THE
JOURNAL OF HORTICULTURE,

COTTAGE GARDENER,

AND

HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

CONDUCTED BY

ROBERT HOGG, LL.D., F.L.S.

Established

in 1848.

VOLUME XVI. THIRD SERIES.

JANUARY — JUNE, 1888.

LONDON:
PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

1888.

ROYAL BOTANIC GARDENS KEW

1877

1877

LONDON:
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

ON the completion of another half-yearly volume of what our friends appear to take pleasure in describing as the "Old Journal," we should be wanting in courtesy if we omitted to acknowledge the expressions of goodwill and good wishes that reach us from readers, old and new, residing in various parts of the old country, and in the Greater Britain beyond the seas.

We have before us as we write a greater number of letters than we have ever received before in the same period of time, and from these letters, which are absolutely spontaneous expressions of opinion, we gather that the *Journal of Horticulture* was never more appreciated than it is now, and for this we are grateful.

While we thank all who evince interest in the welfare of this Journal—all who, finding it useful, incite to greater effort by encouraging words—and they constitute an overwhelming majority—the truth must be told that we thank with equal sincerity the few, the courageous few, who tell us in what way they think its pages might be made more interesting and more serviceable.

No doubt the gardener who wrote: "I think the Journal can hold its own as the best practical gardening paper of the day" expressed his honest opinion; but it was not more agreeable than this sentence from the letter of a nobleman:—"I have been hoping for months past to see something in your paper on packing flowers, for mine either come withered, or wither soon after they come. Cannot something be said on this subject?" Our noble friend had not long to wait, and something was said; then came the postcard response—"Many thanks; just what I wanted."

Testimony to impartiality is the more valuable since it comes from one who has had to meet, and has met ably, adverse criticism such as winners of great prizes have often to endure. From his letter we cite: "I think your paper improves, and I hope it may prosper, as it will do so long as you pursue your present impartial course, not to idolise some and 'sit upon' others." We shall undoubtedly pursue the course indicated. A fair field is open to all who till it profitably and pleasantly, avoiding the introduction of weeds in the form of literary thistles and stinging nettles. Sentences framed to cause pain are more injurious to the reputations of the authors of them than to the intended victims. "Strong" language cannot obscure weak argument, and usually denotes a tottering case.

The chief object of this Journal is to be useful, and no reader who may fail to find in its pages the precise information he needs can act better for himself, and more agreeable to us, than to make his wants known and his difficulties clear; then, so far as is possible, the former shall be supplied and the latter removed or reduced. Questions answered have been of service to many besides those who have asked them. Here is what one who has benefited writes: "You have answered many questions relating to gardening. I have always followed your directions, and am glad to say have always been successful." That is encouraging, but much must be credited to the aptitude of our correspondent in carrying out the instructions.

From the Antipodes letters are before us, and a brief citation from one of them from Otahuhu, New Zealand, must suffice as typical, namely: "Your journal is looked for with a great deal of pleasure; you are doing a good work, and may you long continue to do it." It shall be our endeavour to disseminate sound information, and to present matter of interest to our readers at home and abroad, and with the aid of valued coadjutors, competent in every branch of gardening, we doubt not the result. To all, of every rank and degree, who have contributed by their pens and their patronage in the production of this Volume, our best thanks are due, and are hereby cordially tendered.

THE OPENING YEAR.

IN horticulture, as in other pursuits and affairs of life, there is no standing still. Movement is the indication of life, and it must be onwards or backwards, upwards or downwards, better or worse. To remain stationary, except in resting for renewed effort, means temporary stagnation, and the next step is not certain to be made in advance. By dint of energy and persistent endeavour, the position of the great industry with which our readers are more or less closely identified, has been well sustained during a period that has been the reverse of prosperous to many. In a pursuit embracing so many branches it is not to be expected that progress could be equal in the whole of them, or that it should be uniform in all districts. That department of horticulture which is regarded in the category of luxuries must of necessity be influenced in accordance with the means for indulging in it. These are dependent on the state of trade and other circumstances that affect the incomes of those whose inclinations lead them to devote a proportion to the maintenance of their gardens and the adornment of their homes and surroundings with the choicest gifts of Nature.

It cannot be denied that not a few persons have felt it prudent to reduce their expenditure in respect to other luxuries than those of the garden; but, on the other hand, it is not the less certain that a greater number than ever indulge in the pleasures of gardening, and consequently there is no reason to doubt that the aggregate trade, however much it may be sub-divided, and having regard to all its branches, has seriously diminished. It has rested, perhaps, but only to be invigorated. It is observable, that no matter how intrinsically valuable, by rarity or beauty, plants may be, purchasers are forthcoming for their possession; and also, having regard to that which is popular, never before was a brisker trade conducted. Roses and fruit trees are provided in ever increasing numbers, and there is a greater sale of fruit and flowers than at any past time. But purchasers are growing more and more discriminating in requiring value for money, and only that which possesses real worth finds favour in these utilitarian days.

Novelty without substantial merit has practically lost its charm. New Roses came in such numbers at one time, with great recommendations, but small virtues, that mistrust became engendered in the prolific raisers, and credit was slowly accorded to those varieties which proved essentially superior. It is the same with the flowers that are now freshest in the memory—Chrysanthemums. Taking advantage of the popularity of these, and the demand for distinct and meritorious varieties, continental raisers are inundating us with new sorts, depicted in glowing imagery, which when purchased and grown are found to be essentially inferior. This creates disappointment that eventually culminates in revulsion; and the overhaste to get rich on the credulity of purchasers must sooner or later end in lost reputations. Speaking of Chrysanthemums and as indicating their growing popularity, it may be stated that one manufacturer of flower pots has increased his sale more than a million during the past season in consequence of the extraordinary increase in the cultivation of these plants. This is one instance of onward movement, and though some kinds of plants may have fallen somewhat in public estimation, the balance, taking a wide survey, is still in favour of progression.

The opening year brings with it signs of reviving trade. The

clouds of depression are lifting and a brighter dawn is apparent, giving hope of better days. A steady and certain improvement in commerce leading to briskness of trade will affect beneficially the entire community. The corollary to the increase of wealth is increased expenditure, not alone in the necessities, but the luxuries of life, though to draw the line between the two would be no small difficulty. The production of what may be called or miscalled luxuries on the one hand means increasing the well-being and comfort of the producers. The circulation of wealth is for the benefit of all, and the freer this circulation the more certain are gardens to have their share. We like to see the thrifty man rejoice in the possession of a greenhouse, and the affluent erect ranges of glass proportionate to the circumstances of each case, as these, well furnished, contribute powerfully to human happiness; and this we conceive is not to be described as a mere luxury. We like to see the delightful flowers of spring uprising everywhere, the summer Queen the Rose, and the autumn Queen above mentioned, with other intermediary flowers, in the gardens of the cottager, clergyman, and prince. We like to see fruit grown and cherished by the greatest number, and useful produce grown abundantly and well, because we believe those who indulge in these wholesome and health-giving pursuits are made happier, and the world better through their possession.

We like to see a taste cultivated for all that is pure and beautiful—for music, painting, sculpture, and various works of art—because the acquisition of this taste indicates intellectual advancement, which is not necessarily attained at the sacrifice of physical energy. Some of the most intellectual of gardeners are the most energetic workers, and the best painters amongst them are at the same time well in the forefront amongst the most successful Grape growers and general cultivators of the generation. But it is not of gardeners we speak in connection with the fine arts, but of capitalists who are patrons of them; and it is pleasing to observe that, under the stimulus of trade revival, distinct activity is apparent in the world of pictures, for the best of which there is brisker demand, and the opening year is, in that respect, hopeful. That we regard as a favourable symptom as affecting the art of gardening, and we shall be much deceived and gravely disappointed if this does not receive a stimulus during the year on which we have just entered. We look forward for an increase of interest in gardening matters, and a steady improvement in the horticultural world.

It is not to be expected that prosperity will come with a bound. The period of inactivity in trade, commerce, and agriculture did not burst on the world suddenly, but came, so to say, stealthily, and its full import was not at once apprehended. What was regarded as a passing shadow proved to be a gathering cloud that spread and deepened as time rolled on. Its daily progress, like the growth of weeds, was not observable, but the movement was not the less certain, and only a lapse of time was requisite to show its real proportions. The same steady action in the way of improvement must be anticipated, and it is likely to be all the more sure and permanent for coming slowly, gathering strength by degrees, like the growth of a vigorous tree.

Referring a twelvemonth ago to the then past year of 1886 we observed, "It has not been a bright and prosperous one, and many a dark shadow will be cast over the future (1887); but better times we shall hope will come with brighter days, and it will be a glad-some circumstance if the past year shall have been the last of a series in which trade and commerce have been abnormally inactive, and if the year of rejoicing (over a great historical event) shall inaugurate an epoch of national prosperity. There are not wanting signs of recovery in trade, and there is good hope that the year on which we are entering will mark the era of better times for all." That was our hope expressed at the commencement of the year which has just closed; and it is gratifying to perceive that the new year on which we are embarking has opened under better and

brighter auspices than have been recognised for a considerable time. There is reason to believe we have reached the bottom of the valley of depression and gathered strength for a movement that must be upwards, if we move at all, and, as observed at the outset, there is no standing still in the affairs of life.

But the upward path is all the same a rugged one. Obstacles will present themselves of a nature not easy to foresee, and those travellers who are the most prescient, and make the fewest false steps, will reach the goal of their desire the soonest. It is not necessary to dwell on what is an admitted fact, that integrity in trade is the only safe foundation on which to build successfully, and given a safe base of action the enterprise born of competition and experience will have the same results in the future as have accrued in the past in the establishment of famous centres of business and world-wide reputations. And it is the same in respect to those who serve. To serve faithfully, loyally, and perseveringly is to occupy a position as honourable as is to be found on earth. Some there may be, and are, who feel their services ill requited; yet nevertheless to relax in effort in the path of duty is a step backwards—a false step, that cannot possibly advance those who take it. On the young especially, or those of them who are apt to judge hastily, we would impress that truth, and if they act in accordance with it they will be better men at the end of the year than they were at the beginning. The greater the obstacles they encounter the greater will be the reward in surmounting them, and the day will come when they will dwell with pride on their perseverance and endurance while others fell by the way.

For ourselves we think we know our mission and shall endeavour to fulfil it. It is to advance the work in which thousands are engaged, because we believe it to be good and fraught with benefit to those who participate in it, while exerting a wholesome influence beyond its borders. We shall give aid where aid is sought, so far as it is in our power to do so; and as our resources have been tested in the past we do not think they will fail in the future; and our desire, as heretofore, in dealing with current matters is to be just and fair to all. That our work and labour is not in vain and unappreciated we have had much testimony, this being fairly embodied in the admirable communication of "A Yorkshire Amateur," which will be as welcome to our readers as to ourselves. To our patrons and helpers we tender our cordial greetings on the opening year, and trust it may be prosperous to all.

GREETINGS AND REFLECTIONS.

ONCE more the time has come when we make it a custom to convey to all our friends our good wishes—to press their hands a little more firmly, and to shake them a little more heartily than we do at other times. Once more, therefore, I emerge from my obscurity for the purpose of again offering the right hand of fellowship to all connected with the *Journal of Horticulture*, readers, writers, editors, and proprietor.

Another year—it seems only like a few months—has passed away since I addressed you; and now we again stand, like a number of athletes, all ready to toe the line that marks the beginning of another race—another year. We are here at the beginning of it; who can tell where we shall be at its end? How many of us shall finish the full course? how many fall by the way? how many go down into silence and the valley of shadows?

It is the Methodists, I think, who open the proceedings at their annual conference by singing the hymn beginning,

"And are we still alive,
And see each other's face?"

Our first thoughts on finding ourselves still in the land of the living at the beginning of a new year should be a feeling of thankfulness that we are still spared by that Providence "that shapes our ends, rough-hew them as we may." Death has, as usual, been busy during the last year.

"Leaves have their time to fall,
And flowers to wither at the north wind's breath,
And stars to set; but all—
Thou hast all seasons for thine own, O Death!"

[Death has gathered his crop; some ripe and full of years,

falling calmly to sleep after a life of usefulness; others snatched away full of strength and youth in the midst of busy life and toil. Well, in my opinion, the best preparation for the time and the life to come is to "work while it is day." So ye dreamers, you who are always going to begin next year, or some day, seize the present hour; lose no time, for "there is no time like the present," and "time and tide wait for no man."

But stay! I fear my remarks have rather a melancholy tinge. This should not be so at the beginning of a new year. Perhaps the weather, when I sat down to write these stray thoughts, had something to do with it. Then the sky was dark and cloudy, but, as I pause here, a sunray rests upon the page. I look away to the hills, and there I see the whole landscape, a moment ago all dim and dark, now bathed in the rich warm glow of the setting sun. New and more cheerful thoughts arise—of the awakening of spring, of more light—the shortest day has passed now—of a renewal of energy, of new effort, new life, new hope. Just as this burst of sunshine has chased away the shadows, so we hope shall the warm spring days and the glorious sun drive away the dark winter weather, together with all gloomy thoughts from our minds, leaving in their place nothing but joyful and glad anticipations of the delights which spring and summer shall bring to us.

A special word to the proprietor and editors. The continued success of "our Journal" must be a source of gratification to you. That this success is well earned no reader of the paper can deny. As much depends on the selection of the material as depends upon the writing of that material itself, and it must be evident to all that this task of selection is performed with great care and attention. The plant you cultivate with so much pains and trouble is no barren one; it carries always a noble and heavy crop, and while ever it is conducted on the present intelligent lines, there is little fear of canker or decay in its circulation, or in any of its parts. Long may it flourish!

A word to the writers. Gentlemen,—Your communications are as valuable as ever. During the last twelve months much excellent matter, much interesting information, many useful hints have been published in the pages of "our Journal." It were invidious to pick out any where all have done so well, but just one word in your ear. Cannot you prevent your feelings from getting the better of you? Cannot you avoid the use of verbal brickbats and other similar missiles? Remember that "a soft answer turneth away wrath," and that we readers of the Journal want information on floral and horticultural matters. We want your experience on these, and we do not care to have to search for it among the personal bickerings of the combatants.

And now a word to my fellow readers. During the last year I have made the acquaintance of several of you. I have been where the Grapes grow (was that Gros Colman berry 2 or 3 inches in diameter, friend Taylor?), I have cemented the friendship of others far north and far south, east and west, through the post—by letter only, in fact. I have learned, too, that if one only does one's best and is content to write down his experience fairly and honestly, that the readers of this paper are ever ready to acknowledge his efforts. Here, then, to all friendly letter writers I gratefully express my thanks. Gardening still remains to me, as it ever will, the best, the most health-giving, the most satisfactory, and the most innocent of all my hobbies.

"Nature never did deceive the heart that loved her"

—and she never will. To many, Nature in all her aspects is lovely. In the budding and opening leaves of spring, in the flowers of summer, in the fruits and tinted foliage of autumn, and even in the bare branches, and the snows and frosts of winter, she is always beautiful. To me she reveals herself mostly in the Rose—"the Rose of brilliant hue and perfumed breath," which "buds, blossoms, dies, and still is sweet in death." To others she may do so in the favourite flower of each individual among us.

In conclusion, here's success to the Journal; here's success to ourselves; and here, offering a hand to everybody, is

A HAPPY NEW YEAR TO ALL.

—YORKSHIRE AMATEUR.

HORTICULTURAL PROGRESS.

THERE is no doubt, Mr. Editor, good ground for the congratulations of the concluding paragraphs of your retrospect of the closing year. While the good old ship of Horticulture has, more or less, in the course of the past year, experienced stormy winds and heavy breakers, she has kept her head to the wind, and the records of her log book are not unsatisfactory. Let us hope that the year on which we have entered may leave you cause for still warmer congratulations, and justify you in eliminating from your

next yearly retrospect even the faintest tinge of sadness that the pessimist may be able to detect in some of your remarks, and at the same time justify the hopeful view you take of the future. Perhaps there is no other interest that feels the effects of depressed times sooner than horticulture. Nevertheless, those who can carry their retrospective glance back for half a century can testify to the immense progress that gardening has made, and how it has pretty well kept pace with the unexampled progress of the world's commerce. They cannot fail to be impressed with its immense expansion and the great change in its position and influence.

Fifty years since horticulture was but little thought of beyond the limits of the gardens of our landed proprietors. In the interval it has expanded and overflowed beyond its old boundaries to such an extent as might then have been considered extravagant to hope for. Now our wealthy merchants are perhaps the more extensive and ardent patronisers of the cultivation of fruits and flowers, and fortunately the love of gardening has captured to an extent, once never dreamed of, the hearts of the humbler million. No joyful festival, sacred or otherwise; no mournful event takes place without their floral accompaniments. Consequently as a commercial pursuit its growth has been amazing. Fifty years since there were next to no glass houses devoted to commercial gardening to be found except in our leading nursery establishments. These were exclusively devoted to supplying the then comparatively small requirements of the, already referred to, landed proprietors' wants. Now these old nursery establishments, though they have multiplied and expanded immensely, are insignificant compared to the acres of glass houses found in the suburbs of our great commercial hives devoted to the production of fruit, plants, and flowers, to meet the ever-increasing demands of those who are in "cities pent."

Though perhaps more slowly, yet none the less surely, the science and art of horticulture have made marked progress, thanks, to a very great extent, to the interchange of thought and practice carried on, chiefly by practical men, in the pages of the horticultural press—the progress and growth of which have been no less marked than that of horticulture itself. In all these respects there are many gains to be counted among a few losses, such as, among the latter, the many fine specimens of plants that are now seldom met with, simply because horticulture has become more a domestic necessity, and these objects, though many of them are gems, do not so well adapt themselves to the wants of the time.

All this, when at the same time the hybridisers and importers of plants have been placing new objects in the arena to keep up the interest, and the pot boiling at the same time. Much, or most of all this, horticulture owes to cheap glass, and to those marvellous triumphs of science, our "greyhounds of the deep," our steam marine. It would be unfair to leave our scientists and their labours out in the cold, and all they have done for us is duly acknowledged.

In the retrospect there are some points on which we cannot so freely congratulate ourselves, and they should be referred to as nuts for especially our scientific coadjutors to crack. So far as the improvement in our fruits is concerned, there has certainly been a multiplication of varieties that in some respects is not altogether desirable; but in the quality of fruits there seems to be but little or no gain, and it would seem that there are hard-and-fast lines in this direction that baffle human skill. Take, for instance, the Black Hamburgh Grape. In spite of all the attempts to improve on it, or to raise a black variety with fruits of superior merit, this old variety towers above all rivals for all-round first-class qualities. There has not yet been raised a black Grape that even approaches it. It can easily be placed in the dessert, for nine out of the twelve months. On no other can the palate fall back with such refreshing effect for a length of time without cloying. It has an almost, if not quite, an ideal physique, and it is as nearly faultlessly fertile as possible, and of no other Grape can all this be said. It would really seem that this and certain others of our old varieties of fruits defy the wit, the science, and the art of man to improve on them, and any admixture that can be introduced into their blood only deteriorates their quality. Mother earth seems by them to say, "You cannot extract from me or cause me to bring forth more good qualities in any one variety." Concerning white Grapes, the same remarks apply with equal force to the Muscat of Alexandria. Numbers of white varieties have been raised, but this old variety towers above them all in good points, and it can be placed on the table at least from July till March.

Grapes are not by any means the only fruit that seems to defy improvement. The old Queen Pine Apple stands unrivalled, taking it all round. The old, old Gooseberries that old men remember to have feasted on when they were "toddling wee things" are still the best, and would scorn comparison if they could with the coarser varieties introduced in the interval. Of Apples, many of the old sorts have never yet been equalled, and judging from the past are not likely to be soon excelled.

It would appear that no knowledge accurate enough has yet been attained that enables us to produce fruits that excel old types in more than perhaps one point or two, and these not of premier importance. Can this be a field that is hedged about with an impassable barrier, and is there a limit placed by Nature to the enhancing of many desirable qualities in one variety? Perhaps if our scientists had devoted as much of their time to this subject as they have done to malformation, they might have done something for us, and perhaps they might not. It is for them to tell us. Practical men seem baffled. Are we, then, to sit down quite contented with our old and best types or varieties and despair of getting any to excel them? It is sad to see the public tendency to prefer mere size to quality, for in the markets all good qualities must go to the wall in the face of size and perhaps colour.—D. THOMSON, *Drumlanrig*.

DISA GRANDIFLORA.

As the impression which I am afraid has been generally entertained, that the successful cultivation of this beautiful Cape Orchid is attended with some difficulty, becomes removed, its extended cultivation will be assured, as no garden should be without a few plants of this magnificent cool Orchid. It is sometimes described as the flower of the gods. To those who have only seen an isolated spike or two in bloom this may appear an exaggerated statement, but when seen in grand masses on the margin of streams on the Table Mountains as described by Dr. Harvey, those who have been successful in its cultivation in this country will be inclined to endorse the high encomium as being well deserved.

That the impression entertained of the difficulty in growing the *Disa* successfully is being removed is evidenced by the many more growers who are now taking the plant in hand and growing it well, Messrs. Backhouse of York being perhaps the largest and most successful. In order to attain to the greatest success in the cultivation of any plant it is useful to know something about its native home, but I think especially so in the case of the *Disa*—not that I consider it necessary or possible to reproduce all the natural conditions by artificial means, but the primary conditions must be borne in mind in dealing with the plants and reproduced as near as possible. Those conditions as regards the *Disa* cannot be better described than in the words of Dr. Harvey, who saw them growing on the summit of Table Mountain. "This summit is very frequently enveloped in the mist, especially at the season when the *Disa* blooms. It is very cold also, and the mist comes accompanied with a strong, cold, north-east wind; after this succeeds the scorching sun of lat. 33°. The plant only grows along the steep boggy, spongy margins of a stream which has water in it at all seasons, but which in winter must be so swollen as to cover the plant. The margin is completely clothed with the *Disa*, but immediately beyond is a margin of *Restios*, which bending over afford considerable shade to the roots and foliage, leaving the flower stalks room to peep out at the sun."

From this it will be seen that the three most essential conditions are—a moist atmosphere with abundance of water at the roots, slight shade in hot weather, and a low temperature. I am told the plant will not be injured by two or three degrees of frost, but I have no experience of this, and should be sorry to expose my plants to the grip of Jack Frost even for a moment. The best time for potting the *Disa* I have found to be about the middle of October; all the young growths after flowering will by then have appeared above ground, so that there is no chance of damaging them through inability to see them.

Our plants are divided every year (and are thereby considerably increased in number) and the strongest growths are potted by themselves, sometimes one in a 6-inch pot and sometimes five or six growths in a pan; but I find the growths succeed better in pots than pans. Perforated pots are to be preferred, and in potting the plants should be well elevated. The compost I find to suit them is sphagnum and peat in equal quantity (all the small sifted out of the peat), a liberal supply of small charcoal, and clean crock dust, the whole well mixed.

It is an advantage if the mixture can be prepared a few weeks before it is wanted. The position they seem to like is a cool airy one; here they are placed between a door and a ventilator, both of which are wide open when the weather is warm. In the winter the plants are watered once a week. About February, as growth commences, more water is given, and so on every week as the days lengthen, and as soon as the spikes appear they are watered three or four times a day. As showing that the plant is not difficult to increase, I may say that our stock, which now exceeds 200 plants, originated in one small plant a few years ago. The largest spike ever grown here was grown last year. It measured 3 feet 2 inches in length and had on eleven flowers. There are several forms of *Disa grandiflora* in this country, each claiming some superiority over the others in the brilliancy of colouring, but my experience

goes to show that even on the same spike the colour differs much in brilliancy, according to the time it has been in bloom and whether heavily shaded or not.

Through the courtesy and kindness of Mr. Gumbleton, Mr. Bedford, and Messrs. Backhouse, I have been enabled to procure pieces of their varieties, and look forward with much interest and pleasure to flowering them next July and noting the results.—O. T. C.

MELON GROWING MADE EASY.

Now that the season has come round again when the majority of Melon growers begin to prepare for their next season's supply of this much-esteemed fruit, I think a few notes on the cultivation, such as is carried out here, may not be out of place.

We are expected here to have the first fruit fit for table by the end of April, and to obtain that we find it necessary to make the first sowing on or as near as possible to the 1st of January. The seeds are sown in thumb pots filled with good loam mixed with a little leaf mould. We make a hole with the fingers to the depth of an inch or so, dropping in some sand, then put two seeds in and fill up level to the top with more sand. This we consider a good mode of preventing the seeds decaying. Supply at once with warm water, then plunge the pots in evaporating pans filled with leaf mould, and place them on the hot pipes as near the glass as possible. If the leaf mould is kept damp no further watering will be required until the plants appear, which occurs in a few days. We then place them on a shelf near the glass to keep them as dwarf as possible before potting, which is done as soon as the roots reach the side of the pot. If both seeds have germinated we select the shortest, and of course the strongest, plant for potting, pulling the other one out.

We now come to the potting, and first procure some clean 5-inch pots, crocked, and the soil mixed ready. Good yellow loam, a little leaf mould, Mushroom bed refuse, and a small quantity of sand added make a suitable compost, and it is placed in the Melon house at least a day before potting. Very little is placed under the plants, so as to allow them to be potted as deep as possible. Care should also be taken that the soil is not dry, as they will only require lightly syringing for a day or so. They are then placed on the shelf again, and as soon as they require it are tied to a light stake, as they are liable to snap in their young state.

Our attention is then turned to preparing the beds for them. We first make a small hotbed with leaves and good hot short dung, such as is used for Mushroom beds, about a foot wide and 18 inches deep, then place some turfs of good yellow loam on the top, building up the sides with the same, then filling up with a mixture we prepare beforehand, composed as follows:—A cartload of loam chopped up, one barrowload of leaf mould, one of Mushroom bed refuse, also a small quantity of lime rubble, soot, and a sprinkling of Clay's fertiliser, native guano, or bone meal. The two first has been tried with success, the latter will be tried this year. We make this as firm as we can with a large potting stick, and this mixture can be strongly recommended to those who are troubled with black fly through the growing season, as it has been proved to be a great preventive of that pest, which, to my belief, is encouraged by the Melons being planted in too heavy soil. After the Melons have become well rooted the planting out is done. Three are placed to every light, as they produce fruit earlier than when grown on the extension system. We also plant them deep, burying them to the seed leaf, and then make a little mound round the stems composed of dry turf and soil, and when watering great care is taken not to water these mounds, so that in time they become quite dry, and so keep the stems from canker. With most Melon growers the rule is to plant as high as they can, but if they give the above plan a fair trial they will be pleased with the result.

A stout stake is placed by the side of each plant, and it is secured to the first wire, pinching off all laterals, leaving only the two nearest the wire, then pinch again until the leader has reached the top wire. There will then be found plenty of male and female flowers to make a good set of fruit. When setting the fruit, care should be taken not to syringe the plants the evening before, as if it is not bright next day the pollen will not be dry enough. In a day or two select the best fruits. If large fruits are wanted two will be sufficient to leave; if not, three will swell very well and make good medium-sized fruits. As soon as the fruits commence swelling supply the plants with liquid manure, as from then until the netting period is when they require most nourishment. Watering at all times must be attended to, on a fine day if possible, and early in the morning, and always with warm water, as otherwise the roots suffer and cause a great check to the Melons. They also like an even temperature, say from 70° to 75° at night and from 80° to 85° in the daytime, according to the weather out of doors.

Melons are subject to several pests. Black fly has been already alluded to. Red spider also often attacks them. The best remedy for the latter, I find, is to well syringe the plants with tepid water in the morning just as the sun begins shining on the plants. Mealy bug is another, the only remedy for which is to thoroughly cleanse the house in the winter and syringe it with strong petroleum and water, then taking care not to take any plant in the house with bug on it, as it is impossible to free them in the growing season from this pest, as the leaves are too tender for either sponging or syringing with insecticide.

In conclusion, I should like to name a few out of the numerous varieties there are now in cultivation, and that have done well with me under cultivation as recommended above. Hero of Lockinge I find to be a first-class Melon, one that should be grown by all, as it is always to be relied on as having a delicious flavour. Best of All and Scarlet Premier are very free and hardy, and when well grown of a good flavour. La Favorite is a good one, being free and well flavoured. High Cross Hybrid may be safely recommended as the easiest Melon to grow we have, and not one of the worst for flavour. I have obtained a seedling from Scarlet Premier crossed with the latter, and have no hesitation in saying that when it is well known it will become a favourite. There may be many more varieties good enough to be mentioned with these, but of all I have tried I much prefer these.—P. T. D.

FACTS ABOUT GRAPES.

ALICANTE.

AMATEURS, as well as professional gardeners with only one vinery, usually plant Black Hamburgh, Foster's Seedling, Buckland Sweetwater, and perhaps Madresfield Court, only to find that none of these can be kept in good condition nearly so late as wished. The question then arises, and is very frequently put; What should be substituted for any of these in order to have Grapes as late, say, as Christmas? In such cases I always advise either planting or inarching two or three canes of Alicante, this being the only reliable and comparatively easily grown late variety that will do well under treatment similar to that given the Black Hamburghs. As far as quality is concerned the Alicante is inferior to Black Hamburgh, Madresfield Court, Lady Downe's, and Mrs. Pince, but is superior to either Gros Maroc as usually met with, Gros Colman, and Alwick Seedling, and in addition is decidedly of very attractive appearance. It will bear almost as much bad treatment as Black Hamburgh, and, grown in the same house, will keep at least two months longer. The quickest way to establish it, in an already furnished vinery, would be to either graft or inarch it on Black Hamburgh, Foster's Seedling, or any Vines that can be best spared. There are several methods of accomplishing this, and if successful, a good fruiting rod may result the same season. It is too early to attempt anything of the kind, but those anxious to try the experiment should procure a few short lengths of the variety they require, bedding these in the open ground till the time has arrived for using them. We have tried various experiments in grafting and inarching with excellent results, and will describe these at a seasonable date.

