright-foliaged plant was Aphelandra Louise, in the way of A. Leopoldi,

the leaves being broadly lanceolate, of a deep green marked with broad transverse lines of silver white. A noble Bromeliad named *Brocchinia Andreana* with broad leaves 3 or feet long was conspicuous in the group, as was also *Philodendron Corsinianum*, having huge leaves deeply lobed and of a rich bronzy green. *Nephtythis picturata*, just introduced from the Congo, having bold leaves with silvery variegation, was another ornamental Aroid. The rest of the collection was made up of *Alocasia Pucciana*, *A. Leopoldi*, *A. Lindenii*, *Encholirion roseum fol. variegatis*, *Curmeria Leopoldi*, *Croton Alexander III.* (not remarkable, being too much like older sorts), *Dieffenbachia gemmata*, *Canistrum leopardinum*, *Hoplophytum robustum variegatum*, *Pandanus D'Haenei* (very handsome foliage), *Anthurium leodiense*, *Phrynium variegatum*, *Eugenia oleaeoides elegans*, *Bismarckia nobilis* (a handsome Palm), *Dieffenbachia Kerchoveana*, *Caraguata Peacocki fol. rubra*, and *Pandanus Desmetiana*. The collection of six new plants also came from M. Jacob-Makoy. It included some of the foregoing plants, and *Inga Glazouviانا*, *Amomum vittatum*, and *Nidularium Makoyanum*.

In the class for ten plants recently put in commerce there was but one collection, M. W. Fr. Desbois & Cie, of Mont St. Amand. In this the most noteworthy were *Begonia Arthur Malet*, one of the Rex section, with large leaves of a deep claret purple, broadly zoned with violet purple; *Begonia heterophylla*; *Polygonatum multiflorum*, variegated Solomon's Seal, with silver veined leaves, very pretty; *Phytolacca decandra variegata*, *Adiantum schizophyllum*, *Dracæna Douceti*, *Phrynium variegatum*, *Begonia Louise Cluson*, *Epacris onosmæflora*, and *Pandanus Desmetianus*. The classes for single specimens of new plants were better represented.

The class for a new flowering plant was well contested. The highest award was taken by M. J. Hye-Leysen of Ghent for his remarkable new *Cypripedium Hyeianum*, a variety of *C. Lawrenceianum*, with flowers wholly bright green and white. It was considered one of the most remarkable plants in the Exhibition. It was shown in London last year. The second prize was taken by M. E. van Geert for *Begonia heterophylla*, the lovely New Holland plant, which has been shown in London by Messrs. Veitch this year in such perfection, while the third prize went to M. Jacob-Makoy & Cie. for *Vriesia chrysostachys*, a Bromeliad with a golden yellow flower spike.

The first prize for a new fine-foliage plant not having been exhibited before was taken by M. Edouard Pynaert van Geert, with the beautiful *Begonia Lubbersi*, which has medium-sized leaves of a deep bronzy green, adorned with bright silvery blotches. The same exhibitor also took the second and third prizes in this class, the second with the beautiful *Dichorisandra pubescens taniensis*, a plant reminding one of *Tradescantia zebrina*, but with the silvery and purple markings more clear and bright; the third with *Aloesia Chantrieri*, a handsome leaved Aroid. In the class for a specimen of a flowering stove plant obtained from seed and not before exhibited, was represented by M. Jacob-Makoy, who were first with their *Anthurium Makoyanum*, and a handsome variety with noble leaves and a bright coloured spathe. M. Pynaert van Geert took the second prize with *Begonia President de Boureuilles*, a hybrid with bronzy purple foliage, like that of *B. incarnata*, but with larger flowers of a delicate pink.

The only prize awarded for a new greenhouse plant raised from seed was taken by M. Gust, Gendbrugge, for his *Phormium tenax roseum pictum*, a variety of New Zealand Flax, with leaves of a bronzy rose tint. M. Ch. Vuylsteke of Loochristy was awarded the first and only prize for a new hardy plant, it being *Azalea mollis hybrida flore pleno*, an extremely pretty double-flowered variety of a rich flame colour. The above comprises the plants to which prizes were awarded, but many others of interest and value were shown. Among these we noted *Anthurium Desmetianum*, a form of *A. Andreanum*, with spathes of an intensely deep crimson, and *Nephrrolepis rufescens pinnatifida*, a new Fern, certificated in London; *Anthurium Lawrenceianum*, a fine variety of *Andreanum*, *Phlebodium aureum aleicorne*, with deeply lobed fronds; *Tillandsia Lindenii latispatha*, with the pink spathes broader than in the type; *Phlox decussata variegata*, with leaves broadly edged with creamy white; *Pteris cretica Mayi*, first shown in London; *Podocarpus gracilis*, a very graceful Conifer from Valparaiso; and *Dracæna argentea striata*.

THE NEWCASTLE-ON-TYNE SPRING SHOW.

THE Durham, Northumberland, and Newcastle-upon-Tyne Botanical and Horticultural Society held their twelfth Spring Exhibition on Wednesday and Thursday last, April 18th and 19th, in the Town Hall and Corn Exchange, Newcastle-on-Tyne. The above Society was formed in 1824, and ranks as one of the oldest in England, and within the last dozen years has made rapid progress, keeping pace with the best horticultural shows in the United Kingdom. A business Secretary and an indefatigable Committee are always necessary to success, and in this respect the above Society is exceptionally fortunate in possessing. The late season in the north was considered to somewhat mar the prospects of the Spring Exhibition, which has annually increased in merit since its commencement. Happily, however, this was not the case. The Hyacinths have never been better nor more numerous. Azaleas were also excellent examples of good culture. The flowering plants were good, but not so numerous as in previous years. Spiræas, Lily of the Valley, Deutzias, Genistas and other spring blooming plants were shown in great numbers, and were all examples of good culture, and afforded much pleasure to the numerous visitors who attended the Exhibition. The plants were all exhibited in the Corn Exchange, and the staircase leading to the Town Hall was a point of vantage, where a

pleasing *coup d'œil* of the Exhibition could be obtained. The Show was well arranged. There were three lines at the base of Cinerarias; next were Spiræas, and at the top were plants of *Dielytra spectabilis*. These arranged above each other had a most pleasing effect. Amongst the Azaleas, at intervals, large Palms were arranged. The Hyacinths were arranged on stages 4 to 5 feet high, which were easily seen by the visitors. Sufficient width of paths was left between the rows of plants that all could be seen easily. In fact, never on any previous occasion has the arrangement been so complete as it was this time. Appended is a list of the awards, with the names of the principal plants and remarks on their cultural merits.

For four plants, dissimilar, the Society offered £11 in four prizes. The first was won by Mr. F. C. Ford, gardener to Mr. S. H. Pease, Pierremont, Darlington, the plants being an excellent *Erica Victoria Regina*, well flowered; *Tremandra verticillata*, an average *Clerodendron Balfourianum*, and *Aphelexis macrantha*. Mr. A. Methven, gardener to E. Lange, Esq., Heathfield House, Low Fell, was second with an *Imantophyllum*, having fourteen spikes and thirty-one flowers on each spike, well coloured; in fact, a marvellous plant, along with a *Phaius grandifolius* with nineteen spikes, and *Erica affinis*. Mr. Ed. Adams, Swalwell, was third, and showed some good *Ericas*. For four Azaleas, *indica*, dissimilar, Mr. J. McIntyre, gardener to Mr. G. Pease, Darlington, was first with fine plants, evenly trained and well flowered; they were *Azalea superba*, *Mdme. Jules Lefebvre*, *Souvenirs de Madame Purdeplabel* and *Oswald de Kerchove*; Mr. J. Short, gardener to Arthur Pease, Esq., Hummersknott, Darlington, being second, his best plants were *Azalea Stella* and *Duc de Nassau*; Mr. Methven was third, and the same exhibitor first in the corresponding division for two Azaleas, which were very good, of *Comtesse de Flandres* and *Duc de Nassau*. The Society offered £3 10s. for three Orchids, which only brought two competitors, and it might be suggested that at an exhibition like this it would be well to offer larger prizes for Orchids, as at this time there are many in bloom, which make a great addition to an exhibition. Mr. A. Methven was first for three with *Dendrobium nobile*, a fine plant, *Cypripedium Boxalli*, and *Dendrobium thyrsoflorum* with seven spikes. Mr. McIntyre was second with *Cattleya Mendelli* with two spikes, *Dendrobium thyrsoflorum*, and *Oncidium flexuosum*. Mr. Methven, for a Palm or Tree Fern, was first with *Kentia Fosteriana* very fine. With *Dielytra spectabilis* Mr. Joseph Runton, gardener to Thos. Hodgkin, Esq., Benwell Dene, was first with bright plants and healthy foliage. First prizes were also won by the following:—For Genistas, Mr. Geo. Corbett, Benwell; for Spiræas, Mr. John McIntyre, Sunderland; for Cinerarias, Mr. James Forsyth, Sunderland; for six Primulas, Mr. F. Jackson, gardener to Alderman Scott, Newcastle; and for six Cyclamens, Mr. McIntyre.

For six pots of Lily of the Valley Mr. Jos. Runton was first. All these usual spring blooming plants merit an extra word of praise, as never have they been shown better than this year. For six hardy Primulas Mr. W. L. Thompson, gardener to C. S. Bell, Esq., Woolington, was first. It is always a treat to meet these old favourites. With six pots of Scillas Mr. Runton was also first, and for table plants Mr. McIntyre was first with *Aralia Veitchi*, *Croton aigburthensis*, *Dracæna superba*, and *Geonoma gracilis*. There were in these decorative plants rather a falling off this year. A new feature this year was a prize for Strawberries in pots. Mr. J. Short, Darlington, was first apparently with Keen's Seedling.

For twelve Auriculas Mr. H. Whiting, Killingworth, was first with Frank Simonite, eight pips; Mr. Douglas, three pips; Bizarre Heather Bell, George Lightbody, and Heroine. The varieties Heroine and Mr. Douglas must have greatly influenced the Judges. Mr. E. Oliver, Forest Lodge, was second with fine plants of Col. Champneys and George Lightbody, &c. Mr. Robt. Patterson, Ashburne Gardens, Sunderland, was third, his best flowers being George Lightbody and Ben Simonite. There were six competitors. For six and four dissimilar (Alpines excluded) Mr. W. L. Thompson was first. With green-edged and grey-edged Auriculas Mr. Atkinson and Mr. Oliver were first and second respectively. For twelve Alpines Mr. Jos. Watson, nurseryman, Fenham, was first with Col. Scott, Diadem, King of the Belgians, Slough Rival, and Dolly Varden. For six Polyanthuses Mr. E. Adams was first with Queen of Tyne and Buck's George.

Seven collections of twenty-four Hyacinths were staged, all possessing cultural merits. Messrs. H. Dewar & Co., nurserymen, were first with some magnificent spikes, including *Grandeur à Merveille*, Lord Derby, Koh-i-noor, King of the Blues (splendid), La Grandesse, Lord Derby, and The Sultan. The silver medal of the Royal Horticultural Society was also granted for this collection. Mr. Jos. Watson, nurseryman, Fenham, was second with excellent plants, including Von Schiller, Fabiola, and Blondin. Mr. Ed. Laidlow, Roker Nursery, was a good third. For twelve Mr. Jos. Watson was first, Gigantea, Koh-i-noor, Mont Blanc, and King of the Blues being fine. In the corresponding class for twelve Hyacinths Mr. Runton was first with grand flowers of Von Schiller, Florence Nightingale, Blondin, Lord Derby, and King of the Blues. The Hyacinths extended all down one side of the hall, and were very attractive to many visitors. There were five lots of twelves staged. For nine pots of single Tulips Mr. Atkinson was first with the usual varieties, and for doubles Mr. James Wood, gardener to H. N. Middleton, Esq., Fenham Hall. For Polyanthus Mr. Jos. Watson was first.

Cut Flowers and Table Decorations.—For twelve Camellias first Mr. James Wood with *Alba plena*, Jubilee, Imbricata, Wilderi, and others. For twelve bunches of Rhododendrons Mr. F. C. Ford was first with fine heads, but they were unnamed. Azaleas were also the same. Mr. J.

Short was first. For Roses Mr. J. Garrett, Stockfield, was first. For Show Pansies Mr. Thos. Battensby, Axwell Park, was first, and for Fancies Mr. E. Bailey, Sunderland, was first. Seven epergnes were staged, which were all exceedingly tasteful in their arrangement. Mr. W. R. Armstrong, florist, Newcastle, was first with a graceful epergne. In the top tier was *Dendrobium nobile*, *Spiraeas*, light *Epaeerises*, Lily of the Valley, and *Lapageria rosea* and *alba*, drooping over, suspended by wire. The base was not too heavy, evenly balanced with coloured flowers, and all from the top tier draped with *Asparagus plumosus*. Mr. A. Methven was second, and employed with much effect Orchids, consisting of *Cattleya Mossiæ*, *Dendrobium Wardianum*, *Odontoglossum Alexandræ*, and *Sobralia macrantha*. Mr. Dickerson, Thirlwell, Shotley Bridge, was third. Much comment was expressed at the decision of the Judges. In the corresponding class Mr. A. Methven was first; Mr. Thos. Battensby second with similar arrangements to those already described. Table decorations form a considerable feature at the Spring Exhibition. In this class six competed, and in the other seven.

With a hand bouquet Messrs. W. Perkins & Son, Coventry, were first; Miss Emily Armstrong, Newcastle, second with tasteful arrangements, but rather large for any lady to carry. Messrs. Perkins & Son were also first with a bridal bouquet. Ladies' sprays or coiffeurs are new to Newcastle, but produced a most spirited competition, Messrs. Perkins taking the first position. Of buttonhole bouquets about thirty were staged. Mr. James Hewitt, Newcastle, was first with a simple arrangement, consisting of *Maréchal Niel* Rose, *Myosotis*, and *Euphorbia splendens*. Not for competition were stands of decorative plants from Messrs. Wm. Fell & Co., Hexham; Adamson Bros., florists, Rye Hill; J. Jennings, George Place, Newcastle; and Mr. Thos. S. Ware, Hale Farm Nurseries, Tottenham, exhibited a splendid collection of *Narcissuses*, including twenty-eight varieties, 146 bunches, and occupied a space 40 feet long. *Bicolor Horsfieldi*, *Pallidus præcox*, *Citrinus incomparabilis*, *auratus fl.-pl.*, *Cernuus*, and *Cernuus plenus*, *Maximus*, *Sir Watkin*, *Odorus*, and *Lineolnshire Yellow*.

The financial success has been greater than ever was known before, the sum realised for the two days being £223, which must be gratifying to the Secretary, Mr. Gillespie, and the Treasurer, Alderman Thos. Gray, and Committee.

JAPANESE REFLEXED CHRYSANTHEMUMS.

THE long-talked-of division of the Japanese into sections has at last been accomplished, at least as far as one sub-section is concerned; and as prizes are offered by the N.C.S. for blooms of these in a separate class at the November Exhibition the sub-Committee appointed have done well to publish the names of the varieties that have obtained the majority of votes. Many different opinions will no doubt prevail on this subject, and surprise be evinced to see the varieties *Jeanne Délaux*, *Criterion*, and *Val d'Andorre* included in the list. It is certainly difficult in some cases to know where to draw the line at a reflexed Japanese, weak or strong cultivation making all the difference in some of them; but after this experiment I should like to see other subdivisions attempted another year, and prizes offered for twelve broad petalled varieties, which would include such as *Comte de Germiny*, *Edwin Molyneux*, *C. Orchard*, *Sam Henshaw*, *Lady Lawrence*, *Mrs. H. Cannell*, and *Mrs. Wheeler*, *Japonaise*, *Madame C. Audiguier*, *Mr. Cannell*, &c.; and for twelve lacinated varieties, which would include those with divided florets, as *Meg Merrilies*, *Ralph Brocklebank*, *W. G. Drover*, *Macauley*, *Laciniatum*, and *Album Fimbriatum*; and also for twelve with tasselled or twisted florets, which would include *Mdlle. Lacroix*, *Agrement de la Nature*, *Mons. H. Elliott*, *Duke of Berwick*, *Mrs. Mahood*, and *Belle Paule*. The type of the reflexed Japanese, I think, should be varieties with short but regular reflexing or erect florets, which do not twist or curl; *Elaine*, *Triomphe du Nord*, and *La Nymphe* are good types of the old varieties, but there are many of the newer varieties which when they became better known would be included in this section, varieties with lovely tints and shades of colour which would be lost to cultivation if the competition was always confined to the one section, as now, when large flowers that well cover the board is the chief aim. It is for this reason that I look with favour on this sub-division of the Japanese section, and the four sections I have named would include nearly all the types, but the larger classes would of course always retain the doubtful ones; but there need be no disqualification of varieties. Exhibitors should be allowed to exercise their own judgment, and those that come nearest to the stipulations would of course be considered the most meritorious. It might be considered a tax on private growers to cultivate so many varieties, but the trade, which includes many more exhibitors than formerly, would look after the sub-sections if private growers could not, and in consequence many more beautiful varieties which would be highly prized by the flower-loving public, and grown as decorative varieties on account of their distinct character and colour, would be

brought under public notice than would otherwise be if competition is confined to the larger varieties only.—C. ORCHARD.

THE list of these *Chrysanthemums* which was published in the last issue of the Journal will cause some comment, and perhaps some confusion. Take for instance *Jeanne Délaux*, *Criterion*, *M. Astorg*, and *Val d'Andorre*. These by the list given are admissible in the new class, and can, of course, be shown in the ordinary Japanese class as well. The sorts named are very likely indeed to be found good enough to go into the twelve distinct varieties of Japanese in the large class at Sheffield. Now the question is, Would either of those named be admissible in the class quoted? We have then one variety, possibly more, staged three times in one class. There is no reason why this should not be done. I think this is where the confusion is likely to occur; some growers will think they are admissible, and others not. My opinion is that if a Japanese reflexed class were wanted at all the varieties should be so arranged that they could only be shown in that class. I fail to see how *Val d'Andorre*, for instance, can be classed with *Elaine* with a view to make a distinct stand of Japanese reflexed. Take again *Criterion*, which was awarded the premier prize for Japanese variety last year at Kingston, and is staged in nearly all stands, large or small, in ordinary Japanese classes.

If the list as given is to be binding it should be stated whether or not the same variety can be staged in the same class in both the Japanese and Japanese reflexed sections. This would be a guide to all persons concerned who intend to exhibit or who do not. By this means matters would be simplified.—A YORKSHIREMAN.

[It was clearly stated last week that "the varieties named as Japanese reflexed are only excluded from the true reflexed class, they can be shown in all the Japanese classes as before." This rule was adopted to prevent the confusion our correspondent fears.]

THE Committee of the N.C.S. acted wisely in issuing the select list of the Japanese reflexed *Chrysanthemums*, and that has placed the matter before intending exhibitors as plainly as possible. The majority will find the first twelve varieties sufficient, and I shall try to make up a stand from them for one of the Society's shows.—A SURREY GROWER.

LATE FLOWERS OF BELLE PAULE.

I HAVE sent two blooms of *Belle Paule* *Chrysanthemum* with various sized buds for you to notice, not for exhibitions, but as a late-flowering variety. The cutting I had from Mr. Cannell was inserted on February 8th, 1887. The plant commenced flowering in the early part of December with good blooms, and has continued flowering ever since. We have thirty blooms open and various sized buds. The plant is in a 9-inch pot, and the stem at the base is 4 inches round.—W. DRAY.

[The blooms sent were rather darker in colour than they are usually seen earlier in the year, with the purplish hue not confined to the margin of the florets. They are of moderate size, and undoubtedly useful at this time of year.]

CHRYSANTHEMUMS IN APRIL.

I RECEIVED a few days since, by the courtesy of my friend Mr. Kipling of Knebworth, a box of *Chrysanthemum* blooms, which have, I confess, fairly astonished me both in regard to their size, quality, freshness, colour, and general excellence. I have long shared the oft-expressed opinion that we do not require *Chrysanthemums* at this season of the year, and that after, say February, they should be eliminated from our lists of cut flowers until September, even then giving the autumn queen a full six-months reign. With these lovely flowers, however, before me, I am compelled to acknowledge that they would be a valuable acquisition at any period of the year, and for table decoration especially. I write now, not as an over-zealous enthusiast, but simply as one who recognises the value of good and suitable flowers of any sort. I venture to say that any decorative florist would endorse my views in regard to the usefulness and beauty of these flowers, and no matter what season of the year, would look upon them as an acquisition.

The varieties principally are *Belle Paule*, *Etoile du Midi*, *Kämpfer*, and *Madame Cabrol*. Mr. Kipling gives the preference to *Belle Paule* for freeness, sureness, and general adaptability for late cutting, and certainly the flowers of that variety he sends me fairly warrant his opinions. They are not pale as might be supposed, but have a high flush of colour on each petal. The florets are stiff and have a good substance, and although they are grown naturally, and so have four or five flowers on a truss, the leading flowers are 5 inches over with good full centres. The varieties sent form a complete bouquet in themselves, in colours from the deep bright crimson of *MM. Thibaut et Keteleer*, or some very similar variety, to *Belle Paule*'s rosy purple hue, and to the orange and amber of *Etoile du Midi* and *Kämpfer*, &c., a truly lovely contrast.

Mr. Kipling has achieved much in the production of these blooms, and it would be most interesting to know his exact procedure. He informs me he has up to this date sent a box of similar flowers to Paris each week for Lady Lytton, who is a great admirer of *Chrysanthemums* and a patroness of our N.C.S., and that from the present condition of his plants he considers it as almost a certainty that he will continue to cut a similar supply until the summer sorts show colour, thus spanning the whole twelve months with cut *Chrysanthemums*, a truly remarkable achievement for any single establishment.—WILLIAM HOLMES, Hon. Sec. National *Chrysanthemum Society*.

HARDY FRUIT GARDEN.

SUMMER-PLANTED STRAWBERRIES.—Last summer the runners were both late and weak, and as a consequence those permanently planted did not make nearly so good a start as usual, the season from beginning to end being most unfavourable to Strawberries. In some instances the plants may be sufficiently strong to produce an early crop of fine fruit, but as a rule they ought not to be allowed to bear any this season, all bloom being pinched out as soon as possible; this will encourage the plants to grow strongly, and ought to lead to the production of extra heavy crops next season. The frequent and severe frosts experienced last winter had the effect of much loosening the ground, and as a loose rich root run favours the growth of leaves rather than of good crops of fruit, it is advisable to well trample it again, more especially close to the plants. This refixing of the plants in the soil is necessary whether they are to be fruited this season or not. It ought to be a very difficult matter to push a stake into a Strawberry bed, and where the soil of established beds is at all loose a heavy trampling will prove beneficial. This should be done in dry weather, and be followed with a light surface stirring with flat hoes.

FORMING AND CROPPING NEW STRAWBERRY BEDS.—The spring is a good time to form fresh beds, the young plants transplanting readily with a trowel from the beds in which they were thickly dibbled last summer or autumn. Either new or old varieties can also be obtained from the nurseries, and if such novelties as Laxton's Noble, Captain, Jubilee, and King of the Earlies are procured and well attended to, a few good runners may be obtained from most of the plants. The best of the old varieties are Vicomtesse Hericart de Thury, Keen's Seedling, Sir J. Paxton, President, Dr. Hogg, Sir C. Napier, Traveller, Loxford Hall Seedling, and Eleanor. All of these are of fairly vigorous habit, and may be planted in rows 30 inches apart, a distance of 18 inches dividing the plants in the rows. They require well manured deeply dug ground, should be firmly planted and watered in. A piece of ground well prepared for Onions would just suit Strawberries, and there is no reason why the latter should not be planted among the former as soon as these show through the ground. Three rows of spring-sown Onions might be grown in every space between the Strawberries, or two rows of Tripolis may be planted. Lettuces, Spinach, Kidney Beans, or Turnips may also be grown among either summer or spring-planted Strawberries, provided the latter are not overgrown in any way.

MULCHING AND MANURING STRAWBERRIES.—An early mulching of fresh and not very strawy manure ought always to be given established Strawberry plants. When applied before hot and dry weather sets in much of the fertilising portion of the manure is washed down to the roots, and the mulching further serves to keep the ground cool and moist, which it is almost needless to add are important factors in the perfecting of good crops. In many instances, or where the ground is partially exhausted, a surfacing of either guano, bonemeal, or some kind of advertised artificial manure, and failing either of these, soot, ought, prior to mulching, to be given and well stirred in with a flat hoe. A large quantity is not needed, a sprinkling only of the strong manures being given, but the ground may well be coated over with soot. Now is also a good time to commence applying liquid manure or sewage, this only being of real benefit to the plants while the ground is in a moist state. Growers for market manure and mulch early, strawy manure being used for the latter purpose, the surface of this eventually becoming washed clean enough for the fruit to rest upon; but in most private places a fresh surfacing may well be given later on, or before the fruits are far advanced in growth.

THINNING FRUIT BUDS.—Where the birds have not had too much of their own way there is abundance of bloom on nearly all the fruit trees. It does not follow, however, that extra heavy crops of fruit will set; but on the contrary, it is no unusual occurrence to see the promise of a heavy crop unfulfilled. A tree may be literally smothered with bloom, and yet no crop worthy of the name be obtained, this being in many cases simply the result of exhaustion. All the tree's energies are wasted on the development of the flowers. The strain put upon the trees during the process of forming pollen is too much for them, and they are unprepared to meet the still severer task of perfecting seeds. A timely thinning out of the fruit buds in many cases is absolutely necessary. Nothing is gained by leaving all to open, as the frosts usually destroy all the best flowers or none. Pears are especially floriferous this season, and in numerous instances at least one half of the buds may be well removed at once. The Jargonelle rarely produces too many buds, but as these develop into large bunches of bloom, the latter may with advantage be freely thinned out, the central flower being invariably followed by the most perfect fruit. Williams' Bon Chrétien, Marie Louise, Doyenné du Comice, Easter Beurré, Winter Nelis, and Glou Morceau are especially in need of thinning out this season, there being three times more buds than are needed. Large bush Apple trees cannot well be thinned out, but miniatures or those on the dwarfing stock will pay for it. Cherries, Plums, Apricots, Peaches,

and Nectarines all are too thickly covered with flowers, and the thinning out ought not to be delayed till the fruits commence swelling.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—Alexander ripens from the middle of April in a house to which fire heat is applied at the commencement of December. It is large and rich in colour. Waterloo also ripens with it, is large, and of good colour, but unfortunately a clingstone. Early Beatrice follows, and is a good Peach, and Early Louise and Early Rivers are liable to crack at the stone, which may be mitigated by fertilisation with pollen from other varieties. Early Rivers is a large pale fruit, and particularly rich in flavour. Hale's Early, Early Alfred, and Early York will form the connecting link between the very early varieties and such standard varieties as Royal George (Stirling Castle is a very fine form of Royal George), Grosse Mignonne, &c., which are several weeks later in ripening, there being six weeks between Alexander and Royal George. Hunt's Tawny and Lord Napier Nectarines form an admirable prelude to Elruge and Violette Hâtive, and a good succession may be secured in one house, the only change in the treatment being in not syringing such as have commenced ripening. Trees on which the fruit is ripening must have the foliage and fruit kept dry, but the border must not be allowed to become very dry, or it will act injuriously upon the growth and affect the maturity of the buds for future bearing. As the fruit of the other varieties will not be ripe for some time yet, the atmosphere must be kept moist by frequently sprinkling during the day, syringing the trees in the morning, and again when closing the house. The night temperature will be perfectly safe at 65° to 70°, but 5° less, though it will retard the ripening, will not tax the energies of the trees so much as the higher temperatures. Leaving the ventilators slightly open constantly at the upper part of the house will be an advantage. In the daytime 70° to 75° by artificial means, and 10° to 15° more with sun heat, will be suitable temperatures.

Trees Stoning.—Do not hurry trees undergoing this process, 60° to 65° at night is ample, and 70° to 75° by day, avoiding high night temperatures and sudden fluctuations by carefully attending to ventilation. A little air left on at night will prevent the deposition of moisture on the foliage through the night to any serious extent, and enlarge the openings when the sun acts on the house, yet without lowering the temperature, which should advance with the increased power of the sun and a corresponding increase of ventilation. Avoid, if possible, fumigating. It dries the atmosphere and not unfrequently cripples the foliage, when the fruit may from the check be seriously imperilled and fall. Early closing is an advantage, but it must not be done to the extent of undue excitement, nor continued until late, the temperature being allowed to fall with the declining sun. It is also advisable to allow a little extra latitude to the growth, but on no account allow foliage to be developed that must afterwards be removed in quantity.

Trees Swelling their Fruits.—There are two distinct periods during which the fruit swells most freely—viz., after setting until the commencement of the stoning process, and after stoning. The first is materially accelerated by a genial condition of the atmosphere, and the means employed to secure a good root action, which is best effected by a judicious and gradual regulation of the growth by the process of disbudding and in thinning the fruits. Overcrowding is a great evil, but large reductions of growth at one time, as well as of fruit, are not good. There is no safety save in a steady progress and careful disbudding. The more vigorous the tree the greater is the danger of the fruit being cast in stoning, and the evil is afterwards accelerated by severe disbudding. In the last swelling after stoning the shoots should be well tied down, so that the fruit may have the benefit of all the light possible, but a moderate extension of growth will materially assist the fruit in swelling, care being taken that the principal foliage and fruit be not interfered with. Supply water thoroughly to inside borders when necessary, and weakly trees should receive liquid manure.

FIGS.—*Earliest Forced Trees in Pots.*—The fruit will now be ripe or nearly so, hence the supply of water at the roots must be diminished, syringing being discontinued, and a free circulation of warm air afforded, leaving the top ventilators open a little at night. Although watering is advised to be lessened during the ripening of the fruit the soil must be kept moist, and a moderate moisture in the atmosphere secured by an occasional damping of available surface, but this will only be necessary in very bright weather. As soon as the first crop is gathered syringe the trees twice daily, renewing the top-dressing, and watering at the roots with weak liquid manure. If the second crop of fruit be very abundant they must be thinned out, so as not to overtax the trees for early forcing next season.

Early-forced Planted-out Trees.—The fruit will soon commence ripening, when the border must be examined, and if necessary given a thorough supply of water or liquid manure. Cease syringing the trees when the fruit commences ripening, avoiding a superabundance of moisture about the house, having a little ventilation at the top of the house constantly, and a free circulation until the fruit is all gathered. Do not gather the fruit until it is thoroughly ripe unless it has to be packed.

Succession Houses.—Frequent attention must be given to stopping the shoots at the fifth joint, and subsequently to one or two, but too many side shoots must not be encouraged, as the fruit and wood require light and air for its maturation. Train extensions in their full length, thinning or removing strong growths so as to admit light and air to the

fruit. Attend daily to syringing the trees, and supply water as necessary to maintain thorough moisture at the roots. Renew the mulching if necessary, and keep it moist so as to encourage the roots to and keep them at the surface.

CHERRY HOUSE.—When the stoning is complete the fruit will commence colouring. The temperature must not exceed 65° by artificial means, and 55° to 60° at night, with a little ventilation, increasing it at 70°, and not allowing the heat to rise above 75° without full ventilation, closing at 70°. subject to the leaving of a little air on constantly at the top of the house. From the commencement of colouring until the trees are cleared of the fruit syringing must cease, or the fruit will crack, but a good moisture should be maintained in the house by keeping the surface of the border moist, or if the trees are in pots damping the floors, &c., two or three times a day, avoiding, however, a stagnant atmosphere. Aphides must be kept under by fumigation, their presence for any length of time disfigures the fruit. See that the borders do not want water, and liquid manure should be liberally applied to trees in pots.

PLANT HOUSES.

Stephanotis floribunda.—If a mass of bloom is required, it is a mistake to grow this plant too warm. In a close moist atmosphere the shoots extend rapidly, but are the reverse of short-jointed, and often fail to flower from every joint. If grown from the present time in a night temperature of 60°, with a rise of 10° by day, with a good circulation of air and the shoots fully exposed to the sun, the wood will be firm, short-jointed, and the plant in due time will be covered with flowers. Train the shoots carefully under the roof to thin cords. If tied to the trellis amongst the old wood and foliage they are too shaded to flower profusely from every joint. Where this system cannot be practised and the growths must be trained amongst the old wood on the trellis, they should be pinched rather than allow them to crowd one another after they have shown a good number of blooms. The flowers by this system come forward more rapidly than is the case if the shoots are allowed to extend; it also gives the growths in a backward state a chance to extend.

Bougainvillea glabra.—Do not tie down the shoots of this plant, but allow them every liberty until their bracts are fairly developed. When they reach this stage they can be evenly disposed over the trellis and fully expanded under cooler and more airy conditions, which result in the flowers possessing more colour and substance. Grow this plant in its various stages fully exposed to the sun. Air must also be admitted whenever the weather is favourable. Plants that are full of roots may be fed with weak stimulants every time water is needed.

Clerodendron Balfourianum.—Transfer young plants into 6-inch pots that were rooted early in the year, and which are now well established in 3 and 4-inch pots. After potting stand them where the shoots can be trained under the roof of a plant stove. They must be fully exposed to the sun, and by autumn they will have ripened shoots fully 10 or 12 feet in length. When the 6-inch pots are full of roots feed liberally, so that the young plants will attain as great a strength as possible. Plants that were grown in this way last year and trained round fine stakes inserted near the sides of the pots will now be breaking freely into growth. Bring them forward in an intermediate temperature, so that by the time they come into flower they will be sufficiently hardy to bear the temperature of the conservatory without injury. Well grown plants treated as described will be masses of bloom, and they prove strikingly effective for conservatory decoration in early summer. After the plants have flowered they can be thrown away, unless it is deemed prudent to grow on a portion into a larger size. But when plants are raised annually there is no necessity to retain two-year-old plants.

Clerodendron fallax.—Seedlings that are large enough for potting may be placed in 3-inch pots. Sow seed to provide plants for flowering in 5 and 6-inch pots during November and December. The bright scarlet flowers of these plants are most useful during these months, and render the stove or intermediate structures very attractive. It is a mistake to raise the plants required for this purpose too early, for they cannot well be retarded, and if the centre is removed with the object of delaying the flowering season for a time the heads of bloom produced are small. If too early, however, pinch them at once, and if strongly developed each shoot will produce a good head of bloom. Some of the earliest plants are very useful for supplying the necessary seed for another year.

Clerodendron fragrans.—Where this sweet-scented variety is appreciated either in a cut state or in small pots for various forms of decoration cuttings should be inserted at once. To maintain a good supply cuttings may be inserted at intervals of a month, singly, in 3-inch pots, a good size in which to flower them. If this variety is given too much room it will grow rapidly and strongly, but fail to flower. If confined in the pots advised every plant will produce good heads of bloom, and will vary from 6 to 9 inches in height. For cutting only a few may be grown on, which will flower freely enough after the pots become crowded with roots. Cuttings strike freely in the propagating frame, and do well in a compost of loam, sand, and one-seventh of manure.

Achimenes.—Good cuttings will now be plentiful, and more plants may be raised by inserting shoots in light sandy soil in 5-inch pots. They will root freely enough under the shade of Cucumbers and Melons, provided too much water is not allowed to fall upon them. The earliest will be better in an intermediate than in a stove temperature. They do not run up so quickly, and will by the time they are in full bloom be ready for the conservatory. If a few are wanted for the stove,

allow them to advance in moderate heat. Baskets that have been made up by the insertion of tubers after they were started, are improved by having the whole of the tops taken off; these will do for insertion in pots. This treatment induces the plants to start freely from the base, and four or five strong flowering shoots in the place of one is the result. These plants must not be syringed, and the bright rays of the sun should be shaded from them.

Lily of the Valley.—Plants that are intended to flower during November and have been grown since they flowered in a temperature of 50° to 55° may be placed at once in a cold frame in a sunny position. Harden them gradually and water them liberally. They should be protected in frames until the second week of May, when they may be plunged outside.

THE BEE-KEEPER.

BEES IN APRIL.

THE month of "sunshine and showers" has come in and brought with it a pleasant change. Balmy breezes and gentle rain with now and then a gleam of the daily growing more powerful sun are causing Nature to wake once more from slumber and to bud forth with pleasing variety of life verdure and flowers. An early opportunity was taken in most apiaries—if attention has been paid to the teaching often inculcated and sometimes followed—of examining every stock. We ventured to prognosticate that the past winter had been on the whole conservative of bee life, and this appears to have been the case, for on examining our stocks to-day we found that all were alive, and that the food consumption had, as far as it was possible to judge, been less than usual, this being due, no doubt, to the length of the winter and the small amount of brood hitherto reared.

The first stock examined had passed through the winter packed in the following manner. Immediately after the completion of extracting last summer an upper tier of frames was placed upon the body hive for the bees to clean out preparatory to storing them in readiness for the then future spring. Owing, however, to a press of work these empty frames were never removed, but a piece of ticking and three thicknesses of carpet were placed upon the top; the outer case was then put over all, and so it stood, except that a considerable amount of covering was added about six weeks ago, until to-day, when this upper tier was removed and the state of the stock was thoroughly examined. The honey in the body hive is liquid and far from being exhausted, while the bees are numerous, bright, and active, working eagerly in the adjacent Willow beds at every suitable time.

The second stock was treated in a different way, and ought to have died out long ago and all the honey left have granulated, if the teaching of a certain school of bee-keeping must be accepted. This hive consisted of thirteen frames, each comb containing some honey, and the six outside ones being completely filled. The bees were never very numerous, but came from a strain which have been remarkably strong workers, and have shown other desirable traits of character. On opening the stock and removing the outside combs we found that the honey was liquid and in grand condition, and on examining further the bees were found to be in good condition, and with every probability of working into a strong stock in a short time. And yet they ought to have died, being in a roomy hive and with slabs of ice-like honeycomb on either side, but they lived; indeed the loss of life has been small, the consumption of honey very little, and the condition of the honey in the outside frames excellent. Could they have passed through the ordeal better had the hive been reduced to a few frames only? Would they have wintered as well? The top covering was again ticking and carpet.

A large skep, managed entirely on the warm system, being well packed both at the top and sides, is doing well, but has certainly shown an inclination to fly at times when the other stocks have been quiet and content to stay at home and wait. A stock covered with American enamel cloth has—although we hardly expected

that it would be so—prospered, and is certainly in a forward condition. It is scarcely necessary to enter into further detail, because, as far as it is possible to judge, stocks properly cared for in autumn and well supplied with food seem, notwithstanding considerable variety of conditions, to pass safely through an English winter, provided that the bees are numerous. No queens have yet given out, nor do we expect any mishap, although it is too soon to say that we are “out of the wood.” This thorough examination having been made, the presence of a fertile queen, a sufficiency of food—without too many cells being occupied with honey and pollen—and an addition having been made to the covering in all cases; what, it may be asked, will be done next? Nothing in particular, we reply, except to watch and gradually enlarge every hive until the honey season begins, when supering arrangements will at once have attention. If any stock seems to be making small progress a few cells of honey may occasionally be uncapped, and possibly a frame or two of brood may later on be taken from one stock and added to another. If it is necessary to hurry on the bees and to arrive at the supering point earlier than would be the case if this let-well-alone policy were strictly carried out dribblets of syrup will be administered daily, but—not if it can be avoided.

Those who, in these first delicious days of the year fast growing to maturity have smelt the sweet smell of a strong stock, have had a joy for ever. Their enthusiasm is once more aroused—not the fever-like enthusiasm of a novice taking up a new hobby, but the deep-lying love for his bees which every true bee-keeper must experience. Our friendly readers will pardon perhaps this slight digression from the more practical side, but occasionally the feeling of intense love for bees and Nature wells up in irresistible force and cannot be stayed by the comparatively dry barriers of endeavouring to write for the instruction of others and for self-improvement.

In many apiaries there is now a great deal of “business” being done, hives being constantly opened and various manipulations being continually undertaken. If the bee-keeper will use a few grains of common sense he can hardly fail to see that every work done in the apiary must either be useful or harmful; we may tell him that a young bee-keeper generally does about ten times more work for every stock than is either useful, necessary, or profitable. Above all we must guard the novice, and—tell it not in Gath—a few of the older members of the craft, that “procrastination” is fatal. If work must be done let it be done at once, and well done; if work is not necessary it is neither useful or profitable; and if it is neither useful or profitable, only an amateur with nothing better to do, or a practical bee-keeper who desires to experiment, will undertake it.—FELIX.

INTRODUCING VIRGIN QUEENS.

SEVERAL times I have stated that I could introduce these without risk of failure, and I have also promised in these pages to tell how I do it; therefore I propose in this article to redeem that promise, and make this problem, which has been the greatest trouble to bee-keepers for more than a generation, clear and certain.

Like the introduction of fertile queens, there has been a little truth and a little error always mixed, and there have been so many assertions and counter assertions, that I had to trace the matter carefully, a work extending over several years, and which I did not finish till last season, so difficult and intricate was it, and yet now it is done there is nothing new in it; in fact the only thing I can claim as “new” is the determination of the causes of failure and success, and placing the matter on a scientific basis.

All people who have done any queen-rearing know that queenless bees will readily accept a virgin queen that has just hatched and has not mixed with any other bees, while if she has they never can succeed to enthrone one. Most assert that the queen is killed. Mr. J. E. Pond, jun., says the reception of queens is consequent on their behaviour. If they make themselves at home they are accepted; if they are alarmed then they are balled. In effect he is correct in this surmise, as if a stock of bees is selected that has long been queenless, with no means of rearing a new mother, and a virgin queen several days old be dropped in during

the daytime, the entrance being carefully watched, she will quickly be seen to run out in the greatest alarm. I am not aware that anyone has ever previously noted this fact. Now take this queen and drop her amongst queenless bees that have the means of rearing a successor, and she will remain in the hive, but on opening it she will be found firmly balled. Here we see in the first case the bees were willing to accept her, but she was too frightened to stay; in the second her behaviour insured her being balled. That such was the case may be proved by presenting to the same bees a queen just hatched, which will at once be accepted.

To understand this we must remember what Mr. Bonner Chambers tells us to do—viz., consider what is the habit or custom of bees and queens in a state of Nature. By reflecting a little we shall see that when a queen hatches it is her habit to make herself at home with the bees she emerges amongst; and after having done so it is not the habit of any virgin queen to voluntarily go to another hive, nor is it the custom of a stock of bees to be visited by such a queen. Then, again, it is the invariable custom of just-hatched virgin queens as soon as they eat a little honey—which they always have to get themselves from some cell—to run over the combs in search of other queen cells, all of which they ruthlessly destroy. A fertilised queen, on the other hand be it noted, does not destroy queen cells until the enclosed larvæ has been transformed to nymphs, nor does she have occasion to get food herself; thus the natures of the two classes of queens are different.

Let us now consider (since queens never change their hives until they have mated) what takes place in a hive that has lost its queen—say from swarming or death. If from swarming, then sealed queen cells, brood of all ages, and eggs are left, and before these are too old to be developed into queens a virgin queen hatches out and introduces herself to the bees with the greatest assurance; and if the stock is too weak to throw a second swarm she at once destroys all the other royal cells, whether sealed or not. A similar course also takes place where the reigning queen is lost by death. Therefore, the natural course is for bees to be requeened by unmated queens only; but mark well, it is not natural under any circumstances for such queens to be alarmed or timid when for the first time they are mixing with them.

We have seen that in the experiments, conducted both by myself and Mr. Bonner-Chambers on the Pond's queen-introduction system misnamed Simmins', that the new queen was always safe and unmolested on the third day, solely because she conducted herself in a natural manner, and queen cells were formed, which she made no attempt to destroy. I thought if I introduced virgin queens several days old instead, all cells that were started, or attempted, would be destroyed at once, and the queen being of a natural kind would be well received. However, when I tried it, removing the laying queens in the afternoon and dropping the others in at night, I always failed. At this point I thought of what Huber says—viz., that bees will not accept a strange queen until an interregnum of twenty-four hours has elapsed. This observer, though wonderfully correct in many things, implies that after this time they will accept any strange queen offered to them. This, we all know, is not so, and therefore he is unjustly discredited in other matters. I now began experimenting again. I allowed at least twenty-four hours between the removal of the old queen, and sometimes as much as seven days, and in no case was there ever a failure. The virgin queens experimented with were all several days old—all know they are accepted if just hatched, and all were dropped in at the night time.

Let us consider the natural conditions in this procedure. The bees are queenless; they are aware of the fact, and are beginning to set about rearing a successor, or have already done so. When a virgin queen is found running over the combs she destroys every cell, and they accept her because it is their natural habit to do so under like circumstances. The queen on her part shows no alarm, as it is not their habit to do so in the night time, not having under any circumstances any fear of entering a wrong hive during dark, or risk of meeting an intruder, so that by morning both bees and queen are mutually accepted.

At the fore part of this article I say that when virgin queens several days old are dropped in old queenless bees in the daytime they at once rush out in the greatest alarm. Is this instinct not a most wise provision of Nature to guard against such queens entering wrong hives? We know at the time of mating the queens leave their hives several times—often very many times—and as the hives they belong to have no means of raising a successor it is very unlikely that Nature, which provides for every emergency, should leave it possible for a virgin queen to be killed through entering the wrong hive. True, they are also endowed with good eyesight and memories, but having accidentally got to the entrance of the wrong hive another sense comes to their aid, and in a moment they take alarm and fly away in search of their own hives; thus nothing is left to chance.

Having explained the matter I will now briefly sum up the conditions necessary to successfully enthroning any virgin queen. First the hive must have been queenless twenty-four hours, not for more than seven days unless the bees are without the means of raising a successor, in which case there is no limit. Secondly, the queen must be dropped in alone after dark from the top of the hive, unless she has only just hatched and not been amongst any bees, when the daytime will do. Thirdly, no introducing cage of any description must be used on any account. The value of the knowledge here imparted may be somewhat conceived when we consider what a multitude of virgin queens are yearly destroyed all because it has been considered impossible to enthrone them after they had travelled a short distance. Last summer I sent them by post to the farthest parts of the country often without any previous notice to the recipients, and they were successfully enthroned by following the short instructions I sent with them. Then, again, supposing a person is queen-breeding, and he wants all his neighbours to only fly one particular kind of drone. All he has to do, after getting permission, is to leave as many postcards addressed with the owners as there are stocks, to be notified the day they swarm, and any night during the week take the required number of virgin queens and drop them in. Stocks treated so forty-eight hours after they swarm will rarely cast, and the swarms having all been "taken up," in the fall the old stock hives the following season will be producing only the desired drones. After they swarm other virgin queens should again be dropped in as before, and these will probably be mated to the desired drones, thus the stock hives are likely to be all of pure race. Having made the question so plain and simple nothing remains now but for virgin queens to take their place along with fertile ones in the trade, and as I pointed out in this Journal for March 8th, page 206, they can be bred, sold carriage paid, with safe delivery and introduction guaranteed by odd ones, at 2s. 6d. each, and yet yield a good profit to the breeder, and I hope to see it done in the coming season.

In the issue just named (page 206, last paragraph) read "new non-swarving system" for "new swarming system."—A HALLAM-SHIRE BEE-KEEPER.

TRADE CATALOGUE RECEIVED.

William Bull, Chelsea.—*Illustrated Catalogue of New and Rare Plants.*

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Caterpillars (*J. W.*).—We have received the specimens, which shall be carefully examined, and information thereon published in an early issue of this Journal.

Early Scented Tulips (*J. B.*).—The varieties that are most scented are the Duc van Thols, particularly the golden-yellow variety. Others have more or less an agreeable odour, but none are so pronounced in that respect as to be worth mention on that account.

Large Cineraria (*Robt. Owen*).—We can only briefly allude to samples and letters that arrive as we are preparing for press. The bloom is very fine, $3\frac{3}{4}$ inches in diameter, and the florets five-eighths of an inch across. It is one of the largest that has come under our notice.

Double Cinerarias (*J. K. G.*).—The variety is one of the double Cinerarias, of which there are several in cultivation much better in colour, and with larger blooms. It is, however, worthy of preservation, and will perhaps improve as it becomes stronger.

Kidney Beans (*L. B., Ely*).—The seeds sent are those of the white Haricot Bean, which may be sown and treated the same as Scarlet

Runners, early in May being soon enough for sowing. The dried beans are much used in cookery, and enjoyed by many persons. Their consumption is increasing in this country.

Marechal Niel Rose (*L. H.*).—We have received the unsatisfactory samples of decaying buds. It is a case of debility, notwithstanding the application of fertilisers, as we will explain more fully another week. At the present moment time and space are too limited for making the matter clear, and suggesting a method for reinvigorating the trees.

Stacking Loam (*T. K.*).—It may be stacked in any convenient place out of doors, but not under or very near trees, or their roots would take possession of it and deprive the soil of much of its fertility. It is well to form the heap into a ridge to prevent its being saturated with rain in the winter.

Cropping Apricot Tree (*J. E. L.*).—The number of fruits to leave can only be determined by the condition of the tree. If strong and vigorous, a tree of the size of yours would perfect ten dozen fruits—possibly more with the aid of liquid manure and mulching over the roots to induce the free production of feeding roots near the surface. If the tree is only of moderate strength the crop would be excessive.

Berberis Hedge (*M. C. B.*).—The Berberis would be the better cut down to a foot or 18 inches, and the earlier the better, so as to secure a good growth. It would be an advantage to apply a dressing of leaf soil or decayed manure either as a mulch on both sides or pointing in, but without injuring the roots. If there be any weeds carefully remove them before applying the manurial matter. Go over it with the shears early in August for the removal of irregularities of growth.

Teddington Garden (*Kiltarnan*).—Mr. R. D. Blackmore has obliged us with the following particulars—"The soil of my garden is a fairly strong loam, yellowish, and very binding in dry weather, but containing sand. The depth of loam is nowhere less than 3 feet, and more generally 4 feet to 4 feet 6 inches deep. Under this we have a greyish yellow gravel, tending to large flints in the lower stratum, and about 6 feet in depth. Then we come to grey sand, and the water level at 10 to 12 feet from the surface. The well known De Jonghe of Brussels wrote that he had been struck with the fitness of this soil for Pears more than thirty years ago."

East Lothian Stock (*W. S. S.*).—To have East Lothian Stocks flower in early spring it is absolutely necessary that the plants are strong and at the point of showing flower in the end of October, so that under greenhouse treatment in winter the flowers will be ready to open in February and March. In order to accomplish this do not delay much longer before sowing. Prick out the seedlings at a very early stage, and grow on rapidly in open fairly rich soil, repotting as needed until pots 8 to 10 inches in diameter have been used. Never allow dryness at the roots even during winter. The new crimson white and purple are the best varieties.

Auriculas (*Young Reader*).—Soil composed of two parts or a little more of yellowish turfy loam of medium texture, that is neither very sandy nor very clayey, one part of cowdung dried and crumbled, one of leaf mould, and one part in equal portions of wood ashes, powdered lime rubbish and sand, will grow the plants well if they receive in other respects good attention. Avoid overpotting and overwatering immediately afterwards. They like shade in summer. We consider a frame preferable to a room window for wintering the plants. The same remarks apply to Polyanthus. It is contrary to our established rule to answer the other part of your question, for a reason that you ought to understand after a little reflection.

Red Lead and Pheasants (*R. G. F.*).—Red lead is injurious, in fact poisonous to pheasants if they partake of it, but we have not known a single instance of such occurring, though we have red-leaded Peas, Beans, and seeds liable to be taken by birds for many years, yet the birds (and we have counted over twenty pheasants in the garden at one time) never interfered with the seeds that had been red-leaded before sowing, whilst those not so treated were taken to the destruction of the crop. Sprinkling red lead on Peas after sowing is not likely to save them from being taken by pheasants or mice, and the birds or animals taking Peas so treated are very unlikely to be injured, as they will take the Peas without the lead.

Fungus in Mushroom Bed (*P. D.*).—We fear it is not practicable to apply anything to the bed strong enough to destroy the fungus that infests it without destroying or seriously injuring the Mushroom spawn also. The manure must have contained spores of the invader, and possibly was not sufficiently heated during fermentation before making the bed. You might try experimentally a solution of salt at the strength of 2 ozs. and upwards to the gallon of water. Twice that quantity of salt has been used, but we advise you to proceed cautiously and note the effects on a portion of the bed before giving a general application. Perhaps some of the larger clumps of the noxious fungus could be dug out, and if it "runs" close to the surface of the bed this could be removed, afterwards casing with a mixture of loam and fresh cow manure.

Economical Boilers (*J. R. G.*).—We cannot say, nor can anyone else, which is the "best" boiler. Possibly there is not a "best" for all houses and positions, while very much depends on fuel and management. For heating with coke alone up to 1000 feet of piping coil boilers are good, as are tubulars, which heat, according to size, any extent of piping. Where coal of a caking nature is used one of the many improved forms of the saddle boiler, in which all the heat from the fuel can be exhausted

by having to traverse the various parts of the boiler before it reaches the chimney, is suitable. In these boilers either coal or coke can be consumed, or a mixture of both; for instance, slack and gas coke constitute a good fuel. In the selection of a boiler we should advise you not to have one that is worked, or must be set, with outer flues of brick, but one so that all the heat would be enclosed within the boiler.

Hyacinth Stems Dislocated (Col. Urquhart).—Your Hyacinths and letter were placed before the Scientific Committee of the Royal Horticultural Society, and the following is their report thereon;—"Specimens of this not uncommon phenomenon were sent from Colonel Urquhart of Rosebay, Broughty Ferry, for information as to the cause. The spikes have the appearance of being pinched off when just emerging from the bulb. The cause is apparently twofold. On the one hand the bud-scales at the top are too rigid, while on the other the spike was well nourished, the result being that the insufficient expansion of the scales checked the development of the spike at the place where it becomes decapitated. The probable explanation was the excessively fine season of 1887, the 'ripening off' bringing about the rigidity of the bulb-scales, at the same time favouring the formation of the spike within. Mr. Burbridge observed that it is a noticeable fact that the Japanese gash their bulbs with three slits at the top, to allow of the free escape of the spike, and to prevent such constrictions."

Wet Tennis Lawn (W. B.).—The half of the lawn which is so wet and unsatisfactory is obviously the result of bad workmanship. In levelling, some of the clay should have been taken out and a layer of porous soil added equal in thickness to that under the other half of the turf that is good. Drains in such a case are of small service, as the surface water cannot pass through the clay above them. Where drains are operative it is mainly by subsoil water rising upwards, then passing away through them, the level of the pipes being what is termed the water table, which but for them would be higher and the land might be swamped. Water does not pass downwards and directly into drains, but to the water table, hence pipes a foot below the surface may be "dry," while others 2 or 3 feet below them may "run" freely. The turf should be taken off, some of the clay removed, a thick layer of soil and ashes spread on, firmed, and the turf relaid. Until that is done the bad half of the lawn cannot be made equal to the other. Those who made the lawn were either ignorant or negligent, and you are a sufferer by their imperfect work.

Gros Maroc Vine Bunches Shrivelling (S. N.).—It is a consequence of the immaturity of the buds, which may be due to the extreme vigour of the vine and the overcrowding of the growths, the principal foliage not having had full exposure to light. The shoots, or those parts of them that are to be relied upon for fruiting in the ensuing season, should in the current year have plenty of space for the foliage, so that the buds at the base of the leaves may be perfectly formed through the complete assimilation of the sap, the growth being thoroughly solidified as made, and nutrient matter stored in the buds and adjacent wood, on which depends not only the formation of the buds but their perfect development into fruitful shoots the following season. The laterals on those parts should be kept well in hand, either removed altogether or pinched at the first leaf, no further growth beyond a joint being allowed without stopping, and not these if the laterals interfere with the exposure of the main leaves to light and air. Sometimes the basal buds in vigorous vines do not afford fruit, whilst an increase of length in pruning results in a satisfactory crop, which we think would meet your case—viz., do not prune so closely, thereby securing more fully developed buds on wood with more stored up sap. This grape is not only more fruitful, but the fruit is finer and of better quality grafted on the Black Hamburg than on its own roots, and this applies to all the thick-skinned varieties.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*G. P.*)—We do not undertake to name varieties of Azaleas. These are now so numerous that they can only be determined by comparison with a large collection. (*C. Z.*)—They are probably varieties of *Narcissus pseudo-Narcissus*. (*Japanica*).—*Dendrobium eburneum*. (*G. R. J.*)—The plant is *Hippuris vulgaris*, commonly called the Mare's-tail, to distinguish it from the Equisetums, which are termed Horsetails. (*H. M.*)—1, *Stenocarpus Cunninghamii*; 2, *Anopterus glandulosa*; 3, *Andromeda angustifolia*. (*W. G. H.*)—*Spirea confusa*. (*C. H.*)—1, *Polygala Chamæbuxus*; 2, *Andromeda angustifolia*; 3, *Scilla campanulata alba*; 4, *Corydalis tuberosa*. We cannot undertake to name varieties of Daffodils. Both yours are forms of *Narcissus pseudo-Narcissus*. (*H. O.*)—A fine pale variety of *Crinum ornatum*.

COVENT GARDEN MARKET.—APRIL 25TH.

PRICES continue about the same as last week.

FRUIT.

Apples, $\frac{1}{2}$ sieve.. ..	2 6 to 4 6	Oranges, per 100	2 0 to 5 0

HELPS TO SUCCESS—FRUIT ON FARMS.

THE practice of economy, in the full and most comprehensive sense of the term, which has arisen out of the agricultural depression, has not only enabled really earnest energetic men to curtail expenses, but it has in such able hands assumed an aspect altogether apart from mere saving, for it is brought to bear upon every cultural detail. Much more attention is now given to the growth of crops for which there is a particular demand within a moderate distance of the farm, and we are bound to admit that there is a growing desire for improvement among farmers generally. Only a few hours before sitting down to write this article we were asked by a farmer fast approaching the ordinary span of human life to tell him what in our opinion was the best manure for Mangolds. More than ordinary interest was excited by the question, for his land adjoins an artificial manure factory, and he had doubtless expended much money in years gone by upon special manure mixtures. Of course we were only too glad to do our best for him, and he seemed positively amazed at the simplicity of our formula. He owned to having wasted money upon the dealers' mixtures, about which he knew nothing, and expressed his anxiety to try and do better. It is in such applications that we find our reward for trying to show farmers that improvement in practice is possible.

Much has been said for, and much more against, fruit culture as an aid to success in farming, yet we have no doubt that under favourable conditions it is found to answer. But then common sense must be brought to bear upon the matter, for a man who rushes into fruit culture without practical knowledge of it, simply courts failure. Only under very exceptional circumstances should we ever advise a tenant farmer to plant fruit trees, but he might certainly venture upon the culture of bush fruit and Strawberries with much less risk of failure. But even in this he should feel his way, and only devote a moderate proportion of his holding to it at the outset. If he is to succeed he must grow only the best sorts in the best way, keeping to such standard sorts as Sir Joseph Paxton Strawberry, Prince of Wales Raspberry, Red Warrington Gooseberry, Black Naples and Raby Castle Currants. Then as to culture—Take, for example, the Strawberry. He ought to procure strong runners, and from nursery beds, of them in the autumn preceding the legitimate planting, at the rate of about 17,000 plants per acre. He cannot afford to waste a season, and if from such nursery beds he can procure strong plants for making his beds in rich soil early in the following July, he may feel sure of a fair crop of fine fruit next season.

In the recent issue of the Journal of the Bath and West of England Agricultural Society Mr. W. Weldon Symington, of Rockside, Okehampton, has an interesting paper on Fruit Farming. He says that in 1887 Strawberries when picked into punnets realised from £40 to £50 per ton, the average yield being 1½ ton per acre. Raspberries made 5d. per pound in punnets, and Black Currants 2d. per pound in hampers. Of Black Currants he says the fruit finds a ready sale in all our market towns, or can be sent to the jam manufacturers, who are always ready to take it. Of Raspberries he also says if the season is dry the crop should be picked into punnets, and these punnets packed into boxes for the nearest markets; but if the season is unsettled the jam makers will only too willingly take all the English-grown fruit at fair market prices, and send tubs with skin covers to hold the Raspberries when picked; and if harvested in this way they fetch about 3½d. per pound. There is, however, no waste, and at these prices the crop will be very remunerative. "If," he adds, "the market gardeners, who have to pay £10 to £14 per acre near towns, and proportionately high rates and wages, can make it pay, it is clear that an industrious thrifty working man, with ordinary intelligence and small capital, utilising the labour of his own children, and getting his holding at agricultural prices, cannot fail to make it pay. All my own experiments, even during the recent dry summer, have quite come up to my expectations." This advice we may explain is tendered for the special advantage of tenants of small holdings, but it may nevertheless be turned to account by others who are disposed to adopt such helps to success. Now, we have heard farmers declare they have tried everything that appeared likely to help them in their difficulties, and when fruit culture has had special mention we always feel tempted to inquire how they set about it, and whether the trial was a thorough one. It is all very well to indulge in a sneer at "jam," but to the farmer having a small holding especially we say, If the locality and soil are favourable you may do much worse than to turn some part of your holding to account for the culture of soft fruits, for which there is always a ready sale in one way or another.

(To be continued.)

WORK ON THE HOME FARM.

The sowing of spring corn is finished, and we shall watch the result with more than usual interest, for not only are we trying experiments with different kinds of manure, but we applied it in different ways. Some has been sown broadcast before the corn-sowing, some afterwards, and much has been drilled with the seed. We are inclined to give preference to the latter method; certainly it has the merit of expediency, and we believe it will prove best in other respects. Germination is so quick in the moist warm soil that the earliest sown Barley plant was quickly through the soil, and the rook boys have had to be on the alert early and late to protect the corn from their ravages. Five A.M. is none too early for the boys to be on duty, and they remain till sunset, for we will not allow the corn to suffer for lack of enough boys to scare the

birds. In some instances we have to employ lads big enough for hand work, but under the modern views of education we cannot get boys as we used to do; yet we fail to see if a labourer's boy is well grounded in the three R's, why he should not then be let turn to the education which it is so important he should have in his life's calling. Depend upon it if the boy has more than ordinary intelligence he will make his way and find means to improve his education.

Wheat, to which a top-dressing of chemical manures was given a few weeks ago, already shows the beneficial effects of the fertilisers in its deep green hue and free strong growth, and the rolling of this and other winter corn has had to be done. Harrows have been used where winter weeds were numerous, and hand hoes are now in full swing among winter Beans and Peas. The preparation of the land for and the sowing of Mangolds is being pushed on as fast as possible. In connection with this work we have again had reason to deplore the gross carelessness of some farmers in the application of farmyard manure to the land for this purpose. It was carted and spread in the drills during the hard weather in February and left fully exposed to the air for five or six weeks. With such faulty practice before our eyes, can we refrain from comment upon the ignorance and carelessness of which it is an unmistakable sign? By the time such "manure" was buried in the soil almost all the elements of fertility which it once contained had vanished in the air, and the residue would contribute very little to the development of a fine crop of roots. The lesson is a simple one not hard to learn, yet, if as appears, it is beyond the comprehension of the ordinary farmer, how can we hope that he will ever grapple with the science of manure application to his crops?

OUR LETTER BOX.

Learning Farming (Inquirer).—Your desire to acquire a knowledge of farming before you go out to Canada is certainly commendable, but we are unable to assist you in the way you suggest. It is possible you might obtain such a post as you require by means of advertisements. Are you aware of what sort of career is open to a young man of very limited means in the colonies? At the outset your work would be entirely that of an ordinary labourer; in due course you may save some money and acquire enough land for a farm, and be able to settle down upon it, feeling certain of a home, with sufficient means for all ordinary wants. Even this, however, is only to be achieved by dint of downright hard labour, combined with economy, perseverance, and sobriety. If you think you will eventually be content with such a career, well and good, but do not entertain any chimerical hopes of finding an Eldorado where you will "make your fortune." You are undoubtedly right about the difficulty which a clerk has in making his way in this country, but then much depends upon himself and the particular line he adopts. For a mere copying clerk there is little, if any, hope of advancement, but an intelligent clever young man, who begins in an office with possibilities of rising to a good post, we should certainly advise to persevere. The chief fault of young men at the bottom of the ladder is a lack of perseverance and staying power; they become impatient, and frequently throw up in disgust a post which might eventually lead to better things. How little perfection do we meet with, and yet we are certain that perfection in simple duties commands respect and confidence, and eventually leads to promotion. You will, we hope, understand that these remarks are to be taken in a general sense, and not as casting any reflection upon you. If you really dislike office duties and desire an active life in the open air, you will probably do well to follow the bent of your inclination if your expectations as an emigrant are reasonable and you are healthy and strong, for remember that in our colonies it is literally the strong right arm, combined with energy and intelligence, that enables a man to make his way to independence.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

15th.—Lovely morning, cloudy afternoon, wet evening.
 16th.—Bright and fine, but cloudy at times in the afternoon.
 17th.—Morning generally dull and damp; afternoon frequently bright, but with one or two heavy showers.
 18th.—Generally bright morning; heavy rain and hail storm at 0.30 P.M., and very wet till 5 P.M.; thunder and lightning at 2.30 P.M.; fair evening.
 19th.—Very wet, with thunder at intervals, from 10.30 A.M. to 2 P.M.; otherwise showery.
 20th.—Dull and showery till 11 A.M., then fair, with a good deal of sunshine in the afternoon; rain at night.
 21st.—Fine, but without bright sunshine.
 A wet week. Temperature 6° above that of the preceding week, and nearly 3° above the average.—G. J. SYMONS.