To have the Alicante really good it needs more heat than is given to Black Hamburgh, but this difficulty can be partially obviated by either planting or establishing it by grafting at the warmest end of the house, and giving the least air there. As it is slower in arriving at maturity it is always advisable to forward by early starting or closing the house, say, by the end of February. If the house is devoted to both early and late varieties the end containing the former may be left open another month longer. In this manner it is possible to have all in flower at the same time, and a day temperature of about 65° with a fall of 5° by night will be beneficial to both early and late Grapes. A little fire heat is also of good service when the Grapes are ripening, this, if air is given night and day, invariably improving the quality of both early and late varieties. Without it they usually keep badly. The Alicante forces remarkably well, and I have seen it very good as early as July. At Badminton it is ripened or finished grandly by the first week in August, the quality also being above the average. Being the favourite autumn and winter variety, a long succession is secured by Mr. Nash, more Alicantes being grown than at any other private place probably in the country. "A Tourist" (page 380) has already alluded to the remarkably heavy crops of Alicante grown in a span-roofed vinery at Cardiff Castle, and on two occasions that I have seen this place I have been much struck with the extraordinary weight of bunches Mr. Pettigrew obtains without apparently injuring the Vines. In our case, overcropping results in the formation of small berries and late shanking. It is hard work cutting away so many promising looking bunches, but it must be done unhesitatingly if fine produce is aimed at. The finest bunches are usually formed

on well-ripened young canes, and the smallest on old closely spurred rods. We usually lay in a few young canes each season and prune the laterals on the reserved rods to a plump bud, even if this necessitates leaving a spur 2 inches or 3 inches in length. Those who market their surplus produce will find the Alicante much more profitable than the Black Hamburg. The latter, if ripe in August, must be sold frequently at 1s. or at the most 1s. 6d. per lb., whereas the Alicante will keep plump and heavy till November, when it should be sold for about 2s. 6d. per lb. Both varieties lose weight by being kept long after they are ripe, and many berries also decay, hence the advisability of selling as soon as a reasonable price is offered.

GOLDEN QUEEN.

This, being raised from a cross effected between Alicante and Ferdinand de Lesseps, was expected to prove a desirable companion for the former. It was one of a very remarkable batch of seedlings raised by the late Mr. Pearson at Chilwell, and it was there I first saw and tasted it. As far as habit of growth, fruitfulness, and free setting are concerned, Golden Queen is all that could be wished for, but unfortunately it very rarely colours well, or if it does finish off a rich amber, this soon changes to a muddy yellow, which quite spoils the value of it. A hot summer appears to suit it well, our Vine ripening off a good crop without much fire heat. The berries were fairly large, more solid than usual, and of a decided Muscat flavour—in fact it was very crisp and refreshing, and I was therefore more vexed to observe the change for the worse early in November. Yet another trial will be given it. Grown in a house of mixed late varieties, it was one of the first to break and flower, and I hope to try it in an early house before finally discarding what should have proved an excellent amateur's Grape. The best coloured bunches I have ever seen were ripened on a forced pot Vine, and I would recommend it for trial to those who annually force a few Vines.—W. IGGULDEN.

(To be continued).

DENDROBIUM NOBILE.

I WAS pleased to see the article by Mr. Iggulden in your last issue, page 562, and to find he had been so successful with the pruning process. I had some fine growths this season of *D. chrysanthum*, but unfortunately I was not able to send a growth for you to see when they were at their best. One growth, which measured nearly 5 feet long, had eighty-two flowers on it, and most of the growths had from thirty to forty flowers. *D. Pierardi*, with me, has growths between 4 and 5 feet long.—NOVICE.

VANDAS FLOWERING LATE.

UNDER my charge is a small collection of Vandas, chiefly varieties of *insignis*, *tricolor*, and *suavis*, which, instead of flowering at their usual time, have been producing their spikes at intervals throughout December, and have several expanding now. The plants are perfectly healthy, and I have been somewhat puzzled over this curious freak. The only conclusion I could come to was that the unusually hot summer must have checked them and caused a kind of premature rest, the succeeding moister weather of autumn having induced partial growth and flowering. I should like to know whether any of your readers have had a similar experience, and I shall be curious to see what will be the result another season.—W. L.

LARGE v. SMALL POTS FOR ORCHIDS.

SOME remarks of yours recently upon this subject could, I am sure, be confirmed by many Orchid growers, and in my own experience I have had several examples of the evils attendant on excessive root space for these plants. This of course requires some qualification, as there are many of the soil-loving Orchids like the *Calanthes* that need liberal treatment both in the quantity and quality of their root supplies, but as regards most epiphytal Orchids it is almost without an exception. Many of the stronger-growing epiphytal Orchids when properly restricted in their root space can be safely supplied with liquid manure, and the results are then much more satisfactory than when the roots are spread through a large mass of material which rapidly becomes sourd. The *Dendrobiums* of the noble and *Wardianum* types show this in a marked degree, and *Cypripedium insignis* is similar in this respect.—J. J.

ORCHID NAMES.

It seems that efforts are being made to increase the confusion already so prevalent in Orchid nomenclature and to flood us with hosts of synonyms such as have rendered the study of botany distasteful to so many. After over one hundred hybrid Orchids have been named in accordance with botanical usage—namely, with Greek or Latin titles, is it not somewhat confusing to commence giving them English titles such as Mr. Smith or Mrs. Jones? With all due respect to the authorities, whoever they may be, I wish to enter my protest against the adoption of a system that is both inconsistent and inconvenient. Much outcry is made about the terrible difficulties attending the botanical designations of plants, but the fact is that a large proportion of these are more easily remembered and more euphonious than English names, and they have the advantage of passing current and being as readily understood in most European countries as in our own. When we receive a few from the Continent named after Herr Somebody with an alarming combination of consonants in his name, or Madame la Comtesse of somewhere or other with about fifteen syllables, the folly of the system we have adopted will become evident to all. Many of our names will be quite as difficult to our continental friends. After all, who grumbles at such familiar names as *Rhododendrons* and *Chrysanthemums*? while *Rosa*, *Primula*, *Pæonia*, and others are both simple and elegant. It is quite true that some botanists have with distorted ingenuity produced some fearful compounds, or have adopted very peculiar personal names for plants, but these are only the exceptions, and the evils that will attend any system at the hands of injudicious supporters.—AN OLD ORCHID GROWER.

WOODS AND PLANTATIONS.

AT this season of the year it seems natural to turn our thoughts to the woods and plantations, a portion of the estate which generally now-a-days comes in for a small share of attention, owing in many instances to the reduction in the number of hands formerly employed. This is to be deplored from more than one point of view, as instead of it being a saving it is really in the long run almost ruinous. The actual value of an estate is greatly affected by the condition of its woods and the state of the timber growing thereon. If these have been kept in good thriving order it would most certainly command a higher price or rent than one, on the other hand, that had been very much neglected. The general character is quickly changed if due care and attention are not bestowed on such matters.

Objects of interest and beauty that were carefully studied by those who were in years past entrusted with the planting and laying out of grounds, at perhaps a very great cost, have been in some cases shut out of view by the unchecked growth of vigorous trees and shrubs, spoiling what was once esteemed for the beautiful vistas and landscapes. In another direction some unsightly objects are only too visible through the destruction of trees by gales, &c., originally planted to form a screen. A few instances like the above would soon change the whole tone and character of the most beautiful place; it would also tend very much to detract from its value, and point at once to neglect, which would in turn reflect a great amount of discredit on those who are responsible for their proper care, as it is evident if this course of things continue they must leave such places in a much worse state than they found them. Of course this applies more to the owner than those supposed to be in charge. If the former sees no interest in spending yearly sufficient to keep woods and plantations in a healthy thriving condition, those in charge ought not to be held responsible for circumstances over which they have no control.

Speaking of timber, I am afraid we are not following the good example set us by our forefathers. At one period there seemed almost to have been a mania for planting Oaks and Elms. The results of their labour we now enjoy in the grand specimens we see in the old parks of this country. It is a pity they cannot last for ever, as few can look on them without feeling a kind of proud satisfaction. Yet hundreds are cut down every year, and many others perishing through natural decay, and what a feeble attempt is made to replace them! It is true very large numbers are planted every season, but with a different object, I believe, than that which prompted those of old. Now they are packed in as close as possible to make a show at once, and christened belts and clumps, which are seldom attended to after as regards thinning. Such soon form a jungle, which can never be called ornamental, far less claim any value from the timber point of view.

No doubt the great numbers of coniferous trees that have been imported and raised in this country during the last fifty years have taken the place to a great extent of those which were used in olden times before the planter had such a selection, and while admitting the great beauty and value of many of these I feel sure they will

never last so many years and form such interesting landmarks as our British Oaks and Elms. The two latter are so closely associated with this country's history it would amount to almost a crime were they neglected to such an extent as to be termed a thing of the past, to say nothing of the injustice done to the future generations.

While this matter is worthy of the serious attention of all it does not perhaps affect the ordinary gardener so much as the general plantations of shrubs and ornamental trees in the pleasure grounds in close proximity to the residence. A few weeks or days at this season among such would find ample work for men who perhaps cannot get on with other work. This careful overhauling would in many cases be most advantageous, not only to the trees and shrubs themselves, but to all concerned, saving to a great extent the annoyance felt at the busy season at the sight of some of the most interesting features of the garden gradually being choked by stronger and less attractive occupants, and by the satisfaction of knowing that such work was done at the right time, thereby securing that beauty in the pleasure grounds which is of very great importance in all gardens large or small.—R. PARKER, *Impney*.

UNDER GARDENERS AND EXHIBITORS.

As your correspondent, "A Head Gardener," very truly observes, the above subject is a very large one, but I think in this way, as in all other relations of life, "Do as you would be done by" should be the rule to guide our course of action. I do not think there would be any likelihood of a successful exhibitor acting unjustly towards his subordinates if he would but remember what were his feelings on the subject when he was a young man.

Your correspondent makes much of the experience gained in growing plants, &c., for exhibition, and seems to imply that young men ought to consider this sufficient payment for all the extra labour and anxiety incurred. Perhaps so, but I am not inclined to consider this experience of such inestimable value, as it seems to me that in these days there is a greater demand for good all-round gardeners than for men who can grow a few things superlatively well. If I were starting life again I should avoid all places where exhibiting was carried on to a great extent, as it is not, in my opinion, in such places that a young man can gain the experience most valuable to him in after life.

But even supposing the experience is valuable, I contend that under gardeners are only human in expecting something more material. What is it induces exhibitors to compete? To some extent, perhaps, because of the honour and credit attached to winning prizes, but to a much greater extent because of the value of those prizes. If it were not so we should see as many competitors for a small prize as for a large one. It is all very well to tell young gardeners not to look at things from a pecuniary point of view, but to do their work for its own sake, &c. All very good in theory, but not so easy to practise when one is probably receiving a semi-starvation wage. I never yet knew a head gardener who would work for £2 a week if he could get £2 10s, nor an exhibitor who was as pleased with a 5s. prize as with one of the value of £10.

There are, I know, some gardeners who deal most generously with their young men in the matter of prizes. If one of them would be good enough to tell us what is his practice he might be the means of inducing others to follow his example, and thus create a better feeling on the subject. With regard to gardeners getting all the credit, I admit that this is not always so, but frequently it is the case. I have frequently heard successful exhibitors complimented and congratulated when the young men standing by were not deemed worthy a word of praise. Your correspondent was fortunate in having his merits recognised so early in his career. Week by week we read a report in the horticultural papers of some noted place. The report generally concludes by saying that the condition of things was a great credit to Mr. So-and-so, completely ignoring his assistants, without whom Mr. So-and-so, however clever, could do little. A small matter, some will say, but life is made up of small things.—AN UNDER GARDENER.

EVENTS OF THE WEEK.—To-night (Thursday) the General Committee Meeting of the National Chrysanthemum Society will be held at 7 P.M. in Anderton's Hotel, Fleet Street, to fix the time and place of the annual general meeting, with other important business. On Tuesday, the 10th inst., the Royal Horticultural Society's Committees will meet at South Kensington, and a general meeting of Fellows will also be held to confirm the resolutions passed at the last special meeting.

— THE WEATHER.—A Scottish correspondent writes: "The weather has been similar to that of the preceding week—alternate frost and thaw. On the night of the 26th we had 7½° of frost, and 12° on the night of the 30th. Snow threatened on Saturday and Sunday, and over 2 inches have fallen during the night. The barometer continues to fall as it has done for the past few days. I wish all Journal readers 'A guid New Year. Muckle luck and little maen (moan).'"

— A WELL-KNOWN Brighton horticulturist, Mr. E. SPARY, died suddenly on the 27th ult. aged eighty-four years. For some years Mr. Spary had been proprietor of The Graperies at Brighton and had frequently taken a prominent part in the exhibitions at that town. He had been a subscriber to the Gardeners' Royal Benevolent Institution for thirty-seven years.

— MR. BENJAMIN FIELD, 75A, Queen Victoria Street, London, has sent us a copy of his almanack for 1888. It is in monthly sheets, on which the dates and days are prominent, and contains postal and other information. These sheets are useful in the offices of gardens or other places for handy reference.

— WE have received from the EASTERN TELEGRAPH COMPANY, 50, Old Broad Street, London, a paper knife, with an almanack on the handle and map of the world on the blade, which is as much as can be expected on an article of this kind, that also answers its purpose well. It is manufactured by Messrs. Waterlow & Sons.

— PLANTING OUT POINSETTIAS.—Mr. A. Haggart writes from The Gardens, Moor Park, Ludlow:—"Most people like Poinsettias, but few think of planting them in a bed. The example sent is from a plant we have growing in a bed in the stove. It is bearing twenty-seven heads of blooms, twenty of them about as good as this, the others smaller. I shall be glad if you can tell me if they are often seen branching down the stem as this has done?" We have never seen a finer example than the one before us. The diameter of the head, measuring from the tips of the floral bracts, exceeds 17 inches, and the larger of these are 2¼ inches across, of great substance, and brilliant in colour, while on the stem below the head are eight branchlets producing flowers and bracts. Such examples are not common.

— THE usefulness of ASPARAGUS PLUMOSUS in affording graceful foliage to be arranged with flowers is known to many gardeners, but the popularity of the plant is certain to increase for such purposes. The small side branches last a surprising time when placed in vessels of water in rooms, and we have some now that have been cut for more than three weeks and yet seem to be scarcely the worse. They are fresh, green, and will last much longer.

— THE AUSTRALIAN ACACIAS are represented in British gardens by numbers of species, the majority of which are, however, only adapted for large conservatories, though a few succeed well in pots. Some 300 species are known, and there is a large living collection in the Royal Gardens, Kew, but many botanists will welcome the Iconography of Australian Acacias, a work which has been undertaken by Baron Von Mueller for the Victorian Government. A portion has already been issued, a lithographic quarto plate being devoted to each species. The monograph of the Eucalypti has afforded ample evidence of Baron Mueller's admirable method of dealing with botanical subjects.

— A TREE that is comparatively seldom seen in British gardens SOPHORA JAPONICA, is better known in America under its pendulous form, and makes a very noble tree when fully developed. The whitish yellow flowers are in racemes. The finest specimen in Europe, M. André says, is probably at the village of Villennes on the borders of the Seine, near Poissy. This was planted 1795. It is in the middle of the public park there. The head has a spread of 133 feet, and is a proportionate height. The trunk has a circumference 13¼ feet.

— A CORRESPONDENT of the "Garten Zeitung" communicates some particulars of a specimen of THE JAPAN UMBRELLA PINE that is growing in the garden of Max Daniel Wolterbeck, Valkenburg, near Arnheim, in Holland. It was planted where it now stands, in a very exposed situation, twenty years ago, and is a healthy and beautifully formed tree. Moreover, it has never suffered in the least from frost or other climatal influences. Of pyramidal shape, it is nearly 13 feet high, with a circumference of a little over 21 feet. The year before last it bore for the first time two ripe cones, and the seed produced fifteen

seedlings. Last summer it bore only one ripe cone. Many other handsome Conifers exist in the select collection at Valkenburg. The soil is sand and peat.

— GARDENING APPOINTMENTS.—Mr. Edward Burton, late of Lunefield, Kirkby Lonsdale, has entered on his new charge as head-gardener to Dr. Tennant at the Great Hydropathic establishment, Ben Rhydding, near Leeds, where he will have scope for the exercise of his admitted abilities. Mr. J. Aslett, who was for upwards of five years under Mr. G. Norman at Hatfield Gardens, and also foreman at Lunefield Gardens for nearly two years, has been appointed head gardener to A. Harris, Esq., Lunefield, Kirkby Lonsdale, Westmoreland.

— REFERRING TO VEGETABLE MARROWS, Mr. J. Muir observes: "A correspondent at Kew sends me an interesting note on these. Amateur like, he kept a note of the produce of three different plants of three varieties, and the following was the result—Pen-y-byd thirty-five fruits, Long White thirty-one fruits, Improved Green Bush twenty-five fruits."

— RAPHIDES IN PLANTS.—At a recent meeting of the Jena Naturalists' Society Herr Stahl read a paper of the significance of those excreta of plants known as raphides—*i.e.*, crystalline needles often met with in the cells in large quantity. From experiments he inferred that they were a protection to plants against being eaten by animals. Many animals avoid plants with raphides, or eat them reluctantly; and some animals—*e.g.*, snail species, in eating plants that have raphides, select those parts that are without the crystals. Many plants held for poisonous—*e.g.*, *Arum maculatum*, owe their burning taste simply to the very numerous raphides, which, forced out of their cells, enter the tongue and palate. The juice obtained by filtration has quite a mild taste.

— MR. JNO. CAMPBELL, The Gardens, Mickleover Manor, Derby, sends the following records of the RAINFALL AT DERBY in 1870 and 1887, remarking that "the rainfall for the past year and the year 1870 totals so nearly alike I thought it might be of interest to your readers." 1870.—January, 1.43; February, 1.21; March, 1.72; April, 0.69; May, 0.73; June, 1.91; July, 1.32; August, 0.83; September, 1.13; October, 1.50; November, 2.00; December, 2.22. Total for the year, 16.69 inches. 1887.—January, 2.31; February, 0.27; March, 0.89; April, 1.21; May, 1.31; June, 1.12; July, 1.05; August, 1.75; September, 1.70; October, 1.54; November, 1.53; December, 1.56. Total for the year, 16.24 inches. Mean for the past eighteen years, 29 inches per annum.

— FLORIDA ORANGES.—We have recently had some fine examples of Florida Oranges submitted to our examination, and the fruits were remarkable alike for their thin, smooth rind, and abundant sweet juice, much superior to the ordinary Oranges now in the market. They were grown in the Jacksonville district. Referring to this subject an American paper says: "A new undertaking in the fruit line is the shipment of Florida Oranges to Europe. The first lots were sent over on fast steamers last week, and others are being sent on every sailing day. During the months of November and December, the markets throughout England and Scotland have no supply of Oranges except immature and consequently very sour fruit from Spain and Italy. Florida Oranges ripen early, and will have practically no competition in foreign markets for two months. The transportation costs about fifty cents a box, which is less than the advance of English prices over our own. Orange tree planting has been carried to such an extreme in Florida that nearly all of the suitable land has been utilised, and groves have been planted even where the soil is not of a proper nature for this fruit."

— WHITE SHREW MOUSE.—Mr. G. Abbey writes: "The Shrew Mouse is a well known pretty little animal, the formation of its hair as seen under a powerful microscope is very beautiful. In turning over a manure heap in the park an albino, or white variety of this interesting vole was found (December 23rd). It is one of the prettiest creatures I have ever seen, very lively, and very clear in colour, having the yellow tinge next the skin as present in most white-haired animals, and in white-feathered birds, otherwise it is of snowy whiteness without speck. It was found next to the soil beneath the manure, which is rather dry and littery, no doubt in quest of food, grubs, &c. White Moles I know are not uncommon, but this is the first time I have seen or heard of a White Shrew Mouse. I thought it might interest some of your readers if it be worth recording."

FICUS ELASTICA VARIEGATA.

THOUGH this plant is not new, it is not common, and when well grown is unquestionably beautiful. We first saw it at one of the Liverpool shows a few years ago. It was exhibited, if we remember rightly, by Messrs. R. P. Ker & Sons, and was awarded a first-class certificate. Since then the plant has gradually spread and found its way into several collections, though it is by no means seen everywhere; yet it appears to improve on acquaintance, and we know has been bought freely by some growers who anticipate it will prove good for the market and the million. In its early stages the variegation is not very clear, but the greenish yellow portions change with age to creamy white, and when the plant is healthy and the normal colour rich and deep the contrast is highly effective. The specimen figured was grown by Mr. J. Forbes at Dover House, Rochampton, where so many other things

Fig. 1.—*Ficus elastica variegata*.

are done well, and the gardens of J. S. Morgan, Esq., are among the best kept in the kingdom. *Ficus elastica variegata* is valuable for decorative purposes in halls, rooms, and conservatories, and is suitable for arranging in effect groups at exhibitions.

MRS. PEARSON GRAPE.

HEREWITH I send you a sample of Mrs. Pearson Grape, that we are bottling to-day, in order that you may judge of their appearance and quality; but what I wish to make more generally known is the long keeping qualities of this Grape. We can keep it good well into April, it will finish a much heavier crop than Trebbiano or White Nice, and unlike those varieties is useable when ripe in autumn. The bunches are more compact and handsome, they are also of a more desirable size. We have had them 4 lbs. in weight. I am having a photograph of one taken which, when completed, I will forward to you, also one of our Gros Colmans, which are very large, but the colour is not quite so good as usual. I will give a description of their culture when I send the photos.—J. H. GOODACRE, *Elvaston Castle Gardens*.

[The bunch of Mrs. Pearson is full, well shouldered and handsome,

and the berries of uniform size, about 3 inches in circumference, juicy, luscious, and refreshing. We shall be glad to inspect the photographs referred to, and to publish the cultural notes obligingly promised. Mr. Goodaere has exhibited the largest Gros Colmans we have seen this year.]

ROYAL HORTICULTURAL SOCIETY.

THE following are the members of the three Committees of the above Society for 1883:—

SCIENTIFIC COMMITTEE.

CHAIRMAN.

Sir Joseph Dalton Hooker, K.C.S.I., M.D., C.B., F.R.S., V.P.L.S., The Camp, Sunningdale.

VICE-CHAIRMEN.

Maxwell T. Masters, M.D., F.R.S., Mount Avenue, Ealing, W.
Rev. M. J. Berkeley, F.R.S., Sibbertoft, Market Harborough.
F. P. Pascoe, F.L.S., 1, Burlington Road, Westbourne Park, W.

HON. SECRETARY.

Rev. Prof. G. Henslow, M.A., F.L.S., F.G.S., Drayton House, Ealing.

Bennett, Alfred W., M.A., B.Sc., F.L.S., 6, Park Village East, W.
Boscawen, Hon. and Rev. J. T., Lamorran, Probus, Cornwall.
Boulger, G. S., 9, Norfolk Terrace, Bayswater, W.
Burbidge, F. W., F.L.S., Trinity College Gardens, Dublin.
Church, A. H., F.C.S., Royston House, Kew.
Clarke, Colonel R. Trevor, Welton Place, Daventry.
Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire.
Glaisher, James, F.R.S., Dartmouth Place, Blackheath, S.E.
Green, Professor, Pharmaceutical Society, 17, Bloomsbury Square, W.C.
Lowe, Dr. Wm. Hy., Woodcote, Inner Park Road, Wimbledon.
Llewelyn, J. T. D., F.L.S., Penllegare, Swansea.
Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.
Maw, Geo., F.L.S., Benthall, Kenley, Surrey.
McLachlan, R., F.R.S., Westview, Clarendon Road, Lewisham, S.E.
Michael, Albert D., F.L.S., Cadogan Mansions, Sloane Square, S.W.
Morris, D., F.L.S., Assistant-Director, Royal Gardens, Kew.
Murray, G., F.L.S., Natural History Museum, South Kensington, S.W.
O'Brien, James, Harrow-on-the-Hill.
Plowright, C., F.L.S., 7, King Street, King's Lynn.
Ridley, Henry N., B.A., F.L.S., Natural History Museum, South Kensington.
Scott, D. H., M.A., Ph.D., 8, Thornton Hill, Wimbledon, S.W.
Smee, A. H., The Grange, Wallington, Surrey.
Smith, Worthington G., F.L.S., High Street, Dunstable.
Tait, Alfred W., 115, Entre Quintas, Oporto.
Ward, Professor Marshall, The Laurels, Englefield Green, Staines.
Wilson, Geo. F., F.R.S. Heatherbank, Weybridge Heath.

FRUIT COMMITTEE.

CHAIRMAN.

Robert Hogg, LL.D., F.L.S., 99, St. George's Road, S.W.

VICE-CHAIRMEN.

T. F. Rivers, Sawbridgeworth.
Arthur W. Sutton, Reading.

H. J. Veitch, F.L.S., Royal Exotic Nursery, Chelsea, S.W.

SECRETARY.

Archibald F. Barron, Royal Horticultural Society, Chiswick.

Adams, H. J., Roseneath, London Road, Enfield, N.
Barr, Peter, 34, King Street, Covent Garden, W.C.
Blackmore, R. D., Teddington.
Burnett, J., The Gardens, Deepdene, Dorking.
Cheal, J., Crawley, Sussex.
Crowley, Philip, Waddon House, Croydon.
Cummins, G. W., The Grange Gardens, Wallington.
Denning, W., The Gardens, Londesborough Lodge, Norbiton, Surrey.
Ford, Sidney, The Gardens, Leonardslee, Horsham.
Haywood, T. B., Woodhatch Lodge, Reigate.
Howe, C., Benham Park Gardens, Newbury.
Lee, John, 78, Warwick Gardens, W.
Marshall, William, Auchinraith, Bexley.
Miles, George T., The Gardens, Wycombe Abbey, High Wycombe.
Norman, G., Hatfield House Gardens, Hatfield.
Paul, William, Waltham Cross, Herts.
Pearson, Alfred H., The Nurseries, Chilwell, Notts.
Roberts, J., The Gardens, Gunnersbury Park, Acton, W.
Ross, Chas., The Gardens, Welford Park, Newbury.
Saltmarsh, T. J., The Nurseries, Chelmsford.
Smith, James, The Gardens, Mentmore, Leighton Buzzard.
Warren, W., Worton Gardens, Isleworth.
Weir, Harrison, Hinwick, Lansdowne Road, Tunbridge Wells.
Willard, Jesse, Holly Lodge Gardens, Highgate, N.
Woodbridge, John, The Gardens, Syon House, Brentford.
Wright, John, 171, Fleet Street, E.C.

FLORAL COMMITTEE.

CHAIRMAN.

Geo. F. Wilson, F.R.S., Heatherbank, Weybridge Heath.

VICE-CHAIRMEN.

Rev. W. Wilks, Shirley Vicarage, Croydon.
Major Lendy, F.G.S., F.L.S., Sunbury-on-Thames.
H. Herbst, Kew Road, Richmond, Surrey.

SECRETARY.

Archibald F. Barron, Royal Horticultural Society, Chiswick.

Wynne, Brian, 17, Catherine Street, Strand, W.C.

PACKING FRUIT.

IN many, indeed in most gardening establishments in the kingdom, fruit has to be packed regularly once or twice a week during certain seasons, and often sent long distances both by rail and boat for the family use. In any case when fruit has to be sent either for short or long journeys it cannot be packed too carefully, for unless it is properly packed, no matter how excellent the fruit may be, it will be sure to come to grief before it gets to its destination, and give dissatisfaction to the employer and much annoyance to the gardener who is responsible for not having packed it properly. Some gardeners of considerable experience use dry soft moss for packing in preference to any other material, while others recommend paper shavings and cotton wadding as suitable material. For general packing, and for mixed fruits, including Pine Apples, Melons, Apples, Pears, Lemons, Cucumbers, Tomatoes, Grapes, &c., all to be packed in one box, I use soft hay made from grass about 6 or 7 inches long. I have packed with this for many years, and I find it answers the purpose better than anything I have ever tried. Grass to make this packing material can be found in sufficient quantity in every place in the country where there is a lawn or grass banks, which are kept short by mowing. The same cannot be said in favour of procuring moss, as it is not in every place that good packing moss can be found in a sufficient quantity for that purpose.

We make the hay as follows:—After the grass has been cut the first time in the season a piece is selected, and allowed to grow to the height of 6 or 7 inches, when it is cut and made in the usual way, but it is thoroughly dried before being stored away to prevent it heating. The hay is soft and flexible, and if returned in the empty boxes (as in my case) it improves in quality, and will last for a long time in good condition fresh and free from dust. If it should get a little damp at any time it can be put out in the fresh air on a fine day and turned over several times, when it will soon dry and regain elasticity.

In packing, the Pine Apples, Melons, Tomatoes, and Cucumbers are rolled singly in paper and tied with string. The bottom of the box is covered with about an inch of hay and the Cucumbers placed flat at the bottom, then Melons and Pine Apples follow, and are all packed tightly by filling up every little space between the fruits, so that the box may be turned upside down without fear of the contents falling out. About another inch of hay is spread over these, and the surface made level, when a layer of Apples or Pears—as the case may be—are packed neatly, and all the interstices between filled up tightly, so that the fruit cannot move in any direction. Another layer of hay is added, and the fruit packed in the same way until the box is filled. I always leave sufficient space for the Grapes at the top of the box to finish with in the

following way:—About 1½ inch of hay is spread over the bottom of the space left, and four sheets of packing paper are broken up and made soft by rolling them in the palms of the hands. These are spread so as to cover half of the space at the bottom, and the other half to hang over the sides and ends of the box for turning over and packing in on the opposite sides when the packing is finished. A sheet of tissue paper is then spread over the bottom and up the sides, and the largest bunches of Grapes are placed in the four corners and wedged in with smaller bunches in the middle, and all are packed as closely together as possible. When the box is full another sheet of tissue paper is spread over the top of them and tucked in at the sides. The paper hanging over the sides is tightened and turned over and packed down on the opposite side, and the spaces between the sides of the box and the paper are packed as firmly as possible, so that it is impossible for any of the contents to move, no matter in what position the box is turned. Sufficient hay is packed on the top of the Grapes to render a little pressure necessary in screwing down the lid. The box is then roped, labelled, and despatched some 400 miles by rail and twenty by sea, after which it has to be conveyed some five miles by cart before reaching its destination. I have practised the above system of packing for the last twenty years, and I have never had a complaint made during that time of the fruit arriving in bad condition. Indeed, I have been told repeatedly that the fruit arrived in splendid condition, and that the Grapes looked as fresh after the long journey as if they had been newly cut off the Vines.

Peaches are packed by themselves in tin trays, which hold two dozen each. The tray is divided into compartments and the fruit packed singly. A little hay is placed in each compartment and the fruit rolled in tissue paper, then enveloped in cotton wadding, and dropped gently into its compartment, and the corners packed with hay. The trays are dropped into a neatly fitting box, which hold three, and the lid screwed down tightly to prevent oscillation, which is all the packing necessary to insure them for travelling long journeys without injury.—A. PETTIGREW, *Cardiff*.

THE SEEDLING BRIAR.

MR. W. R. RAILLEM'S article on Roses in the last number of the Journal was very interesting, and I read it with pleasure, as doubtless did many others, but I should like to correct a common error in connection with the seedling Briar. It is said that it sends its roots down deeper than the cutting does. This is a mistake, at any rate it does not apply to places where the treatment of this stock is understood. The seedling Briar, like all other seedlings, sends a shoot straight up into the air and a root straight down into the soil, and if we never transplanted it, but budded it, and allowed it to remain permanently in the seed bed, I am quite ready to admit that it would form a tap root, but I have no doubt that most amateurs have received cutting Briar Roses from the nurseries with long coarse tap roots to them. Well, what do they do with them? "Cut back short, of course," says everybody. This is exactly what should be done with the seedling Briar when it is transplanted for budding. If it is done the roots will grow out just as horizontally as the cuttings do. If Mr. Raillem will allow me, I shall be glad to send him, through the Editor, a plant on the seedling Briar, when he can judge for himself if I am right or not. While on the subject of the seedling Briar, I may say that, in my opinion, the greatest merit it has is that it is grown from seed, seedlings being, as a rule, much more vigorous than cuttings.

A word about Her Majesty. I give my experience for what it is worth, having grown 1500 plants of this variety last season. In my opinion this Rose is a decided acquisition; coarse, no doubt, when grown in fertile soil and heavily manured, but if treated properly—that is, grown in poor soil and not pruned too hard—I believe the blooms will be exquisite in form and colour. I am afraid its weak point is mildew. Like Mr. Raillem, I never noticed thrips until this season, but I had an attack of it then. Lady Mary Fitzwilliam, Captain Christy, Merveille de Lyon, and Her Majesty were in many cases completely spoiled. In dry seasons I fear thrips will always be a nuisance which knows no cure.

I quite agree with Mr. Raillem that the non-ripening of the autumn-grown wood through loss of leaves or other causes is immaterial; it is the lower buds on the spring-grown and summer-ripened branches that we should look to for next season's blooms.—D. GILMOUR, JUN.

ROSE MILDEW.

THE difficulty mentioned by Mr. W. Raillem on page 532, as to mildew appearing on forced Roses in a house which has never had a Rose in it before and during the wintry months, is easily explained.

The simple spores would in all probability be taken into the house with the Roses. They are often present on Roses in large numbers when quite invisible to the unaided eye. The minute damp-proof and frost-proof boxes (perithecia) are only produced on the approach of cold and inclement weather. The fungus in this manner protects itself against impending destruction. In a greenhouse the fungus finds itself in a paradise of unchanging temperature, therefore as it has no need of winter perithecia it does not produce them, but goes on producing the simple spores in the summer fashion during the wintry months. To the fungus winter in the greenhouse represents capital summer weather, just suitable for mildew.—WORTHINGTON G. SMITH, *Dunstable*.

MILDEW AND THRIPS.

IN reply to Mr. W. R. Raillem, in his interesting "Notes on Past Rose Season" he will find the "perfect" mildew destroyer, which is a liquid preparation of sulphur, a great improvement on the old method of applying sulphur. It leaves no sediment on the leaves. The "swift and sure" insecticide makes a capital destroyer of thrips. It is largely composed of petroleum, which is made perfectly soluble in cold water without the aid of an alkali. It can be used on plants in full bloom with safety. These preparations of the Horticultural and Agricultural Chemical Co. of Glasgow have been frequently advertised in your columns, and can be had from seedsmen.—S. C. B.

ROSE STOCKS FOR ROSES.

WE hear a good deal from time to time about the relative merits of seedling Briars, cutting Briars, and Manetti stocks. I once procured a few Roses on all of them, and could not perceive any substantial advantages that one kind possessed over the other. Do all varieties of Roses succeed alike on these stocks? I have also raised several Roses from cuttings, and found all the strong growers so established thrive quite as well and produce equally good blooms as when the varieties were budded on any of those stocks; and, moreover, stocks of Gloire de Dijon, John Hopper, and some others when budded with different varieties appeared to answer as well as Briar stocks, seedling or budded, and the Manetti. There are always plenty of cuttings in gardens where Roses are grown, but it does not do to wait till the regular pruning time in March or April before inserting them, as not one in ten will strike then, but if made and inserted in October or early November few will fail if ripe wood be selected and a length of 6 inches is placed within the ground and 1 or 2 inches remaining above it. Rose cuttings will strike root if inserted now, at least some of them will, but the sooner they are put in after the leaves change in the autumn the better. Inserting buds in some of these own-root Roses was a freak of fancy, the employment of a few idle moments, without any calculation of ultimate results, which, however, proved satisfactory.—A. PEDDLER.

ARTIFICIAL MANURE.—A NEW ROSE.

I DO not go in for Orchids. The only glass structures I have, in common with Mr. Chamberlain, are a few handlights, tumblers, and wineglasses, but will "Dum Spiro Spero" tell me whether the artificial manure he recommends will do for Roses in the open air? If so, as an experimental philosopher, I will try it if he will further tell where I can get it, and when best to apply. My ambition for more than thirty years has been to obtain Rose blooms of the diameter of a dessert plate, and I have hitherto failed! I have a promising seedling Rose, which I purpose naming "The Dean of Rochester." So please register the name for two years, Mr. Editor, until I have fairly tested it.—NIL DESPERANDUM.

EXHIBITING AND JUDGING BOUQUETS.

THE various letters upon this subject have contained numerous points of interest and more or less importance, but there is one matter that seems to have escaped the attention of your correspondents, and to this I now wish to call attention. The principal object of classes for bouquets and other floral decorations at shows is presumably to improve the taste for such work generally, and especially amongst gardeners, who unfortunately seldom receive as much training as they need to meet the very numerous calls upon their skill in these times. That being so, I think classes should be devoted to gardeners as in other departments, some being open or for nurserymen. It places a gardener at a great disadvantage when he has to compete with persons in trade who buy large quantities of the choicest flowers, and can consequently always select the best for exhibition. Besides, the work is often entrusted to specialists whose whole time is occupied in the business, and consequently the advantages are greatly in favour of the trade exhibitor. While these are allowed to enter with gardeners and win all the leading prizes year after year there is not likely to be any great advance in the number of competitors, as in several cases it has practically amounted to a monopoly of the first prizes. No one can reasonably object to the florists taking advantage of this state of affairs, it is part of their business, and they are perfectly justified in endeavouring to win as many prizes as possible; in fact, numerous shows would present a very unsatisfactory display in this department if it were not for their exhibits. It is, however, worth the attention of horticultural societies in all cases where their funds will admit, and if they can expect a fair number of competitors, the classes should be divided as suggested.

The minor matters can be safely left to the judges where professional men are employed, and the chief causes for complaint have arisen when the task has been assigned to amateurs, either ladies or gentlemen. I

have had some experience in the work of the florist both in private gardens and in business, and have also been called upon to judge occasionally, and consequently know somewhat of the diversity of opinions in matters of taste. I have also found there are some persons in this, as in other matters, greatly deficient in the faculty of judgment, being as erratic in their opinions and inconsistent in their decisions as possible; but a man who has had practical experience in the work is the one least likely to err, as he has somewhat of a standard by which to gauge the merits of those he sees. Few people in a general way can assign any reason why they prefer this or that bouquet, buttonhole or decoration, and it is because they have no clear ideas which is more desirable—contrast or harmony, boldness or lightness, numerous colours or a few tints. Each style in competent hands has its own special attractions, and the difficulty arises when excellent representatives of each are competing together, as the minor details of composition have then to be carefully weighed.—GARDENER.

WHEN I first brought this subject forward I did so thinking that if the practice of making and exhibiting bouquets in the loose manner in which I had seen them was at all general at horticultural shows the discussion of the subject in this Journal would tend greatly to put a stop to it, and give rise to some rules being observed at shows which would place all intended exhibitors on an equality. I was glad to see the subject so ably taken up by other correspondents, but sorry to see reference made to individual exhibits. Such references will not serve any good purpose in this discussion, which we yet hope will be brought to a satisfactory conclusion. As regards the size of a bouquet, I think that from 10 to 18 inches would be a size suitable to most exhibitors, then they could use such flowers as they choose in its construction. Good taste in the arrangement of the flowers ought to have more weight with judges than the rarity of the flowers. Rules set down by committees should not be infringed by either exhibitors or judges, and then the balance of good feeling will be maintained by all concerned. The first bad example should be rejected at once; the trouble of doing so would be much less than trying to rectify errors afterwards, for if one bad example is allowed to pass more will follow. If a standard set of rules does not meet with the approval of all committees of flower shows then I think the least they can do is to frame a few simple rules themselves, and see that they are thoroughly adhered to.—G. GARNER, *Amberwood Gardens, Hants.*

"AMATEUR FLORIST" seems to think me inconsistent in my remarks, but I fail to see why. I did not excuse myself, or I should not have confessed the practice of inserting Ferns at the shows; neither did I commence it till I found no notice was taken of it by judges or committees. No one, however, would be more pleased than myself to see it stopped, and the only way in my opinion is to have judges who are thoroughly acquainted with the work, and let them carry out strictly the rules in the schedule. I am sorry "Amateur Florist" thinks me severe on Mr. Chard. I did not intend it to mean exactly as it reads, and if I say I wrote an amendment to appear in this week's paper, but thought it better to wait, he will acquit me of any hostile intentions. It should have read thus:—Had I been the judge I would have withheld the first prize, as neither of the exhibits was worth the handsome prize offered, and this without casting any reflection on Mr. Chard's work, as I distinctly stated Mr. Chard had other exhibits to see to, consequently he had not time to finish this particular exhibit in his usual manner, in other words he was careless. I think I can claim as great acquaintance with Mr. Chard as "Amateur Florist," and I shall yield to no one in my respect for him; and more than this, he, as well as others, including myself, made sure of his being placed first, and one of my objects in explaining it so minutely was to call into question the peculiar judging.

As to the list of prizes which both Messrs. Perkins and Chard can show, may I be allowed to ask at what expense have they been gained? One reason why I cannot show such lists is—first, I have not time to attend all the shows, and another is both have better facilities for obtaining costly flowers than I have, as witness two remarks, one is Mr. Chard's own, where he says he took no showy Cattleyas in his bouquets; and another is one I heard in front of almost, if not quite, the last bouquet Mr. Perkins showed this season, and it was this: "The flowers in that bouquet are worth double the prize money." This brings us back to costly bouquets, and suggests a class for bouquets, Orchids excluded, that would put most exhibitors on a more equal footing, and give those a chance who do not grow Orchids. I do not mean to shut out Orchid bouquets from the shows, as we know they are too valuable to be ignored, but the remark often heard at shows is, "Who can stand any chance against such a bouquet as that?" But if the committee cannot afford two classes by all means leave it open, as good bouquets and table decorations at a show are a great attraction to nearly all visitors, and greater still to your humble servant.—A LEARNER.

NEW PLANTS OF 1887.

THE continual demand for novelties and the efforts of nurserymen and seedsmen to meet this by a proportionate supply afford some of the best indications that the interest in horticulture is far from decreasing. Year by year the records of novelties in the plant world assume considerable proportions, and the lists of certificated plants show in a remarkable manner how large a number of these are really meritorious

additions to those already in cultivation. These, too, include not only hardy plants and florists' flowers that are within the reach of all classes, but also choice stove plants and Orchids of great value. There are thus some to suit the tastes and pockets of all, and this again is a sign that the love of horticulture extends almost equally throughout the various ranks of society. The dweller in towns who takes so much pleasure in his Carnations and Picotees, Auriculas or Chrysanthemums, is just as eager for novelties amongst his especial favourites as the clergyman, the wealthy merchant, or the nobleman with their Roses, Ferns, or Orchids, and great specimen plants which win so many honours at exhibitions. All are constantly watching for new additions to their collections, and the various trade firms, it must be admitted, do their utmost to satisfy them in this respect.

During the past half century enormous numbers of plants have been introduced, from tropical regions generally, and from the southern hemisphere. Distinguished patrons of horticulture perhaps first set the example of despatching collectors to various districts that had been but little explored. The London Horticultural Society took the matter in hand, and through their collectors, Douglas, Fortune, and others, added greatly to the number and variety of garden occupants. Realising the commercial importance of thus introducing plants, the work was speedily greatly extended by nurserymen, who with much enterprise engaged collectors to search the most promising countries for plant treasures. So rapidly did this system extend that one firm is said to have had as many as twelve collectors in their employ at one time. The result of this was that new imported plants became very numerous every season, and commanded in most cases large prices, especially with those that were slow of increase. Most of the leading types of plants have been much extended, and to some extent temporarily exhausted. It was found that the "finds" of sterling value became less frequent, and the expenses continued as great, so that gradually there has been a falling off in the number of special trade collectors, and many firms now rely mainly upon foreign friends or correspondents for the additions to their stock from abroad.

It cannot be supposed that all the plants worthy of cultivation have been discovered or introduced, for in Central America, Africa, New Guinea, and elsewhere there must be abundant scope for botanical research. This is proved to some extent by the numbers of Orchids that are annually sent to this country, and it would seem that collectors of these plants must neglect all others, or they might obtain many novelties when exploring such regions. Occasionally a visitor to a new district brings some striking species or unfamiliar type, as in the case of those imported from Socotra a few years since which awakened much interest, and one of these, *Begonia socotrana*, has been constituted the progenitor of an important group of Begonias. During the present year an expedition to the Island of Fernando Noronha was undertaken under the auspices of the Royal Society, and as the island had never been fully explored by naturalists it was thought the results would be very satisfactory. Fernando Noronha is a few degrees south of the equator, and about 200 miles from the Brazilian coast, a situation that might be expected to yield a vegetation of exceptional interest. From a botanical and zoological point of view the expedition was successful, but it was found that the majority of the types were either identical with those of Brazil, or very nearly so, and it is doubtful if gardens will be enriched by many novelties from that source.

The difference between the numbers of imported and home-raised novelties is this year very apparent in the lists of certificated plants, and the advance of the latter shows that hybridisers and others have been exceptionally busy. The Floral Committee of the Royal Horticultural Society constitutes the principal certificate-awarding body in the kingdom, and to it are submitted the majority of the new plants, either introduced or home-raised. The Judges at the Royal Botanic Society's Shows perform a similar function, but as there are only four shows in the spring and summer months, their duties are necessarily much more restricted. The Floral Committee of the National Chrysanthemum Society deals with the Chrysanthemums, and then elsewhere the judges at provincial shows also award certificates. It would be much more advantageous, however, if judges at shows generally would only give commendations, and leave the certificating to the central bodies of experts.

During the past year the R.H.S. Floral Committee has awarded 194 certificates, and 139 of these were for hybrids or varieties of popular plants raised in gardens or nurseries, leaving only fifty-seven as introductions, of which thirty-nine are Orchids. The Royal Botanic Society has awarded eighty-two certificates, of which sixty-two were garden varieties and hybrids, the remaining twenty being introductions, comprising thirteen Orchids. About ten plants received certificates from both Societies, so that the total number of distinct plants certificated would be 266. At Regent's Park the average number of certificates per meeting is twenty, there being four shows in the season, while at South Kensington with twenty meetings the average is not quite ten each. This would seem to indicate that such awards are granted more freely at the former than the latter, and at South Kensington that nearly 800 new, or presumably new, plants were submitted during the season. The National Chrysanthemum Society's certificates will be referred to separately, so that they need not be included here.

ORCHIDS.

Amongst imported plants Orchids still maintain their precedence, and the fact that the number of certificated Orchids is one-fifth of the total is a pretty good indication of their popularity. For several years

they have exceeded all other classes of plants in the number of novelties, and the difference is very marked this year. The large stocks of plants in the nurseries and the crowded sale rooms prove how extensive is the

familiar plant in Orchid collections, but it is one of the most handsome of the genus. It is related to *A. falcatum*, and has by some writers been classed under that species as a variety, but it is sufficiently distinct to

FIG. 2.—A GROUP OF NEW CALANTHES.

demand. Taking those that have been certificated during 1887 in alphabetical order the first to demand notice is *Aerides expansum* Leonia, a variety which has been known for several years, but was first exhibited at South Kensington on June 28th by F. G. Tautz, Esq., to whom the certificate was awarded. The typical *Aerides expansum* is not a very

merit specific rank. The variety *Leonia* surpasses the ordinary *A. expansum* in the size and colouring of the flowers, and I learn from Mr. B. S. Williams that it first flowered with H. J. Ross, Esq., Castagnola, Lastra à Signa, Italy. The flowers are large with spreading white sepals and petals, the lip of good size, with a bold central lobe and two diver-

gent lateral lobes, bright rose in the centre, the other portion white spotted with purple. The flowers are not quite so closely set in the spike as in the ordinary forms, and though the foliage and habit are strong they are not so dense. With the exception of *Aerides odoratum* this genus is a somewhat neglected one, though it contains many handsome forms.

Next on the list is *Barkeria Vanneriana*, which was shown at South Kensington by W. Vanner, Esq., Camden Wood, Chislehurst, on January 11th last year. The *Barkerias*, though beautiful, are avoided by many cultivators, because they do not always succeed as might be desired. The plant shown by Mr. Vanner was, however, a very healthy one, and had a long scape with a few bright rosy purple flowers near the apex, the sepals lanceolate, the petals more ovate, the lip oval, acuminate, white in the centre.

Two *Calanthes* were certificated last year—viz., *C. Halli*, from Mr. W. Hall, Upper Tulse Hill (November 8th), and *C. sanguinaria*, from Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking (December 13th). *C. Halli* was the result of a cross between *C. Veitchi* and *C. vestita luteo-oculata*, and is a valuable acquisition, the flowers of great size and substance, 2½ inches in diameter and pure white. The plant exhibited had two spikes 12 inches long and four pseudo-bulbs, having been raised from seed six years ago. The compact growth of the plant and substance of the flowers renders this *Calanthe* remarkable, and the white flowers afford a striking contrast with the richly coloured *C. Veitchi* forms.

Calanthe sanguinaria was one of a group of choice varieties and hybrids that merit especial note. Many of these were seedlings of which the exact parentage is unknown, though it is not at all difficult to trace the characters of *C. Veitchi* and *C. vestita* in the majority, the influence of one or the other usually preponderating. *C. sanguinaria* is an extraordinary production, and most valuable for the intensely dark red or maroon colour of its large handsome flowers, which in contrast with the light tinted *Calanthes* appear almost black. This seems to have much of the *C. vestita* habit and floral form with a strange deepening of colour. The other forms included in the group were *C. Veitchi splendens*, flowers of great size, deep colour, and white centre, 2½ inches across from apex of upper sepal to the tip of the lip, the latter being 1¼ inch in diameter; *C. Sedeni*, very deep in colour and compact in the spike; *C. amabilis*, large flowers, pale blush, white centre; *C. burfordensis*, very deep rosy crimson, with reflexing sepals and petals; *C. rubro-oculata*, white, with an intensely rich crimson in the centre; *C. Veitchi lactea*, creamy white; *C. nivea*, flower large, creamy white, with a yellow centre; *C. luteo-oculata*, pure white, with orange centre; *C. porphyrea*, a pretty, neat, bright rose flower, 1¼ inch across, the lip rounded; *C. rosea*, flower very large, blush; *C. dubia*, nearly white, and the pretty graceful *Limatodes rosea* which, as all remember, was one of the parents of *Calanthe Veitchi*. It may also be added that *C. porphyrea* is a hybrid from *Limatodes labrosa* and *C. vestita rubro-oculata*, nearly the same parentage as Messrs. Veitch's *C. lentiginosa*.

The illustration (fig. 2) represents five of the *Calanthes* and their hybrids as shown on the occasion already mentioned. The top left-hand figure is *C. porphyrea*, the bottom left-hand figure is *C. rosea*, the top right-hand flowers are *Limatodes rosea*, the next on the same side is *C. Veitchi lactea*, and the lowest one the dark *C. sanguinaria*. The plants were remarkably well grown by Mr. Bickerstaffe, and the value of *Calanthes* when properly treated cannot be over-estimated for winter groups.—LEWIS CASTLE.

(To be continued.)

HEATING EARLY VINE BORDERS.

THE first week of January is a period at which many Vines are started into growth, and to force them successfully it is important that the heat in the interior of theinery be constant and sufficient to prevent a check from a cold exterior, as this may occur at any time until the end of March is reached. But apart from preventing a check of this sort, there are various appliances which may be used in forcing that will materially assist the Vines in their free and robust development, and amongst these none is more important than the application of bottom heat to the border and roots. It operates like magic on them and is highly beneficial. In some cases a great outlay has been incurred to heat the early Vine borders with hot water pipes, but this plan is far from common, and the absence of it need not be regretted, as a good hotbed answers the same purpose equally well. Where the roots are inside, a hotbed is not so much wanted, although even in this case it is advantageous; but where the roots are in the open a hotbed is absolutely necessary to their success, as it causes the Vines to come sooner into leaf, producing stronger growths and finer bunches, and places the roots more in harmony with the branches than is the case where the border is quite cold and the interior very warm.

A hotbed on a Vine border is made up in the ordinary way, and although it need not be very large, it ought to be made up to retain the heat until the cold weather is past. There is no difficulty in making them up to retain the heat for three months, and the proper time to put them on is at the time theinery is first closed, and the beneficial effects of it will then be felt at the time it is most wanted, which is just as the leaves and bunches are developing. Last spring we omitted to put a hotbed on our earlyinery border, and the deficiency was so visible on the Vines all the year through that the hotbed system will now become an annual practice.—A KITCHEN GARDENER.

THE SETTING, STONING AND SWELLING OF GRAPES.

WHEN I sent you a few lines on the above subject I was under the impression that many intelligent gardeners and others would take the same scientific interest I take myself in any abnormal results from good Vine culture. I thought, indeed, that the interest, if not the instruction, which accompanies this very important, and to me very entertaining study or pursuit, would be heightened by the assumption of at any rate average skill and good management in the examples and particulars which have been given from West Lynn, otherwise I at least should not have troubled you. It seems to me that Mr. Taylor is of a rather different opinion, but if so the reflection is very harmless, except in any possible rebound it may have upon himself. However, on this matter, as on all others outside the subject of Vine "feeding" and what may directly concern it, I shall leave the actual cultivator to speak for himself. Upon this I am challenged, and am happy to reply; for though I naturally make no profession of efficiency in practical gardening, I am quite prepared to stand by and support any of my previous statements of practical detail, gardening or other.

I have said then that the West Lynn Vines are kept well and duly supplied with all the manurial food they require, and being pretty intimately acquainted and connected with agricultural experiments, I certainly should not, as Mr. Taylor seems to think, speak of the sufficiency of any manures from which nitrogen was absent. This is but an initial letter in the alphabet of the subject of manuring. Mr. Taylor, on the contrary, believes the Vines to be starving, and is kind enough to give several leading indications by which it may be made known if such is the case or not. In this connection I will leave Mr. Stephen Castle to answer for himself, only asking Mr. Taylor to inquire of any competent person who saw the Gros Colman Grapes from West Lynn which took a prize at the Westminster Aquarium in the autumn, if he can point to 20 or 25 lbs. of better Grapes cut from a Vine of one rod of this variety, Grapes of more perfect finish, of better berry, of deeper colour, or greater density of bloom. Anyhow, is such a crop likely to be cut from a starved Vine? Again, did Mr. Taylor ever see a starved Gros Colman Vine produce upon three rods forty bunches of, in all respects, good and well finished Grapes, and of the estimated average weight of 2 lbs. per bunch? The same Vine perfecting besides the crop a very vigorous fourth rod of 5-8ths inch diameter, which, though stopped at the apex of the roof might have been carried to the ground on the other side, and ripened all the way. Now, it is only necessary to say that all the Vines at West Lynn have received precisely similar treatment throughout in regard to applications of lime or other manurial food.

When Mr. Taylor says that an application to the surface of a Vine border of 14 lbs. of lime—presumably caustic lime, though he does not say so, or it would be entirely harmless—is enough to destroy everything in the shape of nitrogenous food which that border has previously contained, he must excuse me if I say he is in error. I will say at once, however, that caustic lime has never been applied at West Lynn by my advice or desire except in small quantities for the purpose only of improving the mechanical condition of the soil. As a manure where lime is wanted I have uniformly advised the use of gypsum or sulphate of lime as being more soluble, and therefore more quickly available and better as a food than common lime, and perfectly safe to use in any safe quantity. It was only recently that Mr. S. Castle, by the advice of a great authority, who recommended the caustic lime in preference, without appending the caution he now thinks needed of moderation, used, or wished to use, it in preference to the gypsum. Strange to say also the eue of quantity was taken from Mr. Taylor's own receipt in "Vines at Longleat," and as he there says the effect of the application was extremely successful and immediate, surely it can scarcely have destroyed everything in the shape of nitrogenous matters in his border.

I concede at once, however, that Mr. Taylor has got hold of one element of truth in his statements upon caustic lime, and of it he shall have the benefit without further delay. It is no doubt bad gardening to apply common lime with any ammoniacal manures, and one I should never sanction, though I do not think the practical effects would in any case be nearly so serious as Mr. Taylor seems to imagine, and certainly not so as lime has been used at West Lynn. Still, as I have said, and as Mr. S. Castle knows very well, I prefer, on this very account, not using caustic lime at all as a manure. If common lime is mixed with sulphate of ammonia of course the sulphuric acid which previously fixed the ammonia therein is immediately liberated, as the nose readily detects. The sulphuric acid will leave the ammonia for the lime. A similar result takes place when other ammoniacal matter is placed in actual contact with lime, but such a connection only occurs to a very modified extent in any ordinary practice, and so far from a large dressing of lime robbing a Vine border of all previously applied manure, it could at most only affect the surface where it was pointed in. Besides, I am in a position to prove to Mr. Taylor, if he requires it, by certain experiments within my knowledge, that such a dressing of lime is rendered perfectly innocuous as a destroyer of nitrogenous materials within three months of application. By that time it will have attracted sufficient carbonic acid from the air if it could find acidity nowhere else to neutralise its caustic properties. Such neutralisation would take place still quicker if exposed to the air before application, hence the practice of so doing in great lime-using districts. The lime then becomes carbonate of lime, or chalk, and Mr. Taylor will not contend that chalky soils are by any means necessarily infertile.

There is also within my knowledge a garden of adhesive soil upon which

30 tons per acre of lime (14 lbs. a square yard) worked immediate and starting results. It at once became, and has since remained, of great repute amongst neighbouring gardens of like character for extreme fertility, mainly because of its improved mechanical condition. Will Mr. Taylor point to a case of land rendered sterile by lime—as without nitrogen it must be—whilst having a normal and reasonable quantity of manure judiciously applied as well? Truly lime is sometimes in bad repute as a soil exhauster, but usually because it has been applied to land choked with sour and inert vegetable matter, which, when rendered sweet and snitable for plant food by the lime, has nourished abundant crops. An inference has therefore been ignorantly drawn that equal results would follow all succeeding applications of lime, and that nothing else was wanted. But obviously, when all the previously stored food had been liberated and utilised fresh supplies would be required, and the lime may not have acted in such ease as a food at all. I maintain therefore that the 14 lbs. of lime applied by Mr. S. Castle to the Vine borders in February had ceased to be able to exert much, if any, injurious effect to the food which was given the Vines in May and June—the first time of feeding—and that the much smaller quantity of lime then applied, though wrong in principle, was not sufficient to neutralise to any serious extent the large amount of liquid and other manures. No better proof that this was so could be given than was at once evident in the hearty and decided response of the Vines to the dressing, to their general vigour throughout the season, and the way they finished their wood and crop. Moreover, a Vine or two under experiment—perhaps it might be difficult to suggest many untried experiments of this nature at West Lynn—with sulphate of ammonia, showed that the roots had absorbed too much nitrogen, which would hardly have occurred in the use of a material so very easily robbed of its ammonia, if there had been enough lime to dissipate it quickly into the atmosphere. It is true that potash salts were applied in excessive doses some years ago to a few Vines for experiment only. It will surprise Mr. Taylor to know, however, that those so treated exhibit to this day the marked advantage they have always shown over those having the lighter dressing. Having read the experiments of M. Ville with potash on Vines I am not so much surprised as Mr. Taylor. If there has been any suffering for want of moderation in treatment at West Lynn I should say that it has been shown in too heavy cropping. We all have our weaknesses; and I should say that the chief weakness of Mr. S. Castle, as perhaps also my own, is too much pleasure in seeing a successful, which means a full as well as properly finished crop, with its attendant risks. It is only, however, in individual instances that any injury has been done in this respect. My conclusion, therefore, is that upon the main question at issue the cause of certain unusual local difficulties in the fertilisation of Grapes—which I had supposed to be of wider interest—Mr. Taylor cannot at present be said to have furnished any very helpful or tenable theories.—PROPRIETOR.