GLAZED FLOWER POTS.

CONSIDERABLE attention has lately been directed to glazed flower pots, and I am led to make a few remarks concerning them. After a long experience of these pots every additional year's practice and observation strengthen my favour for them, and I certainly would not now relish being compelled to grow a large and miscellaneous collection of plants in ordinary pots, and except those who have never had experience of glazed pots I have not met with a gardener who after a fair trial has not come to the same conclusion.

I had the pleasure recently of inspecting the extensive general collection of plants at Woodbank House, Dumfries, the residence of C. W. Scott, Esq., every plant of which is in glazed pots, and under the able management of Mr. James Cole, a member of a family in whom high art in plant culture seems hereditary. Mr. Scott, after seeing glazed pots at Drumlanrig four or five years since, at once ordered the disuse of common pots. Mr. Cole told me he should be very sorry to have to return to them, and that he considered a saving of labour in the houses at Woodbank to the extent of fully one man was effected by the use of glazed pots. He ridicules the idea of their having any injurious effects on plants, and points, as well he may, to the luxuriant condition of his *Erica Marnockiana* and other Heaths, his *Azaleas*, greenhouse *Rhododendrons*, &c. I should like to see any practical man look over his *Odontoglossums*, *Cattleyas*, *Lælias*, *Crotons*, or *Nepenthes*, and attempt to point out any injurious effects arising from the glazed pots in which the plants are luxuriating.

I have heard some very droll objections raised by gardeners to these pots, a very common one being "Do you not find these pots exclude the air from the roots?" I am not aware that roots are the better for any more air than is supplied to them by pressure on the surface of the soil or by the holes and drainage in the bottom of the pot, even if the surface could be entirely covered by the glazed ware. "Do you not find the soil keeps too long moist and gets sour?" Never unless from errors in watering, that are as common with ordinary pots; and I fail to see the benefit plants derive from arriving at the "flagging" point twice instead of once a day. In fact very little difference is found in this respect when the roots have taken full possession of the soil. Besides, I prefer potting firmly, so as to pack as much soil and nutritious ingredients into the pot, and leave as little room in it for air and water as is possible, both of which in excess tend to rapid extinction of the nutritious elements of the soil.

It would be interesting to know (admitting the force of such objections which, I do not) how much more air penetrates the side of a common pot when—as they very often are—covered thickly with green slime, or how much more evaporation goes on than in the case of glazed pots. If I knew of any cultural objections to the latter I would not use them, while on the score of appearance, cleanliness, and consequently labour, they have immense advantages. There is more saved in scrubbing and washing than covers their extra cost. In the case of gardeners who have much furnishing in mansions they are very handy, being always ready to pick up in a clean state, doing away with the much scrubbing often needed on emergencies.

Some of the most healthy Ferns I have seen were growing in galvanised iron pots, and no doubt some of your readers may re-

member the first prize *Pelargoniums* brought out at the great London shows over forty years since by the late Mr. Beck of Isleworth, and I question if the *Pelargoniums* of those days were not equal in cultural merit to any that have appeared since. How much air and evaporation passed through the sides of such vessels?

If my fifteen years' experience of glazed pots be worth anything I have no hesitation in saying that it proves the superior appearance, the saving of labour, and the constant cleanliness and comfort of such pots, and such experience has failed to reveal to me any cultural drawbacks in their use.—D. THOMSON.

[On more than one occasion flower pots glazed on the outside so as to render them practically non-porous have formed the subject of discussion in this Journal. So far as we know, all that could be said for and against them has been advanced by competent men; but discussions on passing topics appear to be soon forgotten by the majority, while every few years bring a host of new readers who are of necessity unacquainted with the matters previously treated and that are subsequently reintroduced. Letters have recently appeared of a nature that would suggest the subject as being entirely new to our columns, whereas many articles have been published from writers who are happily still readers of and occasionally contributors to them. Mr. D. Thomson some years ago, as he is now, was an advocate of glazed pots for plants, and we are not betraying any secret by stating that a gardener who was one of his most doughty literary antagonists, and a champion of porous pots, has long since been satisfied that he can grow plants as well in the kind of pots he once thought inferior as in those for which he claimed the advantage of porosity.

We have seen glazed flower pots employed with great success in the cultivation of different kinds of plants. One of the most conclusive examples of their suitability for the purpose for which pots are manufactured is afforded by Mr. Thomson himself. More than once we have had the pleasure of inspecting the plants at Drumlanrig, and their condition demonstrated in the most conclusive manner the perfect adaptability of glazed pots to *Orchids* and all other plants that were grown in them when judiciously watered and otherwise rightly treated as they were and are in that establishment; and after seeing those plants it would be impossible for anyone devoid of prejudice on the matter to condemn glazed pots as essentially unsuitable for plant growth.

Another very striking example of the successful employment of glazed pots equal in its way to the Drumlanrig experience that came under our notice was in the garden of the late Mr. Woodhead near Halifax, these pots being then almost exclusively used in growing one of the most extensive and healthy collections of *Auriculas* we have had the gratification of inspecting. Several houses were filled with them, and we cannot imagine how any plants could be more sturdily vigorous and thoroughly satisfactory. They were not luxuriant in the sense of being Cabbage-like in growth, with large succulent leaves that drooped under the influence of an hour's sun; but were remarkable for the leather-like persistency of their deep green foliage, while their stout stems and large heads of flowers required no sticks to support them. The cool breezes of the Yorkshire heights had no doubt something to do with the splendid condition of the plants, but it goes without saying that they would not have been in that condition if the glazed pots containing them had been even to the smallest extent disadvantageous. It may be surmised, however, that they would have been quite as good in the ordinary porous pots. That was not Mr. Woodhead's experience. He commenced using glazed pots experimentally, and necessity suggested them.

Mr. Woodhead's business often called him from home for longer periods than were good for his plants, which either suffered by drought in his absence or had to be watered before they needed it to "keep them going" till his return, and sometimes they suffered from the excess of water when the weather proved different to prognostications. He had heard that plants in glazed pots required

water less often than in the ordinary kinds because the soil in the former remained moist for a greater length of time, and he resolved to try a few and note the results. These were such as to justify an addition of glazed pots yearly, and eventually the ordinary rough porous pots were discarded, except a dozen or two which he retained for a prolonged test, so to say, and permanent comparison. At the first, and for some months, the plants in these grew as well in the others, but occasionally were caught flagging, and they never finished so well as those in the glazed pots, which numbered a few thousands. This was accounted for, not so much by the occasional check the plants in the porous pots received by getting too dry, but by much nutriment being washed out of the soil by the far more frequent waterings which had to be given to them. It was computed that four times more water passed through the soil than was required to be given to an equal number of plants in glazed pots, and, consequently, the soil's virtues were largely washed out in one case and retained for the support of the plants in the other. That was Mr. Woodhead's opinion, founded on observation and experience, and there is little doubt if analyses of the soil and drainage [water had been conducted that science would have proved the correctness of his reasoning. Mr. Thomson alludes to that aspect of the question in a significant sentence in which he says—"I prefer potting firmly, so as to pack as much soil and nutritious ingredients into the pot, and leave as little room for air and water as possible, both of which in excess tend to rapid extinction of the nutritious elements of the soil."

Growers of those fine and floriferous plants in small pots for market press the soil firmly, in fact hard, without all of them knowing the *rationale* of the procedure, but they know the plan succeeds, and those expert cultivators would grow every kind of plant they take in hand equally large and well in still smaller pots if glazed and with less time occupied in watering; but they cannot do so because pots are sold with the plants, and these have to be disposed of at the lowest possible prices in markets. And besides, the labour of watering can be, and is, reduced by plunging, the plants growing as quickly, if not more quickly, with the pots sunk up to and over their rims; and in that case what becomes of the alleged necessity of air passing through the sides of the pots to support the plants?

If water is given when the soil is in a fit state for its reception, and only then, quite sufficient air is conveyed to the roots of plants and retained there for all their necessities; and when plants in glazed pots refuse to thrive we are convinced it is not the fault of the pots, but of errors in management either in respect to compost, drainage, or watering. Growers of Chrysanthemums for exhibition, who very properly object to plunging the pots, might do worse than try some that are glazed outside, and they would find the labour in watering sensibly reduced, while the wearing or sustaining capacity of the soil would be prolonged; but it would be necessary to exercise great care against overwatering, or the experiment might be the reverse of beneficial.

Glazed pots are necessarily more costly than the ordinary kind, and on that account their use will be limited, though for certain purposes they have claims to attention; and if a demand should arise for them their production would perhaps be cheapened, as manufacturers of ordinary kinds would soon find the cheapest methods of glazing by the natural force of trade competition. Much more could be said on this subject, though it is not easy to add weight to Mr. Thomson's experience, confirmed by Mr. James Cole's success, and all we will do now is to express our conviction that the supposition of ordinary flower pots possessing special virtues because the material is porous, and that the more porous it is the better the pots are for plants, though a popular view, is a popular fallacy.]

A CHAPTER ON BROCCOLI.

SOME of the winter and early spring Broccoli failed to head in due season, and although this might be felt as a hardship at the

time it does not prove to be so, as at present all vegetables are uncommonly scarce, and the Broccoli now heading freely is really the only vegetable many possess. This I am sure will be the means of impressing their usefulness on the minds of those who have them, and probably it may occur to those who are buying them, and paying 3d. each for very small heads, that they could grow them more cheaply. The absence of spring Cabbages is much felt, and the Broccoli have become so prominent that their culture is sure to become more popular. Where gardens are too small to admit of very many being grown I would not have autumn or early winter varieties. Other vegetables are plentiful at that season, but it is in March, April, and May that the scarcity is most felt. The Broccoli season begins in November and continues to the end of May. If some can be grown to give a supply in every month between these dates they will be greatly valued. January and February are, as a rule, the most uncertain months for their heading. Varieties are recommended to head then, but should sharp frost occur they will not do so; and although we have plenty of ground on which to grow Broccoli I am always inclined to limit the varieties that are said to head then, and give more space to later ones, which I know will come with certainty.

As to the value of Broccoli there cannot be two opinions. They are simply indispensable from autumn until summer, and from the middle of April until the middle of May is a very important time in connection with their culture. This is the season to sow the seed of all the varieties. There is no advantage in sowing it before this, as the plants are not wanted too early; but after the middle of May it is late to sow, as although the plants may grow, and will grow if sown in June or July, they do not gain their full size before the winter, and a half-grown plant is always more tender and liable to be injured by frost than a fully grown one. Little half-grown plants are never remunerative.

As a rule we find Broccoli seed very good, and it germinates freely. A half ounce packet of seed of any variety will produce many scores of plants. The seed is best sown in nursery beds either in rows or broadcast, but where space is limited the latter plan is best. Keep the varieties separate, or some early varieties may be planted with the very late ones, then the piece will be patchy before they are all ready for use. Let the seed be evenly distributed, and it should be covered to the depth of 1 inch. Make the soil firm on the surface with the rake or spade, and do not let the birds pull up the young plants as they are coming through the soil. If the seed is sown now the young plants will, under favourable circumstances, appear in a fortnight. They will be 4 inches high by the beginning of June, and some of them may be transplanted then. It is good practice to take an early crop of Turnips, Potatoes, or Spinach off the ground before the Broccolis are put in, and if these are not cleared by the time the Broccoli are ready for planting do not allow them to remain in the seed beds to become overcrowded and drawn, but take the largest out and dibble them in elsewhere at a distance of 3 inches apart, keeping them there until they can be planted in their permanent quarters. This transplanting will benefit them in more ways than one. It will make them grow very compact. It will cause the roots to form a close mass, and then transplanting may be done without their receiving the slightest check. We treat many of our Broccoli plants in this way.

As to the best place in which to grow Broccoli there need be no difficulty. They will grow everywhere. We have had them good on light, heavy, and medium soils, in exposed positions and shaded positions, but we are averse to putting them in the latter. The majority of them having to stand out all winter they cannot be grown too much exposed to harden them. Neither am I in favour of growing Broccoli in rich soil. This will soon induce them to become huge luxuriant plants, but they will not stand severe weather. Some of the best Broccoli I ever possessed were grown in a field. The soil was not so rich as that of most gardens, and it was very firm, and this certainly induced the plants to be very hardy in character. I am therefore in favour of treading the soil firm as soon as the young plants begin rooting into it. The weather is often hot and dry when Broccoli are being planted; but if they are thoroughly soaked at the roots the night before, being transplanted, and well watered once the day after planting, that is all that is necessary.

Having to make the most of our garden, we often try the plan of double cropping. This may be done in various ways. One way is to plant the ground with Potatoes in April, keeping the rows 2 feet 6 inches apart, and when the Broccolis are ready for planting, put a row in between every two rows of Potatoes. In past years I have recommended this plan, but I shall not do so now. The Potatoes are apt to make a great deal of top growth, so as to completely shade the Broccoli at a time that they should be completely exposed and laying the foundation of a substantial growth, that I much prefer to grow them quite unhampered. I find good plants and fine heads can be grown if the plants are put in at a

distance of 2 feet from row to row, and 1 foot 6 inches from plant to plant. The varieties of Broccoli are very numerous. I could name dozens, but only grow about six. We begin with Veitch's Self-protecting Autumn variety, and end with Sutton's Late Queen. Osborn's Winter is still a good sort, and as a main crop variety we grow Webb's Perfection.—A KITCHEN GARDENER.

CULTURE OF THE DOUBLE VARIETIES OF PRIMULA SINENSIS.

[A Paper by W. H. Divers, Ketton Hall, Stamford, read at the Meeting of the Scottish Horticultural Association, May 7th, 1886.]

(Continued from page 334.)

TREATMENT OF THE YOUNG PLANTS.—For ordinary cuttings the period of striking will be from four to six weeks, and when the roots reach the sides of the pots (which may be known after a little experience by the appearance of growth in the top) they may be removed from the propagating frame and set on a moist bottom in a moderately close house or pit, and gradually accustomed to plenty of air, with a little sunshine at times when not very bright, such as early in the morning and after four o'clock in the afternoon. Generally speaking, the cuttings will be ready for a shift into larger pots about six weeks after they are placed in the pit, provided they have grown in the meantime without a check. For the earliest struck plants that are to flower in November and early winter (if they are growing freely) I prefer 32-size or 6-inch pots for the first shift, at any rate for the strongest of them, and this answers for a final shift also. If any of the plants are weak we place them into 48 or 4-inch pots at first, to be eventually repotted if necessary. I know the 32's or 6-inch pots will be thought too large a shift at first by some cultivators, but provided plenty of water is supplied with extra care for about three weeks no harm can ensue, and I find it better than checking their growth by another shift later in the season. The second supply of cuttings for flowering at the end of the season will probably only require 48's or 4-inch pots when they are repotted, as it is best to have the pots well filled with roots before the cold and damp weather of autumn comes on.

SUMMER TREATMENT.—The best place to grow them in after they are potted is a brick pit or a frame facing the south if in the midland and northern parts of England or Scotland. For the south of England, such as Kent or Surrey, a northern exposure is best in the summer months. Here we find pits from which early Melons or Potatoes have been cleared to answer admirably for the young Primulas, as they only require the soil to be levelled and about 2 inches of coal ashes spread on, and they are then ready for the plants. These will still require shading from bright sunshine, but should be allowed more exposure as soon as they are established, say until seven o'clock in the morning and after five o'clock in the afternoon. This is necessary in order to prevent their drawing up to an inconvenient length in the foliage. As the sun declines in power these hours may be altered accordingly. Plenty of air should circulate over the tops of the plants during mild weather both day and night. The plants always thrive best when standing on a moist bottom, such as coal ashes, which should be slightly stirred occasionally to prevent their being covered with moss.

When the pots are filled with roots supply liquid manure occasionally. I prefer the drainings from a cow yard freely diluted with water according to its strength, and given at every second watering; if this cannot be obtained weak guano water may be used, or some sheep dung and soot may be soaked in a tub and the liquid freely diluted with water before using. As the weather becomes cooler and frosts commence, less water must be given and no more liquid manure, or the roots will perish. When the days are shorter and sun heat much less, scarcely any water will be required while they remain on the coal ashes, but give them more exposure to sun and air to stop growth as much as possible, and to consolidate the tissues of the plants. Should any dull damp weather occur in October they must be moved to drier quarters, and this will be especially necessary if there are no means of heating the pit artificially. Shelves or front benches in early vineries will be a good position for them, or small span-roofed houses such as are used for Melon and Cucumber growing—anywhere, in fact, that is dry, well ventilated, near the glass, and that can be kept at a temperature of 45° to 50°, there they will flower and flourish to perfection. A little weak liquid manure twice a week will again be found beneficial, although they do not require it so often or so strong as when growing freely. Care should be used in watering during the cold damp weather so as not to wet the leaves or pour any into the hearts of the plants, all decaying leaves being removed as occasion may require.

A little air must be admitted whenever the weather is at all favourable in order to ward off damp. This circulation of air is

necessary during all stages of this plant's existence, and if provision is made for it there will be no other great difficulty in the way of successful cultivation. In order to obtain this circulation of air among the plants more effectually during the winter season, those required to be kept at rest early in the winter for flowering the following spring must be placed in larger and more lofty houses if possible, as they will not then require so much fire heat to expel the dampness. I lately saw some plants of the old Double White at Burghley which had passed the winter in a cold house—that is, a house which has no convenience for artificial heating, and 15° of frost had been registered outside. How low the temperature went inside could not be ascertained, but the soil was frozen hard in the pots. These plants were in good health, and had a certain amount of flowers on them of good quality, although not such a quantity as those had in a higher temperature. It is only fair to say they had not been very liberally treated in other ways. I would not, however, recommend so low a temperature by any means, and only mention the circumstance to show what an amount of hardship they will endure, and that anyone who has not all the advantages I have mentioned need not be deterred from cultivating them.

VARIETIES.—Besides the old Double White or *alba plena*, there are, as already mentioned, several newer and so-called improved varieties. For yielding a large quantity of flowers and for general usefulness I prefer the old variety, but as specimen plants, and for mounting as separate flowers, the newer varieties are certainly a great advance, and when well grown are extremely pretty. Among the best of these are the varieties sent out by the late Mr. Osborn of Fulham called Gilbert's Burghley varieties, but really raised or selected as sports by Mr. Harris of Denne Park, Horsham, while gardener at Naseby Woolleys, Rugby. It has been stated they were raised from seed, but, if so, it is a curious circumstance that all four varieties sport into each other, and have also produced another distinct shade of colour since they were first sent out.

The best are Lord Beaconsfield, carmine red, and Marchioness of Exeter, large white, generally striped and spotted with pale lilac. I have grown individual flowers of the latter variety here which measured over 6 inches in circumference. Besides these I have at various times met with the following good varieties—*candidissima*, an improved form of the old Double White; Mrs. Eyre Crabb, Princess of Wales, and Blushing Beauty, all of which are white grounds more or less striped and shaded with pink. Among reds and purples are *atro-rosea*, *carminata plena*, Emperor, King of the Purples, *magnifica*, *purpurea erecta*, and *rubra grandiflora* may be mentioned, all of which are worth cultivating for the sake of variety, although, as a rule, they are not such free growers as the old Double White. Many of these newer varieties were at one time grown remarkably well by Mr. R. Kingston of Brantingham Thorpe.

SHADING LATE-FLOWERING PLANTS.—Early in February, if the weather is very bright, it will be found necessary to shade plants in flower during the hottest part of the day. After the dark days of winter the plants are apt to flag very much, and if not duly attended to the flowers soon fade in consequence.

INSECTS.—The double Primula has one great advantage over many of the plants we are called on to cultivate, it is not subject to the ravages of insects. I have only found two kinds of any trouble, and these not seriously so. Mealy bug will sometimes take up a residence among the remains of the old dry leafstalks, and if it does so I need scarcely to caution gardeners against introducing the plants into their vineries and fruit houses. The bug may easily be cleared away from these plants. The other pest is the larva of one of the weevils (*Otiorhynchus sulcatus*), which, in the form of a small white grub eats its way into the stem of the plant just below the surface of the soil, and continues feeding on it until eventually the plant withers. I know of no means to prevent this, as there is no evidence of anything being amiss until the plant begins to droop, but all the mischief is done then. Fortunately it is not of very frequent occurrence. The perfect insect is a small dark-coloured weevil, which is very fond of the leaves of Camellias, Vines, and Peaches. I have an idea that the use of cocoa-nut refuse for potting purposes encourages this insect, and therefore I have not recommended its use, although I know Primulas are very fond of it.

I have now carefully given every particular necessary to grow these plants to perfection. If any have been wearied by so many small details, I claim their forgiveness for the sake of the younger members of the profession. It is only by strict attention to the smallest matters that one can excel in the cultivation of double Primulas, or of anything else.

[In the previous article, p. 334, second column, line forty-five from the top, "when the ventilators are open" should read "when the ventilators are not open."]

ARTIFICIAL MANURES.

CONSIDERABLE credit is due to Mr. Dunkin for the general defence of his initial article on page 128, and I am also glad to note the tendency of our respective views to coincide on the main points, although at the same time I consider that a slight retrospect would help to clear away some of the "dust" that is evidently arising.

In the first instance, where I beg to differ from my opponent is when he advises the application of stimulants in which ammonia-yielding substances preponderate. If we wish for a strong and vigorous growth this, of course, is a natural result of such a proceeding. But, I ask, What is such a growth worth? Does the constitution of a plant improve because its bulk is increasing? I venture to say that such does not always follow; and I consider it doubtful practice to use strong ammoniacal manures alone for any plant, advising rather a judicious blending with some of the solidifying agents, such as potash, lime, and phosphates. That something undesirable follows the use of one kind of artificial manure Mr. Dunkin seems fully aware, and as every effect must have a cause I would recommend him to study the cause that compels him to change from one manure to another, so that a cogent reason can be ascribed for so doing.

This, then, is the point of contention, whether it is the better practice to apply several kinds of manures and stimulants consecutively, or endeavour to provide a food that will meet the requirements of the plant immediately. This your correspondent evidently thinks is a state of perfection never to be attained. But here again I beg to differ from him; for if we observe the vast improvement that has taken place in the composition of the various artificial manures that are continually being brought forward, we cannot but infer that eventually something like perfection will be reached. Not that one manure will ever be invented that will do for all and every member of the vegetable kingdom, any more than a pill will ever be compounded that will cure all the ills flesh is heir to, though such may be affirmed by the vendors.

What I believe is, that as the science of gardening progresses we shall see the cultivator of the future obtaining the manurial ingredients separately, and as he will possess more than a rudimentary knowledge of chemistry he will compound his own manures for special purposes much in the same way that the drugist compounds a standard remedy for a particular disease. I was glad to see Mr. Dunkin is in favour of the study of chemistry as a part of the education of every gardener, as by his previous article he gives one the impression that it is altogether too deep a subject for practical use, and even now he wishes to point out that "it is not wise to place too much reliance in only a rudimentary knowledge of it." Again I differ from him, being of opinion that if only the merest smattering of chemical knowledge were impressed on every lad during his apprenticeship more successes and less failures would be chronicled. For example, would not a very slight knowledge prevent such blunders as mixing caustic lime with farmyard manure? or would minute calculations have to be made to ascertain if a soil was deficient of lime? as a single application of dilute sulphuric acid to a sample would soon decide, and in the same way many other simple tests could be enumerated that would be of inestimable utility to even the rudimentary chemist. I trust that Mr. Dunkin will eventually see his way clear to favour these views and not think it "altogether too troublesome and expensive a method to have different manures for each plant." I do not utterly condemn the practice of changing from one manure to another, as according to the present limited knowledge it is the only general available way to supply the plant with its needs; but I oppose being contented with such clumsy and blind methods, but rather let us aim at a more scientific mode of supplying such a food as a study of a plant tells us is requisite.

This brings to my mind a testimonial I saw in one of the gardening papers from a noted American cultivator of the Camellia, where he says that he has been using for some time a certain artificial manure for plants that have been in the same pots for ten years, and they are, he adds, as healthy and as vigorous as recently potted plants. I ask Mr. Dunkin if he would advise his pet theory to be put into practice in this instance? Do not results clearly show that the manure used was absolutely a perfect food for the Camellia, and such being the case no change was necessary? This is not the only instance of a perfect food being produced successfully for a particular plant, there being at the present time several compounds in the market that the vendors affirm contain all the necessary ingredients to support the Grape Vine, and some of which have stood the test of years, and I certainly favour the excellent idea of manufacturing special manures for special plants. I am of opinion that if education increases as rapidly during the next fifty years as it has done this last half century, the coming generation of gardeners will look back with pity on even the present, and wonder how it was possible for such results to have been achieved under such blind and haphazard treatment. Much in the same way that we wonder how it was possible to practise successfully in some of the ancient glass (?) houses where the dictum "keep close to the glass" was fraught with meaning.

Turning again to Mr. Dunkin's recent article I fail to see where the ease of misrepresenting his statements occurs, as if the giving of "nitrate of soda to a plant that is in a stunted and unhealthy state to get it into active growth again, and then when the object in view is attained to alter the food," is not substantially the same as giving it "a strong stimulant to start it and afterwards give it various compounds." I must be content with the epithet he so kindly bestows on me; still, I consider he is on the right track now that he advises the change to be such

as experience proves to be right, so that I cannot but withdraw the imputation that it was fancy alone which guided his actions.

Referring to the application of lime to soil that has become overcharged with too much organic substances, I did not infer that the lime would spoil the soil to any extent, as may be seen on reference to page 274. What I intended to convey was that the danger of a too heavy dressing of lime would result in more of the ammonia contained in the organic remains being set at liberty than the plants could appropriate, consequently it would be lost, whereas, if trenching was resorted to at the same time that the lime was applied, the fresh soil would imbibe the gases liberated by the lime and so conserve it in an available form for future use. To practically demonstrate this theory, take a small portion of fresh soot, this we will suppose is the soil under operation; add to it about a tenth part of its bulk of fresh lime and thoroughly moisten the whole mass; in a few minutes if the soot is good pungent fumes of ammonia will arise. Now cover the heap with some moderately dry earth, and no fumes will be perceptible unless the gases given off are in excess of the capacity of the soil to imbibe them. When sufficient time has elapsed for all the ammonia to be driven out of the soot, carefully remove the soil and repeat the process, but using the soil in the place of soot, when it will be fully demonstrated that by the action of lime the ammonia can be transferred from one mass of soil to another with the utmost facility. This again is a reason why I contend even rudimentary chemistry is useful, as no one would, after performing the experiment, think of mixing lime with organic substances intended for manure.

Mr. Dunkin's idea that the application of lime imparts to the soil the power of retaining the moisture necessary for the growth of plants is new to me, being under the impression that an important factor in that direction is humus (formed from the decay of animal and vegetable remains), an excess of which renders the soil close and sour and unfit for healthy root-action, consequently it follows that where this material is abundant there is generally no lack of moisture.

As to the solution of the problem, why nitrate of soda applied to a pasture produced the most rapid and also appeared to give more permanent results than either bonemeal, native guano, muriate of potash, or superphosphate, I will give my ideas on the subject, and try to elucidate the mystery, if any, and show how easily false conclusions can be arrived at unless close observation is pursued. In the first instance observe it was a pasture, not a meadow, consequently stock were grazing on it. After the application of the various manures nitrate of soda, being by nature the most rapid stimulant, caused a quick succulent growth of herbage which the stock were not long in discovering; and to show their appreciation of good living they took up their abode on that portion of the field; consequently, as the nitrate was absorbed by the grass, and the grass consumed by the stock, it was returned again with heavy interest to the soil in the form of a properly constituted food for the grass, and, in point of fact, this quarter had the most thoroughly scientific manuring of the whole field. This, I think, I may venture to take as supporting my views, that all highly stimulating manures should never be used alone, but if permanent results are looked for they should be used in conjunction with either natural manure or blended with some of the substance providing mineral agents.

After intruding so far on your valuable space I will conclude by thanking my opponent for the generally courteous way in which he has replied to my criticism.—M. COOMBE, *The Gardens, Ashton Court, Clifton, Bristol.*

RICHARDIAS IN SMALL POTS.

FOR the decoration of the conservatory or the house, either singly in vases or in bold groups in the case of balls or evening parties, Richardias are always acceptable; but in no way are they more useful than when well grown in 6-inch pots. Plants with one, and in some instances two stems, standing 2 feet to 2 feet 6 inches high, carrying from one to four fully developed pure white spathes, are much more valuable for the purpose named than any larger plants with eight or ten stems, requiring 12-inch pots. The smaller plants do not require so much space when growing, and are preferable in many ways to the larger specimens. A group of say one dozen plants arranged closely together form a most agreeable background for Hybrid Perpetual Roses of various colours where such groups are appreciated. If the Roses are well grown the effect is very telling. The bright colours of the Roses come out to perfection against the background of green and white.

The treatment Richardias require is very simple, and consists in dividing the plants into single crowns towards the end of May, when all danger of frost is past. They should then be planted out singly. Ours are placed in a west border, where the soil is of a heavy tenacious character. During the summer the plants should not be too liberally supplied with water, or too much growth and roots will be made to go into small pots. All small growths should be removed from the base of each plant, not more than two shoots or crowns being allowed to develop. The last week in September or early in October the plants must be lifted and potted, using a fairly rich soil, loam predominating in the compost; to this add a small portion of decayed leaves and some finely ground bones. Pot firmly, allowing ample space for applications of water on the surface of the soil. Drain the pots carefully, as abundance of water will be needed later on.

After potting place the plants in a cold frame if possible. Failing this, stand them under a north wall for a time until the roots are running into the new soil, when they should be removed to a cool house, placing them as near the glass as circumstances will admit to prevent

the leaves becoming drawn and weak. Sufficient water should be given to the plants during winter to prevent the plants flagging until growth is advancing towards the end of February, when tepid liquid manure may be freely given. From that time the plants may be subjected to a temperature of 65° by night if they are required earlier than they would be in flower by following cool treatment.—PRACTICAL.

IMPORTED ORCHIDS.

FOR all uninitiated in the cultivation of Orchids imported ones in good plump condition are strongly advised. It invariably follows that if they can be established they can be successfully grown afterwards. Plants that have started and lost their growths should be avoided, for although they will break again, the eyes that do so as a rule are weaker than the first would have been. Some of the back breaks will come away strongly, but every eye lost in transit means the reduction of the plants. Those that have commenced rooting on the journey are the worst to deal with, for they require most careful management afterwards.

Upon arrival wash the plants thoroughly in tepid water, remove dead and decaying pseudo-bulbs, and cut off with a sharp knife all leaves that have been injured or bruised. The plants should then be placed in some position where they will dry quickly, and be arranged in the various structures in which they are to be grown. For the first fortnight Vandas, Aerides, Saccolabiums, Cypripediums, Cattleyas and others will do in a temperature of 50° to 55°. They are better for a short time in an intermediate temperature than in the stove proper. Those who have two or three structures for these plants may place them in after the first fortnight. In each case suspend them from the roof with their growths downwards, so that no water will lodge in the axils of the leaves. At first the moisture of the house will be ample, and after that time they may be syringed once daily until they are thoroughly plump and fresh. Syringe freely two or three times a day when the weather is favourable.

The plants named are better suspended until they commence rooting than if placed in pots or baskets. In fact if they are potted no soil should be employed about them until the formation of roots. The plants should be secured in position by crocks or charcoal. *Odontoglossums*, *Lælia albida*, and many others may be laid on a board or on damp moss in a temperature of 45° to 50° until they start, when they may be potted.

To attain success too much water must not be given in the early stages of the plants' growth. The supply should be gradually increased as the shoots and roots extend, and they must not be placed in too high a temperature at first to induce them to break. The plants are partially ruined if the first growths are prematurely forced out of them. Such plants only make weak growths in the first season, and are frequently a long time before they attain the strength they would have done under cooler and more natural treatment.—N. G.

CATTELYA TRIANÆ.

A MUCH longer succession of flowers can be obtained from this Orchid than by growing the whole stock in the same temperature. The earliest are grown in the stove suspended from the roof in baskets, and not only flower earlier, but produce finer flowers and larger pseudo-bulbs than those grown the whole of the season under cooler conditions. No doubt this is due to the more thoroughly matured condition of the growth. There is, however, one drawback to the maturation of the pseudo-bulbs early in the season—namely, they are very liable to start again into growth. This must be prevented, and can only be accomplished by the removal of the plants after growth is completed, as far as appearances are concerned, to a much cooler structure, where liberal ventilation can be given and a greater amount of light admitted. By this means a second growth has been prevented, and the ripening and rest they receive under such conditions have proved beneficial.

While in flower these plants may be employed in rooms for a time where gas is not used, and cold draughts do not strike upon them, without the slightest injury. They are also perfectly safe in the conservatory, and a few Orchids at this season of the year add much to the attractiveness of such structures. Care must be taken not to overwater them while in these positions, most of the injury done to them arises from this cause. They need no more water than is sufficient to keep their pseudo-bulbs from shrivelling. Good

plants of this description should not be crowded amongst others, for in so doing they lose half their beauty and effectiveness. The most prominent position in the house should be selected and the plants tastefully grouped by themselves, or with the addition of Ferns. Nearly all Orchids look well when grouped with an undergrowth of Ferns to hide the pots, pans, or baskets in which they may be grown.—B.

EPIDENDRUM BICORNUIUM.

THE beautiful species which so many people fail to grow satisfactorily is to be met with in splendid condition at two or three gardens near Croydon, perhaps the specimen at Croydon Lodge being the best. This is grown in a strong moist heat, where it makes larger growths and blooms freely every year. The enclosed bloom is from a plant now flowering at Birdhurst, Croydon, the residence of J. C. Lanyon, Esq. It is grown similar to the above, and each spike has carried about a dozen pure white sweet-scented flowers, which have been in perfection some time.—G. W. C.

ORCHIDS AT CHELSEA.

MR. WILLIAM BULL'S exceedingly beautiful exhibition of Orchids in his King's Road nursery is now regarded as one of the interesting events of the London season by the numerous visitors who annually make a journey thither during May and June. It was opened on Tuesday last, and in saying that the display is fully equal in all respects to those of preceding years, an ample idea will be conveyed to all who have seen previous efforts. There is the same wealth of flowers, the same graceful association of foliage plants with the Orchids, and the same taste manifest in the arrangement. But to show that there is always room for improvement, greater variety has been introduced, and the exhibition consequently presents a kind of conspectus of the most useful and beautiful Orchids for general cultivation, together with rarities and curiosities in abundance to satisfy the connoisseurs. No one could inspect an exhibition like this without being impressed with the fact that the value attached to Orchids is very far from being fanciful, and Mr. Bull justly claims to have assisted materially in popularising a most fascinating class of plants.

The house in which the principal display is provided is span-roofed, 120 feet long by 25 feet wide, with a central bed and two side stages, which are filled with Orchids, Palms, and Ferns, the rich colours of the Cattleyas, *Lælia*, *Masdevallias*, and *Dendrobiums* being agreeably contrasted with delicate *Odontoglossums* of the crispum type, and such graceful species as *O. citrosimum* with long drooping racemes of soft tinted flowers. Facing the entrance is a charming bank of *Masdevallias* and *Odontoglossums*, and conspicuous throughout the house suspended from the roof is the useful yellow-coloured *Oncidium concolor*. But to enumerate all the attractions of the display would occupy more space than can be spared this week, and we must therefore content ourselves with announcing the fact that the exhibition has been opened and is well worthy of a visit.

TWO HOURS AT SWANLEY.

SWANLEY, Cannell, and the Home of Flowers are practically synonymous terms. Mr. Cannell has made Swanley a familiar name in the horticultural world. A few years ago two or three cottages and a roadside inn were all that could be seen in the way of dwellings, and the surrounding land was devoted to agriculture. Now quite a busy townlike community has sprung up and is still growing, while all around are fruit farms, and in a hollow nestles what may almost be termed a village of glass, the structures which shelter the plants covering an area greater than all the cottages did at the time of the floral invasion. It is astonishing to see what has been accomplished in so short a time by the energy, industry, and business capacity of one man. What is the secret of this success? Enthusiasm tempered with sound judgment founded on practical knowledge and governed by common sense.

Mr. Cannell commenced business on the slope of a railway embankment. It was a mere "patch" of barren ground, but if it would grow little or nothing it would hold a few frames and a small greenhouse, and in these he could grow *Fuchsias*, doing all the work himself. He called this the "Fuchsia Nursery," and commenced advertising *Fuchsias* to be sent by post. The more he advertised the more he sold, and the more he sold the more he advertised, until he made for himself a position and a name that is familiar to the lovers of flowers in this and other lands. The railway embankment being no longer adequate for his expanding trade he migrated to the present scene of his labours. And a busy scene it is, for he does not do quite "all the work himself" now, but employs 110 persons. How many he will have in ten years' time to work his last addition of 300 acres no one can venture to guess, as he is as healthy and active as ever in body and mind, and has diligent sons to aid him.

Mr. Cannell has not only established his great business in popular flowers, but has done it without injuriously affecting the trade of anyone else; but on the contrary, he has increased the operations of many by inciting a love for flowers and creating a greater demand for them

than existed before, and he now largely supplies the "trade" in all parts of the country with plants for executing orders, and thus all parties are benefited. His stock of plants of a softwooded nature, such as the million can grow, is enormous, and in respect to certain kinds unequalled. Even plants that would almost seem to have gone out of fashion are provided at Swanley in tens of thousands. For instance, a 100 feet long house is packed with gold and silver, bicolor and tricolor Pelargoniums in small pots. "What are all these for nowadays?" the visitor asks in astonishment. "Oh," Mr. Cannell replies, "somebody is always wanting them, and trade and private orders are always coming in, and a good many are wanted abroad, so we keep up the stock, the best in the world, and the world seems to know it." It is the same with Verbenas, which are also in thousands, clean thrifty little plants, growing like Radishes, and in finer varieties than were ever seen during the great Verberna-growing period. Nobody else keeps complete stocks now of the new and choice varieties, so the world comes here, and there appears to be sufficient Verberna growers in it to keep the department lively, and, observes their great patron, "more would grow them if they knew how beautiful and sweet they are, and how delightful when well grown in pots under glass in greenhouses or frames, to say nothing about the bedders in the garden." Then we come to a 100 feet house of succulents—Cacti in all their sections, Mesembryanthemums, Echeverias, Sedums, Sempervivums, Aloes, Haworthias, Rocheas, and others—some chastely beautiful, others singular and even grotesque, and altogether such an assemblage as is not to be found in any other trade establishment, so it seems there are sufficient fanciers of the curious in vegetation to keep this house a-going.

If there are such stocks of plants that are not commonly grown, what is to be said of those that are wanted in almost every garden and greenhouse? What, for instance, of the 1200 varieties of Chrysanthemums? The number of plants is bewildering, as it is of Fuchsias, Pelargoniums, Begonias, Gloxinias, Dahlias, with several houses full of Primulas seeding, others gay with single and double Cinerarias, one 200 feet long crowded with tree Carnations, some packed with Cyclamens, and so on, not an inch of space in the crystal village being wasted; and the plants appear to boil over out of the houses into frames, and from frames into the open, as fast as they become hardy enough or the weather becomes mild enough for their reception. But the prolonged cold is a serious impediment to free progress, and the season is one of the most difficult that has had to be encountered at Swanley. A country nurseryman, who travels largely, but who had not seen the Home of Flowers before, was struck with astonishment with the immensity of the provision for the season, and his pocket-book was in constant requisition, for he could not resist the claims of such Zonals as Mrs. D. Saunders, Dante, Edith Little, Hyacinth, Rose, Swanley Gem, Empress, Love Gold, with others, and especially the Swanley Double White, the dwarfest, freest, and best yet seen, and that is probably destined to spread all over the country, and beyond it. But why name names, for are they not all to be found in the catalogue, with the descriptions of the flowers, fairly, yet fascinatingly displayed in the inimitable Cannellesque style? "Never," said the country nurseryman, who had bribed me with a good dinner to be his guide on the occasion, "never have I seen so much in its way in so short a time; and now let us have a rush for Philip Ladds."

If Swanley is a Home of Flowers, and it is, it may be with equal accuracy described as a Home of Fruit, for even nearer to the station than the plant emporium is the wonderful establishment where Grapes and Tomatoes are grown to the extent of scores of tons, varied with a small culture of Maréchal Niel and Gloire de Dijon Roses, covering the roofs of twenty span-roof houses of an aggregate length of nearly half a mile—all for supplying blooms for market. But that represents a mere "patch" of the glass in this remarkable establishment, for the houses, which are admirably built, cover ten acres, and the proprietor has three other "places" of a similar nature. They are a few miles apart, for the reason ascribed by the shrewd man, that a hailstorm might make a grand smash in a particular place, but it would be a wonder if it smashed all the places thus distantly situated at once.

Speaking about the Roses, it may be stated for the information of those amateurs who are afraid of using the knife how this forest of Roses is treated, and for the information of those whom it may concern how two other crops, so to say, are got out of the same houses. Under the Rose-covered roofs Spiræas are grown, splendid plants for market, the shade just suiting them. In other houses are packed small Camellias in thousands, the shade suiting them too. Here, then, we have a crop of plants in pots on the floor—the soil—with a narrow path between them down the centre of each house, and a golden harvest of blooms on the roof above them. But there yet remains the crop of fruit. The crop of Rose blooms is nearly over now, and very shortly every stem of every Rose tree will be cut down—the whole of the growths that have produced the flowers—to the base of the rafters, and the roofs will be clear again. Then the borders are planted with Tomatoes for fruiting in the summer, and in the meantime the Roses push forth shoots again, and these grow vigorously up to the apex of the house for producing the next year's crop of blooms. "But these must shade the Tomatoes, and Tomatoes will not do in the shade," say the orthodox. Mr. Ladds, however, does not work on professional gardeners' lines; but while they are preaching and teaching what cannot be done, he sets about quietly and quickly doing it. He believes his heterodoxy to be a good deal more profitable than their orthodoxy, and prefers employing men who have not learned what he regards as "fancy notions." When he spends thousands of pounds in preparations he wants his money back again,

and he manages to get it much quicker than it would come in under ordinary methods of procedure.

There is scarcely a gardener in Britain who would have believed the gravel bed on which the houses stand could be made to grow Roses and Grapes profitably, but new borders of fresh soil would have been regarded as essential. Fancy clearing out the "poor" soil 2 feet deep from even half of 10 acres of ground, and carting in fresh in its place. It would mean ruin. Mr. Ladds removes no bad soil, but "shoves" in manure till he makes it good enough for growing anything. That is his plan, and the poorer the soil the less likely is it to turn sour with the dressing. If any reader should think the soil is not so gravely as represented let him visit the place and look at the surface of the ground between the rows of Strawberries alongside the finest vinery in the kingdom, and he will see little else but gravel, and a thicker and better covering than is seen on many a carriage road; yet in this mass of small round cobbles grow the Grapes and the Roses.

But to the Tomato shade. In the first place the plants get a good start before the Rose shoots cover the roof, and then the shade is not very dense, as there are glints of light passing through to the plants beneath, and thus useful if not heavy crops of Tomatoes are "stolen" from the Rose houses. These houses are low, just high enough for a 6-foot man to walk through them; they are side by side, supported on pillars here and there instead of divisional walls, so that if you stoop down and look along underneath you may see perhaps an acre of ground covered with a series of span roofs. That is the cheapest way of building a great block of glass for growing a "lot of stuff" for sale.

Before leaving the Roses it may be remarked that many thousands are grown in pots, Niphetos maintaining its position as a producer of white blooms for market. But a new Rose merits a passing note. It is not known by rosarians generally, but apparently will not long remain in oblivion. It was raised from seed by Mr. Ladds' plant-growing foreman, Mr. Herbert Kelsall, and although three years only have elapsed since the seed was sown, six thousand plants are now growing luxuriantly, and many flowering freely. It is one of the most vigorous of growers, the strong shoots terminating in great clusters of buds. These being cut as they open daily, only half, or less than half, open blooms were visible, these having much of the pointed shape of Niphetos, and of light lively rose colour. The plants grow and flower over a long period, and in sturdy robustness surpass all others in the establishment. The value of this unnamed seedling for the purpose for which the plants are grown is exemplified by the extent of its propagation, and Mr. Kelsall may be congratulated on his work. Many thousands of plants of different kinds are grown besides Roses, but these cannot be alluded to now, though a word must be said on the Grapes.

Four varieties are mainly grown—Black Hamburgh, Black Alicante, Muscat of Alexandria, and Gros Colman, the last-named the most extensively. Here again orthodox methods are cast to the winds, more particularly as regards distances in training the rods. Three feet at least for the majority of Grapes, and 4 feet or more for the robust growers represent the teaching of advanced gardeners, but does not represent Mr. Ladds' practice, and he probably cuts a far greater weight of fruit out of houses of a given length, and in say three years from planting the Vines, than any wide-planting advocate has yet produced; but it must be distinctly understood the object in view is not a few 4-lb. to 7-lb. bunches for exhibition, and enriching the tables of distinguished diners, but the greatest possible number of bunches, ranging from a little under 1 lb. to about 2 lbs. or so, for packing in large bulk to meet the requirements of the majority of purchasers in the chief markets. This is accomplished by training the rods 18 inches or less than that asunder, and even those of Gros Colman do not exceed the distance named. The sight is unusual, and the heavily cropped Vines of last year appear as if they would be still more heavily laden, as they are growing strongly and showing fruit abundantly. When the crops are ripening, the bunches must nearly or quite touch each other, and what the sight must be then in the chief Gros Colman house, where there will be an uninterrupted view of nearly 700 feet, both sides of this span of 25 feet being packed from base to apex, can in some degree be imagined, but not fully comprehended without a peep through this tunnel of fruit. All being well I intend to steal a glance of the scene in September if it cannot be managed in a more legitimate way.

In a block of several houses Cucumbers are growing after late Tomatoes, and 150,000 Tomato plants are in preparation for planting. The gravel path in one big house was being broken up just as if picking up a carriage drive, and seedling Tomatoes inserted in it a few inches apart, to be eventually lifted and planted—the most extraordinary nursery bed that was probably ever seen. Possibly it was thought, as weeds grow in gravel walks, Tomatoes would grow there also, and not be of a succulent character, and so the space was turned to account. If some "high" cultivators were to see a man engaged in work of that kind they would think he was crazed.

Two houses are just completed. They would have been in one but for an inequality in the ground. The space covered by the triple spans is 800 feet long by 75 feet wide. The roofs are supported on pillars, and the space well heated. The ground is mainly covered with Strawberries and Roses in pots, but the ultimate object is, I think, a vineyard, into which I quite intend smuggling myself on some pretext or other, perhaps to buy the crop as it hangs, at some future time. Mr. Thoms is Mr. Ladds' fruit foreman, and only a man of great capacity like his master could manage successfully such a gigantic charge. My friend whom I ventured to take down to Swanley is a man of rather large ideas, but after a two-hours rush through the two establishments had, I fancy, a

little conceit taken out of him, and left with his former remark emphasized, "I never saw so much in the time in all my life!"—A LONDONER.

ACACIAS.

YOUR illustration of *A. cultriformis*, page 301, and the bountiful supplies of flowers we have had from our plants of late, induces me to write most favourably of this useful class of spring flowering greenhouse plants. It is impossible to over-estimate their value for greenhouse and conservatory decoration in March and April. They are all yellow, but that is not a defect, as they differ in shade, some being very pale, others of the deepest gold. Their habit of growth is excellent, and they flower in the greatest profusion. Plants so small as to be confined to 6-inch pots produce large quantities of flower, and large bushes, particularly those that are planted out in beds or borders, bear armfuls, or, I might almost say, cartloads of flowers. A backward spring may retard many flowers in cool houses, but no severe weather will prevent the Acacias expanding.

The habit of many is very graceful; the foliage is an agreeable green, and they are therefore well adapted to become permanent occupants of the greenhouse or conservatory. When planted out they do not flower all the year round, or anything like it, but no one could say they were unsightly when not in flower, and I am greatly in favour of their being planted out. When once established they will not only bear any amount of cutting when in flower, but the branches taken off in spring will be replaced by many more before the season is over. I do not approve of old seraggy plants being turned out of pots because they are not doing well with the hope of improving them, as this is certainly not giving them a chance to make a good beginning, but if healthy young plants are placed out at this season they will soon make rapid progress. Soil composed of three parts loam, one of peat, and a liberal dash of sand suits them in both beds and pots. Plants growing above perfect drainage succeed better than when drainage is deficient. We never shade our plants, but give them copious supplies of water when making their young wood.—M. M.

JOTTINGS.

IN a busy horticultural life memoranda accumulate with surprising rapidity, and to relieve one's memory, or to permit the cancelling of congested note-books, a few paragraphs will be occasionally contributed under the above heading. Some will touch on small matters, and their chief object will be to serve as hints to those who have the time or opportunities to elaborate them, or to record observations and items that can scarcely be classed under any other special title.

PRIMROSES.

We had to wait rather longer than usual this season for our display of Primroses, but they have amply satisfied us for the delay, and are still in most floriferous condition. These and the Violets always seem to be the most welcome of the early flowers, and neither required any political associations to increase their popularity. Primroses in particular, even the common varieties, possess such fresh distinctive charms that they commend themselves to all garden-lovers, and now there are so many varied and brightly coloured forms they constitute quite a large group of useful plants. My collection is small, but it is increasing, and it probably affords me as much pleasure as many that are more extensive. About two years ago I obtained some plants of Mr. Gilbert's beautiful white Primrose named Harbinger, and with them formed a bed near the house, where they have for the past fortnight been crowded with large flowers. They flowered very well last season, and some seed was ripened from which nearly 200 plants were raised. These have all flowered in the present season, and include some interesting variations, though, strangely enough, only three out of all the number have come like the parent—namely, with white flowers. The flowers from which the seed was obtained was carefully self-fertilised, as the idea was to procure a larger stock of such a valuable variety as Harbinger undoubtedly is when true. The other seedlings are all delicate yellow Primroses of a very fine type, except three, which are of a rich crimson shade, the flowers well formed and inclining to the Polyanthus habit, as also do some of the yellow varieties. The majority of the latter were planted out, and are fully equal to Harbinger in all its good points except the colour; the flowers are $1\frac{3}{4}$ inch in diameter, of good shape, very freely produced, and the plants strong. Harbinger and the crimson seedlings have now been crossed, and I shall expect to secure a still more varied progeny. I do not know the history of Harbinger, but it seems to have been selected from Primroses of the Polyanthus type, and the seedlings show a rather interesting reversion to the original stock in one generation.

Enormous quantities of Primroses were brought into the metropolis for Primrose Day, and it would be impossible to estimate how many thousands of bunches were sold on that day, but the following facts will give some idea of the demand. At the Crystal Palace, Sydenham, a Primrose Fête was held, and Mr. W. G. Head employed

in a very tasteful arrangement upwards of 14,000 bunches. These were disposed in an undulating bank 60 yards long by 2 or 3 yards wide, with 5000 bunches of other flowers, 150 pots of Daffodils, and 300 British Ferns in pots specially forced for the purpose. The majority of the Primroses sold in the market at early morning at very small prices, but subsequently as much as 2s. 6d. per dozen was realised.

NARCISSUS TRIANDRUS ALBUS.

Under the name of *Narcissus calathinus* this charming plant has been repeatedly noticed in the past two years, and it was grown as such in the Royal Gardens, Kew. It has, however, since been found that the name is incorrect, and that the true *N. calathinus* is much scarcer. As *N. triandrus albus* (fig. 45) it is, however, equally worthy of cultivation, and it is one of the best of the smaller flowered Narcissi for pots. I have an example in flower now that shows the characters of the plant admirably. A 32-sized pot contains about fourteen bulbs, each bearing a scape with from one to three flowers, the total being thirty-two elegant creamy white slightly drooping flowers. They have been expanding for the past fortnight, and will last for at least another week, as they are not all

Fig. 45.—NARCISSUS TRIANDRUS ALBUS.

fully open yet. Several of the scapes have three flowers each, but in Messrs. Baker and Burbidge's work on the Narcissus it is figured with four flowers to a scape. The plants have been in an unheated house all the winter, but were placed out of doors in a sunny position last summer to ripen the bulbs, with the result that they have flowered much more strongly this season than last.

COVENT GARDEN MARKET ON MAY DAY.

The different seasons have their special attractions in the Covent Garden Flower Market, but scarcely a better time than the present could be chosen for an early morning visit. On May 1st the market was particularly full and busy, plants and flowers being apparently in strong demand. Amongst the plants Marguerites in 48 and 32-size pots were remarkably numerous, fine graceful little bushes well flowered, and especially valuable for decorative purposes and window boxes. Pelargoniums, both Zona's and the decorative or regal varieties, contributed a wealth of colour. Cinerarias also afforded some rich tints, with Fuchsias, Spireas in thousands, capital dwarf Hydrangeas with large heads of pink flowers, Deutzias, Heaths, and Rhodanthes. The last named, particularly the white variety, are great favourites, and grown as the plants are in frames they have not the drawn thin appearance so frequently seen in gardens. Forced plants of *Lilium candidum*, with the pure *L. longiflorum*, also occupied a considerable space on

several stands. The foliage plants were chiefly Palms, such as Kentias, *Geonoma gracilis*, and *Cocos Weddelliana*, with Ferns (*Adiantums* and *Pterises*), the much-enduring *Aspidistras*, and *Cyperus laxus* or *alternifolius*.

The cut flowers were also in strong force, Daffodils and Wall-flowers nearly sharing the honours in point of numbers, but the latter were in the majority, for some of the larger growers took the market by storm, bringing some waggonloads of stout bunches of dark fragrant flowers. Daffodils were there in all shades, from white to the richest golden form of the trumpet flowered section, together with the delicately pretty Poeticus varieties. Forget-me-nots, Roses, Violets, Gardenias, and *Stephanotis* were prominent in other directions, while of Hyacinths there were some hundreds of boxes, showing that the exportation of flowers from Holland to this country has by no means been stopped by the Society formed for that purpose, though it has probably been checked. On the previous day a large sale was held in the market, when shallow boxes containing several dozens of spikes were sold at from 1s. 6d. to 4s. each, the white varieties realising the latter price.

On Thursday a "Fruit Show" of a rather remarkable character will be held in the Floral Hall, for one of the salesmen announces that he will have 5000 Pine Apples on view, to be subsequently sold by auction. Such exhibitions as these and those in the flower market are even more interesting to horticulturists than the ordinary competitive displays.

WHINHAM'S INDUSTRY GOOSEBERRY.

Amongst useful varieties of Gooseberries for market culture Whinham's Industry has gained an astonishing popularity. It is very early (three weeks, it is said, before any other). The fruit is large and red, crops heavy, and valuable either for picking green or when ripe for jam. One firm in the north of England that has made a specialty of the variety, in 1886 sold 35,000 bushes, in 1887 over 53,000, and in the present year 95,000. These were dispatched to America and various parts of the Continent, including the home supply.—L. CASTLE.

THE NATIONAL AURICULA SOCIETY. (SOUTHERN SECTION.)

THE annual Exhibition, of which a report appeared in last week's Journal, was held under very discouraging circumstances, for anyone who has ever grown Auriculas must have felt what a terribly late season we have. I had not one single truss out, and it is only where there were appliances for heating that it was possible to have flowers in bloom. It is idle people talking about there being no change in our climate. We may be in the midst of a cycle of late seasons, and there may have been such a cycle before, but ever since I have grown Auriculas, a period of fifty years, I always calculated on, and was not disappointed in having a good bloom by the 20th of April, which was the date the older growers of the early part of this century used to assign as the orthodox time of blooming. In those days the application of heat to Auriculas was never dreamt of, and I believe had it been mentioned would have been universally scouted. I am one of the old-fashioned people, and I still unhesitatingly declare that the practice is an injurious one. However carefully it may be done it is injurious. I have not the slightest doubt that it tends, while perhaps increasing the size, to destroy the refinement of the flower, and this is one of its greatest charms. Doubtless had it not been for the use of heat there would have been very few flowers on the 24th, and so the evil is somewhat mitigated, but where exhibiting is not the chief object, growers will, I am sure, do best to grow their plants in the old way.

In my opinion the Exhibition of last Tuesday was a long way behind most of its predecessors, I fancy in the numbers, and in quality certainly of the flowers exhibited. It was unfortunate, too, that the day was so dull. The hall at the best of times is not light, and with such a day it was especially dull, and I need hardly say that a good yet subdued light is absolutely necessary in order to see well the beauties of the Auricula. My reasons for regarding the Exhibition of Tuesday as not up to the standard we would wish to see are—1, There was in most of the stands an undue preponderance of selfs; in many cases fully one-half of the flowers were of this class. Now, while they are very beautiful, I think it will be generally admitted that it is the least advanced and the most easily grown of the four classes of show Auriculas. Whoever attempts to grow seedlings is, I believe, pretty sure to get a large proportion of this class amongst them. They are, moreover, the earliest to bloom, and I think this is the reason why so many of them were shown. The season is a remarkably backward one, and hence those flowers which came in early were seized upon to make up the stand. A well-balanced stand of twelve ought to contain three each of the four divisions. 2, In many of the stands Auriculas were shown with only three pips, and I do not call that a truss. The old rule used to be that every edged flower must have five, and every self seven pips, and often even where there were only three pips they were not all fully expanded. I must think that, considering the number of plants many exhibitors grow, that they must have been very hard up to have put up plants with such small trusses. 3, There was in most cases a great deal of coarseness in the flowers. I have before my mind several plants with flowers utterly

out of character, many with great goggle eyes, as my old friend Mr. Jeans used to call them, many with body colour too heavy and running into the edge, and others with crimped and curled petals, as if all the heat they had been subjected to had not even been enough to open them fully. 4, The very few really first-rate examples of the old-established varieties. There was, for instance, in my judgment not more than one or two really first-rate trusses of George Lightbody, not one of Prince of Greens or Acme, but one or two of Lancashire Hero. In the classes for single plants this was the more conspicuous; classes where one has been accustomed to look for and find good examples in profusion of these "cracks," there were very few of them. I have no doubt that the wise rule of restricting growers to two plants has lessened considerably the number of those exhibited, but it ought and would in ordinary circumstances have done so, but as I have already said, the lateness of the season and the consequent need of a good deal of heat have contributed very much to the mediocre character of many of the blooms exhibited to-day.

I think that perhaps the most interesting part of the Exhibition was the number of seedlings exhibited by such raisers as Messrs. Horner, Douglas, Bolton and others. One is very much astonished to think of what the old raisers did without any scientific knowledge or any artificial hybridising, for I do not believe that Headly, Lightbody, Read, Lancashire, Heap, and others ever hybridised their flowers, and, as I believe, it will be a long time before the flowers that were raised by them will be beaten out of the field. Now-a-days careful hybridising is the practice with most seed raisers; good results have already been obtained, but it may be after all with the Auricula as with the Rose, chance seedlings will still hold the palm. Mr. Douglas's account of seedlings raised in recent years in last week's Journal was very interesting. I think, perhaps, he has been rather hard on the older varieties, as many others besides those named by him will, I hope, remain in our lists and collections and last my time at least. There is, however, one thing to be remembered, that seedlings do not always retain their character, and develop in after years some defect which was not conspicuous in their youthful days.

With regard to the seedlings exhibited the other day there can be no question, I imagine, that the variety named Bessie Potts, raised by Mr. W. Bolton of Warrington, and exhibited in Mr. Horner's stand of twelve, was the "topper" of the Show, indeed it gained the premier prize as the best Auricula in the Show. It is a very beautiful green-edged variety, the edge very bright, the eye bright and lively, the body colour good and not too heavy, and altogether a very bright and pleasing flower. Monarch (Horner) was also a very fine green-edge, somewhat larger than the preceding, but not so refined, with a somewhat duller eye. Mr. Horner's Irreproachable (grey edge), a bold and taking flower. There were several selfs exhibited, and I noticed what seems to an old fashioned grower to be an innovation—selfs with two colours or shaded. Such for instance is Laura (Horner) where there are two distinct shades of colour, whether permanently so or not I do not know, but I do not like it, it is bringing the self Auricula much too near to the white ground Alpines. Mr. Horner had a very beautiful self in Constance, of a crimson maroon shade, good form and substance, and Mr. Bolton had a very beautiful maroon self, called Mrs. James Tinsley. Of older varieties Heroine (Horner) still holds its supremacy, and whenever a good plant of it is exhibited there is very little chance of any other variety beating it.

Such is my estimate (right or wrong I must leave to others to decide) of the Exhibition of last week. I must again ask those who read these notes to bear in mind that I was brought up in a very rigid school of critics, that in my day a truss of ten or twelve pips was not considered a desideratum, seven pips in the opinion of the older florists making a perfect truss, and that coarseness was considered a fatal defect. I am not one of those who think there is no progress, and who are for ever praising the "good old times." Many of the varieties which used to hold the foremost place have passed out of cultivation. We had then no George Lightbody, Richard Headly, Acme, Pizarro, Smiling Beauty, &c., and perhaps the time may come when those we so highly prize now will give way to better kinds. The younger men who are going in for seedling raising have, I hope, a "good time" before them, and I wish them every success.

It remains but to say that the South was well supported on this occasion, and that for the first time in its existence the President of the Royal Horticultural Society presided at the luncheon. Let us hope for a better season in 1889, when the labours of all engaged in working the Society may have a more satisfactory result.—D., Deal.

CABBAGES CLUBBING.

I DO not think anyone could be more troubled with Cabbages clubbing than we were at one time, but of recent years it has been unknown in this garden. We have had to pull up ninety out of a hundred plants in a row. There is no mistaking the disease. The plants become yellow and wither in the leaves. When drawn up a little swelling is noticed on the stem amongst the roots, or close to them, and if this is opened with the thumb nail, or cut in two with a knife, a white maggot is found inside. It is this that does the mischief, and it must be treated like any other grub. Gardens in which Carrots, Onions, and Parsley suffer from grubs are always liable to foster Cabbage clubbing.

Lime and soot are our only cure for clubbing. At one time our Onions, Carrots, and Parsley were so uncertain that I resolved to extir-

minate their enemies, and to do this a dressing of lime was given to the whole garden. The year afterwards some of the worst quarters were sprinkled with gas lime before being dug. Soot was applied to the crops while growing, and since that time I have not known one of our Cabbages to club, and we grow some thousands annually.—*J. MUIR, Margam.*

EVENTS OF THE WEEK.—On Tuesday next the Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, James Street, Victoria Street, when Orchids, Narcissi, and Asparagus are announced to be the leading features. On Saturday, the 12th inst., the summer Show will be held at the Crystal Palace, Sydenham. Several sales of Orchids are also announced for the present and following weeks.

— **AN EXHIBITION IN THE TEMPLE GARDENS.**—The Royal Horticultural Society will hold an exhibition, under the patronage of the Lord Mayor, in the gardens of the Inner Temple, London (by the kind permission of the Treasurer and Masters of the Bench) on May 17th and 18th next, and schedules have just been issued giving the following particulars. Twenty-four classes are provided for groups of miscellaneous plants, Orchids, Roses, Azaleas, Pelargoniums, Clematises, Palms, fine-foliage plants, Ferns, hardy plants, Calceolarias, &c., a sum of £100 having been voted by the Council to be allotted by the Judges to the various classes according to merit on the day of the Show. Exhibitors must give notice of their intention to exhibit to Mr. A. F. Barron, R.H.S. Garden, Chiswick, not later than May 12th. On the morning of the Show exhibits will be received up to 9 A.M., when the gate will be closed, and all staging must be completed by 10.30 A.M. The Exhibition will be closed at 7 P.M. Schedules and all information can be obtained from the Secretary, the Society's offices, 111, Victoria Street, S.W.

— **GARDENERS' ORPHAN FUND.**—A meeting of the Committee was held last Friday, Mr. G. Deal in the chair. It was announced that applications had been received from ten candidates for the six elections that are to take place at the first annual meeting on July 13th, in the "Canon Street Hotel." At the dinner, which is to be held in the Hotel on the evening of the same day, it is hoped 500 gardeners and friends will attend, as it is desired to make the first gathering as great a success as possible. The chair will be taken at 5 P.M. by Sir Julian Goldsmid, Bart, M.P.

— **THE CENTENARY OF THE LINNEAN SOCIETY** occurring this year, a special celebration will take place in connection with the annual meeting on Thursday, May 24th. The occasion will be marked by two particularly interesting features—the presentation of the Linnean gold medal to Sir Joseph Hooker, K.C.S.I., formerly President of the Royal Society and Director of Kew Gardens, and to Sir Richard Owen, K.C.B., so long Superintendent of the Natural History department of the British Museum; and the delivery of eulogies on Linnaeus by Professor Fries, the present occupant of the chair of botany at Upsala.