To Mr. W. Taylor the thanks of the gardening fraternity are due for exposing my errors. My first thought is what a vast amount of ignorance, or at least want of thought, there must be to let the question go a begging so long. The answer, however, when it did come if in a little space comes with great force, especially from so high an authority. That W. Taylor should be the one to detect my weak points I am neither surprised nor cast down. Having no pet theory, if by noting particulars of practice and its results in reference to the Vines under my charge I am constrained to appear in the pages of the Journal, I must expect criticism. Without doubt criticism is good even though at times severe, and so with the Editor's consent I shall be always open to supply a line, not necessarily to record my successes, but if needs be the reverse, for the general good. The present question is this—Why, with such immoderate treatment of them, I should to-day have a bunch of Grapes worth so calling to look at? Yet with no desire at all to speak boastfully; I am not afraid to meet some of the great authorities with several bunches now or in the spring. Climatal conditions vary much I believe. We have a good salt breeze, especially at high tides with wind from the north. All the more reason for being careful in front ventilation at any time, but more particularly after the Grapes are ripe. Those who are in favour of front ventilation after Grapes are ripe are welcome to their opinion. I emphatically say the soundness of my berries is due mainly to the fact of very little air being admitted after the Grapes were coloured. This is not an entirely new idea, but represents my practice. Having, as I thought, dealt very fully with my details in Vine culture, more especially with a view to obtain perfect berries, I thought Mr. Taylor would scarcely desire more information. I wish he had to prune my Vines, his hands and shoulders would let him know the wood is ripe. I send a few cuttings in order that you can judge for yourself. I take it this is the best year I ever had for ripening wood. I fancy there is an abundance of pollen, and if the rods were gently tapped, as is done by most growers, there would be sufficient to dust the immediate leaves thickly. Pollen is, I am well aware, a necessity, yet how is it that at times a few small bunches on weak laterals show such an abundance of pollen, yet these do not produce the best berries? My son seriously proposed sending a parcel of fat worms from my Vine borders for inspection, this too at the worst time of year; but I daresay the Editor does not want any, he can have them if he wishes. This is my answer as to the quality of my "starved" borders. Once in Sussex it was my lot to have a very tenacious clay to deal with, here I have a stiff, plastic marl that will cut up like pieces of liver. To keep such a material open requires more than ordinary measures.

What I am still hoping to see solved is why stoning should be so generally defective. Lime was to be the panacea for all my faults in

this respect, and I was told we could not use too much. That I have benefited the borders mechanically I am well aware, and the Vines are healthy. Any further writing will, I hope, be less beside the mark. I shall leave caustic lime alone and use gypsum in future for stoning. Had I only one house I could not be so sure, but have no doubt now the fault of defective fertilisation was in the temperature or atmosphere. Seven houses should present a variety, not a conformity of results. It is a very general complaint, no matter how large the berry, that stones are needed. How many think to examine for this question of stoning? Until I get a majority of four-seeded berries I shall not be content. It may interest the Editor to know I have one small bunch of Buckland Sweetwater in the Grape room now, cut last week, plump, and yet having very few berries with more than two stones. If Mr. Taylor's very inquiring letter is the cause of others entering the field I shall be glad, even though the evidence may be against me. Setting, stoning, and swelling of Grapes cannot but be very important subjects. Ventilate the whole matter thoroughly. Surely some good may come of it. I cannot help wondering if the great authorities always succeed in producing the normal quantity of stones.—STEPHEN CASTLE, *Manager, West Lynn.*

[The wood sent is good; perhaps Mr. Taylor will send a sample for comparison. The worms will be better where they are than at this office.]

CHALLENGE TROPHIES.

THE letter of Mr. Wm. Bardney, in your issue of the 15th instant, is not to my mind conclusive as against challenge trophies. If money prizes are sufficiently large, why object to challenge trophies? If Mr. Bardney's contention was carried out to its logical conclusion, the prizes in the premier classes in an exhibition would be unfairly large in comparison with the remaining classes. Instances are not wanting where societies have been eventually injured by too much attention being paid to sensational prizes, to the exclusion of sufficient encouragement being given to the local and general classes. It is questionable if the popularity which these great prizes would give to an exhibition would not be counteracted by the damping effect which their strain upon the resources of a society would have upon the general classes. Each exhibitor in the latter has his circle of friends, who take greater interest in his success than perhaps they do in the premier classes, and a more healthy rivalry is created by sufficiently encouraging all classes of exhibitors than by giving undue prominence to the larger classes. One of the most encouraging signs of the permanence of the interest in Chrysanthemum growing which has sprung up in recent years, is the hold it has taken upon the masses. By all means let the principal prizes be sufficiently large to induce eminent growers to exhibit, and thus put a high standard before the rising cultivator, but if a prize of £10 or £15 and a challenge cup, with a chance of winning valuable prizes in the other classes, is not sufficient, it is questionable if a large prize, such as would be the case if the cup were to be finally won at the first competition, would have that effect. The letter of the Secretary of the Hull Society seems to have the true ring in it, and at the risk of being opposed to the opinion of such a competent authority as Mr. Bardney, I must give my opinion in favour of challenge vases.—BEVERLEY.

AMY FURZE—A NEW CLASS WANTED.

IF "T. W." cannot perceive any material difference between his suggested plan of relegating hybrid and flat-petalled Japanese to classes of admittedly reflexed blooms of Chinese origin, and the counter proposal to form a special class for the two former, his perplexity is not to be wondered at in respect to decisions arrived at under the present rules and schedules.

Your correspondent does not appear to understand how a bloom of Amy Furze may, when young, be considered as a reflexed, while when developed it is regarded with less favour as such. When this variety was first exhibited and certificated at Kingston it was regarded by all who saw it as having a closer resemblance to that type than to any other, hence was described as a reflexed variety in the reports and in catalogues. The true character of the variety was not then developed. Last November Amy Furze was certificated in two collections of plants at the Crystal Palace, and though the blooms on the plants were small and had not displayed their full character the variety was not certificated as a reflexed, but because of its distinctness and attractiveness. Some developed examples in stands of reflexed blooms weakened those stands without a doubt, and must have done so in the estimation of every competent judge in the kingdom, simply because whatever of the reflexed character they may have displayed when young had departed from them, and they then showed unmistakably their Japanese origin and properties. When blooms are staged as reflexed, as such they must be judged, and to act on any other basis must, obviously, be to act erroneously.

I have worked with upwards of a dozen of the best judges in the kingdom this year, and not in one instance has there been any evidence of

obstacles arising from "peculiarities" or "leanings," but, on the contrary, complete unanimity in acting on recognised principles. Individual fancies appear to be in another direction.

As I understand the whole subject of classification is to be considered by the Committee of the National Chrysanthemum Society, the varieties admissible in a possible new class will no doubt be officially indicated; were I to enumerate them the individual peculiarity theory would perhaps be trotted out again, for though it only amounts to a phantom, yet phantoms have sometimes a disturbing influence.

Besides, it is not the duty of judges to make laws, but to understand those that are provided for their guidance, and to obey them; and when the law is not clear it is the rule to give the benefit of any doubt that arises to an exhibitor, instead of disqualifying his exhibit, and to judge the blooms on their merits, according to the standard of the type they are staged to represent. Dr. Sharp and Cloth of Gold, which "T. W." mentions, are reflexed Chinese Chrysanthemums, with no Japanese blood in them. The best blooms score the highest, those that are very small and much quilled on the one hand, and overblown and dingy on the other, being estimated accordingly.—A JUDGE.

PRINCESS BLANCHE.

LATE Chrysanthemums can be classed in two sections; any notes of certain varieties being seen or exhibited in bloom at this season of the year cannot be taken as a guarantee that such varieties are naturally late bloomers, for many of the earliest ones, like varieties of early Peas, can be made to produce the best late crops for succession. There are those that should naturally bloom in November, but from some cause—such as damage to the first buds by winds, frosts, or insects, or being intentionally disbudded, a secondary growth is caused which is growing on when the earlier buds would have been in flower, and which consequently retards the blooming beyond the natural season. Late propagation or weak cultivation will have the same effect in prolonging the flowering season. There are others that may now be properly termed midseason varieties, but which in the ordinary way are called late blooming varieties—viz., Princess Teck, and what may now be termed the Teck section, Hero of Stoke Newington, Mrs. Norman Davis, Lord Eversley, and Chas. Gibson, also Ethel, and Mr. J. H. Jones, Lady Carey, Lady Slade, Angelina, Pelican, and also Ceres, the latter being the latest, but neither of these is so late as one or two others that have been recently introduced. We have now one or two naturally midwinter varieties, one of which, Princess Blanche, is the object of this note. To anyone requiring white flowers at Christmas or in the new year—and there are few who do not—this variety is especially valuable, and cannot be too widely cultivated to fill up the gap generally felt between the two seasons. For using in combination with Poinsettias, Euphorbia jacquiniæflora, and other gay midwinter flowers for table or room decoration, they would be very effective. It is a variety of 1886 of the Japanese section; it has a very dwarf robust habit, with bright glossy foliage; the flowers are pure ivory white, measuring from 4 to 6 inches in diameter, florets glossy and of great substance, outer ones broad, pointed at tips and somewhat recurving; the centre ones are narrower which slightly twist and curl with age, giving them a true Japanese character.

In reference to Mr. W. J. Murphy's inquiry, page 568, I consider Lady Matheson cannot be classed in any other section but Japanese, although it no doubt has much incurved blood in it. It is a mid-season variety with flowers of a creamy white shading to primrose in the centre, florets semi-tubulated, slightly incurving at the tips. The other variety mentioned I am not acquainted with.—C. ORCHARD.

RIVAL CHRYSANTHEMUM SHOWS.

I OBSERVE that my friend Mr. Woodcock is unwilling to admit that the Chrysanthemum Exhibition annually held by the Sheffield and Hallamshire Gardeners' Mutual Improvement Society is a representative one in any sense, and when I stated that "there ought only to be one representative exhibition," he agrees to it as an abstract proposition only. The fact that such shows have been held annually for ten consecutive years, and for seven years without a rival, and that they have been considered by the public at large as the Sheffield Chrysanthemum Shows, gives them "the right of priority" and the right—up to the time of the establishment of the Sheffield and West Riding Chrysanthemum Society three years ago—of being considered as representative of Sheffield as a town; and the fact that there are some gardeners (myself included), amateurs, and others who do not see their way to subscribe to the rules of that Society and so avail themselves of its privileges, does not deprive them of those rights; neither does the possibility of there being numerous better Chrysanthemum plants and flowers in the neighbourhood than are to be seen at those shows; but I should like to know where there is a flower show of any kind that contains within itself all the best examples of garden produce within the district? and supposing there ever was such a phenomenon, where is the non-exhibitor at such to be found that would admit it? Would he not declare that he "had better stuff than that at home?" But after all, what does it signify which is "The Original Pie Shop?" The public will flock most to that shop which provides the best pies and best accommodation, and as there is not sufficient custom in Sheffield to keep two such "Pie Shops," the proprietors of one of them will sooner or later have to "file a petition."

Inasmuch as the Sheffield and West Riding Chrysanthemum Society manage their exhibitions in a broader and more generous spirit, I think they are undoubtedly most worthy of the support of the

public, and I believe they will continue to have that support; but I regret very much that stumblingblocks to the union of the two Societies should have been made out of such unsubstantial things as "representation" and "priority;" however, the sooner they are kicked out of the way the better. Mr. Woodcock and I are in unison as to the desirability of the amalgamation of the two Societies. He says nine-tenths of their members are desirous of such union, and I am informed that many members of the other Society are also willing for the two Societies to join; that being so, what obstacle prevents the union? Probably it is the question of the individuality of the two Societies. I would suggest—but I do it in fear and trembling, and my friends who know me best will fully appreciate my extreme nervousness—that the Sheffield and West Riding Chrysanthemum Society omit the words "West Riding" from their title, for Sheffield requires no "handle" or anything else to its name, and call it simply "The Sheffield Chrysanthemum Society;" and that the Sheffield and Hallamshire gardeners merge the Chrysanthemum Exhibition they have annually held in connection with their Mutual Improvement Society into this one distinctive Sheffield Chrysanthemum Show. This would be a graceful act on their part, and one that would redound to the credit and benefit of their Society. It would be a good thing for a deputation from each Society to meet and discuss the position of affairs in a friendly spirit and arrive at an amalgamation if possible.—J. UDALÉ, *Elford*.

CHRYSANTHEMUM AMY FURZE.

I AM very glad your correspondent "T. W." has called the attention of your readers to the anomalous position of Amy Furze. "A Judge," on page 546, says the more it displays its Japanese origin the more it weakens a reflexed stand. An experienced Judge on the same page says, though out of place in such stands, blooms are judged on their merits when in them; if so, where do they weaken a reflexed stand? Again, he says as they develop their character, they become spreading Japanese, and lose points as reflexed flowers. Who is to tell the turning point of a reflexed flower into a Japanese? I quite agree with "A Judge" that it should be confirmed as one thing or the other—not a reflexed flower one day and a Japanese the next; that seems to me to be a most questionable position. I think a flower should be classed as what it is when fully expanded. If you did that I think Amy Furze would be a Japanese. I do not know if either of the two Judges officiated at the Liverpool Show, where a stand of six reflexed blooms was passed over without a prize—a stand, in my opinion, and in the opinion of many others, that was the best in the Show. Amy Furze was supposed to be the fault in that stand. Was it judged on its merits in that case? Perhaps "Another Judge" can give us his opinion.—T. H.

MRS. C. CAREY SPORT.

I SEND you a sport from Mrs. C. Carey. It is now, I think, eight years ago since I sent that variety out. I have never heard of it varying in colour before.—H. CANNELL.

[This is a very remarkable "sport," much larger than the blooms of the (white) variety accompanying it, and, unlike them, has not twisting and incurving florets. The bloom is as large as an average Belle Paulc, and not very dissimilar in colour from some dark forms of that variety.]

PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY.

THE members of the Professional Gardeners' Friendly Benefit Society held their annual dinner on Wednesday evening, the 28th of December, at the "Green Dragon Hotel," Guildford Street, Leeds. Mr. James Inman, the President of the Society, occupied the chair at the after-dinner proceedings, and Mr. William Grix (the Vice-President) the vice chair. Among the gentlemen present were Alderman Scarr (the Mayor), Mr. Joseph Bradley, Meanwood; Mr. Henry Hick, Manchester; Mr. Robert Leatherstone, Mr. John Sunley, Milford Junction; Mr. J. R. Beckwith, Mr. Joseph Smith, Mr. George Hemming, Mr. J. W. Frankland, Mr. William Green, Mr. J. F. Ryder, Mr. William Sunley, Secretary; and Mr. Thos. Jamieson, Treasurer. Letters of apology were received from Mr. Henry Oxley, and Mr. W. L. Jackson, M.P. The last-named gentleman expressed the hope that the Society, which had now arrived at manhood, would have a great future of usefulness. The Chairman, in the course of his remarks, attributed the success of the Society to the support accorded to it by its honorary members; also the praiseworthy endeavours of the Society's officers, one and all, in the furtherance of its interests—especially Mr. Sunley, the Society's indefatigable Secretary, who for the whole of the twenty-one years the Society had been in existence, had made the Society's interest his study, and as a mark of appreciation a testimonial was being raised for him. The Secretary (Mr. Wm. Sunley) read the report of the Committee, which stated that the progress of the Society during the twenty-one years of its existence was a subject of satisfaction and congratulation to the members. The income for the past year had been £130 17s. 1d., and the expenditure £92 19s. 11d., leaving a balance in hand of £37 17s. 2d. The total amount now placed to the credit of the Society was £865 9s., or an average of £7 8s. 9d. each financial member. There were now twenty honorary and 117 financial members—numbers which gave promise of the future prosperity and stability of the Society. In replying to the toast of the Mayor and Corporation, Alderman Scarr said that if he were not Mayor of Leeds he should tell them that he was a land reformer. He believed the time was fast approaching when the

gardener's craft would be better recognised than it was at present, as the first necessity for the sustenance of the country. (Applause.)

A most pleasant and enjoyable evening was spent, a number of the members contributing songs, &c.

PLANT NAMES.

[A paper read at a meeting of the "Chislewick Gardeners' Mutual Improvement Association," on December 21st, 1887. By F. W. Burbidge, F.L.S., M.R.I.A., Curator Trin Coll. Botanical Gardens, Dublin; formerly of the R.H.S. Gardens, Chislewick; and also of the Royal Gardens, Kew.]

(Continued from page 571 last vol.)

ON the walls of a room in the great temple of Karnac at Thebes are sculptured portraits of plants foreign to Egypt, and these have been by some archæologists supposed to be the oldest botanical illustrations in existence. It appears that Tuthmosis, Tuthmes, or Thothmes II. (of the XIII. dynasty), made an expedition, or campaign rather, into Arabia, and he brought back to Egypt many trees and plants of that country, and these he caused to be carved on stone after the custom of the time. Here, in fact, you have a royal plant hunter and botanist to boot something like Solomon. These sculptures not only represent the plant or tree, but the leaves and fruits or seed-pods are shown separately after the fashion in modern botanical illustrations. Paper casts of this work have been made by Mr. W. Flinders Petrie, the well-known archæologist, and these copies will no doubt soon appear in our national museums. Dr. Mahaffy, the professor of ancient history in the University of Dublin, tells me that the time of Tuthmes III. may with tolerable certainty be placed between 1500 and 1600 B.C., that is to say about or a little after the epoch of Moses, and so you will perceive that these stone portraits of plants are well-nigh coeval with those inscribed "tables of stone" which Moses set before the Israelites after leaving Egypt, and which had been handed down to us as the ten commandments. But practically speaking we must take it for granted that botanical studies and nomenclature began with the Greeks, as we shall presently see, and from them passed to the Romans, and because this was so, the botanists of Europe in following the literature of Greece and of Rome, naturally enough gave us names in what were the learned languages of the time. Now-a-days you will find Latin plant names even in the more recent botanical books of Japan, but alongside these is always given the popular or Japanese nomenclature. As to Greek, I have heard a prophecy that in less than half a century it will be no longer taught in colleges or in the higher schools. I hope this may be true, and that our youth may be led to learn the living languages of Europe instead, and with these get a sound technical and commercial education which will enable us to compete for a time with the well-taught men from other nations in Europe who flock to our shores.

The late Dr. John Hill Burton in the introduction to his work, "The Book Hunter," strips Greek nomenclature of some of its rags and leaves it pretty much in the condition of the "Greek Slave." What he says of it is this: "No doubt the ductile inflections and wonderful facilities for decomposition and reconstruction make Greek an excellent vehicle of scientific precision, and the use of a dead language saves your nomenclature from being confounded with your common talk. The use of a Greek derivative gives notice that you are scientific. If you speak of an acanthopterygian, it is plain that you are not discussing perch in reference to its roasting or boiling merits; and if you make an allusion to monomyarian malacology, it will not naturally be supposed to have reference to the cooking of oyster sauce.

"Like many other meritorious things, however, Greek nomenclature is much abused. The very reverence it is held in, the strong disinclination on the part of the public to question the accuracy of anything stated under the shadow of a Greek name, or to doubt the infallibility of the man who does it, makes this kind of nomenclature the frequent protector of fallacies and quackeries. It is an instrument for silencing inquiry, and handing over the judgment to implicit belief. Get the passive student once into palæozoology, and he takes your other names—your ichthyodorulite, trogontherium, lepidodendron, bothrodendron—for granted, contemplating them, indeed, with a kind of religious awe or devotional reverence. If it be a question whether a term is categoric (a word that may be logically used by itself as a term), or is of a quite opposite description, and ought to be described as subcategoric, one may take up a very absolute, positive position without finding many people prepared to assail it. . . . The great erect stone on the moor which has hitherto defied all learning to find the faintest trace of the age in which it was erected, its purpose, or the people who placed it there, seems as it were to be rescued from the heathen darkness in which it has dwelt, and to be admitted within the community of scientific truth by being christened a monolith (a single stone). If it be large and shapeless it may take rank as an amorphous megalith (a shapeless big stone), and it is on record that the owner of some muirland acres, finding them described in a learned work as 'richly megalithic' (richly big-stoned) became suddenly excited by hopes which were quickly extinguished when the import of the term was fully explained to him. Should there be any remains of sculpture on such a stone it becomes a lichoglyph (a carved stone) or a hieroglyph (sacred sculpture), and if the nature and end of this sculpture be quite incomprehensible to the adepts they term it a cryptoglyph (secret carving), and thus dignify by a title of honour the absoluteness of their ignorance. The vendors of quack medicines and cosmetics are aware of the power of Greek nomenclature. . . . But perhaps the confidence in the protective power

of Greek designations reached its climax in an attempt made to save thieves from punishment by calling them 'kleptomaniacs' (insane thieves)."

Ruskin, in his "Queen of the Air," says; "I wish they (the philosophers) would use English instead of Greek words. When I want to know why a leaf is green they tell me it is coloured by 'chlorophyll,' which at first sounds very instructive; but if they would say plainly that a leaf is coloured green by a thing which is called 'green leaf,' we should see more precisely how far we had got. However, it is a curious fact that life is connected with cellular structure called protoplasm, or, in English, 'first stuck together,' whence conceivably through deuteroplasm or second stickings, and tritoplasm or third stickings, we reach the highest plastic phase in the human pottery, which differs from common china ware primarily by a measurable degree of heat, developed in breathing, which it borrows from the rest of the universe while it lives, and which it as certainly returns to the rest of the universe when it dies."

In a word, is it not time to be serious and to utter a "not loud but deep" protest against verbal mountebanks who seek to hide their ignorance and to beguile us by very often needlessly using Greek or Latin names? Botanists, however, may the more especially be excused if they have evinced a leaning towards Greek names, seeing that two of the early philosophers or physicians of Greece wrote on plants at a period when learning was at a low ebb in Europe generally. The first was Theophrastus of Eresius (B.C. 374—286), and the second was Dioscorides (A.D. 40), and to the writings of these two men much attention was at one time given by early European and British botanists, and tons of editions and translations of their books, with countless commentaries have been made.

When we come to the Roman or Latin authors we find Cato (B.C. 150), or six centuries after the foundation of Rome itself, writes of gardens, which he says, "should have a southern aspect and be well supplied with water," and he is very particular in his directions for the cultivation of Asparagus. He also mentions seven varieties of Olive, six good varieties of Grapes, four or five Apples, five of Pears, six of Figs, three of Nuts, and also alludes to Pomegranates, Servicees, Quinces, and Plums. But it is Pliny the Elder (A.D. 23-79) who is most explicit as to the fruit and other importations into the Roman gardens of his time. Even at this early date in the Christian era the Romans possessed nearly all the fruits grown by us to-day, if we except the Orange (introduced into Italy in the fourth century), and the Pine-Apple. The Fig and Almond had been brought from Syria, the Citron from Media, the Pomegranate from Africa, Apples, Pears, and Plums from Armenia, the Apricot from Armenia or Epirus, the Peach from Persia, Cucumbers and Melons possibly from Armenia or Persia, while Cherries had been brought from Ceras, in Pontus, about seventy years before Christ. Pliny mentions many more varieties of fruit than Cato, so we may rest assured that the industry of a century had made many improvements in Roman gardening. Cato and Pliny may be taken as examples of the many other writers on gardening among the Romans, and it is scarcely necessary to state that our earliest English works on gardening were at least framed on Latin models even if not often directly copied or translated from them. But with the advent of Englishmen like Turner (1538-1568), Gerard (1597), and Parkinson (1623-40), and the first of European plant collectors of any note, Carolus Clusius, whose great "Historia" was published in 1601, botany in England began to spread and take deeper rootage among all intelligent people, and the ground was ploughed ready for the good seed of Bacon (1561-1626) and of Evelyn (1620-1706) to take root and bring forth that harvest of a hundredfold which it is now our privilege to enjoy.

Of modern and living botanists and their works it was originally not my intention to speak, but it is scarcely possible in a paper professedly dealing with plant names to avoid allusion to the "Genera Plantarum" of Sir Joseph Hooker and the late Mr. George Bentham. So far as genera are concerned it is a colossal work, and it will be the standard authority for many years to come. It is not easy to comprehend the stupendous amount of labour such a work must have absorbed, and it could only have been produced by the most acute and experienced botanists situated in the best botanical environment in the world. There are two other works, and these are cheap enough for every gardener to possess, and possessing them he will be pretty well prepared to meet any question which may arise on botany or on garden plants. These books are "Treasury of Botany," second edition, by the late Dr. Lindley and Mr. Thomas Moore; and "Johnson's Gardeners' Dictionary," as revised by Mr. N. E. Brown of Kew. A very valuable, but more expensive "Dictionary of Gardening," in four volumes, is now in course of preparation by Mr. George Nicholson of Kew, and this has the advantage of many fine wood engravings. Loudon's "Encyclopedia of Plants," now and then to be had for about a sovereign, second hand, is also very valuable, although somewhat out of date; and those who are beginning the study of botany should see Sir J. D. Hooker's "Primer," published for a shilling by Macmillan and Co. Two valuable works besides the above are Cassell's "Popular Gardening" and "Epitome of Gardening," by Dr. Masters and the late Mr. Thomas Moore, which is the best of all cheap (5s.) manuals on modern gardening. As a book of reference on English cultivated fruits there is nothing approaching the latest edition of the "Fruit Manual" by Dr. Hogg. Barron's "Vine Book" (second edition) should be in the hands of all interested in Grape culture, and the English translation of Vilmorin's "Jardin Potagère," by Mr. Robinson, called "The Vegetable

Garden," is the most reliable work on vegetables, their nomenclature and culture. Books like these are as necessary almost as tools in all good gardens, and employers who added the above to their gardeners' libraries assuredly would get more than interest on the money expended.

To return to our text. The late Dr. John Lindley, who at one time was the autoeratic Secretary of the Royal Horticultural Society, although a botanist pure and simple, yet felt the urgent necessity of a more popular nomenclature than that in use during his time. In his "Vegetable Kingdom"—the best historical work of its day—in the preface, page xvi., we read his opinions on this question as follows: "No one who has had experience in the progress of botany can doubt that it has been more impeded in this country by the repulsive appearance of the names which it employs than by any other cause whatever; and that, in fact, this circumstance has proved an invincible obstacle to its becoming the serious occupation of those who are unacquainted with [what are called] the learned languages, or who, being acquainted with them, are fastidious about euphony [right sounding] and Greek or Latin purity." Lindley tried to anglicise the terminations in cases like *Myriospermum*, which he reduced to *Myrosperm*, and *Malanthium* to *Melanth*, but he met with but slight success. But if such English names as he had proposed did not become universally adopted, he consoled himself by their rejection to the "masterly inactivity" of indifference, rather than to any intelligent and reasonable opposition. He was fully convinced of the importance of popular English names, and aptly points out that persons the most careless of the difficulties of articulation would prefer to speak of a "Fringe Myrtle, rather than of a *Chamaelaucium*, and of a Grit-berry than of a *Comarostaphylis*. Mere translation of Latin or Greek names into English is, as Lindley points out, neither necessary nor expedient, and he forgets not to show that Latin or Greek names of a pleasing sound, such as *Mimosa*, *Arbutus*, *Fuchsia*, *Primula*, *Orehis*, *Iris*, *Narcissus*, &c., have already passed into popular currency, and that nothing would be gained by interfering with such names as these; but it will be a long time before such names as *Gravenhorstia*, *Andrzejofskya*, *Caluecchinus*, *Krascenninkovia*, and *Pleuroschismatypus*, or even *Cryptophorantus* roll sweetly and infallibly from the gardener's tongue! Having had considerable experience in public gardens, I know how rarely what is termed the scientific names of plants satisfy the intelligent popular mind. "What is this lovely plant?" says a lady visitor. "It is *Cienkowskia Kirkii*," you answer, or it may be *Owtrowskia magnifica*, or if a *Palm Phœnicophorum Seyhellarum*, and in nine cases out of ten comes the reply, "Ah! yes, but what is its English name?" This, then, is the real difficulty—viz., how to make plant names intelligible to those who know but "little Latin and less of Greek." Of course we shall be met with the old parrot cry against the use of English names. When the *Funkias* were christened "Plantain Lilies" it was objected that the plant being neither a Plantain nor a Lily the name was double erroneous, and quite inappropriate, but the name is a good distinctive one and "came to stay" as the Americans have it. One nurseryman acknowledged to me that he liked the popular name "Plantain Lily" because he never could get people to buy these plants under the name of *Funkia*, so repellent was the sound of the word to English feeling. Besides, if we say "Siebold's Plantain Lily," that is as definite as *Funkia Sieboldi*. "Bronze Leaf" is quite as definite and as euphonious as is *Rodgersia podophylla*. Very few people ever purchased *Agathæa cælestis* until Mr. Cannell, I believe it was, called it what really it is "Blue Marguerite." "Winter *Gladiolus*" is a better name than *Schizostylis coccinea*, and which of you would not sooner say "May Apple" rather than *Rodophyllum peltatum*? Again, some while agreeing to the use of old and well fixed or assimilated English names as those of Chaucer, Turner, Parkinson, Gerard, or of Shakespeare, object to the coining of new names for new introductions or for old plants having no fixed popular name. But we who like English names do not at present object to any plants being named in Latin or Greek, and of course we might object as reasonably in the one case as our opponents in the other. The apparent fact is, we must be "liberal unionists," and agree to a well-regulated system of dual nomenclature, Latin-English, or English-Latin, as the case may be. English names have, in the main, sprung up spontaneously in the minds of the people just like legends and fairy tales, and are often associated with them. They are the very poetry of botany. Latin names don't look well in English poetry, they represent a sort of invasion some day to be absorbed or overcome and banished by the sturdy Saxon tongue.