— **THE WEATHER.**—"B. D." writes from Scotland:—"April (30th) is going, weeping gently, presumably for her cold and ungenerous behaviour. She has been unsparing of both smiles and tears, but her breath has been that of winter instead of spring. The last week was cold throughout the first half with high east wind, and the second with equally cold westerly gales. Frost occurred on the nights of the 24th and 25th, the ice being fully one-eighth of an inch thick on shallow water on the morning of Thursday last. Hedges and trees begin to assume a greenish tint, and pasture is improving." In the south the weather has been milder than the previous week, and Monday was quite a summer day, with a slight chilliness in the wind.

— **THE SCOTTISH PRIMULA AND AURICULA SOCIETY** announce that their second Show will be held in the Calton Convening Rooms,

Waterloo Place, Edinburgh, on Wednesday, May 9th, this year. Show and Alpine Auriculas, Polyanthuses, Primroses, and Primulas have twenty-one classes devoted to them, the prizes ranging from 20s. to 2s. 6d., but in addition, Mr. W. Straton, Annfield, Broughty Ferry, presents a gold medallion as a special prize for six self Show Auriculas. Certificates will also be awarded for seedlings considered sufficiently meritorious. The Hon. Secretary and Treasurer is Mr. W. Straton, and the Assistant Hon. Sec., Mr. J. Grieve, Pilrig Nursery, Edinburgh.

— **AURICULAS AT SHEFFIELD.**—We are informed that in consequence of the prolonged cold and consequent lateness of the season Mr. B. Simonite's Auriculas will not be in bloom before the second week of the present month.

— **A RE-ISSUE** of Mr. W. Paul's cheap popular book on **ROSES AND ROSE CULTURE** (Kent & Co., 32, Paternoster Row) is just to hand, and comprises within its ninety-two pages much interesting and useful matter for amateur rosarians. A chapter on new Roses is included, selections of Roses for particular purposes, and a list of varieties reared or introduced by English Rose growers.

— **MR. JOHN CROOK**, gardener to Mrs. Sherwin, Farnborough Grange Gardens, Hants, writes as follows in reference to the **SEEDLING PRIMULAS** shown at the last meeting of the Royal Horticultural Society:—"Thanks for your notice of Primula under certificated plants. Three of the six plants shown were seedlings, obtained by crossing *P. ciliatum* with other hardy Primulas. Mr. Douglas thought the reddish crimson one was a break in colour. The object I had in view was to obtain a race of hardy Alpine Primulas with larger and more highly coloured flowers. Many of the existing varieties are unsatisfactory growers with small flowers. The seedlings are quite hardy, strong in habit, and free flowering."

— **AN ESSAY** read some time ago before the members of the Nottinghamshire Horticultural Society by Mr. Chas. E. Pearson of Chilwell, entitled **THE PELARGONIUM AND ITS CULTIVATION**, was subsequently issued in pamphlet form, and has now reached its second edition. It comprises in eleven pages cultural information respecting Zonal, Show and Ivy-leaf Pelargoniums, including details on summer and winter culture, diseases, insects, raising new varieties, potting soils, stimulants, aspect for houses, &c. It is brief and practical.

— **MESSRS. J. LAING & SONS**, Forest Hill, S.E., have at the present time a large display of **CALADIUMS**, which is one of the specialties in the well known Tuberous Begonia nurseries.

— **GARDENING APPOINTMENT.**—Mr. Archibald Baxter, for nearly five and a half years general foreman at Wentworth House, Rotherham, has been appointed to succeed the late Mr. Tindall as head gardener at Sprotborough Hall, Yorkshire.

— **WE** are requested to state that offices have been opened in London, at Cornwall Buildings, 35, Queen Victoria Street, E.C., for the **AUSTRALIAN IRRIGATION COLONIES**, which are now being carried out on the River Murray, under special Acts of the Parliaments, and regulation by the Governments of Victoria and South Australia, by Messrs. Chaffy Bros. (Limited) late of Ontario, Southern California. The work is intended to remove a chief obstacle to the development of colonisation on the Australian continent—namely, the frequently recurring and disastrous droughts.

— **SCHEDULES OF SHOWS.**—The schedules of Exhibitions to be held during the present year are accumulating, and the following are to hand this week. The Winchester Horticultural Society will hold their fifth Rose and Flower Show in the Guildhall of that city on Thursday, July 12th, and a Chrysanthemum Show in the same building on Tuesday and Wednesday, November 13th and 14th. The Wimbledon Royal Horticultural Society announce their summer Show to be held in the grounds of Wimbledon College on Wednesday, July 4th, and the autumn Show on Thursday, November 15th, in the Drill Hall, Wimbledon. The South Essex Horticultural Society will hold their next Exhibition in the grounds at Knotts Green, on Thursday, June 14th. Chrysanthemum Shows will take place at Barnsley on Thursday and Friday, November 15th and 16th, and at Brighton on Tuesday and Wednesday, November 13th and 14th. We do not remark any special alterations or additions to these schedules for the current year.

— ACCORDING to a paper in the *Board of Trade Journal* for April, the production of attar of Roses constitutes one of the most important branches of native industry in Bulgaria. The valley of Kezanlyk, known as the VALE of ROSES, is the centre of this production, which extends as far as Carlovo, and the villages which lie sheltered from the north wind by the vast chain of the Great Balkans. In 1885, and no later statistics have been published, the manufacture of attar of Roses in the district indicated amounted to a value of 1,100,000 francs.

— A NEW HOLLY.—We are informed that at the sale of the Lawson Nursery Stock at Bangholm, Edinburgh, last week, the new Golden Variegated Hodgins Holly, which originated in the Bangholm Nursery, Edinburgh, consisting of twenty-four plants, was sold to Messrs. Little & Ballantyne, Carlisle, this being the entire stock. Assuming the variegation is clear and constant, and the plant inherits the free growth of the type, this "Golden Hodgins" should be an acquisition.

— MESSRS. OAKSHOT AND MILLARD request our opinion on samples of CINERARIAS that have been presented for examination. One of the blooms exceeds 3 inches in diameter, and though the others do not quite equal it in size, they are good in form, substance, and coloration. We have not yet received a bloom exceeding in size the one sent by Mr. R. Owen that was referred to on page 352 last week, and when we do the circumstance shall be recorded.

— A BERKSHIRE correspondent appeals for information as follows:—"Can any of your contributors inform me if either of the LAWN EDGING CUTTERS in the market give really satisfactory results? Some few years since I tried one of them, but from the impossibility of varying the depth of the cut to suit the depth of edge it turned out a failure with us. I should be very glad to learn that this difficulty has been surmounted, as we have something like a third of a mile of edging to keep in order, and the labour of doing it with the shears is a great tax on the gardener."

— WE are informed that Messrs. Shirley Hibberd and H. Herbst have been added to the Committee of Management of the Chiswick Gardens.

A PROPAGATING PAN.

AT the last meeting of the Royal Horticultural Society, Messrs. Thos. Pascall & Sons, South Norwood Pottery, S.E., exhibited samples of

Fig. 4.

a new propagating pan, and the Floral Committee recommended that it be sent to Chiswick for trial. It is very simple, as the accompanying cut (fig. 46) indicates, and is likely to be found useful by amateurs and others who have few conveniences for propagating plants. The trough is hollowed on the under surface, so that it fits evenly on hot-water pipes. The lower part is filled with water, and upon two small ridges at the side a perforated tile rests, the soil in which the cuttings are to be inserted being placed on this. The top can be covered with a piece of glass, and most softwooded plants, like *Alternantheras*, strike readily. The troughs are 14 inches long, $6\frac{1}{2}$ inches wide, 6 inches deep, and the bottom is made to fit a 4-inch hot-water pipe.

GLADIOLI NOTES.

WITH regard to "A Northern Amateur's" destructive criticism of what you were good enough to publish at p. 319 I do not think a better reply could be found than is furnished by the notes from Mr. Murphy, which precede those of your correspondent. That gentleman "cannot justly complain of disease, exhaustion, or degeneration," and then follows "one of the great agencies which command success." "The corms must be ripened or failure will result." When, may I ask, was the culture of the *Gladiolus* at its lowest? Was it during the hot summers between 1867 and 1876? During that period we know that the *Gladiolus* was established as a florists' flower, and nothing was then heard of any difficulty in keeping it. But by the time the disastrous seasons of 1879, 1880, and 1881 had

passed the hope of keeping stock of the *Gladiolus* had been so lessened that "D. Deal," myself, and perhaps others, had simply to advise the purchasing of stock every season. Last year we entered on, let us hope, another series of hot summers, when the difficulty of ripening the corms will be overcome. For my own part, I can only repeat that want of maturation and not disease has been the difficulty I have had to contend with. A few points of your correspondent's letter I may be allowed to reply to. First as to French corms being badly diseased. For the past few years I have had my stock from Messrs. Stuart & Mein of Kelso. These are imported directly from France, and I cannot say I have found a diseased corm among any of their parcels. Curiously enough this firm, though growing sometimes not more than seventy corms, is peculiarly successful when exhibiting. I believe they have beaten both Messrs. Kelway & Son, who grow twenty acres, and Mr. Campbell of Gourcock, who has no difficulty in staging 150 spikes at one show after another.

Secondly, I do not know why some sorts do not succeed here any more than I do not know why certain Pansies and Carnations and Picotees do not. However, the fact remains.

Thirdly, I certainly grow *Gladiolus* primarily as decorative plants. Some of the varieties I favour are so beautiful as regards colouring that I must say I have little sympathy with anyone who would neglect them on account of a lack of size or shape of flower or length of spike. The men who measure the beauty of the *Gladiolus* by inches and feet are few.

Fourthly, Your correspondent is entirely in the wrong in assuming that the plant which I referred to as producing seventy-eight single flowers did not do so from one single growth. Moreover, it was from the half of a cut-up corm, its twin being very little behind in number of blooms. The rest of your correspondent's note hardly calls for remark—B.

AT last, April 23rd, I have finished planting my small stock, not above 500 roots, and during all my long experience of the plant I have never been so late. The very unfavourable state of the weather, and consequently of the ground, hindered me for some time, and then a sharp attack which laid me by for a week hindered me, and it was only by snatching bits of times that I was enabled to get it done. I cannot say that I look very hopefully to my bloom this year owing to this. I do not so much mind the lateness of the season as the unkindness of the ground.

I am, as your correspondent calls me, an "old time" correspondent; but perhaps he means that I am so wedded to theories that I cannot give them up when I see good reason for so doing, if my consistency is delicious to him, his splendid begging of the question is beyond all praise. When I have maintained that the *Gladiolus* is subject to a disease which is often fatal, and is more so in some seasons than in others, I am not stating a mere theory. Years ago I submitted corms to that most distinguished vegetable physiologist, the Rev. M. Berkeley, and he distinctly stated it was a disease similar to that which attacked the corms in Holland. Some years later I submitted corms to Mr. Worthington Smith, who carefully examined them, and published in the *Gardeners' Chronicle* engravings of dissections he made of the roots, and clearly established that it was a disease, and so I have seen no reason to alter my opinion. This year, as I have stated, amongst some corms that I reared in a frame were some so "evil" that I could not plant them. I sent two up to an authority, and the verdict is the same, bad examples of the *Gladiolus* disease. Happy are those growers who know nothing of it. I have often heard the same cry from other growers, but after a time somehow or other they lose their corms, although, as they have determined that there is no disease, some other reason must be found for it. As I have said, however, the prices of *Gladioli* are now so much lowered, and the very best varieties can be obtained at so moderate a cost, that the losses by disease or any other cause can be readily supplied.

There is, of course, a greater difficulty in harvesting the late-flowering varieties, such as *Duchess of Edinburgh* and *Phœbus*, but when your correspondent says anyone who knows the former of these two varieties "will see the impossibility of growing it a second year," there is a complete begging of the question: So far from that being the case, the corms which I planted this year were at least four years old, and each of them when harvested measured 10 inches round, and were in perfectly sound condition. As I have already said, I think that one of the best ways to remedy this defect of ripening in the later blooming sorts is to leave them in the ground longer. They may be left there until the first week of December, and unless it is a very wet autumn no injury arises. I do not think there is much danger of their throwing out fresh roots, a fear I once had myself. I believe that as soon as the new corm is formed on the top of the old one it throws out fleshy roots, and the effect of leaving them in the ground will be simply to make them a little more vigorous, but not to detract from the strength of the corm; but after all, perhaps the best way is not to have much to say to these late blooming varieties. I know none of them that is not equalled in colour and beauty by those which flower at more seasonable times, and I cannot see much use in growing kinds of which it is very doubtful whether you will ever get a bloom, and therefore I think that after this year I shall not attempt to grow any of those contained in division 4 of my list.

There will be always a difference of opinion with regard to varieties, and wonder expressed why some are omitted in any list given; and why

others are included ; still, I went very carefully through my list, and had, I think, fairish reasons for omission. Thus, of those mentioned by your correspondent I consider Le Phare and Orphée both too small for the requirements of these days. Dietateur is with me one of the very latest ; indeed, it never bloomed properly with me this season, and so I determined not to grow it again. Amitié had utterly failed with me for two years, and so I gave it up, looking upon it as I do Madame Desportes, beyond my power, in this locality at least, of keeping it sound. Eugène Souhet I am again trying, but it has as yet failed to

these things should be carefully taken into account before we conclude that there must be want of skill, intelligence, or care because failures take place.—D., Deal.

PAVETTA NATALENSIS.

PAVETTAS are not numerous in cultivation, but one, *P. borbonica*, is a favourite in some choice collections of stove plants, the leaves being

FIG. 47.—PAVETTA NATALENSIS.

please me ; the same I may say of Phidias. Teresta I might include, although I have never grown it but one year. Diamant is much too flimsy to suit my taste. Panorama rarely opens with me a sufficient number of blooms to make a good spike. Sylvie is also thin, and Penelope poor in colour.

It is evident there are some varieties which succeed better in certain localities than in others. Some of those named by your correspondent with which he is unsuccessful do well here, and I remember a first-rate grower in Scotland telling me that he could do nothing with Meyerbeer, with me so easily grown that I have often thought of growing it in clumps like *brenhleyensis*, and leaving it in the ground to take its chance, and yet the grower could do nothing with it. It is well that all

beautifully variegated with green and yellow, and having a red midrib. Another less familiar plant is *Pavetta caffra*, which has heads of white *Ixora*-like flowers, and near to this comes *P. natalensis*, which has been recently introduced from Natal by Mr. W. Bull, Chelsea, to whom we are indebted for the illustration (fig. 47). The flowers are pure white in dense semi-globular heads, and the long styles which protrude considerably beyond the mouth of the corollas give the heads a very distinct appearance. The plant will succeed in a cool part of the stove, in an intermediate house, or in a warm conservatory, and requires a good sandy peat as soil, or a small admixture of light turfy loam.

ROSE SHOWS IN 1888.

- June 26th.—Boston.
 „ 28th.—Brockham and Rydc.
 „ 30th.—Eltham and Reigate.
 July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
 „ 4th.—Croydon, Farnham, Hitchin, and Richmond.
 „ 5th.—Bath, Farningham, and Norwich.
 „ 6th.—Sutton.
 „ 7th.—Crystal Palace (National Rose Society).
 „ 10th.—Gloucester, Ipswich and Oxford.
 „ 11th.—Ealing and Tunbridge Wells.
 „ 12th.—Birmingham, Carlton-in-Worksop, and Winchester.
 „ 14th.—New Brighton.
 „ 16th.—Newcastle-under-Lyne.
 „ 17th.—Leek and Ulverstone.
 „ 18th.—Birkenhead.
 „ 19th.—Helensburgh.
 „ 20th.—Darlington (National Rose Society).
 „ 21st.—Manchester.
 „ 24th.—Tibshelf.

In the above list the only exhibitions not held by the National Rose Society, or by Societies in affiliation with it, are those at Birmingham, Boston, Carlton-in-Worksop, Manchester, Newcastle-under-Lyne, and Richmond. In the case of Birmingham and Boston, where the shows extend over two days, the date of the first day's exhibition only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSES FROM CUTTINGS.

THAT Roses from cuttings succeed admirably admits of no doubt whatever. A goodly number of plants can soon be raised by propagating them at the various times when cuttings are most easily obtained. One of the periods when a sure strike can be depended upon is the present, as after the forced plants have flowered and the wood has become partly ripened, two cuttings can be taken from each well grown shoot without injuring the plant. Shoots cut so that two joints are above and one joint below the soil when inserted are all that are necessary. Cut the bottom leaf off the cuttings, place about five cutting in one 3½-inch pot—pressing the soil firmly, which should be composed of two parts loam to one of leaf soil, with a free admixture of sharp sand, placing some of the latter on the surface to be carried down to the bottom of the hole made to receive the cutting with a dibber, as roots are more quickly formed in sand than soil. If the soil in the pots is watered previous to the insertion of the cuttings the work can be done much more firmly and the cuttings stand a much better chance of striking than when they are inserted in loose dry soil. In either case water should be given to settle all firmly down. Place the pots in a gentle bottom heat in either a hotbed or propagating frame, where the cutting can be kept close with the exception of the admission of the air occasionally to evaporate condensed moisture. Upon no account should the foliage be allowed to flag, therefore shade when necessary, and occasionally sprinkle the leaves with water. Roots will quickly form, when the plants must be removed to a warm house for a time, giving them a position near to the glass to prevent their being drawn during the growth. Place them singly into small pots, using a similar kind of soil, returning them to their former quarters until established, when the plants should be gradually hardened, and either placed out into their permanent positions or be kept in pots for the remainder of the season. If the latter intention is to be adopted a shift into pots 4½ inches diameter will be an advantage, using soil with more loam and some partly decayed manure, plunging the pots in ashes for the remainder of the year.—S.

CLIMBING ROSES.

“THAT variety is a point of primary importance in garden scenery will hardly be disputed, and in the Climbing Rose we have a distinct and interesting object. What can be more picturesque than an Ayrshire or Evergreen Rose, scrambling up the stem of some old tree, which is probably bare of branches on the lower 10 feet or 12 feet of the trunk, although its lofty head is a fine feature on the outskirts of a lawn or shrubbery? Deftly and rapidly these Roses wind around the rugged trunk, pushing upwards till they reach the branches above, among which they entwine themselves, the clusters of flowers drooping gracefully, intermingling with leaves and branches, and moderating the glare of the sky openings.

“Yon old wall or oak paling, solid as a fence, is not altogether sightly; the inroads of time have set a mark upon the surface; in the wall a soft brick is crumbling in decay, on the fence are thick patches of mosses and lichens. We would not in many cases entirely hide these fences, but there is too much of them exposed to view. We would break the continuous blank lines and spaces, and what more suitable for the purpose than Climbing Roses?

“Again, the arches at the crossing of walks may be appropriately clothed with these facile plants, and they are equally well adapted for trailing over arcades, arbours, and rustic temples.

“For the above purposes the Ayrshire, Evergreen, and Multiflora Roses are the best. They grow vigorously when well fed, often making shoots 10 feet or 12 feet long in one season. They are very hardy, and when fairly established flower most abundantly. For low fences the Hybrid China, Hybrid Bourbon, and the strongest-growing Hybrid Perpetuals may be used; and if a wall with a south, east, or west aspect is bare and unsightly, whether high or low, some few of the Noisette and Tea-scented are the best kinds that can be planted against it.

“When planting against fences, whether walls or palings, it is well to nail the principal shoots to the fence immediately after pruning. Where subject to strong winds, and if the growth has been very vigorous during summer, it may be well to stick in a nail here and there during and after the season of flowering. For this purpose nails and shreds should always lie ready at hand. The Banksian Rose, which is one of the most interesting and beautiful of Climbing Roses, requires special treatment. It is common to hear it said, ‘This Rose grows freely enough, but seldom flowers well.’ Now, this is usually due to the system of pruning. Very little pruning is necessary here. The gross shoots, if any, should be pinched or stopped in the growing season, and the thin, weak, wiry shoots should be removed early in the spring. The aim should be to obtain and preserve a goodly number of moderate-sized well-ripened shoots, and these should be pruned sparingly, for it is such, and such only, which produce flowers.”—WILLIAM PAUL (in *Roses and Rose Culture*).

ROYAL HORTICULTURAL SOCIETY.

APRIL 24TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters, in the chair; Messrs. Michael, O'Brien, Pascoe, Burbidge, Dr. Scott, Professor Church, and Rev. G. Henslow (Hon. Sec.).

Daffodil, Fringed.—Mr. Burbidge gave the following further particulars about the remarkable form described at the last meeting. He said that there existed but a single clump in the lawn of Rev. Mr. Gabbett, Croom Rectory, by Limerick. The flowers had come true for several years. It was associated with *N. spurium* and *N. Telemonium* (plenus), the former seeding itself. It appears to be a sport from *N. spurium*, but nothing certain is known of its actual origin.

Ilyacinths, Self-Mutilation of.—Specimens of this not uncommon phenomenon were sent from Colonel Urquhart, of Rosebay, Broughty Ferry, for information as to the cause. The spikes have the appearance of being pinched off when first emerging from the bulb. The cause is apparently twofold; on the one hand, the bud-scales at the top are too rigid, while on the other the spike was well nourished, the result being that the insufficient expansion of the scales checked the development of the spike at the place where it becomes decapitated. The probable explanation was the exceedingly fine season of 1887, the “ripening off” bringing about the rigidity of the bulb scales, at the same time favouring the formation of the spike within. Mr. Burbidge observed that it is a noticeable fact that the Chinese gash their bulbs with three slits at the top, to allow of the free escape of the spike, and to prevent such constrictions.

Hazel Catkins, Proliferous.—On a further examination of the Hazel brought to the last meeting by Dr. Masters from Mr. Syme, Mr. Henslow observed that, besides bearing female catkins at the base of the male, the latter were proliferous, the basal branches being covered with staminate flowers resembling the so-called “Egyptian Wheat,” a variety of Rivett's, on which several of the spikelets grow out into ears; so that five or more may proceed from one stalk. These two peculiarities—the proliferous state of the male catkins and the presence of female ones—corroborated the conclusion arrived at by Mr. Meehan of Philadelphia, who observed in various declinuous trees, that the female flowers were always associated with a relatively greater degree of vigour; or conversely, that an increased vigour produced female flowers, when normally nothing but male would have appeared.

Eucalyptus, Hardiness of.—Dr. Masters received a communication from M. Naudin, in which he speaks of the hardiness of *E. urnigera* at Brest and elsewhere, where it is subject to occasional severe frosts. He says that *E. coccifera* will compare favourably with it, as also *E. viminalis* (falsely called *E. amygdalina*) which is nearly as hardy. The last severe winter has shown the different degrees of hardiness among the various species of *Eucalyptus*. He says that a considerable number, even of very young trees, were absolutely insensible to the frost, while others, much larger and older, have had their foliage scant or less damaged. Even *E. globulus*, usually so hardy, has had some of its leaves frozen, principally through the melting of the snow by the sun's heat. Mr. Burbidge remarked on the general presence of bloom or wax on the young leaves, and its absence on the older—probably a provision against too great transpiration in the young state. Mr. Henslow offered a similar interpretation of the scimitar-form of the older leaves to that of the obliquity of Pears and Fir cones. When the stalk stands at an angle with the vertical, the weight of the leaf acting vertically downwards, the tension being along the stalk, the leaf consequently grows much more on the outer side to meet the strain of the resultant of these two forces—the vertical position, as of that of the stipules of *Acacia*, being probably adaptations to avoid too great radiation in the dry climate of Australia.

Plants Exhibited.—*Anemone Fanninii*, from South Africa, a large plant, with lobed orbicular hairy leaves and large greenish-white flowers. *Befaria glauca*, from Colombia, and called the Andean *Rhododendron*; the flowers are pink, nearly regular, with seven petals and fourteen

stamens. It is the representative in the southern of the Rhododendron of the northern hemisphere. These two were received from Kew, and botanical certificates unanimously awarded to them.

□. *Plants Sent for Name.*—Epidendrum tridactylum, with small greenish flowers, of no beauty; Pleurothallis insignis, with slender pale grey lobes to the perianth; Pinguicula grandiflora, and the pink variety from the Alps of Dauphiné, above Grenoble; Nymphæa tuberosa var. flavescens. A protest was made against the name "Marliacea," furnished with the specimen, as tending to establish a confusion with the true name as given above.

Japanese reflexed varieties with a view to preserve those that stood a very great chance of being elbowed out of existence altogether by the increasing rage for size in the blooms as now staged in the Japanese classes, and that the varieties named as Japanese reflexed should not be shown in any other class but the one provided for them. I think the duties of judges will be increased by the present arrangement. If blooms of Triomphe du Nord are placed with Val d'Andorre, the former being probably 5 inches in diameter, of proportionate depth for the variety, while the latter will most likely be 8 inches across, both good blooms of their respective variety, but the smaller sort cannot be counted as valuable in a stand as the larger.—A YORKSHIREMAN.

CHRYSANTHEMUM SHOWS.

We have received notices of the following fixtures for the Shows of 1888:—

- National Chrysanthemum Society, Metropolitan Shows, September 12th and 13th; November 7th and 8th; and January 9th and 10th, 1889.
- Provincial Show at Sheffield, November 16th and 17th.
- Kingston-on-Thames, November 6th and 7th.
- Portsmouth, November 7th, 8th, and 9th.
- Teddington, November 8th and 9th.
- Crystal Palace, November 9th and 10th.
- Ascot, November 13th.
- Southend, November 13th.
- Devizes, November 13th.
- Brighton, November 13th and 14th.
- Cardiff, November 13th and 14th.
- Putney, November 13th and 14th.
- Winchester, November 13th and 14th.
- Barton-in-Humber, November 14th.
- Bournemouth, November 14th.
- York, November 14th, 15th and 16th.
- Market Harborough, November 14th and 15th.
- Brixton, November 15th.
- Reading, November 15th.
- Pembroke, November 15th.
- Lindfield (Sussex), November 15th and 16th.
- Sheffield and West Riding, November 16th and 17th.
- Liverpool, November 20th and 21st.
- Rugby, November 21st and 22nd.
- Birmingham, November 21st and 22nd.
- Hull, November 22nd and 23rd.
- Pontefract, November 23rd.
- Bolton, November 23rd and 24th.

CHRYSANTHEMUMS IN APRIL.

THE very interesting letter on this subject from Mr. W. Holmes, Hon. Sec. N.C.S., detailing the success achieved by Mr. Kipling in producing Chrysanthemum flower the whole year round, will I hope bring out for the benefit of Journal readers the experience of other growers who may have experimented in a like direction. I therefore give an instance from my own practice in support of the possibility of such being done. In July, 1886, I planted out on some good rich land in our kitchen garden a number of late struck plants of Madame C. Desgrange and La Vierge. These grew rapidly and luxuriantly, producing very large and fine foliage, with plenty of flower buds, but as we had a wet and cold autumn they all failed to open. I, however, had the plants potted, and they were kept in frames and cold houses through the winter. They retained their foliage very well, and in March, 1887, the flower buds, formed the previous October, and which had been dormant through the winter, commenced to expand, and in most cases developed large and fine blooms. I exhibited good flowers cut from them at our Sheffield Society's meeting in May, 1887, and they continued producing useful flowers until July.

JAPANESE REFLEXED CHRYSANTHEMUMS.

I WAS very much interested in the letter from Mr. Orchard under the above heading in last week's Journal. I think the reasons therein given, why the introduction of sub-sections in the large Japanese class, are very good and pointed. It is undoubtedly true that, owing to the large number of new varieties now being annually introduced, and the anxiety of exhibitors to grow only such varieties as will produce large flowers, a great number of beautiful but smaller varieties would soon be lost to cultivation, unless some such plan as suggested by Mr. Orchard be adopted. I hope his suggestions will meet with general approval from Chrysanthemum growers, and the N.C.S. Catalogue Committee in particular.—W. K. W.

It is said on page 348, "The varieties named as Japanese reflexed are only excluded from the true reflexed class." I do not remember (with one exception, Amy Furze) the sorts named being staged in the true reflexed class. My impression is that a class should be made for

VEGETABLES FOR EXHIBITION.

TURNIPS.

If these are wanted for an early show, or say in June or July, the seed should be sown on an east border, and this site, or any cool fruit quarter where the bushes or trees do not yet cover the whole of the ground, is suitable for successional sowings. In very hot dry weather we find a wide north border is a still better position for Turnips, these doing well with us even in such a hot and dry summer as we passed through last year. They grow quickly, and are of better form and clearer skinned when sown on fairly rich yet firm ground. We alternate them with Leeks on two east borders, and as a liberal dressing of manure is applied to the ground the season it is cropped with Leeks none is required for Turnips. Early Milan is of extra quick growth, being sometimes available in six weeks from the time of sowing, and as this useful variety forms but little top the rows may be 15 inches apart, and the plants finally thinned to about 8 inches apart in the row. To succeed that I can recommend Snowball, this perhaps being the best for the summer shows. Veitch's Red Globe is suitable for the later crops, but though a really good Turnip I should always prefer to stage a good dish of the White Snowball. These two varieties ought to be sown in drills 15 inches apart, and a space of 9 inches from plant to plant be allowed. Seeing that Turnips are not improved in either quality or appearance if left on the ground long before they are shown, it is advisable to make more than one sowing in order to be certain of having fresh clean roots for any particular occasion. The first sowing should be made eight or nine weeks before the Turnips are wanted, and in order to encourage the desirable rapid growth it is a good plan to sow in the drills with the seed either a little guano, soot, or some kind of artificial manure. Plenty of soot and lime dusted over the plants and between the rows will act as a fertiliser, and also a preventive of flea, slugs, and other enemies. The flat hoe should also be freely used between the rows, and the thinning should be done before the plants overgrow each other. All this tends to encourage rapid growth, and good space being allowed the development will be equally as satisfactory. The handsomest roots are usually those that form the smallest tops.

RUNNER BEANS.

Much that has been advanced as to the preparation of the ground for Peas is also applicable in the case of Runner Beans. Dryness at the roots, overcropping, and crowding in the rows are the most frequent causes of failure, and must be guarded against if pods fit for exhibition are desired. A rather cool position should be assigned them; the rows ought to be a good distance apart, or not less than 6 feet, and between these may be grown two or three rows of either Potatoes or Cabbages, these coming off the ground before the Beans are far advanced. I prefer to sow thinly in a single drill drawn about 2 inches deep, eventually thinning the plants to 12 inches apart. One strong stake about 8 feet high or less to be placed to each plant; these, to prevent destruction by winds, being laced together near the top with a single and continuous line of stakes securely fastened with tar twine, the plants to be duly secured to the stakes and stopped when the top of the stakes is reached; then if kept well supplied with moisture at the roots, liquid manure also being occasionally given, plenty of pods will set in the hottest weather, these to be freely thinned, and only the best shaped of them reserved. It is advisable to make two sowings—the first early in May, and the other one month later, this being more often necessary when the pods are needed in August. If one row only is depended upon for giving a long succession of straight brittle pods, in addition to stopping and liberal treatment at the roots, all the earliest pods ought to be kept closely gathered, and on no account should any be left to perfect seed. A fortnight may sometimes be gained by raising the plants in pots or boxes under glass, transferring them to the trenches late in May, and protecting them from spring frosts. This is also the surest way of germinating the seed and saving the plants of any extra choice variety. All should be freely mulched with strawy manure, or some substitute, early in the summer.

At one time Carter's Champion was the most popular for exhi-

hibition purposes, but this is now perhaps superseded by Laxton's Girtford Giant and The Czar, the latter being white-seeded; Veitch's Mammoth Scarlet and Carter's Jubilee, all of which can be made produce very fine pods. Ne Plus Ultra, however, surpasses all of them, and if it can be obtained true to name will delight the grower, as it produces long, broad, and straight pods, beautifully green in colour, or such as judges are bound to take note of.—EXHIBITOR.

KITCHEN GARDEN.

MAIN CROP CARROTS.—These should now be sown. They are an important crop, as they keep up the supply of roots all the winter and until the young Carrots come again. We have still many of our main crop Carrots of 1887 in store, and when they are grown and stored to last until now or later they give much satisfaction in the kitchen. All who have professional cooks to supply would do well to note this. The Intermediate is the best variety for the main crop. The long ones do not suit the majority of soils, but the intermediate is shorter, very thick, and of first-rate quality. Any soil a foot in depth will grow it well. We never fail to take the precaution to fork a little lime or plenty of soot into our soil before sowing Carrot seed. This invariably prevents the roots being injured by grubs. The rows should be from 15 inches to 18 inches apart, and the drills 2 inches deep. Sow good seed thinly, tread over the drills, then rake the surface, and finally give the whole a firm rolling.

KIDNEY BEANS IN THE OPEN.—We regard Kidney Beans as the most tender of all vegetables. If the seed is sown too early it will perish without germinating. If it germinates and the young plants are caught by the slightest frost the leaves will be blackened, and the plants, if not killed, severely injured. It is this that makes us delay sowing Kidney Bean seed until the last week in April. It is, however, safe to sow now, and a few rows of Dwarfs and one row of Runners may be put in as a first crop. The Dwarfs, especially Cooling's Ne Plus Ultra, fruit some weeks earlier than the Runners, and as it is very desirable to have Kidney Beans as early as possible a few Dwarfs should always be sown. They must have the most sheltered and sunny position in the garden. Along the bottom of a south wall is a good place for the first row. A south border is also well adapted for them. The soil must be rather rich and not too heavy. Sow the seed 3 inches deep and not too close. Where the Dwarfs are grown there will be no particular hurry in getting the Runners into fruit. They may therefore be sown in any ordinary quarter of the garden. Make a trench about 15 inches deep, place some good manure at the bottom, fork it well into the soil, sow the seed on this, and cover with 3 inches of soil. The young plants will have a little shelter at first in the trench, and as the hot dry weather comes on they will not suffer so much as if sown on the level. Laxton's White Czar is one of the best Runner Beans.

BETROOT.—The whole may be sown at once. The Turnip-rooted variety gains a suitable size sooner than the long varieties, and a few short rows of this may be sown for early use. Dell's Crimson is the best of the long-rooted varieties. It does not grow too large, and the tops are very compact. We have often grown quantities of culinary roots of this variety in the flower beds, but there is no difficulty in growing Beet in any garden. The Turnip-rooted may be grown in the shallowest soils. The others will do in soil that suits Carrots, Parsnips, or any penetrating roots. Sow thinly in drills 15 inches apart, and see that mice do not destroy the seed.

TOMATOES.—These are gaining favour annually; amateurs are taking to them, and find them interesting to grow and highly agreeable on the table. They cannot be grown in too many gardens. Plants intended for placing in the open air in May or June should not be kept too long in a hothouse, but place them in a cool frame and induce them to make a sturdy growth. These will go on without receiving a check, and they will fruit early. Some may think that if they can only obtain large plants they will be sure to have early fruits, but mere size does not mean fruitfulness. We have had plants bearing fruit 6 inches from the ground that were more prolific than others 4 feet high. The secret of success is transferring them to the open without giving the slightest check. Early Tomato plants under glass are now fruiting freely. Webb's Sensation is large and fine. There is nothing equals the single stem system for early fruit and plenty of it, indeed it is a good plan at all times, and the side shoots should be constantly removed. Do not allow many of them to form and then cut them all off together. This would ruin any plant, but if removed as they form, the whole strength of the plant will be thrown into the main stem. Plants that have been recently placed out in pits for summer fruiting should be confined to one stem from the first. Avoid supplying much water until they are well rooted, then give plenty, but do not use liquid manure until the fruit is abundant. Early plants in full crop may receive it three times weekly with advantage.

RIDGE CUCUMBERS AND VEGETABLE MARROWS.—Where seeds of these were sown together in a 6-inch pot turn the plants out of the pot when 6 inches or 8 inches high. Break the ball carefully, and remove each plant with as many roots as can be secured, then place them singly in a 3-inch pot. Grow them in a little heat and keep them close until they are advancing freely, when they may have more air and be gradually hardened to plant out about the middle of May. If the plants are large enough now to place out make up a little hotbed, place a mound of soil on the top of it, plant in this, and cover with a hand-glass or some other protector. Seeds may now be sown in mounds of this kind, especially in cases where there are no means of rearing young plants under glass.

FRUIT FORCING.

VINES.—Early Houses.—Forcing has had to be carried out almost exclusively by the aid of artificial heat, it being equally as necessary to maintain the day as the night temperature. Red spider has not increased this season as it does in bright and dry weather, for then the atmospheric moisture and water at the roots are not proportionate to the demands of evaporation, but lately, owing to the dull weather, evaporation has not been considerable. Where red spider has obtained a hold prompt measures for its destruction must be adopted. Some resort to the syringe, but this is not to be recommended, as after the Grapes are advanced in colouring the bloom on the berries is liable to be more or less damaged by the water. Sponging the leaves, though a good means of preventing the spread of the pest, and if taken in time effectual, yet is in most cases resorted to so late as to render it but a partial remedy by a tedious operation. The judicious application of sulphur to the hot-water pipes is the most effectual preventive. Flowers of sulphur should be mixed with skim milk, and when the pipes are heated to between 180° and 200° apply the sulphur with a brush and maintain the pipes at the temperature named for about an hour, and then the heat may be allowed to fall to the ordinary degree. A calm evening should be chosen, and the following evening repeat the process. Take care not to overheat the pipes, nor to give an overdose, or the skins of such varieties as Frontignans and Muscats will be seriously affected, especially those but partially ripened. Where fermenting material on outside borders has become cold and heavy a portion should now be removed, but leave sufficient to avoid giving a sudden check. Early Grapes that are ripe will only require enough fire heat to maintain a circulation of dry air, allowing the temperature to fall to 60° at night.

Second Early Houses.—Vines that were started with the new year are now commencing to colour. The inside borders must have due supplies of water or liquid manure in a tepid state, the quantity being such as to thoroughly moisten the border to its depth, and give a mulch of short material, but no great means should as yet be employed to produce a dry condition of the atmosphere, as the Grapes swell considerably in ripening. A good moisture must therefore be maintained in the early stages of colouring, sprinkling the house in the early part of the day, and at closing time provide a little ventilation constantly to induce a change of air and prevent the deposition of moisture on the berries. A warm genial condition of the atmosphere with a circulation of air is essential to ensuring thoroughly swelled berries. Maintain the temperature at 70° to 75° by day from artificial means, and 80° to 85° through the day from sun heat, advancing in the early afternoon to 90° or 95°, falling with the declining sun or light to a night temperature of 60° to 65°, 5° more both day and night being necessary for Muscats. As the fruit advances in colouring the moisture should be gradually reduced and the ventilation increased, but there must not be any diminution of the temperature until the Grapes are thoroughly ripe. Grapes that are liable to crack, such as Madresfield Court, may, when ripening commences, have the needful supplies of water or liquid manure, and then have the inside border mulched with 4 to 6 inches thickness of dry material, which, with early ventilation, insures this remarkably fine Grape arriving at perfection.

Succession Houses.—The remarks as to thinning, dishudding, stopping, and tying given in former calendars still apply; especially let all superfluous bunches be removed so soon as the number to be left on a Vine is decided. Examine the borders of all succession houses at least once a week, and when dry supply water freely. Inside borders will take almost any quantity of water after the Vines are in full foliage, and with a full crop of Grapes liquid manure should be applied at every alternate watering. Outside borders will not as yet require water.

Late Houses.—Late Vines making rapid progress must be tied out and stopped as soon as they have made sufficient growth to cover the trellis with foliage. The weather has not been without its effect upon the foliage of the Vines, for the leaves are somewhat pale in colour and thin in texture, greatly needing sun to give them a healthy green colour and air to improve their texture. Every advantage, therefore, should be taken of sun heat to increase the ventilation early in the day, but close early, excessive fire heat being injurious.

Newly Planted Vines.—With advancing growth—an evidence that the roots are active—close attention will need to be given to the roots to see that they do not suffer from over-dryness. Allow all the wood to remain that can be exposed to light, but supernumeraries intended for fruiting next year should be confined to one rod or cane, and the laterals pinched at the first joint.

Vines in Greenhouses and Unheated Houses.—The Vines are making rapid progress, and in many instances the growths will require dishudding, stopping, and tying. One shoot is sufficient to each spur

unless they are wide apart, when two may be left, but there must be scrupulous attention to prevent overcrowding; every leaf must have exposure to light and air. Reserve those that show the best bunches, rubbing the others off. Stop two joints beyond the bunch, but rather than crowd the foliage stop at one joint beyond the bunch, or even level with it. Tie down the shoots carefully and gradually. Old Vines sometimes do not bear freely on spurs, being weak. It is best to lay in shoots from the base and along the rods at intervals of 2 to 3 feet, which will increase root-action, the Vines attaining increased vigour, and longer pruning will usually afford better crops of Grapes; indeed, old Vines with fresh canes bear excellently. Apply a light dressing of artificial manure to the border, and point it lightly in. Inside borders may be given tepid water or liquid manure, when dry a thorough soaking, and a mulching of short rather fresh manure will by keeping the surface moist encourage active roots.

MELONS.—*Early Plants.*—Directly the fruit begins ripening lessen the supply of water at the roots, but not so as to distress the plants, for if the foliage has been kept clean and the roots in good condition a second crop of fruit can be had. Atmospheric moisture should be withheld, and a circulation of warm dry air ensured, increasing the temperature to 70° or 75° artificially, and 80° to 90° with sun heat. Cut the fruits before they are very ripe, keeping them in a fruit room for two or three days, or until they are in proper condition to be sent to table. Cracked fruits are produced by a close and moist atmosphere with too much moisture at the roots, which induces an excess of sap. If any fruits show a tendency to crack cut the shoots about halfway through with a knife a few inches below the fruit, and diminish the supply of water at the roots and in the atmosphere, leaving a little ventilation constantly to prevent moisture condensing on the fruit.

Successional Plants.—Continue to fertilise the blossoms when fully expanded, the atmosphere being kept rather drier and warmer, and ventilation attended to early, with a little constantly if there is danger of moisture condensing on the blossoms. Stop the shoots at the time the fertilisation is done one or two joints beyond the fruit. To secure a full crop take care to have a number of fruits on individual plants in the same stage of growth. Earth up the plants with some rather strong loam and rich after the fruits begin to swell, ramming it down firmly, placing a little fresh lime around the collar to prevent canker. Plants swelling their fruits should be syringed freely in hot weather at about 3 P.M., damping the floor several times a day, and in the evening sprinkle available surfaces with liquid manure or guano water, 1 lb. guano to 20 gallons of water. Shade only to prevent flagging; ventilate freely in favourable weather, commencing from 75° to 80°, increasing or decreasing it during the day as may be necessary, maintaining a day temperature of 80° to 85°, or 90° with sun heat, closing between 80° and 85°, and if an advance after closing be made to 90° or 95° it will materially assist the fruit in swelling and lessen the necessity for fire heat at night, but it must be accompanied by plenty of atmospheric moisture. If thrips appear fumigate moderately on two or three consecutive evenings, taking care to have the foliage dry, and for red spider dress the hot-water pipes with flowers of sulphur.

Train out the growths in pits and frames. Still maintain a good bottom heat by linings, and employ thick night coverings as the nights are yet cold. Sow seed for planting in pits and frames as they become cleared of bedding plants, potting the young plants as required.

TOMATOES IN HOUSES AFTER BEDDING PLANTS.—Structures of this kind may be very profitably utilised for Tomatoes. The plants do very well in 10-inch pots, a single plant in each. Drain the pots efficiently, place a layer of rough pieces of turf over the rocks, and then turn out the plant, using turfy loam with about a fourth of well decomposed manure. A considerable space should be left in the pot for fresh additions of soil as the plants advance in growth, and feeding with liquid manure will secure an abundant crop of fine fruit. Train the plants as single cordons to wires 9 inches from the glass, removing all laterals or side shoots, but being careful to preserve a leader. The plants will have fruit from the first show at about every second joint, and the lead should not be stopped until the limit of the trellis is reached, then remove all growth as it appears. Shorten the leaves about a third of their length. The plants may be 12 to 18 inches apart. Keep the house rather close until the plants are established. Ventilate a little at 65°, increase it at 75°, and above that ventilate freely. Close early so as to run up to 80° or 85°, which will enable the grower to dispense with fire heat after the middle of the month.

PLANT HOUSES.

Cyclamens.—The earliest seedlings now well established in 3-inch pots should be transferred at once into 5-inch pots. Be careful not to disturb the roots of the plants much, as if good specimens are needed by early autumn they must be grown without a check. Keep the house close and moist for ten days or a fortnight after potting, until the roots are spreading freely in the new soil, then ventilate daily on all favourable occasions. The object must be to maintain a dwarf sturdy growth. If kept too warm or too close the foliage will be drawn up weakly, and the beauty of the plants will be totally destroyed. Nothing is gained by hurrying these plants, but the reverse; to do them well they must be grown on steadily from the first. The syringe may be freely used on fine days, and the house closed early in the afternoon. Do not attempt to shade the plants, the sun at the present time will do them no harm. Unsatisfactory results may often be traced to overshadowing, for shade, however light, has a tendency to

render the foliage weak. Arrange the plants as near to the glass as possible, but be careful to provide for them a moisture-holding base. It is better to have them a little farther from the glass than to arrange them on dry open trelliswork. Later plants may be placed in 3-inch pots, and those raised from seed sown early in the year in 2-inch pots. Grow the plants on under the same conditions, and do not allow the temperature at night by fire heat to exceed 58° or 60°. Use for a compost good fibry loam, and one-third leaf mould, with one-seventh of manure and sand.

Cinerarias.—The earliest plants should be placed in 4-inch pots, and if they have not been growing under greenhouse treatment gradually harden them until they can be placed in cold frames without being checked. Place later plants now in pans into 2 or 3-inch pots according to their size, and bring them into cool quarters as quickly as possible. Prick out seedlings, and sow a pan or more of seed and let them come forward from the first in cold frames.

Primulas.—The earliest Chinese Primulas may be transferred without delay from 2-inch into 4-inch pots. Remove the small leaves from the collar of the plants and pot them well down, so that the plants can be moved about without fear of their breaking at the collar. The plants root freely from the stem, and are not so subject to damp at the collar as those that have much bare stem above the surface of the soil. Keep these plants in a temperature of 50°, and gradually harden them by the admission of air until they can with safety be grown in a shady position in the greenhouse, or, better still, in cold frames. Place those in pans into 2-inch pots, and prick off those raised from seed sown a few weeks ago. A good pinch of seed may now be sown for yielding plants for flowers at this period next season.

Double Varieties.—Cuttings may be taken and rooted at once; they root freely enough in a temperature of 55° if shaded from the sun, inserted in sandy soil and placed under handlights. The safest method is to remove the large leaves from the old plants, and place light sandy soil about their stems. If placed in an intermediate temperature where the atmosphere is moderately moist they will quickly emit roots. When in this condition they can be taken and potted singly. If kept close for a fortnight afterwards scarcely one will fail to become established.

Primula obconica.—Plants raised from seed sown as soon as it was ripe last season will be ready for placing in 5-inch pots. Grow the plants in cold frames and shade them from bright sunshine. This Primula will do well in the same soil as Chinese varieties. Transplant into pans and boxes the plants raised from seed between two and three months ago.

Primula floribunda.—This is a capital companion plant for the above, and is really charming in the spring with its small but bright yellow flowers. With careful treatment it will seed freely, and by this means a good stock for decorative purposes may soon be raised.

Primula Harbinger.—If this has flowered it should be thoroughly hardened and planted outside in light rich soil in a shady position, or the pots may be plunged in a-hes. When kept in pots care must be taken never to allow them to become dry; they should during bright weather be liberally syringed to keep them free from red spider.

NOTES ON BEES.

PREPARING BEES FOR THE HEATHER.

ALTHOUGH the season proper for bees working only commenced this year with April, yet well managed hives are as forward as they generally are in much milder seasons, and bee-keepers are hoping for a bountiful honey season. To show how to make the most of it is the object of this article, and believing that the plans of bee-keepers are well laid to get the advantage of the early harvests from fruit blossoms, Clover, and Limes, I will skip instructions for these seasons, and give in detail those likely to give the largest harvest from the Heather, which those situated within available distance from it should be prepared to do.

The interest in taking bees to the Heather is increasing yearly, but not to the extent it might. Heather honey, too, is in better demand than other sorts, and in nine cases out of ten better relished—an incentive sufficient to impel bee-keepers even at 100 miles distance from Heather to take full advantage of it with hives that would more than remunerate for the little expense involved in their removal. In the majority of cases bees are sent to the Heather without due regard to their condition, hence the cause of so many failures, hives making little that were expected to become heavy. Prime swarms are most commonly those which

give the best returns, but are as often as not in an unfit state to gather much surplus when the Heather is in bloom. This unfitness may arise through the season being unfavourable during June and July, causing the bees to restrict or wholly suspend breeding by the middle of the latter month. An aged queen will have the same effect. Then owing to these and other untoward circumstances the bees may have dwindled, comparatively speaking, to a mere handful of bees unfit to collect honey enough for their own immediate wants. Through the same or similar causes non-swarmed hives may dwindle down.

No time of the year is so important for the bee-keeper to have his hives properly attended to as the middle of July, whether it be to put them in order for the Heather or, where that is not available, to stand the severest winter's campaign, and come out in spring in a fit state to gather honey from "every opening flower." How to put hives into that satisfactory state, which in a good season means a profitable one, and with the least trouble or expense, I will describe in as concise a manner as possible.

It is to be hoped that no bee-keeper has ignored the advice so often given to have at least as many nuclei with young but fertile queens as the number of stocks he intends to keep. Now, while the queen of any hive is, according to Nature, always desirous to deposit eggs in the cells from December until June, and the bees are as anxious to nurse and bring all these eggs to maturity, even to the risk of losing their own lives through impending want, it is different with them after the day turns. The queen begins to flag, and the bees have a tendency to eat the eggs, and eat or draw out the immature grub, and this, too, even though the hive is rich in honey, but the weather dull and unfavourable, the hive being still further reduced by the bees' propensity to rob, which they almost invariably do on the decline of honey gathering.

At no time during the whole season is feeding so important (except in urgent cases of want) as it is at this juncture, and the bee-keeper should not neglect it. Nuclei having young queens are not so liable to discontinue breeding or draw their brood as hives having done service throughout the year. There seems to be an instinct in them that increase of population is not only desirable but necessary. It is not desirable, however, that young queens intended for the following year should be encouraged to lay excessively. It is better to watch that none of the eggs or brood is destroyed, and encourage the aged queen about to be deposed to lay to the fullest extent by feeding constantly, but in moderation, because the management given at other times is different now. As the breeding goes gradually on in both hives (which applies to any number), transfer the combs containing the most advanced brood from the hive containing the old queen, and insert them in the hive of the nucleus (providing no disease is present), at such intervals that no brood will be chilled, which should be accomplished in from eight to ten days. Meanwhile add sheets of foundation to the old stock, and feed, to encourage comb-building, these newly built combs taking the place of the older ones transferred to the nucleus at the end of the season.

The eggs and brood of the two queens will have built up a stock much stronger than any stock with but one queen could possibly be. After all the combs containing eggs or brood have been removed from the old stock, depose the queen by the carbolic process, and with due precautions join both hives and bees together, but not until the bees of the old stock have been queenless at least twenty-four hours. If the bee-keeper is expert at the business he may perform the whole operation at the first manipulation, but the foregoing details, if properly performed, will prove satisfactory to the greatest novice.

DISEASES OF BEES.

"A Hallamshire Bee-keeper" some time since made a suggestion as likely to have been the cause of the death of my bees at the moors. I beg to inform him that he is wide of the mark. Had the deaths arisen through either the form or structure of the hive I could easily have detected it, nor was the weather during August

anything like chilling the bees to death within their hives. Hives having their frames across the entrances are certainly not the most suitable kind of hives for bees and keeping them healthy, or working them to proper advantage. But do not think they would cause so wholesale a destruction. It is in detail they are defective, beginning with a little evil, and ending in a large one.

I once saw twenty hives, three of them being the "Combination" type; they were the only three that succumbed to the severity of the winter. I was not sorry for the owner, as he was perfectly cognisant of the great pains Mr. Woodbury took to take evidence and collate every fact relating to the subject for the benefit of the readers of this Journal, and denounced the hive having its frames across the entrance, which was also our verdict. In other matters touched upon by "A Hallamshire Bee-keeper" I quite agree.

Some eight or ten years ago an acquaintance wrote a letter to me stating he had been at the moors with his bees. Owing to the hot day his hives had suffered greatly, and he was afraid some were ruined. Previous to that I had examined the ventilators of his hives which were deficient, but my advice to remedy matters had not been taken. In answer to his letter I wrote informing him that owing to the overheating, "foul brood" (a disease he said he had never seen) was almost certain to appear in a virulent form. The same autumn I was with him examining some hives of a friend. The moment I turned the first one up foul brood in its most virulent form presented itself, and the stench from it before it was inverted indicated the plague. Yet, bad as the case was, he denounced my action when I tore the combs out and buried them. It was dry foul brood and was not infectious, just the very opposite from my experience and that of "A Hallamshire Bee-keeper," and I agree with the latter that in this stage it is most infectious.

The following spring the same gentleman asked me to see his bees, as they were not working as well as he wished. On an inspection being made foul brood was rampant in many of his hives. I advised him to stamp out the disease at once, which was again unheeded, and word again came to me that they had done better than expected. By the next spring matters were even worse. Not a single hive was free from the disease. I have not seen them since.

The various diseases that bees are subject to may be classed under the following heads—Infectious, Constitutional, and Climatic. The first ought to be stamped out on its first appearance, and everything connected with the hive disinfected and the bees purged. Overheating and chills must be guarded against as the best preventives. The contents of the hive should be destroyed, and the ground for a considerable distance around the hive turned over. The constitutional diseases will to a great extent remedy themselves, but no queens nor drones should be raised from such hives. The last-named disease, will, I fear, continue with us until these foreign races most subject to it, if not the only ones ever affected, become thoroughly acclimatised.

That some of the diseases we are experiencing for the first time are due to climate and constitution, or a combination of both, we need have little doubt. We never saw the common bees attacked by some of these diseases. It is singular, and perhaps worth recording, that during my long experience with the Carniolians I have never seen or known a diseased stock, but neither have I had foul brood amongst my other stocks for a longer time, or, might I say, since I made a complete revolution with the ventilating floor, the best of all antidotes to the common form of foul brood.

Then if bee-keepers would think more for themselves—leaving not a stone unturned until they had investigated the cause and nature of every disease that came within their observation—bee-keeping would be to them and their neighbours more pleasant as well as more profitable. Study well, and become impressed with "A Hallamshire Bee-keeper's" remarks, particularly his closing paragraph at page 140, and they will not regret it.—A LANARKSHIRE BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Books (A Beginner).—Mr. Barron's work on the Vine can be had post free from this office, price 5s. 3d.; and Mr. Molyneux's work on the Chrysanthemum for 1s. 2d.

Cotoneaster (W. S. S.).—We do not know of any Cotoneaster that clings to walls after the manner of Ivy. We know of no plants that will answer your purpose so well as green and variegated Ivies and Ampelopsis Veitchi, this latter clinging to walls like glue, but is deciduous, the leaves assuming a brilliant hue in some positions in the autumn.

Table Plants (J. S.).—You will find the following good plants for exhibition and general use—Cocos Weddelliana, Geonoma gracilis, Thrinax elegans, Crotons angustifolius, interruptus aureus, Johannis and Rodeckianus, Dracaenas Sydneyi, jucunda, nigra rubra, and gracilis, Reidia glaucescens, Asparagus plumosus nanus, Cyperus laxus. Aralias Veitchi, gracillima and elegantissima, and Pandanus graminifolius.

Canadian Wonder Beans—Vine Foliage (Thomas Wickson).—We hope we have deciphered your name correctly. The Beans are very good indeed, and the crop you have gathered affords evidence both of the adaptability of the variety for forcing and your own good culture. The Vine leaves are unusually good, being quite large enough, stout in texture, and deep green in colour. The Vines under good management cannot fail to produce fine Grapes.

Anthurium—Chrysanthemums (J. C.).—The spots you mention are generally caused by having the plant in too low a temperature with too much moisture in the soil or atmosphere. Perhaps the temperature has fallen below the degrees you name upon some cold nights. At this time of year plenty of moisture will suit it, and by encouraging growth the plant will probably soon recover. We do not remember your previous letter respecting the Chrysanthemums, but the following dozen bright or deep red Japanese varieties will no doubt meet your requirements:—Flambeau, Roi des Précoces, Cossack, Ornaments, Tokio, Garnet, Jupiter, M. N. Davis, Mr. W. Holmes, Simon Délaux, Cullingfordi (reflexed), and M. Henry Jacotot.

Snails in Conservatory (Inquirer).—If you place small heaps of fresh brewers' grain or bran in suitable positions about the house, and examine them an hour or two after dark, you will probably find them covered with the snails that are eating your Ferns, and with perseverance you will soon be able to clear out most or all of the destructive molluscs. In the meantime you might syringe the plants now and then with soft-soap and quassia water, with the object of rendering them less tempting to the snails, and which might consequently take to the grains or bran more readily. If you have reason to believe they lurk down amongst the rhizomes of the plants or in the soil give them some fresh and quite clear lime water. This will not hurt the Ferns, while snails cannot endure it.

Strawberries Falling (P. T.).—The roots of the plants are dead, but whether this is the result of their having been kept too dry, as they were on arrival, or of an overdose of liquid manure, we are unable to say. If the plants were growing satisfactorily until you gave them the soot water, you may conclude it was too strong, and instead of assisting them has caused their destruction. Liquid manure is like some medicines, excellent when rightly used, otherwise dangerous and even deadly. We have many times advised that soot water should only be used when clean and of the colour of very pale ale or weak tea, not black like porter or stout. We have seen plants of various kinds seriously injured, and not a few killed, by the injudicious use of liquid manure that was intended to assist their growth.

Caterpillar on Tea Rose (A. H.).—This is the caterpillar or arva of the swallow-tail moth (Urapteryx sambucata), the English name suggested by the points at the ends of the under wings of the insect, and the Latin by its occurrence upon the Elder in some seasons. The caterpillar feeds a short time during autumn, then lays up for the winter in some crack or crevice, reappearing about this time or even earlier. Actually it is found feeding on many species of trees and herbaceous plants, chiefly, however, out of doors; but if one has crept into a house to shelter during the winter season it will probably feed there in the spring on anything that may be handy. Though not a scarce insect, it appears in too small numbers to be injurious, especially as the food is so varied, and it is hardly necessary to kill the moth, which may be seen floating about the gardens in the June twilight.

Francoa and Plumbago (Constant Reader).—If you reside in a district where the Francoa is exclusively grown in pots under glass you

would be justified in showing it as you suggest; but if the plant is more or less grown outdoors in your locality it would not be wise to include the flowers in the collection. The shoots of your Plumbago should not be stopped after this date; unless they are already far advanced, then pinch them at once, and allow the shoots to extend until they come into flower. We do not advise the shoots to be pinched, and should prefer to retard the plant from starting into growth early in spring. It takes eight or ten weeks from the time of starting to the time of flowering, but this entirely depends upon the temperature in which it is grown. We prefer to start it in an intermediate temperature, and then bring it forward as cool as possible.

Pears—Cotyledons—Crassula jasminea (W. B.).—The Pears probably suffered by the drought of last summer, and may have been gathered too soon. They should not be removed till they fall into the hand when slightly raised and without twisting the stalk. They often hang till the middle of November when the autumn is mild. The fruit resembles the Easter Beurré. Cotyledons can be propagated by inserting their leaves in sandy soil either in well drained pots or shallow pans. Place them in a temperature of 55° to 60°, and keep the soil rather dry until young plants appear; succulent plants at any time are more liable to suffer from excess of water than the reverse. The Crassula can be propagated by cuttings inserted in similar soil and temperature, and the plants should be grown on a shelf in a greenhouse well exposed to sun, as upon the ripening of the growth their flowering chiefly depends. Few growers have much difficulty with the plant.

Weevils Eating Ferns (J. H.).—The enemy which is making such "sad havoc" with your Ferns and Lapageria is the very destructive Weevil, Curculio, or Otiorynehus sulcatus. These beetle-like pests will eat almost anything, and are by no means easy to eradicate. In the grub state they eat the roots of plants, and when developed devour the leaves and flowers. Search for them sedulously, especially at night, catching all you can, and so prevent a further increase. Shaking the plants violently over a white cloth at night will dislodge many, and they will be visible on the white surface, and can be the more readily secured. A bitter decoction of aloes, quassia, and tobacco is said to render plants distasteful to the weevils. Early in spring as much of the old soil should be removed from the Ferns and other plants as can be safely done, and probably many small white grubs, the larvæ of the weevils, will be destroyed. Keep the soil moist, and a solution of hellebore, made by pouring boiling water on 2 ozs. of the powder, then increasing to a gallon of water before using might do good. It will not injure foliage or roots.

Vine Leaves Decaying (D.).—Too much moisture in the house consequent on its being "crowded with Ferns and other plants," and also its being possibly kept too close, especially at night, would contribute to the decay in patches of the very thin leaves. The root action is also, we suspect, defective, or, what amounts to the same thing, several of the roots have found their way into ungenial soil. The Vines will probably improve as the season advances, especially if you take care the growths are not overcrowded, and that the plants are watered soon enough for the atmosphere to become moderately dry before night; and we should expect still better results if you could raise the temperature 5°, and leaving the top ventilators open to the extent of an inch or so all night, increasing the ventilation early in the morning as soon as the sun influences the temperature of the house. If by a thick mulching of manure you could incite the free production of roots near the surface, then apply phosphatic fertilisers, such as bonemeal or special manures that are advertised, the leaves would soon assume a stouter texture, and be less liable to decay through the effects of unfavourable atmospheric conditions. The Vines are evidently in a weak and unsatisfactory state.

Caterpillars on Azalea and Vine (J. W.).—On examination, the caterpillars forwarded appear to be those of the very variable moth Peronea hastana, which possesses many synonyms from this circumstance, and is also found feeding on a great variety of plants, on some as diverse as the Rose and Willow, for instance. Its occurrence upon the Azalea does not seem to have been noted before. These leaf-rolling larvæ or caterpillars belonging to the tortrix group are often exceedingly like each other in allied species, and it is possible that the Grape insect may be a different species, but bearing resemblance to the Azalea eaters. If it be the same, we should presume the larvæ that attack your ripening fruit are a second brood, the moths of which emerge from the matured larvæ of the spring season. One difficulty in dealing with these caterpillars, which conceal themselves in folds of leaves and silken wraps is the protection they thus obtain from any syringing process. The destruction of tortrix caterpillars has been attempted by a solution of petroleum in water, afterwards washed off with warm water, also by means of a solution of nicotine soap, and by a liquor composed of a decoction of quassia chips made alkaline with soda. All leaves containing the pupæ or chrysalids should be promptly removed.

Lifting Snowdrops (C. W.).—The most suitable time to lift the bulbs is from the beginning to the middle of July. The time will vary a week or two according to the season. They should not be lifted until the foliage has ripened or leaves the bulbs with ease; the skin of the bulbs should also be thoroughly brown. Lifting is best done during dry weather. If lifted just before the foliage leaves them there is no difficulty in picking the bulbs from amongst the soil. They are usually lifted in Lincolnshire with a fork, and boys are employed for picking them from the soil. When the foliage has completely dried there is some difficulty in thoroughly clearing the land of them. When lifted

they should be spread out thinly in a cool airy shed, or where partially shaded from full sun for a time until they become hard and dry. Injury to the bulbs often results from fully exposing them to the sun directly they are lifted from the ground. Allow them to dry and harden first, and then fully expose them to the sun. Before this is done they can be sorted, and the small bulbs, or "seed" as they are called in the districts where Snowdrops are grown, can be planted again by the end of July or early the following month; the sooner they are in the ground again the better. With the first rains that thoroughly moisten the soil they commence root activity. Very frequently a good season's growth is spoiled by delay in planting until the season has too far advanced.

Bed for Carnations (T. L. P.).—As the position on the south side of a wall will, perhaps, be hot and dry in the summer, you must provide a depth of at least 2 feet of good soil for the plants. It does not follow that the present soil need be excavated to that depth, as it may probably suffice to clear out the stones and rubbish down to the heavy loam, then break this up well and enrich it with manure, also spreading on a good thickness of manure before filling up with fresh compost. This should be 18 inches in depth. There is no better soil than turfy loam, inclining to heavy rather than light, that has been in a heap for six months or more, and perfectly free from wireworms that are not infrequently present in loam recently dug from a pasture. To five barrowfuls of loam add one of decayed manure—that from a cow stable preferably—dry enough to be broken into small particles for mixing, half a barrowful of wood ashes and the same of vegetable refuse, with an 8-inch potful of soot and the same quantity of bonemeal. Turn the whole a few times, or till the ingredients are uniformly incorporated. Provided the compost is neither very wet nor very dry when placed in the bed, and is pressed down rather firmly, it should grow Carnations well. It may be desirable to cover the surface of the bed between the plants 2 inches thick with very short manure, or if you prefer something that may be deemed more presentable, with cocoa-nut fibre refuse. The sooner Carnations are planted the better, and they should be strong, and now established in pots for flowering well this year. They can then be planted without any material disturbance of the roots, and great care must be taken that the balls of soil from the pots are not by any means dry, neither excessively wet, when inserted.