Now I wish you to clearly understand that this is a question not of Latin *versus* English names, but of Latin and English names combined. What is desirable is a state of constant and well-regulated co-operation, and not one of competition or supercession. Latin or Greek names must of necessity be employed by the botanist who at the present time wishes his names accepted by the botanists of other countries beside our own. So that at the outset we fully grant to the botanists the right and freedom to use Latin or Greek whichever they like, merely asking that such names as they may coin shall be as short and as pretty and as euphonious as possible. But while granting this much for cosmopolitan usage, and for the sake of expediency and precision, some of us say and believe that pretty and suggestive English names should also be applied to all plants that are named or worth naming in Latin or Greek. Formerly the botanist did actually supply these secondary and necessary English names, as a glance at the earlier volumes of the "Botanical Magazine" will show, but in recent years, just when they were most required, this praiseworthy old fashion has been discontinued. The first English botanist to mention popular names as well as scientific

ones was, as I believe, Turner in his "List of the Names of Herbs," published in 1549.

After all, is it not curious to find Latin names used so much in gardens, while common English names serve for the more important industry of farms! What farmer would use Latin for horse, or cow, or heifer, or sheep, or for his crops? No! simple English is good and precise enough for all the "kindly fruits of the earth" as for "the cattle on a thousand hills." We speak definitely enough of a donkey or of an ass, but if either of them should eat a Thistle is that Thistle forever to be defined as *Carduus arvensis*? I believe there are name-mongers who would oblige the unoffending ass to swallow the name as well as the Thistle if they could. We are told to "call a spade a spade," and some of us would like to call this *Carduus* simply "Field Thistle." Certainly, as things are, we are obliged to use Greek or Latin names, but, believe me, a time will come—not in our time, but still certain to come—when there will be only one universal language in the whole world, and that will be the English tongue.

(To be continued.)

KITCHEN GARDEN.

TOMATOES.—These are the most profitable of all early vegetables. In many cases they prove more remunerative than Cucumbers or Grapes, and all who have a heated pit or house should grow them. We are about to plant out our first Tomatoes. They were propagated from cuttings in November, and now they are sturdy well-rooted plants 6 inches high. They will be planted in small mounds of moderately rich soil along the front of a low pit, and they will be trained with a single stem under the glass. When near the light, and in a temperature of 60°, there is no difficulty in getting them to grow and fruit at once, and such plants will bear many ripe fruits in March and April. All who have plants from autumn cuttings should treat them well to secure early fruit, and those who did not take our past advice and secure cuttings should sow a pinch of seed at once. It will germinate freely in a temperature of 65°, and the young plants will progress favourably in the same temperature, but they will not fruit as soon as the cuttings. Where only a few fruits are required for private use the plants may be fruited in a 10-inch pot. Do not give them too rich a soil. Keep them well in the light, and never allow them to make superfluous growths. There are many corners in glass houses where a plant may be placed that will soon be valuable, and whatever way they may be grown, be sure and grow them, as they are much too valuable to be neglected early in the season.

MUSHROOMS.—The first of our beds were formed in cool sheds about the middle of October. These began to produce Mushrooms before November was over, and they are bearing now, but they show signs of failing; and where such is the case clean all hay or any other covering from the surface and supply the bed six or eight times with water heated to 90°. This will soon put fresh life in the manure and spawn, and a second crop almost equal to the first will be the result. Next day, after watering, place a thick layer of hay over the surface, and change this as it becomes too damp. Place a good covering of dry hay over all beds due to produce Mushrooms; it keeps them warm, and prevents the cold winds injuring the "buttons." Make up more beds for yielding in February and March.

HOTBEDS.—These are indispensable for the production of the first crops of Horn Carrots, new Potatoes, and young Radish. We have tried them in all the winter months, but the greatest success attended those framed and planted at the end of January or the first week in February. Indeed we have found Carrots sown then just as early and better in quality than others sown in December. When sown in the latter months they have a long period to struggle into existence and gain strength, whereas, if sown after the new year they have the weather more and more in their favour weekly, and this is a great advantage. We are, therefore, not forming any beds yet, but merely collecting the material, and all should do this. Tree leaves, stable manure, and refuse of all kinds may be used to make up the beds. See that the frames are put in good order, and wash and clean the glass lights.

FORCING.—We have now quantities of Asparagus, Seakale, and Rhubarb. They are all forcing freely and yielding abundantly, but although one supply of each may be much valued at Christmas or the new year, they will be greatly appreciated all the spring, and where roots are plentiful place fresh roots in heat every three weeks, or oftener if the demand requires it. The more the season advances the easier will forcing become, and where there are surplus roots it is much better to force them early than late, when the produce decreases in value. Rhubarb roots especially are often too plentiful in gardens, and if they were forced now the produce would fetch six times the price obtainable in May, or when it grows naturally.

LIME IN VEGETABLE QUARTERS.—In our opinion lime is not used so often and freely in vegetable quarters as it should be, and when any

quarter exhibits the slightest inactivity a dressing of lime will invariably improve it. It is also astonishing how well vegetables thrive on lime. We do not apply lime in any given quantity, but use our judgment as to the requirements of different quarters. We do not believe in a heavy dressing compensating for a great deficiency, as it may be overdone, but small dressings frequently applied are most beneficial.

FRUIT FORCING.

MELONS.—Sow the seed at once for the first crop. They may either be sown singly in 3-inch pots, or a dozen or more may be placed round the edge of a 6-inch pot, to be afterwards placed singly into 3-inch size. In either case the pots should only be about two-thirds filled with soil, covering the seed about half an inch deep, plunging the pots in a bottom heat of 80°. Good fibrous loam and leaf soil in equal proportions gently pressed down will form a porous compost for the young rootlets, it being important for this early sowing that the pots be efficiently drained. It is of the greatest importance that the seedlings be kept near to the glass. The varieties of Melons are so numerous that it is difficult to make a selection, but Benham Beauty, Blenheim Orange, Read's Scarlet-flesh, and Scarlet Premier may be named as good in the scarlet-fleshed section. Eastnor Castle, William Tillery, Hero of Lockinge, and Longleat Perfection of the green and white-flesh sections are first-rate. Ripe fruit from a sowing made at this time may be expected at the close of April or early in May. A temperature of 65° to 70° night, and 70° to 75° day is suitable.

CUCUMBERS.—Young plants just coming into bearing should not be overcropped, and assist them by removing staminate blossoms as they appear. Plants in bearing will require to be cut over at least twice a week, removing all weakly and exhausted growths, reserving as much of the young growths as expand their foliage, overcropping tending more than anything to disaster, inasmuch as it must end in denuding the plants of a large extent of foliage. Stop the shoots at one or two joints beyond the fruit, but young plants should be allowed more freedom, avoiding overcropping. The temperature by night should be 65° to 70°, 70° to 75° by day, with a rise of 10° or more from sun heat, admitting a little air at 80° if the external air be moderately warm and soft, but if cold and sharp it is better to allow the temperature to advance a little higher than admit too much cold air even when the sun is powerful. A little flowers of sulphur dusted on the foliage, walls, and pipes is a good preventive of mildew and red spider, and quicklime rubbed well into any part of the stems affected with canker will subdue it. The floor and other available surfaces should be damped in the morning and early in the afternoon.

Sow now for planting next month in pits or frames heated by fermenting materials, which should be in process of sweetening for making up the beds. If no convenience exist for raising the plants a bed of fermenting materials should be made up forthwith, the seed to be sown so soon as the bed affords a suitable temperature—70° to 75°. Plants from this sowing will be available for house planting to afford a late spring and early summer supply of fruit. Telegraph, Cardiff Castle, and Tender and True are good varieties.

PEACHES AND NECTARINES.—*Early Forced.*—In the earliest house the trees will be in blossom. As soon as they expand the night temperature may be maintained at 50° to 55°, the latter only when the nights are mild, 55° by day as a maximum in severe weather by artificial means when the sky is overcast, 65° by day from sun heat, and if the air be mild a few degrees (5°) more may be allowed. Syringing at this dull time must cease, but damping the floor and border may be practised in the morning and early afternoon on bright days. Lose no opportunity of ventilating freely when external conditions are favourable, and when the pollen is ripe choose the warmest and driest part of the day for aiding its distribution by shaking the trees or trellis, or taking a camel-hair or feather and gently applying the pollen to the stigma. If there be a deficiency of pollen of any variety it may be taken from those that afford it plentifully, and applied to the stigmas of the flowers sparsely furnished with that essential of a good set. The outside border must be protected with litter or some other protective material, the inside border not being neglected for water.

Second Early Forced House.—The house containing trees to afford ripe fruit early in June should now be closed, damping the trees and house two or three times a day, turning the heat on by day for an hour or two in the morning, but not so as to exceed 50° by artificial means, allowing it to rise to 65° with sun heat and free ventilation. It will suffice if frost be excluded at night. The borders must be brought into a thoroughly moist state by repeated waterings, and the outside border protected with litter, but not of a depth to heat violently. A gentle warmth of not more than 60° to 65° will do no harm, but more heat is hurtful. All that is wanted is a covering to prevent chill from frost and snow.

Late Houses.—These should be put into order forthwith, and if any trees are swelling the buds more rapidly, which is not the case where the roof lights have been removed, than is desired, a covering of mats over the lights will prevent the temperature being raised by sun heat to a prejudicial degree, retarding the flowering considerably.

Strawberries in Pots.—Do not push the plants too rapidly in severe weather, 50° to 55° will be sufficient at night for those that were started last month, and 60° to 65° by day, but it is always well to err on the safe side; therefore 5° less in the absence of sun, the weather being cold, is advisable. More plants should be introduced to shelves in Peach houses or vinerias started about this time. The pots should have the

drainage rectified if necessary, the surface of the soil freed of moss or other matter, and the pots washed. A surface dressing may be given of rich material, as a pinch between the finger and thumb of Amies', Clay's, Jensen's, Beeson's, &c., manure, stirring the surface lightly. If space some fine manure mixed with some bonemeal and soot—a quart each to a bushel of the manure and well incorporated—will prove advantageous and a great encourager of surface roots. Suitable varieties for introducing now are La Grosse Sucrée, Vicomtesse Hericart de Thury, Sir Harry, and President. Noble (Laxton) promises to prove an admirable variety for forcing.

Cherry House.—The house being closed last month as advised, fire heat may now be applied so as to maintain a temperature by artificial means of not more than 40° at night and 45° in the day, advancing 10° by sun heat, ventilating at 50°, and closing at that point. Ventilate very freely in mild weather, and avoid hasty treatment in the early stages of growth. See that trees in pots or tubs are not neglected for water, and sprinkle the trees and house occasionally in the morning and afternoon in bright weather.

PLANT HOUSES.

Loam.—If not already under cover a good supply should be wheeled in without delay and broken up ready for potting purposes as opportunities offer. It is best to break it up with the hand, so that worms can be removed as the work proceeds. That intended for choice plants should have the fine removed, in fact all that will pass through the meshes of a ¼-inch sieve. The latter can be passed through a fine sieve, so that there will be three sizes ready for potting and seed-sowing when these operations require attention. It is surprising how rapidly work can be pushed on at that busy season when the soil is ready for lifting on the bench and only needs mixing. Every effort should be made at this season of the year to have all in readiness to forward work that will press heavily in every direction.

Peat.—This should be sorted into three distinct qualities, for Orchids, Ferns, and hardwooded plants. For the first that possessing the most and toughest fibre will be satisfactory; for the Ferns the lightest and least fibrous portion will do very well, while that of the hardest should be selected for the third class of plants. In the preparation of that for Orchids break up with the hand and remove all the fine from amongst the fibre. The soil portion will be found useful for small Ferns and many stove plants in a small state. In each of the other two cases the peat may be stored as broken up, but roots and the rhizomes of Ferns in each case should be removed, for they have a tendency to create fungus when they decay. Remove all grassy matter from the top of the turves, but do not throw it away, as is too often the case. It is valuable for placing over the drainage to prevent the fine particles of soil clogging it and thus render it useless.

Manure.—Cow manure that was stacked under cover in autumn and is sufficiently dry, should be rubbed through a half-inch sieve. Horse droppings that have been prepared by being frequently turned to sweeten it, may also be passed through the same sieve. This must not be stored too thickly afterwards, or it will heat violently, and thus be practically useless. Old Mushroom bed refuse may be passed through a larger sieve, and stored ready for use under cover. That which remains in the sieve should be preserved ready for placing over the drainage of Fuchsias, Balsams, Coleuses, and plants that require liberal supplies of manure. The necessary supply of artificials must be ordered so that they will be ready for use when wanted. Those purchased in bags should upon arrival be placed in tins or large jars that can be made secure at the top. The necessary quantity of half, quarter, and fine bones may also be obtained ready for the time when they are needed.

Leaf Soil.—This useful vegetable soil must be stored in quantity. It should be passed through a half or three-quarter-inch sieve, to be certain of removing all small pieces of wood or Beech nuts, and it is often necessary to pass the mould through a finer sieve. Provide a good heap of very fine material, for it will be found invaluable for mixing in fine composts that are needed for seeds. A good supply of rough material must also be at hand, and in a suitable condition for placing over the crocks in pots, pans, and boxes, that may be required for a variety of purposes.

Sand.—The necessary supply for the season can also be provided if it was not stored in autumn, which is the best time to purchase it before it becomes saturated by heavy rains. Two samples, one coarse, and the other fine, will be found the most serviceable, although this is not absolutely necessary. For years we have only had one sample, and that a very fine one. For special purposes a supply is washed as opportunities occur.

Charcoal and Crocks.—The former should be sorted into various sizes, and there is an insufficiency of small, some may be broken up so that it will not have to be done when it is wanted. All crocks may be washed and then passed through various sized sieves. Five or six different sizes must be prepared, and then the drainage of pots is not a long process. When the crocks have to be broken when needed it takes nearly as long as potting the plants.

Sphagnum Moss.—Sort this from time to time until sufficient has been prepared for potting all the Orchids and other plants that need it. Keep the rough material for placing over drainage, the green heads being selected for top-dressing, and the remainder can be chopped up ready for use. The selected heads will quickly improve if they are placed in an intermediate temperature and syringed occasionally.

Pots.—See that the stock of these is ample for the purposes required

if not secure them at once. It is a mistake, and betokens bad management, to have to wait for pots. Attention to these small matters are frequently of the utmost importance in achieving success.

THE FLOWER GARDEN AND PLEASURE GROUND.

Preparing Composts.—In most pleasure grounds one or more heaps of rubbish are formed, and these accumulations ought to be turned to good account. Supposing all the sweepings, grass from the mowing machine, road and walk trimmings, leaves and rubbish generally are all thrown together, all this in frosty weather or at any time when other important work has to be stopped, should be completely turned and mixed, at the same time throwing out all sticks and other insoluble rubbish. The latter and as much useless wood as can be collected should be burnt and the ashes added to the big heap. In this manner a fairly valuable compost is created, and which will be found most suitable for mixing with the ordinary soil when trees and shrubs are planted. Very frequently such material is all that we have for either manuring or mulching the flower beds, and its use and early digging has gradually improved the character of our naturally heavy soil.

Leaf Soil.—A bountiful supply of good leaf soil is unfortunately not within reach of half the gardeners in the country, and very many that might have abundance either neglect to save it or else spoil the leaves by allowing them to unduly heat themselves. Hotbeds invariably spoil the leaves, and the very best leaf soil for all purposes, and which is especially suitable for tender bedding plants is obtained from dry ditches in the woods. Where available this should be collected and used in preference to any prepared somewhat artificially. If a mass of leaves has been collected, especially for leaf soil, this should be frequently turned in order to insure a regular and even decay without generating any mould or fungus. It is the centres of the mass that is first overheated, and this literally spoils the whole heap. Frequent turnings prevent this and admit of all sticks and rubbish being separated from the leaves. Fairly good leaf soil will, in the course of two seasons, be formed in the deep holes filled with leaves, this being the method sometimes adopted of getting rid of them.

Hotbeds for Propagating Purposes.—A hotbed formed of well-prepared heating material, notably a mixture of leaves and stable manure, are most suitable for either raising plants from small seeds or cuttings. Where possible this hotbed should be placed in a forcing house or earlyinery. The manure ought to be first thrown into a heap and allowed to ferment for a few days, being then turned inside out and again allowed to heat, and once more turned. When it has sweetened somewhat mix manure and leaves together, and in the course of a week the heap ought to be ready for use. Either all manure or all leaves and all tan, or a mixture of tan and leaves may be used, anything in the way of a fermenting hotbed being preferable to the dry heat generated by the hot-water pipes.

A Useful Heap of Soil.—When the busy spring months arrive there is little time to spare in collecting soil suitable for surfacing seed beds, seed boxes, or for potting and boxing off a great variety of bedding plants. A large heap ought to be prepared in advance. Usually all the rubbish and old potting soil that accumulate under the potting bench is wheeled to a heap where it is well out of the way. This should be screened or passed through a half-inch sieve, and the rubbish sorted over and as much of it as possible burnt. Then if this fine sandy heap is mixed with the soil removed from the surface of Cucumber and Melon beds a heap of really good compost results, a little good leaf soil and sand rendering it fit for almost any purpose connected with raising and growing bedding plants.

Commencement of the Propagating Season.—Many experienced a great difficulty in procuring a sufficiency of bedding Pelargonium cuttings, and will have to depend largely upon spring-struck plants. It is much too early to attempt striking cuttings, but when the earlyinery is started all the old plants of Zonal Pelargoniums may well be started too. Hardwooded cuttings will not strike with any certainty, but if the old plants are induced to grow strongly sufficiently matured young shoots may be obtained for striking, and these in their turn will give a good cutting. As a rule the spring-struck plants flower quite as freely as those struck in the autumn, and those with variegated foliage are frequently the best when rooted in the spring. Old or stock plants of Heliotropes, Ageratums, Verbenas, Abutilons, Petunias, and Marguerites if shortly introduced into gentle heat will soon give a batch of good cuttings, and an early start be thus obtained.

Plants in Frames and Pits.—Where the bulk of the bedding plants are wintered in well heated houses and pits not much difficulty is experienced in keeping them alive. Many, however, have yet to store a lot of plants in unheated frames and pits, and these are now having a trying time of it. Pelargoniums, whether in pots or boxes, ought to be kept quite dry at the roots for at least another six weeks, and have all decaying leaves removed whenever seen. Verbenas, Lobelias, Ageratums, Heliotropes, and Petunias must not be allowed to flag for want of water, but even these ought to be kept on the dry side. All the watering necessary should be done in the mornings of clear days, and plenty of air given at the back of the lights whenever the weather is not frosty. We have already had several severe frosts, but we usually experience the most penetrating in January. All frames and cold pits ought now to be surrounded with dry litter or leaves enclosed with hurdles, while the frames whenever severe frosts are anticipated should first be covered with either dry mats or old carpeting, these being covered with a good depth of strawy litter. It may be necessary to leave them closely covered for a week or more, as it is unwise to uncover when the air is

still frosty. Should the frost reach the plants at any time, however slightly, do not suddenly uncover, but allow them to thaw gradually and in the dark. Badly frozen plants should be freely damped overhead with cold water, and then kept closely covered till thawed. A rapid thaw is most injurious.

THE BEE-KEEPER.

NOTES ON BEES.

THE WEATHER.

DURING the months of November and December the weather has been changeable, frost, snow, and rain alternating with extreme mildness for the season, the temperature often being above 50° Fahr. The lowest temperature during November was on the 24th, the thermometer registering 19°, and the lowest during December was 10° on the 22nd in North Britain. On the last day of November and on the first day of December the thermometer stood above 50°, and the bees were alert, many of them on the wing, and a great number gathering water, evidence that, owing to the mildness, breeding had begun earlier than is usually the case. One hive in particular was very busy, and killed the last of its drones on the 1st of December. This hive, I believe, had a young queen, which, I believe, was fertilised as late as the 27th October, but I have not sufficient data at present to confirm this, but a few weeks will prove it, as the bees were half-bred Syrians, and the only drones living were Carniolian. In addition to the above hive, either two or three had preserved their drones until the two days mentioned. On the 1st of December I saw many searching for peameal as well as searching the Arabis, which is still in flower, a sure sign that breeding was going on, and that they still remembered the peameal site, although more than two months had elapsed since they had been supplied with any. The only other thing worth recording at present among my hives is one wintering on one comb. The bees of this hive had been neglected in feeding, and what they did get owing to the cold in October was stored in one comb, which the bees had built in the endeavour to concentrate all the heat possible. I transferred the comb and bees to a division of a square hive, adding a small super of honey on the top. The queen was deposed and a pure one introduced, and as this was the coldest day in November, manipulation was carried on inside at a temperature of 60°. When a hive is weak and showing signs of distress an apartment (with but one pane of glass) should be heated until the temperature is at least 60°, then the hive placed near the window so that the bees will readily creep back after they have rid themselves of all encumbrances. When the room is very warm more light may be admitted, and the bees will fly more readily, and although they rest upon the floor will all rise and return to their hive. The wintering of bees without combs is not new. Upwards of thirty years ago a swarm of bees were kept in an attic and regularly fed, with no comb whatever.

HINTS TO BEE-KEEPERS.

Hives properly and thoroughly prepared during September and October for the winter should not be disturbed or altered in site or appearance, and if previous instructions have been attended to, need not be meddled with until April or May, and probably not even then. Beware of shading hives during snow, if the bees have their liberty, as the slightest obstruction near their hive mars them, and many bees are lost, so that the cure is here worse than the disease. Snow is the greatest enemy we have to contend with, but is most dreaded after the days lengthen, when the temperature is likely to rise above freezing. So long as it is below freezing little danger may be apprehended. With our ventilating floors bees are easily managed during spring snowstorms, but hives without these run a great risk in being shut in during the time snow lies on the ground. The safety valve lies in darkening the entrance, ventilating

from another part of the hive, and this applies to all times and forms of confining bees to their temporary hive.

THE PURGATORIAL PROCESS.

At page 527 "A Hallamshire Bee-keeper" asks if I can refer him to a publication containing information on the above. Beyond what I described, and that the most can be found in the *Journal of Horticulture* from 1862 and onwards, I do not know of any publication that will give the desired information. Previous to the first Crystal Palace Bee and Honey Show I wrote and entered an essay on the subject, along with other articles for competition, but the magnates would not admit them for competition, although they accepted the entry money and granted a receipt for the same. The essay contained my experience with the disease, and modes of cure, the most effectual being baking in a dry oven all hives affected, and putting the bees through the purgatorial process. As the exhibits were not so much as returned, I have not the MS., but I believe a portion of it at least was published in the *British Bee Journal*.

At page 77 in my essay to the Highland and Agricultural Society, the following occurs. Although it is not so explicit as it might be, still there can be no doubt in the minds of unbiassed persons that two changes at least were intended to eradicate the disease. I have often changed the bees to clean quarters four times before giving them a permanent hive. "Meanwhile the bees from affected stocks should be put through the purgatorial process—i.e., into an empty hive for at least forty-eight hours, then after that changed again, so that the impure honey carried along with them may be expended in comb building." It will be observed, although the second change is not stated to be temporary, the closing words make it obvious enough. As to keeping them in confinement, although bees will build comb in confinement, still, when at liberty, they will do it more readily, and get rid of all infection, and to better purpose, than if the bees were confined. In one of the numbers of this Journal there is a letter of mine, describing the baking process, and the effects of the fumes from the stove upon the disease.

THE STEWARTON HIVE.

In answer to "T. J. J.," "J. T.," and others, on the merits of the Stewarton hive, I will now give the desired information, trusting the unavoidable delay will not lessen the interest in the much-maligned hive, that for producing honey of the greatest quantity, and of the finest quality, stands unsurpassed. The first query on my list is by "J. T." "Would you advise me to use the Stewarton hive solely, and do you use it solely yourself?" It depends entirely upon circumstances whether the Stewarton hive may be the only one used in the apiary. If the produce is for the bee-keeper's own use it is the best hive, but if the bees are kept solely for profit, and the comb in the large supers found to be unsaleable, then it would be more judicious to use the square form, which is also the Stewarton hive, having been used throughout Ayrshire before the octagon form invented and introduced by "Bee Robin." But even the octagon form need not be a hindrance if small parcels are wanted. The Stewarton was the first hive to carry sectional and divisional supers. The sections used were half and quarter—i.e., the supers were made in halves and quarters, and the bars of supers were from the first moveable. If these half and quarter-sized supers, or the full-sized ones, do not suit your tastes, nor the market, then there is an alternative of using sections suspended to the top bar as recently described. The only objection to these is, the outer sections are of a different size from the centre ones, but as the outer bars are not too large, they form capital sections, as they did originally. Where dripped honey is in demand no better hive exists for the purpose than the Stewarton one. I do not use the Stewarton hive solely myself, having three or four sorts of hives. I have a per-centage of them, but would not hesitate to have the Stewarton only; but the square ones, being cheaper at first, and better adapted for producing uniform small

parcels, and being in reality the Stewarton hive, I tried most of the cheap square pattern. This hive, with its improvements, is perhaps as good for wintering bees as the octagon at first was, but I must admit that, on the whole, the Stewarton hive gives me the best returns, therefore can recommend it to others where equal-sized combs are not a desideratum.

SUPERING.

From what has been written on this subject of late it appears almost superfluous to extend the discussion, but as the query has been put by the same person, "Which is the best system of placing supers on hives? Should the empty ones be placed above or beneath the partly filled ones?" It is a law with bees, as it is in Nature, they abhor a vacuum; therefore when an empty super is placed beneath a partly filled one, the bees are, for the time being, thwarted in their natural order of working. It may, however, be advocated that supering is unnatural. So it is to some extent, but when an empty super is put on a hive, the bees, with favourable weather, fill it by arranging themselves so that there shall be no space between it and the brood nest, in the most natural and comfortable way to themselves, and when a super or more has been filled in this way and left on the hive, it is the last honey that will be consumed by the bees.

Should unfavourable weather set in while a Stewarton super is being filled, by judiciously regulating the slides its purity is preserved, but not so in the case of supers wrought on other hives of a different construction. When an empty super is put over a partly filled one, the under one is not affected by the process, whether the weather keeps favourable or not. But if the empty super takes the place of the full one, the latter becoming the super proper, should the weather become unfavourable at this time, the bees will either remain in the upper one in a listless idle state, soiling and emptying the combs, or they will start in earnest and carry the honey down. They may commence, if the weather is partially favourable, fill the empty super with comb at the expense of the upper one, and in nine cases out of ten no supers will be had; whereas, had the bees been allowed to nearly fill their first super before another was added, and it was placed over the one in progress, remaining there until the bees took possession of it, then, but not before, should the first super be raised over another one partially begun. This course followed, the bee-keeper will not disappoint himself, and secure more honey and purer comb than if the empty super had taken the place of the full one, which at all times is contrary to the natural working of the bees.

The foregoing applies wholly to full sized supers, but where sections are used as I recommended, or small supers, by far the best plan to work them is to raise the one half of the partly filled ones on the top of the other half, and on the warmest side of the hive, if that can be distinguished, then put empty ones in the place of those removed. There can be no objection to this plan, and the bees will not desert any of the supers, nor remove any of the honey, and if the bees are numerous enough, and the weather favourable, a manipulation every two days will be necessary, removing the supers when finished, adding empty ones as required, but never underneath partly filled ones for the reasons given above.

Supers are generally filled so quickly that it is impossible any discolouration can take place, or rather that any stain can be conveyed to the combs by allowing the first super or supers to be nearly finished before changing their position. Should there be any likelihood of that occurring, it can be prevented by the working of the slides as stated above. During the Clover season of this year the system of placing the partly filled super uppermost answered very well, but at the Heather it proved a failure in every case tried. It may be many years before we have such a summer as the one of 1887 was, and I know that during more than forty years there has not been more than four or five favourable to the placing the partly filled super above an empty one; and as there

is no advantage gained by following the practice it is better the bee-keeper should err on the safe side.—A LANARKSHIRE BEE-KEEPER.

COLLAPSED COMBS.

HAVING lately had a few swarms of bees placed under my care, I had a swarm put in a home-made hive, and through some cause, probably the frames being not properly fixed, the combs fell to the bottom of the hive. I should like to know through your columns the best way to proceed with them now. My intention is to cover them securely and leave them as they are till February, and then transfer them to another hive. An answer through your columns would oblige.—A GARDENER.

[An omission of an important nature has been made in not stating when the combs collapsed, which materially adds difficulty in giving proper instructions how to proceed. If a few frames of comb can be procured, either from some in store or from the other hives, place these into an empty hive, filling which fill a few frames with comb-foundation and drive the bees from the hive having the collapsed combs into it, after the frames have been secured against falling out when inverted by serewing a strap of wood over the tops of the frames. After the bees have been all driven (and this operation should be performed in a close warm compartment having but one window), remove the bottom rails from the frames. Now invert the hive to its original position, and draw out frame after frame until all are removed. Then you have full command of the combs, which must be carefully lifted out, as they are probably delicate, having collapsed through that rather than any defect in the arrangement of the frames. Then proceed to transfer the combs to frames, fixing them with wire to the best advantage you can. Be careful to straighten the combs after heating slightly should any be crooked, and the better the frame is filled the easier the combs are held. After this operation, with the bees still in the warm apartment, replace the transferred combs amongst the bees. To wait until February you would have the advantage of getting a finer day for the operation, but the disadvantage of having brood in the combs, losing much of it by the manipulation, as well as the combs mutilated and fastened together by the bees attempting to restore their dwelling. After all is finished and all the bees safe inside their hive, keep it still in the room till after dusk, then place it on its site. Of course, feeding must not be neglected if required. Bees take feeding in January readier than further on in the season.]

TRADE CATALOGUES RECEIVED.

H. & F. Sharpe, Wisbech.—*Wholesale Catalogue of Garden and Agricultural Seeds.*

Robert Veitch & Son, 54, High Street, Exeter.—*Catalogue of Kitchen Garden and Flower Seeds.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Kitchen, Flower Garden, and Farm Seeds.*

Stuart & Mein, Kelso, Scotland.—*Amateurs' Gardening Guide and Spring Catalogue.*

Oakshott & Millard, Reading, England.—*Spring Catalogue, 1888 (Illustrated with Coloured Plates).*

Harrison & Sons, Leicester.—*General Catalogue of Choice Seeds, 1888.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Chrysanthemum Sport (*J. W. Pontefract*).—The sport is very similar to Mrs. H. J. Jones, but the flowers sent are of a rather lighter tint. By all means preserve and increase the sport, as it will be found useful for late flowering.

Apple (*A. H.*).—We are obliged by your letter, and shall be glad to receive the specimens of both varieties to which you refer in due season.

It is often extremely difficult to arrive at a true decision by an examination of a few fruits alone, as soils and stock influence their character.

Wood and Sons (*L. S.*).—In answer to your inquiry we have no reason to doubt the high character and integrity of this firm. Their specialties have given satisfaction to many cultivators, and their merits can be tested by comparison. We do not recommend dealers for reasons that must be obvious on reflection.

Dressing Vine Border (*H. T. H.*).—There is a great excess of nitrate of soda in the formula you submit for Vines. You may apply the other ingredients at once, supplementing with a dressing of nitrate of soda when the Vines have fairly started into growth, if you think they require a further stimulant, at the rate of about 2 ozs. to each superficial yard. A pound of the other ingredients may be applied to the same area if the border lacks fertility.

Thomson's Manure (*E. B.*).—By a clerical error it was stated last week that 2 or 3 ozs. per square yard is a proper quantity to apply. According to the directions in the pamphlet of the manufacturers 2 lbs. should be forked into Vine borders in the spring and half the quantity after the Grapes are thinned. This may seem a large quantity, but it is to be remembered that the roots of Vines in old borders are often far below the surface, and light sprinklings under such circumstances can have no appreciable effect on the Vines. For new borders half cwt. of the manure is recommended to be mixed with a ton of soil.

White Celery (*J. O.*).—We are obliged by the specimen you have sent. Though you say it is smaller than usual, it is quite large enough, equalling in that respect well grown examples of Major Clarke's or the Leicester Red. The stems are broad, solid, and crisp, and the flavour is all that we could desire, and quite "nutty." We think it a pity that such a good variety is not placed in commerce. Our correspondent "A Thinker," about whom you and others make inquiries, stated some time ago he intended taking a long rest, but how long we are not able to say. We believe he is quite well now.

Gas Lime (*An Old Subscriber*).—This is a hydro-sulphuret of lime with a little ammonia, and, rightly used, is beneficial both as a grub antidote and in affording nutriment to crops. You may find much fuller particulars respecting it and methods of using in an excellent article by G. Abbey in our issue of June 9th, 1887, than it is practicable to give in the form of a reply. If you do not possess that number, it will be worth your while sending 3d. to the publisher. Gas lime should be applied two months before sowing or planting, soot shortly before seeds and plants are inserted; it will do much good, and probably an after dressing of salt would be of benefit on your gravelly soil for all the crops you desire to grow.

Gesnera cinnabarina (*E. James*).—This is one of the most brilliant and beautiful of stove plants for flowering in the winter. Those which you have seen and admired were probably started about midsummer. We have potted tubers at that time, and started them in a frame, and have grown the plants in it till September, or as long as the weather was warm enough, then placed them on a shelf in the stove. They usually commenced flowering in January, or when the Poinsettias were nearly over, producing an effect not surpassed by those plants during a period of two months. Fine plants may be grown in 6-inch pots, forming dense pyramids of orange-scarlet flowers and handsome velvety leaves, which contribute materially to the beauty of the plants.

Bones for Vine Border (*F. S. D.*).—Turf being considerably lighter than ordinary loam and liable to reduction in bulk from decay, the proportion of bones must be calculated accordingly. A ton of crushed bones may be added to every 40 cubic yards of turf, so that for the 330 cubic yards you would require 8 tons of bones, which we consider are more lasting in effect in the crushed state than in the form of meal. You must be preparing for a very large border, and it is worth consideration as to whether it would not be better to make it in sections than to fill the whole space at once. You do not state the length, width, and depth of the intended border, but assume you have made no mistake in your calculations.

Raspberries Falling (*S. P. L.*).—The long drought and great heat of summer was the reverse of favourable to new plantations of Raspberries, and good canes for fruiting this year could scarcely be expected if the soil was not kept moist by occasional heavy watering and constant and thick mulchings of manure or other material for arresting evaporation. Further, when newly planted canes are left their entire length strong suckers cannot be relied on, and it is always better to shorten the canes to within about a foot from the ground. It is true when unshortened they may bear some fruit, but rarely a good crop, and the support that this requires arrests the growth of suckers. We consider it preferable to sacrifice a poor crop of Raspberries the first year than a good one the second, in years succeeding. Procure well-rooted canes; plant them on the first favourable opportunity in good and well-worked soil, cut them down, and mulch thickly with manure for a foot at least beyond the extension of the roots. It may be well also to remember that rather small canes well rooted are better than very strong canes with few roots for establishing a plantation quickly.

Tomatoes for Market (*Constant*).—You had better read Mr. Bardney's article on page 441, November 24th, 1887, and if you do not possess the number it can be had from the publisher in return for 3d. in stamps. Mr. Bardney, who has had experience in the matter, observes that large fruits such as are seen on exhibition tables are not appreciated by purchasers, who prefer about four fruits to a pound to those weighing

8 to 12 ozs. each, and they should not be deeply corrugated. For early crops for sale he intends growing Sutton's Earliest of All more extensively. It is also one of the best for outdoor culture. Laxton's Open Air Tomato has also been found good for this purpose. For culture under glass Mr. Bardney found Hackwood Park (removing a few of the first fruits that grow too large and coarse), Acme, and Hathaway's Excelsior the most profitable. Other cultivators may possibly have found some other varieties equal to those mentioned for the purpose in question, and if so it might be useful to name them and indicate their merits. We have noticed that the most extensive growers of Tomatoes for market aim at producing heavy crops of medium-sized fruit rather than a lesser number of large fruits, though the weight of the crops might be equal in both cases.

Outdoor Mushroom Beds (Cambridge).—Possibly the beds were too small or insufficiently covered for retaining the heat, or it may be, as you suggest, the manure was "too rotten." In the latter case the spawn would not "run," and if it did not do so within a week of its insertion, and continued spreading for two or three weeks more, we fear your prospects are not very bright for a good crop of Mushrooms; but if the manure was not too much decayed and the heat was sufficient for a month for the growth of the mycelium, the subsequent cold would not destroy it, and Mushrooms may appear when the weather is warm enough, perhaps in April. All you can do is to adopt a waiting policy, and we do not advise you to incur any material expense in the matter. On a mild dry day turn the covering, removing that which is decaying from the soil and place it on the top, and if you can find any old mats, sacking, or sh eting to place over the litter this extra covering will be an advantage—that is, if the spawn was not spoiled at the outset, which may or may not be the case, though from what you say we suspect it did not spread freely, and that is why we dissuade you from incurring expense you desire to avoid in covering materials.

Chrysanthemums (H. H. C.).—We have no recollection of recommending the varieties you name, nor should we be likely to name them as forming a good selection, and certainly not if varieties with fairly large blooms were requested, for the two Cedo Nullis and Golden Madame Marthe are Pompons, and good of their kind, but essentially small, and cannot be otherwise as compared with large flowering varieties. Most of the others you name produce blooms varying from 4 to 8 inches in diameter when well grown. We observe they are all Japanese varieties except the Pompons, and we are in doubt, therefore, as to whether you need a list of Japanese exclusively, or whether you desire other types, such as incurved and reflexed, to be included. If you will be good enough to inform us on that point, also state whether you wish to grow blooms for exhibition or plants for greenhouse decoration, your letter shall have our attention, and varieties chosen that are likely to give satisfaction if well cultivated. It is important to know your object. For instance, the three varieties, Mrs. G. Rundle, Mrs. Dixon, and George Glenny, white, yellow, and primrose respectively, are amongst the most free and useful for decoration, but the blooms (incurved) are seldom large enough for exhibiting in stands.

The Thanatophore (T. M.).—The statement on page 541 as to Mr. B. S. Williams using the thanatophore as an exterminator of insects at Holloway, and that it is there found effective, and injures neither Orchids nor Ferns, is quite true. If it did not destroy the insects and did injure his plants he certainly could not afford to use it. At the same time we are quite aware that it has not given satisfaction to all who have tried it, though it has to many. We have made inquiries on the subject, and if we were to publish all the replies we have received you would be more perplexed than you are now; and as we must publish all or none we choose the latter alternative. The owner of a valuable private collection of Orchids, which has been collected at great expense, finds the vapour from the thanatophore the best and cheapest of all agents for keeping them clean. Another extensive cultivator of these plants has not found it answer his expectations; a third offers to sell his thanatophore, and a fourth was so pleased with one he tried that he procured another. So far as we can judge those who have failed with the appliance have (1) either procured one not large enough for their houses, (2) erred in some way in its management, or (3) used inferior tobacco juice, this varying considerably, some not appearing to answer at all for the purpose in question. We are not justified in publishing the names of correspondents who have written to us on this subject, and thus impose on them an amount of private correspondence that would be inconvenient; and we think Mr. Williams can supply all requisite particulars.

Writing for the Press (P. A. R.).—The articles to which you refer in two journals were written by the same person, but some of them were carefully edited, while others were not. We have pleasure in revising articles that contain sound or interesting information, and not a few gardeners have so far profited by that form of teaching as to now be able to express themselves in a manner that is most commendable and not disadvantageous to them. Whatever a man undertakes he should endeavour to give a good finish to his work, whether in the garden or in the press. Slovenliness in either capacity should be sedulously avoided, and in both success simply resolves itself into a question of perseverance and taking pains. Competency is not attained in one or two lessons, but is within the reach of every intelligent man, even if, through no fault of himself or his parents, his education is more or less faulty. All such who endeavour to improve have our sympathy and assistance, if their communications indicate latent ability. Writers whom we cannot countenance are those who copy articles from

one or more papers and endeavour to foist them on editors or others as original communications. Not long ago a pilferer was exposed in a gardening paper for transcribing articles from this and another Journal and getting them inserted as his own; and after that it will scarcely be believed that this same individual had the impertinence to send us matter for publication, without a word of apology for his reprehensible act. We observe he is again figuring in the press, and we advise him to act with great circumspection or he will be getting himself into trouble. At present we refrain from publishing his name and address.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (J. R.).—1, Cellini; 2, Scarlet Pearmain; 3, Formosa Pippin; 4, Blenheim Pippin; 5, Kerry Pippin. (J. M.).—Large Apple, Dumelow's Seckling; small one, Reinette Van Mons.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (A. B. R.).—The plant is Bouvardia Alfred Neuner, a favourite with bouquetists just now. (Bury St. Edmunds).—The Silver leaf or Silver Tree is Leucadendron argenteum. (W. R. T.).—1, Dicksonia antarctica. 2, Dicksonia squarrosa. As you say these Ferns are much alike, but if you compare them carefully you will at once see the difference. (S. T. M.).—It is a portion of the stem of Coccoloba platyclada or Muhlenbeckia, as it is now called. The Acacia you mention is not platyptala, but platyptera, which refers to the broad-winged stems.

COVENT GARDEN MARKET.—JANUARY 4TH.

TRADE again quiet, with no alteration.

OUR RENT AUDIT.

YES, even under the depression we hold an annual rent audit dinner, and we still find it "pays" to do so in the full sense with which that term is used by farmers. This annual gathering answers our purpose in several important ways, and though the collection of rent is in these hard times a matter of primary importance, yet not for that alone do we consider it worth while holding an audit. We meet many of the tenants of property under our control every week, and glad are we to know that our market stand is regarded by them as a sort of rallying point, where they can meet us and each other for cheery kindly greetings, and for the transaction of business, but at the rent audit we enter fully into an interchange of opinions—a discussion of the year's work and its results, and of possible improvement of practice in the future.

After dinner discussions are said to have the characteristic of a somewhat rosy tinge—a hopeful cheery view is then taken of life's burdens, and we grant that it is so in a very considerable degree at our rent audit. To have paid his rent in full under existing circumstances is an achievement of which any farmer may well feel proud, and doubtless the happy sense of it imparts a zest to his enjoyment of the dinner which nothing else could do. But on the other hand the deed and the dinner impart the courage of opinions which are subsequently often outspoken in an unmistakable manner. Well, we like to hear the views of earnest practical men, and it is part of our experience that farmers are not a very demonstrative section of the community. We strive in the speeches which come after the dinner to excite discussion, and by the proverbial rubbing of heads together to impart and gain something which may do some good to all of us during the ensuing year.

Our readers hardly need to be reminded that our views upon the cultivation of the soil are clear, comprehensive, and we may add thoroughly practical; we take advantage of the audit to lay those views clearly before our hearers, and we boldly challenge discussion. The year, its work and results are all passed in review, the success or failure of crops, possible improvements in practice, new lights on any branch of farming are taken one by one, and details are treated of as fully as possible without becoming tedious. By imparting a popular tone to our address, by making slight personal appeals to any farmer whom we have found to possess special knowledge upon some important point of culture, we are able to fix and hold the attention of our hearers. We do not claim to carry them entirely with us, for there are dissentients among them who give as much "chaff" for our corn; but then criticism is always useful, for it promotes discussion, and we often find that the man who is most strongly in opposition to our views for the moment eventually adopts them and becomes our staunch supporter. This important fact is probably owing to our habit of avoiding any pretence to infallibility; we give a plain statement of our work, and explain results whether good or bad.

Perhaps we were a little egotistical when we told how our best Wheat field was that upon which only chemical manure had been used, with the satisfactory result of a crop of fully 56 bushels of

corn and 2 tons of straw per acre, and we could not but invite attention to figures for one moment, as we explained that by the moderate computation of market values our corn and straw represented a total value per acre of £16 4s., or 32s. per quarter for the corn, and 50s. a ton for the straw. We know that straw can be had in some places for a little less than this, but we also know that in dairy districts it brings very much more. Compare such a crop with the average yield of about 30 bushels per acre, and we may fairly claim that farm land generally is not made to yield anything like a full crop. Depend upon it, many or most farmers would find their calling much more profitable if they had less land and higher farming, not model fanciful farming, but downright good practical work, which is the embodiment of our oft-repeated lesson—sound land, clean land, well drained, thoroughly porous, and well stored with all the requirements of the crop it is under. We know in our own practice that so-called "bad" fields are only bad because of bad treatment, and that when brought under high cultivation they often excel other parts of the farm. We had two examples of this upon two of the farms we have in hand this year; both were under Wheat, and we had little, if any, Wheat at all better than those crops, so that we were told the "bad" fields were for the first time bearing really good crops.

WORK ON THE HOME FARM.

Frost and snow have made our shepherds busy, an extra amount of care being now required for the management of the ewe flocks. We are using no roots yet, nor shall we do so till the lambing, when some Mangolds will be given—a few at first and more later on. We are first inate in having plenty of grass, which has been held in reserve for some months specially for the present time. The ewes are upon it in small folds, and they have as much Pea straw in racks, and Barley straw chaffed in troughs, mixed with a few Oats. We are deaf to the entreaties of the dealers in oilcake to purchase some now for the ewes. We cannot afford it, and if we could we do not require the cake. Our sheep are well nourished, and we have no doubt that their progeny will be fine healthy animals. There are a few cases of foot-rot among them, and now that they are heavy with lamb they cannot be thrown to dress the feet; but we have them taken out for a quiet turn upon a road every morning, which certainly tends to keep under that troublesome disease. Preparations of the lambing folds must now be put in hand in order to have our arrangements complete by the middle of the month, when we expect our first lambs. Judging from the appearance of the ewes we shall have many early lambs or many twins. We select a place for the fold as much sheltered from cold winds as we can. Luckily we have a deep belt of underwood on the north and east of our fold, which we make quite snug by a wall of straw between hurdles and with numerous coils all round it inside, for which hurdles thatched with straw are used both for the sides and roofs. The bottom of the fold is kept well littered with clean straw throughout the lambing, and with good wholesome food and kindly gentle treatment we hope to avoid anything like serious losses among sheep or lambs. We repeat our warning to flockmasters not to let pregnant ewes have Turnips nor to be folded upon heavy wet land; if they do so losses are often serious, and the care and labour of a year rendered useless, to say nothing of the value of the sheep now.

REMARKS.

- 25th.—Fine morning, with bright sunshine and white frost; fair till about 9 P.M., then drops of rain.
 - 26th.—Fine throughout and cold.
 - 27th.—Sharp frost in the night; cold but very sunny.
 - 28th.—Fine morning; bright afternoon.
 - 29th.—Fine and bright all day.
 - 30th.—Bright and fine, and a little warmer.
 - 31st.—Foggy morning; fair afternoon and evening.
- A fine and cold week, the mean temperature being almost exactly at freezing point. Slight falls of snow, but not enough to measure.—G. J. SYMONS.

CHOICE GARDEN
CONIFERS.

SUCCESS with Conifers, as with most other hardy trees, depends, to a great extent, upon the suitability of the situations chosen for them and the care exercised in the selection of varieties. For extensive pleasure grounds and parks there are many strong-growing Conifers that can be advantageously planted in numbers. On the other hand, in gardens near the house, or wherever space is restricted, quite a different selection must be made, and ultimate success will depend greatly upon the judgment exercised in this matter. The position, soil, and climate of a garden also require consideration, as many fine Conifers will thrive in the south and west of England that prove quite unsatisfactory in the north, or in any cold exposed localities. In regard to this, however, protection in the early stages is a matter of much importance, as numbers of reputedly tender Conifers only need some adequate screens from cold winds for a few years until they are well established and growing freely. In most northern gardens abundant examples of this are afforded, and where suitable protection, by stronger-growing trees or shrubs, has been afforded, at the critical time, comparatively little difficulty is experienced in forming good collections of Conifers from Yorkshire or Northumberland in England, to Perthshire and beyond in Scotland.

For lawns and pleasure grounds in proximity to the dwelling house single specimens of the dwarf, bushy, or fastigate Conifers, are preferable, but in their employment and the system of planting adopted there is room for the exercise of much taste. An undue proportion of the Biotas, Thuias, or plants of similar habit produce a most displeasing formality, and attempts to place such Conifers in clumps is usually unsatisfactory to a remarkable degree. Well-developed specimens of the green or golden Arbor-Vitæ, Yews, &c., have a fine appearance when not too closely placed, but it is necessary to have a fair proportion of the more graceful Retinosporas or Cryptomerias, with some deciduous trees and shrubs to avoid a monotony of tint. An admirable example of this mode of planting is seen in Baron Schröder's garden, The Dell, Egham, where the numerous specimen Conifers on the lawn and near the house are backed up with massive beds of Rhododendrons, the fragrant and profuse deciduous Azaleas, Kalmias, and other American shrubs. Beyond these are belts of common Laurels, with miscellaneous strong-growing deciduous trees, shrubs, or Conifers, which, while yielding adequate protection, serve as a kind of frame to a tasteful garden picture. In large gardens the pinetum, when well planted and properly attended, is one of the most important departments, but there are thousands of gardens where such extensive experiments cannot be undertaken, and it is still possible to have within moderate compass a fairly representative collection of the principal coniferous types.

Shallow poor or dry soils are the worst for Conifers generally, and though some can be found to thrive on chalky soils they are not very numerous, especially amongst those of dwarf habit. For moist situations several can be named, but all object to stagnant water in the soil. A well-drained deep rich soil is the best for Conifers of all kinds, and when planting near a house it is advisable to form suitable stations wherever these conditions are not naturally provided. Remove the soil to the depth of 3 or 4 feet and of a width proportionate to the size of plant, refilling with good turfy loam and leaves from which all the woody portions have been taken. This should be trodden rather firmly after the tree is in position

and a liberal supply of water afforded. For some Conifers leaf soil is used very freely, and we have seen serious evils result from this, especially where it contained a quantity of woody substances, as fungoid growth is produced that speedily renders the soil sour and the trees unhealthy.

In suitable situations the handsome silvery *Abies Engelmanni glauca* is one of the most effective of lawn Conifers. Unfortunately, however, it cannot be relied upon except in the south or western counties, as the late frosts in spring are very apt to disfigure if not to kill it. Still it possesses such attractions that it is worthy of a trial wherever there is the remotest chance of success; and when it grows freely, forming a well-proportioned specimen 5 or 6 feet high, it is effective in an extraordinary degree, the dense glaucous substance on the leaves and branches glistening like silver under a bright sun. Some confusion has existed respecting this and *Abies Parryana glauca*, some authorities being of opinion that as they are both from the Rocky Mountains of Colorado and similar in general aspect, they are identical. However this may be in some places it is certain that in others, and more particularly in the northern gardens and nurseries, the Conifer grown as *A. Parryana glauca* is distinct from *A. Engelmanni glauca*, and while usually possessing less of the glaucous character is sometimes quite of a bluish tint and is much more hardy. This latter quality has recommended it to many persons who have failed with the other variety, and most of those who have tried it speak favourably respecting its merits. *A. Engelmanni glauca* should, however, be preferred wherever it can be reasonably expected to succeed.

Another beautiful glaucous Conifer of moderate growth is the Silver Fir, *Abies (Picea) nobilis*, which should be included in every garden. A good specimen of this Fir is a fine study, as in addition to the prevailing silvery tint there is also a tinge of steely blue in the older leaves that affords a charming harmony. It deserves the best position that can be afforded it, but should not be placed too near the house, as where it succeeds it will attain considerable size if undisturbed. *Abies magnifica*, *A. grandis*, and *A. Veitchi* are all beautiful members of the *Picea* section. The first two are well known, but the last named, though as yet comparatively scarce, is likely to become a great favourite, owing to its distinct graceful habit. Several others of this group, such as *A. amabilis*, *A. concolor*, are scarcely less attractive than those named.

The Hemlock Spruces, *Abies canadensis*, *A. nigra*, *A. Mertensiana*, and *A. Hookeriana*, though free-growing Conifers, are useful for the dampest positions, more especially the borders of lakes and streams. Capital effects can be produced in such positions with these, *Taxodium distichum*, *Thuia Lobbi*, some of the *T. occidentalis* varieties, and the Virginian Juniper, a few clumps of selected Willows of different colours assisting greatly in rendering this part of a garden or pleasure ground agreeable at all seasons. For large rockeries the dwarf forms of *Abies excelsa* are well adapted, *clanbrasiliana*, *pumila*, and *pygmæa* constituting a trio of distinct varieties for that purpose.

The Biotas and Thuias are important garden Conifers, both the green and golden varieties being some of the most generally planted. They have an extremely neat appearance, and possess the double advantage of being hardy and easily grown. The Chinese Arbor-Vitæ, *Biota orientalis elegantissima*, is one of the best both in habit and colour, as it assumes a fine golden tint in the spring and summer, the American Arbor-Vitæ, *Thuia occidentalis* and its varieties forming fine companions for this. The feathery and varied Retinosporas, especially the golden forms of *R. obtusa*, *R. plumosa*, and *R. pisifera*, are invaluable, as they present a marked contrast with most other Conifers both in habit and colour. *Cryptomeria elegans* is also a handsome lawn plant, its peculiar purplish tint having an admirable effect in a good situation. The varieties of *Cupressus Lawsoniana* are almost numberless, and in some avenues of these trees, like that at Keir House, Stirling, all raised from seed, scarcely two are alike, and the difference in some

cases is surprising. A variety called nana is well adapted for lawns, but one of the best is erecta viridis, which is quite a model, so regularly columnar is it in shape, and the shade of green is so bright and distinct that it is at once noticed amongst many others.

Other well marked types are afforded by the Irish Yew, the golden *Taxus baccata elegantissima*, the bold *Thuja dolabrata*, the Umbrella Pine, *Sciadopitys verticillata*, and the Maidenhair Tree, *Salisburia adiantifolia*, which aid in diversifying a collection surprisingly. There are few Pines that look well in a small space, but *Pinus contorta*, *P. Bungeana*, *P. Cembra*, and *P. parviflora* are amongst those best suited for the purpose.—ARBOR.

THE PEAR SEASON.

THE two outstanding features are the extra fine quality of the fruit and the abnormally early ripening of all the varieties. Only two sorts have this season failed to ripen well here, the one *Triomphe de Jodoigne*, the other *Van Mons Léon Leclerc*. It is seldom indeed that the latter is good, and we fully expected this year would have seen it of good quality. The former has been good in the district, on much heavier soil than ours. The best flavoured Pears have been *Dr. Hogg*, *Winter Nélis*, and *Knight's Monarch*. We had no fruit of *Seckle* this season, and *Joséphine de Malines* was of deficient quality compared with the two named above. *Dr. Hogg* is, of course, an early Pear, but a very commendable one. *Winter Nélis* is so well known that it hardly requires any further word in its favour. It is our favourite variety here; a pity that it should be so uncertain in its time of ripening. We had a very large quantity this year, and could not keep the latest beyond the last month of 1887, while last year we had it good in April, and it was the new year before it began to ripen. *Knight's Monarch* is a much firmer fleshed variety, not so juicy, but to some tastes preferable to the above. The fruit lasts for a long time, as only a few ripen together. When growing it requires to be well thinned at an early stage, as the tree very often sets much too large a crop. Of the larger sorts, *Williams' Bon Chrétien*, *Souvenir du Congrès*, *Beurré d'Amanlis*, *Flemish Beauty*, *Beurré Bachelier*, *Hacon's Incomparable*, *Louise Bonne of Jersey*, *Marie Louise*, *Easter Beurré*, and *Beurré Rance* gave the most satisfaction.

Williams' Bon Chrétien on a standard finished a grand crop, which had been thinned very freely. Flavour very musky, and to some palates on that account disagreeable. Wall fruit in comparison was not so good, though larger. *Beurré d'Amanlis* and *Flemish Beauty* were both very good, the latter being quite beautifully marked with red on the sunny side. *Beurré Bachelier*, though wanting in the luscious flavour of the richest kinds, was very pleasing and refreshing, and suited some tastes. It is much in the way of *Napoleon*, though very much larger. The tree, moreover never fails to bear a crop. *Incomparable* was one of our best autumn sorts. *Louise Bonne* off a standard also good. *Marie Louise* fine as usual, but very quickly past. *Easter Beurré* is often only fit for kitchen use here, but this season it was really fine, the best of the fruit from a west wall having developed a bright flush on the exposed side, which rendered them of great value for big desserts. The best flavoured fruit, however, was grown on standard trees which carried large crops well thinned out. Towards autumn the branches were borne down by the weight of fruit, and for many weeks these trees formed very pleasing decorative objects.

Beurré Rance is at present in use. Some seasons it fails to ripen, and most often it is March to April before it is fit for table. In other gardens in this neighbourhood it is past, so that we are rather late with it. The fruit has this season developed very highly that peculiar gritty melting flesh for which it is held in repute. *Glou Morceau* is not yet quite ripe, and we shall give it the benefit of a little heat to ripen any we may require for home consumption, as this is one of the varieties which is improved considerably by ripening in a warm atmosphere.

Other good Pears of the year were *Thompson's*, a luscious, but not very large Pear; *Duchesse d'Angoulême*; *Olivier des Serres*, very fine; *Fondante d'Antonne*; and *Crassane*, the latter much better than usual. The same remark applies to *Nec Plus Meuris*, which is still in the fruit room. *Pitmaston Duchess* was also good. *Passe Colmar* not so good, and *Beurré Diel* fine in appearance but bad.

Altogether the Pear season has been one of the very best. It has been, moreover, a good educational season, as it has shown some sorts to be so entirely unsuited, if not altogether worthless, that we can have slight hesitation in removing and replacing them with other and better kinds, and it has further enabled us to decide to allow some kinds which were all but condemned to remain a while

longer. But above all the season has shown in a well marked manner that with Pears, as with other things, strict selection is the thing that pays.

The prospect for another season is most glowing. Those who have failed to thin out shoots and weakly spurs in the past should freely thin now. It is not so good a time as when the foliage is on the trees, but it is always a safe and paying practice to cut clean away weakly spurs which never can bear fruit, and which merely produce small foliage of no use to the tree, and certainly of much harm to the stronger and healthier leaves, which would do much better work if the small were out of the way altogether. One perfectly developed bud is worth a hundred of the kind that may be seen in very many gardens throughout the country. The former will come to fruit, the latter never. Nor is it certain that too many good buds are an unmixed good. I thinned a large number of very promising buds out last year, and though the amount of blossom was in consequence apparently deficient, that which was left was of good quality and did not fail to set freely, and I imagine the more freely because of its comparative scarcity.—EAST LOTHIAN.

DENDROBIUMS.

MR. IGGULDEN gives excellent advice on the culture of these beautiful Orchids, but he does not seem quite successful with *Dendrobium Falconeri*. I would advise him to try it on the stem of *Lomaria gibba*. If he has one about 1 foot long it would be ample for a fair-sized plant. A strong wire can be pushed through and turned to hang it up by. I have on several occasions seen it very fine treated in this way. Once several years ago I saw a splendid specimen at a Reading Spring Show. It was carrying, if I remember rightly, about 150 of its lovely flowers, and was growing on a *Lomaria* stem. The plant was, I believe, grown by a doctor, whose man informed me that it made its growth in a small cucumber house, and was well rested in a vinery till its buds began to show, when it was put back into a warm house till in flower; treatment which evidently suited it.—C. PAGE.

CYPRIPEDIUM SCHOMBURGKIANUM.

THIS *Cypripedium* is not a new species, but it is so long since it was first found, and is now so rare, that it is practically as interesting as a fresh discovery. There are many other Orchids that were found by the earlier collectors and have been recorded in botanical works which are now lost to cultivation, and their re-introduction would be as welcome to many as novelties. *Cypripedium Schomburgkianum* was found by the traveller whose name it bears, Dr. Richard Schomburgk, as long ago as 1842, but if any efforts were made to import plants to this country they were unsuccessful and no living plants reached cultivators here. Recently, however, it has been rediscovered, and a large healthy plant with over 100 growths was sold at one of the London auction rooms last week. The highest bid was 21 guineas, and the purchaser was Mr. Measures of Camberwell, who has thus added another treasure to his valuable collection. The growth and foliage resemble *C. Pearcei*, also known as *Cypripedium* or *Selenipedium caricinum*, but I have seen no description of the flowers beyond the fact that they are said to be fragrant.—C.

VANDA TRICOLOR.