Plums not Setting (D. W.).—The spur with the foliage and incipient fruits sent appears quite healthy, but only one out of the number of fruits apparently ready for swelling was set, and nothing could prevent the others falling. This may be either the result of a deficiency of pollen through the cells not bursting, which is not uncommon, or of too much sun during the blossoming period. While a free circulation of dry air with sun for drying the pollen are essential for its liberation and dispersion, we have often noticed that when the sun is very bright indeed and the air unusually dry, that Plums fail to set not only under glass but in the open. The petals of the flowers wither and fall too soon, and the embryo fruit is deprived of support at a critical time, collapse following. The same result we have observed with Peaches under glass, and have known half of a tree to set and swell a full crop of fruit while the other half was almost barren, simply because one half of the tree had a skiff from the syringe when the petals appeared to be turning limp under the influence of the sun while the spray was withheld from the other half where scarcely any fruit followed. It is only under exceptional circumstances that it is necessary to supply moisture for supporting the blossoms, or for preventing an exhaustively dry atmosphere at the time indicated, but the necessity occasionally arises, and then when nothing is done moisture is extracted from the blossoms and embryo fruit more quickly than it is supplied by the roots of the trees, and the small check thus sustained affects the crops prejudicially and sometimes seriously. There is never such a good set and free swelling of fruit in gardens and orchards as when an occasional light warm shower falls, with sufficient intervals of sun for the bursting of the pollen cells for the purpose of fertilisation. This is quickly effected, and the soft genial atmosphere sustains the fruit then in formation, while an arid atmosphere deprives it of vitality. As during the blossoming of your trees you had "splendid sunshine," these remarks may not be inapplicable to your case.

Gloire de Dijon Rose (J. R. G.).—The buds, shoots, and leaves sent indicate that the tree is in an enfeebled state, or, in other words, its sap is far too much subdivided through a number of small channels to exert sufficient force for the expansion of the buds. You do not say whether the tree is under glass or in the open; however, wherever it may be we should cut it severely back, probably to the extent of removing three-fourths of the growths, then, with the roots in good soil, and adequate moisture afforded, young growths would push strongly and long stout shoots ripen during the season for producing fine blooms another year. If some blooms are satisfactory now, or likely to be, the pruning of the parts bearing them can be deferred till after they are cut, then proceed in the manner advised in answer to another correspondent, who is in a similar difficulty to yourself, but with a *Maréchal Niel*. You will observe in an article on two establishments at Swanley that the great grower of Rose blooms for market, Mr. Philip Ladds, cuts down the whole of the growths of his *Maréchal Niel* and *Gloire de Dijon* Roses in twenty houses as soon as the golden harvest is gathered, covering the roofs with new growths annually. But no one can grow Roses successfully, no matter how good the soil and correct the pruning may be, if the growths are not kept scrupulously free from insects. In reference to your observation that "there is scarcely any green fly on the plant," we have to say that there are more aphides on the leaves you have sent in a small box than we should permit on a very large

plant or tree. It is true only a few of the insects are "green" and the majority are yet too young and small to be seen clearly at a glance, but they are there, and if your plant is large we venture to say it is infested with thousands of aphides, and the glutinous substance on the leaves that seals their pores is the result of them. The tree cannot thrive till it is thoroughly cleansed, and all such growths as those before us should be promptly cut off and burned. The information you received on heating from our able coadjutor we know would be good.

Making Mushroom Spawn (J. Thorpe).—It is easy enough to make Mushroom spawn bricks after seeing how the work is done, and watching the process for a season, and not difficult to state the ingredients of which bricks are composed and the process generally, but not one person out of fifty would succeed in the first attempt by following printed instructions alone. An expert might publish the requisite details for making a pair of hoots, but it does not follow that the instructions could be successfully carried out by a person who had never seen the work done. All makers of Mushroom spawn do not make bricks of exactly the same materials. The following particulars are given in the *Cottage Gardeners' Dictionary*:—"Mix three parts of horse dung without litter, two of cow dung, one of decayed tanner's bark, and one of sheep's dung, and one of good loam, mix to the consistency of mortar, and mould in small frames like those used by brick-makers, 6 inches long, 4 broad, and 2 deep. Three holes to be made half through the bricks, an inch apart, with a blunt dibble, for the reception of the spawn. They should be put on their edges on boards for the convenience of moving during fine days, as they must be made perfectly dry when the spawn is inserted, which they often appear to be on the outside when they are far otherwise internally. Before they are perfectly dry they require great care in handling and turning, from their aptitude to break; but in about three weeks, if dry weather, they become quite firm. To pervade them with the spawn, a layer of fresh horse litter, which has laid in a heap to sweeten, as for a hotbed, must be formed, 6 inches thick, in a dry shed. On this a course of the bricks is to be laid, and their holes completely filled with spawn; and, as the bricks are laid in rows upon each other, the upper side of each is to be scattered over with some of the same. The bricks are not placed so as to touch, so that the heat and steam of the dung may circulate equally and freely. The heap is to terminate with a single brick, and when completed covered with a layer, 6 inches thick, of hot dung, to be reinforced with an additional 3 inches after a lapse of two weeks. The spawn will generally have thoroughly run through the bricks after another fortnight. If, however, upon examination, this is not found to be the case, they must remain for ten days longer. The bricks being allowed to dry for a few days before they are stored, will then keep for many years." Lumps of spawn for insertion may be had from the best bricks obtainable; it must be pressed firmly in, and may be plastered over with cowdung. Some persons pile the bricks on edge, so that they do not quite touch each other, in order that the heat from the manure can pass between them. You can now try your hand at the work, but it is possible you will have to try again before you succeed in your object.

Maréchal Niel Rose Falling (L. H.).—Your *Maréchal Niel* Rose tree that covers the roof of the greenhouse and gave 650 blooms last year is in a debilitated state. It has been exhausted by the burden, and in expecting 800 blooms this year you expected more than the tree could produce. Buds formed freely, as they often do on weakened trees, but they did not expand because of a lack of strength for their development. The condition of the buds, stems, and foliage sent all clearly indicate exhaustion, and your tree is in very much the condition that a Vine would be in that had been allowed to grow with little or no pruning for two or three years, and to ripen as well as it could all the bunches that were produced. The crop in such a case would soon be worthless compared with that of a properly pruned and well managed Vine. You say you pruned your Rose seven weeks ago. That, according to the extent of the pruning, might be of some benefit, but the operation was performed months too late for the production of strong growths that can alone produce grand blooms. The proper time for pruning this Rose when it flowers under glass in the spring is as soon as the blooms are cut, and then the pruning should be as severe as that applied to Vines in the autumn or early winter. If your tree were ours we should cut away nine-tenths, and perhaps nineteen-twentieths, of the growths now, then by syringing the stems and maintaining a close moist atmosphere, also giving probably much more warm liquid manure to the roots than you are in the habit of doing, we should force fresh shoots to push from the stems, and these growths would be very different in character before the end of the season from the present weak shoots, and would yield much finer blooms in the spring than your tree in present state could possibly develop. Some persons cut back all the growths of *Maréchal Niel* after flowering down to the base of the rafters, and cover the roof during the season with vigorous growths that follow the pruning. These are not allowed to grow into a thicket, but are disposed so that the leaves can expand under the direct influence of light. The wood then ripens, and handsome blooms follow in abundance. Other growers cut back the branches to a few main stems, much in the way that Vines are spurred. Last spring we visited Cheshunt just after Mr. George Paul had pruned a *Maréchal Niel* in a large house. Nothing was left of the growths that had covered the roof, but a few strong naked branches 3 or 4 feet apart were all that remained, and these were slashed here and there with a knife to arrest the sap and force latent buds to start from the rod-like stems. With the roots in good soil the *Maréchal* may be pruned to any extent, and, as a rule, the more severe this is the greater is the vigour of the growths resulting. If you

can remove some of the surface soil from the roots, adding fresh loam and manure, making it firm, and surfacing thickly with rich manure, the dressing will be of great benefit; but without it the tree may be invigorated by pruning on the lines suggested, and giving an adequate supply of manure to the roots.

Manure for Fruit Trees (*A. S., New Zealand*).—While you appear to be quite aware that Toomson's, Jensen's, and other advertised fertilisers for Vines are also good for fruit trees, you are in the unfortunate position of not being able to obtain them in your colony, and ask for some ingredients you can obtain and mix for your purpose. Superphosphate of lime can be had in most agricultural districts, and is good for fruit trees, applied at the rate of a quarter of a pound to the square yard, or less if the trees are making fairly good growth. Bonemeal and chloride of potash, about twice the quantity of the former, applied at about the rate mentioned, form an excellent mixture; and if the trees do not grow fast enough it may be supplemented with a dressing of somewhat less than half the above quantity of sulphate of ammonia; but forcing very luxuriant growth of trees when young is not highly desirable, though the wood may perhaps ripen better with you than in England. What is wanted is free yet short-jointed wood, gradually solidified as the growth extends, for the formation of strong yet fruitful trees. The mineral ingredients should be applied when the earth is moist, or say three months before the trees start into growth, the ammoniacal for such trees that need it (and all will not be alike) a month or two later; but the earth should be still moist, as, if it is dry, and continues so for a considerable time after chemical fertilisers are applied, they remain comparatively inert. Many persons are in the habit of applying them too late in the spring in this country, then if the summer prove dry, good results are not apparent, and the manures are condemned without a fair trial. The finer bonemeal is ground the quicker it acts, coarser particles, or crushed bones, being slower in action but more lasting in effect. With a labour wage rate of 5s. per day of eight hours, cleaning many acres of land must be costly; still, if weeds are unchecked they will deprive the trees of much of the soil's fertility, and have their share of the manure supplied. A covering of long grass, as you suggest, placed round the trees as far as the roots extend, would, if thick and dense enough to exclude light, and placed in position soon enough, have a tendency to suppress the growth of weeds, and would at the same time act beneficially in arresting evaporation, and thus securing more uniform moisture in the earth for the support of the trees. We think the plan worth trying under the circumstances, and the mulching cannot be applied too early in the spring. Both for the purpose of mulching and manuring you may calculate that the roots will extend somewhat beyond the spread of the branches, and material will be wasted by applying it close round the stems alone. Mr. Pettigrew finds the Gammy Noir the best Grape for vineyard purposes in South Wales. He procured his stock from France, the variety, so far as we know, not being grown for sale by British nurserymen. We shall be glad to see the fruit you hope to send us some day, and are pleased to hear that the Journal is a welcome guest and serviceable in New Zealand, where we have several subscribers. We shall have pleasure if we are able to give you and other colonials useful hints at any time, and like to feel we have a link with friends of kindred tastes and engaged in a common work in the "Greater Britain beyond the seas."

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*N. C.*)—It is a variety of *Rosa polyantha*. (*R. O.*)—1, *Adiantum scutum*; 2, *Aralia gracillima*; 3, *Reidia glaucescens*; 4, *Pteris serrulata scutata*; 5, *Pteris umbrosa*. (*G. B.*)—1, A very poor specimen, but it resembles *Grevillea Thelmanniana*; 2, *Polygala Dalmaisiana*. (*W. W.*)—*Euonymus japonicus*.

COVENT GARDEN MARKET.—MAY 2ND.

MARKET well supplied with a steady business doing. Little or no alteration in prices.

FRUIT.

	s.	d.	s.	d.		s.	d.	s.	d.

HELPS TO SUCCESS.

At its monthly meeting on the 14th ult., the Canterbury Farmers' Club listened to a very important paper by Mr. E. Tallerman, on the practical measures necessary to be taken to insure a more profitable realisation from fruit. Owners of English orchards and fruit plantations do not at present make the best of their crops. An assertion was made at this meeting that in Kent the year before last thousands of tons of fruit were actually wasted owing to the low price in the metropolis not being sufficient to meet the heavy demands made by the railway companies for freightage. The same result happened that year in the Plum districts of Pershore and Evesham, and grievous lamentations were made, not only by sufferers, but by all who witnessed the immense waste, and it was pointed out at the time that such would not have been the case on the Continent, where the surplus Plums would have been dried and packed in boxes for future marketing, and the Cherries and other fruits have been either converted to jam, or subjected to an equally practical process of preservation. The object of the paper read was to show the Kent farmers the necessity of combining together for the establishment of refrigerating and evaporating establishments for the preservation of fruit, which, having been once provided, the market need never be glutted by over-abundant supplies. By thoroughly working the co-operative principle their fruits could be applied to a great many different purposes, as is at present done in America. Not only was the improved fruit marketing of the United States fully described, but also the tasteful and tempting methods by which fresh fruits are made up in baskets in France, although even in that country large quantities are boiled in sugar and converted to crystallised dessert fruits of various kinds. The drying process of the Spaniards, Turks, and Greeks were also detailed, and it was pointed out that the courses pursued by foreign fruit growers could be all the more advantageously adopted in Kent, as it was within easy reach of so many large centres of population. Mr. Tallerman

went also minutely into various processes, stating that green fruits might be safely stored in a cold dry air chamber, and kept in a fresh condition for from two to four months at a temperature of from 40° to 45°. For fruit evaporation he said that the numerous vast houses in the Hop districts could be utilised as evaporators at times when they at present remained unoccupied. He also briefly described the machinery necessary to be provided for the canning, bottling, and crystallisation of fruit, and for its conversion to jam. The discussion which ensued took a practical turn, and the necessity of such a co-operative association as suggested being established was thoroughly admitted.

We have given the foregoing paragraph from a report of the Canterbury meeting as tending to enforce the teaching of our last article. It is also important as affording additional proof of the great want of thoroughness and knowledge of their business on the part of many farmers, and this is all the more remarkable because it has reference to actual fruit farmers, men to the manner born, yet who have hitherto been content simply to cultivate their fruit and dispose of it solely as raw produce without a thought of turning part of it to account as a manufactured article. Glad are we to know, however, that the heavy losses of ripe fruit the year before last has induced several farmers to turn their attention to jam making and other methods of fruit preservation. We would urge them especially to see that such preserved fruit is really a pure first-rate article. If they do this so as to build up a reputation and sustain it unblemished by any trick of trade they may feel assured of a demand for it. We mention this because we find it as difficult to purchase pure jam as it is to obtain really good butter. The jam generally has a slimy consistency which betrays the presence of gelatine, and there is a poverty of flavour which points to heavy adulteration, and of butter quite two-thirds is unpalatable either from cows having improper food or from the foul odours taken up by the milk in cow house and dairy.

Perhaps the greatest helps to success are painstaking and thoroughness, no matter to what branch of farming they are applied. In the great corn-growing districts farmers are very apt to pooh pooh advice about fruit or dairy farming, yet how many of them are worthy to take rank as first-class corn farmers? Do we require a test plain and unmistakable? Take the returns of corn averages in any part of, or for the entire country, and there you will see that 30 bushels per acre is a full average for the Wheat crop; yet we regard that fact as proof positive of the general deficiency in cultural knowledge of farmers, and may insist upon it that the average should be at least 10 bushels higher. We occasionally see reports of extraordinary crops of this or that which are the outcome of special efforts. Why, we ask in the name of common sense, do we not make special efforts every season and with every crop?

(To be continued.)

WORK ON THE HOME FARM.

Satisfactory progress continues to be made with work on the land. Mangold sowing followed Barley sowing closely, and the work was done expeditiously and well. The preparation for Swedes was next taken in hand, and we hope to have them sown shortly. On the home farm a small field next the large Mangold field, which was also intended for Mangolds, is so foul with couch grass that we decided not to sow it with Mangold, but to give it a bastard fallow, and sow White Turnips for spring feeding. April has certainly had more tears than smiles this year, and corn hoeing has really been out of the question. Charlock is now visible, and the hoes must be made to move briskly by having all the work done by the acre, and by a slight advance in price to encourage the men to exert themselves. One of our bailiffs, in his zeal to excel, had had the hoes at work among winter Beans in showery weather when we last went to inspect the farm in his charge, and we had to caution him not to waste labour. We have had all the couch grass upon the surface of the Barley fields picked off by the rook boys, who are better so employed than sitting under a hedge. We hold that everything possible and reasonable should be done to get rid of weeds. We cannot afford to let weeds rob the soil of one grain of fertility, and we had much better spend 3s. or 4s. an acre now upon weed eradication than to see the flaunting yellow Charlock or scarlet Poppy later on as an unmistakable sign of our want of energy and care. We have an old allotment, which we have taken in hand, so badly infested with Chickweed that in this showery April now stirring with duckfoot or other harrows would destroy, and we have decided to plough, harrow, and sow with Lucerne,

so that the Lucerne plant may get a sufficient start of the inevitable Chickweed to enable us to get the land clean.

The loss of a couple of the best lambs from what the shepherd termed strong inflammation led to an inquiry, which showed that he had been trying to force them on by using too much lamb food. The lusty animals eat it greedily, become too full in condition, and the result was a fit of apoplexy ending in death. We have taken much pains to explain the cause and effect of this to the shepherd in order that he may not again err through overmuch zeal. Depend upon it there is nothing like the master's eye to frequently overlook and check the doings of ignorant workmen.

THE FARMERS' CLUB AND FARM INSECTS.

At the monthly meeting of the Farmers' Club held on Monday evening at the "Salisbury Square Hotel," Mr. A. Pell in the chair, Miss Ormerod of Torrington House, St. Albans, read to a large audience, including several ladies, and with the aid of diagrams, an interesting paper on "Farm Insects." In commencing the reader expressed her belief that during the last few years there had been a great increase of insects both in farm and orchard crops, though very little in the number of kinds that troubled them, and said that increase appeared to be an unavoidable consequence of lessening the amount of wild ground by the march of cultivation, and also by the spread of towns and villages. After careful search of records she thought the injurious insects here at the present day—that was those that were seriously hurtful to their living field and orchard crops, and vast numbers besides less commonly known—had been here for fifty, seventy, or a hundred years, and except the Hessian fly she did not know of any insect pest to growing crops which were newly introduced into this country. The enormous green and blue-and-white striped caterpillars of the death's head moth, which especially preyed on Potato leafhopper, were present in great numbers, and in all parts of the kingdom in 1826. After alluding to various modes of arresting the ravages of insects she said they were now steadily advancing in knowledge of the habits of crop pests and of practical measures which could at a paving rate be brought to bear upon the yearly causes of loss. Good cultivation and such preparation of the land as would destroy the shelters of pests under clods above the surface, or in cells beneath it, were amongst the best ways of avoiding much mischief from a commencement of attack. Among the causes of the evil Miss Ormerod mentioned the screenings of foreign corn, which she thought should either not be spread, or before being spread should be rendered innocuous. In concluding she declared herself very emphatically against the sparrow as a pest to the farmer. Taking a broad view of the state of affairs all over the country, she observed, they saw increase of Passer domesticus (to distinguish him clearly from his harmless namesake the hedge-sparrow), and they also saw increase of farm insects. Besides the downright mischief to corn and other things farmers were suffering now, and would suffer severely unless the matter were taken in hand, by the sparrow driving away the truly insectivorous birds, and notably the martin. The numbers of this bird were demonstrably lessening, and if the small proportion of caterpillars that the sparrows take were considered by the sparrow-lovers to be such an important help to us, it must be a very much more important evil to have the martins driven away which destroyed the perfect insects by legions just when they were about to lay their eggs. They had, Miss Ormerod said, a strong warning before them in the United States of the mischief following the unchecked multiplication of the English sparrow; and she estimated the total loss from insect ravages in farm crops and fruit farming, and among farm stock, at from £8,000,000 to £10,000,000 per annum. A discussion ensued, and on the motion of Mr. Herbert Little, seconded by Mr. T. Carrington Smith, a vote of thanks was given to Miss Ormerod for her paper.

REMARKS.

22nd.—Cloudy morning; wet from 0.30 P.M. till 7 P.M.; dull evening.
 23rd.—Dull and damp till 2 P.M., then wet till midn ght.
 24th.—Dull and damp all day.
 25th.—Cloudy and cool morning, bright afternoon.
 26th.—Fine, and at times bright, though generally dull.
 27th.—Fine bright morning, though cold, with slight frost early; cloudy, with slight showers in early afternoon; fine and bright again from 2.30 P.M.
 28th.—Fair morning, bright early, and much warmer; not so fine in afternoon, with drops of rain.
 Another cold week, being about 4° below the previous one. It is rather curious that in each month of this year one week, and only one week, has been of more than the average temperature. Slight frost in air and a sharp one on grass on the 27th.—G. J. SYMONS.

PRIZE ESSAYS AND PRIZE
WINNING.

SOME time ago Mr. S. Thacker, a great supporter of the Notts Horticultural Society, offered prizes for essays on the duty of the gardener to his employer, to be sent under seal with a motto, and to be read by a gentleman at one of the Society's meetings. The essays were admirably read on April 11th by a Nottingham gentleman, Mr. Woodward, though he had not seen the MSS. until just before the meeting. The first prize of 20s., accompanied by the first-class certificate of the Society, was adjudged to "Excelsior," the *nom de plume* that was first adopted by Mr. N. H. Pownall, Lenton Gardens, Nottingham, in his contributions to the *Cottage Gardener* many years ago, and who has subsequently enriched the pages of the *Journal of Horticulture*. The certificate he has won will be prized by him, and he deserves it better than many deserve the prizes they win at shows. There are able gardeners in various parts of the kingdom who have done much more towards the advancement of horticulture, and in promoting superior cultivation, than half the showmen have; but the educational work of the former, in the form of essays, read or published, founded on useful knowledge acquired by long practice, is seldom recognised, while "honours" without number have been dispensed to exhibitors for plants, fruit, and vegetables, that have, on the face of them, the stamp of inferiority, and not only so, but prizes have been adjudged to men for what they never grew, but bought, begged, or borrowed for the occasion. Thus the pot-hunters and schemers are rewarded, while the brain-workers, who strive and study to improve themselves and benefit others, are, with few exceptions, severely overlooked. Offering prizes for essays on subjects pertaining to gardening, and as affecting those engaged in it, whether as masters or men, is a step in the right direction; but power should be reserved to withhold them when devoid of substantial value and literary merit, as some we have seen undoubtedly are. Mr. Powuall's is not one of them, and we have pleasure in assigning it a place in our columns. Here it is:—

SUBJECT: THE DUTY OF THE GARDENER TO HIS EMPLOYER.

A general subject, dealing with the gardener in general, or the profession as a whole, and the employer in general, or the body of employers as a whole. The connection between these two representative people is the duty of the one to the other, the lesser to the greater, the servant's duty to the master; and that connection, seeing that no special type of employer or master is indicated, and no particular gardener specified, whether the gardener with "acres of glass and regiments of men" under him, or the gardener of spade and wheelbarrow, worked by himself, can only be treated in a general way, broadly and comprehensively, primarily and essentially so as to principles, and only relatively so and in a lesser degree as to details. To attempt to go into details, having no guide in what direction to go, would most surely land the writer in uncertainty and confusion. There are great principles which embrace all the relations of employer and employé, and these should govern, and must govern, the gardener's duty to his employer, whatever sort of gardener or employer each respectively may be. It is clearly impossible to reduce the subject to one class of gardeners and one particular section of employers. The foundation of the principles alluded to lie in two wise sayings—"Do as you

would be done by," and "Whatsoever thy hand findeth to do, do it with all thy might."

The first thing between the gardener and his employer is the contract, or engagement. It is the duty of the gardener towards himself, as well as towards his master, to see that his engagement is based on fair, honourable, and profitable lines, and that that engagement is made perfectly clear and open, and as far as possible put into "black and white." It is his duty in this contract to see that he gets proper remuneration—a cheaply paid servant is often a dear one to the master; the time or hours of work positively fixed, holidays arranged, severance of connection provided for, the privileges and allowances as to house, coals, light, vegetables, commission on sales, if any, &c., all made plain and unmistakeable, so that there may be no after difference, but that everything may work smoothly. In these arrangements, and in all others which may arise, the gardener must consider and act upon the golden rule of "Doing as he would be done by." The contract or engagement concluded, the gardener must see that the engagement thus entered upon be loyally and efficiently carried out.

It may appear to some a small matter and a superfluous one, but it is none the less the duty, the bounden duty, of the gardener to his employer, that he, the gardener, personally respect himself, and order himself rightly. "Know thyself" is the teaching of the ancients, and means very largely respect thyself, reverence thyself, rise to the level (and above, if possible!) of thyself. This done, there will be no room for pride and self-conceit. In person the gardener should be scrupulously clean and tidy, appropriately, becomingly, and serviceably dressed. He must be sober and industrious, courteous in manner and speech, faultlessly honest in everything, and careful that all who are in any way connected with the garden be honest also. Whilst his hands are fully occupied he must be constant in filling his brain with wholesome ideas by observation and reading. He must be quick as well as sound in judgment, and prompt and decisive in action. He must economise his time so as to get the most out of it he can, and always on the watch to make his time and labour bulk out into usefully resultful ends. He must keep down bad personal habits as drinking, smoking (if a smoker the habit must never be indulged in in working hours), gambling, flirting with his female fellow-servants, dawdling, or, as it is commonly expressed "awming," about, late hours, &c., as well as fussiness, faddiness, and fidgettiness in his work, and also conceitedness, previously hinted at. These habits all apply with strong force to the young gardener, and some of them to the elder gardener. The first-named bad habit, it must be said with sorrow, unfortunately seems to beset the elder gardener, and has been the ruin of many a good man. Loss of interest in his work and neglect of his personal appearance, to say nothing of other things, often come out of this habit, and both are a breach of the gardener's duty to his employer. Bad habits are easily formed, but are not so easily broken off.

The gardener's duty to his employer in all money matters must be exercised wisely and conscientiously as to what he buys himself, in plants, seeds, manures, or other garden necessities. He must see to it that he does not get anything but what will do good to his employer or his estate, not indulging in fanciful purchases but only in really necessary things, and taking great care that what he gets shall be equal to the money spent. It must be also a duty with him to see that his work be well done, and constantly, not just once or twice and then left off; to see that whatever comes into the garden, whether by his orders or his employer's, shall be true and good in quality and of full value as to weight and quantity. His garden accounts must be kept with the strictest regard to economy, and so managed and cared for as if he had to pay them himself. It is his duty to his employer, and very much so to himself, that he keep correct account of the produce of the garden and how consumed or disposed of. His tools and implements must be always kept in workmanlike order

The gardener's duty to his employer in his work will make him study it at first, and day by day ever after, thoroughly, as a whole and in detail, and down to the lowest and most commonplace detail. Nothing must be lightly passed over, nothing scamped, but everything attended to with punctuality, promptitude, and with the highest skill, both as to plan and execution, which his head can devise and his hands carry out. He must "put his conscience into his work." He must, above all things, study the special requirements of his employer, and also the particular needs of his employer's establishment. Whatever his own fancies and desires may be they must be subordinated to the wants of the establishment he has to provide for, and parenthetically it may be here said, for the guidance of the young gardener entering on a situation that the rule is, Vegetables are the first consideration, fruit the next, and flowers the last. Exceptional cases may turn this rule upside down, or modify it in some degree; but if they do they only make the rule more absolute. It is the duty of the gardener to at first find out exactly which is chief, and then arrange accordingly. Though he may make one point chief he ought to strive to do all things well. In order to fit him to do his work all the better he must keep himself abreast of the times by making himself acquainted with the best thoughts of the day, in all new ways of doing work, adopting such as are good, in new inventions of gardening necessities, being cautious about adopting any until quite satisfied that "there's something in them;" in new plants and new ways of growing them, in new seeds, or roots, or manures, or implements, and indeed in all other matters which make up the economies of gardening. This must be done as a duty to his employer, and to show that he is "a workman that needeth not to be ashamed."

There are one or two qualities which might be, and ought to be, cultivated by the gardener, which would materially assist him in doing his duty to his employer. Energy and industry are understood to be guiding qualities, indeed they are indispensable; and if to this the gardener can add concentrativeness, or that power of will and thought whereby a man can settle his whole mind on any particular duty he has in hand until he has finished it, this will contribute largely to successful labour. Tact and common sense are qualities which every born gardener has as a birthright, or ought to have, and if he has besides what the Americans call "gumption," which they say is more than tact and common sense (which is the gift of being able to do, and say "the right thing in the right way, at the right time") then the gardener will become more excellent as a man and a workman day by day, and, therefore, able more fully to do his duty to his employer.

Now let us come to the conclusion of the matter.

Not so much as to a master or employer will the true gardener do all this, though that position he will ever recognise and maintain, but, as man to man, "doing as he would be done by." Putting himself into his employer's place he will act towards him as he would expect his employer to act towards him if their positions were reversed, or, indeed, as he—the gardener—expects his employer to act toward him in their present relations. He will make his employer's interests his interests and serve him, "not with eye service but in singleness of heart." By so doing he will gradually rise in his master's estimation, and his own, in his profession, and will have that best of all friends a good conscience.—EXCELSIOR.

THINNING GRAPES.

DURING the next few weeks the bulk of Grape-thinning will require pressing attention in gardens throughout the country; and as it is work that cannot be delayed without causing a wasteful expenditure of the energies of the Vines carrying the crop, all good cultivators make a point of straining every nerve to keep the work from getting behind, and with this object in view contrive by some means to thin every bunch as soon as it can be clearly ascertained which berries have set properly, and may consequently be depended on to result satisfactorily. Grape-thinning is by many considered a tedious operation. Perhaps it is in some cases, but of all

gardening operations it is the one I like the best when I have before me shapely well set bunches, some of which with good thinning and proper attention should make models of good form, while others bid fair to become masses of gigantic size. Each variety, nay each bunch, requires to be thinned according to the length of the footstalks and the size to which the berries grow. This helps to make the work the more interesting, and many pleasant hours have I spent in thinning the berries and studying the habits of most of the best varieties in cultivation.

No hard-and-fast line can be laid down as to the distance the berries of each variety should be apart when thinned, because the same varieties growing in different houses often differ considerably in the length of the footstalks, and in the case of Black Hamburgs much difference is apparent in this respect in Vines growing in the same house. The berries of those with the greatest length of footstalk should be left much closer together than those with shorter ones, for the simple reason that as the berries increase in size they will force each other upwards and outwards as far as the length of footstalk will allow. For compact bunches of Black Hamburgs when the Vines are vigorous an inch apart over the lower part of the bunch is about the right distance, but this distance should be gradually lessened as we approach the top of the bunch, as it is a common error to over-thin the shoulders with the result that as the berries swell, their own weight bearing them down, and leaves vacant spaces on the top of the bunches, which quite spoils their appearance.

The mistake of over-thinning is not always made at the first thinning, but when the berries are about half grown they rest upon each other and appear to be too close together to allow of their swelling to their proper size. Sometimes this may be the case, but my experience teaches me that this is just the stage at which they are the more likely to be over-thinned, in the case of those bunches that have long footstalks, as it is surprising to all but those that have closely watched them how the berries, as they increase in size, will gradually force each other into their proper positions till the bunch is filled out evenly from point to shoulder. It is without doubt a good practice to look over all Grapes when they have completed their first stage of the stoning process, to remove any berries that are not likely to have room to swell to their full size, but it must be done with caution to avoid the mistake I have already pointed out.

Madresfield Court, one of the most handsome of all Grapes both in bunch and berry, should be well thinned, but an inch apart is generally far enough, in consequence of the berries being oval in shape instead of round, and the same remark applies to Muscats. Gros Colman requires more space for its berries than any other Grape grown, as they not only grow to a large size, but the footstalks are nearly always short, $1\frac{1}{4}$ inch, and sometimes a little more is not too much. Gros Maroc requires only a trifle less space. An inch apart is far enough for Lady Downe's and Alicante. If this room is given all over the bunch, the footstalks being very stiff keep the berries in their proper positions till they are full grown. Shoulders are often formed on one side of a bunch. When they are small we remove them, as they only spoil the shape of the bunch and do not add much to its size. Double bunches, when large, we sometimes leave, as a good solid bunch of that description, with shapely tapering bunch on either side, look well on an exhibition board.

TYING OUT LARGE BUNCHES.—For medium-sized compact bunches this operation need not be resorted to, as when properly thinned the berries will gradually form themselves into their proper positions and make handsome specimens, provided the outline of the bunch is good. With large bunches, however, the case is quite different, and unless tying out is practised to a considerable extent much of the bunch must be cut to waste, and many fine bunches of Gros Guillaume and Trebbiano, which might have been made into splendid specimens, have been thinned down until they have become very moderate in size. Having had considerable experience with bunches which when cut weighed from 5 to 12 lbs., I will describe our mode of procedure. Gros Guillaume sometimes produces bunches of enormous size with large spreading shoulders, and at others bunches that are well proportioned and solid in build, but in nearly all cases the footstalks are longer than those of any other Grape, excepting Buckland Sweetwater, which requires exactly the same treatment in the matter of thinning as Gros Guillaume.

To tie out and thin a large bunch of the last-named Grape requires much patience. Our first proceeding is to fasten a piece of raffia to the shoulders on the top of the bunch, bring them nearly up to a horizontal position, and arrange them at equal distances all around. It is not enough to have only one piece of tying material to support each shoulder, but these should be placed an inch apart all along the shoulder, otherwise as the berries swell their weight will weigh the point of the shoulder down and perhaps break the stem of the shoulder at the point where the tying material is

fastened. Having arranged (and tied to wires under the roof or the Vine shoots) the top tier of shoulders, we next tie up those underneath in the same way, taking care that these are brought up in a line with the centre of the angle formed by the top ones. The next tier is again angled with these, and so on till we approach nearly to the bottom of the bunch. The branches of course become smaller as the bunch tapers to the point. Some here will perhaps contain only four or five berries, but still they should be tied up to fill the vacant space that has been created by raising those above them. This is the principal point to be observed in the manufacture, so to speak, of large bunches, as by these means the berries are evenly distributed over as great an amount of space as they can fill up when growing to their full size. When this tying out is completed the most tedious part of the work is done, for it will be found that very little thinning of the berries will be necessary. A few small or imperfectly set ones may require removal, and possibly a few from the centre of the bunch, but it is seldom indeed that more than this is required. By following out these instructions many bunches that when set appear loose and straggling may be converted into large solid bunches. Trebbiano should be tied out in the same way, but a little more thinning will be required, because the berries often come in clusters, and the footstalks are not so long as those of Gros Guillaume.—H. DUNKIN.

AURICULAS.

I FEAR that I cannot agree with some of the criticisms of my friend, "D., Deal," upon the London Show of the National Auricula Society. He kindly invites "other estimates," and so disarms contention; but as I do not come with sword and spear, so there are no such weapons for me to lay aside, but I do think him under the influence of a few mis-impressions.

One which, on the whole, is no little mistake, concerns the selfs. That there was an undue preponderance of selfs in most of the stands—that selfs, as if they were an inferior, are the least advanced class, and that they are the most easily grown. For my own part I showed no greater proportion of selfs than I always do, but that is of little consequence. I am not the London Exhibition. But I think that the self so enriches and emphasises a group, and is so greatly the light, and warmth, and resting-place for the eye among the edged flowers, that without the self in full evidence the others would be but a dazzle of naked jewels, one sparkling against the brilliancies of the others, till only an accustomed eye could detect much variety among them. Popularly, indeed, the flower is known by its selfs, and many visitors here have said, "Well, except for those lovely 'selfs,' as you call them, I only see two or three sorts in the collection!" I do not, of course, maintain that the self is as powerful and masculine a flower as the perfect green-edge. She is pre-eminently of the gentler sex; a flower to whom some less outward adorning is given by her nature, and of whom, therefore, there is that less required. But I would accord her abundant honour in what may seem to some her humbler sphere, but which is, to those who are intimate with the difficulties of the self Auricula, a sphere anything but easy to fill with credit. The Southern schedule only demands so many dissimilar varieties in the stands, and while any marked disproportion of one class is a weakness, so that even the emerald green-edges might be overdone were it not for their scarcity; yet if one class has to appear more than another, then the self, in a rich range of her lovely colours, is the one to make the weakness look most beautiful and attractive.

But the self "is the least advanced class." How the least advanced? Is she the weaker vessel? Is she the inferior creature? Is she so little because she has not the "edge," which would be inconsistent with her distinctive character? Are her properties so facile that anybody can raise a good self? Truly nay to all this. Rather, here is the delightful deception of her beauty, in that it looks so simple and so easy of attainment, and is yet so hard. Herein is the charm of her advancement that you think you can win that homely calm-faced flower at your will; and, lo! you cannot. As my friend, "D., Deal," says "Whoever attempts to grow seedlings is pretty sure to get a large proportion of selfs among them." That is so, and here was the misconception of the old school florists that selfs came anyhow, to say nothing of the aimless wanderings of such as put their trust in chance-saved seed. Plenty of selfs, but what selfs? The most abject, marked, and painful failures. There is, thanks to "self" deception, no class of Auricula more difficult to raise than a really first-rate self. Those who trust to the sporting of edged-class seeds are not even in the way of it. An edged flower does not seem to know what a good self ought to be. I never knew a self worth anything that owed a filial relationship with the "bloated aristocracy (!)" of the "edges."

I have taken perhaps more pains with the self than with any Auricula. I think the best Auriculas I have yet raised are selfs,

yet they have not "come spontaneous," but only from a pure and the best self parentage, and there was not much to work upon when I began. Now, the "advance" of the self has been from the notched petal to the fully rounded "rose leaf" one, and from the narrow paste of an even outline to the broad and circular, to petals of greater substance and breadth and smoothness, and far more richness of colour and texture. I think also that the self is proving worthy of another possible recognition of her advancement, that she should suffer from no mere class disability in competing for the proud position of the premier flower of an exhibition. A perfect self is a better Auricula than a less perfect green-edge. The edged one has more to do than the other; but if it does not do it then the other that has done all it could is the higher flower.

But this by the way. "D., Deal," considers that the self is cheap a'so, as being the most easily grown. Certainly the habit is often, but not always, the more robust, and the self will no more brook ill-usage than the edged flower will. She is like her brethren. To put, if I may, words of Shylock (*mutatis mutandis*) to the lips of the self:—"I am a Jew. Hath not a Jew eyes? hath not a Jew hands, organs, dimensions, senses, affections, passions? Fed with the same food, hurt with the same weapons, subject to the same diseases, healed by the same means, warmed and cooled by the same winter and summer as a Christian is? If you prick us, do we not bleed? If you tickle us, do we not laugh? If you poison us, do we not die? And if you wrong us, shall we not revenge?"

May I say, also, that "D., Deal," is mistaken in supposing that the self Laura is a shaded flower. The Laura of the London twelves was the same Laura (the same plant) in the Northern sixes a week later at Manchester; and it is vain to suppose that, had she been truly a shaded self, she could have escaped the strict eye of all the judges. Of the florist brotherhood, several of my most severe Northern friends saw Laura both at home and at the shows, and they all spoke to me of the pure beauty of the flower. It is simply impossible that a shaded self should pass undetected through this keen and varied scrutiny, and an exhibitor who ventured in the North with a shaded self would run grievous risk of making wreck of all his chances. There is only one body colour in Laura, and I can only think that in certain lights, the Lights (save the mark!) the Lights o' London Show, "D., Deal," may have caught a dismal ray through the flower from behind it, transmitted through the varying density of petal tissues, that may account for what he supposed was shady. But I look to-day on Laura faded, and she has died true to her pure colour, one of the highest virtues of the self.

But even more than at the fault with Laura I do wonder that my friend apparently never lingered, with even so much as a butterfly touch, over the charm and power of the black self Ebony. I do feel fond and proud of her; and at the Northern Show, where she appeared after all the wear and tear of London, Ebony was the best self I had, and was beloved of all who saw her. She is our first self in black yet obtained with all-round excellencies, with colour most happily shown off against mealed foliage, and with a golden tube and brilliant paste not excelled even by Heroine, in which they are properties so strong. I am sorry that the practised eye, taken in an illusion over Laura, should miss the lustrous beauty of dark laughing-eyed Ebony (it is only an innocent flower that can seem to smile in the colours of deep mourning). If I had a florist friend at my side he should write all this for me lest I should seem to boast, but indeed I do not mean to do so.

On the subject of heat, I must mention another complete misimpression of "D., Deal." He infers that all the crumpled and curled petals, all the coarse and over-sized blooms, were "as if all the heat they had been subjected to had not been even enough to open them fully." Now, as a matter of fact, heat, as "D., Deal," evidently understands it, is the very "How not to do it after this fashion." Such heat will not so much as properly open an Auricula—the last thing it will do is to give it size. The Auricula pip that has been heated is a very different thing from the blustering blossoms of which "D., Deal," rightly complains. It is a small round thing, of little substance, colour, or duration—a bud that has dropped out into a flower which a good green pea or a threepenny-piece would utterly eclipse. It may even not go that little way, but remain much the bud it was until the throat gives way, and it is gone. I am nigh unto weariness in combatting this perhaps plausible but utterly incorrect assumption, that Auriculas which in a late season are shown wonderfully expanded and ready, or hopelessly rough and over-grown, are obtained by forcing the plants by the same means into the opposite extremes. I am bold to say that no Auriculas that win a place at the great shows have been grown in heat as that term is generally, and I think by "D., Deal," understood.

As an illustration of what is true and safe on this vexed question may I repeat my own experience and practice? The

Auricula houses here have no hot-water pipes or flues, though they have the advantage of a full south exposure, and of the back wall being built against the solid earth, and so impervious to frost from behind. If need be, the plants are so shaded as to leave the sunshine playing upon the back wall all day, and so supplying a gentle warmth at night, which is taken care of by strong sheets of sacking over the glass roof and sides. When the plants are forward enough, the wall is allowed no sun, and the lights are left open far into a fair and balmy night. If I much need a plant or two that may require more generous warmth to perfect the bloom I may take it for the last few nights to the cool Orchid house, at a maximum of 55°, a temperature no higher than that of a pleasant evening out of doors. I never take them into the intermediate house or the still higher Orchid temperature.

Indeed, when heat is spoken of as applied to Auriculas, it means practically a heat no higher than such as these plants might naturally expect in a properly genial spring. When the weather denies them that at a critical time, why, I apologise to them for the weather and try to make it up to them, not so much by putting heat in as by keeping cold out. It is perhaps at least worth mentioning this, because from reading some deprecations of "heat" for Auriculas, it might be inferred that some favoured plants were treated to the Cattleya house, or even to an evening with the East Indian Orchids, or, if kitchen company were congenial enough, to the early Cucumber frames. But I do not either see from theory, or find by practice, that a warmth equal to a kindly spring temperature is other than helpful to the Auricula when close upon its time of bloom in a bitter season. Conserving of natural heat by early closing and coverings on cold nights, is by far the best way, and a heated flue is by far the worst, in fact not safe.

The Auricula will not bear any heat of an untimely or unnatural degree. An artificial temperature of 70° will cause the buds to open small, and one much over that will prevent the flowers from opening at all. The pollen is prematurely shed, and the tube and throat are encrusted. If there be a natural shade temperature of 65° or 70° in spring it does not destroy the flowers, but they live very fast under it. Thus the cry that the Auricula growers of to-day use heat that would melt the spinal marrow of their great forefathers, ends in the little wool that after all we are but as the nurse to Nature, and treat our plants but as she would have them treated if she could, "weather permitting."—F. D. HORNER, *Burton-in-Lonsdale*.

VEGETABLES FOR EXHIBITION.

DWARF FRENCH OR KIDNEY BEANS.

THESE are usually available before the Scarlet Runners, and in June and July have good weight in a collection of vegetables. At many shows prizes are also offered for a single dish, and in any case they well repay for good culture. Unlike the Runners they are not continuous bearing, and consequently the sowings must be timed so as to have the pods at their best when most wanted. As a rule the seed should be sown about eleven weeks before the produce is to be shown, but as these also transplant readily from pots or boxes, a few days will be gained by sowing under glass. For the June shows, and any held early in July, it is advisable to grow them under glass nearly, or quite, all the time. A few plants in a frame disposed on a gentle hotbed, or in a pit or frame in succession to early Potatoes, will, with very little trouble bestowed upon them, yield superior pods. Raise the plants singly in 3-inch pots, and in due time plant them in good loamy soil 18 inches apart each way. They will require staking, and ought not to perfect many pods at a time. For the July shows they may be started in a frame, this being removed or the lights taken off when it is seen the crops will be quite early enough without any further protection. In some districts they may be had good from south borders early in July, but for later shows a sunny open spot better suits them. A fairly liberal dressing of solid manure ought to be well mixed with the top spit, this encouraging the roots to remain within reach of the warmth they appear to greatly need. The roots should be fully 2 feet apart, the seed sown thinly, and the plants eventually thinned to 10 or 12 inches apart. They should be moulded up early, and staked before they fall over. It is only the thinly grown erect plants that produce perfectly straight and symmetrical pods, and these, let me repeat, ought not to be heavily cropped. Successional sowings ought also to be made, as there is no certainty about the duration of a crop. During dry seasons they need plentiful supplies of water and liquid manure, but as a rule on heavy and medium soils summer mulching is all that is needed. Canadian Wonder is, on the whole, the most popular for either frames or the open air, but I rather favour the Negro Mammoth Longpod, this yielding abundance of straight dark green pods.

CAULIFLOWERS.

A friend of mine who grows wonderfully good Cauliflowers is of opinion the secret of success may be summed up in three words—viz., "plenty of manure," and there is no doubt he is quite right, for it is useless to attempt to grow good Cauliflowers without plenty of manure. This, coupled with deep cultivation and good attention in the supply of water as required, and plenty of liquid manure, is necessary, whether the produce is required for home use or for exhibition. For the early shows or those held in June the Dwarf Erfurt Mammoth, Mont Blanc, Early London, and Walcheren are all suitable, the plants being raised in the autumn previous and wintered either in handlights or cold frames. These, if duly planted about 2 feet apart each way, will give fine clean heads, which, if properly blanched, much improve the appearance of a collection of vegetables.

For the July shows Veitch's Pearl and Sutton's King of the Cauliflowers are good, the plants being raised in the autumn (seed sown late in August) in common with the earlier varieties, and similarly treated. They form a natural succession to these, and both may be grown to such perfection as to almost equal the popular Autumn Giant. Early in August it is possible to have Eclipse fit for exhibition, and this may be truthfully described as an early form of the Autumn Giant. To have this variety or Veitch's Autumn Giant by the middle of August the plants must either be raised in the autumn previous, or else the seed must be sown in gentle heat early in February. In the latter case, when the seedlings have developed the first rough leaf, they ought to be pricked off, four plants being put round the sides of each 4-inch pot. They should then be set on a sunny greenhouse shelf close to the glass, there to be kept and well attended to until the first week in April, when they should be hardened off, and a fortnight later divided and planted out 3 feet apart each way. When growing strongly these or any Cauliflowers required for exhibition should receive a mulching of partially decayed manure, and in dry weather liberal supplies of liquid manure. Here let me add that if fifty plants cannot thus be favoured be content to grow half that number, and "do" them well. The watering should be no mere dribbles, but each plant ought to receive at least a 3-gallon can of water or liquid manure at a time. This will suffice them for ten to fourteen days, according to the weather or the nature of the soil, when more must be given. It must not be thought that no further trouble is needed. Remember that caterpillars soon disfigure the hearts, and if the latter become green or open badly they are unfit for exhibition. Just as the "curds" are forming the caterpillars become very troublesome, and must be closely looked after and destroyed. Hand-picking is the only remedy, and the plants ought to be examined two or three times in a week. The blanching, a detail often neglected, ought to be commenced a fortnight previous to the early shows; and if either Cauliflowers or Veitch's Autumn Broccoli are wanted for the November shows these should be taken in hand a month or more before the date of the show. The leaves must be well brought up together, and kept so with the aid of a strand of matting, the aim being to thoroughly exclude the light from the heart. Unless the light can be so kept out greening occurs and the curds "break" or fly open, it may be several days before the date of the show.—EXHIBITOR.

KEENS' SEEDLING STRAWBERRY.

THIS fine old favourite variety is now seldom cultivated anything like so extensively as it deserves, and in some places it has lost favour altogether, or is ousted by newer varieties, which at first are often considered superior, as owing to the extra attention they receive when fresh to hand they appear at first an improvement, and I confess that I am not exempt from this weakness. There are, however, fortunately many gardeners that wisely cling very tenaciously to the old tried varieties, and safely depend on them for their principal supply. An excellent example of this practice is carried out in the princely gardens at Penrhyn Castle by Mr. Speed, who had his shelves at Eastertide laden with fine dark crimson fruit of the above variety, presenting a sight rarely met with. I do not remember to have seen such handsome fruits so early in the season before, and being the true old Keens' Seedling, the quality is guaranteed. Mr. Speed resorts to no mechanical dodges to secure a good set, but depends on good cultivation, and by judicious watering and ventilation he secured rich colour and large size, evidently testifying their grand quality and capability to endure their 250 miles journey to London without serious damage.—J. H. GOODACRE.

PAULINE AS A STRAWBERRY FOR FORCING.

AMONGST the instructive notes which have already appeared anent forcing Strawberries, I have been somewhat surprised to see no notice taken of Pauline as an early variety. It may be that its peculiar shape is not liked, but beyond that I cannot account for its neglect, as it colours well, fruits freely, and for an early Strawberry the flavour is very good. In that respect it is so much appreciated at the table that

my employer has wished me to grow no other early sort. It has a stronger tendency than any other Strawberry with which I am acquainted to start off with the leading bloom extra strong, and this it maintains throughout, the fruit being larger and better than the succeeding ones. I tried the effect of pinching off this leader, but beyond losing the best fruit there was no noticeable difference, as in either case with liberal treatment all the fruit attained a very fair size. Another point in its favour is that from its habit of growth it can be grown in small pots, in fact it succeeds better with us in $5\frac{1}{2}$ -inch pots than in any other.—M. D.

ROSE SHOW FOR DURSLEY.

At an influentially attended meeting held in the Chantry for the purpose of starting a Rose Show in the neighbourhood, it was unanimously decided to hold the first Show in the cricket field on the 4th of July next. W. J. Phelps, Esq., was nominated President of the Society, the Rev. Nigel W. Greesly and several gentlemen in the vicinity being appointed Vice-Presidents. The Hon. Secretaries elected were Mr. H. J. Small and Mr. E. W. Cooke, while the office of Treasurer will be undertaken by Mr. V. K. A. Bowie. A representative Committee was also formed, having Mr. Owen as Chairman. There are many amateur rosarians around Dursley, and the Cotswold Roses have already more than a local reputation. This, added to the well known beauties of the locality, point to a success, if the weather prove favourable, which will doubtless make it an annual gathering of some importance. A schedule will be framed and issued at an early date.

ROSES IN WINTER.

To produce Roses in any quantity during the months of December and January it is necessary to devote a house entirely to their culture. Those with more limited means at their disposal need not despair of having blooms during that period if they follow intelligently the advice here given.

I shall not enter into the structural details of the house farther than is necessary to make my cultural remarks intelligible to those who have no knowledge of the subject. Rose houses are generally constructed so that they have a very presentable appearance. This may add to the enjoyment of those who wish to visit the house frequently to watch the delicate buds grow and develop. This is all that flagged floors and other such arrangements are good for. Such houses are not well suited to the Rose, they are frequently too dry. At certain seasons it is very difficult, with liberal ventilation, to maintain the necessary amount of humidity in the atmosphere, and then red spider, aphides, with mildew, often have their origin. The walks should be formed of ashes or gravel. A span-roofed house is the best, although a lean-to will do very well with a southern aspect. The first should run north and south. A lofty structure is not needed so long as it is sufficiently wide to accommodate a central bed with a bed on each side. The borders should be deep enough to allow of drainage and about 18 inches of soil. Whether the beds be above the ground level, or the same level as the ground, is very much a matter of choice and locality. It also depends upon the structure. If low, and the locality is well drained, then they are better on the same level as the ground. Whether the natural soil be removed is another question that must be decided by each cultivator. If the soil is drained and suitable for Roses outside it would be unwise to remove it. Borders or beds for Roses when grown indoors are frequently overdrained, and this is one of the reasons they suffer so generally from mildew and red spider. Even supposing the plants are kept free of these pests more water is poured on to the borders than is good for the well-being of the Roses. Large quantities of food that should be appropriated by them is carried down the drains. Such borders soon become unfertile, in many instances before cultivators are aware of it, and puny growths follow.

What ventilators are arranged should fit closely, or injury to the young tender foliage will result from the admission of cold draughts. The lights or roof of the structure must be portable, so that they can be removed at a certain period of the year. This is necessary to ripen and mature the wood, to insure an early but a complete rest. Under glass without such provision is made Tea Roses will persist in growing, particularly towards the close of summer, and would flower profusely during September, through the following month, and well on into the next in many seasons, but this depends entirely upon the summer treatment they receive. Plants that flower in autumn are useless for the purpose we have in view, and, therefore, if planted out the house must be so constructed that they can be fully exposed when it is deemed necessary. Those who grow a few only for this purpose may have them in pots, and they will be able to manage them successfully by placing them outside, so that the object pointed out can be attained.

Those who wish to have Roses during the winter must abandon the idea of either planting or growing a number of varieties in pots. One variety only should be grown, or two at the most. Safrano is decidedly

the best winter flowering variety at present in cultivation. It is the variety that is so largely grown and imported by the French. Next to this is Isabella Sprunt, but the first will produce more buds than the latter. The last is equally as good a bloomer in the autumn, and can scarcely be excelled during the months of October and November. It will flower most freely again in February. It is, however, a good companion for Safrano, and should be planted in any house specially set apart for winter Roses. It, like Safrano, has a good constitution and grows vigorously; both will bear winter forcing for many years without exhaustion. In planting a house for this purpose or for growing in pots, I should have one Isabella Sprunt for every three plants of Safrano. In advising the culture of these two I am not overlooking the claims of Niphetos, which is unquestionably the best market variety that can be grown, because its blooms realise the best price, but it does not flower with that same freedom during the winter as Safrano does. It is of weaker constitution altogether, and therefore incapable of bearing the severe strain of early winter forcing in succession. At that period the blooms only come small and demand no better price than the larger buds of Safrano, which during the winter is highly esteemed in the market as well as in the dwelling room. The one, Safrano, is fragrant, and the other, Niphetos, is not, or it is so faint that it cannot be detected by many at that period of the year.—WM. BARDNEY.

(To be continued.)

SUCCESSFUL ROSE-GROWING.

I SHOULD, with your permission, like to record an instance of the successful culture of some Maréchal Niel Roses in the garden of J. W. Larking, Esq., J.P., The Firs, Lee. A year or two ago Col. Edgar Larking, a son of the gentleman named, being very fond of Roses, thought he would like to gratify his tastes in this direction by building a house purposely for growing Tea Roses. The house, a span-roof, 50 by 12 feet, was accordingly built of light sashbars, with grooves on each side to receive the glass, which was bedded in with putty. The roof has a sharp pitch and the eaves come down to the ground level, the whole resting on an angular wall plate on a substructure of concrete. Down the centre of the house is a sunk path 3 feet wide, and on each side separated by a $4\frac{1}{2}$ -inch brick wall, a bed about 4 feet wide and 3 feet deep. In the bottom of each of these beds there is about 6 inches of brick rubble, this overlying a bed of pure gravel, and insuring the most perfect drainage. The soil for filling the beds was composed of two-thirds top-spit, turfy loam, partly marly and partly of a fibrous lighter nature, and one-third of well decomposed pig manure, charred vegetable refuse, and road scrapings. This was turned over several times during a period of two months and then introduced into the house.

In the autumn good specimens of all the leading varieties of Teas were obtained worked on the Manetti stock, and these were duly planted and pruned, some being intended for covering the roof and others as dwarfs. Strange to say, though every attention was paid to these, and not allowed to be unduly excited into growth, they did not succeed as they might have done. The growth the first year was not at all robust, and although close pruning and every attention was paid to them the second year their progress was not of such an assuring character as to warrant trying experiments with them for another year. It was ultimately decided to discard most of the varieties, and in future to grow the Maréchal Niel on standard Briars exclusively.

The soil was examined by several competent growers and pronounced in every way suitable for Rose culture. Some said the absence of bottom ventilation contributed to the non-success of the plants, but even after a short trial of admitting bottom air by removing the putty and allowing the panes to slide up and down there was no perceptible improvement.

In the autumn, then, good vigorous standards of Maréchal Niel were planted on one side of the house. No fresh compost was added, but special pains were taken to render the soil as firm as possible about the roots and the bed generally, so as to encourage the production of stout vigorous growth. The bed was muled with decayed manure, and all through the winter plenty of air was given, so as not to excite the buds into premature growth. In February each of the strongest shoots were pruned back to the best placed outward bud near their base, and any smaller than a quill pen cut out entirely. In due course the buds gave birth to sturdy shoots, and where more than one had formed on the spur the weakest of them were rubbed off. Throughout the summer the shoots grew vigorously under the skilful care and attention of Mr. E. Trollope, the able gardener at The Firs, and he is now rewarded for his pains and skill with shoots measuring, in some instances, upwards of 8 and 10 feet long, and these covered with blooms in all stages of development. At the time of our visit a few days ago we counted no less than 1500 blooms open, and as others had been gathered and a large number were still in the bud state, it will, I think, be admitted that the plants have bloomed uncommonly well. The foliage is of the healthiest description, perfectly free from insects and mildew; and moreover, evident pains have been taken by Mr. Trollope to avoid overcrowding and insure the proper maturation of the wood by thinly disposing the shoots over the trellis. It must be gratifying to the latter, and to Col. Larking, to see this signal success coming as a reward for the pains and expense bestowed on the culture of the plants.

Before closing I may add that Mr. Trollope is a firm believer in close pruning, and when I state what he proposes to do with the plants under notice in the way of pruning, I shall probably frighten those who are afraid to use the knife or scissors on plants or trees. It is the latter's intention to cut all the shoots back to the best placed bud situate within 6 inches or less of the stock as soon as the plants

have ceased flowering. This may appear to be pruning with a vengeance, but it is not so. It is owing to the absence of vigorous pruning like this that so many Maréchal Niel Roses fail to retain their heathiness and capacity for producing not only abundance of blooms, but of good quality also. Directly the Roses are pruned they will be encouraged to break freely, and to produce even stronger and better growth for next season's flowering than they have this.

Samples of blooms have been sent you, I believe, Mr. Editor, and you will consequently be able to judge as to their quality and the soundness of Mr. Trollope's practice in Rose culture.—A KENTISH GARDENER.

[The blooms both in substance and colour are all that can be desired. We have also seen the plants, which are most creditable to Mr. Trollope and his predecessor, Mr. T. W. Sanders, who planted and tended them in their early stages of growth. We have not seen better results after one season's growth than as represented by these Maréchal Niels on Briar stocks.]

BELGIAN WORK AND WAYS.

MORE than the usual number of "Britishers" will probably visit Belgium this year on the occasion of the general Exhibition that is to be held in Brussels through the summer. In connection with that display of the world's goods a series of flower shows will be provided on the dates mentioned on page 339. One of these, according to the programme, appears to be of an extensive character, and may be expected to be fairly representative of Belgian horticulture at that period of the year. The garden-loving public who contemplate a trip across the water will naturally arrange the time when a floral exhibition is held in the beautiful city referred to. A short sojourn in Belgium is very pleasant for persons who have not yet travelled beyond their native shores, and also for those who have. To the first the experience will be totally new, while those who have had a previous glimpse will "find their way about" more readily on a revisit, and on that account their touring will not be the less agreeable. The facilities for travelling are now so great, and the benefits of a change of scene and society so fully recognised not only by the "faculty," but almost by everybody, that ever-increasing numbers indulge in short or long continental trips, according to the time and means at disposal, and it is well known by those who occasionally take long journeys at home that they can go "abroad" at less cost than by crossing from one side of the land to the other within our seagirt isle.

Broadly speaking, hotel charges are somewhat lower in Belgium than in England, with the exception that the continentals "put it on" for soap when travellers do not "find themselves" with that indispensable article of civilisation. As regards railway travelling, second class fares do not much exceed third class in England, nor ought they, for the carriages are not nearly so comfortable; and Englishmen who are in the habit of "going third" at home because there is not a fourth, seem inclined to raise themselves a step in the social scale abroad, and loll in second class carriages even if they do not luxuriate in "firsts." However, they will find polite civility everywhere, and as the railway fares are printed on the tickets the matter of charge is simplified when the value of the "pieces" is understood, and this is stamped on most, if not all of them, in francs and centimes, a hundred of the latter making one of the former; so hotel and other bills are in two columns simply, instead of the more complex and familiar £ s. d. When an English gardener changes £2 or £3 sterling into Belgian small silver coins, he seems to have a pocketful of money, for he obtains 25 francs, that remind him of shillings, for a sovereign, or fifty coins of half the value that he can fancy are sixpences. There are also 2 franc and 5 franc pieces in silver, and 5 centime and 10 centime coins in copper, and the latter also in smaller white metal. These for practical purposes correspond to our halfpennies and pennies, but are not quite of equal value. All this is very familiar to many readers, but not to all, and as there are always gardeners going to Belgium for the first time these simplicities will be indulgently passed by those who know them for the sake of those who do not.

It is somewhat of a mistake in writing to suppose that everybody is acquainted with the trifles that pertain to a subject, hence so much soaring over the heads of those who really need the precise information that is left out. Can it be that some of those who essay to enlighten are fearful lest the plainness of their teaching should be taken as the measure of their own capacity? If so, the sooner such vain notions are cast overboard the better into the sea of crude absurdities. I am practising what I preach, so just one word more about money. An English sovereign is a passport everywhere. It is more eloquent than the tongue often, and better understood in a foreign land, while any Belgian cabman, so far as I know, will take an English shilling in lieu of a native franc without grumbling; but if you in ignorance do not pay the coachman quite enough, and he does not understand your language nor you his, he will contrive to impress on you by his attitude what he means, and it is more likely than not that his blandishments will extract from you a trifle more than he expects. You will then have the satisfaction of seeing a man happy. But if these useful members of society once get hold of money they have a habit of keeping it, and of course they get hold when they can. If a likely passenger is seen landing and hails a cab, a second man is apt to jump on the box and assist in a general way if he can find anything to do; but if when arriving at the journey's end you pay a little extra to the coachman under the impression that he will pass a moiety to his friend, you may depend on it he will not, or at least that is the idea conveyed in expressive gesticu-

lations by the attendant, who is most reluctant to leave you. His attachment seems almost touching at that particular moment, but tip him half a franc and he smiles his adieu, and I believe would know you again and greet you joyfully five years hence if he caught you stepping on the shores of his native land. The point, then, to remember is this, if a footman out of uniform will join the coachman to see to your things, the plan is not to pay one what is enough for both, as you will have to pay the other all the same unless you wish to keep him near you for a longer time than may perhaps be convenient.

No one should cross the water without knowing where to go. Wandering about hotel hunting is a thankless task, and does not always end satisfactorily, and it is best to secure "quarters" before leaving home. A choice can be found in the continental Bradshaw, which is useful to have when moving about. The chief cities of Belgium are not far apart, an express train running between any two of them in about an hour, so a great deal may be seen in a short time. There are various ways of reaching the busy little kingdom, but only one method—crossing the water. The timid who hesitate to do this must wait till the Channel tunnel is open, and when that will be no one knows, for there does not appear to be any great hurry about it. I for one would rather go over the sea than under it, and a journey from London to Antwerp is as safe as one from London to Manchester. Of course a person crossing the water may be a little upset, especially if he invites an attack of *mal de mer*, and perhaps if he does not, but there is a great deal in anticipation. If a person thinks he will be "bad," and feels as if it were "coming on" before he goes aboard, he may not have long to wait; but if he neither thinks nor cares anything about it, the probability is that he will pass over as right as the mail.

On my last journeys out and home again, not one out of the many passengers, so far as I could see and hear, suffered the slightest inconvenience, and most of them appeared to have very good appetites. This reminds me of a table episode. Not many persons who know what a good dinner they can have in the saloon of a Great Eastern steamer for 3s. 6d. will waste time in dining ashore before the evening departure from Antwerp. At the table was an American gentleman not in the least taciturn. He wanted "more Peas," which are not usually very plentiful in April, and because the dish was getting empty he somewhat rashly concluded there were no more aboard, and talked loudly of "imposition," and kept talking just long enough, for at an opportune moment when about concluding his peroration, a dish containing enough for ten people was quietly set before him. He was "done," and knew it, as everybody else did, and perhaps because he knew that too his appetite seemed to leave him, and he thought he would go on deck and "have a smoke." There is no stint of food on a well appointed steamer, for there, if anywhere, the best seems most abundant, and it is quite certain that for once in his life our lively voyager had enough Peas.