I NOTED "W. L.'s" remarks as to the flowering freak of the above, and may mention that one plant flowered strongly twice last season in May and September, continuing in bloom for two months, at the latter period some of the spikes having as many as fifteen blooms on them.—DUM SPIRO SPERO.

HABENARIA MILITARIS.

THAT the terrestrial Orchids from temperate climates are neglected by cultivators has long been apparent, but it was brought to my mind very forcibly when I saw this brightly coloured *Habenaria* at one of the London sale rooms last year. Only one plant was entered there in flower, and that a small one, but it attracted as much attention as some more valuable and showy Orchids on the same occasion. A good proportion of the orchidists who attended on that day made its acquaintance for the first time, for though known to botanists for some years it is very rare in cultivation. A plant flowered at Mr. B. S. Williams' nursery, Upper Holloway, in the autumn of 1886 for the first time

in that collection, and Mr. Fitch's sketch, then made, appeared in the "Orchid Album" in May 1887 (t. 281) as an accurately coloured and faithful representation of this distinct species. At a meeting of the Royal Horticultural Society on August 13th, last year, Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, showed a plant in flower, and was awarded a first-class certificate for it. From this specimen the illustration (fig. 3) was prepared.

It seems to have been first made known by Mr. Godefroy-Lebeuf, who found it in the mountains of Phu Quoeh in Cochin China, and it was subsequently named *Habenaria pusilla*, but larger living plants were afterwards brought by M. Regnier, and the specific title *militaris* was adopted as more appropriate. Like most terrestrial Orchids of this character it has fleshy tuberous roots producing a stem and tapering or elliptical leaves, which fall off after the flowers have decayed—namely, towards the end of October. The flowers are borne on the upper part of the stem in a kind of raceme, the most conspicuous portion being the lip, which is deeply four-lobed with a long spur at the base, large and bright scarlet; the sepals and petals small, greenish white, and inconspicuous. A compost of turfy loam and peat in equal proportions, with plenty of sand, suit it with an intermediate temperature when it is growing, and a cool one when it is resting during the winter.—L. C.

GARDENERS AND LOCAL MUSEUMS.

It is exceedingly desirable that in every well-defined district of our country there should be a museum of natural history objects, more particularly of those that occur in the district. There should also be a register kept of all known species, as specimens cannot be usually exhibited of everyone that occurs, some being rare and exceptional. Such a list would be of service to gardeners, amongst others, as indicating what insects are to be guarded against. In the formation of a local museum gardeners might, if inclined, render considerable help as regards insects and plants. We might add birds also, for most gardeners have special opportunities for observing birds, and can obtain, at times, nests and specimens that are of interest. Insects of all the orders are constantly seen by gardeners. Some of them are mischievous, but many are harmless to cultivated plants, and these are often hastily destroyed, when their preservation would be an advantage to the community if they were placed on view. Gardeners could help each other, and naturalists also, by taking observations as to the species of a district, their times of appearance, abundance or scarcity, when some outline list is constructed in which the principal injurious and beneficial species are embraced. Then as to our native plants. How often one may discover in a garden something generally regarded as a mere weed, but which is an example of some British species, local or unusual, which has arrived there by accident. As yet we fear the names of not a few familiar weeds are unknown to the majority of gardeners, possibly not so much from indifference as want of time.—NATURALIST.

THE CULTURE OF MISTLETOE.

In your paper of December 22nd you have a very interesting article on the Mistletoe. At the end of the article the writer wishes to know "why in these days of general depression it cannot be profitably cultivated at home," and intimates that it is worthy of the attention of our agriculturists. I have had a good experience of Mistletoe, and have sold tons of it in this, as well as other seasons. Hundreds of tons are also sent out of this country to the various markets, but it is grown at a direct loss to the growers, as treble the value of Apples might be grown on the trees from which it is cut. A fruit grower is indeed a sloven who allows Mistletoe to accumulate on his trees. Other reasons which add to the unprofitableness of its growth are the excessive charges for carriage and other restrictions made by the railway companies. They charge the very highest rate on their scale, compel you to prepay carriage, and to send entirely at your own risk. They will not carry except on these terms. How heavy these charges press your readers may judge when I state that I have paid over £5 per ton carriage this year for carriage to one market, and to other markets where the carriage is from 50s. to 60s. per ton, plenty of good Mistletoe has been sold wholesale at 6s. per hundredweight, salesmen's commission to come off this. I may state I never saw the Mistletoe better and more berried than this season, and yet make lower prices. No; our agriculturists must look to other sources of profit than growing Mistletoe, but I believe that fruit growing can be made to pay, and enclose you a short paper I read before the Herefordshire Chamber of Agriculture in 1885, in which I state my views on this subject, and after between two and three years of further experience I am more confirmed in this view. The great

burden our growers have to carry is the cost of transit by railway to our markets against the cheaper water carriage of our competitors on the other side of the water.—JNO. WATKINS, *Pomona Farm, Hereford.*

[The paper referred to contains much sound information.]

PREPARING EARLY POTATOES FOR FORCING.

WE dry our seed Potatoes in hampers in an open shed after they are dug, and then store them in a disused ice house with the well filled up. They keep excellently in this position, for the temperature is uniform. The early and second early varieties, for outside planting, are just showing signs of growth. This is a capital time to arrange them singly, eyes upwards, on the vacant

Fig. 3.—*Habenaria militaris*.

shelves in the fruit room. If done at once they can be moved and arranged in much less time than is the case after they have started into growth. If they are allowed to remain in heaps after this date the majority will commence to grow rapidly and weakly, which will necessitate the removal of the sprouts. If plenty of shallow boxes are at hand, they may be arranged in them so that they can be taken direct to the position to be planted when that time arrives. Many store the boxes one above another, and this is certainly preferable to no preparation, and saves time at planting, but where space is not limited this method is not advised. They are as well this way as any for a time, but after they start growth the shoots of all the lower boxes grow rather weakly, even if a cavity between the boxes has been provided. If possible, the boxes should be placed singly, and the position selected not too dark, for we prefer strong green sprouts to those that are blanched. There is no comparison between the growth of early Potatoes that have been care-

fully prepared prior to planting and those that have been knocked about and had the first growths rubbed off. The former come through the ground and show a marked difference in strength; the latter may have more shoots, but they are weaker.—N. G.

GOOD VEGETABLES.

GARDENERS making up their seed lists would do well to give a trial to Veitch's Paragon, and also to their Exhibition Brussels Sprouts. The former was the best of several kinds we had last year, and this season I have grown only the above two sorts, and never have had such a supply. Exhibition is rather the earlier of the two. Paragon has a habit of growth which completely shelters the sprouts from the weather, the foliage rising in successive tiers, and each tier lapped over the other, so that a most complete roof is formed. We plant 3 feet apart each way, and find it pays to do so.

I have never yet had a better Turnip than Snowball. It is good all through the summer, and does not run to seed quickly, while it is one of the very best for winter. I have now grown it for the past four years to supply young Turnips in winter, and it is excellent.

Another good old vegetable is to be found in Lettuce Hicks' Hardy. I have known it for the past twenty years, and have not yet found a more generally good sort. As a rule we get out of it for a few weeks in late spring, but the rest of the year, in summer, autumn, and winter, it keeps us going. In spring or early summer Tom Thumb is very useful, and much better than any new kind we have yet tried. A pinch of seed sown just now under glass, and in a growing temperature, and the plants either placed in boxes or frames, come on very rapidly, some planted in a warm position out of doors keeping up the succession until those raised outdoors come in.

Of Cauliflowers, of which we have now so many good sorts, I doubt if there is a more generally useful summer and early autumn variety than the Dwarf Erfurt. Sown in the same way as recommended for Lettuces it comes in very early, and none stands the drought of summer better than it does.

Perhaps the best paying Tomato is Hackwood Park Prolific. When well grown it is an enormous cropper, grows to a large size, the flavour good, though not the best in that respect, and the colour is very taking.—B.

SEAKALE—GROWING AND FORCING.

THE present season seems to be a suitable time to offer a few remarks upon the cultivation of this useful vegetable. The weather of last week may be taken as a warning of a severe winter, which naturally reminds us of the past two winters, in which nearly all the Broccoli was killed by frost. The question then arises, How are we to keep the table supplied with vegetables if such is the case again? With me the only Broccoli that stood the two winters referred to was Sutton's Late Queen. This is a capital variety, but does not come in till the end of April.

The difficulty is easily overcome where Seakale is considered equal to other vegetables, and in some places it is more of a dainty dish than Cauliflower or Broccoli. I have more than once heard the remark from the lady herself, "I am never tired of Seakale." The plan I practise is to plant a good piece of ground every spring. I do not force it the old-fashioned way on the ground it grows with pots and leaves, which I consider is a waste of labour as well as being unsightly in a well kept garden. I have a dark chamber partitioned off in one part of the stoke-hole, and a brick pit 18 inches deep and 2 feet wide running round against the wall. In a temperature of 65° to 70° both Seakale and Rhubarb forces admirably, and such a place might easily be made in almost any stokehole. Fresh crowns are obtained every four or five days enough to produce three or four dishes. The long roots are cut off, and the crowns are planted thickly in the pit in leaf mould or cocoa-nut fibre, and watered as often as required. The roots are cut up into pieces 2 or 3 inches long and placed in boxes on their ends with some soil, and put into a cool vinery or cold frames until spring, when they have again formed crowns. A piece of ground having been prepared for them they are then planted out a foot apart each way, or if there is plenty of ground 18 inches between the rows and a foot in the row would be better. When they have begun growing freely a dressing of salt and some liquid manure two or three times during the summer will greatly assist them. These lines are not intended for the old and experienced, but for those who are just starting in the gardening world, with but a tender knowledge of some of the things they will be expected to do.—R. M.

CHRISTMAS ROSES.

AN interesting letter on these appeared recently. I do not think they are so much grown in private gardens as they deserve to be. For cut flowers they are first-rate at this season of the year, coming in just as the Chrysanthemums are going off, and if grown under glass they throw their flowers up beautiful and white. Here we grow them in a

frame from which frost is excluded by hot-water pipes. They are planted out in good soil and remain undisturbed all the summer, as we think they do best when left alone, taking care to mulch them well and see that they never suffer by want of water. In this way we have them in bloom the week before Christmas, and they continue throwing abundance of flowers for some time. When they become too crowded they will be all lifted and replanted in fresh soil further apart, making a larger plantation. The plan recommended by "B."—viz., dividing them after flowering, is no doubt a good one, but we think they do better planted out than in pots and taken up and replanted when they get too close together.—G. HILTON.

EVENTS OF THE WEEK.—During the current week the chief events of horticultural interest are the continuation of the Mid-Winter Chrysanthemum Show at the Westminster Aquarium to-day (Thursday), and the annual general meeting of the Members of the Gardeners' Royal Benevolent Institution, at 3 P.M., at Simpson's, 101, Strand, to be followed by a dinner in the evening.

— AT a general meeting of the ROYAL HORTICULTURAL SOCIETY on January 10th, James Bateman, Esq., F.R.S., in the chair, the following candidates were duly elected Fellows of the Society:—viz., Alfred G. Beebe, Richard Bradshaw, R. Giles Bradshaw, Henry Brown, Alexander Cheal, Miss R. Debenham, William S. Dent, T. G. H. Eley, Joseph Harris, H. Herbst, John H. Tite, John Mackerell, Frank R. Parker, Charles H. Smith.

— A GENERAL meeting of the ROYAL HORTICULTURAL SOCIETY was held in the crush room of the Royal Albert Hall on Tuesday the 10th inst., at twelve noon. Dr. Robert Hogg presided, and the business was confined to reading the minutes of the last special meeting and submitting for confirmation the resolutions passed on that occasion. These were carried unanimously, the only modification being that clause 7 of the circular was adopted with clauses 6 and 8. The appointment of the Committee was also duly confirmed, and a meeting was held subsequently.

— MR. R. WESTCOTT writes as follows respecting FACTS ABOUT GRAPES:—"Mr. Iggulden, in his Review, page 4, refers to Golden Queen as thus far being disappointing in point of colour. He will find if he gives it, as he intends doing, a longer season, he can get it to colour quite equal to Mrs. Pearson, but, unfortunately, both of them, like Gros Maroc, are more pleasing to the eye than the palate."

—"DUM SPIRO SPERO," in answer to "Nil Desperandum," states:—"The ARTIFICIAL MANURE referred to on page 539, last vol., is suitable for any plants that require watering either in pots or planted out."

— THE sudden death is announced of DR. ALEX. DICKSON, Regius Professor of Botany in the University of Edinburgh, at the age of fifty-one. Dr. Dickson was staying at his residence in Peebleshire, and while engaged in the game of curling was seized with illness on the ice, and died on the 30th December last. Before his appointment to the Edinburgh Chair he had successively filled the Chairs of Botany at Dublin and Glasgow, and on the death of Professor Balfour he was appointed his successor in 1879.

—"G." writes—"For several seasons I have grown READING RUSSET POTATO very satisfactorily, and in 1886 it was especially good; in the past season, however, the tubers cracked very much, and this has practically spoiled the crop, though the quality is all that could be desired. My land is rather heavy, but I have not noticed this peculiarity in such a marked degree in any other variety this season."

— MR. JAMES DICKSON sends us the following WEATHER RECORDS from Castlemilk Gardens, Lockerbie, N.B. In 1887 the mean temperature taken from protected and exposed thermometers was 42.6°, the rainfall 30.96 inches, which fell on 160 days. June was the driest month, 0.68 inch falling in five days; July the wettest, 5.34 inches being registered on eighteen days. The sunshine averaged 120.3 hours

a month, the least amount being 33 hours in January and 238 in June. In 1886 the mean temperature was 45.92°, the rainfall 42.45 inches and falling on 189 days, and sunshine averaged 99.4 hours a month.

— THE CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—Mrs. S. A. Lee, F.R.H.S., 4, Arlington Park Villas, Chiswick, has, with the object of encouraging original research and observation, offered a sum of £10 to be distributed in four prizes for essays on horticultural subjects as defined below. The competition is confined to the junior members of the Association, or those under the age of thirty at this date, and who have attended any of the meetings during the current session previous to this date. A member may compete in one only of the two classes. Class I.—Prizes of £3 and £2 to be awarded for the two best essays on any subject relating to horticulture. The writer may choose his own subject, and treat of it from a scientific or practical point of view, or both. Class II.—Prizes of £3 and £2 to be awarded for the two best essays on "Water, its Use and Abuse in the Cultivation of Plants." The manuscripts bearing a motto, or *nom de plume* only, must be sent in to Mr. J. Barry, Secretary, not later than 1st April, 1888. Competent judges will be appointed to adjudicate upon the essays, and the results announced later on by arrangement.

— MR. WILLIAM JOS. WATSON, Newcastle-on-Tyne, writes:—"I have to-day (the 9th inst.) received an intimation from the Awards Committee of the Royal Mining, Engineering, and Industrial Exhibition, held in Newcastle last year, that I have been awarded a silver medal for my bed of Conifers and hardy shrubs, and a bronze medal for fernery and cabinet combined."

— THE General Committee meeting of the NATIONAL CHRYSANTHEMUM SOCIETY was held at Anderton's Hotel on Thursday, the 5th inst., at 7 P.M., the President, E. Sanderson, Esq., in the chair. There was a large attendance of members, comprising Messrs. W. Holmes (Hon. Sec.), J. R. Starling (Treasurer), R. Ballantine (Vice-President), H. Cannell, G. Stevens, G. Gordon, L. Castle, R. Dean, R. Owen, C. Gibson, J. Kendall, &c. It was decided that the annual meeting should be held in Anderton's Hotel on Tuesday, January 31st, at 7 P.M., and that all the General Committee meetings in the present year be held in the same place. The Hon. Secretary announced that Messrs. Webb and Sons, Stourbridge, had offered their usual special prizes for the next November Show, Messrs. Deverill and Fidler also contributing prizes. Messrs. H. Cannell & Sons, Swanley, offer valuable prizes for their new varieties, and after considerable discussion it was decided that these classes should be judged in the ordinary way. A proposal that a meeting of the Floral Committee should be held on the occasion of the Midwinter Show, January 11th and 12th, at the Royal Aquarium, Westminster. Seventeen new members were then elected and two Fellows, the Winchester Society being affiliated. Mr. Holmes stated that the Lewisham Society owed a considerable sum for subscriptions, which they had been unable to pay, and he was directed to request the return of the medals.

— SIR HENRY THOMPSON, Hurstside, West Moulsey, exhibited specimens of A TUBER-BEARING STACHYS at South Kensington last December, but though they were submitted to the Fruit Committee of the Royal Horticultural Society, no opinion was expressed concerning their food value. This plant has been referred to under the name of *Stachys affinis*, but it has proved on further examination to be distinct from that species, and is now appropriately termed *S. tuberifera*. It is known in Japan and China, where it is cultivated, and it has also received some attention in France, and is known in the Paris market under the name of "Crosnes." The tubers are small, but produced very abundantly, and contain about 18 per cent. of starch to 74 of water, with a few other matters in small quantities. The tubers are somewhat conical in shape, formed of a succession of rings of a consistency similar to that of the Jerusalem Artichoke. It is said to be hardy, but whether it will be of much value as a vegetable can only be proved by experiments on a larger scale than have yet been attempted here.

— THE Annual General Meeting of the ROYAL METEOROLOGICAL SOCIETY will be held, by kind permission of the Council of the Institution of Civil Engineers, at 25, Great George Street, Westminster, on Wednesday, the 18th inst., at 8 P.M., when the Report of the Council will be read, the Election of Officers and Council for the ensuing year will take place, and the President (Mr. W. Ellis, F.R.A.S.) will deliver

his Address. The above Meeting will be preceded by an Ordinary Meeting, commencing at 7 P.M., at which the following paper will be read:—"The Non-Instrumental Meteorology of England, Wales, and Ireland, 1878-85," By G. M. Whipple, B.Sc., F.R.Met.Soc., F.R.A.S.

— WE do not know what the writer referred to will think of the following note from a leading gardener:—"Mr. Thinker' has had a long holiday. Cannot you persuade him to take up his pen and let your readers have a few more of his observations? I have always considered his notes to represent the essence of the Journal and of horticulture. Of all the paragraphs he has written there was only one with which I could not agree, and that not because I considered him to be wrong, but because I was not sure that I was right."

— "THE WEATHER IN THE NORTH," writes "B. D.," "has undergone a complete change during the past week. The frost gave way on the 3rd, since then we have had a good deal of rain and wind. This (9th) is a beautiful spring-like morning; temperature during night 45°. Snowdrops and Crocuses are well above ground."

NOTES ON TOMATOES.

SOME useful notes on Tomatoes were given by "A Kitchen Gardener" on page 566 (last vol.), and a few additional remarks may be interesting and instructing to some readers of the Journal. Like your correspondent, we have had a first-rate crop of Tomatoes last season. They were grown in a span-roofed pit between 40 and 50 feet long, and afforded a sight which I shall not easily forget. The crop referred to was gathered from plants grown in pots (12-inch) and trained to wires about 6 inches from the glass. I can fully endorse all "A Kitchen Gardener" says about growing them in a small quantity of soil. We fill the pots with about three parts of soil, then top-dress when the plants are in full bearing, and towards the end of the season assist them with liquid manure. We take three stems from our plants, and find them do as well and fruit as freely as plants with one stem, and in this way do not require so many plants to fill the house, and less time is occupied in watering in summer, and that is something we have to study in these times. This year I intend to try some of the newer varieties as well as three or four of the good old sorts, such as Vick's Criterion, Hathaway's Excelsior, &c. Our earliest variety will be Sutton's Earliest of All.—G. HILTON, *Smithills Hall*.

GLAZED FLOWER POTS.

I HAD long noticed that when the soil in a flower pot began to get dry it always cracked away from the pot, and that the only way then was to plunge the pot, as when watering as usual the water runs between the ball of earth and the pot and does not affect the soil. I tried flower pots glazed inside and out, and I found that this did not answer. I then tried painting a pot on the outside, and then I found a wrinkle. I now wanted pots glazed only on the outside, and how was I to get them? The manufacturers would not undertake to make a small quantity, but I got a brickmaker in the neighbourhood to make some and I found the glaze. These pots answered admirably.

Now I found another difficulty: the gardeners thought they would be looked upon as marked pots, and set their faces against them. If this prejudice he laid aside and a trial of the glazed pots made by the Cumnock Pottery Company, I am sure the result would be gratifying. It certainly is better than placing a pot inside a pot. The decrease of trouble is something gardeners ought to rejoice at. I have left pots that under ordinary circumstances would have required watering daily two and three days without ill effects. Caladiums in these pots simply grow to perfection. I have had Albert Edward with leaves 2 feet long by 18 inches broad. Coleuses colour to perfection in them also. In fact, most plants do better than in ordinary pots. I hope these remarks will lead others to try the plan. I daresay other potteries besides the one mentioned would supply the article desired. I have no interest in the above-mentioned pottery company or any other. I only mentioned them as they had supplied me.—DUM SPIRO SPERO.

EXHIBITING AND JUDGING BOUQUETS.

I HAVE been watching with interest the articles on this subject, and am of the same opinion as Mr. Garner. But referring to individual exhibitors will not serve any good purpose in this discussion. I wrote my first letter giving my ideas as a successful exhibitor of how bouquets should be made and judged, and as I then said I should like to see a dozen or more show in every class. How much more credit there would be for the winner than when just three or four, or at the outside six, show for a good prize. "Learner" seems bound to refer to table decoration, and my carelessness, though hundreds saw the table and were of very different opinion. I have been at several shows since then with success, and possibly I have met "Learner," and with all my carelessness secured the first prize. I am afraid "Learner" will not make a very popular judge if he withholds prizes whenever the table shown is too light for his taste. In regard to the expense, I have been over the list of prizes, and find that twenty-nine first prizes were taken within ten

miles of home, and in many instances with much more simple flowers than were used by other exhibitors, the prizes being double and treble the value of the flowers. The long distance shows I did not gain by, nor could I expect to when travelling 300 miles from home. The size of bouquets is the chief point to be considered. Let that be settled satisfactorily and exhibitors can show what flowers they can obtain. How often we all see good flowers spoiled by bad arrangement, crowded in bouquets and floral decorations. Let the size be the guide and all will be fair.—J. R. CHARD.

IN my letter last week there are two mistakes, partly my own. Instead of "one of my objects," read "my only object," and for "he took no showy Cattleyas" substitute "he took to showing Cattleyas in his bouquets."—A LEARNER.

ROSE NOTES.

No doubt many of your rosarian readers would, like myself, be glad to see that you had devoted a column specially to Roses, and I shall expect to see something of interest under its tasteful heading every week. Amateur Rose-growers are now very numerous, and there is so much connected with their agreeable hobby worth repeating, that we may hope and expect some of the veterans to assist us younger enthusiasts with hints and advice.

This very mild weather is not encouraging, and the buds of some of my Roses look ready to start, and this they will do quickly if the present temperature continues much longer. Then with the never-failing frosts we shall have some serious damage to buds and shoots. My Roses are not pruned yet beyond what may be termed a little "tidying up" in the way of shortening straggling branches, and they will be left as long as possible before the final cutting in is done to save the back buds.—M., *Surrey*.

ROSES IN WINTER.

I AM at a loss to know how the beautiful Tea Rose buds and blooms that are now somewhat plentiful in the market are produced. I have a good light greenhouse in which they ought to grow, but do not understand how to set about the work for inducing the plants to flower in the winter. I have some good sized ones in pots, but have gathered no buds since November, and scarcely expect to have any for two or three months. Will some gardener who really has Roses in the winter oblige by telling me how he manages his plants?—A SUBURBAN AMATEUR.

THE ROSARIANS' YEAR BOOK.

THE issue of this work for 1888 is just to hand, containing, as usual under the editorship of the Rev. H. Honeywood D'Ombra, much that is useful and interesting. The frontispiece is an excellent portrait of Mr. T. B. Hall, Larchwood, Rockferry, who has been a most successful exhibitor since 1879, having taken no less than "154 first prizes, seventy-six seconds, thirty-nine thirds, and three fourths; eleven gold, six silver, and three bronze medals; and, to crown all, the challenge trophy at Edinburgh." Following some particulars like the above is "A Symposium on Stocks," in five chapters, by Messrs. E. Mawley, D. Gilmour, jun., B. R. Cant, Rev. J. H. Pemberton, and John Burrell. "My Tea House" is contributed by Mr. T. Hall; "Decorative Roses," by Mr. T. W. Girdlestone; "The Rose and the National Rose Society in 1887," by the Editor; "Why I Came South," by Mr. Alexander H. Gray; a tabulated list of prizes won by amateur members of the National Rose Society in 1887, by Rev. F. R. Burnside; "Standard Roses," by Mr. George Paul; "Our Rose Cot at the Children's Hospital," by Mr. D. Gilmour, jun.; and Mr. Mawley's "Weather of the Past Rose Year." The subjects named will give an idea of the variety and interest of the "Year Book" for the present season, and with this note we must leave it now, though hoping to refer to it again in another issue. It is published by Bemrose & Sons, 23, Old Bailey, London, and Derby.

WILLIAM ALLEN RICHARDSON.

CAN this, to my mind the most charming of summer Roses, be made to flower freely under glass at this season of the year, or in early spring? What I mean is, is it suitable for growing under glass or for flowering only in the garden? Admiring some boxes of blooms at a flower show, I have ordered some plants, and do not want to spoil them. I have a span-roofed house, and could have one or two plants in pots, or perhaps plant them out; but is it worth while—that is, would there be a fair chance of success with careful watering, cleanliness, and ventilation?—A LADY GARDENER.

INTRODUCTION OF THE MOSS ROSE.

IN reply to a correspondent, Mr. E. Markham, this old favourite is said to have been introduced or raised in Holland probably at the close of the seventeenth century, for Dr. Martyn in his edition of Miller's "Gardeners' Dictionary" says it is in Furber's catalogue in 1724. We have seen a copy dated 1727; it is entitled "Catalogue of English and Foreign Trees

Collected, Increased, and Sold by Robert Furber at his Nursery over against the Park Gate at Kensington, near London." Faulkner in his "History of Fulham" says that Mr. Rench was the first to introduce the Moss Rose into this country, the original plant of which is supposed to have been brought from Holland. Rench lived at South Field Farm, near Parson's Green, a farm possessed by his family for two centuries. He was buried in Fulham churchyard, where there is this inscription to his memory on a headstone—"Under this stone are deposited the remains of Nathaniel Rench, late of this parish, gardener, who departed this life January 18th, 1783, aged 101 years." So he may have introduced the Rose before 1724, for in that year he was forty-two years old. The Moss Rose was first portrayed in the "Botanical Magazine," plate 69. It is described as the *Rosa muscosa*, or Moss Rose, and the plate is dated December, 1788. Mr. Curtis observes that, though Miller thought it a distinct species, Linnæus considered it only a variety of *Rosa centifolia*.

GRAPES SETTING AND STONING.

I HAVE read repeated contributions by your correspondent, Mr. Stephen Castle, on the above, and before making a note or two on his article on page 536 I would first say that no more amiable correspondent contributes to your pages than Mr. S. Castle. He was known to me over twenty years ago, and it is a pleasure to watch the footsteps of an old friend. I have not devoted such keen attention to Grapes for the last few years that I used to do, still I succeed fairly well. Making a practical observation on Muscat setting, I would say that one of the best sets, if not the best, I ever had was in a house where very little air was given when the Vines were in bloom. Indeed, I have been very chary about letting air or draught suddenly into the house when the Vines are in flower, no matter how mild the weather may be. Of course, when the sun comes out strongly it is impossible to do without ventilation. The application of this practice has a bearing upon the matter similar to Mr. Castle's reduction of front air throughout the season, which means "ventilate but keep out draughts." From the same Muscat Vines above referred to, from liberal or uncaredful ventilation, when the weather apparently invited it, I could have found you many a sample of bad setting, such as the shoulder only well set perhaps and all the rest of the bunch very ragged.

I am not particular about keeping my houses dry at flowering time; indeed I would rather see them moist, and syringe them in the afternoons to keep red spider in check. Syringing at that time once a day has never yet caused a failure, whereas by the lack of moisture I have seen many a case where red spider obtained a good footing and remained the rest of the season. The principle of having the ovary well set, using a practical term, holds good as a matter of course in all fruit culture. But many a good set is enfeebled afterwards, and may be so from various causes. For example, Muscats early in the year will not swell the same amount of fruit as later, and will act similar to Melons of different ages on the same plant. After a certain stage some will swell and some will not properly, though there is very little doubt about their being properly set. Again with Peaches I feel certain that after having had a perfect set the embryo fruits nearly all fell from unfavourable circumstances—namely, dry soil at the roots and cold draughts.

The circumstances that with me have produced the finest Black Hamburgs are as little forcing as possible considering the usual practice—so much so that I was in doubt often whether they were not too cold. Of course, this was during summer.—R. M.

IN answer to Mr. S. Castle's question whether the Grapes other than Alicante, and which set without much trouble, have more seeds than the Alicante, I am able to inform him they have, but are rather irregular. We are thinking of fertilising all the bunches this season. What I cannot understand is that such a free setter as the Alicante should give us so much trouble. At the late Birmingham Chrysanthemum Show no one could fail to notice the large berries of the Alicante exhibited by Mr. W. Taylor, whilst others seemed to me deficient in seeds. I mean those exhibited by other growers. Does Mr. S. Castle have the same difficulty with the Black Hamburgs if not artificially fertilised?—A. YOUNG.

ALLOW me to assure "Proprietor" and Mr. Stephen Castle that I readily grant the Vines at West Lynn are treated with more than average skill, and that I fully expect some day to find the produce from them rather too good for my comfort, for such indomitable pluck and enthusiasm as is possessed both by "Proprietor" and his energetic manager is sure to triumph in the end.