There is not much of Belgian work and ways in this part of the narrative, and, bar the Peas, little in connection with gardening. Never mind. Everything cannot be told at once, and besides, I once wrote some gossipy out-of-the-way articles of this nature, and plenty of evidence was forthcoming that they were at least as acceptable to a number of readers as dry details about digging and planting, watering and ventilating, keeping up heat and keeping down insects. The severely practical and sadly sober-minded who are only happy with their noses on the grindstone, can skip what they do not like in this column and turn to the solid fare they will find in others before and after it. A little light reading is a relief to many after a hard day's labour, and as some of them have fully too much of land working they will not object to be taken to sea for a change, and to learn something of what they may expect to see and experience when they set sail for a short trip to the Continent. Desiring to see the most abroad in the shortest possible time from home, I, like many others, leave London at 8 P.M., rush down to Harwich, step on board the steamer sailing at 10, and landing at Antwerp after breakfast next morning, ready for a day's ramble. By writing or wiring the steward beforehand you will find your berth reserved, this avoiding confusion that arises when a crowd of passengers are clamouring for room, all wanting attending to at once, and everybody first. The steamers are large and most comfortable, equalling in every way well appointed hotels, the electric light in every compartment, while the attention of the officials to the wants and even the foibles of passengers leaves nothing to be desired. All do not "turn in" at once, but some want this and others that, all appearing to get what they wish, then a march on deck, long or short, according to the weather, and one after another vanishes. The last trip was as smooth and quiet as a first-class railway carriage, and the passengers slept so well that not one was on deck to see the sun rise majestically as if out of the water. I was the first on deck for the ozone, and Flushing was in view. We had crossed the sea without knowing it, and henceforth our course was up the Scheldt, the river pilot twisting his way about till the famous cathedral spire of Antwerp was in view, and which we passed, "slowing" for the pier, an hour afterwards, every watch on board that was right on leaving home and had kept good time on the way, being twenty minutes behind.

If you want to go to Ghent from Antwerp you land close to the station of the Pays de Waes line, only the start is on a steamer for crossing the river. If you wish to go to Brussels, it will be a wonder if a train is not waiting alongside. We do not step into trains in Belgium, but climb up. The Belgians head us in some things, especially by twenty minutes in the morning, but they are behind us in others, and have not yet provided raised platforms, and it is quite a struggle with some passengers to take their seats. I took mine in a cab, and

made my first call on an esteemed and long proved friend, Mr. Charles Van Geert, one of the most substantial and respected of Belgian nurserymen and genuine of men. Both with himself and his son, who actively conducts the business, I spent a few pleasant hours, and with the latter had a run into the country, forty minutes by train, to the most interesting nursery of its kind I know, and of which it would be difficult to find its equal as regards arrangement and the richness of its contents in the form of deciduous trees, flowering shrubs, and Conifers. It is a veritable arboretum, so tastefully disposed as to form a delightful pleasure ground to the handsome château which has been rebuilt as a summer residence for the family and friends. It is the nursery on the Continent to which planters of hardy ornamental trees turn, and is of European fame. A consignment of Conifers was being packed for Germany, every specimen fit for an exhibition, and large as some of them were there could be no thought of one of them failing to grow when planted with ordinary care. Conifers are replanted at Calmpthout at almost all seasons of the year, and the special care that is bestowed on them ensures their safe removal. The soil is of a sandy nature, and every excavation that is made for a plant or tree, large or small, is lined with chemically prepared leaf mould, into which the roots entwine and divide, clinging to it in the form of a wig-like mass of fibres. It is an excellent idea well and systematically carried out. The nursery has extended greatly during the past few years, and additional land is purchased for improvement. This will be scientifically and experimentally

conducted both as regards manures and crops for a few years, that may be of benefit to Belgian agriculturists who are not "advanced." It will be a school of instruction under the inspection of an official from the agricultural department of the State, and crops and methods of culture will be tried that are at present not common in the kingdom. Eventually the land will probably be planted with nursery stock when a further extension is needed and the soil is brought into the best condition for its reception.

The district it appears forms a happy hunting ground of the cockchafer or May bug (*Melolontha*), also of the leather jacket grub, the larva of the *Tipula*. These are most destructive and difficult to extirpate. For keeping them in subjection their natural enemies, Starlings, are wisely encouraged and protected. A hundred nest boxes (fig. 48) had just been erected in different parts of the nursery. These are like miniature dog kennels, a foot or so long, with a round hole in the end of each near the top, fixed about 15 feet above the ground on poles inserted in it. They are promptly taken possession of by the birds, which increase in numbers and do their natural work better than it could be done in any other way, and are of immense benefit to the district. One larger box was made some years ago in two storeys, with holes giving access to the upper and lower rooms, but the birds would never enter the lower, so each pair have now a small one-storey tenement to themselves, and the plan answers well. These boxes are an interesting feature of the grounds and decidedly useful.

Fig. 48.

There is little left of the Antwerp nursery, the home of the family; only what was the old garden of the original proprietor is retained, with a few glass structures containing a good stock of Palms and Camellias. The present owner bought a good deal of surrounding land some years ago, when it was cheap, being beyond the fortifications, and in those days the kingdom was less settled than now. Looking ahead, Mr. Van Geert also bought land in the country, and eventually the time came when the expected happened, and the home nursery was brought within the new and formidable lines of defence. The growing commercial prosperity of the city increased the value of this land enormously, and slice after slice was sold for building purposes. Fine streets now occupy the site and show association with it, and record family sympathy by their names—Van Geert Street, Horticulture Street, Linnæus Street, Dodoens Street, and at present a new street is being built by Mr. Van Geert's sons and daughters. So does the old order of things pass away and is succeeded by the new. But the name of the man who has done so much and so well is built firmly in the foundations of the city, and will survive the storms of centuries.

In the large and substantial house of Mr. Charles Van Geert, jun., built by his father a few years ago, is an interesting memorial window representing the portraits of the earlier Van Geerts, one, the father, I think, of the present representative head of the family, the other of his relative, Mr. Jean Van Geert, who was a pioneer in the horticultural industry of Ghent, and whose portrait appears in the May number of the *Revue de l'Horticulture Belge*, that contains a complete history of its horticultural society and famous exhibitions, admirably written by Mr. C. de Bosschere and appropriately published, with an account of the last great Show on the day it was opened—a smart piece of work on the part of Mr. E. Pynaert Van Geert and his able coadjutors. A feature of one of the rooms of the house referred to has perhaps been mentioned before, but forgotten. Over a handsome fireplace, instead of the familiar pier glass in which you look at yourself, is a large plate glass, through which you have a full sweep of the street as you sit round the fire. It was a conception of the owner; but there is another arrangement similar, and anterior to it. Some years ago, when Dr. Hogg was building in Sussex, the idea occurred to him to have a view of the beautiful country

from the room over the fireplace, and it was carried out, the smoke from the fire being conducted through side flues. The arrangement is novel and agreeable. These coincidences of invention are worth recording whether there are more of the same kind or not.

I think I saw enough in one day in and outside Antwerp before going on to Ghent, and have said enough at one sitting and for one reading; but on returning I called on a great amateur cultivator residing in the famous old city, and shall perhaps be able to say a little more about Belgian work and ways another day.—A JUROR.

EVENTS OF THE WEEK.—Exhibitors will have a rather busy week, especially those who like to arrange for a succession of shows in a few days. On Saturday, the 12th inst., the summer Show will be held at the Crystal Palace, Sydenham; on the following Wednesday (16th inst.) the first of the Royal Botanic Society's summer Shows for the present year will be the great event; and on the next two days, Thursday and Friday, the Royal Horticultural Society's Exhibition in the Temple Gardens will attract attention. The Whitsuntide Show at Manchester will also be opened on Friday, the 18th inst.

— AT A general meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday in the Drill Hall of the London Scottish R.V., Harry Turner, Esq., in the chair, seventy-five candidates were duly elected Fellows of the Society.

— THE WEATHER.—"In Scotland," says "B. D." "the first week of May has been showery, boisterous, and rather inclement. On Wednesday, the 2nd, heavy showers of sleet and hail, accompanied by thunder, occurred in some districts. There has been no frost, and vegetation progresses but slowly." The weather in the south has been bright and mild with several extremely fine days and occasional showers. Vegetation is advancing rapidly.

— WE have the pleasure to state that MR. JAMES DOUGLAS, The Gardens, Great Gearies, Ilford, succeeds the late Mr. J. Woodbridge on the Council of the Royal Horticultural Society. It would not be easy, we presume, to find a better representative of British gardeners. Mr. Douglas has been a Fellow of the Society for many years, and has served on the Fruit and Floral Committees, and therefore in that respect his claims, though not advanced by himself, could not be overlooked for the distinction conferred.

— MR. HYDE CLARKE has the following paragraph in "Notes and Queries" respecting the ORIGIN OF THE ROYAL BOTANIC SOCIETY—"The founder of the Royal Botanic Society was Mr. Philip Barnes, F.L.S., of Norwich. Having learned from an official of the Woods and Forests that the lease of Jenkins' nursery grounds in the Inner Circle was about to fall in, he planned the Society, and by great labour accomplished the undertaking. I was one of his earliest supporters, and am now the father of the Society, as my neighbour, Mr. G. G. Hardingham, retired from the Committee. This year is the jubilee year, and it is to be hoped a bust of Philip Barnes will be placed in the museum of the gardens. The first Secretaries were Mr. J. de Carle Sowerby, the naturalist, cousin of the founder, and Mr. P. Edward Barnes, B.A., his son."

— WE have had the pleasure of inspecting Mr. McIntosh's BULB BEDS AT DUNEEVAN early in the week. The Hyacinths were passing their best, but the display was the finest we have seen either there or elsewhere. Between 4000 and 5000 spikes, not a few of them of exhibition standard, two-thirds of the varieties single, grouped about 6 inches apart, and each supported with an almost invisible galvanised stake, and the colours effectively mixed, produced an effect of the most pleasing and satisfying description. Early in the season the margins of the beds were bright with Crocuses, the arching foliage of which forms a graceful foil to the Hyacinths. The Tulip beds were very brilliant. The varieties which are found to be the best for massing are *Chrysolora*, pure bright yellow; *Belle Alliance*, rich crimson scarlet, surpassing in vigour and effect *Vermillion Brilliant*; *Rosamunde*, rose and white,

very chaste; Molière, purplish lilac, with orange base; and Wouvermanns, rich purplish magenta; five hundred plants in the bed having a remarkable effect. Some of the Tulips have been a little checked by the prolonged cold, but notwithstanding the display is very rich and good. The Rhododendrons promise to flower well this year, and at present an unusually rich orange form of *Berberis Darwini* is in full beauty. In the kitchen garden the blossom on most of the pyramid trees in the choice collection of fruits is abundant, and the high keeping of the garden reflects the attentive and continuous care of Mr. T. Taylor, the gardener. Unfortunately the prolonged indisposition of Mr. McIntosh prevents his fully enjoying his garden. He has not been able to visit London for five years, but has the advantage of weekly calls from his good friend and neighbour Mr. G. F. Wilson, and it would not be easy to find more earnest patrons of gardening than these two gentlemen are, whose names are so familiar in the horticultural world.

— AN excellent idea of the beauty of well-grown *CALADIUMS* can be gained by an inspection of the large collection in Messrs. Laing and Co.'s Stanstead Park Nursery, Forest Hill. Some dozens of varieties are represented of all sizes, from the dwarf red and green minus *erubescens* and the white variegated *argyrites*, a few inches high, to giants with leaves 20 inches long by 15 inches wide. They are most diversified in colours and markings, some having white semi-transparent leaves of great delicacy, others are boldly veined with red or crimson, or green, or white, and some are most peculiarly spotted, blotched, or marbled. The range of variation is astonishing, and as foliage plants, when grown in an open sandy soil, a high temperature, and well supplied with water, there are few plants can equal these during the early summer months.

— ACTIVE preparations are being made for the TUBEROUS *BEGONIA* EXHIBITION both indoors and out. About 100,000 seedlings have been dibbled out in pans or boxes, and when large enough and the weather is safe—*i.e.*, early in June, the plants will be placed out of doors. A space of ground of about an acre has been cleared for these, and when arranged in their respective colours in long borders and bearing their large flowers, the Stanstead *Begonias* will be amply worth another visit.

— PARLIAMENT SQUARE, Westminster, has at the present time a very bright floral display, two dozen BEDS OF TULIPS being in their best condition. There are twenty-four beds, circles and oblongs alternately, and each bed is planted with one variety, the colours in the adjoining beds being well contrasted. The varieties are Comte de Mirabeau, white; Globe Rigaud, purple feathered; Molière, purple; Keyzers Kroon, red and yellow; Joost Van Vondel, dark rosy crimson, very large flowers; Brutus, bright scarlet, small flowers; Proserpine, deep rose, handsome; Vermillion Brilliant, rich vermilion; and Yellow Prince, bright clear yellow.

— AT the ordinary meeting of the Royal Meteorological Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 16th instant, at 7 P.M., the following papers will be read:—"Report of the Wind Force Committee on Experiments with Anemometers conducted at Hershham," drawn up by G. M. Whipple, B.Sc., F.R.Met.Soc., and W. H. Dines, B.A., F.R.Met.Soc. "On the Measurement of the Increase of Humidity in Rooms by the Emission of Steam from the So-called Bronchitis Kettle." *This paper will be in type before the meeting. Any Fellow wishing to take part in the discussion can obtain a copy on application to the Assistant Secretary.

— MESSRS. CARTER & Co. desire to say they have been requested to supply lawn seeds for the requirements at the forthcoming Italian Exhibition, also that they are sowing lawn seeds at the Anglo-Danish Exhibition, South Kensington.

— MR. JOSEPH MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, for April, 1888:—Mean temperature of the month, 43.4°. Maximum on the 28th, 66.3°; minimum on the 6th, 23.2°. Maximum in the sun on the 28th, 122.6°; minimum on the grass on the 9th, 16.2°. Mean temperature of air at 9 A.M., 44.2°. Mean temperature of the soil 1 foot deep, 42.7°. Nights below 32°, in shade ten, on grass seventeen. Total duration of sunshine in month, eighty-four hours, or 20 per cent. of possible duration. We had six sunless days. Total rainfall in month, 1.49 inch. Rain fell on sixteen days. Average velocity of wind, 12.6 miles per hour. Velocity exceeded 400 miles on seven days, and fell short of 100 miles on one day. Approximate averages for April:—

Mean temperature, 46.4°. Rainfall, 1.66 inch. Sunshine (seven years) 132 hours. A dull, cold, and rather windy month, with average rainfall and much N.E. wind. Mean temperature the same as last year, but lower than any other recent one except 1879. Vegetation very late.

— MR. E. SQUELCH, The Gardens, Boigne Grove, Maidenhead, writes to say he COMMENCED CUTTING ASPARAGUS in the open air on April 24th and some on May 1st. The beds are in full bearing. They were a fortnight earlier last year. He asks if this is remarkably early for the exceptionally cold and late spring?

— PLANTATIONS IN BENGAL AND BURMAH.—At a meeting of the Royal Scottish Society of Arts last week in the Hall, 117, George Street, Mr. J. N. Inglis, C.E., read a paper on "Plantations Producing Fuel and Timber for Building Purposes in Bengal and Burmah." He remarked so great was the demand for wood for building purposes in Bengal, that in the last quarter of a century trees seldom arrived at maturity before the axe was laid upon them, and large tracts of the country along the railway and inhabited parts were bare of trees. Trees and shrubs were now planted round every village. Famine, which was unknown in former years, was becoming a painful reality; but if a country was sufficiently wooded, it was almost certain to obtain the requisite rainfall. Referring to the plantations on the banks of the canals in Burmah, Mr. Inglis said that the cost of planting a tree and bringing it to maturity was about 15s., and that it was sold by the Government to be used for building purposes at about £5.

— A VALUABLE paper, describing a new method of extraction of the ALKALOIDS FROM *CINCHONA* bark by cold oil, as used at the Government Cinchona Factory in Sikkim, was lately drawn up by order of the Lieutenant-Governor of Bengal, and has now been issued. Dr. King, the Superintendent of the Sikkim Plantation, carried on a long series of experiments on an acid and alkali process of manufacture, by which he succeeded in producing an excellent quinine. He never, however, succeeded in recovering much more than half of the amount contained in the bark on which he operated. The acid and alkali process had, therefore, to be abandoned as wasteful and inefficient. A process depending on the maceration of the bark in spirit was next tried, but, after much experiment, it was in turn abandoned. During a visit which Dr. King paid to Holland in 1884, he obtained some hints as to a process of extraction by means of oil. Benefiting by the advice of some chemical friends, Mr. Gammie, the resident manager in Sikkim, has been able to perfect this process, with the result that the whole of the quinine in yellow bark can be extracted in a form indistinguishable, either chemically or physically, from the best brands of European manufacture. This can be done cheaply, and the Bengal Government has caused an account of the matter to be printed, in order that private growers of Cinchona may be enabled to take full advantage of the process, and that a permanent reduction in the price of quinine may ensue. —(Nature).

— A REPORT by the American Consul at Mayence, on FOREST CULTURE IN HESSE, has been lately issued in the Consular Reports of the United States. The writer discusses the organisations and functions of the department having the care of forests, the duties of the various classes of officials employed in forest cultivation, the economical results of the system pursued, the course of instruction followed in the schools of forestry, the organisation and methods of the institution for experimental forestry, and the degree and amount of control assumed by the State over private forests.

— THE WAKEFIELD PAXTON SOCIETY.—There have been two meetings of this Society recently. At the first Councillor Milnes, the President, was in the chair, and Mr. Brown, gardener at Hatfield Hall, occupied the vice-chair. Mr. W. K. Woodcock of Sheffield read a long and very able paper on "Garden Literature, Past and Present." Councillor Howden, in proposing a vote of thanks to Mr. Woodcock, kindly promised to defray the cost of certain works on horticulture which Mr. Woodcock recommended should be added to the Society's library. Mr. B. Whiteley seconded the motion. Mr. Squire Pickersgill of Bond Street presented three beautiful quarto volumes to the Society, and on the motion of the President, seconded by Mr. H. Oxley, he was accorded a very hearty vote of thanks for his kindness. At a special meeting subsequently, when there was a very good attendance, the same two gentlemen presided. The Rev. F. D. Horner of Kirkby Lonsdale, and formerly vicar of Normanton, delivered an exceedingly interesting lecture on "The Auricle," and it was listened to with the greatest

attention. On his way home from London and Manchester he halted for a night at Wakefield, and not only gave the local Paxtonians and florists an opportunity of admiring the specimens with which he had gained high honours in keen competitions, but he clearly, fully, and in a very happy style pointed out to his hearers how to grow similar plants. At the close of the lecture Mr. Horner answered a number of questions and gave much interesting and valuable information. On the motion of Mr. W. Hudson, seconded by Mr. Jesse Hardwick, and warmly and eloquently supported by Mr. Herbert Chapman, a very hearty vote of thanks was accorded the lecturer.

— SNOW'S WHITE WINTER BROCCOLI, SANDRINGHAM VARIETY.

—Mr. W. J. Murphy, Clonmel, writes— I am surprised your correspondent, "A Kitchen Gardener," should have omitted Snow's White Winter Broccoli, page 356, from those he recommends. A quarter of a century since the lecturer on horticulture at the Government Farming and Gardening Institute at Glasnevin, I remember well, gave this first place. Since then I have tried dozens, and now retain but three for my own use or for commendation among my many gardening friends. They are Snow's, Mammoth White, and Late Queen. The two last do well in strong rich loam, and if planted with a "crow bar," and without stirring the soil, they will stand the winter best and be more compact.

THE CULTURE OF CYCLAMEN PERSICUM.

THE cultivation of the Persian Cyclamen does not, as a rule, receive the attention it deserves, for it is one of the most useful plants for general decorative purposes for the autumn, winter, and spring. As the time is now at hand for taking in hand those that have done flowering for this season, a few remarks concerning their culture may be of service to some of your readers. Your correspondent, "K" (page 339), in his brief remarks on the Cyclamens at Ripon has rather taken the wind out of my sails, as the system he records does not differ very much from the one that I have been the most successful with; but I have never used bottom heat, although it may be advantageous.

The soil in the pots should be allowed to become sufficiently dry, so that it will freely part from the roots without doing them much damage; but it must not remain dry for long, as it is a mistake to dry the corms off. If the plants have healthy foliage on them let it remain, but should it be infested with red spider, thrips, or any other insects it is best removed. The soil should be entirely shaken from the roots carefully, so as not to injure them more than can be helped. They may then be put into clean pots properly drained, selecting the size of pot in proportion to the quantity of roots and size of corm. If the corms are young, and it is desired to have large plants, they may be put into the same size as they came out of, and shifting to a size larger when they get well rooted. For general decorative purposes 4½ and 6-inch pots are mostly suitable, and plants sufficiently large can be produced in these sizes for all ordinary purposes. The soil should consist of equal portions of loam, leaf soil, and decayed manure, with a good sprinkling of sand and a little soot thoroughly mixed previous to using. It is very important that this thoroughly mixing of the ingredients should be done, otherwise the plants will vary in their growth, some receiving more than enough of the rich soil and others, on the contrary, have a deficiency, consequently will not do so well. In potting the soil must be well worked among the roots and made quite firm, leaving the corm well above the surface. If the soil is in a rather dry state at potting time it will require watering after. If moderately moist no water will be required for a few days beyond a light sprinkling over each day. They should be placed in a house or frame as near the glass as possible in a temperature of about 60°, and given a moist atmosphere, and kept rather close until growth commences, when more air may be admitted to build up a good strong growth. After they are well started they require to be kept on the moist side, dryness at the root and in the atmosphere being fatal to their well-being. A slight shade during the hottest part of the day will be necessary, but they should be allowed as much sun as they will bear, especially during the autumn months.

If green fly attack the young leaves fumigate at once, and if thrips or red spider, dip the plants in some well known insecticide, but great care is necessary in this operation, otherwise the foliage in the earlier stages of their growth will be injured, and a check given to the plants. The humid temperature should be maintained well into the autumn to give the plants sufficient strength to prepare for the forthcoming bloom. As they approach the flowering period more air should be given, also a reduction of the moisture in the atmosphere made, and with the assistance of a little

weak liquid manure, a light position, and a temperature of about 50°, a good show of blooms should be the result.

Inferior strains of Cyclamen should not now be tolerated, as a good strain can be procured from the various seedsmen who make a speciality of them, and fine flowering plants can be had in from twelve to fifteen months from the time of seed-sowing, but the present is not the time for sowing seeds.—W. SIMPSON, *Knowsley*.

ORCHIDS AT BIRMINGHAM.

NEAR to Selly Oak station is The Uplands, the residence of Charles Winn, Esq., who is a very successful exhibitor of Orchids at the Birmingham Shows. At the Chrysanthemum Show held in November last his gardener, Mr. G. H. Barnes, exhibited specimens of *Cœlogyne cristata* in his collection, and again at the spring Exhibition on April 11th and 12th plants of the same species were included. To obtain such a succession of blooms the plants are grown in different temperatures, the former being helped along in the heat of the *Cattleya* house, whilst the latter are retarded in the cool house with *Masdevallias*, the pseudo-bulbs in both cases being well developed. Such a valuable chaste flower is always welcome; and that the flowering season can be prolonged without the least injury to the plants is a fact worth recording.

The *Cypripedium* house, although only 26 feet long and 24 feet wide, is filled with many rare plants; something like 120 species and varieties are grown, and those in flower justify the remark that only the best have been obtained. *C. Druryi* has eighteen growths, and is flowering well; *C. Morganii* has six growths, five of which have appeared in eighteen months; the richly coloured *C. grande atratum*, *C. præstans*, and the new hybrid *C. Lathamii*, raised in the Birmingham Botanical Gardens, are all doing well.

It is the practice of Mr. Barnes to steam the house every afternoon. This is done by closing the ventilators and turning the hose on to the hot-water pipes until the house is full, afterwards opening the lights a little to let out the superfluous moisture; and in addition to this the plants are syringed lightly two or three times daily. Besides keeping insects in check this system is very beneficial to all the occupants, for the plants are as vigorous and healthy as any I have met with. The *Cattleya* and other houses are similarly treated when there are few plants in flower, but to attempt it in a flowering house would be at the risk of losing the bloom. *Odontoglossum vexillarium* appears to like this treatment. Many of them have thrown up three spikes from a single growth. One small plant is carrying twelve spikes from four growths.

The long span-roofed cool house is filled with choice forms of *Odontoglossum Alexandræ*, together with many supposed hybrids. *O. Rossi majus* was rendering the house gay, one large specimen having over sixty flowers; and *O. R. m. rubescens* had six blooms on a spike. At one end is a panful of *Cypripedium spectabile* with three dozen growths. Two years ago there were only two small potfuls of *Disa grandiflora*. These were divided and carefully nursed, and now, besides several pots, there is a pan containing about thirty-seven flowering growths.

The *Cattleyas* and *Dendrobiums* are as select as the *Cypripediums*. Among the former I noted a fine piece of *C. exoniensis* with twelve large bulbs, each bearing a bright green leaf. The true old form of *C. labiata* is also included, and good plants of the gorgeous *C. Trianae formosa* were in bloom, together with a host of other Orchids.—G. W. C.

MANURES FOR PLANTS.

LAST week I noted a communication on feeding plants, and although I am unable to speak on the merits of the case from the point of view of your correspondent, having failed to follow the discussion, I have some notes on the subject which may not be out of place without in any way encroaching on debatable points. The notes referred to were suggested by a case which was brought to my notice last autumn. From a commercial point of view the subject was one of some importance to the owner of the plants—Chrysanthemums—grown for cut flowers. Looking at them they appeared to suffer from starvation, and that was what I made bold to tell their owner, but he brought forward the very conclusive evidence that the plants had been regularly supplied with liquid manure, so that starvation was not a satisfactory solution of the case. However, I held by my opinion, and advised the flushing of the soil with hot water, and thereafter applications of either superphosphate of lime

or good guano applied as a surface dressing once a week. This advice was followed, and a very valuable crop of flowers was the result, though not so good as would have been secured had the liquid manure been stopped a month earlier, and the artificial manure applied.

Now, I have no doubt many of your readers will, like my friend, feel a difficulty in appreciating starvation in a case of this sort. Shortly, the solution is this. The plants had been growing well, the soil was well filled with roots, then came the liquid manure containing very imperfect plant food, and the plants simply starved in the midst of seeming plenty. My theory was that the food they required was not more of a so-called stimulating nature, such as nitrate of soda or sulphate of ammonia, for they had been getting plenty of food of that nature, but one of what may be called a more solid nature, and the superphosphate acted like a charm.

At the same time it may be pointed out that plants may receive even too much food of that nature. A few of our own plants appeared to be standing still at the "housing" time last autumn; but three doses of hot water washed the superfluous material away, and no harm was in the end done. If we consider the matter I think it is possible to procure a perfect plant food. Any scientifically composed plant food is sufficient for any plant requiring help in that way. It is quite possible, no doubt, that there may be in the composition something which is not required for every plant. But that is a matter of no importance so long as what the plant does require is present in fair proportion. Growers who have not studied the matter, and who apply a dry manure, are apt to fly directly to either nitrate of soda or to sulphate of ammonia, either of which is valuable when properly used, but neither so useful as superphosphate of lime and that again must yield to the best guano, which, however, is much more expensive.

A very useful and fairly cheap manure for everyday use among softwooded plants is composed of three parts sulphate of ammonia to five parts superphosphate; slight applications of this given to plants weekly directly the roots begin to work after potting, and increased in quantity as the roots increase in number, will give the very best results. I am not so particular about a potassic element in a manure as I once was, as its utility in the case of short-lived plants is doubtful, and the others serve the purpose perfectly. Superphosphate is extremely valuable on account of its root-producing tendency. Plants which receive plenty of water and not allowed to become dry, pushing out roots and making away with every bit of the undissolved material, while in the inside of the pot, the process of root-production goes on unceasingly. Plants may be grown fairly well in almost any kind of soil if sufficiently fed, but it is a mistake to allow the plant to thoroughly obtain possession of every bit of soil in the pot before feeding from the outside begins. The sensible system is to conserve what food there may be in the soil by beginning to apply the manure directly root-action is in a state of activity, and so continue the rooting medium in such a fertile condition as there may be a reaction betwixt the good soil and the applied manure.

Apart from these manurial foods, there is an element so essential to the well-being of plants, and the effect of which seems to be so imperfectly understood by young gardeners, that before closing these notes I may roughly point out its chief characteristic and the part it plays. The element I refer to is water. We know that water has so great an attraction for most things, that it is quite possible to grow some plants fairly well in water alone, the water in some manner having taken up as much of the other foods necessary to plant life as to sustain them in vigour. If we wish to strike cuttings rapidly and successfully we place them in a medium of sand and water, and one of the curiosities of plant culture is to root a plant and grow it among sphagnum or common moss, keeping the material well saturated with water. In the same manner bulbs may be cultivated in sponges, all the care necessary being to soak these from time to time. I think, then, that the chief characteristic of water in connection with plant culture is the all-important work it performs as a solvent of the food contained in soils, and along with that the absolute necessity of its presence in quantity in the soil, in order to the uninterrupted production of roots. If the supply is stopped long enough for the soil to dry, the youngest and most important roots perish, and the plants go on "short commons." If sufficient water is given to again saturate the soil, the most active roots are absent, and the plant continues to suffer until a fresh crop of feeding roots are produced to attack the food waiting them. The difference, then, betwixt a carefully watered plant and one allowed to become dry occasionally is, that the former goes forward without check, and the latter has a series of stoppages to make up, losing perhaps in the process its healthy greenness of foliage, or lack of size in flower, if nothing else happens. In connection with the employment of artificial manures water becomes either a medium of the greatest utility, or, if carelessly applied, the means of doing the plant much harm. A well watered plant is always ready for its slight application of manure; a neglected plant with feeding roots dead may be poisoned with the same. It is therefore wise to allow a dried-up plant to recover somewhat before again applying manure.—B.

FLOWER FARMING.

FREQUENTERS of the Covent Garden Flower Market during the spring and early summer months can form something like an adequate idea of the extensive demand for cut flowers, and of the enormous supplies furnished by home and continental growers. Delicate indoor flowers are sent in from various places, and are pur-

chased mainly for the finer bouquets, wreaths, and buttonholes, but it is in the supply of hardier though often equally beautiful flowers from outdoors that the increase has been so rapid in recent years. The market is now amply provided with the best of the hardy flowers as they come in season, and some very gay effects are produced there during April, May, and June, the three chief months for floral trade. One of the most energetic workers in the extension of this business is Mr. J. Walker of Whitton, who at this time of year may be found every morning at his stand in the market disposing of the choicest Daffodils, Tulips, and Anemones by thousands, or later on he is equally busy with Pæonies, Irises, Gladiolus, and Ranunculuses. During five or six months Mr. Walker furnishes some of the finest home-grown hardy flowers to be seen in the market, and it might be therefore supposed that his farms and system of management would possess more than ordinary interest to anyone concerned in horticulture. Being favoured with an opportunity last Friday of inspecting these establishments, I

FIG. 49.—NARCISSUS PALLIDUS P. RECON.

will endeavour to briefly describe what was seen and learnt during an extremely agreeable visit on a bright May day of the old-fashioned type.

THE HAM FARM.

Though Mr. Walker's name is better known in association with the Whitton Farm, his more recent acquisition near Ham Common is much the larger, and is rapidly becoming the more important of the two. About 114 acres of land have been obtained and are devoted to bulbs, fruit trees, and vegetables, the two former as permanent crops, the last-named being employed to alternate with the bulbs. The soil is deep, of a peculiarly light sandy loam, such as at first sight would be thought excessively dry, but which seems to possess a never-failing supply of moisture below, though free from any approach to stagnation. The situation is open to the sun, yet fairly sheltered from winds, although these occasionally prove somewhat disastrous, as would be the case anywhere in our little island. Altogether, the soil and situation seem to be as favourable for the culture of bulbs as could be wished, and it would be difficult to say in what particular our Dutch friends on the other side of the German Ocean have the advantage. The land is readily worked with the plough, manure is liberally applied for the various vegetable crops, and then the bulbs are planted to remain one or two seasons, following again with vegetables, especially with Peas. A considerable space has been planted with Plum, Pear, and Apple trees, with Currants between the trees in the rows, and beds of Daffodils between the rows. This system will be carried out more extensively as soon as it has been found which varieties of fruits are likely to succeed best. The Pears are healthy vigorous trees from Sawbridgeworth, on the Pear and Quince stocks, the latter for early fruiting being planted alternately with the former. The Apples are similarly promising, all on the Paradise stock, and in two

or three years' time this farm will probably be almost as interesting for its fruit as its flower production.

TULIPS.—Just now, however, we are most concerned with the flowers, and the Tulips afford such a brilliant display that they merit first attention. A series of parallel beds, 6 feet wide and 300 yards long, are planted with Tulips, several rows or a whole bed being devoted to one variety. Each bed contains six or seven rows according to the strength of the plants, and in this "little plot of Tulips," as their owner terms it, there must be between 200,000 and 300,000 bulbs. The effect of such a number of plants in flower under a bright sun was dazzling in the extreme, and such large masses of brilliant colours could not be seen anywhere but in what is considered the special home of bulbs in Europe—Holland. The varieties grown are not very numerous, but are selected for the possession of certain important qualities, such as good habit, substantial flowers, clear, well-marked, or effective colours, and durability. For example, the early Duc Van Thols are found to be too unreliable for culture on a large scale, and several other well known varieties have been discarded. A great favourite is the handsome Keyzers Kroon with its bright red yellow edged flowers, and one bed of this was grand last week. Another good variety is Thomas Moore, of sturdy habit, with well formed bronzy red flowers, a colour much in demand just now. Duchesse de Parme is a useful Tulip, very hardy and bearing flowers of capital substance, rich scarlet edged with yellow. Rosa Mundi is white, edged with rose; Rose Gris de Lin, dwarf, sturdy, of a soft rosy tint; L'Immaculée, compact, free and useful, one of the best pure white varieties, White Pottebakker being also useful but much stronger and taller than this. Proserpine, deep rose, is a well known excellent bedding variety, and is similarly useful for cutting; Artis, deep rich red, is another capital variety of fine habit; Sunbeam, very dark scarlet, is showy and even; Yellow Rose, Canary Bird, Yellow Pottebakker, and Yellow Prince are the principal yellow varieties, all good, of slightly differing shades; Double Rose being a good double of a pale yellow tint; Princess of Austria is a very late variety with vivid scarlet flowers, compact in habit, and comes in well after the others, leading up to the Gesneriana varieties. In a favourable season a succession of flowers extending over a month is obtained, the Duc Van Thols commencing the period, but this season the buds were destroyed by larks, and owing to the delicate texture of their flowers they are soon damaged in bad weather. A keen strong wind soon spoils a large stock of flowers, and hailstorms also cause much injury, as every flower in the slightest degree defective is rigidly rejected when cutting for market. The flowers are gathered before they are fairly expanded, and placed in pots of water in cool sheds, where they will last for several days if necessary, but usually they are transferred immediately to the Whitton Farm, where they are tied in bunches of a dozen flowers each, and dispatched to Covent Garden Market the same night or early the following morning.

It might be added that the beds are slightly raised with alleys between, and the bulbs are all lifted at the end of June, planting being done in October when the weather is suitable. No protection is provided beyond that afforded by a hedge on one side of the quarter devoted to the beds, but the most tender are planted near to this, and the others in succession according to their respective hardiness.

DAFFODILS.—The numerous forms of Narcissi that are adapted for culture on a large scale and which yield abundant flowers for cutting constitute Mr. Walker's great specialty, and the Tulips are only a kind of by crop. The Daffodils are grown by millions, two or three acres of one variety, and some idea can be gained of the stock when it is said that in the height of the season 2000 dozen bunches of twelve flowers each can be cut in one week, and as many as seventy dozen bunches of the beautiful *N. obvallaris* have been taken into market in one morning, cut from eight beds each 200 yards long. The beds are the same width as those for Tulips—namely, 6 feet, and formed in a similar way, with seven rows in a bed of all the stronger growing varieties, but they are planted close together in the rows. About one-half of the bulbs are lifted as soon as the foliage turns yellow—namely, towards the end of July; they are immediately conveyed to sheds, sorted, allowed to dry gradually, and replanted at the end of August. Some varieties will succeed if left in the beds three years, but others require lifting every year; in fact Mr. Walker advocates annual lifting for all, and it is only the labour and expense that deter him from carrying this out as part of his system. The strongest varieties are planted 3 inches beneath the surface, and the weakest $1\frac{1}{2}$ or 2 inches. The flowers are always cut with as long a stalk as possible, and a good indication of the respective strength of the bulbs can be afterwards detected in the growth of the portion of flowerstalk remaining; in the strongest bulbs it will extend to 5 or 6 inches, while on the weakest it will scarcely lengthen an inch.

In growing such a large quantity of plants the selection of

varieties is an important matter to ensure a succession of flowers over as long a period as possible. This is accomplished at Ham in a remarkable manner in fine seasons. *N. pallidus præcox* (fig. 49) commences flowering in February, though this year its flowers were not cut until late in March. Then follows the Tenby Daffodil, *N. obvallaris* (fig. 50), which is a more reliable early variety though a little later than *pallidus præcox*. It is more hardy, and many persons prefer its bright golden flowers to the paler tints of the other. Of *N. obvallaris* it has already been noted there are eight beds 200 yards long, all the plants wonderfully strong and evidently thoroughly at home. They are two very useful varieties, but *pallidus præcox* is distinct in one respect—it produces a larger succession of flowers than any other. The large trumpet Daffodils follow those named; then come the incomparabilis varieties, which at the present time are so beautiful. The poeticus varieties, such as *ornatus*, are also in flower now, the later poeticus *recurvus* will be in flower in a fortnight, and the season is concluded in June with the double poeticus, the handsome fragrant "Gardenia flowered Narciss," which is so popular. The trumpet Daffodils comprise the stately bicolor *Horsefieldi*, and *Empress*, *Emperor*, *Princeps*, *spurius*, *maximus*,

FIG. 50.—NARCISSUS OBVALLARIS.

and many others, some of which will be noted in referring to the Whitton Farm. Two very beautiful varieties of *N. incomparabilis* now being cut in large quantities are *Cynosure* and *Stella*, the former with a pale yellow perianth with a rich gold crown, the latter with white perianth and delicate yellow crown. Both are very graceful, and for arranging in large vases they are admirable. The double forms of *incomparabilis*, *Sulphur Crown* and *Orange Phoenix*, are also in great demand, and corresponding space is devoted to them. The *Campernelle* and the double *N. odorus* are grown extensively, and the vigorous plants are now yielding these delightfully fragrant flowers in thousands. One bed of the *Campernelle* is very remarkable, the bulbs have been planted two years, and have ten to thirteen flowers to a root. Several *Tazetta* varieties are included, but they are not in such favour as the other sections.

The graceful *Poet's Narciss*, or *Pheasant's Eye*, as it is popularly styled in the market, is in most demand, and a large space is devoted to its best varieties. *N. poeticus ornatus*, which is distinguished by its broad round pure white perianth lobes and orange or red tinted crown, is in its best condition at the present time; some thousands of flowers are being gathered every day from the twelve beds 200 yards long which are filled exclusively with this variety. Then of the later *N. poeticus recurvus* there are between two and three acres, the plants being readily distinguished at a glance from the other poeticus varieties by the slightly glaucous and drooping or recurving foliage. The flowers will not be expanded for a week or two yet, but they come as a most useful succession to the *ornatus*. About two acres are occupied with the double poeticus, and these will afford a fine June display and supply of flowers.

In a sheltered portion of the farm beneath the young fruit

trees are some rows of the brilliant scarlet *Anemone fulgens* and its variety *multipetala*, which seems to succeed very well, and is had in flower as early as February in mild seasons. The plants grow strongly and flower freely, but it is essential that they be protected from wind or their beauty is soon destroyed.

Before summing up the results of Mr. Walker's extraordinary work we must glance at the Whitton Farm, and as that would take too much space this week, the notes will be reserved until next issue.—L. CASTLE.

ROYAL HORTICULTURAL SOCIETY.

MAY 8TH.

SUFFICIENT exhibits were contributed by amateurs and trade growers to render the meeting in the Drill Hall, James Street, on Tuesday an interesting one, but the visitors were by no means so numerous as might be expected at this time of year. The Fruit Committee was not very long occupied, but the Floral Committee had a number of novelties submitted to its consideration, of which twelve were honoured with certificates. Upon the side tables were arranged the collections of Daffodils and hardy flowers from Messrs. Barr & Son and T. S. Ware, the centre table being devoted to Roses, Orchids, and miscellaneous plants.

FRUIT COMMITTEE.—Present: Harry J. Veitch, Esq., in the chair, and Messrs. John Lee, Joseph Cheal, G. W. Cummins, Charles Ross, Charles Howe, W. Marshall, J. Wright, J. Smith, R. D. Blackmore, and Harrison Weir. The duties of the Committee are usually light at this period of the year, and only a few examples of fruit and vegetables were submitted for examination.

Messrs. Barron & Sons, Elvaston Nurseries, Borrowash, sent a seedling Apple, which had been before the Committee on a previous occasion. It is named Barron's A1. It is a medium-sized firm fruit, greenish yellow streaked with red, and evidently a good keeper; flesh firm and brisk in flavour. The Committee were favourably impressed with this culinary Apple, and expressed a desire for information respecting its origin, history, and the character of the growth of the tree. A dish of Asparagus was sent by Mr. W. Palmer, gardener to W. F. Hume Dick, Esq., Thames Ditton House, Thames Ditton; also Cucumbers grown on the north side of a span-roofed house, on the opposite of which had been grown a crop of Melons. The fruits were good, and the Asparagus was noticeable for its great length of colour, greenish purple, while the stems were large and succulent. A cultural commendation was awarded.

Mr. E. Beckett, gardener to H. H. Gibbs, Esq., Aldenham House, Elstree, sent dishes of Lady Downe's Grapes, and President Strawberry. For the latter, which were fine and well coloured, a cultural commendation was awarded; and for the Grapes, which were cut on January 2nd, and were very firm, a vote of thanks was accorded.

Some seedling Rhubarbs were examined by the Committee, but only two of them were thought to possess merit, one of them being too much like the Victoria and the other Linneus, to merit further consideration.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. H. Herbst, W. Bates, B. Wynne, J. Fraser, G. Duffield, C. T. Drucry, T. Baines, G. Nicholson, R. Dean, C. Noble, H. Ballantine, C. Pilcher, J. Dominy, H. M. Pollett, J. O'Brien, E. Hill, A. J. Lendy, J. Fraser, W. Goldring, G. Paul, J. Walker, the Rev. W. Wilks, and Dr. M. T. Masters.

Roses.—Several beautiful collections of Rose blooms were exhibited, and very notable amongst them were those from Mr. J. Walker of Thame. Two boxes were shown comprising twenty-four blooms each of *Niphetos* and *Maréchal Niel*, the former deep substantial pure blooms, the latter wonderful examples, grandly formed, full blooms, of the richest colour. They were cut from plants on the Briar stock, and some of the specimens are said to be thirty years old (silver Banksian medal). From Mr. H. Bennett, Shepperton, came five boxes of Pedigree Roses, *Princess Beatrice*, a finely shaped Hybrid Tea, of a bronzy yellow hue, very handsome, an undoubted acquisition; the charming little pink *Polyantha Rose*, *Little Dot*, and about twenty dozen blooms of *Lady Mary Fitzwilliam*, all handsome full blooms of good substance, varying from a very pale blush, nearly white, to a deep pink shade (silver Banksian medal). Mr. W. Rumsey, Waltham Cross, showed a choice collection of Tea and Noisette Roses, the varieties best represented being *Boule d'Or*, *Souvenir d'Elise Vardon*, *Souvenir d'un Ami*, *Safrano*, *Rubens*, *Madame de Vallombrosa*, *Etoile de Lyon*, *Marie Van Houtte*, *Niphetos*, and *Maréchal Niel*. The graceful *Polyantha* varieties, *Mignonette* (pink) and *Paqueritte* (white) were also included (silver Banksian medal). Messrs. W. Paul & Son, Waltham Cross, were awarded a certificate for the yellow Tea Rose, *Madame Hoste*, and also showed plants of the new deep crimson H.P. Rose *Gloire de Margottin*, and a semi-double form of *Rosa rugosa alba*, named *Madame Georges Bruant*.

Orchids.—Though, according to the programme, there should have been a special display of Orchids at this meeting, there were really fewer than usual, but these comprised some interesting plants, notably Mr. B. S. Williams' group of *Cypripediums* from the Holloway nurseries, for which a silver Banksian medal was awarded. All the plants were very strong healthy specimens, and all were in flower. Very fine were *C. Swianum*, *C. Druryi*, *C. selligerum majus*, *C. Boxalli* and its variety *aureum*, *C. Io grandis*, *C. argus*, and *C. grande*, with three to ten flowers each. A large variety of *Oncidium sarcodes*, named *superbum*, was also shown with a new *Amaryllis*, Mr. R. H. Measures, the flowers pink, barred and edged with white. H. J. Buchan, Esq., Wilton House,

Southampton, sent a plant of *Cattleya Lawrenceana delicata*, a pretty variety, with soft mauve tinted flowers. From Mr. P. Blair, Trentham Gardens, Stoke-on-Trent, came a plant of *Odontoglossum cirrhosum*, Trentham variety, which has large white flowers, heavily spotted with maroon. A. H. Snee, Esq., The Grange, Carshalton (gardener, Mr. Cummins) exhibited a remarkably strong plant of *Odontoglossum Marriottianum*, which was grown in the open air during the summer of 1887. It had several stout pseudo-bulbs and strong growths, with two fine racemes of sixteen and seventeen flowers each (cultural commendation). A scarce Orchid, *Odontoglossum crinitum sapphiratum*, was shown from the same garden, with one small flower, the sepals and petals yellowish, the lip triangular in shape, white, spotted with bright purple. Capt. Maxwell, Terregles, Dumfries, sent a variety of *Odontoglossum Andersonianum*, with pretty creamy white flowers heavily spotted with brown. B. D. Knox, Esq., 17, Gloucester Place, Portman Square (gardener, Mr. Laurence), exhibited *Odontoglossum Ruckerianum*, the flowers dotted with brown, and beautifully flushed with purple; also *Oncidium curtum Gardnerianum*, like *O. sarcodes* (vote of thanks). G. C. Daux, Esq., East Moulsey, showed a plant of *Dendrobium densiflorum*, with three long racemes (vote of thanks).

Daffodils and Hardy Flowers.—Silver-gilt Banksian medals were awarded to Mr. T. S. Ware, Tottenham, and to Messrs. Barr & Son, King Street, Covent Garden, for large groups of choice Daffodils and hardy flowers. In Mr. Ware's collection were several novelties, a white variety of *Anemone appenina* and *Polemonium confertum* being selected for certificates, while a large pan of the rich blue *Gentiana verna* was a most attractive feature. Messrs. Barr & Son also obtained two certificates for *Narcissus bicolor* Mrs. J. B. M. Camm, and *N. incomparabilis Gloria Mundi*. The numerous forms of the Leeds type were well shown, the pure white variety *Beatrice* being very attractive. These two groups formed a most important addition to the display, as they filled the tables near the walls, extending the whole length of the hall.

G. F. Wilson, Esq., Oakwood, Wisley, was adjudged a vote of thanks for a series of varieties of *Gentiana acanthis* collected by Mr. Scott Wilson in Switzerland in 1885 and 1886. They were specially interesting as showing a marked variation in colour from deep blue through several shades of pale blue to nearly white, and one was of quite a pink tint. Five or six distinct varieties were exhibited. Professor M. Foster, F.R.S., Shelford, Cambs, showed several Irises, one named *Iris Suworowi*, var. (*lineata*) had small flowers veined with brown, and central bright blue crests; the other was of the *I. iberica* type, but smaller, with pale "standards" and purplish mottled "falls."

Miscellaneous.—Mr. F. Ross, Pendell Court Gardens, Bletchingley, showed flowers of *Cantua dependens* with long orange-tinted tubes and rosy crimson lobes, pale on the inner surface. It is grown at Pendell Court trained to a wall in a cool house and flowers profusely every year (vote of thanks). Specimens of *Callistemon salignus* were also sent from the same garden with long dense creamy white spikes. Mr. J. Doughty, Angley Park, Cranbrook, Kent, exhibited a bright scarlet *Carnation* named *Angley Park*; Mr. W. Seaman, gardener to J. Briggs, Esq., Brentwood, sent a seedling *Coleus* with deeply crenated tapering leaves splashed with yellow, crimson, and green; Mr. J. Knight, The Oaks, Epsom, showed flowers of *Carnation* Mrs. G. F. Wilson and *Rob Roy*, white and salmon tipped with red (vote of thanks); Mr. C. Smith, Brighton, exhibited plants of *Mignonette* Smith's *Defiance* (vote of thanks), of bushy habit, the spikes long but not so large as some varieties; compact single specimens in 48-size pots were shown.

Magnolia conspicua was admirably represented by some dozens of handsome pure white flowers shown by Mr. J. Hudson, Gunnersbury House Gardens, Acton. The tree from which they were gathered is over 30 feet high, well proportioned, and loaded with flowers, which are unusually large and pure. Messrs. Paul & Son, Cheshunt, contributed a specimen of *Rhododendron exoniensis* with large white *Azalea*-like flowers; a basket of *Tree Pæonies*; *Acer Negundo aurea variegata*, a golden variety in which the colour was not fully developed; the brown and bronze-leaved *Prunus Pissardi* was, however, in capital condition, amply demonstrating the distinctness and value of this tree. *Rose Lady Alice*, recently certificated, and the graceful *Fairy Rose Red Pet* were shown by the same firm. Mr. C. Turner, Slough, had a collection of beautiful *Alpine Auriculas*, several of which were certificated. Messrs. Kelway & Son, Langport, Somerset, sent flowers of varied *Amaryllises* cut from bulbs that are grown in cold frames from May or June until January or February, when they are lifted, potted, and placed in a house to develop their flowers.

Messrs. J. Veitch & Sons, Chelsea, sent a well-flowered specimen of the Tasmanian shrubby plant, *Olearia Gunni*, which has a great number of white starry flowers resembling *Michaelmas Daisies*. Messrs. G. Bunyard & Co., Maidstone, showed a double white *Deutzia* named *Pride of Rochester*, much like the double variety of *D. crenata*. Mr. W. Thompson, Tavern Street, Ipswich, sent plants of a seedling *Primula*, with deep purple flowers, dwarf and free (vote of thanks). Mr. J. H. Virgo, Walton-in-Gordano, Clevedon, exhibited a large-flowered variety of *Myosotis dissitiflora*, named *grandiflora*, also a darker variety named *Blue Perfection* (vote of thanks); and Mr. R. Dean, Ealing, had a basket of the dwarf free large-flowered *Wallflower*, *Bedfont Yellow*, which has been previously certificated. *Primula Sieboldi* *Snowflake*, pure white, and a large dark *Polyanthus* named *Mr. John Woodbridge* (certificated) were also contributed by Mr. Dean.

Messrs. H. Cannell & Sons, Swanley, were accorded a vote of thanks for a large yellow *Calceolaria* named *Souvenir*, very effective either for culture in pots or bedding.

CERTIFICATED PLANTS.

Odontoglossum Pescatorei, Poë's variety (J. T. Poë, Esq., Riverston, Nenagh).—A fine variety with large well formed flowers, white, with bold deep purplish spots.

Phillyrea decora Vilmoriniana (Paul & Son).—A compact shrub, with long narrow dark green leaves, and small white flowers thickly clustered in the axils of the leaves. It is especially recommended for planting in towns, as it has been found to stand the smoke well.

Auricula Harry Turner (C. Turner).—An Alpine variety, velvety purple shaded to a light edge, pale gold centre, large flower of good shape and fine truss.

Auricula Mrs. Harry Turner (C. Turner).—Another Alpine variety of dark maroon colour with a mauve margin and pale centre. Very pretty and distinct.

Auricula Hotty Dean (R. Dean).—A beautiful dark velvety purple Alpine, shaded white with a creamy centre.

Polyanthus John Woodbridge (R. Dean).—A strong and handsome variety with rich crimson maroon flowers of good size and gold centre. Trusses large and bold.

Azalea Veraeniana (Turner).—A large double-flowered variety, with a few salmon and pink streaks on white. Showy and of compact habit.

Rose Madame Hoste (W. Paul & Son).—A Tea variety, with delicate pale yellow flowers of considerable size, very deep, the petals broad.

Narcissus Incomparabilis Gloria Mundi (Barr & Son).—A beautiful variety with pale yellow perianth and deep orange expanded crown. One of the best of the section.

Anemone appennina alba (T. S. Ware).—A white or faintly tinted variety of the well-known blue *Anemone appennina*.

Polemonium confertum.—A dwarf plant with curious small leaves and pale bluish bell-shaped flowers in compact heads.

Narcissus bicolor, Mrs. J. B. M. Camm (Barr & Son).—A distinct variety of the trumpet section, with white perianth and delicate creamy tinted crown.

SCIENTIFIC COMMITTEE.—Present: D. Morris, Esq., in the chair; and Messrs. Burbidge, Lynch, O'Brien, McLachlan, Pascoe, Michael, Smee, Ridley, G. Murray, Professor Scott, Professor Church, Dr. Hogg, and Dr. Masters.

This meeting was held in the new library, at 111, Victoria Street.

Eichornia tricolor.—Mr. Lynch showed flowers of this tropical aquatic plant from Pernambuco, where it was gathered by Mr. Ridley. The flowers are in erect terminal panicles, each of a rich blue colour, with a small yellow spot on the lower perianth-segment. Mr. Lynch had grown it in a pot submerged to the rim. A discussion ensued as to the culture of these beautiful plants, Mr. Burbidge narrating his method of inducing *Pothos crassipes* to flower. This he does by not allowing the plant to float, but by placing it in a pot on a shelf fully exposed to light, and thus checking its wandering tendencies.

Chrysanthemum homatoma.—Mr. Lynch also showed flowers of this plant little if at all better than our common ox-eyed Daisy, though in its native country, as shown in the following extract from Lowe's "Flora of Madeira," it must be a fine thing:—"In the island of Madeira a bush of this species on its native black or grey and barren crags—one mass of lovely rose-pink flowers, and conspicuous from afar like a Camellia or Rose bush—is a truly splendid and surprising sight."

Haplocarpha Leichtlinii.—A pretty yellow-flowered Composite, with the backs of the ray-florets flushed with purplish-brown. It seems as if it would make a handsome bedding plant.

Pilocarpus pinnatifolius.—A Rutaceous plant, with dark green pinnate leaves, the segments broadly oblong. The plant is interesting as being the source of the drug Jaborandi, and of the substance known as pilocarpine.

Pentapterygium serpens.—A curious Vacciniaceous plant, from the Sikkim Himalaya, with angular tubular flowers of a bright red colour. The leaves are in two rows, small, ovate, and the stems which bear them spring from a very large woody tuberous growth. The plant grows upon the branches of trees.

Zinnia elegans.—A Mexican weed, shown to illustrate the vast advance that has been made in the culture of the plants, and the art of the florist.

Dipladenia boliviensis.—Young stems of this plant were shown, in order to show the herbaceous stipular outgrowths at the base of the leaf, and which are divided into narrow lobes in a palmate fashion. These, instead of falling off or drying up, become woody, and may serve to aid the plant in climbing from tree to tree.

Dendrobium Quelchi.—Mr. Ridley exhibited a photograph of this North Australian Dendrobe, which is nearly allied to *D. bigibbum*, but is not yet in cultivation.

Monstrous Lalia purpurata.—Mr. Smec exhibited flowers of this species variously malformed. One had three anthers (A1, a1, a2).

Odontoglossum retusum.—Mr. Bonney, Swanley, Kent, showed a plant of this rare species, remarkable for its orange-scarlet flowers. A botanical certificate was awarded.

Erythronium grandiflorum.—Mr. Loder sent a fine spike of this flower, with no fewer than fourteen flowers, most of them fully expanded. This is the finest specimen of this plant yet exhibited.

Lily Disease.—From Mr. L. Castle came leaves and stems of *Lilium candidum* in a decaying condition, probably from the effects of a fungus (*Peronospora*). Mr. Geo. Murray undertook to report on the specimens.

Fir Branches and Squirrels.—The Editor of the *Scientific News* sent shoots of the common Spruce Fir gnawed off by squirrels, which seem

specially destructive this season. The object of the animal in inflicting this injury is not obvious.

Malformed Cucumber Blossoms.—Messrs. Carter sent specimens of Cucumber flowers in which the calyx was leafy, and also showing other deformities, which were referred to Dr. Masters for further examination and report.

Iris Sari var., &c.—Professor Foster sent the bloom of an Iris which had been received from Nazareth, and which is said to grow wild there. In coloration it somewhat resembles *I. iberica*, but in essential features—rhizome, foliage, form of flower, &c.—is more nearly allied to *I. Sari*. Subject to the results of further study, Professor Foster "would be inclined to call it provisionally *I. Sari var. Nazarena*; but I do not wish to name it definitely at present. The other smaller Irises, as *I. Suworowi* (Regel) and the one with beard on inner perianth segments, is what Regel described as *I. lineata* (Foster), but which is really only a variety of *I. Suworowi*."

Gentiana acaulis.—Mr. G. F. Wilson showed flowers of this species with a curious spongy outgrowth from the outer surface of the corolla, on which Dr. Scott promised to report at another meeting.

Fertilisation of Tigridia and Hippeastrum.—A paper was read on this subject from Dr. Bonavia, in which he described how bees search for the nectar under each edge of the inner petals of *Tigridia*; but as they do not touch the stamens and pistil they must have discovered the concealed glands through scent, and so rife the flower, just as ants do, without pollinating it. *Hippeastrum* is fertilised by pollen-seeking bees or bee-like insects in India. One kind of bee balances itself on the wing opposite the tuft of anthers, and then, suddenly making a sort of somersault among them, brushes off the pollen with the hairs of its body, when the stigma gets dusted all over with pollen. A second kind, after balancing itself, by a sudden movement brushes off the pollen with the hairs of its legs. Lastly, a third kind of bee settles on the anthers, scoops out and devours every grain of pollen. After alluding to the fact that some flies are also pollen-eaters, the author suggests that certain humming-birds provided with feathers on their feet may possibly be the true fertilisers of *Hippeastrum* in its native country.

In the course of the discussion on this subject it was pointed out that humming-birds hover over the flowers and perforate them with their beaks, and hence that the tufts of feathers on the legs of some of the species are not likely to act as pollen-brushes. Mr. Morris related how in Jamaica the humming-birds, which at first had not attacked the flowers, suddenly began to split the tubes of the *Cinchona* flowers, and thus ensured the fertilisation of the flower. Mr. Burbidge called attention to the fact that in South America the Scarlet Runner does not set its fruit, but in this country it fruits freely, owing to the bees, which bore through the base of the flower—a curious illustration of a foreign flower rendered fertile by the agency of British bees. The meeting then adjourned.

NATIONAL AURICULA SOCIETY.

(NORTHERN SECTION.)

MAY 1ST.

THIS Show was held at the New Town Hall, Manchester, and was very successful. Auriculas were not staged in as large numbers as in previous years owing to the plants of several northern growers not being in full bloom, the weather having been against their development. Those shown were, however, very good in quality. In *Polyanthuses* the flowers were above the average both in quality and numbers, and some very fine seedlings were staged showing a decided advance. The following were the awards.

Six Auriculas, dissimilar. The first prize was awarded to the Rev. F. D. Horner, Lowfields, Burton-in-Lonsdale, Kirkby Lonsdale, for the following—F. D. Horner, a grand green edge, and this plant was selected as the premier flower in the Exhibition; Ebony, a fine black self raised by Mr. Horner; Laura, another of his seedlings, with good tube, paste, and violet plum colour; George Lightbody, very fine, and Greyhound. The second prize went to Mr. Wm. Bolton, Mersey Street, Warrington, with James Douglas (Bolton) very fine; Lancashire Hero, Sapphire, Mrs. Dodwell, fine; R. Headly, and Mrs. James Tinsley (Bolton), a self of a very promising character. Third, Mrs. Kirke Penson, Ludlow, with Sapphire, G. Lightbody, Conservative, Acme, a seedling black self, and a seedling green edge. Fourth, Mr. T. Buckley, Stalybridge, with Sapphire, G. Lightbody, Acme, Frank Simonite, Lancashire Hero, and Pizarro. Fifth to W. Brockbank, Esq., Didsbury, near Manchester, with F. D. Horner, Heroine, Rd. Headly, Mrs. Douglas, Heather Bell, and a seedling green edge; and sixth, Samuel Barlow, Esq., Stakehill House, Castleton, near Manchester, with six seedlings.

Four Auriculas, dissimilar, the Rev. F. D. Horner was again first with F. D. Horner, G. Lightbody, fine, John Simonite, and Iris, a grand deep violet self with gold tube and round paste; second, Mr. H. Wilson, Halifax, with Mrs. Potts, Mrs. Dodwell, Colonel Taylor, and George Lightbody; third, Mr. W. Brockbank, with Acme, Lord Lorne, R. Headly, and a seedling green edge; fourth, Mrs. Kirke Penson, with Prince of Greens, Acme, George Lightbody, and a seedling self; fifth, Mr. Wm. Bolton, with Frank Simonite, A. Meiklejohn, F. D. Horner, and Sapphire; and sixth, Mr. T. Barlow, with Complete, Reliance, F. D. Horner, and seedling self.

Pair of Auriculas, first, Mr. Simonite, Sheffield, with Heroine, fine and Conservative; second, Mr. Wm. Barnfather, Leek, with G. Light-

body and Negro; third, Mr. J. Beswick, Middleton, with Acme and F. D. Horner; fourth, Mr. J. Butterworth, Middleton, with Trail's Beauty and A. Meiklejohn; fifth, Mr. E. Shepley, with Acme and Blackbird; sixth, Mr. W. Taylor, Middleton, with Trail's Beauty and C. J. Perry; and seventh, Mr. J. Stelfox, Stalybridge, with Pizarro and Trail's Beauty.

Pair of Auriculas (maiden growers), first to Mr. W. Barnfather, with George Lightbody and Negro; second, Mr. J. Butterworth, with Trail's Beauty and A. Meiklejohn; third, Mr. E. Walker, with Prince of Greens and a seedling self.

In the class for single green edges, Mr. W. Bolton won the premium with F. D. Horner; the Rev. F. D. Horner was first and seventh with Lancashire Hero and Ivy Green; Mr. E. Shepley, second, with Mayflower; Mr. W. Taylor, third, with Lovely Ann; Mrs. Kirke Penson, fourth, sixth, and eighth, with Colonel Taylor, Prince of Wales, and Prince of Greens; and Mr. C. Royds, Rochdale, fifth, with new Green. For grey edges, Mrs. Kirke Penson won the premium with George Lightbody, second with G. Lightbody, and seventh with C. E. Brown. The Rev. F. D. Horner was first with Lancashire Hero; Mr. W. Taylor, third, with A. Meiklejohn; Mr. W. Bolton, fourth and sixth, with Greyhound and Quicksilver; and Mr. W. Taylor, eighth, with Trail's Beauty. In the white edges the premium was awarded to Mr. H. Wilson for Mrs. Dodwell, also first and fifth for Miranda and John Simonite; Mr. C. Royds was second with Conservative; Mrs. Kirke Penson, third and seventh, with Acme and Silvia; Mr. B. Simonite, fourth, with Heather Bell; Mr. W. Brockbank, sixth and eighth, with Reliance and Smiling Beauty. For single selfs the premium was secured by the Rev. F. D. Horner, with Florence; he was also first with Gazelle; Mr. W. Brockbank was second with a seedling; Mrs. Kirke Penson, third, with Sapphire; Mr. W. Bolton, fourth, with a red seedling; Mr. C. Royds, fifth, sixth, and seventh, with Mrs. Douelas, E. Lancaster, and Pizarro; and Mr. J. Beswick, eighth, with Lord of Lorne.

Four alpine Auriculas, dissimilar, shaded.—First, Mr. S. Barlow with Mrs. Barlow (fine), Sir Trevor Lawrence, Charley Needham, and a seedling; second, Mr. J. Beswick with Queen Victoria, Utility, Emir, and Diadem; third, Mr. Wm. Brockbank with Q. Victoria, Mrs. Ball, Diadem, and a seedling; fourth, Mr. W. Bolton with Diadem, Placida, Unique, and an unknown variety; fifth, Mr. E. Stelfox with Queen Victoria, Diadem, J. Leech, and a seedling; and sixth, Mr. J. Butterworth with Conspicua, Diadem, Dazzle, and Prince. For single Alpines, shaded yellow centres, premium is Mr. Buckley with Diadem. First, Mr. Brockbank with Diadem; second, third, and fourth, Mr. S. Barlow with seedlings; fifth, Mr. E. Stelfox with Mercury. For single Alpines, white centres, Mr. W. Taylor premier with seedling, and Mr. W. Brockbank with Slough Rival, seedling, and Mrs. Dodwell.

Polyanthuses, three dissimilar black grounds.—First, Mr. W. Brockbank with Cheshire Favourite, Black King, and Black Cap; second, Mr. J. Butterworth with Cheshire Favourite, George IV., and Exile; third, Mr. S. Barlow with Favourite, George IV., and Exile; fourth, Mr. J. Thornley with Regent, Cheshire Favourite, and Exile; fifth, Mr. A. Mottershead with Regent, Cheshire, and Hero; sixth, Mr. A. Oldham with Exile, and second with a seedling. Three dissimilar red grounds.—First, Mr. A. Oldham with three seedlings; second, Mr. J. Butterworth with Regent, Lancer, and George IV.; third, Mr. W. Brockbank with Regina, George IV., and Ensign; fourth, Mr. W. Taylor with Regent, Lancer, and George IV.; fifth, Mr. G. Geggie with William IV., Lancer, and George IV.

Single Polyanthus, red grounds.—Mr. Henry Geggie, Bury, premier, with Lancer, and also first with Lancer; second, Mr. A. Oldham, with a seedling; third, Mr. J. Butterworth, with George IV.; Mr. G. Thornley fourth, with Prince Regent; Mr. W. Brockbank fifth, with Lord Derby; Mr. Henry Geggie sixth, with Sydney Smith; and Mr. W. Taylor seventh, with William IV. Single Polyanthus, black grounds.—Premier to Mr. J. Butterworth, with Cheshire Favourite; first, Mr. J. Hilton, with Exile; second, with Cheshire Favourite; Mr. W. Brockbank third, fourth, and sixth, with Black Knight, Lancashire Hero, and Jubilee; Mr. A. Oldham, fifth, with seedling, and seventh with James Lees. For twelve Fancy Auriculas, Mr. Samuel Barlow was first and Mr. William Bolton second. For twelve Fancy Polyanthus, dissimilar, Mr. S. Barlow was first, also for twelve Primroses.

Several collections of Narcissi and other miscellaneous plants were staged, including collections from Barr & Son of London; Dickson and Robinson, Old Millgate, Manchester; James Dickson & Sons, Newton Nurseries, Chester; and Messrs. R. Barker & Co., Frampton, Boston. There was a grand display of Cyclamens by Mr. John Odell, Hillingdon, Middlesex, also groups of greenhouse plants from Mr. John Hooley, Stockport; a collection of twenty or thirty Rhododendrons from Mr. Thomas Lloyd; and very fine cut Hyacinths from Messrs. Dickson, Brown, and Tait, Manchester. The following awards were made:—First-class commendation for Hyacinths, Messrs. Dickson, Brown, & Tait; first-class certificates for Narcissi to Messrs. Barr & Son; for Narcissi to Messrs. James Dickson & Sons; for Cyclamens to Mr. J. Odell; and for Crown Imperials to Richard Barker & Company, Frampton, Boston.

A GOOD SHADING FOR PLANT HOUSES.

THE time is drawing near when certain plants will require protection from the direct glare of the sun. So far this season we have not had too much sunshine for the majority of plants, and perhaps on that

account some may suffer the more if we have a spell of unclouded sky, unless shading to a certain extent is applied.

There are various methods of shading glass structures. Roller blinds cannot be improved on I think, but everyone cannot obtain them. Thin linewash is sometimes syringed on the glass, but I cannot recommend it for general use, as it destroys both paint and putty. The following recipe I can recommend as being a good one:— $\frac{1}{2}$ lb. best gluc, $\frac{1}{4}$ lb. Brunswick green, $\frac{1}{4}$ lb. white lead dust. Boil the gluc in one quart of soft water, put the Brunswick green and white lead dust in while boiling, and allow the whole to boil for a few minutes longer, at the same time stir the mixture with a piece of stick.

It is much the best to prepare the shading a few days before it is required for use. When cold it will resemble thick jelly, and if it is fairly warmed through to soften it a little just before use by placing the vessel containing it on hot-water pipes, no difficulty will be found in painting the glass inside, not outside, the house, so as to form a heavy or light shade.

The glass should be perfectly dry when the shading is applied, otherwise it will not adhere to the glass. This is the third season we have used it here. The shading can easily be removed from the glass in the autumn with warm water, a sponge, or piece of cloth, afterwards syringing the glass with clear water. Two shillingsworth of the articles named would be sufficient for a fernery or stove "lean-to" 40 feet long and 14 feet wide.—G. GARNER, *Amberwood Gardens, Hants.*

JAPANESE REFLEXED CHRYSANTHEMUMS.

"A YORKSHIREMAN" appears a little troubled about certain varieties, such as Val d'Andorre and Criterion, being included in the list of sorts admissible in the new class. May I venture to suggest a way out of the difficulty which may not be so complex as to severely tax his faculty of apprehension? It is this—when he is making up his stand, if he has the temerity to exhibit, to leave out those to which he objects, and stage those which he considers more suitable. This will be the easier, since I do not see how twenty-four varieties can by any amount of squeezing be arranged in a stand of twelve blooms in not less than eight varieties. He has the option of excluding twelve or sixteen sorts and making up a "twelve" out of the remainder. If he has any difficulty in doing this I shall be glad to give him a helping hand, for I should not like the southerners to run away with all the prizes from the first N.C.S. provincial.—A SHEFFIELD BLADE.

A LITTLE longer reflection will, perhaps, convince "A Yorkshireman" that the difficulties in the way of constituting a good stand of Japanese reflexed blooms for exhibition are not so great as he appears to imagine. For my own part I fail to see that any trouble will be caused to either exhibitors or judges by the new class, and I anticipate that these classes both at the metropolitan and the provincial shows will form a very interesting feature. Really fine blooms of Elaine in contrast with the dark Jeanne Délaux would alone make an effective stand, and there are plenty of others in the select list to choose from. All the Judges will have to do will be to determine the respective merits of the blooms in each section, and it will make no difference whether they are shown elsewhere or not. Jeanne Délaux, Val d'Andorre, and Criterion are undoubtedly fine varieties for exhibition in the Japanese classes, and there would have been some cause for complaint if they had been excluded from those stands.—AN EXHIBITOR.

LATE CHRYSANTHEMUMS.

THERE is no difficulty in securing Chrysanthemums in bloom all the year round. I have had good Fair Maid of Guernsey until June simply by keeping the plants growing right on and cutting the blooms as they expanded. Madame Desgrauges, cut down and restarted, and kept growing, produces growths which bloom in May, perhaps earlier, but I cannot say from experience. I imagine from the peculiar habit the latter has of throwing up fresh growths from the bottom that this sort might be flowered nearly the whole year round.—B.

RIPENED WOOD.

I QUITE endorse your correspondent, "W. B.'s," remarks at page 137, where he said the wood may be too ripe to produce good blooms, especially amongst incurved varieties, notably John Salter, Princess of Wales, Prince of Wales, and Mr. Brunlees. I have seen Faust very fine when the wood appeared somewhat green but still firm. The varieties of the Queen family produce finer and better shaped blooms when the wood is not too ripe. Princess Teck is similar. This subject was brought forward in the Journal some five or six years ago.

I have heard and read of many good Japanese varieties, but have

found no one that seems acquainted with Marsa. Yet it is a very handsome variety, purple, flaked white, with twisted florets in the centre; the blooms are of good substance and keep well.—A NOTTS GROWER.

table decoration, &c. The plants colour better in a compost containing loam than in peat alone. I have found picturatus, interruptus, majesticus, Queen Victoria, Weismanni, longifolius, and longifolius aureus

SHEFFIELD AND WEST RIDING CHRYSANTHEMUM SOCIETY.

THE second quarterly general meeting of the above Society was held on Thursday evening last at the Society's meeting rooms, Mrs. Webster's Museum, Orchard Street, Sheffield, Mr. Jno. Haigh in the chair, when an excellent paper was read by Mr. Joseph Walker on "Specimen Plants, How to Grow and Train Them," for which the essayist received much well merited applause, with the unanimous and cordial thanks of the meeting. There was a good attendance, and several new members were added to the list already on the books. The Hon. Sec., Mr. W. K. Woodcock, read letters he had received, stating that a party of members from the National Chrysanthemum Society had been arranged to visit Sheffield on Saturday, May 19th. The letters were received with very lively satisfaction by all members present, and a Committee was appointed to make the necessary arrangements for ensuring the comfort and convenience of the visitors during their short stay in Sheffield, also for according to them a truly Yorkshire greeting from the patrons and members of the S. and W.R.C.S. —W. K. W.

NEW GLASS RANGES AT BYRKLEY.

THE engraving represents a range of glass houses Messrs. Foster and Pearson are erecting for Hamar Bass, Esq., at Byrkley, Burton-on-Trent. A new kitchen garden is being formed there of considerable extent. It is situated on one of the highest parts of the old Needwood Forest, and has a slight slope towards the south and west. The subsoil is stiff clay, which has caused considerable expense in preparing the ground. The main range of greenhouses is 330 feet in length, and consists of plant house 40 feet by 30 feet and 22 feet high in centre, four vineries each 34 feet by 16 feet 9 inches, two Peach houses each 31 feet 9 inches by 12 feet, two Rose houses each 31 feet 9 inches by 12 feet, two greenhouses 28 feet by 18 feet 6 inches, and two stoves or Orchid houses 28 feet by 18 feet 6 inches. At the back of range are cool Orchid house 30 feet by 12 feet, fernery, and all the conveniences usual in a large establishment. As the ground falls very much at left hand end, the space under some of the houses has been utilised for Mushrooms, root stores, and other purposes. There are two ranges of half-span pits, as shown in the illustration, each 100 feet long, which will have ample heat for all purposes. The whole of the houses will be heated by three of the Chilwell Nursery boilers, made in the improved form with steel tubes. The work has been carried out under Robert Edis, Esq., architect, London, and the whole of the details have been carefully arranged with the advice of Mr. Bennett, Rangemore Gardens.

INCREASING CROTONS.

THE present is a good time to increase the above, especially by mossing the stems, as they emit roots more freely at this season than at any other time during the year. It is a simple process, and is especially recommended where plants are grown out of bounds or are becoming tall and unsightly. Good plants may be obtained in six or eight weeks in this way. In the first place make an incision by just running the knife round the stems 6 or 7 inches below the point, as circumstances will permit. Some sphagnum moss must be at hand, also a pan containing sharp silver sand with a slight admixture of leaf soil. The moss should first be moistened, when sand, &c., may be intermixed with it, then take as much as will form a ball round the incision about the size of a hen's egg when tied on closely and securely with raffia. The plants should be placed in a brisk heat where shade from bright sunshine can be afforded. A Cucumber house suits admirably, and there the plants will fill the pots with roots in about five or six weeks. Cut off the stems immediately below the moss, and at once place them in 4-inch pots. In about fourteen days they will be ready for repotting, and may be exposed to more sun in order to colour them. By the above means well-furnished plants are obtained better than from cuttings.

Crotons prefer good fibrous loam and peat in equal parts, adding plenty of sand and chareoal, especially for plants in small pots for

amongst the best varieties for table plants, although there may be some new ones I am not acquainted with.—J. P.

FIG. 51.—GLASS RANGES AT BYRKLEY.

HARDY FRUIT GARDEN.

YOUNG FRUIT TREES.—These now require attention, and in fact must not be neglected at any time through the growing season. In the first place all that are newly planted, and any that have not made satisfactory progress since they were moved, ought to have nearly or quite all the flowers cleared off them at once. Strong trees planted early in the season may be allowed to perfect a sprinkling of fruit, especially if not wanted to cover much wall or other space quickly, but to let those put out late make the attempt to swell off as many fruits as they will is very unwise. This phase of "gardener's greed" is one of the causes for so many trees becoming stunted and comparatively worthless. A moderate crop of fruit on trees that this season give signs of growing vigorously will, however, prevent grossness, and probably avert the necessity for root-pruning to induce fruitfulness.

PEARS.—Espaliers or horizontally trained trees of these or Apples will in most instances have formed a cluster of young shoots on the shortened leader. These should be freely thinned, so as to leave a good central shoot to continue the lead and two others for laying in on each side in an oblique rather than horizontal direction, these being intended to develop into another pair of permanent side branches. At the point of each already formed side branch several growths will attempt to form. Supposing no pruning had been resorted to as advised the strongest shoot will be at the point. Reserve this and duly lay it in, the rest being freely thinned out, and any left stopped at the third or fourth joint. All other lateral growth should also be thinned out or disbudded, leaving only those facing outwards, these also being stopped at the fourth joint. This will divert much of the sap to the support of the leading branches, and lead to the early formation of serviceable trees. Cordons of any description require much the same treatment as to thinning out and stopping, the main branch or branches only being allowed to grow unstoppped. Maidens as well as older trees planted last year, and not shortened in any way, made but little progress, but in addition to flowering freely give promise of growing strongly. It is the much-pruned trees that fail to bear well.

PLUMS.—Many of those planted against walls or fences this season, and not pruned in any way, will form little or no top growth during the summer, but they will make good progress at the roots and start away strongly next year. Should they start into active growth it will be necessary to remove some of the shoots and stop many more at the fourth or fifth joint, leaving those only to run out that are required for furnishing the wall space. Whether they start strongly this season or not, laying on the branches as received from the nurseries is a quicker method of furnishing the walls than the plan sometimes adopted of cutting back all the main branches. Supposing they only form a few leaves and buds this season, next year they will grow vigorously and also perfect a few fruits. It is advisable to lay in young shoots on the upper side of the main branches, and according as they extend, other branches being required to fill in between the widening spaces. If the central branch has been cut back with the view of obtaining more shoots for the centre of the tree, timely selecting and thinning out should be resorted to, about three of the best placed shoots being laid in.

CHERRIES.—Those against walls are usually pruned and trained similarly to Plums, the only exception being the Morello. The main branches of all but this variety should be clothed as soon as possible with short fruiting spurs, this being by no means difficult of attainment. They ought to be thinly trained, the main branches being not less than 9 inches apart, more shoots to be laid in wherever they are required. Thin out and stop as advised in the case of Plums. The Morello branches may be trained rather more thickly, also fan-shaped, on the upper side of these laying in a number of young shoots, these being destined to bear fruit for one year only and then cut away if not needed for furnishing, their places being taken by other younger branches saved the same year. Trees received and planted with eight or more well regulated growths not shortened in any way will not make much progress this summer, but next season will make up for this disappointment. Thin out the young shoots of any starting well now, leaving one near the base on the upper side of each branch, another about the middle, and the leader. If there is a central branch one, or, if needed, two shoots may be laid in on both sides of these. A few of the foreright shoots on the main branches, or those growing outwards from the wall, may be lightly stopped, these fruiting next season, but the side growths not required for furnishing should be removed at once.

PEACHES AND NECTARINES.—When strong, well-balanced, fan-shaped trees are planted it is advisable to shorten back the branches to about one-half of their length. It is late to prune them, but they may be disbudded, and that answers better than late pruning, the disbudded or upper half of the branch being cleanly cut away when the trees are in full leaf. Disbudding must also be resorted to in the case of the lower half of the branches, one shoot at the base on the upper side and a leader only being reserved, unless there is good room for another near the leader. These branches should be carefully laid in, and if the season

is at all favourable they will ripen well and be fruitful next year. Young trees, the second year after planting, are apt to form shoots that are too rank and sappy to be serviceable. These may be detected quite early, as they are usually from the centre of a triple wood bud, and if removed early one of the side-buds may take its place with advantage. Later on strong shoots may be depressed and checked in growth, the removal of several leaves also checking them. If maidens are planted for the purpose of being grown into fan-shaped trees these ought to have been cut back to within 6 inches of the union of the scion with the stock. If this has not been done closely disbud all the upper growth, and reserve about three shoots only on each side of the lower portion of the stem, these to be kept laid in to their full length. Those to be trained with a central stem in an oblique direction, and fruiting branches laid in right and left, should have a central growth reserved in addition to the six or more side branches. This method of training is to be commended to those who wish to furnish a high wall quickly, and also where the trees do not last many years.

APRICOTS.—These may be trained and pruned on the spur system, similarly to Plums, or they may be trained and fruited exactly the same as Peaches. The former is the method most generally adopted, but the latter, though it entails rather more labour, is the most profitable in the long run.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Trees Started at the New Year.*—The fruit is stoning, and must not be subjected to a higher temperature than 60° to 65° by artificial means, commencing to ventilate at 65°, and not allowing 75° to be exceeded without full ventilation. Tie in the shoots as they advance, removing superfluous growths, as it is important that no more be trained in than can be fully exposed to light and air. If the shoots are crowded thin them well as soon as the stoning is completed. Allow one fruit to every square foot of trellis covered with foliage, which will be one to each shoot of last year, although vigorous shoots may be allowed to carry two fruits; by apportioning the fruit according to the vigour of the trees or degrees of vigour the evenness of vigour may be maintained throughout the tree. After stoning, maintain a good moisture in the house, and water the inside border copiously, which in well drained borders will not be required less than once a week, mulching the surface with about 2 inches thickness of short half-decayed manure. Unless it is desired to accelerate the ripening, continue 60° to 65° as the night temperature, and 65° artificially by day in dull weather, and 75° with sun heat, closing at the latter with plenty of moisture in the house. In a high temperature and moist atmosphere Peaches swell to a great size after stoning, but are not so tempting in appearance nor so well flavoured as those in less heat and moisture and with freer ventilation.

Trees Started in February.—The fruit of these will soon be commencing stoning, and should have the number reduced, leaving two fruits on strong shoots, but one will be sufficient on the weaker. The fruit retained must, in all instances, be best situated for receiving air and light. Thin the shoots where crowded. The temperature by artificial means may be kept at 55° to 60° at night, and 60° to 65° by day artificially, ventilating from 65°, and fully between 70° and 75°.

Trees Started in March.—The fruit is swelling and requires to be freely thinned. It can now be seen which fruits have taken the lead. Two or three will be ample to leave on strong shoots, and proportionately less on weaker growths. Afford liquid manure to weakly trees, but vigorous trees being more prone to cast the fruit must have clear water only. Remove all superfluous shoots, the remaining shoots being trained to the trellis as they advance.

Late Houses.—The fruits are well set, and syringing will be needed in the morning and on fine afternoons to rid the trees of the remains of the flowers. Commence thinning when the fruits are the size of horse beans, removing the smallest and worst placed, leaving very few more fruit than will ultimately be required for the crop. Disbudding and heeling-in the shoots should be carefully attended to. A temperature of 50° at night will be safe, and 55° by day artificially, ventilating freely about that, unless it is desired to hasten the crop when a temperature of 55° at night and 60° to 65° by day artificially may be secured, with 70° to 75° by day, ventilating from 65°.

Unheated Houses.—There has so far not been any frost to interfere with the prospect of the crop, which promises to be abundant, indeed the fruits have set splendidly, fully nine-tenths more fruit than will be required for the crop. A moderate syringing on fine mornings will be a great assistance in ridding the fruit of the remains of the blossoms, but there must not be any attempt at an afternoon syringing for the present, and no sprinkling practised likely to cause a moist temperature at night, as the weather is not yet to be depended on, and a sudden severe frost occurring whilst the house is moist is very much more likely to prove disastrous to the crop than if the atmosphere is dry. Ventilate at 50°, not allowing an advance above 65° without full ventilation, and close at 50°, or before if there is a prospect of frost at night. If water be necessary apply it sufficiently early in the day to allow of the surface becoming fairly dry before closing time.

PINES.—Changeable weather necessitates careful attention in the cultivation of Pines, especially as regards plants with the fruit in an advanced condition, a moderately high and moist temperature being necessary to their well being, which condition renders them more susceptible of injury, the effect of sudden outbursts of sun telling disastrously, especially upon the crown, which is not infrequently scorched if the ventilation is not carefully attended to. Large, well-finished fruit are only to be obtained by attention to details, especially when the

plants are cultivated in pots. Watering will require attending to once a week, but avoid indiscriminate periodical waterings. Plants that have heat at the roots by means of hot-water pipes need more water than those having the heat furnished by means of fermenting material; the former should have water as often as required, on every occasion employing some stimulant. 1 lb. of guano to twenty gallons of water is a suitable quantity. Admit air at the top of the house at 80°, and maintain the temperature during the day at 80° to 90°, closing at 85°; but unless it be desirable to enlarge the crowns do not quite close the house. Fire heat must be employed to prevent the temperature falling below 70° at night, and to raise it to 75° in the day, the bottom heat being kept at 80° to 90°, or with the bottom heat steady, a few degrees variation in the atmosphere is not of great consequence. Syringe the house and plants two or three times a week according to the weather, and maintain the atmosphere in such a condition as is likely to secure the perfect development of the fruit.

STRAWBERRIES IN POTS.—There must not be any lack of moisture at the roots of these plants, as when the sun is powerful the fruits are apt to have the skin dried, and they do not swell truly afterwards. After the fruit commences swelling a brisk moist atmosphere is essential to insure good fruit, supplying liquid manure liberally until the fruit changes colour, when it must be discontinued and watering less at the roots. Admit air freely whenever the weather is favourable, avoiding drying currents. Nothing is so advantageous as well thinning the fruits, especially of the large varieties, such as President, James Veitch, Dr. Hogg, and British Queen, also those very handsome varieties Sir Joseph Paxton and Sir Charles Napier. Sir Harry also attains to a good size when well thinned, and is one of the finest Strawberries for forcing. A dish of Strawberries composed of a dozen to the pound is very much more taking in appearance than when the number is double for the weight. See that late plants are free from aphides, and fumigate if there be the least trace of them. Do not keep fruiting plants a day longer in the houses than is absolutely necessary, as it is hardly possible to force Strawberries without their being infested with red spider. Water the plants twice a day, and in bright weather three times.

CHERRY HOUSE.—Cherries are ripening rapidly and the fruit must be kept dry, but keep the surface of the borders moist by damping with the syringe, air being admitted constantly, or condensation will seriously affect the fruit. Damping the border is calculated to mislead as regards its condition, which at this stage must be quite moist, therefore if necessary a thorough supply of water must be afforded without delay. Tie in the shoots as they lengthen, and stop those not required for training-in at about the fifth leaf. Black aphides can be kept under by dipping the leaves or shoots in tobacco water. Ventilate freely on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to ensure a circulation of warm dry air. Netting will be necessary over the ventilators to prevent birds attacking the Cherries.

CUCUMBERS.—A clear growth is of the utmost importance in the successful cultivation of fruits. If aphides appear fumigate twice on consecutive evenings, having the foliage dry, but the floors well damped. Red spider is almost sure to appear. Remove the worst infested leaves, and keep the atmosphere charged with ammonia vapour by damping the floor in the evening with guano water, supplying the roots with the same about twice a week. The hot-water pipes may also be moderately coated with sulphur. Be careful that the plants do not suffer through insufficient supplies of water, applying it at the same temperature as that of the bed. Plants in bearing all the winter will now be showing signs of exhaustion, and had better be removed and young plants placed in without delay. Assist young plants which show signs of weakness by removing the staminate blossoms and the first fruits, stopping at every third or fourth joint, removing all weakly and superfluous growths. Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially houses facing south, but shade early to prevent flagging. Houses with the roof-lights facing east and west will not require shading. Little or no fire heat will be required by day, shutting the valves at about 8 A.M., and opening them again at about 5 P.M. Syringe the plants moderately between 3 and 4 P.M., keeping a good moisture all day by damping the floors.

Sow seed for raising plants to occupy pits and frames, a fair bottom heat being first secured by using the less decomposed material from Seakale, Vine borders, or exhausted hotbeds, which, with about a fourth of fresh material, will afford all the bottom heat now required. The days as well as nights lately have been cold, in which case close pits and frames as early in the afternoon as is safe, not allowing the temperature to exceed 90° to 95°, and employ good night coverings. See that a good bottom heat is maintained by duly renewing the linings. Prepare for planting out ridge Cucumbers under handlights, the plants being hardened off previously.

PLANT HOUSES.

Polystichum proliferum.—Mature fronds pegged down in early autumn will by this time have produced numbers of well-rooted young plants. These should either be potted singly, or two or three together, in 2 and 3-inch pots. In these sizes few Ferns are so useful for room decoration. Grow them in the shade for a time in an intermediate temperature until well established, and afterwards they will succeed admirably in a cool but shady frame. When required solely for winter use they must have from September an intermediate temperature, so that steady growth will be the result. Unless they are kept growing during the winter the mature fronds have a rusty appearance instead of that light green colour that is so characteristic of the young fronds.

Very ornamental specimens are produced for decoration by placing two or three of these little plants in the centre of 4-inch pots, and then surrounding them with *Selaginella Kraussiana* (denticulata of gardens).

Pteris tremula.—Small plants still in pans and boxes may be placed at once in 3-inch pots, and from these when ready transferred into 5-inch pots. The last size is most suitable for this variety, for in smaller pots it does not develop itself sufficiently well to be attractive. *Lomaria gibba* does well in the same size, as well as many other Ferns which need attention at the present time. *Pteris serrulata* is most useful in 3-inch pots, and its crested form is doubly ornamental in pots 2 inches larger. The whole of these will thrive well together under the shade of Vines or Peaches if no better position can be accorded them. When required for furnishing purposes the object should be to push them on in their early stages, and as they attain a sufficiently large size grow them as cool as is consistent with keeping them in good health. It must be remembered that plants last in rooms double the length of time when grown and hardened for the purpose than when removed direct from heated structures.

Small Adiantums.—For purposes of decoration in small pots *A. concinnum* and the old *A. euneatum* are two of the most serviceable. The former if ready now for 2-inch pots will be shapely plants by autumn in 5-inch pots, while the latter will be of a useful size in pots 1 inch less. If the small pots in which they are first placed can be plunged in some moisture-holding material to prevent the soil drying quickly they will make rapid growth. Grow these varieties where the syringe can be kept from them. They may also be grown with a fair amount of light, so that they will be hardy from the first. All the shading needed is to screen them from the strong rays of the sun. They will grow much more rapidly in loam, leaf mould, and sand, than in a mixture of loam and peat.

Selaginella Kraussiana.—A good stock may be prepared in 3 and 4-inch pots as well as in shallow 6-inch pans for decorative purposes during the autumn and winter. Fill the pots and pans with light material and dibble small shoots thickly over the surface. If placed in a shady position and dewed once or twice daily with a fine-rose can the surface will be quickly covered. To insure the plants lasting well in rooms they must be grown to the desired size and then stood in a cool house prior to use.

Isolepis gracilis.—Some of the plants that have been in pots for six or eight months will be considerably past their best. These may have all the old leaves removed, and if divided into two or three and placed in the same size pots they will be again of useful size in about two months. Others may be divided into very small pieces, so that they will be well established plants in 3-inch pots by autumn, which can be kept in good condition until the following April or May. Nothing is gained by growing the plants in heat, in fact they draw up weakly, and directly they are removed the leaves fall about, destroying their effective appearance. They will grow in any cool structure that is moderately close, where they can be kept moist and shaded from the sun. The compost must consist of loam, leaf mould, a little manure and sand.

Cyperus.—The plants of *C. alternifolius* in 2-inch pots and now growing freely may be transferred at once into 5-inch pots, providing a compost of loam, one-seventh of manure and sand. In this size they will be found invaluable for groups in halls and rooms during the winter. Grow them in heat for a time until well established, and then as cool as is consistent with keeping them advancing slowly. Moderately matured heads if inserted in small pots in heat will yet make good plants by autumn. In a moist atmosphere they soon form roots, and young growths push from the crown. If the heads are placed in a tank of tepid water in the stove they soon commence forming roots and can afterwards be potted. By either of these means better furnished plants are produced than is the case by division of the crowns.

FLOWER GARDEN.

Tuberous Begonias.—Roots of these that have wintered satisfactorily without being set in heat or coddled in any way, will be sufficiently advanced to put out with the other bedding plants. They start better in, and are transplanted more readily from boxes of good loamy soil, but they must not be crowded together, and should be not less than 4 inches apart each way, the larger tubers requiring more room. This admits of their being transplanted with a good ball of soil about the roots. Seedlings raised early in the year may be grown to a good serviceable size by the end of May, though not if they are kept long in pans. They ought first to have been pricked off in pans, and when of good size transplanted into boxes. A rather rich light loamy soil with plenty of sand added suits them, and if carefully shifted into these boxes in preference to either pans or small pots, being disposed not less than 3 inches apart each way, and kept in gentle heat, useful plants will result.

Beet.—A good strain of garden Beet, such as Dell's Crimson, Carter's Perfection, and Veitch's Improved Black is very effective in the flower garden. It forms a capital edging to beds filled with Marguerites or other large plants, and contrasts well with golden or silver variegated or flowering plants in a ribbon border. The seed may be sown now either where the plants are to grow or in boxes of light soil, and thinly in each case. Seedlings when about 4 inches high can be transplanted readily from boxes or from the open ground.

Violets.—Old beds of these are not nearly so profitable as comparatively new plantations, and it is advisable to replant some every spring. The Czar or any of the newer forms of Russian Violets are the most reliable, but in favoured districts the double flowering Marie Louise, the

Old Tree, and Queen of Violets are fairly hardy and floriferous. The former section have nearly ceased flowering, leaf growth taking the place of flowers. These may now be lifted, divided, and replanted in rich loamy soil. If given an open position the pieces may be dibbled out firmly 9 inches apart, a distance of 12 inches dividing the rows. Nothing is gained by crowding them, and if they are watered in very hot dry weather or in any way mulched with manure, short grass, or other suitable material, they ought to grow sturdily and flower well for the next three seasons. The doubles to be similarly treated after they have ceased to flower. Many err in planting Violets, especially the singles, in shady or cool spots. It is the sturdy plants grown in full sunshine that are the hardiest and give the most flowers.

Lawns.—A good sweeping or bush-harrowing followed by a heavy rolling is very beneficial to these. The former distributes the worm-casts and dislodges moss, and the rolling fixes many of the grasses that annually root afresh. Where the turf is thin or poor it may be greatly improved by a liberal use of soot, or a thin sprinkling of bone manure or guano may well be given, the rains washing these in. It is not yet too late to sow a mixture of lawn grass seeds as sold by most seedsmen, this being a good method of improving thin turf. Stir the surface with a rake prior to sowing, cover with a little fine soil, roll frequently after the young plants appear, and mow with a scythe two or three times before the machine is put on. Grass is now growing rapidly, and unless the machine is used early it will be first necessary to go over it with a scythe.

THE BEE-KEEPER.

COMB OR EXTRACTED HONEY?

THE sale of sections seems to be gradually growing less. Comb honey of the best quality will fetch a fair price, but anything of an inferior character is hardly saleable at all. There are many reasons to account for the public taste, which seems to prefer the extracted honey to that which still remains sealed by the bees themselves in combs of spotless purity. The retail dealer has never regarded section honey with a very kindly eye, and we need hardly wonder that the less easily damaged bottle honey is preferable in his eyes to the more beautiful and very easily damaged honey in the comb. It is not every man of business who deals in honey who can find fit and safe storage for sections; and yet, unless he has a large demand, it very commonly happens that the goods will be damaged by exposure to sun, light, damp, or draught. They may be injured by the slightest fall, and dust will effectually tell against their ready sale. The bee-keeper, too, has some difficulty to contend with in the production of the peerless white comb which we sometimes see exposed for sale in window or case. He has to take special care when desirous of obtaining sections of good saleable quality, not only to keep the wood clean and white, but to prevent the possibility of the hard midrib, which is not seldom found in the produce of apiaries where no special care is taken to use only the very purest foundation of the most perfect thinness and make. A few days' want of care in neglecting to remove the finished combs will, in many instances, damage the product beyond possibility of remedy, while at the end of the season—and the end may come abruptly and without much warning—not a few unfinished sections remain to tantalise the bee-keeper when he thinks what might have been had the honey flow continued but a few days longer.

The production of comb honey in sections has, no doubt, increased to a wondrous extent during the last few years, but we do not think that the increase in the production of honey in the comb has been in anything approaching to equal proportions with that of run or extracted honey. Here, again, the reasons are, no doubt, manifold. The first that strikes us is that there are few bee-keepers who are able to produce with certainty sections of first-class quality—well sealed, well filled, clean and spotless. Others, again, knowing the difficulties they have to contend with, prefer to produce the more homely and more easily saleable article, even if they realise a 1s price for the produce when the time for selling it arrives. If the market for section honey once becomes really dull by reason of the supply exceeding the demand, or as certain bee-keepers would say, by reason of the supply not being distributed

among the population, then extracted honey will certainly be the more paying article.

These remarks are, of course, only preliminary to the deductions which we desire to draw from these facts; for facts they appear to be so far as we can judge. If a bee-keeper can secure a market beforehand for sections of good quality, or even if he can see his way to disposing of them, he may, unless he has the misfortune to over-estimate his market, with confidence turn his attention to the production of comb honey, but unless he has a considerable experience in doing so we certainly advise him to proceed with caution. Success will beget success. Failure may succeed success, and if it does the bee-keeper must then reconsider his position. Sections are so much more perishable in their nature, and so comparatively difficult to produce, that a practical bee-keeper will only attempt to produce them when the relative price of comb and extracted honey warrant him in the supposition that there is "something in it." With extracted honey at 6d., and comb at 8d., we should trust in the main to the latter, but if there was any real and seemingly lasting change in the relative prices obtained for the two articles, it would at once be our duty to turn our attention to the lower priced yet more easily obtained product. It may be we are wrong in thus sounding a note of warning; it may be that in certain localities the demand for sections is on the increase. We shall rejoice to hear that this is so, for honey in the comb has a far greater attraction for us than the more commonplace yet excellent extracted or run honey.

Whichever kind we desire to obtain, the method is the same as that which "A Lanarkshire Bee-keeper" and others have frequently pointed out in long past years when this Journal—the mother of principles in bee-keeping—held the field as a journal of advanced views in bee-keeping and kindred topics. I may be allowed here to offer an apology to "A Hallamshire Bee-keeper" for my apparent movement from a position which I took up a few months ago when laying down that, however honourable it was for a man to use his energies for the benefit of others, it was of no practical moment to the bee-keepers of to-day who was the originator of a given appliance, principle, or method, provided that they have the advantage of it. In writing on the introduction of queens quite recently a quotation was made from a work by Mr. S. Simmins of Rottingdean, not with the intention of awarding to that gentleman the palm of inventing the method, but simply because the language was terse and clear. It was careless, and has, no doubt, led to some little misconception; but the mistake was quite unintentional, as it is certainly not my desire to say that any individual was the first to discover the principle, since I have not sufficient time at my disposal to investigate a subject of such delicacy and importance to the originator of the principle, whoever he may be, and to his friends.

The discussion on queen introduction, although it has certainly been against the method described in Mr. Simmins' own words, has been both interesting and profitable, and when the fitting time arrives I shall not fail to make further experiments with a view to clearing up, for my own satisfaction, certain points which have been urged by those who are well able to speak upon the subject, and whose words carry great authority in any discussion on the best methods of introducing queens. If I find myself in the wrong I shall not hesitate to confess my error, and to thank those who have not only enabled me to see my mistake, but have endeavoured to set my feet on a pleasant road leading to certain success.—FELIX.

THE HALLAMSHIRE LAW.

IN the issue for April 19th our friend, "A Lanarkshire Bee-keeper," still asserts my law is not new. He was kind enough to write me privately to the same effect, and said Mr. J. Lowe's articles appeared in the Journal between 1862 and 1865. I at once began to search the *Cottage Gardener* and *Journal of Horticulture* from 1869 to 1870 inclusive without finding any trace of it. I did find, however, several advocating giving the bees sufficient time to miss their old queen before

offering them another, but this is not the law. The quotation from his essay, page 58, does not apply, as the whole sentence reads as follows:—"The only safe method of joining queens is to allow sufficient time to elapse, so that the bees miss the queen; then after that cage the alien queen in one of 'A Renfrewshire Bee-keeper's' cages, between combs, and on the third day if queen cells are in progress excise, after which, or should none be built, the queen may be released." Here we see the law is clearly not alluded to, as the presence of unsealed brood is implied, or where would the "queen cells" have come from "on the third day?" Our friend has also named the late Mr. Woodbury as the author, but his articles in the Journal just before he died clearly show that he had no faith in it as a safe and sure method; as he advocated dividing a strong stock, removing the queenless half to a fresh stand, so as to draw the old bees off, and cage the fresh queen for two days amongst the remaining young ones; this he recommended as the safest plan to follow. Therefore I cannot admit that he had grasped the law, for at the end of two days the old bees, left queenless and broodless on the old stand, would have accepted the fresh queen, even more surely and certainly with less trouble than the young half. When trying this plan in my younger days I was always very unfortunate, as every bee that could fly left the old stock hive and the brood as soon as they missed their queen, and so left too few bees to care for or keep the brood warm. When their old queen is left with them there is not this difficulty or risk.

I wrote our friend to inform him the result of my search, and saying I could not understand it at all. I know very well he has had the same idea for years, and has been so near the law as to advise in his articles that it was unsafe to liberate a queen if the bees had the means of rearing another. And even in his articles to the Journal as late as March 1st and 8th last, he advises the excision of all queen cells on the ninth day, and then caging the queen in one of his "safety" cages; this, it will be noted, is an application of the law. When I published it two years ago I quoted our friend as one who had been working it in a way though with a cage. Now while his cage is safe there are others that are not so, as I have pointed out in the Journal for April 12th; but the evil is this, everybody fancies a different cage, most of which allow eggs to drop through, and as they cannot see the difference they use them and so lose their queens. The law is to enable everyone to foretell the result, and so dispense with all cages, for to use a "safety" cage in a safe process is like fireproofing inflammable material, disinfecting disinfectants, &c.

Well, our friend kindly wrote back an explanation. Here is what he says:—"Your 'law' is not unlike a person cooking some savoury dish, putting things in their proper place and time, but at the same time I can see nothing new, further than the way you have put it, so that everyone can understand it. I believe your articles have thrown more light on this subject than all other writers have ever done." Now, if this point or principle is what he is contending for—viz., that there is nothing new in it, or nothing novel, except the way it is put, there is then no "bone of contention" between us, for we really agree. I know others have had the same idea, have deprived the bees of their queen and all means of rearing a successor, and successfully enthroned a stranger; but what have these people said about the most important element of time before offering them the alien? Why, just this. "Give the bees sufficient time to miss their queen," as quoted by our friend and Mr. Raynor; and as everyone has different ideas as to what is "sufficient," whether in time or money, therefore one may have given five or six days and succeeded; another may have not given as many hours, and so invariably failed, and if these happened to be big "guns" in the bee fraternity, then the idea would soon be scouted.

If I have explained the idea so that all may understand it and apply it with confidence and certainty, then it is to all intents and purposes "new." A thing or process may be new by simply eliminating some error. As to whether it is new, at least in its effect, I will just quote from a paper by the Rev. George Raynor, read on the 31st of July, 1886, before the British Bee-keepers' Association on "Queen Introduction," which was, some time after it had been published and discussed both in the Journal and the *B. B. J.*, in which it was hotly opposed by Dr. Walker and Mr. C. N. Abbott, its late editor.

Mr. Raynor's paper is published in the *British Bee Journal* for August 12th, 1886, and was freely copied into many other journals. From page 367 I make the following extract:—"The only other method of direct introduction which demands notice is that which is said to have been originally discovered by Huber—viz., that 'If a colony of bees have no queen and no means of rearing one they will invariably accept a fertile queen when presented to them.' This rule requires, of course, an absence of brood and eggs, which seems to be the only stipulated condition. No matter how many or how few, how old or how young the bees may be, or at what season of the year the introduction is made, it is bound to succeed." Then he says, "If anyone wishes to make the experiment, and has no objection to losing his queens and demoralising his bees, let him deprive a colony of its queen and its combs, and place it upon empty combs and those containing honey only. Give the bees time to discover the loss of their queen, and offer them another at the entrance or the top of the hive, and she will be at once seized and enfeebled, and either maimed and rendered useless or killed outright. This, and not a kindly reception, is what invariably takes place in my experience, and I have tried the method many a time in my earlier days—in those happy days gone by. Colonies which have been long queenless are the least disposed of all others to receive a queen." No one in the room questioned what he said, as all endorsed his statements.

The law had been much ventilated at that time, and as it is two years ago, and many will be inclined to try it this season, I think I cannot do better than copy it out, so that a comparison can be made with the part I have italicised—viz., "Give the bees time to discover the loss of their queen," which, as I have said, is no direction at all. In the law I have laid down forty-eight hours as the minimum, while if the queen is presented within twenty-four or twenty hours the result will always be as Mr. Raynor says, as Huber found out 100 years ago; while if an interval of forty-eight hours at least take place, and the conditions are as required in the law, I will defy anyone to show me a failure.

THE LAW REPEATED.

"If a hive of bees have no queen or means of rearing one (that is, have neither queen, eggs, unsealed brood, nor queen cells in their hive) they will invariably accept a fertile queen at the entrance or dropped in from the top, providing they have been deprived of such means of requeening themselves forty-eight hours.

"No matter how long they have queenless, or how old the bees may be, or what time of the year it is, nor even if fertile workers be present, unless they have begun to lay eggs no failure will ever result, so that there is no exception whatever to the law, nor must the queens ever be caged, the application of it can be varied scores of ways."

Surely there will be no difficulty in understanding and carrying out the above. Before I published it bee-keepers all the world over were crying out for a simple and safe way of enthroning their queens. I have not given them simply a "way to do it," but a law, so that they can manufacture their own "ways."

A CAUTION.

Some are asking if it is impossible to lose their queens when introducing them in accordance with the law, that I think I cannot do better than point out how queens may be lost, none of which prove the law to be wrong or liable to any exception. In 1887 I had a virgin Syrian amongst some black bees. They were not strong—four Woodbury frames. She was the only yellow bee in the hive. After she had been in a month I looked to see if she was laying. She could not be found, nor any trace of her. I looked many times with equal success, so I came to the conclusion they were queenless, and I dropped in a black queen. This was killed, which made me think at the time the law had exceptions. However, subsequently I found this identical Syrian in the hive laying. Since then I have seen many virgin queens take wing and fly away when opening the hive, and the novice might very easily think the hive was queenless when it had a queen; though she might be out somewhere when he was looking for her. When in doubt lift a comb out with adhering bees, put the queen amongst them, if she is balled then you may be sure they have a queen or means of rearing one. If the bees form a circle or ring round her, or move on one side to let her pass, or more particularly commence to vibrate their wings, which is quickly taken up by all the bees on the comb, then you may safely depend on it they were queenless.

Strong stocks, prepared in accordance with the law, during the time young queens are on the wing from nuclei, should always be treated thus to be sure, as such stocks will most certainly requeen themselves naturally in accordance with the law, at the expense of some other hive less strong than themselves. I have seen such cases every season, and though I can tell at a glance whether they have done so or not, still everyone may not be able to tell that way. I had a very annoying experience last summer. A stock belonging to a friend lost its queen; the virgin to take her place also getting lost, put the stock hopelessly queenless. He told me the bees were running about the front of the hive as if they were mad. I at once said if such was the case they were hopelessly queenless, and to oblige him I went to examine it. I found such to be the fact. It was very strong, all brood hatched, and the remains of some dozens of queen cells. Subsequently I gave him a Cyprian queen to drop in; this he found turned out dead. When he told me and showed me the dead queen, I at once said the stock had requeened itself at the expense of one of the others. I went to help him find it. I first opened the hive in question, when I found a fine hybrid queen that had just begun laying. This gave us a hint to examine the hybrid lots only. I pointed to a skep and asked, "When did that swarm?" "Three weeks last Sunday," said he. "Ah," said I, "the queen is from that." I tossed them a queen, they received her, all at once went into the hive, and in less than an hour were in full work providing for the brood the queen was laying eggs for.

In the fall or early spring there is not that risk of stocks requeening themselves in a natural manner, but still there is the risk of the stock, supposed to be hopelessly queenless, being headed by a virgin queen, which may perchance be on the wing. Only this afternoon, April 28th, I found two virgin queens in hives I supposed were headed with laying queens. Sealed brood were in both hives. I expected one queen being deposed early this season, as she was a very old one, but I know no reason for the other, as she was of last season's rearing. I at once removed these queens, and the stocks will be ready in two days to receive queens expected from abroad. I found a strong stock of Carniolians queenless, no brood or eggs. I suppose the queen had run out of the hive with the bees, when they turned out for their first airing. They very often do this, and this queen must have done this very trick last year, as I found her one morning about 20 yards from her hive. Being satisfied they were in the condition of my law to receive a queen, I gave them a Cyprian from another stock—which will have the queen cells destroyed on the eighth or ninth day,

to be ready to receive a queen from Mr. Benton—in about thirty seconds the whole stock set up a noise that could well be heard 30 yards off, so delighted were they. These were old bees, and I do not know how long they had been queenless.—A HALLAMSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

John Laing & Sons, Forest Hill, London, S.E.—*Catalogue of Begonias, Orchids, and General Plants.*

Corry, Soper, Fowler, & Co., 16 and 18, Finsbury Street, London, E.C.—*Illustrated Trade Catalogue of Garden Requisites.*

Hogg & Wood, Coldstream, Berwickshire.—*List of Farm Seeds.*

TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Pruning Roses (F. C. S.).—We do not publish the story, as it is not quite good nonsense.

Report of Auricula Show (W. B., Leek).—We are greatly obliged by your consideration, but a report of the Show was in type when your letter and enclosures arrived.

Watercress (Kins).—You will perhaps find the information you need in a reply to "W. P." Mr. Shirley Hibberd's pamphlet on this subject is, we think, published by Groombridge & Sons.

Odontoglossums (R. Pennell & Sons).—All the varieties sent are good, and two of them are excellent—namely, the broad fringed form of *O. crispum* and one of the *O. Ruckerianum* style. They are well worth preserving.

Flower Bed Design (Journal).—As a rule all the dark coloured carpet plants show to better advantage surrounded with a bright line of contrasting colour, the width to be determined by the size of the beds. A narrow margin of Golden Feather kept pinched would look well round the central mass of *Lobelia* and *Centaurea*. There is nothing to show whether the design embraces a number of panels for one large bed, or whether there are seven separate beds on grass or gravel. If the beds or panels are large enough they should all be margined with the most suitable plants that may be provided for furnishing the beds.

Stocks and Pansies for Spring (J. E.).—The East Lothian Stock would in all probability suit your requirements. You cannot sow them too soon now, and as your situation is exposed grow them in soil that is not rich. In February or the beginning of March a thick layer of horse droppings or cow manure laid about the plants and on the surface of the soil will cause them to develop good spikes. As you suggest, they will be easier managed sown in a box, thence pricked into pots, using very light soil, and when well established plant out where they are to remain and bloom. Sow the Pansies in June in a moist position in the open ground, and transplant to get strong for flowering. Thomson's work on the Vine is published by Blackwood, and can be had, if in print, through a bookseller. We think Taylor's "Vines at Longleat" is out of print.

Strawberries not Swelling (J. W. T.).—Fumigation directly after the fruit was set would affect the Strawberries prejudicially; indeed the cause of their becoming brown and hard is due to sudden drying of the atmosphere either by fumigation or a sudden influx of air, as not infrequently occurs on bright weather following a dull and cold period. Exposure to very bright sun after dull weather, particularly when the plants are near the glass, is also a cause of the fruit becoming brown and hard. The only remedy is a moist and more genial condition of the atmosphere. No amount of water at the roots will compensate for excessive evaporation from the fruit.

Swanley—the Gardeners' Orphan Fund (H. J. C.).—Although the notes referred to sound to you "more like a fairy tale than a sober statement of facts," as you believe them to be, it is a very stern fact that as much more might have been written, and must have been written, to give anything like a full description of the establishments in

question. Mr. Ladds continues to use his horizontal tubular boiler for heating his glass structures. We shall be very pleased to see you when you come to the Gardeners' Orphan Fund dinner, and to be of such service as we can to you and your friends. The Committee hope that as many gardeners as possible will bring friends with them on the occasion. The Fund cannot fail to do "much good, and meet a real want in the horticultural world," and you have the honour of being one of its originators.

Double Primulas (C. W. N.).—As you would see towards the close of Mr. Divers' exhaustive paper on the cultivation of these plants, the larvæ of the destructive weevil *Otiorynchus sulcatus* occasionally causes the death of some by eating their way from the roots into the stems; but we scarcely think this is the cause of some of your plants "going off." When they get old, or produce a good length of woody stems above ground, as in the example sent, the sap vessels become so contracted that they are no longer able to convey the requisite amount of nutriment for sustaining the plants in health. The leaves then fall, one after the other turning yellow and shrivelling. There is a correlative failure of root action, and disease culminating in death ensues. The fungus on the stems is not the cause of the unhealthy condition of the plants, but the result of it. Turfy loam and leaf mould or cocoa-nut refuse packed round the stems prevents their shrinkage, and the plants are kept healthy the longer.

Curtailing Boiler Flue (Verndale).—The "engineer" no doubt constructed the furnace on the principle that it might be required to burn coke, cinders and other description of fuel, and unaware that anthracite coal would be used. The principle in setting a boiler is to concentrate as much heat as possible on the boiler, having exposed to the direct action of the fire as much boiler surface as practicable. Contracting the flue over the boiler will only increase the draught, causing the heat not abstracted by the boiler to more speedily ascend the chimney; therefore, if you have plenty of draught it would be well to leave the flue as it is, so that as large an extent as possible of the boiler surface may be exposed. Top flues over saddle boilers are not, however, of much benefit beyond preventing the cooling of the boiler surfaces, assisting in maintaining the heat about the boiler, and are not employed with boilers that present a large surface to the direct action of the fire. Have you not a damper to regulate the draught?

Propagating Euphorbia jacquiniæflora (P. Banks).—The plants after flowering should be kept dry, but not so as to cause the wood to shrivel, and be cut back to firm ripe wood. From this shoots will push when the plants are placed in gentle heat, as they should be in March, and when these are between 4 and 6 inches long they should be taken off with a heel, the base pared smooth, and inserted about an inch apart around the sides of 5 or 6-inch pots, be placed in a gentle bottom heat and covered with a frame or bellglass, keeping them close, moist, and shaded from bright sun until rooted, as will be known by their growing freely; they must then be inured to the air of the house, and be potted singly and grown in a very light position. To prepare the cutting pots drain them with crocks one-third their depth, place a little cocoa-nut fibre over the drainage, and fill to within three-quarters of an inch of the rim with a compost of light loam, leaf soil, sand, and dust charcoal in equal parts, surfacing with half an inch of pure sand. Apply water through a fine rose, and an hour or two afterwards insert the cuttings, giving them a gentle watering. They should be inserted about a couple of inches deep.

Marking a Lawn Tennis Court (A Constant Reader).—For "single court" the width is 27 feet, and 78 feet in length. It is divided across the middle by a net, the ends of which are attached to the top of two posts, which stand 3 feet outside the court on each side. The height of the net is 3 feet 6 inches at the posts, and 3 feet at the centre. At the end of the court, parallel with the net, and at a distance of 39 feet from it, are drawn the base lines, the extremities of which are connected by the side lines. Half way between the side lines and parallel with them is drawn the half-court line, dividing the space on each side of the net into two equal parts, called the right and left courts. On each side of the net at a distance of 21 feet from it, and parallel with it, are drawn the service lines. The above are the dimensions given in "Lawn Tennis," by Lieut. S. C. F. Peile, published by Messrs. Blackwood & Sons, London. For "double court" the width is 36 feet, and within the side lines at a distance of 4½ feet from them and parallel with them are drawn service side lines, which are not drawn beyond the half-court lines. In other respects the "double court" is similar to the "single court" described above, but to aid the marker a diagram is necessary, for which you are referred to the work named above.

Watercress Beds (W. P.).—You do not say whether you wish to grow Cresses in or out of water. If to be grown in water the bed may be any length, the width being 9 feet. As you require a large bed a suitable size would be 260 feet long and 9 feet wide. The soil should be stiff, so as to form a suitable receptacle for holding water. A trench is made of the required dimensions, and need not be deeper than to secure a regular depth of water of 3 or 4 inches. In a stiff soil there is little difficulty in getting the trenches to hold water, but in a porous soil it is necessary to use clay at the bottom and sides of the trench, and when clay is used there must be space allowed for about 4 inches depth of good soil. In adhesive soil all that is necessary is to make the bottom quite firm, also the sloping sides, with a slope from one end to the other, so that the water will have a gentle run—*i.e.*, flow in at one end and run out at the other. The bottom being dry, water is allowed to run in to soften it, and this whether the soil is the original stratum or fresh.

Any good garden soil will do. The cuttings or small sets should be placed at a distance of 3 to 4 inches apart, and having roots they will grow away quickly, water being let in to keep the plants thoroughly wet. In the course of a week dress with well decomposed cowdung, spreading it evenly over all the plants, and press it down with a heavy board to which a long handle is fixed obliquely similar to a turf beater. The water is then raised to 3 inches, or better 2 inches at first, and never should be more than 3 inches. No further attention is necessary until gathering, unless weeds appear, when they must be removed. In summer the plants will afford a gathering every fifteen to twenty-one days, but in winter the gathering will be less frequent. After every cutting a dressing of manure—viz., decayed cowdung, about six bushels to the size of bed named, is given, spreading it over the plants and beating it down with the rammer before mentioned. In twelve months from planting the Watercresses they are exhausted, the manure forming a tolerably thick layer at the bottom of the trench, and tends to raise the level. This should be thrown out upon the border adjoining or separating the trenches, or otherwise employed as manure. The bed should be renewed annually. September is a good time to make the beds and to plant. For growing Cresses in borders a moist soil should be chosen, and shady but not with overhanging trees or shrubs. Dig the earth fine, and form a ditch all round, or trenches may be drawn with a hoe, and filled with water until it becomes like mud. Cover with an inch depth of drift sand, and then insert the slips 4 to 6 inches apart, watering well until established. They will be ready for gathering from in a few weeks. The shoots should be cut and not picked. Cresses grown in this way are not so mild flavoured as those grown in manured trenches in water, but the quality depends in a great measure upon the attention in watering, which cannot be too liberal. Some prefer the "land" Cresses, from their being free from aquatic insects.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (A. Lewis).—The Apple is Winter Colman. We do not know of a cheap pamphlet such as you suggest.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (F. S.).—Goldfussia isophylla. (W. P.).—1 and 2, Insufficient without flowers. 3, Send again when it is in flower. 4, Megasea purpurascens. 5, Francoea sonchifolia. 6, Alyssum saxatile. (W. J.).—1, Brassia verrucosa. 2, Begonia late-virens. (J. C. R.).—1, Narcissus incomparabilis Stella. 2, N. poeticus ornatus. 3, Anemone fulgens. 4, Anemone appennina. 5, Anemone nemorosa flore-pleno. (W. P.).—1, Dorianium caucasicum. 2, Ribes aureum. 3, Ribes sanguineum.

COVENT GARDEN MARKET.—MAY 9TH.

OUR market still keeps steady, supplies all round being good. Business remains the same.

FRUIT.

	s. d.	s. d.		s. d.	s. d.

SYSTEMATIC FARMING.

A PURPOSE and plan in agriculture, as much as in anything else, if well considered and entered upon with all due deliberation and care, should form the basis of successful practice, and we are certainly wont to accord respect to the man who so acts. But before trusting him entirely, and taking any of his proceedings as a guide for our own, it is certainly worth while inquiring if he achieves results at all commensurate with the apparent excellence of his system.

We fell into some such train of thought as this in our walk round the home farm before sitting down to write this article, for we had before our eyes the results of systematic farming, and we are bound to own they were unsatisfactory. We may explain that at Michaelmas, 1886, about eighty acres of arable land were added to the home farm. These eighty acres had been in the hands of a tenant who, upon the expiration of his lease, demanded a reduction of 50 per cent. upon his rent as an offer to re-hire the land. Such a concession was felt to be uncalled for, and so the land came in hand. Now the late tenant farmed about a thousand acres adjoining this land, all which was kept strictly under a four-course shift. He was an old practitioner who gave his entire attention to his work, riding over most of his land twice daily, and he had the reputation of being an excellent farmer. But to be quite fair, and judging solely from the results before us, we could not regard them as being worthy of praise, rather did we find much to which exception must be taken. The land was wet in some parts, and the whole of it was poor and foul with weeds. By judicious drainage and the application of manure a speedy remedy was found for the first two faults, but the third was by no means so easily set right, for some of the fields are so badly infested with Charlock that it will be a labour of years to eradicate it. This land, be it remembered, had been for many years under a rigorous four-course shift, for which, in addition to having a regular change of crops, the special advantage is claimed of being "summered," or subjected to a long fallow every fourth year, which means that it is left unworked, ploughed several times, and so it is said to be thoroughly rested and cleaned.

To take another example, we may turn to a farm of nearly four hundred acres which came in hand last Michaelmas. Knowing as we did that land so left is quite certain to be low in fertility, we have taken care that every field has had a full dressing of manure before a crop was sown in it, but we cannot so readily apply a remedy for foulness, and some of it is so badly infested with couch

grass that we found the bailiff much disheartened when we were there a few days ago. He was engaged in trying to get some twelve acres ready for sowing Mangolds, but the soil was so permeated with twitch that it was turned up by the plough in compact clods, and there was nothing for it but drying by sun and wind, and a free use of cultivators, rollers, harrows, and ploughs. All the labourers were at work, too, with forks wherever they could use them, and we hope by getting off as much twitch as possible before sowing, by having the rows so wide apart as to admit of a free use of horse hoes, that most of the weeds will be destroyed before midsummer. This farm, too, had been under the four-course shift for sixteen years, yet some of the land is more foul with couch grass than any we have yet had to deal with. The plea of wet summers cannot be advanced by way of excuse for this foulness of the land, for there never was a better opportunity for the destruction of weeds than we have had during the last three hot dry summers. No; it is just owing to the careless, easy-going practice so common to farmers, and, we may add, to the fact that two-thirds of them have too much land. Far better would it be for the man farming a thousand acres moderately well to reduce his holding by half, and to cultivate that in the best possible manner. Depend upon it his profits would be doubled, and prosperity would crown his efforts, despite low prices and foreign competition.

Shall we ever see the time when the nature of the soil and its treatment will be rightly understood and acted upon? How sadly is every effort at improvement clogged and hindered by ignorance and prejudice. There is still a majority of men of fair intelligence who regard the muck cart as an indispensable adjunct to good farming. If only the stern lessons of adversity tend gradually to teach them better, it is all we can hope for. Science or precise knowledge, tempered by common sense in combination with intelligence and energy, will no doubt eventually do for agriculture what it has done and is doing for so many other things. Above all things we must have thoroughgoing practice or our best efforts will be in vain. Is it too much to ask for land clean, dry, and fertile? Three very simple things are they not? Yet they are indispensable to success.

WORK ON THE HOME FARM.

May Day saw most of the Barley well above the surface. Weeds, too, were abundant, and wherever Clover or mixed seed were to be sown we decided either to hoe or harrow up the Charlock. With sun and wind the drills might follow in the course of a day or two, and then it would be well to follow with a light roller. Some farmers prefer using a heavy Cambridge roller, but we object to that because of the severe bruising of so much of the young plant. It is unquestionable that much harm is done to the Wheat plant too by using heavy rollers upon it after it is in full spring growth. The Wheat generally is a full strong plant, and we have only one partial failure of about 5 acres on a heavy land farm, and this has been drilled with Oats. Upon mixed soil the Wheat is so forward that several extra hands had to be taken on in order to get the hoeing done in time to avoid damage to the corn. This work is all paid for by the acre, at a price proportionate to the labour required, some hoeing being much heavier than other. In any case payment by measure and not by time is best in the interest of all concerned, and if a good foreman can be had we like him to select his own men and to be responsible for the work being well done. It always answers best to attack the weeds as early as possible, for growth proceeds with such rapidity at this season of the year that prompt action must be taken to keep abreast of the work. Corn hoeing began so late in the season that by the time it is finished the men will be wanted upon the Mangold land, where weeds are generally plentiful enough.

We laid down two pieces of land to permanent pasture last year; one was on heavy land, the other on medium rich loam. Upon the former we have only half a plant, and more seed must be sown; on the latter there is a full plant which is so forward in growth that we shall soon have the sheep and lambs in folds upon it. They will be passed over quickly in small folds and have trough food as well, and this process will be repeated as often as necessary till autumn. A field of Sainfoin sown last year upon rather poor land will be eaten down by sheep in folds shortly, we then intend saving the second growth for seed. The bailiff of that farm, upon receiving orders about the Sainfoin, told us he had heard that sheep folded upon Sainfoin would destroy it by "eating the heart out of the plant." We had to explain that the sheep must be in small folds—a hurdle to a sheep—and have a fresh fold every night. A field so folded, and then kept for seed last year upon the home farm, has now a fine strong full plant, forward in growth.

THE LATE MR. J. C. MORTON.

WE regret to learn that Mr. John Chalmers Morton died suddenly on May 3rd last. He has been Editor of the *Agricultural Gazette* since its commencement, and in the issue of this periodical for May 7th the following account is given of Mr. Morton's life and work, together with an excellent portrait.

"Mr. J. C. Morton was the son of Mr. John Morton, agent, for upwards of fifty years, of the Earls of Dueie, upon their Gloucestershire estate. Mr. John Morton married the sister of the celebrated Dr. Chalmers, and we recollect his mentioning, with obvious gratification, that, upon his introducing himself to an English Quaker gentleman who had spent some time in Edinburgh, and was an enthusiastic admirer of the great Scotch preacher, he had replied, 'Oh, I know all about you: you are a son of the Doctor's sister, and his favourite sister.' Mr. J. C. Morton was educated at the Merchiston Castle School, Edinburgh, of which his uncle (Charles Chalmers) was the head master. After leaving this, he attended some of the University classes. He made himself distinguished as the best mathematician among his generation of students; taking the first prize given for mathematics by the University of Edinburgh. At this time Professor Low was holding classes for agricultural students; and Mr. J. C. Morton's name was included among these. Before he reached his nineteenth birthday he was summoned home to undertake the direction, under his father, of the Whitfield Model Farm just established in the immediate neighbourhood of Tortworth. Here he acquired an insight into the best English (and Scotch) farm practice; and, as he was fond of asserting, went to the first meeting of the R.A.S.E., and, with two exceptions, to every subsequent one. In 1844 the proprietor of the *Gardener's Chronicle* (then edited by Prof. Lindley), determined to establish, in conjunction with it, the *Agricultural Gazette*; and they selected the young manager of the Whitfield Model Farm to undertake the post of Editor. He came to London in 1844; and 1300 consecutive weekly numbers of the paper were brought out, without a single break, under Mr. Morton's personal supervision. He then took a holiday for six weeks, and only twice since has he suspended the labours of his full, industrious life, to give himself the change of a brief visit to the Continent. He never seemed to wish for a holiday. He fulfilled, in addition to his Editorial functions, the duties of Inspector under the Land Commissioners; and, in his constant journeyings to and fro to visit new buildings and improvements (effected, on land estates, by the aid of the office, 3, St. James's Square) seemed to have found the 'differentiation' in his labours which served him in the place of rest or amusement.

"In 1885, with fifty of the most eminent men in their several lines, Mr. J. C. Morton brought out the *Encyclopædia of Agriculture*. He also, for a while—when the late Mr. H. Thompson occupied the post of ornamental editor of the R.A.S.E. Journal—did the chief work of an editor, contributing at intervals many papers of very real value, of his own writing. His paper—on the varieties of Wheat—is still the most complete treatise on this important subject. He also served for six years with Dr. Frankland and Sir William Denison, as the Royal Commissioners for inquiring into the pollution of rivers. Throughout a long and varied career, Mr. J. C. Morton, more than anyone we ever met, secured the confidence and good will of all whom he encountered. But it is not necessary to dwell on this feature of his character in these columns. How often has he told here himself of his encounters and conversations, of the queer people he has met with; and has he not proved to demonstration to what good purpose he could turn their quaint communications? It was characteristic of Mr. J. C. Morton that he never 'pushed himself,' though no one was more eager than he to recognise merit in anybody else, and to press the claims of deserving folk in every way that lay in his power. Much as he had to do, and much as he was forced to write, he always found time to go to the aid of anyone whom he thought required his assistance, and to send words of encouragement to those to whom he found that he could not go."

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 2nd.—Generally dull.
 - 30th.—Delightful spring day.
 - 1st.—Fine and generally bright till 11 A.M., afterwards overcast and gusty, with sunshine at intervals.
 - 2nd.—Fair morning with some sunshine; wet afternoon; bright in early afternoon, but wet again later.
 - 3rd.—Sunshine and showers.
 - 4th.—Cloudy till nearly noon, clear and fine after.
 - 5th.—Frost early, then bright and warm.
- Rather warmer, but still not up to the average, no high temperatures have yet been recorded.—G. J. SYMONS.

HOWEVER interesting the fortnightly Shows of the Society may have been in the exhibition hall at Westminster, it cannot be said they have attracted a large share of public patronage. It is doubtful if a number of small shows at short intervals represent a safe and sound policy; and certainly they do not impress visitors, who in these days of great efforts expect something more imposing. At the time of writing, preparations are in progress for representing the work of the Society on a larger scale and in a different position; and when these lines appear the result will be seen under canvas in the Temple Gardens on the Thames Embankment. A better site for a flower show could scarcely be imagined, and as the Lord Mayor is expected to lead the way, a large following should be insured, provided the present bright weather continues, but a falling barometer is not encouraging. We can only hope for the best—summer-like days, a fine Show, and a great success.

The Society's officials and friends have concentrated their efforts upon this gathering, and the opportunity has been afforded by the courtesy of the Treasurer and Benchers of the Inner Temple of utilising the garden in a most appropriate manner, and providing the citizens of London with a novel and beautiful Exhibition. The Inner Temple Garden contains about 3 acres of land adjoining the Thames Embankment, from which it is separated by ornamental iron railings. The greater portion is laid out as lawn, which looks as fresh and neat as that in any country or suburban garden. Near the Embankment and at the upper part are flower beds, now gay with highly coloured and varied Tulips, but which are filled at other periods with different seasonable attractions. The great popular period of this Garden is in November, when a glass house at the lower part of the ground is occupied with Chrysanthemums, to inspect which the public have been admitted for a number of years. There the late Mr. Broome won considerable fame in the cultivation of these plants, and there Mr. J. Newton has ever since provided an annual Show that has materially assisted in extending the popularity of Chrysanthemums as town plants. For some time free Chrysanthemum Shows were also provided in the Middle Temple Garden, both under Mr. Dale and Mr. Wright, but these have been discontinued in the past two years to the regret of many persons. During the summer months the Benchers of the Inner Temple also most generously throw the garden open during the evening, a privilege which many persons and children "in city pent" most heartily appreciate.

The Inner Temple Garden, therefore, possesses a special horticultural interest, though an exhibition of such importance and magnitude as that which will be opened to-day has never previously been held within its bounds. Historically, the Temple records, most briefly treated, would fill a large volume, for many eminent literary men and great lawyers have been, and still are, connected with it. One matter, however, is worth a passing reference—namely, the tradition perpetuated by Shakespeare that it was in this garden the Wars of the Roses originated. In his Henry VI. a scene is introduced in the Temple Gardens, where "the Earls of Somerset, Suffolk, and Warwick, Richard Plantagenet, Vernon, and another lawyer" indicate their respective favour for the Houses of York or Lancaster by plucking white or red Roses. As Mr. J. C. H. Flood remarks in his interesting little

work, "An Hour in the Temple," "the 'other lawyer,' like the fox in the fable who had caught a cold and could not smell, appears to have remained neutral, as a wise lawyer would under such circumstances. This incident is extremely effective in a dramatic sense, but it is founded on nothing more than coinage of the poet's brain, and there is no tradition in the case. It is an amusing scene, in one sense, for it seems to indicate that even so grave a project as a civil war could not be undertaken without 'counsel's opinion,' because there were two lawyers present, and the 'parties' had previously been talking matters over in the Hall. This, it appears, was not sufficiently private for such a discussion as they were pursuing, hence we may infer that in Shakespeare's time the Temple Garden must have been a far more secluded spot than it is now."

But we must turn to the preparations for the Show, which have kept Mr. A. F. Barron and his assistants busy for the past few days. Two marquees of most spacious proportions have been erected, one over 200 feet long and 30 feet wide, parallel with the Embankment, and the other at right angles with this, 160 feet long, 60 feet wide, and about 30 feet high. An area of something like 16,000 square feet is thus covered with canvas, and it will be seen how large a number of exhibits can be accommodated, but most judiciously abundant space will be afforded for visitors. In the entrance marquee, the right hand side will be mainly devoted to market growers' groups contributed by Messrs. May, Hayes, Sweet, Page, Poupert, Hawkins & Bennett, Rochford, Gregory & Evans, and others. These will be arranged upon the grass, a stage on the opposite side being filled with collections of cut flowers, Messrs. Barr and Son, T. S. Ware, J. Walker, and Collins Bros. contributing Daffodils and hardy flowers. A bright array of well grown plants may be expected here, and tastefully arranged with small useful Palms and Ferns they will afford some effective groups and a brilliant vista.

The other marquee will be occupied with larger plants, and there one side will be appropriated to Roses in pots from Messrs. W. Paul & Son, Waltham Cross; C. Turner, Slough; Paul and Son, Cheshunt; Jackman, Woking; and Rumsey, Waltham Cross. It is anticipated that fully 1600 square feet will be filled with Roses, and this alone will be an exhibition of considerable beauty. Upon the opposite side will be miscellaneous groups in competition and otherwise, while upon the centre stage the Orchids and other choice plants are to be arranged.

Baron Schröder, Sir Trevor Lawrence, Major Lendy, Mr. Phillbrick, Messrs. Sander & Co., and Mr. J. Cypher promise groups of Orchids from their valuable collections, while important contributions from Messrs. J. Veitch & Sons, B. S. Williams, J. Carter & Co., J. Laing & Sons, and H. Cannell and Sons will add to the interest of the Exhibition. Pelargoniums from Messrs. Turner & Hayes, Calceolarias from Messrs. James and Cannell, Caladiums from Forest Hill, and a collection of Channel Island produce from Mr. Munro, will all constitute attractive features. This large marquee if well filled will have a grand appearance, and such an experienced show superintendent as Mr. Barron knows exactly how to make the most effective use of plants and groups in a spacious tent.

The schedule enumerates twenty-four classes, including three for groups of plants arranged in a space not exceeding 150 square feet, from nurserymen, market growers, and amateurs respectively. To Orchids six classes are devoted, three being for groups of Orchids, one for a collection of cut flowers, and the other two for collections of Masdevallias, with Odontoglossums and Cattleyas, with Lælias. Roses in pots and cut blooms have two classes, Azaleas, Pelargoniums, Clematises, Palms, fine-foliage plants, exotic and hardy Ferns, hardy plants and Calceolarias, with the miscellaneous non-competing exhibits, which always occupy so large a space at shows of this character. It was originally intended to confine the Exhibition to one day—Thursday—but it was subse-

quently decided to extend it to Friday evening, and an ample opportunity will thus be afforded to all who are desirous of visiting a beautiful and extensive display of plants and flowers. The groups of Covent Garden Market plants will be specially worthy of inspection by gardeners in these days of plant growing for room decoration, as the best examples of culture will be represented. We understand the Duke of Bedford provides prizes for collections of "market plants," for which there will be spirited competition, and the arrangements are sure to be very effective, but of these prizes no information has been supplied to us.

We have pleasure in making this Exhibition as widely known as possible, though no request for its publicity has been made to us by the officials, nor did we see any bills or circulars referring to it till Tuesday afternoon. We know from the letters of correspondents that the existence of the Show was not generally known early in the week, and that gardeners coming to London to see the "Botanic Show" on Wednesday, made arrangements for Thursday in ignorance of the fact that an Exhibition under the auspices of the Royal Horticultural Society was to be held in the Temple Gardens on that day.

The Show will be opened to the public at 1 P.M. to-day (Thursday), the price of admission (by ticket) being 2s. 6d. until 4 P.M., after which, and on the whole of the second day, the admission will be 1s. The entrance is on the Embankment, and readily reached either from the Temple or Blackfriars station, the former being slightly the nearer of the two.

It should be added that the officials of the Royal Horticultural Society have been freely assisted by Mr. Newton, gardener to the Inner Temple Society, and every facility has been afforded in making the necessary arrangements.

NOTES ON VENTILATION.

To know how and when to ventilate can only be mastered by carefully observing its effects upon different plants, together with a thorough knowledge of the constitutions and requirements of the plants being treated. The quantity of air we can give a house of plants will also very much depend upon how we begin with them, and the time of year they are started into growth. A house of Melons, for instance, planted in January must of necessity make their growth with very little ventilation, and that helps to render their leaves thin and fragile, consequently they must be more carefully ventilated than those planted two months later, because, to begin with, the latter would have more light and air, which would result in a robust constitution, and hence be capable of enduring sudden changes of temperature with impunity.

There are very few operations more difficult to teach young assistants than that of ventilation, simply because they fail to realise its importance further than to prevent the rise or reduce the already too high temperature. Very much more than that, however, is included in "giving air," for the manner in which it is done often determines the difference between a healthy and a sickly house of plants, while it is certain we should hear of and see less mildew, red spider, aphides, and other insect pests if the ventilators were always rationally worked.

Like many other gardening operations, it is impossible to give detailed instructions for ventilating that can be strictly applied under all circumstances, hence only a few general principles can be pointed out, and some practical observations made upon them, while these will be useful in proportion as they are intelligently applied. Medical advisers tell us that it is not when getting hot, but when cooling, that the system is the most susceptible to chills, so that after getting hot we should try to reach the normal temperature gradually and uniformly, hence we should avoid draughts. Now, experience proves that these remarks are to a large extent as applicable to plants as animals, so that we do not think of taking plants directly from hothouses to the open air, but we prepare them for the change by "hardening them."

The fact that many plants can be grown so well without ever opening the ventilators proves that high temperature does not injure them, and the young gardener should bear this in mind when he has neglected to open the ventilators, and the temperature has run up 20° or 30° too high; he should remember that the evils which follow will very much depend upon how he manages the ventilators, and nothing should induce him to let in a large volume of cold air, not even the certain knowledge that his negligence will be dis-

covered. Far more care is needed in ventilating when the temperature has been allowed to rise too high than when ventilated at the proper time, because the air that would be comparatively warm, or just cold enough to be invigorating in the latter case, would be chilly and often productive of baneful results in the former. The aim should be, under such circumstances, to reach the normal temperature as imperceptibly as possible by opening the ventilators gradually. Not more than a quarter of an inch should be allowed at first, and this should only be at the top of the house, unless the bottom ventilators allow the air to circulate round the hot-water pipes before coming in contact with the plants. Even then the top and bottom ventilators should not be open at the same time until after the proper temperature be reached, for that would create a draught, which is always injurious, more especially to over-heated plants; indeed, according to our experience the bottom ventilators are better kept closed, except in houses where plants have finished their growth, or on very warm still days. They are certainly better closed in the early part of the year if we wish to be free of red spider.

But the rational use of ventilators is not to reduce but to prevent the rise of temperature beyond a certain point, so that on favourable days a little air should be admitted as soon as the temperature begins rising, and it should be gradually increased as required. Sudden checks must be avoided in fruit and plant culture, for nothing is more productive of insect pest and disease. We want if possible to supply our houses with fresh air without creating a draught, and without unduly lowering the temperature, but this can only be effected with the ordinary arrangements by the exercise of care and forethought. It may seem superfluous to say that more air will pass through an inch space when the wind is rough than would pass through a foot when it was still; but, self-evident as it is, we have often to reiterate it to our young assistants. The direction of the wind should always be noted, especially when it is rough, and if possible ventilate from the opposite side.

There are days, however, and we have had many of them this spring, when it is better to allow the temperature to rise considerably than to open the ventilators. There is nothing more trying for forcing than hot sunshine with a high scathing wind, or alternate hot sunshine and sudden cold storms, and that especially after a period of dull weather. On such days we prefer keeping the fires low and the ventilators nearly closed, with plenty of moisture, and for tender plants shade. This we find much better than opening the ventilators during such trying weather, which require very great care and constant attention, or, to say the least, an attack of red spider would be the result. Low span-roof houses are best ventilated through iron grates fixed into the wall a little above the ground line, and just under the hot-water pipes, and if more air be wanted open the doors at one or both ends as required. Plants very much object to a stream of air flowing directly on them; it often has the effect of drying and stunting them, and this cannot be avoided if top ventilators be used in low houses, hence the advantage of grates and opening the doors. Top ventilators, however, should always be provided, as they are useful during hot still weather.—J. H. W.

A CHAPTER ON CELERY.

"OUR Celery was not good last year" is an expression I have heard from scores of growers, but I am inclined to think this was more the fault of the grower than the Celery. Others say, "Celery requires a lot of attention to bring it to perfection." Here, again, I do not agree with them. It certainly needs attention, but very little sound cultivation is all that is required to bring Celery to the greatest perfection, it is often over-cultivated and sometimes neglected. Many understand that Celery requires a rich soil to produce fine heads, but this is no reason why it should be grown in little else than manure. I can remember the time when a layer of it was placed in the bottom of each trench to the depth of 9 inches or 1 foot, a little soil was thrown in, the plants placed in this, and they grew freely and looked well until we began to use them, when a sound stick was the exception and soft pithy growth the rule. Now not one-quarter of the manure is applied, that used is thoroughly mixed with the soil, and a "pithy" head is rare. This was giving it a "lot of attention" in the way of manure, but three parts of it was worse than superfluous. It looks well to have plenty of early Celery, and when fully grown by September some might think they were lucky, but on the contrary, as Celery is seldom used in any quantity until November and throughout the winter, and it is then it ought to be ready; but when matured before the summer is over and long before it is required much of it will be past its best, if not useless, whereas if only one or two rows were grown for the earliest supply, a few more for late autumn and a large quantity for winter and spring, the produce would always

be used when at its best. Good ordinary Celery may be grown in quantities in one trench. Four, six, or eight rows may be planted; but if first-class produce is desired not more than two rows should be grown in each trench, as this admits of its being earthed up so much better than when crowded. We grow most of ours in single trenches. The trenches are 1 foot wide, and a space of 18 inches is allowed from trench to trench. This is not such a waste of ground after all, as there is only 2 feet from row to row, and surely if good Celery can be raised as close as rows of Potatoes can be planted it is an advantage. In the case of winter Celery we have also found the single rows the best, as it is much more easy to protect single rows than wide beds.

We have not lost ten plants during the last half dozen years through the plants "bolting" prematurely. This I attribute to the care taken in watering them from the time they are visible until established in the trenches. Nothing is more injurious to young Celery plants than allowing them to become too dry at the roots. One overdrying is sufficient to cause half of them to bolt. If the weather is dry watering does not cease at the time they are planted, but if necessary they are watered until first earthed up, then they are safe. We do not water them every day, but the whole trench is well soaked once a week. This is ample to keep them in good condition.

Celery should be grown in firm soil, as this retains the moisture and causes the plants to grow robustly, which is always desirable. As soon as the plants are in, the soil is firmly trodden round them, and this is repeated if necessary before the first earthing up. Our earliest plants, which are now in the trenches, were raised from seed sown in a good heat, the seedlings being pricked out into boxes and hardened gradually. A sudden change of temperature is apt to cause some of them to go wrong, but if hardened like bedding plants no evil results follow. Of all the manures I have ever tried for Celery growing none equals that from an earth closet.

Every plant should be transplanted with a good ball of soil to the roots. When the soil is all shaken off them and only the bare roots remain, it takes them a time to recover, but if the soil is well retained about the roots they may be planted without the slightest check. Three or four years ago we thought to have some beautiful and clean Celery for exhibition. We sifted some very fine ashes and earthed up with these. The weather was very hot at the time, the ashes became quite warm, and the plan was a failure. A light soil quite free from worms is the best for earthing-up with. If grubs are present they will make rims on the stems and disfigure them, but by using a sprinkling of soot in the soil they may be avoided. We have wrapped a piece of stout grey paper round each stem before earthing-up slightly, in imitation of the "paper collars" for Celery once popular, and this is the best of all ways of keeping the sticks clean and preventing the soil getting amongst the leaves. The paper is left on, but as it is moistened and the plant expands it bursts and does not act as any impediment.

Frequent earthing is preferable to one or two large additions. If once the soil falls into the centre of the plant there is an end of a first-rate stick of Celery. No fuss need be made in rearing the latest Celery plants. They do not require artificial heat. When a frame is cleared of bedding plants, early Potatoes, sow the Celery seed afterwards. If there is no soil in the frame place a quantity there, but if any remains from the Potatoes level this down and sow the seed. If the seed is sown thinly, so that the young plants will have a little space to develop, they may be kept in the seed bed until planting time. Those who have no frames and who would still like to possess some Celery in winter may sow the seed in the open on and after this date. If in a warm situation the seed will soon germinate, and the plants will gain a good size for placing out in July, which is a good time to plant winter Celery.—
A. KITCHEN GARDENER.

GARDEN SPORTS.

WHEN the flowers of a plant raised from seed differ from the parent in form or colour it is customary to call it a "seedling," but when a bud or branch or a plant differs in like manner it is called a "sport." Of course the plant raised from seed is a seedling, and so are all others raised from seed, whether varying in character or exact copies of the parent. Would it not, therefore, be better to speak of those seedlings which differ from the parent as "seed sports," and those which arise from bud or branch variations as "branch sports?" The variation, whether from seed or bud, except in cases of fertilisation of flowers, artificial or otherwise, is presumably due to the same causes, but if this is not so I shall be glad if someone more learned than myself in these matters will point out the difference. We all know that the seeds of certain varieties of plants produce exact copies of the parent from which the seed is gathered, and others vary in a greater or less degree;

we also know that "branch sports" are much less frequent than "seed sports," and we cannot influence them, so far as I know, as we can in the case of "seed sports" by artificial fertilisation. There our knowledge seems to end. But I strongly suspect that in both cases any cause that tends to produce an abnormal condition of a plant favours the production alike of "seed sports" and "branch sports." I have come to this conclusion from a long course of observation and experiment, and will give a case of each in illustration of this view.

First of "seed sports." If we sow the seeds of a variety that has had no special cultivation, the offspring will probably vary but little from the parent, or not take the development in size, form, or colour that it would from a plant highly cultivated. This is recognised by our writers on gardening when they recommend those who are working for the improvement of races to gather the seeds from the most advanced varieties only, and, while endorsing this view, I would add, gather only from such as have been highly cultivated. In the first extensive sowing of Rose seeds which I made the seeds were gathered from varieties subjected to ordinary cultivation, and the result was but little variation or advancement. In successive sowings the seeds were gathered year by year from plants subjected to higher cultivation, and the variation and advancement continued to increase. This, be it remarked, was independent of artificial fertilisation; the seed sports seemed to be more marked as the result of high cultivation in the parent.

A curious case of sporting from seed came under my notice some years ago. In a border were grown side by side seedlings of *Petunias* and *Malope grandiflora*. One year a seedling *Petunia* produced flowers very similar to the *Malope* in form and marking, the leaves being those of the *Petunia*. So evidently was this the case that many practical gardeners casually remarked it must be a hybrid between the two. I submitted the flowers to the late Dr. Lindley, who rejected this explanation, but offered no other in its place. The spot had been occupied two or three years successively by *Petunias* and *Malopes* treated as annuals. This individual died after flowering without producing any seed, although every effort was made to preserve it. Some of your correspondents will, I hope, have something more to say on this matter.

Then as to "branch sports." *Camellias* and *Chrysanthemums* have hitherto given us the greatest number of "branch sports," but they are becoming more frequent amongst *Roses*. During twenty-six years, from 1850 to 1876, I met with but one "branch sport" among my *Roses*, and that was a branch of Mrs. Bosanquet, which produced red flowers. Now see how many "branch sports" have been produced over the last ten years, and others are continually coming into notice from different cultivators. It may be said this is due or partly due to the breaking of fresh ground by hybridising the so-called species. Well, admitting this to be a factor in the case, there still remains, it seems to me, a large residuum most reasonably accounted for by the highly nitrogenised manures on which *Roses* have been fed over the last few years principally with the view of getting large flowers for our flower shows. A case in point is the double scarlet Thorn. This was a "branch sport" from the double pink Thorn, and originated in a garden adjoining a garden to which I was a frequent visitor. The "sport" was a strong central branch of a young tree, forced, I have no doubt, into greater vigour and higher colour by the excessive richness of the sap, for the border in which it grew was loaded year by year with the richest manure. There is one fact worthy of notice as a point of difference between "seed sports" and "branch sports." The former seldom re-assume the likeness of the parent, the latter often do so; hence, unless "fixed" by cultivation their commercial value is somewhat less.—WILLIAM PAUL, *Paul's Nurseries, Waltham Cross, Herts.*

FLOWER FARMING.

A FEW notes on the flower production at Mr. J. Walker's Ham Farm were given last week, and the present chapter must be devoted to the Whitton Farm, which has for a much longer period constituted the head-quarters of the Daffodil and hardy flower market trade in that part of Middlesex. It is a district of market gardens, fruit, flowers, and vegetables being extensively grown round Twickenham and Whitton, and when the fruit trees are bursting into flower is a most agreeable time for spending a few hours there.

THE WHITTON FARM.

DAFFODILS.—The flowers gathered at Ham are transmitted to Whitton, where in spacious sheds numbers of women and girls are busily engaged in making up bunches and packing for market. The flowers are all carefully assorted and tied in neat bunches of a dozen each, so arranged that the flowers for convenience of packing all turn in one direction. Packing is delayed as late as possible, and the flowers are closely placed in shallow wooden boxes, no

packing material being employed ; a piece of paper only is laid over the bottom and sides of the box, and the flowers are covered in a similar manner after the boxes are filled. The flowers are stood in pots of water until wanted. If it is desired to hasten their expansion they are placed on shelves in a lean-to greenhouse ; and if, on the other hand, it is necessary to retard their development they are placed in a cool dark shed, where they remain perfectly fresh for some time if they were not too advanced when gathered. Cutting the flowers at the right time is an important point, and to accomplish this the beds have to be frequently examined, the boys chiefly employed in this work being soon trained to recognise the exact stage at which the flowers must be gathered.

Though there are only twenty-four acres at Whitton, the ground is so closely cropped that a surprising quantity of Daffodils and other flowers is obtained. The varieties at Ham have already been noted, but a much larger collection is grown at Whitton, representing the most distinct forms in all the sections, the special qualities and characters of which Mr. Walker points out with the exactness and enthusiasm of a connoisseur. Commencing with the large trumpet varieties some grand beds of *N. bicolor* Empress, Horsefieldi, and grandis are seen—a most valuable stock of these fine Daffodils. Another grand variety, Emperor, is similarly well grown, and it is found that this and Empress succeed much better in the heavier soil at Whitton than they do in the sandy soil at Ham, while the reverse is the case with Horsefieldi, which prefers a light soil, though it is not very particular in this respect. As a large light yellow variety in this section Emperor is far ahead, while as a dark yellow a similar place is accorded to maximus, a finely proportioned flower of rich colour. With a good stock of Horsefieldi, Empress, and grandis, a constant supply of flowers extending over a month is obtained, as they expand in the order named, though Empress is cut before Horsefieldi is exhausted. These are all represented by strong plants, which produce three and four large flowers to each bulb. Other beautiful varieties of the trumpet type that are reliable, distinct, and of good habit, are the following, named nearly in the order of their flowering. The Tenby Daffodil (*N. obvallaris*) and Troilus, which are very hardy and endure exposure to wind, sun, and rain admirably ; Ard-righ, Henry Irving, and Golden Spur are useful, the last named being a particular favourite. Captain Nelson and J. G. Baker are notable for their finely formed flowers. Dean Herbert, J. Walker, M. Foster, J. B. M. Camm, and Mrs. J. B. M. Camm are also amongst the best of the group.

To what are termed the hybrids, such as the Leedsi, Barri, Backhousei, Nelsoni, and Burbidgei varieties, numerous beds are devoted, and some exquisitely beautiful forms are included of the most delicate tints. To enumerate all that possess distinctive merits would make a large catalogue, but a few were noted as the best amongst the best. Nelsoni aurantius has a fine expanded crown, orange with a reddish tint ; William Wilks, one of the Backhousei type, has a white perianth and large gold crown ; Leedsi amabilis is very free, five to six flowers to a bulb, the perianth white, with a long creamy tinted crown ; Leedsi Beatrice has a white perianth and short creamy crown which gradually becomes white ; Leedsi Minnie Hume, a charming variety, delicate yellow crown and white perianth ; Leedsi Mrs. Langtry, white perianth and creamy yellow crown ; Leedsi Duchess of Westminster, very handsome, white perianth and pale yellow crown, and a large well-formed flower. Barri conspicuus and the graceful Burbidgei forms are all worth attention.

White Daffodils are in demand, and a large stock is grown, precedence being given to cernuus, but cernuus pulcher, Niobe, Colleen Bawn, Leda, Mrs. F. W. Burbidge, Mrs. Thompson, and Dr. Hogg are handsome, though some of these are a little delicate. In the interesting paper recently read before the Horticultural Club by Mr. Walker, he remarked that, "Of the hybrids the two I find the most difficult to grow and multiply are Dr. Hogg and J. G. Baker. I do not know who is responsible for naming these two weak varieties after two gentlemen possessing so much—what shall I call it?—fibre, grit, or will ; but I have a strong opinion that there should be some trace of the quality of the individual in the flower. As an instance of this incompatibility, Mr. Barr, in his book of 1885, has a single incomparabilis that he calls Wellington ; now imagine an incomparabilis with a flimsy perianth and called Wellington."

The *N. incomparabilis* varieties are most numerous, and even the greatest enthusiasts in Daffodil culture admit that there are too many. A few only are grown extensively, and the best of these were noted at the Ham Farm. Of *N. poeticus*, *ornatus*, *recurvus*, *grandiflorus*, and *poetarum* are chief varieties.

In the paper just noted Mr. Walker referred to an interesting subject, the reversing or change of characters in varieties when removed to different soil. In regard to *N. pallidus præcox* he says :—"It will be found that there are not two flowers alike ; it seems as if each one was a seedling, whereas the flowers of our Tenby

variety are all so much alike that it would lead one to suppose they had all originated from one bulb. It may be worth our while to inquire if we obtain any of our varieties from reversions. I for one believe that we do ; some persons are of the contrary opinion. It may be very difficult to get direct and trustworthy evidence on this point, although strong circumstantial evidence can be produced. I believe a change rarely takes place in the progeny of bulbs of one's own growing, but rather from bulbs received from outside sources that have been grown for a long time in soil altogether different in its nature from one's own. It would seem that it is when the bulb receives a violent change the old blood is set a-going. Mr. Dixon's opinion about Sir Watkin is that the bulbs he received in 1884 had been grown in the same place for quite eight or ten years. Those I obtained were planted in soil that had been broken up about two years previously, and had been meadow land for a long course of time. When they had flowered in 1885 we had one flower with an orange cup, which we call Lady Wynn. The same may be said of Mrs. Thompson, which I contend is a sport from cernuus pulcher. I have no doubt that the bulbs grew in the Aldborough Rectory garden from the time Leeds' collection was divided until the time of Mr. Nelson's death. It would appear that the greater length of time the bulbs are grown in one place, before being removed and planted in soil of a different nature, the greater the change that is likely to take place."

MISCELLANEOUS HARDY FLOWERS.—Though Daffodils are such a great specialty at these farms, they by no means have exclusive possession and attention. For instance, herbaceous Pæonies are cultivated in large quantities for cutting, and a selection of 100 named varieties, carefully reduced from all those obtainable, fill a series of large beds, and yield numbers of their showy flowers during the summer. Pyrethrums are similarly extensively represented, while Irises, German, Spanish, and English, are grown by thousands. Yellow Crown Imperials are flowering now, and the Turban Ranunculuses, which are grown in four colours, yellow, orange, scarlet, and white, are evidently thoroughly at home in long beds, where they remain throughout the winter protected only by a layer of litter on the surface. Tulipas of the Gesneriana and retroflexa types occupy much space, while of Liliiums there is a grand stock both of *L. candidum* and *L. testaceum* ; long rows of these two species under the fruit trees will yield a bountiful supply of their pure white and buff coloured flowers. The useful white Gladiolus Colvilli The Bride is another feature, and seems to be in the most vigorous health, while at the present time *Doronicum caucasicum* is yielding a profusion of its fine yellow flowers, the much taller and stronger *Doronicum Harpur Crewe*, which grows at Whitton to the height of 4 or 5 feet, being also expanding its flowers. Poppies and numerous other flowers are included to extend the supply and increase the diversity, but the principal features have been noted.

FRUIT.—The greater portion of the Whitton Farm is really an orchard of Apples, Pears, and Plums, with Gooseberries between the rows, and so closely cropped is the ground that enormous supplies must be obtained. The Gooseberries are vigorous fruitful bushes that are subjected to no systematic pruning beyond thinning the growths where too thick, or removing old exhausted shoots. Some thousands of bushes of Lancashire Lad are grown, and this variety is especially esteemed for market gardens where land is heavily rented, as owing to the erect compact growth of the bushes they can be planted closely together, and they do not encroach very much on the space between the rows ; moreover, the variety is very prolific. A few rows of Crown Bob are also grown, but in some districts this is almost exclusively relied upon. Between the lines of Gooseberries are rows of Lilies and Doronicums or Wallflowers, and in the more open spaces are Lilies of the Valley in large quantities, the Victoria and Wallis's varieties being the favourites. The former is much earlier, and is well advanced now, a considerable difference being noticeable in this respect between the two varieties, though they are equally fine in the size of spikes and flowers. Several houses, pits, and frames are devoted to Strawberries, 5000 plants of Sir Charles Napier being grown. These are now flowering or setting their fruits, and are promising a most abundant crop, which will come in at a time when such fruits bring a most remunerative price—namely, after the main stock of early forced Strawberries is exhausted, and will come in advance of the outdoor crops.

It will be gathered from the remarks in this and the previous article that Mr. Walker has developed an extensive business of a somewhat novel character, but this has only been accomplished by the most untiring energy, well directed enterprise, and *hard work*. From three o'clock in the morning until ten o'clock at night makes a long day, yet that is the routine at this time of year and until the season for lifting the bulbs arrives. That, again, is a busy and important period, then follows planting, and after that a little leisure. To carry on a business of this kind in face of the com-

petition of the present day requires a well constituted body and mind, unflagging industry, and something more than money interest in the work. Success comes to a few without an effort, or as the product of others' labour, but the most substantial commercial prosperity is seen in such establishments as Mr. Walker's, the result of independent intelligent perseverance.—L. CASTLE.

SUCCESSFUL ROSE GROWING.

OUR Journal is always interesting, last week more so than usual, because it contains a record of the above—that is to say, an attempt to grow Tea Roses, ending, after a slight struggle, in a resolution to discard most of them, and to grow *Maréchal Niel* only, and that on standard Briars. Well, this is success with a vengeance, not the sort of success I should care about; in my opinion it looks too much like failure.

Here we have several competent growers putting their heads together to examine the soil, which, by-the-by, is just about twice too deep. The Roses were on the *Manetti* stock, and, "strange to say," they refused to do any good. It would have been much more strange if they had grown and done well. The idea of anybody attempting to plant out Tea Roses on the *Manetti* stock and expecting them to do anything but fail, is amusing. The idea of competent men not knowing that the stock was in fault is equally so. We are told that *Maréchal Niels* are now growing and blooming well. These will continue in flower for a few weeks, and then—there will be about eleven months to wait for more blooms. No, I should not care for this, there is too much waiting and too little result. I want to see a few other Roses. I want blooms about six months out of the twelve. I want *Niphotos*, and *Catherine Mermet*, *Etoile de Lyon*, *Sunset*, *The Bride*, and ever so many others. I do not wish to disparage *Maréchal Niel*; but wait, "I say, look here, what's this big lump, this swelling? and see, there's one here too. Why, hang it, there's one on all of them." Enter the competent man—"Ah! that's a canker, no cure, they will all have to come out." Out they come, and then—what next?—D. GILMOUR, JUN.

ROSES IN WINTER.

To meet the wishes of some correspondents it will be necessary to add to the details already given to render any structure which may be erected or devoted to the purpose suitable to meet the more lengthened supply of blooms that may be desired. When the supply is lengthened into March and April a greater number of varieties may with advantage be grown, and the useful and beautiful Hybrid Perpetuals cannot be excluded from the list at that period. The structure must be so arranged that they can be accommodated during the flowering period, or even while they approach that stage. A house entirely laid out with beds on the side as well as the centre is not altogether suitable for the purpose. It would be better to have the house in two or even three divisions. Small houses may be objected to, but they are decidedly the most suitable for supplying flowers in succession during the winter and spring months, for then each portion can be treated according to the varieties in it and the purpose for which they are intended. When numbers of varieties are planted in one good sized house the whole of the plants are excited into growth when many of them would be better resting, the few flowers they would yield during the early months of the year would not give satisfaction. When the season has fairly advanced they will not flower so freely or grow so strongly as they otherwise would have done had they not been started into growth too early.

The first portion of the house can be planted, as recently detailed, with *Safrano* and *Isabella Sprunt* for flowering during December and January, with the old *Gloire de Dijon* trained under the rafters of the roof. No variety for the roof is better for that period, for whenever it is started into growth it is certain to flower. If the house is in any way lofty, say 8 or 9 feet from the floor to the ridge, an arched trellis should be formed over the central bed to which the Roses can be trained so as to bring them nearer the glass. If the house was constructed specially for the production of blooms for market it would be much lower, and no such trellis would be erected, the bush system would be adopted, and strong shoots trained as horizontally as possible to induce them to break strongly from the base when the necessary pruning was done.

The second portion of the structure if growing for market would be entirely planted with *Niphotos* on the same principle as the first division, with *Lamarque*, *Reine Marie Henriette*, and *William Ailen Richardson* under the rafters if I wanted variety; if not I should train *Niphotos* up that position, or plant it alternately with *Perle de Lyon*. If either of these was employed the others would be planted at the walk edge of the side beds, and cut away as the slower growing two occupied the space. These would be started to commence flowering at the end of February, and with good treatment would continue yielding flowers until they were plentiful outside. The earlier division would also do this. If this division was arranged for the supply of a private establishment the side beds would be narrow, wide enough only to

support those trained under the rafters. A stage to the front of slates resting on the second wall from the outside, and the front on angle irons supported with iron legs let into a stone to prevent their sinking. The stage should be covered with some moisture-holding material. On this Hybrid Perpetuals would be grown. To those named for the roof would be added *Belle Lyonnaise* and *Cheshunt Hybrid*. The centre bed only would be filled with Tea varieties, and these would include in addition to *Niphotos*, which would occupy about one-third of the space, *Rubens*, *Madame Lambard*, *Innocente Pirola*, *Perle de Lyon*, *President*, *Souvenir d'un Ami*, *Madame Falcot*, *Souvenir de Madame Pernet*, *Madame Angèle Jacquier*, and *Marie Van Houtte*. I am not sure whether *Sunset* will not supersede *Madame Falcot*. The *Bride* might also be tried in this division; it promises well, but it is yet too early for me to form a just estimate of its constitution.

If arranging a house for market purposes I should have no third division unless there were no other place for *Maréchal Niel*. If possible devote the whole roof of a house to this Rose; otherwise have a third division for this variety trained under the rafters only, with as much growth as allowed in that position between the rafter. This would permit a large amount of light to penetrate to those below. Now what would occupy the central portion of this division would depend upon the size of the other houses and the supply the second division would yield of *Niphotos*. If plenty of that, then this division would be exclusively devoted to the production of that old inhabitant of our gardens, *Général Jacqueminot*, which is without question the best and most satisfactory red Rose for the market that can be grown. For that purpose this variety is worth a house to itself, which if grown in pots would leave the house after it was turned out to be utilised for other purposes. If the alternative object was in view the variety named would cover the roof, side stages would be erected for Hybrid Perpetuals, and the centre again filled with Tea Roses. This time a more comprehensive assortment would be selected—*Grace Darling*, *Etendard de Jeanne d'Arc*, *Alba Rosea*, *Catherine Mermet*, a good Rose but rather shy, *Comtesse Riza du Parc*, *Duchess of Edinburgh*, *Jean Ducher*, *Madame Cusin*, *Madame Denis*, *Madame Hippolyte Jamain*, *Madame Willermoz*, *Princess of Wales*, *Souvenir d'Elisc*, and *Souvenir de Madame Paul*. The two first are practically new Roses, and both are valuable additions to the list of Teas. Both are strong growers with full blooms, the first being a pleasing pink and the latter white. *Grace Darling* flowers very freely and opens its flowers well during the months of October and November; the other produces buds freely at that period of the year, much after the style of the old and useful *Souvenir de la Malmaison*, but they are too full to open freely during the autumn months. It has a tendency to come green at that time of the year, but would probably improve in this respect if subjected to heat.

The following Hybrid Perpetuals may be grown for early forcing or for flowering during March and April, and all that are named may be relied upon as varieties that I have proved will do well in pots—*Général Jacqueminot*, *Louis Van Houtte*, *La France*, *Prince Camille de Rohan*, *Jules Margottin*, *Marie Baumann*, *Charles Lefebvre*, *Abel Grand*, *Magna Charta*, *John Hopper*, *Alfred Colomb*, and the old *Bourbon Souvenir de la Malmaison*. In preference to growing the whole dozen I would rather grow the first six and the last; if a pink other than *La France* is needed, *Abel Grand* would be included. *Magna Charta* is one of the earliest and freest flowering H.P.s that can be grown in pots, but it is scentless, and this is the reason it is not accorded a higher position in the list. Most of the H.P.s will do well in pots if brought forward under cool conditions to precede those grown outside, but some do better than others, and the following are reliable:—*Baronne de Rothschild*, *Merveille de Lyon*, *Duke of Teek*, *Madame George Paul*, *Bessie Johnson*, *Camille Bernardin*, *Victor Verdier*, *La Duchesse de Morney*, *Docteur Andry*, *Fisher Holmes*, *Senateur Vaisse*, and *Coquette des Blanches*. These are only given for the sake of variety, those named first are preferable.

The amount of piping needed for forcing Roses during the winter months depends upon the size of the structure. Frequently a flow and return 4-inch pipe will be ample, or it might have to be doubled. Sufficient should be arranged in each house so that an intermediate temperature can be maintained to keep the structure 55° during severe weather without being compelled to have the pipes hot. Dry heat from pipes is decidedly objectionable for Roses.—WM. BARDNEY.

(To be continued.)

FACTS ABOUT GRAPES.

FROZEN VINES.

No amount of frost appears to injure the exposed stems when the Vines are in a dormant state, but should they become frozen when the sap is liquified much harm may result. In this district last spring we experienced a series of exceptionally severe frosts, the thermometer falling on the night of March 16th to within 3° of zero. As may readily be imagined such a severe frost so late in the season proved most injurious, but under glass all we found injured was a rod of *Madresfield Court Grape*. This was in full leaf, and the bunches on the point of flowering. Directly the sunshine reached it the bunches and leaves all drooped badly, yet, strange to relate, a second rod from the same stem was not affected in the least by the frost. The roots of this Vine are entirely in an outside border, this being well up to the woodwork of the front of the

house, so that only a very short stem is exposed. Even this was supposed to be sufficiently covered with strawy litter, but events rather disagreeably proved we were mistaken in this respect. Both rods started from near the roots, but the oldest, or that injured, overlapped the other and thus protected it. It was not the roots, these being well covered, that were frosted, but the very short portion of exposed stem must have been frozen through, this causing the crude watery sap to swell and thereby rupture the sap vessels. It was thawed as quickly as possible, but for weeks the foliage had to be shaded, and even then flagged badly in bright sunshine. This convinces me that the injury was rather of a permanent character. True, we managed to save a few bunches, but these were not half so valuable as those on the uninjured rod, and the wood was also much smaller. This season it is breaking strongly, but it yet remains to be seen that it is quite recovered from the severe check received. I have seen Roses with their tops under glass and stems outside crippled by frosts, but these sooner recover than did our Vine. In the course of a conversation on this topic with an experienced friend in charge of a large garden in Kent, he mentioned having once found the whole of his Vines in an early house flagging badly after or during the prevalence of a severe frost. They were rooting in an outside border, and it was this, not the stems, that was badly frozen. Luckily so for him I should say, or the thorough watering of the border with hot water would not have restored the Vines and saved the crop.

If there are any persons who do not take the trouble to thoroughly protect the exposed stems and roots of Grape Vines, or indeed of any greenhouse climber or Rose, these instances ought to convince them they run great risks in not attending closely to this matter. The stems of both early and late Vines ought to be well enclosed with haybands, felt, or old sacking. If this is done neatly there is no necessity to remove them after all danger from frosts is past, as it is doubtful if the stems are not also better for being sheltered from cold winds and bright sunshine. I am not an advocate of the practice of smothering the border throughout the year, keeping it in a sour inert state. Unless prior to active growth commencing it is annually lightly forked over or loosened to the depth roots are plentiful, and renewed with a surfacing of fresh turfy loam and bone meal, or better still, either Thomson's Vine manure or Jensen's fish-bone manure, a frost would then do good, benefiting it much the same as it improves ordinary garden soil. No risks, however, should be run in the case of Vines forced or started before March, and these ought to be early covered by a good depth of dry leaves faced over with strawy litter.

HOTBEDS ON VINE BORDERS.

Are these of any real service to the forcer or not? I am disposed to think they are, and will give my reasons. The practice of forming a hotbed on an outside Vine border is old-fashioned doubtless, but I have never undertaken to prove all time-honoured customs are wrong, and have only fallen foul of a few of them. Probably the now very general practice of forming inside borders in the case of early Vines has something to do with the lapse of the practice under notice; but even in this case a gentle hotbed on the border is beneficial in starting the Vines strongly and in bringing roots to the surface. As it happens there are yet numerous instances where Vines rooting solely or principally in outside borders have to be forced so as to have the fruit ripe in May, June, or early in July. It is these that stand in need of being warmed at the roots, and unfortunately this is not very easily accomplished. A hotbed about 3 feet deep and formed with leaves and stable manure in about equal proportions will, in spite of the tendency of the heat to rise rather than descend, materially raise the temperature of the border. Then, instead of the crops being nearly matured before root-action actually commences, the warmth in the border will start the roots much earlier, to the great benefit of the Vines. Unless so assisted hard forced Vines rarely last long in good health, the falling off being first noticeable in the stems, these refusing to increase in size and usefulness. Hotbeds are also of great service in attracting roots to the surface, where I suppose we all like to find them, and in our case we can tell to a foot where they are formed. Not only are they of great assistance to the old Vines, but those newly planted, also stand in need of them. Supposing dormant canes are planted, these, whether inside or out, start and grow rapidly for a time, quite delighting those in charge. Then comes a sudden stoppage, and no more real progress is made till the roots are active. If the latter are lively by the time the stored up food is exhausted no check to top growth is experienced, and grand rods result the same season, hence the advisability of giving them the benefit of a gentle hotbed. Let me repeat "gentle hotbed," for in my younger days I saw a house of Vines ruined owing to the roots being killed by a hotbed the reverse of gentle. The Vines at the time were in flower and all suddenly hung their

heads, never to again properly recover. I was the first to discover the collapse, and the head gardener responsible found the cause. The hotbed had been formed with nearly all stable manure, and which had not been properly prepared. A change from cold to warmer weather caused the heat to suddenly rise, with the result already mentioned. If a hotbed is formed on a Vine border it ought first to be prepared as if intended for a Cucumber bed; stakes should be kept plunged in it and frequently examined. If these are found to be unbearably hot to the hand the centre of the bed ought at once to be opened out and the excess heat allowed to escape. Later on the bed may be restored to its former state and the heat further husbanded by having mats or more dry litter spread over the surface.—W. IGGULDEN.

GLADIOLI NOTES.

REFERRING to Gladioli notes by your correspondent "B.," May 3rd, p. 364, I have from time to time during the last fifty years taken in hand the cultivation and propagation of nearly every kind of bulbous plant grown in this country, more particularly the Gladiolus. We devote here annually upwards of twenty acres to its culture. Surely this is proof, if proof is wanting, that it must be a simple process. No bulbous plants that I know of, except the Narcissus and Snowdrop, which are weeds in the woods and fields in this county, are of easier culture. Our nursery grounds here are composed of clay on limestone, heavy loam on gravel, red sandy loam and black bog. On all these soils under good tillage they do equally well. We prepare the land by ordinary manure and deep ploughing in December and January. In February and March, or as soon as the land is sufficiently dry, we harrow it to get it into a good tilth. Early in March it is drilled with a horse drill 18 inches apart and about 4 inches deep. The roots are then planted in the ordinary way of planting Potatoes and covered with the hoe. The spawn is put in in a similar way by hand, the drills being only about 1 inch deep. The same process is carried out in raising corms from seed.

A great deal has been written about the well-ripening of the corms, disease, degeneration, and exhaustion. The first three complaints are not worth commenting upon; the last is easily understood by every successful horticulturist. If we want to rear a plant or a bulb to perfection, we must deprive it of the means of reproducing itself until it is fully matured. We should get few fully developed Dutch bulbs if the flowers were not plucked. The most congenial seasons for the Gladiolus are those accompanied with high temperature and moderate moisture; low temperature and excessive moisture are unfavourable. After all, without care and skilful knowledge failures are certain.

A word as to late varieties. Duchess of Edinburgh (Kelway) is undoubtedly the finest of all the hybrids. It increases freely and develops splendid corms. This, as well as Phœbus, Leviahan, Ala, Marsianus, and Sassia ripens well here, and are in perfection in the first week of September. If possible, we manage to get up all our corms before the foliage dies down. It would be a rare thing to see a corm perish from early lifting provided they are properly dried off. On the contrary, when they are left in the ground to die down, and are taken up in wet weather and stored in an unhealthy state unfavourable results follow.

One word more. Will your correspondent "B." kindly tell us where and when Messrs. Stuart and Mein were so successful, as stated in his article?—JAMES KELWAY, Langport, Somerset.

AURICULAS.

My friend, Mr. Horner, would have made a capital lawyer, for he can get up a case for a client in first-rate style, and I must not attempt a defence *in extenso*. Unfortunately I am not convinced by all he says on the subject of self flowers. I know that the outside public esteem them very highly, and probably the rougher and coarser they are the more would they admire them, just as I remember a lady going to see my brother's collection and especially admiring those beautiful ones with all the "pretty fluffy stuff amongst them," this being some cotton wool he had placed amongst some of his flowers which were going to be exhibited. These are not the kind of people whose judgment on the Auricula is to be taken into account. I acknowledge the beauty of the self, but I still maintain that they are behind the edged flowers.

I am very sorry not to have sufficiently admired my friend's babies, as I know there is no point on which people are so tetchy as about their own bantlings. I fear I have been guilty of as great a mistake as if I had told a friend that his child had red hair. Red! oh, dear no; auburn! It may have been the light, or rather the absence of it, which led me to see two shades in Laura, dear child! But it apparently struck the reporter of one of the gardening papers in the same way. As to Ebony, what can I do to make my peace? Honestly I did not notice it. I am sorry, for evidently my friend is not of the opinion of a coloured woman who was once in our workhouse here, and who, when a white

baby was born to her, was so glad that it was not black, for my friend seems greatly to rejoice in his nigger baby, and when I have the pleasure of seeing it again I hope it will be sufficiently advanced to receive my apologies.

As to the question of heat, Mr. Horner has detailed his practice, but are other growers so careful? I still believe that a good deal of the rank coarse growth and crumpled character of many of the blooms must be laid to the door of fire heat, it may be, injudiciously applied.—*D., Deal.*

CRYSTAL PALACE SHOW.

MAY 12TH.

THE summer Show at the Crystal Palace, Sydenham, on Saturday last, as usual attracted a large number of visitors, who found plenty to admire. Mr. W. G. Head has adopted a method of arrangement which may be termed the "extension system," in preference to the concentrated style of grouping the exhibits. When these are confined to a smaller area bolder general effects can be produced, but when a show is visited by some thousands of persons the disadvantages are very much against it. On the contrary, when the plants and flowers are arranged over a good portion of both naves with a series of groups round the centre transept, the exhibits can be much more readily inspected.

The season has been unfavourable to cultivators of specimen plants as well as in other departments, and the fine-foliage plants, particularly the Crotons, showed the effects in a deficiency of colour that marred their beauty considerably. Caladiums, however, as shown by Messrs. Laing & Son, Forest Hill, were an exception, as, though they were not quite at their best, the delicate markings of the foliage were well developed. Roses from Cheshunt, Slough, and Waltham Cross; Azaleas, Pelargoniums, Orchids, and stove and greenhouse specimen flowering plants constituted the chief features, together with large miscellaneous non-competing collections, very notable amongst which being the Daffodils and hardy flowers from Messrs. Barr & Son and T. S. Ware, with Mr. Bennett's and Mr. Rumsey's Roses.

The most successful exhibitor in the stove and greenhouse classes was Mr. W. Chapman, gardener to J. Spode, Esq., Rugeley, Staffs, who won the premier prizes both for nine and six specimens. His plants were large globular examples of *Erica Cavendishiana*, *Ixora coccinea*, *Tremandra ericeifolia*, *Dracophyllum gracile*, *Erica profusa*, *Anthurium Schertzerianum*, and others of the conventional exhibition character. Mr. H. James, Castle Nursery, Norwood, also competed in these and other classes, seventeen in all, but a large proportion of second and third prizes were awarded him, as his plants were not in their best condition. Azaleas were not fully out, but Mr. C. Turner's nine large and eighteen small plants which gained the first prizes in their respective classes were compact and well flowered specimens of the most effective varieties. From the same nursery came the leading show and fancy Pelargoniums, the chief amateur exhibitors of those plants being Mr. D. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, and Mr. F. Hill, gardener to H. Little, Esq., The Barons, East Twickenham.

The Roses in pots from Messrs. Paul & Son, Cheshunt, won first honours in the class for eighteen plants in 9-inch pots, healthy, well-flowered, handsome specimens of moderate size; Messrs. G. Jackman and Son, Woking Nursery, and Mr. C. Turner following. Mr. P. Perry, gardener to W. G. Rowlett, Esq., Woodlands, Cheshunt, was the only exhibitor of six Roses in the amateurs' class, and secured the chief prize for good plants. *Caleolarias* and *Gloxinias* do not demand special mention, as they were not in first-rate condition.

Orchids were contributed by Mr. James, who was first with nine plants and a specimen, and third with a group which seemed to have been arranged too hurriedly to do it justice; by Mr. H. Little, who had some excellent specimens in his second prize collection of nine; and by Mr. F. Cooper, gardener to Walter Cobb, Esq., Silverdale, Sydenham, who won the first prize for six plants.

Messrs. J. Laing & Son, Forest Hill, won premier honours for a bold group of miscellaneous plants arranged for effect, which had an imposing appearance at one corner of the transept. Palms, *Dracenas*, Crotons, and Caladiums constituted the background; choice Orchids, Tuberous Begonias, *Imantophyllums* and Azaleas furnishing abundance of colour. Messrs. Laing & Son were also first with nine Caladiums, which have already been referred to as characteristically fine specimens. Mr. A. Offer, Handcross Park Gardens, Crawley, competed in several of the classes for fine-foliage plants, showing large specimens, but not well coloured; and Mr. T. N. Penfold, gardener to the Rev. Canon Bridges, Beddington, contributed some excellent Ferns, which won him first prize in the class for nine. Mr. G. Parrott, gardener to W. Wright, Esq., Denmark Hill, being second to Mr. Offer in the amateurs' class for six Ferns.

In the bouquet and buttonhole classes Messrs. Perkins & Sons, Coventry, took the lead with their customary tasteful elegant contributions. Miss Hassell, Southfleet, Gravesend, was first with three vases of flowers, and Mr. Prewett, Hammersmith, gained a similar position with twenty-four bunches of cut flowers; Messrs. P. Perry, E. Chadwick, and A. Gibson gaining the prizes in that order for twelve bunches of flowers.

In the class for best brace of Model Cucumber, grown from seed supplied from Messrs. Carter & Co., 237 and 238, High Holborn, the first prize won by Mr. G. Collins, gardener to J. A. Rose, Esq., Wandsworth Common. Messrs. Sutton & Sons' prizes for the best six specimen *Gloxinias*, grown from seed or tuber supplied from Reading, were won by M. Jacoby, Esq., Lynwood, The Avenue, Gipsy Hill, and Mr. W. Monk, gardener to G. R. Higgins, Esq., Eastlands, Dulwich. For the

best brace of Cucumbers, either Sutton's Improved Telegraph or Sutton's Purley Park Hero, Mr. W. Monk was first, and Mr. A. Gihson, gardener to T. F. Burnaby Atkins, Esq., Halstead Place, Sevenoaks, second.

Extra prizes were awarded to Messrs. Barr & Son, for a group of Daffodils; Mr. W. Rumsey, for eight boxes of cut Roses; Mr. Thomas Ware, collection of *Narcissus* and spring flowers; Messrs. H. Cannell and Sons, for *Caleolarias* and *Mignonette*; and Mr. H. Bennett, for four boxes of cut Roses. First-class certificates awarded to Messrs. Barr and Son for *Narcissus*, Madame de Graaff, Leeds; Mrs. Langtry, incomparabilis Sir Watkin, bicolor grandis, Leeds; Duchess of Westminster, Barri Dorothy Wemyss, Leeds; Beatrice, incomparabilis Beauty, and bicolor J. B. M. Camm; to Messrs. J. Laing & Sons for *Caladiums* Charlemagne, Marquis F. de Albertas; to Mr. H. Bennett for *Polyantha* Little Dot; to Mr. J. Chambers for *Viola*, Snowflake; and to Mr. H. James for *Anthurium Schertzerianum sanguineum*.

EVENTS OF THE WEEK.—To-day (Thursday) the Royal Horticultural Society's Show in the Inner Temple Gardens will be open to the public at 1 P.M., and it will also be continued on the whole of Friday. Upon Friday the Whitsuntide Show at Manchester will be opened, and will continue until the following Friday. The Royal Horticultural Society's Committees will meet on Tuesday, the 22nd inst., at the Drill Hall, Westminster.

— THE WEATHER IN THE NORTH.—The week ending 14th inst. has not been a very genial one. With much brilliant warm sunshine there has prevailed more or less throughout cold northerly winds, and several of the nights have been decidedly frosty. The effects can be seen on the shoots of *Phloxes* and the young growths of *Roses*, the latter making little progress. In the southern counties the weather has been bright with cold winds and several frosts at night. We hear that the recent keen winds have injured *Peach* trees on walls severely, and several gardeners complain that the prospect of a crop of *Peaches* is practically ruined.

— HORTICULTURAL CLUB.—The usual monthly dinner and conversation took place on Tuesday last at the "Hotel Windsor," Victoria Street, Westminster, where the future home of the Club will be, and was largely attended. Amongst those present were the Revs. E. Handly, W. Wilks, and F. H. Gall, Dr. Masters, Mr. John Lee (Chairman), Messrs. Cousens, Moss, H. Turner, Girdlestone, Walker, &c. The Secretary stated that Mr. T. F. Rivers, owing to illness, was unable to undertake the subject he had intended to have spoken upon, "Peaches," but that Dr. Masters had most kindly consented to take his place and speak on the subject of "Sports," which he did, and illustrated his remarks by some specimens of *Conifers* received that day from M. Naudin's garden at Antibes. An interesting discussion followed, and was joined in by the Rev. W. Wilks, Messrs. Cousens, Walker, Lee, and others, and a very pleasant and profitable evening was spent.

— MR. THOMAS CROSSWELL, gardener to W. M. Bullivant, Esq., Homewood, Eden Park, Beckenham, writes:—"With my employer's permission I have sent you a sample of *VICOMTESSE HERICART DE THURY STRAWBERRIES* that we are now picking from. Our batch of plants of this variety was not potted into their fruiting pots (6-inch) till August 29th. Owing to the dry season we, like many more, were unable to obtain young plants earlier, and consequently the desired pots crammed full of roots were not in our case realised. In fact, at the end of the growing season, which for them was very short, I considered the prospect of a crop of fruit was very poor. Nevertheless, they are now carrying from ten to sixteen berries on a plant, and my employer has favoured me with the remark that "he thinks he has not seen a finer shelf of fruit." [The *Strawberries* are very good indeed, both as regards size, colour, and flavour. We have not had a better sample of the variety sent to us this season.]

— A PROFITABLE NECTARINE TREE.—Early Nectarines if of good size and well coloured realise high prices in Covent Garden Market. Mr. T. King, gardener at Devizes Castle, has just cleared a tree of Lord Napier which perfected eleven dozen fruit. The whole of these were sent to Covent Garden, the earliest fetching 36s. per dozen, the next 30s.,

and none less than 24s. per dozen. At these rates they pay very well indeed, as very hard forcing, or the expenditure of much fire heat, is not absolutely necessary. The Peach houses at Devizes Castle are in a very sunny position, and the trees are in a most healthy state, being more thinly trained, and better ripened in consequence, than is usually the case.—I.

— **NURSERY AND SEED TRADE.**—We are pleased to learn that an amalgamation is to be effected on the 1st July next of the two great nursery and seed firms, Messrs. Francis and Arthur Dickson & Sons and Messrs. James Dickson & Sons, Chester, the two firms having for some thirty-five years separately carried on most extensive businesses in Chester. Previously for many years the firms were in one, and known as "Francis & James Dickson." We believe that at the present time, although there are throughout the country several businesses carried on under the title of "Dickson," those of the name residing at Chester are the only ones left of the original Edinburgh family, several firms using the name not having anyone actually bearing it connected with them. The amalgamation now referred to will, we are informed, secure for the joint business the continued fullest personal management of those who have for so many years been so closely and successfully connected with the two separate businesses. To this statement we may add that upwards of forty years ago, before the division of the nurseries between the two families of the first proprietors, an old local nurseryman of Chester remarked to us that his father told him that "the nursery trade was 'done,' Wales and the surrounding district was planted, and very little more would be wanted. But," added our informant significantly, "Look what these Dicksons have done." It was an instance of the power of trade enterprise over trade apathy that the steady old time workers could not anticipate, and if they could see the nurseries of "these Dicksons" now what would be their astonishment? We wish the firms, soon to be re-united, a continuance of the prosperity that has been won by high-minded conduct and sound business enterprise.

— "M. C." writes, "In reply to your correspondent, Mr. Squelch, on page 382 *re* EARLY CUTTING OF ASPARAGUS, I do not consider it exceptionally early to cut Asparagus from the open on the date mentioned by Mr. Squelch. I live not more than half a mile from Mr. Squelch, and cut from Asparagus from the beds on April 15th, and have been cutting regularly since that date. My beds are not at all protected."

— "S." sends the two following notes:—"FRITILLARIA RACEMOSA.—This is one of the most uniquely coloured flowers amongst hardy plants in bloom at the present time. Unlike the indigenous species, *F. meleagris*, the flowers are, as the specific name denotes, produced in racemes, three or more being borne on a stalk, and as these generally expand simultaneously they present a very elegant appearance. The Fritillary that it perhaps most resembles in point of colour is that of the Fyrenaian species, but the scentless blooms are more bell-shaped, and the bright tinted green markings in combination with the varying shades of chocolate impart a very singular appearance to what is certainly one of our most uncommon-looking flowers."

— "FRITILLARIA MELEAGRIS.—Many of the meadows situated in the Thames valley are now embellished with blossoms of 'Snake's Heads,' as these flowers are popularly designated. In some places they are so abundant as to admit of being gathered in clothes-baskets full, and it is not an uncommon occurrence in the streets of Oxford and other places to see hawkers with them. If it were more generally known how easily these quaintly formed and prettily marked flowers are cultivated in pots more people would soon be familiar with them."

— At the last meeting of the WAKEFIELD PAXTON SOCIETY, held at the "Saw Inn," Councillor Milnes, the President, was in the chair, and Mr. Arthur Goldthorpe officiated as Vice-Chairman. There was a moderate attendance, and Mr. John Smith, the President of the Leeds Paxton Society, read an interesting paper on "The Daphne," for which he received a hearty vote of thanks.

— THE *Kelso Mail* recently announced the death of MR. WILLIAM THOM of Newton-Don, a horticulturist who was well known in the north. "Mr. Thom was a native of Linlithgowshire, having been born in the village of Carriden on the 25th of June, 1808. He was early apprenticed as a gardener in the vicinity of his native place, and subsequently gained great experience in his profession in the counties of Linlithgow, Renfrew, Perth, and Mid-Lothian. It was while in the

latter county, at Riccarton, that the famous Fuchsia Riccartoni was brought out under his care. He afterwards removed to East Lothian, where, at St. Germain's, he was head gardener to the late amiable Mr. William Anderson. It was while here that Mr. Thom became a notable exhibitor at all the great horticultural shows in Edinburgh and a terror to competitors. The single Dahlia, now so fashionable, then gave place to the double, and in its culture Mr. Thom found a congenial pursuit; and his success in it may be judged from the fact that he more than once carried off first honours at Edinburgh against all comers. At Martinmas, 1847, Mr. Thom went to Newton-Don, and for many years he continued to take a deep practical interest in the affairs of the local horticultural society. At Newton-Don his intelligence and energies were afforded wider scope than the garden merely. As land steward he showed a sound practical knowledge of the science of forestry; and his numerous friends among the farmers of the district have long been aware of his shrewdness and sagacity in the management of land and farm crops."

— **GARDENING APPOINTMENT.**—We are informed that Mr. Wythes, gardener to Lady Hatherton, Teddesley Park, Staffordshire, has been appointed to succeed the late Mr. Woodbridge as gardener to the Duke of Northumberland, Syon House, Brentford.

— **A SPRING DISPLAY.**—A border 20 feet long and 2 feet wide of *Triteleia uniflora* is now in perfection at Elford Hall, Tamworth. The border is one dense mass of delicate pink and white blossoms, and anyone once seeing them in this way will never again be satisfied with them in pots or in small patches in the open border. The bulbs remain undisturbed year after year. *Magnolia conspicua* trained against the mansion is covered with hundreds of flower buds, and in a few days will be one mass of rosy pink cups. The flower garden is gay with Blood-red and Belvoir Yellow Wallflowers, *Myosotis dissitiflora*, Alpine Auriculas and Polyantheses, and altogether has a very satisfactory appearance under Mr. J. Udale's charge.—B.

— **THE LOCAL GOVERNMENT BILL.**—Mr. A. H. Smee, who is a member of the Council of the Royal Horticultural Society, a Fellow of the Chemical Society and of the Epidemiological Society, a Fellow of the Royal College of Surgeons, also Chairman of the Beddington, Carshalton, and Wallington Conservative Association, has, after a close examination of the above Bill, arrived at the conclusion that it will, if passed in its present form, be decidedly inimical to the interests of occupiers of cultivated land, such as market gardeners, farmers, and owners and tenants generally in rural districts. At a low computation it has been estimated that the working of the county and district councils will cost the country at least £5,000,000 per year extra. As at present arranged the Government will pay about £3,000,000 of that, leaving a deficiency of £2,000,000 to be paid out of the rates. The present rateable value may be taken as £160,000,000, and thus the £2,000,000 mean practically an increase of taxation of something like 2d. in the pound, presuming that the estimate should prove a fairly correct one. Mr. Smee, however, thinks it may be greatly exceeded, and is of opinion that the Council of the Royal Horticultural Society should by the appointment of a special committee or otherwise, watch the Bill in the interests of cultivators, and take steps to prevent, if possible, a further burden being imposed on them that many are unable to bear. Mr. Smee has further printed some letters in pamphlet form addressed to Lord Salisbury and Mr. Bonsor, M.P., containing what appears to be cogent arguments against the Bill on the appointment of sanitary authorities. He suggests that the Bill should be carefully studied by committees of provincial horticultural and agricultural societies, with the view to its being well understood and its possible effect made known before it is too late to effect modifications that he thinks are needed on the grounds indicated. As this Bill is essentially non-political, and will be discussed irrespective of party feeling, we think it right to direct the attention of our readers to Mr. Smee's suggestions.

— IN the course of an interesting description of Chester-le-Street, Durham, the *Newcastle Weekly Chronicle* gives the following note on PROFITABLE VINE CULTURE. "The problem of profitable Vine culture in England has been solved by Mr. Joseph Witherspoon of Chester-le-Street. He has conclusively proved that by skilful management and untiring industry, Grapes, Nectarines, and Peaches can be raised in this country and sold at a price that gives a fair return for capital and labour. In view of this fact we have thought that a sketch of his vineries and a few details of his career may prove interesting to our readers. Joseph

Witherspoon was born at Hopparth Gardens, Chester-le-Street, on the 2nd of February, 1831, consequently he is now in his 58th year. In 1845 he entered on a seven-years apprenticeship with Mr. Wm. Stoddart, cartwright. He became editor of the *Chester-le-Street Times* in 1870, which post he held for eleven years, and it was whilst so engaged that he bought the plot of ground now the site of his vineyard known as the Red Rose Vineries. In 1834 his parents removed from the Hopparth to the Red Rose Hall Gardens, on the Red Rose Hall estate, where they resided for thirty-seven years. Collectively, the several vineries are 480 feet in length, average 19 feet in width, and for several years have produced 150 dozen Peaches and Nectarines, and 4000 bunches of Grapes. He has won many prizes for Grapes, including £5 for six bunches at the International Exhibition held at Edinburgh, but the victories that he remembers with most pleasure were winning the first prize in the Town Hall, Newcastle, only seventeen months after his Vines were planted, there being fourteen competitors, and the £5 prize at the show held in connection with the exhibition held on the Town Moor, Newcastle. But Mr. Witherspoon relies greatly on his method of marketing, by personal delivery. He makes sure that his patrons secure his Grapes with bloom as fresh as when hanging on the Vine. Save to visitors he takes no private orders, all his fruit being forwarded to agents in Newcastle. Mr. Witherspoon says that his success is due to unremitting study and close attention, coupled with the use of a hot-water boiler which he has invented, and which is known as the 'Red Rose Boiler.'

— NORTS HORTICULTURAL AND BOTANICAL SOCIETY.—At the last monthly meeting of this Society, held on the 9th inst., there was a large attendance. Cut flowers and flowering and foliage plants were exhibited, money prizes being offered for the first time for the most meritorious collections. Mr. Alfred Page (Hon. Treasurer) exhibited an excellent collection of hothouse ornamental foliage and flowering plants, including Gladiolus, Caladiums, Cyrtopodiums, Pelargoniums, Orchids, Masdevallias, Caladiums, and a fine sample of the *Dendrobium nobile*. Mr. W. H. Farmer (gardener, Mr. Attenborough) showed some magnificent pots of Mignonette, various cut flowers, and Roses. Mr. S. Thacker had a pretty display of delicate Orchid blooms, which were much admired. Messrs. Pearson, Chilwell, contributed a splendid collection of Narcissi and Daffodils, there being eighteen varieties, also thirteen varieties of forced Tulips and four trusses of a new variety of Pelargonium. Among the other exhibitors were Mr. Hallam, a collection of cut Roses; Mr. Massey (gardener, Mr. Bateman), a collection of Alpine Auriculas; Mr. Halford (gardener to Mr. Taylor), a fine spray of Cytisus; and Mr. C. J. Mee (Wollaton Hall Gardens), a choice collection of cut flowers, including a remarkably fine forced spray of ordinary white Lily, forced Lilac, and Wistaria. He also had a specimen of forced Rhubarb and Kidney Beans. The Judges awarded the prizes, which amounted altogether to £4, to the following exhibitors:—Mr. Page (gardener, Mr. J. W. Davis), £1 1s.; Messrs. Pearson (for Tulips), Mr. S. Thacker, and Mr. C. J. Mee, 14s. each; Mr. W. H. Farmer, 8s.; Mr. Hallam, 7s.; Mr. Massey, 5s.; and Mr. Halford, 1s. Illuminated certificates of merit, framed in oak, were presented to Mr. N. H. Pownall (Lenton Hall Gardens), and to Mr. H. Walker (Hardwicke House Gardens), for essays on the subject of "The Duty of a Gardener to his Employer," read at the April meeting of the Society. A certificate was also awarded to Mr. J. Taylor for specimens of Cinerarias and Primulas exhibited at the March meeting. An interesting discussion on the respective merits and cultivation of the various plants and flowers took place, Mr. Thacker being voted to the chair. Mr. Pearson gave some valuable hints with respect to the arrangement of flora for exhibition on scientific against artistic principles. In the early portion of the evening Mr. A. Morley, M.P., accompanied by Mr. Cyril Flower, M.P., visited the exhibition, and was shown round the room by Mr. E. Steward (Secretary). The Judges were Messrs. Gadd, C. E. Pearson, and Pownall.

— ENGLISH TOBACCO CULTIVATION.—The Judges appointed to determine the award for the prize of £50 offered, by the London Chamber of Commerce for the best specimens of British-grown Tobacco met last Friday in the Fenchurch Street Warehouse of the East and West India Dock Company. There were eleven entries submitted, but only four of these fulfilled the conditions of the competition so far as weight was concerned, the minimum quantity being fixed at 400 lbs. In the result these were placed in the following order of merit:—(1) Messrs.

James Carter & Co., High Holborn, W.C. (to whom the Judges recommended that the prize should be awarded); (2) Mr. W. L. Wigan, Larkfield House, Maidstone; (3) Sir Edward Birkbeck, Bart., M.P., Norwich; (4) Mr. John Graves, Church Villa, Skirbeck, Boston, Lincolnshire. Amongst the samples not intended for competition was a very fine lot of Irish growth, sent by Mr. John Cairus, 12, Windsor Avenue, Fairview, Dublin, which was much admired. Some specimens forwarded by Sir Spencer Maryon Wilson, Uckfield, Sussex, were also highly commended. None of the samples of Tobacco submitted were really in a merchantable condition, so that it would appear that English growers have a great deal to learn, especially as regards curing. A full and detailed report will be issued by the London Chamber of Commerce in due course, relative to the whole of the specimens submitted for competition, and it has been arranged that the qualities of the Tobacco shall be tested both chemically and for manufacturing purposes.

GARDENERS' ORPHAN FUND.

THE progress that continues to be made in the furtherance of this charity is very gratifying, and nothing but good can be the outcome of the exertions of friends on its behalf. A step in advance is now being taken on new lines. As the result of a special Committee meeting held on Friday night last, the following letter of invitation, which explains the object in view, was promptly issued to the growers of plants for Covent Garden Market.

"Dear Sir,—I beg to inform you that His Grace The Duke of Bedford, has very generously given his consent to an evening promenade being held in the Flower Market, Covent Garden, in aid of the Gardeners' Orphan Fund.

"The proposition is for the stand-holders to stage their market produce at an earlier hour than usual (the hour and day to be subsequently fixed), and to admit by special invitation the Members of both Houses of Parliament and their families, together with the *élite* of London society, to view their products.

"To carry this scheme out it will be necessary to obtain the co-operation of the stand-holders, and for that purpose a meeting will be held at eight o'clock, on Monday evening next, the 14th inst., at the "Hummus Hotel," Covent Garden, when your attendance is cordially invited.—Yours faithfully, A. F. BARRON, *Hon. Secretary*."

Though the notice was so short, there was an excellent attendance at the meeting; and J. R. Bourne, Esq., the Duke of Bedford's London steward, was unanimously elected as Chairman on the occasion. After Mr. G. Deal had lucidly explained the history, object, and working of the Fund, the Chairman expressed his great sympathy with the charity, and said that every facility would be accorded for carrying out the object in view, and ventured to assert that if the skilled cultivators gave their willing co-operation, that such a floral fête would be provided as had not been seen by the public of London, and which, in its way, could not be equalled in Europe. The following resolution was then proposed, and carried with spontaneity;—

"That in the opinion of this meeting, the Gardeners' Orphan Fund is in every respect worthy of the sympathy and support of all horticulturalists, and those present hereby pledge themselves to render every assistance in their power to successfully carry out an evening Floral Promenade Fête, suggested to be held in the Wholesale Flower Market, Covent Garden, kindly offered for the occasion by His Grace the Duke of Bedford."

A Committee of market growers was next formed to act with a Sub-Committee of the Orphan Fund to carry out the project, the former (with power to add to the number) consisting of Messrs. Hayes, Walker, Sweet, Munro, Poupert, with the Chairman of the meeting and Mr. J. Asbee, the Superintendent of the Market; the latter comprising Messrs. Deal, Dean, Barron, Wynne, Herbst, Richards, and Wright.

Mr. Asbee then addressed the meeting, and in a stirring speech expressed his belief that there is not a man in the Market who would not do his best in furnishing his stand for the occasion. The Flower Market can only be seen at its best by the public at daybreak, and few persons have any idea of the beauty of the scene. The vast majority of persons judge Covent Garden by its Central Avenue; they have never seen the great "Flower Market" furnished, and for the first time it will be opened in the evening of a day to be fixed on behalf of the Fund, in which he knew all the "growers" had great sympathy. They would display their enterprise and skill, and their fame would be spread by visitors to the coming feast of flowers.

Cordial votes of thanks to the Chairman and Mr. Asbee brought the proceedings, which were of an enthusiastic character, to a close.

A STRAWBERRY PUZZLE. FORCED STRAWBERRIES BARREN.

MAY I inquire if some of your readers can give an explanation of the large percentage of barren Strawberries here for the last seven years—viz., 60 to 80 per cent. of the pots proving barren? The number potted is 1200 each year. The varieties are La Grosse Sucrée, Vicomtesse Hericart de Thury, Keens' Seedling, President, and Sir Joseph Paxton. Outside they fruit well, but in pots they fail largely. They have been tried under every condition of soil and pot we could think of—viz., in

5½, 6½, 7 and 8-inch pots; in double pots—viz., 7-inch plunged in additional material; in 8-inch pots; in the top spit of a fine clay pasture; in ordinary soil; in a fine clay pasture, top spit decayed, and one-third cow manure added; with and without liquid manure made of horse dung, and a small quantity of soot weak twice per week, with plain weak guano water. Two hundred two-year-old plants were tried with a like result. They have good heat, 60° to 70°, and abundant moisture, three to four times a day, are near the glass, quite close to it, in a special Strawberry house.

The runners are not taken from barren plants, but from fruiting plants, sometimes raised in 5-inch and sometimes 6-inch pots; they have plenty of sun and air (3-foot alleys), and are repotted. Runners are taken sometimes from two-year-old plantations, and at other times from four-year-old plantations. We cannot discover the cause of the failure.

well as to many others that possess sufficient merit to insure them a permanent place in gardens. When trained to the roof of a greenhouse or conservatory, and bearing its long pendulous dense racemes of brilliant blue flowers, the beauty of this charming Leguminous plant can be fully appreciated, especially if it be associated with climbers bearing lighter or distinctly coloured flowers, as the contrast shows it to better advantage. If planted in a border the soil must be specially prepared, a compost of peat, light turfy loam, and sand being suitable, providing good drainage, whether it be grown in a pot or border, as, like many of its relatives, it cannot endure stagnant moisture about the roots. Some care, too, is needed to keep the plant free from insects, particularly

FIG. 52.—HARDENBERGIA COMPTONIANA.

Can any of your readers suggest a probable cause and remedy? Seven next years ago we had magnificent crops, but the same man failed the two succeeding years, and all trials by others since are failures.—T. J.

[We shall be glad if our Strawberry-foreing readers will state their views on this case in compliance with the desire of our correspondent.]

HARDENBERGIA COMPTONIANA.

FOR many years this plant was generally known as *Kennedya Comptoniana*; in some gardens or nurseries it still bears the same designation; occasionally, too, it may be seen under the generic title *Glycine*, but that given above is the one now adopted by most botanists, and is gradually supplanting the others. It matters little, however, in a horticultural point of view what name a plant bears. "A Rose by any other name would smell as sweet" is a truism which applies to this as

mealy bug, which has a great liking for it. Little pruning is requisite, except to remove the old bare or weakly shoots.

The flowers, though small, are borne in such dense racemes that their size individually is scarcely noticeable. The petals, keel, and standard are bright rich blue, the last-mentioned portion of the flower having a ring of white at the base, which renders by contrast the blue colour even more intense. The racemes vary from 4 to 6 or 8 inches long, but they do not often reach the largest size, except in old established plants, and young specimens are sometimes rather shy in flowering.

Hardenbergia Comptoniana is a native of Australia, and was introduced to this country early in the present century. The woodcut (fig. 52) represents a spray from an established plant, and well shows the chief characters both of flowers and foliage.

CANTUA DEPENDENS.

SEVERAL Cantuas are grown in gardens, the best known being *C. buxifolia*, and a new relative of this is *C. dependens*, shown in fig. 53.

flowers are then seen to greatest advantage. In this way Mr. Ross grows *C. dependens* at Pendell Court, and the fine flowers he recently showed at the Royal Horticultural Society's meeting, as represented in our

FIG. 53.—CANTUA DEPENDENS.

They are all evergreen plants from Peru, and allied to the Phloxes and Polemoniums of our borders, though differing from them widely in habit. The Cantuas require a greenhouse temperature, and seem most at home when planted out and trained to pillars or walls, as their long drooping

engravings, amply indicated the success of the system adopted. The flowers have an orange red coloured tube, with bright rosy crimson spreading lobes, and they are produced freely from the axils of the leaves, being somewhat clustered at the ends of the shoots. A compost

of light turfy loam, sand, and peat, or leaf soil, suits the Cantuas admirably, whether grown in pots or planted out.

THREE GOOD POTATOES.

It may be late to write about Potatoes after the planting is practically completed, still there is time for planting for raising a stock of tubers in the autumn, not for use, but further planting; therefore a brief record of experience with three of the newer sorts may just be in time to be useful.

On light soils M.P. is one of the best second early varieties that can be grown. Planted with the main crop of Myatt's it is ready to dig and be eaten when they are ready. When large enough, even before the skins are set, it is highly presentable when cooked, being very white, mealy, and in quality all that can be desired. Last season it cropped heavily with us, and although the haulms were dead before rain came there were very few small tubers. This should prove valuable for market purposes. Although ripe and ready for use early in the season it is perfectly good until the end of the year.

Welford Park, a very strong-growing late kidney variety, cropped heavily with us. The tubers are excellent in quality, and the ground was full of them, the rows 2 feet 3 inches apart, and the sets a foot asunder.

Chiswick Favourite, if I judge rightly, has a future before it, and will, I venture to predict, supplant for field culture the well-known and largely cultivated Scotch Champion. It is too robust in growth for small gardens. The crops were heavy, tubers large, round, and the eyes shallow. The quality is all that can be desired, and although the tubers have grown large I have only cut one that showed the least signs of being hollow in the centre, and nearly all are well-shaped.

The last season pointed out valuable lessons, and the observant may and should profit largely in the future. Those who worked the land thoroughly and applied manure liberally had the best of it last year, for high-class culture showed itself unmistakably in both the field and garden. We had nearly double the weight of Potatoes from land that had been trenched over that which had been dug only one spit deep, though the last had the benefit of position. Both were planted at the same time with seed of the same variety. The contrast was so striking that we trenched deeply for the next autumn crop. For cropping with Potatoes more of the bottom soil may with advantage be brought to the surface than would be wise for many crops. A crop of Potatoes with Brussels Sprouts, or Autumn Giant Cauliflowers, planted between the rows gives the soil turned to the surface every chance of being sufficiently crumbled and in good condition for any crop in the following year.—WM. BARDNEY.

ARTIFICIAL MANURES.

I CANNOT refrain from congratulating Mr. Coomber on the evident earnestness with which he has set about clearing away some of the dust that for a time obscured the main points of this controversy, and as he has fully impressed upon my mind the importance of tracing every effect to its cause, I will endeavour to bring that principle into action by trying to find out the cause of so much "dust arising." After duly considering the facts of the case I come to the conclusion that in this instance the cause is the inconsistency of some of his statements in the first place, and also by the placing of too high a value upon a rudimentary knowledge of chemistry, his observations conveying the idea that a smattering of chemistry is more to be depended upon than a large amount of experience. I fully believe in the principle that competition and legitimate criticism are often the incentives to progress, and I trust that this controversy has caused us to reflect more thoroughly on the means we take to obtain the object in view, and ascertain by the help of hard facts how far theories can be reduced to a practical system having advantages over practice already proved to be good. Now, my opponent and myself are travelling in the same direction, as I fully recognise the importance of chemical knowledge in our treatment of plants and crops, but we differ considerably in our manner of putting that knowledge into practice. I am perfectly willing to abandon the well-tried method of giving plants at certain times a change in the form of the manure supplied to them, provided I have absolute proof that I can obtain better results by other means, and I hold it is altogether illogical to do so until then. My views are perfectly in accord with his when he says I oppose being contented with such clumsy and blind methods of supplying plant food. But I think it will serve no useful purpose to aim at such nicely proportioned chemical combinations as my opponent advocates, as scientific research has proved that in some cases only 10 lbs. and in others 50 lbs. of phosphoric acid put into the soil is taken up by a given crop, and it is quite unknown why this is so. It also shows that it is not necessary to measure out phosphoric acid and potash, for reasons I shall presently explain.

Your correspondent asks, Does the constitution of a plant improve because its bulk increases? My answer is, Yes, provided that plant has within its reach a sufficient quantity of the principal solidifying agents, such as phosphoric acid, potash, &c., to supply the drain that is made upon its resources when building up that growth, and also that the weather is favourable for ripening it. This is, I consider, the rock on which the arguments of my opponent split. He does not take into consideration the various stages of growth that plants pass through, and the condition they are in at the time manures are applied, and this is quite as important as placing the right kind of food within their reach. There is a right and wrong time for applying certain portions of plant

food. On these lines gardeners have been working in the right direction when giving weak liquid manure at first, and gradually increasing its strength as the strain on the energies of vegetation becomes the greatest, and then gradually withholding it, or rather certain parts of it, as that strain is lessened. The aim of gardeners is to produce the greatest possible bulk (consistent with good quality) in a given space, and to do that we must have vigour, and that vigour should be limited in extent to the amount that can be properly ripened and solidified. This is not regulated by the influence of phosphatic substances alone, but also by the influence of light, air, and water, so that in addition to the food plants receive from the soil they depend in a great measure upon light and heat. In wet cold seasons garden and farm crops should not receive so much highly stimulating food as in bright ones, and if food is given upon the lines I am about to state this difference can be more easily adjusted than by what I will call the "properly proportioned combination theory." The results of the latest scientific investigations show that the true system of manuring plants is this, that we should give to the soil phosphoric acid and potash, and all other solidifying elements, paying the greatest attention to the two named, and in doing this no waste will result, because the soil has the power of retaining within itself for the use of future crops that portion of these elements not required for the use of the present one, and Nature has so ordered it that the amount of growth made by vegetation is regulated by the supply of nitrogen at its command; but soluble nitrogen should be measured out to the plants, and not be given in excess, because the entire supply is at the disposal of the plants even in times of the greatest need.

A knowledge of these facts enables us to supply plants with the right food at the right time, and also shows us that such stimulants as nitrate and guano and ammoniacal manures in general can be applied at the wrong time, as they are quick in their action on vegetation, and if more is given than the plants can assimilate in a given time it is simply waste, as water soon washes it from the reach of the roots, and in cases where the soil is not kept moist it may kill many of the tender roots. A want of nitrogen can be determined by the eye, as plants that have not a sufficient supply within their reach become pale and sickly in colour and stunted or feeble in growth; but such is an extreme case, and a supply of that element should be given whenever the result of daily observation shows that the encouragement of more vigour is desirable; but how much more vigour is desirable, and what quantity of these stimulating substances is required, can only be determined by actual experience. Our aim must be to produce such vigour in each particular plant as we have seen attended with the best results, because the amount of vigour from which the highest results are obtained are fixed by climate and weather, and therefore the varying conditions of these elements in each particular season must be taken into account. Here, then, is a simple and practical way of putting the science of chemistry into practical use in such a manner that the powers of keen observation with so much utility to gardeners can be brought into full play.

My views are fully in accordance with those of Mr. Coomber concerning the onward march of gardening, and I also fully recognise the importance of not being contented with blind and clumsy methods of carrying out our aims. But we must not go the other extreme and take it for granted that because theory tells us a certain thing should be so, that such is the case; the true test lies in proving by the help of hard facts which of the two confers the greatest advantages. These experiments must to a great extent be carried out by special investigators, as it is too wide a field of labour for gardeners (their time is too much taken up in attending to and arranging the practical details of gardening), till the result of the experiments already pointed out can give them simple and sound principles to work upon.

In support of his ideas my opponent puts forward the statement of an American cultivator of the Camellia, when he says that he has been using for some time a certain artificial manure for plants that have been in the same pots for ten years, and they are, he adds, as healthy and vigorous as recently potted plants, and so long as they remain in that highly satisfactory condition no one would think of advising him to change, as there are exceptions to every rule, which are often the result of special circumstances of which we have not the full particulars. As a set-off against this I will give an instance in support of what he calls my "pet theory." I recently saw an account of the splendid Eucharis house at Gunton, where Mr. Allen grows these plants so well, and in the remarks on their cultivation it states they had been fed with liquid manure made from cow or sheep's dung, and guano for a "change." Mr. Coomber not having attempted to put forward a cogent reason why plants so frequently become candidates for the rubbish heap when they pass from the hands of the market grower into well managed private gardens, I will give my ideas on the subject. They are doubtless fed with strong stimulants regularly when in market growers' hands in order to produce plants of large size in small pots, and by the time they change hands they are quite dependent on these regular supplies of food; yet in nine cases out of ten nothing but clear water is given without any gradual system of reducing such rich food being resorted to. The change is too sudden, and the result what may be expected. In my original article on this subject I pointed out the importance of gradually withholding stimulating manures from plants intended for decorative purposes. Before concluding I must touch on one other point. Does nitrate of soda leave the soil in an exhausted condition, as my opponent has contended throughout this discussion? This question has been dealt with in a work by Professor Paul Wagner, translated by G. G. Henderson, from which I will give an extract.

Is it true that manuring with nitrate of soda causes an excessive absorption of phosphoric acid and potash, and thereby diminishes the fertility of the soil? Though the opinion that nitrate of soda exhausts the soil very much, so that succeeding crops grow badly, and therefore that the advantage of manuring with nitrate is very problematical, is now rarely advanced, yet it seems to me necessary to correct in this place the error which lies in that opinion, and to make the actual circumstances clear through the results of new investigations. The following must be noted in the first place. If by manuring with 200 lbs. of nitrate of soda the yield of the field is increased by about 600 lbs. of Oats and 1000 lbs. of Oat straw, then, in round numbers, 22 lbs. of potash and $7\frac{1}{2}$ of phosphoric acid are contained in this extra crop, and of course the soil will be so much the poorer through manuring with nitrate, unless these qualities are restored to the field. It is evident that larger crops will withdraw correspondingly larger quantities of nourishing materials from the soil, and that the question as to which substances and what quantities of these must be restored to the soil in order to preserve its fertility gains in importance as the yields increase; but it would be very illogical to wish to raise an objection to the use of nitrate of soda from the fact that it converts nourishing materials lying in the soil into plant substances, for it is the proper aim of agriculture to transform into field produce the raw material at our disposal in the soil and in manures.

This, then, I think clearly shows that nitrate of soda when judiciously used is capable of increasing the yield of crops and inducing a fertile growth in plants, in accordance with the sound judgment that is brought to bear upon its use, taking into consideration the circumstances already explained; and the conclusions I draw from these facts are, that plants do not really require such a nicely proportioned chemical combination as my opponent has contended. Provided the principal elements they require are present, and that the nitrogenous manures are used in the way described, his own description of the action of nitrate on the pasture bears out this statement, as it clearly shows that it was the nitrate of soda that stimulates the grass so as to bring out the full productive powers of the soil; and also that the deficiency thus caused in it was returned with interest in the form of phosphate of lime, carbonate of potash, and sulphate of potash, and various other substances, of which the dung and urine of animals are composed. I find, therefore, from a study of these valuable investigations that the manures I recommended in the first place to be given to plants for a change contain in conjunction with the soil all the really important elements needed for plant food, only those elements were not given in what my opponent would call a "properly proportioned combination of the elements needed," but used in a such a way that our knowledge of the habits of growth and purpose for which the various subjects were intended could be the better regulated according to the changing circumstances of light, air, heat, and water. It now only remains for me to thank you for the valuable space you have allowed me for the defence of my views; and also my opponent for the spirited and energetic but friendly way in which he has criticised them.—H. DUNKIN.

[We think it due to our correspondents to express our acknowledgments of the ability displayed by both, and of the admirable tone maintained through the interesting controversy, which may be continued if desired.]

BLenheim PARK.

AMONGST other improvements in progress at this celebrated ducal demesne we understand that the accumulated deposit of many years in the extensive lake is being removed, and that when the contemplated work is completed it will present as fair an appearance as it did more than half a century ago. The trunks of some of the old Oak trees in the park are of huge dimensions, some of them more than twelve paces round, veritable gnarled giants that have survived the storms of centuries. Many of them are passed on the approach to the gardens.

Little has been left standing of the old glass structures in the kitchen garden, or it would be more correct to say that there has been an immense addition in recent years to the plant houses. There is one block of, as near as we can remember, 118 feet in length with glazed corridors at each end. These in addition to others have been designed for cultivating Orchids, and it is manifest that a full measure of success has attended the undertaking, regarded both as to the enormous numbers of some of the kinds grown and their strikingly healthy appearance. An establishment that can furnish 1200 spikes of cool Orchids at once is, it must be admitted, one of an exceptionally limited class, and one that necessarily demands the most skilful management.

The progress at Blenheim has not, however, been entirely with respect to the glass department. The large bush and standard fruit trees that may be remembered as growing in the enclosed garden have been transplanted to a situation immediately outside, where they are now in eminently satisfactory condition. A selection of the best known varieties has been planted within the walls, and in numerous other respects there is much that is noteworthy. At every turn there is indication of the bold spirit of enterprise that prevails, together with evidence of promising success. The time is not far distant, judging from what has already been achieved, when Blenheim, from a horticultural point of view, will emerge from its final stages of transition a more perfectly appointed garden than at any other period in its history. The beauties of Blenheim it may be said are not confined to the 12 or more acres of garden proper which Mr. Whillans has so successfully dealt with, but there are panoramic views to be obtained that, like the sight of the 12,000 *Odontoglossum Alexandra*, the groups of *Cypripedium*, and the

lengths of dense masses of *Stephanotis*—festoons of fragrance—above *Gardenia* shrubs that are impressed on one's memory, invests the anticipation of a summer visit to the Park with feelings of real pleasure.—S. P. E. S.

ROYAL BOTANIC SOCIETY.

MAY 16TH.

THE summer shows of the above Society are invariably most attractive, and in fine weather large numbers of visitors attend. Unfortunately, although the Show was an exceedingly good one, the weather was very unfavourable, and the attendance in consequence was not so large as usual. The plants were admirably arranged by Mr. Coomber, the general effect at the entrance being varied yet harmonious, the side banks and slopes being occupied with numerous large specimen Roses, stove and greenhouse plants, and Azaleas, with fine central groups of Orchids, and choice non-competing plants and flowers.

A magnificent bank of Orchids was formed by the competing collections, and Mr. J. Cypher, Cheltenham, contributed two especially fine groups, winning the premier prizes both for twelve specimens and a group of *Cattleyas* and *Lælias*. The dozen specimens comprised fine masses of *Cattleya citrina*, *C. Skinneri*, *C. intermedia superba*, *Lælia purpurata*, and *Odontoglossum vexillarium*. The *Cattleyas* and *Lælias* in the other class included fine varieties of *L. purpurata*, two of which, *nobilis* and *Arch Duchess*, were certificated. Mr. James, Norwood, was second in both classes with large specimens. Mr. F. J. Hill, gardener to A. Little, Esq., The Barons, Twickenham, was first in the amateurs' class for twelve Orchids and in the corresponding class for *Cattleyas* and *Lælias*, and in both cases the plants were admirably grown examples of choice species and varieties. An interesting group of Orchids from Messrs. H. Low & Co., Clapton, occupied one of the side banks, for which a small silver medal was awarded.

Considerable space was occupied by Roses, which afforded some softer shades of colour than the Azaleas that usually occupy a good portion of their space. In the larger classes, Messrs. Paul & Son, Cheshunt; C. Turner, Jackman, and Rumsey were the prizewinners. Mr. P. Perry, gardener to W. G. Rowlett, Esq., The Woodlands, Cheshunt, exhibited well in the amateurs' class, and Messrs. Wm. Paul and Son, Waltham Cross, had a large non-competing group of Roses in pots and cut blooms, for which a silver medal was awarded.

Azaleas from Mr. C. Turner won first prizes, both with six large specimens and twelve small ones, all being profusely flowered and brilliant plants. Mr. G. Wheeler, gardener to Sir Julian Goldsmid, St. John's Lodge, Regent's Park, was first in the amateurs' class for six Azaleas, followed by Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park.

Mr. H. James took the lead with twelve and six specimen stove and greenhouse plants, including Azaleas, Heaths, Anthuriums, and various hardwooded plants. Mr. W. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley, secured first honours for six stove and greenhouse plants in the amateurs' class with well-grown and evenly trained specimens of moderate size, but in excellent condition; and his premier collection of twelve specimens was equally commended, a vigorous example of *Statico profusa* and an evenly trained globular plant of *Dracophyllum gracile* being noteworthy.

Pelargoniums, both show and fancy varieties, formed handsome groups on opposite banks near the entrance to the tent, Mr. C. Turner gaining the leading honours, followed with fancy varieties by Mr. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, who was also first in the amateurs' class for show varieties, followed by Mr. Hill.

With hardy plants Messrs. Collins Brothers & Gabriel, Waterloo Bridge Road, won first honours, showing a fine group of nearly 100 effective specimens. Mr. T. S. Ware, Tottenham, was second with a much larger collection of smaller plants, and, in consequence, not quite so effective. Messrs. Paul & Son, Cheshunt, were third with a large group of small plants. Fine-foliage plants and Ferns were staged by Messrs. H. James, R. Butler, H. Offer, and G. Wheeler, who were awarded the principal prizes, the Palms generally being very healthy examples, but the *Crotons* were very deficient in colour.

Miscellaneous exhibits in addition to those already noted were as follows:—Messrs. J. Laing & Sons, Forest Hill, had a magnificent group of Azaleas, *Imantophyllums*, Tuberous *Begonias*, choice Orchids, *Gloxinias*, *Caladiums*, *Dracænas*, Palms, and Ferns, admirably arranged (large silver medal). Mr. B. S. Williams contributed a choice group of Orchids and fine-foliage plants (large silver medal). Messrs. Wm. Cutbush & Son, Highgate, exhibited an effective group of greenhouse plants (silver medal). Messrs. J. Carter & Co., High Holborn, had a group of fine *Cinerarias* (bronze medal). From Messrs. Cannell & Sons, Swanley, came a group of single and double Tuberous *Begonias*, representing some very fine varieties, also stands of Zonal *Pelargoniums* (bronze medal); from Mr. D. Phillips a group of *Pelargoniums* (bronze medal). Mr. J. Walker, Thame, showed two boxes of wonderfully fine *Maréchal Niel* Roses (bronze medal). Messrs. Barr & Son, Covent Garden, showed a large group of Daffodils and hardy flowers (large bronze medal).

Floricultural certificates were awarded to Mr. C. Turner for *Azalea indica* Theodore Reimers, double, purplish crimson; Louise Vervaene, double white; *Amidu Cœur*, large double red; and *Vervaenianum*, double salmon and white, fine. To Messrs. Carter & Co. for *Mimulus* Carter's Jubilee Prize, fine deep red, gold centre; to Mr. H. Bennett, Shepperton, for the bronze yellow Tea Rose, Princess Beatrice; to Messrs.

Laing & Sons for *Caladium Charlemagne*, large, deep red; *Comte de Germiny*, red, spotted white; and *Clivia sulphurea*, pale orange yellow; also for *Clivia Orange Perfection* and *Gloxinia Madame Bleu*. To Messrs. H. Cannell & Sons for Tuberosus Begonias, *Lady Mary Fitzwilliam*, double rose; *Miss W. F. Bennett*, double pale yellow; and *Enchantress*, double salmon. To Mr. J. H. Virgo for *Myosotis dissitiflora grandiflora*, and to Messrs. Barr & Son for *Narcissus poeticus grandiflorus*, and to Messrs. W. Paul & Son for *Tea Rose Sappho*, rosy salmon in the bud, becoming pale yellow when expanded; and to Paul & Son, Cheshunt, for *Geum miniatum*.

Botanical certificates were awarded to Mr. J. Cypher, for *Lælia purpurata* Arch Duchess, with blush sepals and petals and deep crimson lip; and *L. purpurata nobilis*, with broad white petals and a large rich crimson lip.

AUSTRALIAN APPLES.

By this post I have sent you sample of five Apples plucked on or about 1st February last from my garden, and I shall be glad to hear in what condition they reach you. They are all of the usual size grown here except *Ribston Pippin* and *Jonathan*; most of the *Ribston Pippins* this year were from 9 to 12 inches in circumference. *Home Rule* is a fine keeping Apple, good for dessert and culinary purposes; it generally has a nice red cheek. *Jonathan* is generally one-third larger, and is bright red all over, a grand keeper, and good for any purpose. *Burton's Pippin* and *Royal Russet* are good market Apples, and no doubt are well known to you. American Apples are largely grown here and do well. If these Apples arrive in good order I shall be glad at any time to send you a sample case of the best varieties grown here, including many colonial-raised kinds. At present I devote only 10 acres to fruit culture.—JOHN PATTERSON, *Calrossy, N.S.W., March 22nd, 1888.*

[We are obliged to our correspondent for his letter and samples, but sorry to say that only one fruit, *Jonathan*, arrived in a really sound state. *Home Rule* was fresh in appearance, but when cut proved discoloured and "fuzzy." *Jonathan*, beautiful dark red, with a bloom upon it like *Red Astrachan*, flesh yellow, remarkably juicy, with a very rich flavour unlike an Apple, and the aroma a mixture of rose and vanilla. *Home Rule*, a handsome Apple, like *Golden Noble* and *Stirling Castle*, the first being 13 inches in circumference.]

THE LATE MR. JOHN SMITH.

MANY horticulturists will learn with much regret that Mr. John Smith, the second ex-curator of the Royal Gardens, Kew, died on Friday last after a fortnight's illness at his residence, 12, Hamilton Terrace, St. Margaret's, Twickenham. It will be remembered that Mr. Smith resigned his post at Kew two years ago in consequence of ill health, which had been caused to a great extent by a succession of severe domestic afflictions, and it is somewhat strange that he has survived his predecessor so short time, whose official career was marked by similar family troubles. Mr. Smith was born in Roxburghshire, and commenced his gardening career in 1841 by being apprenticed to Mr. C. Pillans, gardener to the Duke of Roxburgh, Floors Castle, Kelso. During the three years spent in this garden, which was then one of the most noted in Scotland for the skilful practice there displayed, he laid a good foundation for his after experience. At the end of that period Mr. Smith proceeded to Alnwick Castle Gardens, and he remained in the service of the Duke of Northumberland for twenty years. He worked at Alnwick Castle in a subordinate position until 1855, but the time so spent was most valuable in results, for by his assiduity and perseverance he gained the esteem of his noble employer, who assisted him in many ways. In the year named he went to Syon House Gardens to gain some knowledge of tropical fruit culture, returning to Alnwick in 1856, but was shortly afterwards appointed gardener on the Duke of Northumberland's estate, Werrington Park, Cornwall. Three years later—namely, in 1859—Mr. Ivison resigned the management of the Syon House Gardens, and Mr. J. Smith succeeded him. In 1864 the curatorship of Kew became vacant, and the appointment was offered by Sir William Hooker to Mr. J. Smith, whose qualifications for the post were well known. From then until 1886 he creditably discharged the difficult duties connected with the office of curator, and was much respected for his courtesy and kindness of manner.

PLANTING HARDY PERENNIALS.

THE weather being now more favourable for the planting, in continuing my selection of good plants I will first name—

Lithospermum prostratum.—An evergreen, shrubby alpine. This, when smothered in spring with brilliant blue flowers, is delightful in the extreme; it is of easy culture, succeeding well in deep, rather moist sandy loam, and given a position sheltered from east and north-east winds it always appears happy. I attach more importance to position for this plant than to soil, for if planted in exposed parts of ill-constructed rockeries, as is usually the case, one-half of the plant is blackish brown. Never plant it on a cold clay, it only lingers out an existence for a time.

Linum perenne album.—This very graceful plant does well in ordinary loam, and the great succession of its silvery white blossoms throughout the summer meet with many admirers.

Lobelia cardinalis and varieties.—Although I do not consider

myself justified in including this among genuine hardy plants, it is so attractive and easily taken care of that I mention it by the way. It is perfectly hardy in certain soils and in certain seasons, but not those that Britishers too frequently experience. I know few plants that can be employed with such grand effect as these. Take as an example a few *Cannas* in the centre of a circular bed, around which may be *Chrysanthemum frutescens* with the vermilion scarlet of the *Lobelia* pushing its spikes well above all; or, again, *Nicotiana affinis* and the *Lobelia* blended make an excellent bed, and so on may we use the bronzy, crimson-leaved form called *Queen Victoria*, a most handsome plant when judiciously employed. When frosts arrive it may be lifted with a ball and cared for after the manner of *Calceolarias*, when the clumps will be grand for use again.

Lychnis chalcidensis.—The vivid scarlet heads of this fine perennial herbaceous plant have no equal among hardy plants. It is certainly one of the grandest of old-fashioned flowers. No plant is more easy of culture or more accommodating among hardy plants, while its glowing scarlet heads surpass anything I know. The type may readily be increased from seeds, and apart from this may be mentioned the double scarlet and double white; the first of these has flowers the same telling colour as the type, while the latter has whitish flowers, which cannot by any stretch of imagination be regarded as pure.

Lychnis diurna fl. pl.—In most hardy plant lists this is given (though erroneously) as *L. dioica* fl. pl., a totally distinct plant. In May the above commences flowering, and continues for some time; the flowers are of a rosy crimson hue, and produced in quantity. It is a very handsome free flowering perennial, adapted to almost any ordinary garden soil. If the spikes are taken off as they fade it will flower more or less throughout the summer.

Lychnis Haageana.—A very attractive and variable plant easily raised from seeds, the flowers ranging in colour from scarlet to milk white. It grows a foot or 15 inches high in good garden soil.

Lychnis viscaria splendens plena.—This is without doubt one of the best perennials in cultivation, both from a decorative point and also from its free and compact growth and flowering. From a close tuft of narrow leaves spring numerous stems thickly set with lively rosy red flowers, not unlike those of a double *Stock*, with the spikes produced in great quantities from even small plants. Its usual height is about 15 inches, consequently it is most attractive. This one is especially suited for massing, and may be used with great advantage in large or small gardens. It increases readily by division, and spare plants, if divided and planted at once, would make fine tufts for flowering next year. A fairly rich soil is beneficial to its well being.

Lychnis vespertina fl. pl. (Double White Campion).—This is the only pure double white *Lychnis*, and certainly a gem. It is synonymous with *L. dioica alba* pl. It is impossible to praise this too highly. Those who may require one of the most profuse of all perennials should get this if they do not already possess it. When well established it forms a perfect bush 3 feet high and as much through, and is not easily forgotten when seen in perfection. The blossoms individually are nearly 2 inches across, pure white, fragrant, and may be had in abundance from June to the arrival of autumn frosts. I have prolonged the flowering to Christmas by lifting and potting in the end of September. Few hardy plants are more deserving of liberal culture than this, and none repays so quickly and fully. Its comparative rarity may be traced to some little difficulty in propagating it, but as I have fully gone into this in the past pages of the *Journal* I will not detail it now.

Lupinus arboreseens.—As fashion runs just now the soft pleasing yellow of this plant should find many admirers. As the specific name implies, it is tree-like in habit, and this fact gives rise to wonder why such an one, call it a tree, or flowering shrub, or what you may, is not more extensively employed in shrubbery planting. Given a few years, a handsome bush 12 feet across might easily be formed, and this in flower would, I think, make a feature in any garden. The association, too, of its glaucous glistening foliage with that of more sombre hue would also be an advantage, while its racemes of yellow fragrant flowers would be very pleasing. It is an excellent plant for the large rockery, where plenty of space for free development may be afforded, and while I have never seen it employed in isolated positions on the lawn, I am of opinion that it might make a very handsome plant for the purpose.

Lupinus polyphyllus vars.—The purple and white of these *Lupins* are very attractive, make bold effective plants when established, which they do quickly. They grow 3½ feet high, and should be placed in the back row. These are herbaceous, the same remark applying to *L. nootkatensis*, a dwarf species, 18 inches high, and having dark blue spikes of flowers.

Megaseas.—A distinct and attractive group of plants, with bold leathery leaves and panicles of variously coloured flowers. The hardiest are *crassifolia*, with rose-coloured flowers; *cordifolia purpurea*, purple magenta; and *ligulata*, having fine panicles of rose-coloured flowers. All are good for conservatory decoration, and the last named is used by Mr. Ingram at Belvoir in the spring garden with grand and telling effect. The several other species of this group, which is usually included with the *Saxifragas*, are more or less tender, and require either a frame or warm sheltered position to grow them well.

Monarda didyma (Bergamot).—A most refreshing plant by reason of its agreeable fragrance when drawn through the hand on passing it. For forming lines or for massing this is very effective. Its average height is 2½ feet, erect, numerous whorls of bright scarlet flowers being produced in great numbers even from a single plant. Will grow in any soil or situation.—J. H. E.

SALE OF THE LATE MR. DAY'S ORCHIDS.

SOME remarkable prices were realised at the sale last week of the late Mr. Day's Orchids, held in Stevens' Rooms, Covent Garden. A plant catalogued as *Cypripedium Stonei platytænium*, with two leads and twelve leaves, was sold for 152 guineas; but as there was a doubt as to its genuineness, Mr. Stevens gave a guarantee that should it flower within three years and prove not to be true, the money will be returned. Good prices were also realised for the following:—*Cattleya exoniensis*, 11 guineas; *C. Skinneri*, 10 guineas; *C. Reineckiana*, 11 guineas; *C. Wagneri*, £15 4s. 6d.; *Cypripedium Morganæ*, £35 14s.; *Vanda Lowi*, 10 guineas; *Cypripedium orphanum*, £29; *C. Sallieri*, £14; *C. Curtisi*, 14 guineas; *C. ænanthum*, 11 guineas; *C. præstans*, 20 guineas; *C. Charles Canham*, £34 13s.; *C. Curtisi* and *C. Harrisianum superbum*, £20; *C. Arthurianum*, 20 guineas; *C. leucorhodum*, 68 guineas; and *Cœlogyne cristata alba*, 30 guineas.

ODONTOGLOSSUM CAMBRIDGEANUM.

ONE of the numberless beautiful *Odonoglossums* which are designated natural hybrids or varieties flowered some time ago at Cambridge Lodge, Camberwell, the residence of R. J. Measures, Esq., and was, I understand, referred to Professor Reichenbach for determination and name. It is notable for the size of the flowers and their bright colours, the sepals being a rich reddish brown tipped with yellow, the petals of similar colour, with an irregular yellow centre and deeper yellow tips; the lip beautifully fringed, bright crimson in the centre, and a broad marginal band of creamy yellow. The flowers, though not "filled up," as like the varieties of *O. crispum* with broad petals and sepals, have a graceful and distinct appearance.—L.

CHELTENHAM SPRING SHOW.

MAY 10TH.

THIS proved to be a most successful Exhibition in every respect. The weather on the whole was favourable, and the numerous visitors had every reason to be well pleased with the varied and excellent display brought together. It was held in the grounds connected with the Winter Garden, and very much credit is due to the energetic Secretary, Mr. W. H. Bridgwater, and the Committee generally, for the way in which everything was managed.

In the principal classes for choice flowering plants, Mr. J. Cypher, as might be expected, had matters very much his own way. His twelve stove and greenhouse plants were remarkably fresh and good, and consisted of *Ericas Cavendishi*, *affinis*, and *ventricosa magnifica*; *Azaleas Cedo Nulli* and Mrs. Turner; *Anthuriums Schertzerianum* and *Veitchi*; *Pimeleas spectabilis* and *Hendersoni*; *Hedearoma tulipifera*, *Aphelexis macrantha purpurea*, and *Aphelexis spectabilis*. In the class for six plants, Mr. Simcox (gardener, G. Neville Wyatt) was first, and Messrs. Heath & Son, the exhibits being praiseworthy in each instance. With ten large Indian *Azaleas* Mr. J. Cypher was well first, *Roi d'Holland* being exceptionally good, and Messrs. Heath & Son were second. The best six *Azaleas* were shown by Sir A. Ramsay, Bart., among whose generally excellent group, the most noteworthy being perfectly flowered specimens of *Bernhard Andreas* and *Stella*. Mr. Simcox was second. There was also a class for small untrained plants, and with these Mr. J. Cypher was first and Messrs. Heath & Son second. Similar positions were held by these exhibitors in the class for twenty plants grouped for effect, this giving a good opportunity for the introduction of a few choice Palms and other fine-foliaged plants, as well as a few in flower. Mr. Cypher was also first for a beautiful basket of plants, the second prize being well won by Mr. Wanson, gardener to Mrs. Thompson.

Orchids were a great feature in this display, grandly flowered plants being staged. In the nurserymen's class for nine specimens Mr. J. Cypher was well first, having a fine *Cattleya Mossiæ* with thirty blooms, *C. Skinneri oculata*, *C. Mendeli* with twenty grand blooms, a very fine variety of *Lælia purpurata* carrying sixteen blooms, *Odonoglossum vexillarium* with fully 100 blooms, *Cattleya citrina*, a grand plant carrying twenty-four blooms, a very fine specimen of *Oncidium ampliatum*, *Dendrobium nobile* crowded with flowers, and *Calanthe veratrifolia*. Messrs. Heath & Son were second with large well flowered specimens. In a corresponding class for amateurs Mr. Simcox was first, principally owing to the greater variety included in the collection, among which, however, being several made up specimens, as well as some good pieces of *Odonoglossum Andersoni* and *Cattleya Skinneri*. Sir A. Ramsey was second with a well flowered lot of plants, his best being *Cattleyas Mendeli* and *Mossiæ*, *Lælia purpurata*, and *Saccolabium præmorsum*.

The best eight *Roses* in pots were staged by Messrs. Heath & Son, Mr. G. Clift, gardener to Mr. Graves, being a good second, the last named having a capital specimen of *Niphetos*. The herbaceous plants in pots were very good and attracted much attention; Mr. E. Smith was

FIG. 54.—ODONTOGLOSSUM CAMBRIDGEANUM.

first and Messrs. Heath & Son second. *Gloxinias* were well shown by Messrs. Simcox and — Lewis, gardener to Mrs. Lingwood; *Calceolarias* by Sir A. Ramsey, Mr. Lewis, and Mr. J. Pilgrim; *Cinerarias* by Messrs. E. Smith and J. Pilgrim; *Pelargoniums* by Mr. W. Sparkes, gardener to H. Chapman, Esq., and Mr. J. E. Pilgrim; *Fancy Pelargoniums* by Mr. G. Mayo, gardener to P. H. Osborne, Esq., and Mr. H. P. Sparkes; and *Pansies* in pots by Mr. Enos Smith, the exhibitors receiving the awards in the order named. Messrs. Heath & Son were first for twelve cut blooms of *Roses*, and Mr. A. James, gardener to the Rev. G. Coventry, second. Mr. Simcox was the only exhibitor of twelve varieties of stove and greenhouse plants (cut blooms) and was deservedly awarded the first prize. With three tastefully arranged vases for the dinner table Mr. Mansfield, gardener to Mrs. Gillilan, was first, and Mrs. McNeill second.

Vegetables are always good and plentiful at the Cheltenham shows, and on this occasion were fully equal to any shown in more favourable seasons. In addition to two classes for collections, there were also others provided for single dishes of *Asparagus*, *Cucumbers*, *Mushrooms*, *Potatoes*, *French Beans*, *Tomatoes*, *Peas*, and *salading*. The principal prizewinners were Messrs. A. J. Skinner, A. James, J. J. Smith, A. Cook, Turk, G. Clift, J. G. Kitching, and Wright, gardener to C. Lee Campbell, Esq.

There were several other exhibitors in various classes whose contributions we are unable to notice, but the Show altogether was very satisfactory and creditable to the district.

KITCHEN GARDEN.

THINNING YOUNG VEGETABLES.—The recent weather has caused Carrots, Turnips, Parsnips, and other young vegetables to grow rapidly, and if they become very crowded much harm will be done; it is therefore most important that thinning receive attention. Some are afraid to thin early, as they think should some of the plants fail those remaining will take their place, but they are much more apt to fail when crowded to excess than when they can develop freely from the first, and if failure is to be avoided from beginning to end, early thinning should invariably be practised. In thinning always draw up the weakest plants, and if they are left 3 inches or so apart the first time they can be thinned to the proper distance subsequently as they gain size. It is at first they are most apt to become crowded, and when once relieved their success is certain. Where the crops are extensive take a narrow Dutch hoe and push it through the rows, leaving a little bunch of plants every 3 or 4 inches, then thin these with the hand. A drag hoe may also be used for this purpose.

KIDNEY BEANS.—Those in pots have been doing good service of late. At this season they fruit almost as freely as in the open, and it is a good plan to gather the pods frequently, as when they get the least old they have an injurious influence on the younger ones. If you want to cut the crop short allow the pods to remain on after the Beans begin to form inside them, but if constantly gathered before this occurs they will grow and swell freely to the last. As soon as they are all gathered throw the plants away, and do not allow them to remain in vineries or Peach houses now, as red spider increases rapidly, and it is sure to spread to the fruit trees. The first crop has been sown in the open, but the plants are not yet through the soil, and if more is sown under protection they will pod before those in the open air are in flower. Potato frames are now being emptied, and the soil may be levelled down and the Beans sown as in the open ground.

CELERY.—Plant all early Celery out in the trenches at once; single rows are the best for fine choice heads. Do not apply too much manure to any of them. The best produce is secured from moderately rich soil. Make the soil very firm round the plants. Water thoroughly immediately after the planting is done should the weather be dry, and plant Lettuces on the top of the ridges between the trenches. Our finest Lettuces are secured from this position. Sow Celery seed for the autumn supply of plants in boxes or a frame; give a little heat until the plants are 1 or 2 inches high, and then keep them cool and robust. Our old Celery is still lasting, but it is going to seed, and is only useful for flavouring. Do not throw any away until the new is ready.

AUGUST PEAS.—There will be some Peas ready in June and plenty in July, but good Peas are scarce in August. This is a mistake. Peas may be more difficult to secure in August than July, but if as much attention were given to August Peas as to the first crops how useful they would be. It is dry weather that tells against August Peas, but if this was properly provided for they would always be a success. The trench system of sowing should invariably be adopted. Form the trenches to the depth of 1 foot or 15 inches, fork the manure well down below this, and then sow the seed 6 inches or so from the surface. The weather will have little or no influence over them then, the pods will form freely and the Peas come tender and juicy. Now is the time for sowing Peas for bearing in August, and cultivators should try and do a few rows thoroughly well, as the produce would meet with much favour.

BROCCOLI.—Veitch's Model and Sutton's Late Queen are now heading well. The first is the better flavoured of the two, and should be grown largely for use in May. The present is a good time for noting the qualities of late sorts, and only the best should be grown in another season or sown now. If some of those which have not yet shown heads are dug up and laid in in a cool border they will be retarded for a fortnight, and will be very acceptable in cases where early Cauliflowers are behind. All Broccoli seed should now be sown. Give it moderately good soil and sow thinly.

CUTTING ASPARAGUS.—We have not written of this before because until now we had little to cut. With us it is three weeks later than in the majority of seasons, but it is coming now, and evidently has not suffered by being late. Established roots will not be injured by cutting every stalk that comes up during the next fortnight. The more good roots are cut the more are the growths that are dormant induced to grow. Careless cutters often only take the tops, and cut the stems half way up, but this is a great waste, as they are generally good down to the soil level, or a little below it, and every one should be cut as low as this at least.

EARTHING UP EARLY POTATOES.—The early Potatoes in the borders are now 6 inches high. The whole of them should be earthed up. Use a drag hoe, draw the soil well up to the stems on each side, and this will protect the stems and prevent the surface tubers becoming green.

HERBS.—Plants of Sage, Thyme, &c., requiring more room may now be transplanted. Give them rich soil. Keep Mint free from weeds. Give Sweet Basil more room under glass. It cannot yet be grown in the open. We keep it in pots or boxes until some of the frames are emptied of their spring crops, and then fill a frame with it. Do not grow superfluous herbs, but Mint, Sage, and Thyme are always wanted. The former may be increased by dividing the roots; the latter two are easily raised from seed that should be sown now.

Plant out a row or two of early Celery, transplant Asparagus without delay, make up blanks in early Cauliflower plantations, thin Turnips, sow more Peas, earth up Broad Beans, pull up all weeds, and sprinkle soot over autumn Onions, when the weather is favourable for such work.

FRUIT FORCING.

VINES.—*Temperature.*—The last few days of bright weather have greatly improved the condition of Vine foliage. Employ as little fire heat as possible, for with sun heat and plenty of atmospheric moisture more real benefit is gained in a week than in a month of dull weather with the aid of fires. The Vines being in full growth the temperature may be allowed to rise to 90° or 95°, closing the house at 85°, employing fire heat only to maintain a temperature of 70° to 75°, and to prevent falling below 65° at night. These remarks apply only to Vines in full growth, as those that have the Grapes approaching ripening should have a rather free circulation of air, those well advanced in ripening being kept cooler and drier. Air should be admitted very early in the morning, as the sun's rays act powerfully on the condensed moisture formed on the foliage during the night, causing scorching, unless air has been previously admitted.

Watering.—It is usual to supply water at stated intervals—viz., to render the border thoroughly moist when starting the Vines, when the Grapes attain to thinning size, and when they are commencing to ripen. Those are very good as regards watering from a feeding point of view, and ought to be carefully attended to; but inside borders must be watered more frequently. There are more failures from insufficient than over-watering, the borders being properly constructed and the drainage complete. Watering twice a week in the case of those with the roots restricted to borders of limited extent, and once a week for those that have a good run of border, is not too much from the Grapes swelling after thinning until the berries are changing colour. There is, however, a great difference in the retentive power of soils. Some loams are naturally very loose, sandy, or gravelly, and they have the usual opening materials added, as lime rubbish and charcoal, which makes them still more sieve-like; the consequence is the greater need of the watering pot, besides the danger attending the finish of Grapes grown on such soil through insufficient supplies of water leading to attacks of red spider and thin foliage, which does not store nearly so much assimilated matter as the thick and leathery leaves on Vines in a firm soil of a rather retentive nature. Such soil will require water less frequently, but in no case must there be lack of moisture at the roots throughout the swelling period.

Houses of Ripe Grapes.—Afford fire heat only to prevent the temperature falling below 60°, and to admit of a rather free circulation of air. Do not allow the border to become very dry, but keep it moist, and mulch with rather dry litter from which the dung is removed; it will retain moisture a long time, and lessen the evaporation from the surface of the border, though a little moisture in the atmosphere is not injurious to the Grapes, and is highly beneficial to the foliage, which must be kept clean and healthy. Fumigation must be resorted to if thrips appear; for red spider there is no safer remedy than the tedious process of carefully sponging the leaves with soapy water. A double thickness of herring nets should be placed over the roof lights where Black Ham-burghs are hanging in order to enable them to keep their colour.

Late Vines.—These will be in flower in most places. Maintain a minimum temperature of 70°; shaking the rods twice a day will be sufficient in most cases to distribute the pollen effectually, but in the case of shy setters fail not to resort to artificial fertilisation, going over the bunches carefully with a camel's hair brush. All the large-berried varieties, such as Gros Colman, Gros Guillaume, &c., which are good setters, should be thinned while they are in flower, and with those that are liable to have very closely set berries it is a good plan to thin them before the flowers expand, as a practised eye can tell which flower buds by their vigour that are likely to set, and the removal of the weaker strengthens them wonderfully. Whilst the Vines are in flower do not pinch or stop the laterals, but when the blooms are fairly set remove the laterals at once, so as to prevent overcrowding.

Planting Growing Vines.—Those struck from eyes in February or March and grown on in pots or turves may from now to the early part of June be planted out, giving them a good soaking with water at 90° to 100°, mulching the surface with a couple of inches of short rather lumpy manure. A humid atmosphere should be maintained, and shade afforded from bright sun until they become established.

FIGS.—*Early Forced Trees in Pots.*—When the fruit has all been gathered remove the loose portion of previous mulchings, and supply well decomposed manure, which will encourage root action and assist the trees to perfect the second crop. If the trees have become infested with red spider or scale thoroughly cleanse them by means of soapy water and a soft brush or sponge, and ply the syringe freely twice a day. Although a second crop is serviceable a good first early crop is much more valuable; therefore be content with a moderate second crop, or none at all if the trees have been severely taxed by a heavy first crop, as they

must have vigour to give a full crop when early forced year after year ; therefore give them a chance to recuperate, make and perfect growth with ample stored up matter for a full crop another season.

PLANT HOUSES.

Salvias.—These should be in a position where they can be hardened thoroughly for planting out by the end of the month in all localities that are free from late frosts. The tops of the shoots may be rooted, and these if stopped twice, once before planting out and once after, will make capital plants for placing in 6-inch pots in autumn.

Bouvardias.—Plants that have been fairly hardened may be planted out in frames of light moderately rich material. They lift well in autumn when one-third or more of the compost consists of rough leaf mould. If possible select for them a position exposed to the sun where the bottom is firm, so that they will be compelled to root in the compost given them. The frames can be kept closed for a time until the plants are well established, when they may be gradually hardened and the frame removed. If desirable to grow them in pots thoroughly harden them if forward enough, so that the pots can be plunged outside whenever the weather will permit of this being done. The shoots under both systems of culture should be pinched from time to time as they need it. When abundance of bloom is solely the object of the grower, the planting out system is the most economical method of culture that can be followed. They can be lifted with large balls of roots and placed on the bed of the house in which they are to flower without seriously checking them. Young plants now in 2 and 3-inch pots may be transferred at once into others 2 inches larger.

Solanums.—The earliest plants have commenced flowering ; they should be placed in cold frames, where air can be liberally admitted. Plunge the pots to prevent the soil drying too quickly ; if once the plants become dry at their roots the foliage will suffer, and if repeated many times it will have a sickly yellow instead of a dark green appearance. Syringing will not damage the flowers provided it is not done during damp dull weather, and it will assist in keeping the plants free from red spider. Pinch the shoots of young plants raised from cuttings, and place them when ready into 5 and 6-inch pots in a compost of loam, one-seventh of manure and sand.

Heliotropes.—Plants that are intended for standards should be placed into 6-inch pots. They will do well in the compost advised for Solanums, with the addition of a little leaf soil. Grow them for the present in an intermediate temperature, and remove all shoots that issue from the axils of the leaves until the necessary length of stem has been attained. Then they will be ready for 10-inch pots, their flowering size. If sufficient cuttings have not been rooted of White Lady, the most useful light variety for winter flowering, they should be inserted at once. Directly they are rooted place them singly in 3-inch pots ; and pinch the shoots from time to time. Do not grow the plants too warm after they are started in their first pots. Have the plants well hardened, so that by the time they are ready for 5 and 6-inch pots they can be plunged in a sunny place outside.

Mignonette.—Plants of tree varieties that are intended for standards and pyramids should be placed at once in 6-inch pots. Use a compost of good fibry loam two parts, one part of leaf mould, a liberal dash of sand may be added, and one-seventh of decayed manure. Place upright stakes to all the plants, whether intended for the former or the latter. For standards only one plant in each pot will be needed, from which all the lateral growths should be removed as they appear until the necessary length of stem has been produced. For pyramids have four plants in each pot, and the whole staked upright until they are placed in their flowering pots. The central one should have all laterals removed up to 6 or 7 inches high, when it may be allowed to branch, but the main leaders must be trained upright. The remaining three plants may have the laterals removed for several inches, but the distance entirely depends upon the width of the trellis at the base. At present they occupy an intermediate temperature, but artificial heat must be gradually dispensed with, so that by the end of the month they can be grown without any.

Roses.—Such Roses as Maréchal Niel, Gloire de Dijon, Reine Marie Henriette, and others of similar growth that have been in cold houses have ceased flowering. These must be pruned hard, so that strong young wood can be laid in for another year. If left as they are such plants soon become a crowded mass of small growths, and poor flowers only are the result. If fine flowers are needed strong growth must be encouraged, and this is largely assisted by hard pruning.

THE BEE-KEEPER.

NOTES ON BEES.

HOWEVER hopeful we were at the beginning of April that the month would be favourable and genial alike to bees and vegetation, we were sadly disappointed, as more wintry weather could hardly be experienced in this country. In the north on only four nights of the month did the temperature remain above 25° Fahrenheit,

and only two above 32°. The whole month throughout was of a much lower temperature than that of January, and consequently the bees were little out ; but when they did venture many were lost. Only on part of two days they carried natural pollen, and until the 5th of May there had not been a chance to resume. Every day there was more or less rain and snow, some of the showers being very destructive to fruit buds, and were accompanied by high winds, aggravating the damage. Feeding in many cases will have to be resorted to if bees are to be kept alive and in condition to gather honey should that time come during the summer of 1888. We do not remember such a cold spring since about 1842, when in that or the subsequent year a foot of snow fell on the 15th May, breaking the trees, destroying all fruit blossoms, and killing nearly every young bee in and out of the nest.

The effects of the protracted cold is prominently seen on the Snowdrops, not one seed pod being visible ; and as the Crocuses never opened these also are likely to be destitute of seed too. Many other hardy plants have disappeared. My Auriculas, Primroses, and Polyanthus have been almost destroyed, not from the cold alone, which, when unaccompanied by snow, seems to do them no harm, but whenever snow falls they are spoiled ; even the hardy Arabis is cut down. Contrary to the generally received opinion that snow protects vegetation, it is and always has been the reverse with me, and your correspondent, Mr. W. J. Murphy, Clonmel, seems to be of the same opinion, with this difference, that the ill-effect with him is when sunshine occurs after snow. After snow my flowers are destroyed. For weeks this spring we never saw the sun, and although we had no deep snow still it was seldom absent, and has done its work.

THE EFFECTS OF THE WINTER ON BEES.

Owing to the long-continued cold the consumption of stores has been great and many hives have died, and owing to the mildness of January bees began to extend their brood more than is customary at that season, and queens that were older than six months, and perhaps unable now to keep up breeding through excess at the beginning, are deposed. Scarcely a post comes but brings a letter to that effect. I have in almost every case found this to be the case after inquiry. Young queens for stocks are the only guarantee we have for profitable hives during summer.

Although my plans and ideas have been condemned in no measured terms, it is a fact that the latter are approved. Even the "powerful screw" could not be dispensed with in the Raitt honey presser. Those who have unfortunately been led to adopt a presser different from the condemned Lanarkshire one will find there is no provision made in the Raitt honey presser to prevent the pollen being mixed with the honey, which spoils it. I now explain what I would have done long since, but for obvious reasons withheld. When honeycomb is not free from pollen, as is often the case, the comb ought not to be placed upon its edge, but into a wider cylinder and laid flat, the cylinder filled, and the pressure brought gradually upon the mass. Whenever the slightest particle of pollen is seen to make its escape, stop. This is most important, and bee-keepers should become impressed with the fact. If they wish to succeed they must present to the public honey unalloyed and free from all impurities, and keep to tried appliances.

BELLGLASSES AND FIXING FOUNDATION.

Although bee societies condemn bellglasses, and I do not approve of them, still bee-keepers, as a rule, derive pleasure from following out their own plans and contrivances, and many have a desire to see their bees at work in bellglasses, and to have the latter prettily filled for the table or for presentation. The difficulty of fixing the foundation or guides without sticks or smearing the glass with wax has hitherto been a barrier to bee-keepers. Foundation can be fixed to bellglasses, or glass for ornamental designs, without the beauty of the comb being spoiled by either sticks or wax. First cut narrow strips of paper and slightly gum on to outside of the glass the design wanted, then cut the foundation to proper lengths,

and breadths, and fit exactly to the surface of the glass opposite the paper design. Now paint the edge of the foundation and the glass opposite the paper with strong gum, and steady foundation with blocks until it has set, when it may be placed in or on the hive. If properly done there will be no trace of anything to mar the beauty of the bellglass.

MY OWN APIARY.

Notwithstanding the backwardness of the season all my hives, by the aid of peameal and natural stores only, are in an advanced state, with one or two exceptions. I have not even disturbed a single covering nor fed any bees. All manipulations during winter and spring after October should be dispensed with, except in cases where either foul brood or a queenless stock is suspected. Stimulating by feeding does more harm than good, spreading brood the same, and the systematic practice of breaking sealed honey is but a waste of both it and bee life. Any of these manipulations are unnecessary. We put our bees in the autumn with a sufficient supply of natural gathered honey, and in as many cases as we possibly can with large stores of pollen. We have yet to see a pollen-bound hive, but our hives are of size consistent with rational bee-keeping, and the ventilating floors keep our bees and combs dry, and the former healthy and hardy. The entrances to our hives are kept narrow during the winter and spring, and I am now waiting patiently, if not anxiously, for sunshine to give more doorway to my populous hives, the result of my recorded management in this the most untoward season for bees.

CORRESPONDENCE.

Amongst the many letters I am receiving the following one from the north and the other from the south of Scotland will, perhaps, be interesting to your readers, and goes to verify the foregoing. "J. C. T." says:—"For my own part you know I am no trader, simply an enthusiast, but like most bee-keepers, started on wrong lines and have suffered much loss thereby. If I must again start anew I would much like to make sure of a hive which has stood the test of a practical bee-keeper, so that I would not have to change again." "W. H. C. D." says, "The one half of my hives I had fitted with ventilating floors have stood the winter well, being perfectly dry, the bees well preserved and healthy. The other half are not so satisfactory; the floors are damp and the combs mouldy, and many of the bees are dead. I will, the first opportunity, have them all altered to your pattern."

This is simply the hive I have described previously, which I have used with but slight alterations for forty years, which has been long known as the square Stewarton and Lanarkshire hive, but now claimed by novices.—A LANARKSHIRE BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.