But enthusiasts are just the persons who make the greatest blunders. Perhaps I have made more in my time than any other grower. The less enthusiastic are more timid and are satisfied with an ordinary amount of success. What we call a failure might sometimes be classed as a success by persons of less ambition, and when I speak of Vines being starved at West Lynn it must be understood that I speak only in a comparative sense, and that were these same conditions found under a less able manager I should speak and write differently. But "Proprietor" and Mr. S. Castle do not want my flattery, they want to grow Grapes with which to meet myself and other successful growers on the exhibition boards with a fair chance of success. Therefore I shall endeavour to speak plainly.

With reference to my statement that the quantity of caustic lime used was sufficient to destroy everything in the shape of nitrogenous food, and which statement "Proprietor" more than questions, adding facts about lime becoming carbonised, which nobody disputes, I must point out that there are conditions to be taken into consideration in the vinery which do not occur in the laboratory or the corn field. In a well-fed Vine border the greater part of the best roots are very near the surface, and from these surface roots, owing to the action of atmospheric influences, assuming the horders to be inside, it is reasonable to suppose the plants draw their first supplies in the spring. Supposing, then, you apply caustic lime in large quantities, "washing it well in," will not this liberate most of the ammonia near the surface, some of it going off into the air and much of it down at least lower than the surface roots, and these being inactive at the time are helpless? "That such a dressing of lime is rendered perfectly innocuous within three months of application" is altogether wide of the mark, unless the application was made only in the autumn, and it must be remembered that Mr. Castle applies it in autumn, spring, and summer.

"Proprietor" cites the case of a garden within his knowledge on which the application of 14 lbs. of lime to the yard worked immediate and startling results. Quite so, but would a similar application, or

FIG 4.—PLUM WALL AT MANRESA HOUSE.

indeed any application of lime on the same garden in the following year have had a similar effect? Were the said garden in the hands of "Proprietor," he would have preferred farmyard manure for the second dressing. So, too, in the case quoted from "Vines at Longleat," an unusually heavy dressing of lime was given while the roots were active, but heavy feeding followed, and possibly the lime given then is not yet all exhausted.

"Proprietor" says, "I maintain, therefore, that the 14 lbs. of lime applied by Mr. S. Castle to the Vine borders in February had ceased to be able to exert much, if any, injurious effects on the food which was given to the Vines in May and June." Granted. But the Vines would flower in April, and the roots would only commence action somewhat earlier in the same month, after considerable top growth had been made. It is just at this time when the stored up material in the Vine itself is no longer sufficient for its wants that the question of setting, stoning, and consequently swelling is determined. Anything which interferes then, even for a single day, with the young tender rootlets taking up the needful supplies mars the chances of success. Many failures are caused at this time with too much or too little water, also with strong manure, and of course failure must also ensue if the nitrogen has all been driven off.

In such cases the vigour of the Vines is not decreased, it is often increased in the course of the summer owing to the fact that there are fewer seeds to perfect.—WM. TAYLOR.

I NOTICE a slight printer's error in my last article. I am made to say "the use of gypsum is perfectly safe in any safe quantity," which amounts to saying it is safe when it is safe. I said it is safe in any sane quantity, which is intelligible.—PROPRIETOR.

WIRE FENCES ON FRUIT WALLS.

In the Journal of August 18th, 1887, a description and illustration appeared of the famous Vine at Manresa House, Rochampton, and it was stated that on another occasion an innovation in growing wall fruits, that might be fairly called the Davisian method, would be referred to as simple, profitable, and economical. The engraving represents a wall 8 feet high, against which Victoria Plum trees were planted four years ago, and the soil being good the trees soon reached the top of the wall. Mr. Davis having practised what is known as the "extension" system of fruit culture for years before it was written about by younger men, did not even restrict the growths when they reached the top of the wall, but trained them in the simple manner represented. It was not, however, an experiment with him, for he had proved the value of the plan as applied to a Pear wall for some years, and which is now in evidence, or was very much so a few months ago, for there were more Pears on the fence on the top than on the side of the wall below.

The plan of increasing the crops from wall trees is simple in the extreme, and the cost trifling in comparison with the profit resulting. As will be seen, ordinary flat iron standards are affixed on the top of the walls and fencing wire stretched along from end to end. Some of the standards are made to grasp the wall, reaching down a foot or so, and there fastened to the masonry, and are about 12 feet apart. The Plum wall is heightened 5 feet, and last year the value of the crop on the trellis probably exceeded that on the 8 feet of wall below, and more than defrayed the cost of the extension, which will last for years.

Mr. Davis is emphatically an utilitarian, and in whatever he does and he does a great deal, he has an eye to profit, the surplus fruit from the garden being sold. On the day of my visit in August he had gathered 400 Peaches, and he had perhaps 200 Melons cut in the fruit room, his crop being 700 from two pits—the varieties Moreton Hall and Hero of Lockinge. His annual sale of fruit of various kinds is about 5 tons.

The Manresa Gardens, though not showy, are worthy of inspection in early August. When the Grapes on the Great Vine are nearly ripe the sight is one to be remembered, and alone worth a considerable journey; the wire-fenced walls and other good work will receive a passing glance; and the bright intelligence and genial character of Mr. Davis enhances the pleasure of a visit to those of kindred tastes with himself.—J. W.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 10TH.

THE Swanley Primulas constituted the principal attraction at this meeting, the Cyclamens from Teddington, the Rhododendrons from Chelsea, with several exhibits of Orchids from amateurs furnishing other interesting groups.

FRUIT COMMITTEE.—Present: Dr. Robert Hogg in the chair, and Messrs W. Marsball, C. Howe, C. Ross, A. H. Pearson, J. Wright, G. T. Miles, G. W. Cummins, J. Cheal, J. Woodbridge, H. J. Veitch, J. Roberts, P. Crowley, T. F. Rivers, John Lee, R. D. Blackmore, P. Barr, Harrison Weir, and G. Norman. A seedling Apple was sent by Messrs. W. Barron and Son, Borrowwas, Derby. It is a large, flattish, and rather angular fruit, bearing a general resemblance to Branley's Seedling; and as it is said by the exhibitors to keep firm till July the Committee expressed a desire to see it again later in the season, as its value will largely depend on its long keeping property. Mr. A. Dean, Bedford, sent two dishes of Apples for identification, and seemed a little amused subsequently that this could not be satisfactorily accomplished by such a body of "clever" men. They were able, however, to determine that the names attached—Royal Pearmain and Winter Pearmain—were incorrect. The fruit bearing the latter name seemed intermediate in character between Brabant Bellefleur and Striped Beefing, and it was thought to be a variety worth looking after, as its size, firmness, and good colour would be likely to commend it for the market. Messrs. Veitch, Rivers, and Pearson secured specimens for comparison with others in their collections. Fruits of Messrs. Pearson's Newton Wonder, for which a first-class certificate was awarded at the last meeting, were again placed on the table. They appeared to show the parentage of Blenheim Pippin and Damelow's Seedling; the variety therefore ought to prove worthy of its honour.

Mr. J. Roberts, Charleville Forest, Tullamore, sent two bunches of his seedling Grape, White Gros Colman. They were medium sized, and in shape resembling the typical form, the berries also being like it in shape, but small for Gros Colman; skin thin, flesh juicy, sweet, with a peculiar aroma. Many of the berries were much spotted and soft, and because of its apparent non-keeping properties no award was made for the variety.

Mr. T. Francis Rivers exhibited a dish of the Royal Medlar, also a sample of jelly made from the fruit. The fruit was much approved, and considered to excel the Nottingham Medlar, being larger, and at least equal in quality. It has been grown at Sawbridgeworth for many years. The jelly met with unanimous approval, being firm, rich, with a new and most agreeable flavour, and when known will probably be widely esteemed. Mr. Rivers thinks Medlar growing and jelly making will prove remunerative, as the trees can be grown in hedges, or, indeed, may form attractive and profitable fences. Some years ago he cut down a Thorn hedge, grafted Medlars on the shortened stems, and this hedge now bears abundant and profitable crops of fruit, costing nothing to grow. A first-class certificate was unanimously awarded.

Mr. E. Newton, Sussex House, Hitchin, sent a small dish of Tomatoes, apparently Laxton's open air variety, gathered from plants that fruited early in the season, and now grown "in a house glazed on his new system." It is right to add, however, that Tomato plants have borne continuously for two years long ago. A vote of thanks was awarded for the Tomatoes.

Messrs. Hurst and Son sent specimens of Hearting Kale that did not appear to possess any special merit calling for remark.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. W. Wilks, H. Bennett, H. Herbst, W. Bates, G. Nicholson, W. Goldring, R. Dean, J. Dominy, H. M. Pollett, C. Noble, H. Ballantine, B. Wynne, J. O'Brien, E. Hill, G. Duffield, and T. Baines.

Messrs. H. Cannell & Sons, Swanley, Kent, were awarded a silver-gilt Banksian medal for one of the best groups of Primulas they have ever staged, comprising 170 excellent plants, well grown, with abundant handsome flowers of some very fine varieties. These were as follows, commencing with the single forms:—Swanley Red, Improvement, and King of the Primulas, all distinct but remarkably rich shades of red, the last named of strong habit and bearing large trusses of flowers. The Queen White with a delicate blush tint, flowers of great size; Emperor, peculiar salmon red large flowers, foliage dark; White Perfection, fern leaf, pure white, massive flowers, dark foliage; Princess Beatrice, compact habit, rosy pink edged with white, very distinct; Swanley Giant, rich purplish crimson, very large and handsome; Cannell's White, pure white, a grand flower, compact habit and light foliage; Princess of Wales, very delicate pink, fringed flowers, light foliage, a charming variety; Swanley White, a well-formed flower, dark foliage, red leaf-stalks; Swanley Purple, an intensely rich crimson purple, dark foliage; Miss Cannell, an extremely large flower of excellent form, white or faintly tinged with pink, dark foliage. The double varieties were Miss Eva Fish (certificated), Marchioness of Exeter, full, white or blush fringed flowers, dark foliage, very free and handsome; Earl of Beaconsfield, rosy red, neat flowers and good truss, free dark foliage; Annie Hillier, delicate pale pink, the buds white; Alba plena and Alba plena fimbriata, both well-known varieties, and King of the Purples, fine purplish crimson, full. A silver-gilt medal was also awarded to Messrs. H. Page & Son, Grove Nursery, Twickenham, for a group of remarkably well-grown Cyclamens in 48-size pots, the colours varying from very dark red to the purest white.

Orchids were not very numerous, but they included several of a rather interesting character, four being honoured with certificates. As

a specimen the plant of *Cypripedium insigne* from A. S. Smith, Esq., Silvermere, Cobham, was the most notable, and the cultural commendation awarded was well deserved. The specimen was over 3 feet in diameter, in vigorous health, and bearing fifty-one large flowers. A. H. Smee, Esq., The Grange, Wallington, Surrey (gardener Mr. G. W. Cummins), sent a plant of *Odontoglossum Rossi Smeeana*, with white lip and petals and pale sepals, quite distinct from other varieties. *Epidendrum polybulbon* from the same garden is one of the diminutive Orchids, not exceeding 2 inches in height, the pseudo-bulbs small, with one or two leaves and a single flower each, the narrow sepals and petals brown tipped with yellow, the lip white. *Laelia anceps Proterocana*, a rich crimson variety, with the lip unusually dark. F. G. Tautz, Esq., Studley House, Hammersmith (gardener, Mr. J. C. Cowley), showed several hybrid *Cypripediums*, the best of which, *C. Tautzianum*, was certificated. *C. Marshallianum* was worthy of a similar award, it is a hybrid from *C. concolor* and *C. venustum*, showing much of the former in the shape of the flower, which is dotted with dark red on a light yellowish ground, the leaves are mottled with light and dark green. *C. concinnum* is one of the *Harrisianum* type, and *C. pleuroneuron* is a curious and rather pretty form, with deep red glossy petals, a pale yellowish lip and a rounded dorsal sepal heavily veined with dark green. R. J. Measures, Esq., Camberwell (gardener, Mr. Simpkins), exhibited a plant of the bold *Cypripedium Saltieri*, which has large yellowish flowers suggestive of both *C. insigne* and *C. villosum* in form, *C. apiculatum* and *C. regale* are both of the *Harrisianum* group, and *C. Fostermannii* is an introduction from Sylhet, where it is said to be found in a district subject to sharp frosts; it is of the *C. insigne* character with the lip and petals curiously mottled with yellow and brown (vote of thanks).

Messrs. J. Veitch & Sons, Chelsea, had a group of hybrid *Rhododendrons* chiefly from the new *R. Curtisi*, together with a collection of brilliantly tinted flowers of their general stock. The Orchids comprised a hybrid *Phalænopsis* (certificated) and *Cypripedium Galatea*, a hybrid of unknown parentage, but something of the *C. insigne* form. Messrs. Hugh Low & Co., Clapton, sent a plant of *Angræcum calligerum* with white flowers, the sepals and petals narrow, the lip of similar shape and size, furnished with a white spur 4 inches long.

CERTIFICATED PLANTS.

Oxera pulchella (Mr. F. Ross, Pendell Court Gardens, Bletchingley).—A handsome climbing plant of the natural order Verbenaceæ, and related to the *Clerodendrons*. It is a native of New Caledonia, where it was found during La Pérouse's voyage. A plant was flowered at Pendell Court in December, 1886, and figured in the "Botanical Magazine" June last year (t. 6938). It has flowered again most freely this year, as the specimen exhibited well indicated. The plant is a strong climber with smooth bright green elliptical opposite leaves, and the flowers are borne in dense pendulous axillary cymes. The corollas are white, broadly funnel-shaped, with two long stamens and a greenish white calyx of four sepals. It requires an intermediate temperature and a rich soil.

Primula sinensis Miss Eva Fish (H. Cannell & Sons).—A double variety with very full large flowers, lilac purple edged with white, a most distinct colour. The foliage is light green and the trusses large.

Cypripedium Tautzianum (F. G. Tautz, Esq.).—A hybrid which originated in the Veitchian collection from a cross between *C. niveum* and *C. barbatum*. It is an extremely promising novelty, the colour peculiarly rich and distinct. The flower is neat in form, the lip after the style of *C. niveum*, white on the under surface, and of a fine rosy crimson tint on the face. The petals are veined and spotted with deep crimson, the lower edge white, the dorsal sepal white veined with crimson.

Laelia anceps Schralera (Baron Sebröder).—A handsome variety with an intensely rich crimson lip, lighter in the throat and veined with gold, the sepals and petals suffused with a warm crimson hue.

Phalænopsis F. L. Ames (J. Veitch & Sons).—A hybrid between *P. amabilis* and *P. intermedia* Portei, with plain green foliage, the flowers white, with a tinge of red in the throat of the lip. Notable for its neat elegant outline, and interesting as an addition to the few hybrid *Phalænopses* yet raised.

Angræcum Sandermanum (Sanders & Co., St. Albans).—A graceful species of the small flowered section. The plant shown was growing on a small moss-covered raft 8 inches by 3, and had two racemes of about fifteen flowers each, the leaves oval and smooth. The flowers 1½ inch in diameter, pure white, with ovate petals and lip, the sepals narrow and acute, the pedicels creamy, the spurs long and straight.

Rhododendron Primrose (J. Veitch & Sons).—A single variety with large well-formed clear yellow bell-shaped flowers. A handsome addition to the greenhouse hybrids.

SCIENTIFIC COMMITTEE.—Present:—Mr. F. P. Pascoe, Vice-President, in the chair; Messrs. Boulger, Lynch, Smith, O'Brien, Michael, McLachlan, Ridley, Murray, Scott, Morris, Smee, Wilson, Drs. Masters, Lowe, Profs. Church, Ward, and Hon. Sec. Rev. G. Henslow.

Potato with Cavity.—Mr. McLachlan showed a Potato with a cavity which was caused by a predaceous beetle. The cavity was lined with cork cells.

Aluminum Plants.—Prof. Church alluded to experiments proving that aluminum was very prevalent in plants—e.g., gums and gluten, &c.

Coccus, new sp.—Mr. Morris exhibited a new species discovered on *Strobilanthes cuspidatus*, growing at Kew.

Clerodendron, n. sp.—He also exhibited a new species remarkable for its climbing hooked petioles.

Monstrous Pears.—Rev. G. Henslow exhibited several varieties, which together seemed to show that a Pear consists partly of swollen axis below the core, and partly of hypertrophied bases of sepals surrounding the core.

Aeidium on Silver Fir.—Mr. Plowright sent specimens and a communication on parasitic fungi on the Fir.

Plants Exhibited.—Mr. Lynch showed several interesting specimens from the Botanical Gardens, Cambridge.

Hybrid Rhododendrons.—Mr. Veitch forwarded five interesting hybrids of the Borneo type.

N.B.—A full report will appear in our next issue.

CHRYSANTHEMUM AMY FURZE.

UNFORTUNATELY there is frequently unpleasantness generated, and keen disappointment experienced, through the hasty and imperfect classifying of new varieties—or so-called new varieties—of Chrysanthemums. Amy Furze is an example of the evil of classifying a new variety before possessing adequate knowledge of its true characteristics, and the instance at Liverpool cited by "T. H.," on page 14, is an example of the annoyance that may be experienced by exhibitors of such doubtful varieties. I am not acquainted with the names of the other Judges who have been writing upon the above subject, and I assume "T. H." to be a disinterested person in regard to the exhibit passed over at Liverpool. I, therefore, feel free to reply to him, but I should think it a mistake for any judge or judges to enter into a controversy with a disappointed exhibitor.

The examples of Amy Furze at Liverpool showed their Japanese origin unmistakably, and inasmuch as it is undoubtedly a Japanese when in its true character—as shown at Liverpool—the judges officiating there had no hesitation in giving the prizes to those stands that contained the best examples and stipulated number of true reflexed flowers. It is quite possible the stand referred to by "T. H." was "the best in the Show," but if that stand contained a Japanese variety—and "T. H." says it contained an Amy Furze, and he says in his opinion Amy Furze is a Japanese variety—the Judges did right in withholding the prize from that stand, and "T. H." himself has given them his support in their action by his own arguments. If "T. H." asks why we did not disqualify that stand, I may reply that the matter was mentioned by one Judge to the other, and he replied, "Oh, it is not necessary, the Liverpool men are shrewd enough to see why it has been passed over."

No such blooms of Amy Furze have been seen in the south, and every-one competent of judging must have known that those at Liverpool were either Japanese or nothing. If compilers of catalogues make a mistake in classifying Chrysanthemums, that is no reason why exhibitors should make a mistake also, and judges follow their example; and if exhibitors would only follow the dictates of their own common sense instead of relying upon the infallibility of the compilers, who, in most cases, are quite as fallible as themselves, they would not so easily make the mistakes they afterwards so bitterly regret.—A LIVERPOOL JUDGE.

CHALLENGE TROPHIES.

MR. BARDNEY in his article on this subject (see page 522) refers to Liverpool as one of the shows at which challenge vases used to be competed for. Will Mr. Bardney kindly explain the date or dates on which these competitions took place? If he can succeed in this, he certainly has the advantage in memory of.—A LIVERPUDIEN.

A GOLDEN MRS. HEALE.

CAN anyone inform me whether this valuable acquisition is yet in commerce, and if so where it can be obtained? That such a sport is in existence I have good authority for stating. I also hear it was certificated at Bath, although it originated, I believe, in Yorkshire. Surely a yellow sport from the beautiful Mrs. Heale is too precious to be lost sight of.—AN EXHIBITOR.

PLANT NAMES.

[A paper read at a meeting of the "Chiswick Gardeners' Mutual Improvement Association," on December 21st, 1887. By E. W. Burbridge, F.L.S., M.R.L.A., Curator Trin. Col. Botanical Gardens, Dublin; formerly of the R.H.S. Gardens, Chiswick; and also of the Royal Gardens, Kew.]

(Continued from page 16.)

OF course, I know that "English names" when misapplied cause great inconvenience, or, as an American humourist once said, "Whenever you see the nurserymen advertising 'Bachelor's Buttons' keep right on sending your money, for no two men's 'Bachelor's Buttons' are alike, so that you are sure of a different plant every time." But this simply comes from a loose application of proper names, and even Latin and Greek nomenclature, and their synonymy when likewise misused result in precisely the same confusion and inconvenience.

The pomologists also have been somewhat afflicted by constantly recurring synonyms. Thus we find Mr. A. J. Downing, in his "Fruit and Fruit Trees of America" (second edition, 1869), writing as follows: "Towards settling this chaos in (fruit) nomenclature the exertions of the Horticultural Society of London have been steadily directed for the last twenty years. That greatest of experimental gardens contains, or has contained, nearly all the varieties of fruit from all (temperate) parts of the world possessing the least celebrity. The vast confusion of names, dozens sometimes meaning the same variety, has been, by careful comparison, reduced to something like order. The relative merits of the kinds have been proved and published. In short, the horticultural world owes this society a heavy debt of gratitude for these labours, and to the science and accuracy of Mr. Robert Thompson, the (then) head of its fruit department, horticulturists here will gladly join me in adding the fullest testimony."

But, as I have said, scientific nomenclature now labours under a heavy income-taxation of synonyms also, and there is an ill-directed tendency to add tertial varietal names in Latin, which should at once be disclaimed. For example, if you write to a nurseryman to-day for a dozen *Odontoglossum Alexandræ*, or *Cattleya Trianae*, or even seeds of *Helianthus annuus*, you will get them, but no two plants resulting will be quite the same; some varieties will be worthless, others more or less beautiful, but as in the case of "Bachelor's Buttons," no two plants will be alike. Of course, very few cultivated Orchids of note nowadays have less than three names, and if you order *Odontoglossum Pescatorei*, "Veitch's variety," or *Cattleya Trianae*, "Dodgson's variety," then you may be sure of what you are getting; and, believe me, you will open your eyes when the invoice advises you of the price you will have to pay.

The question of botanical and of popular names then stands thus. The botanist says and writes *Viola odorata*, and we claim a right to speak of the same plant as the "Sweet Violet." *Bellis perennis* is our "Daisy," or "Day's Eye," so called from the time of Chaucer, say nearly five hundred years ago. *Galanthus nivalis* is the Snow Flower of Evelyn (born 1620, died 1706), and the Snowdrop of every English child to-day, and the *Orchis mascula* of the Warwickshire meadows are no doubt the "Long Purples" of Shakespeare. Speaking of Orchids reminds me that their names are ridiculously confusing, but for the future much trouble will be saved by referring for the genera to the "Genera Plantarum," and for the species Veitch's work now in progress is by far the clearest and best hitherto attempted, and when complete will be that used by all amateurs and gardeners.

I, of course, acknowledge that as at present used loosely, and as registered more or less badly in all dictionaries—the two best ones not always agreeing with each other—there are many popular plant names that do lead to confusion. For example, if I wrote to a nurseryman for plants of (1) the "Crape Myrtle," (2) the "Hedge Lily," (3) the "Tiger Iris," (4) the "Foam Flower," (5) the "Sweet Nancy," or (6) the "Fire Bush," I should not be quite sure of obtaining them simply because there is no full and general registry of such and similar names to which a nurseryman may refer to see what plants I really mean. But if I wrote for (1) *Lagerstrœmia indica*, (2) *Convolvulus sepium*, (3) *Tigridia pavonia*, (4) *Tiarella cordifolia*, (5) *Narcissus biflorus*, or (6) *Embothrium coccineum*, I am certain of getting exactly what I desire. This points to the fact that at present botanical names—bad and misleading as some of them are generally acknowledged to be—are nevertheless much better arranged and registered and indexed in books than are the pretty popular names we plead for and admire. Hence it follows that before the dual system of naming I recommend can become a practical reality we must have a second Linnaeus, or staunch co-workers like Hooker and Bentham, who will devote time and labour to the drawing up of a complete dictionary of popular names. I see no legitimate reason why we should not originate and organise an "English plant name society," and work out our object under its auspices and regulations. Until this work is done we can never trust to popular names alone; but, as I said before, we must for the time being have Latin or Greek names first, for expediency, and employ popular names so far as we can afterwards, to avoid the pedantic jargon caused by interlarding our ordinary English conversation with long names not altogether "understood of the people." Of course it is now fully understood that Latin names are to be restricted to wild genera and species, and all mere varieties and garden forms are to be distinguished by English names only, as agreed to generally at the "Narcissus Conference" held on April 1st, 1884.

In conclusion, I shall ask you once more to remember that plants and most other natural objects or crops in the garden are after all more important than their names, and I am sure I need not remind you of the poet's dictum that "names make haste to follow things." It does not so very much matter whether you call a Grape "Black Hamburg" or "Frankenthaler," but it *does* matter to you as gardeners whether your Grapes are well grown and give pleasure to your employer and to yourself! If your Orchids are unhealthy, and your stove plants disfigured by red spider or thrips, it will not be much to your credit, or to your employer's satisfaction, to know their names and natural orders. Or if your employer happens to be of a practical turn of mind, your love of botany and its nomenclature will be of but slight help, especially if her majesty the cook has told him what he already knows too well—viz., that your Celery is green and stringy, your Potatoes wet and soapy, and your Asparagus or Peas smaller in size and worse in flavour than those he gets with his friends or at his club.

Foreign competition and the quality and cheapness of imported

fruits, vegetables, and even fresh flowers, all bear heavily on the gardening of to-day. You may be called upon to grow for the market as well as for the household supply, and all science, physiology, or nomenclature are nothing unless they make of you better practical men, and this they will assuredly do if you study them diligently and rightly. Above all, I beg of you never to use a word of Latin, or of any other language, if good plain Saxon will serve as well.

Believe me I do not wish you to study names of any kind until you become mere verbal aerobats, proud only of your own or of other's word-jugglery, but I do hope that you may win for yourselves, as British gardeners, the golden spurs of all those "good men and true" who have gone before you.

NATIONAL CHRYSANTHEMUM SOCIETY.

JANUARY 11TH AND 12TH.

THE midwinter Show of this Society was held in the Royal Aquarium, Westminster, on Wednesday and Thursday, and proved exceedingly successful, the exhibits both in quality and quantity far surpassing those at the late shows in previous years. The competition was keen with Chrysanthemums, as many as seven large collections being entered in the first class; there were also six stands of twenty-four blooms, seven of twelve blooms, six of twenty-four Japanese, seven of twelve Japanese, and ten of six Japanese. There were besides several bouquets and miscellaneous entries like the stands of Golden Gem in competition for Mr. W. Owen's prizes, and a stand of the Governor of Guernsey from Mr. T. S. Ware, an excellent soft yellow late flowered variety. In some of the stands there were really fine blooms, amongst the Japanese especially, the incurved being generally rather small, and in some cases quite out of character where such varieties as Empress of India were shown. Mr. R. Falconer Jameson of Hull had, however, two unusually good blooms of John Salter in his stand of twenty-four blooms, and a few other fair specimens were scattered about. One of the most notable Japanese varieties was D. B. Chapman, of a peculiarly rich purplish crimson colour, with very narrow much curled florets.

Mr. Joseph Lowe, Uxbridge, was awarded first honours for a collection of blooms, and staged eight boxes comprising over 200 blooms. The best were Thunberg, Grandiflorum, Princess Teek, Virginale (Anemone) Elaine, Lowe's Bronze, bronze red, Ethel, and Sarnia. Mr. G. Bolas, gardener to H. Chandos Pole Gell, Esq., Hopton Hall, Wirksworth, was second with six stands of blooms, mostly small, but fresh, and Fleur de Marie, Belle Paule, Cœur Fidèle, and Madame C. Audiguier were the best. R. F. Jameson, Esq., Hesse Hall, was third with fresh blooms.

With twenty-four blooms Mr. Jameson won first honours, showing fresh and good blooms of John Salter already noted, Fleur de Marie, White Christine, Louis Bonamy, Miss Marguerite, Pink Christine, and Lord Aleester. The second prize was awarded to Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, for a neat collection, and Mr. W. Walters, Sunnybank, Burton-on-Trent, was third.

With twelve Japanese blooms Mr. J. Kipling, gardener to Earl Lytton, Knebworth, was first with a very bright stand, Etoile du Midi, Boule d'Or, Golden Gem, Le Centaure, Cry Kang, Thunberg, and Belle Paule being the best. Mr. H. Lister, gardener to Lord Brooke, The Gardens, Easton Lodge, Dunmow, Essex, was second, showing Fanny Boucharlat, Thunberg, Mdle. Moulise, and Fair Maid of Guernsey, very good. Mr. R. Debenham, St. Peter's, St. Alban's, was third.

Mr. Sullivan secured first honours for twenty-four Japanese blooms, a beautifully fresh collection, including four blooms of the distinct D. B. Chapman, already noted, with good examples of Ceres and Gloriosum. Mr. J. Horsfield, Heytesbury, was second with large blooms of Gloriosum, but the others were rather irregular. Mr. R. Jameson was third. For twelve Japanese Mr. F. Kipling was first; and for six blooms Messrs. W. & G. Drover, Fareham, easily won premier honours with grand blooms of W. G. Drover, Gloriosum, Bicolor, and Mrs. W. Meuke. Mr. Brown, Richmond, was first for a tasteful bouquet.

The Primulas from Swanley and Reading formed an exhibition in themselves, the former being the same as those at South Kensington on the previous day, and are fully noted in the report of that meeting. At the Aquarium they were awarded the prize in the open class for a collection. Messrs. Sutton & Sons had, as usual, a grand group of plants in numerous varieties, representing their well-proved strains, together with a large collection of Cyclamens of great merit. In the miscellaneous classes for Cyclamens, Primulas, and forced plants there was also a capital display, which added greatly to the beauty of the show. A grand group of forced plants from Messrs. H. W. Williams & Son, Fortis Green, Finchley, gained the first prize, Primulas, Tulips, Hyacinths, Azaleas, Solanums, &c., being shown with Ferns and other foliage plants. The same firm was first with thirty-six Tulips. Messrs. Page & Son, Twickenham, had a fine collection of Cyclamens, Mr. May of Twickenham being first in Class 10, followed by Mr. R. Clarke, Twickenham. For twelve Cyclamens Mr. H. Carter, gardener to Alderman Evans, Ewell Grove, Ewell; Mr. W. Kemp, gardener to H. Barry, Esq., Bushill House, Winchmore Hill, and Mr. P. Cornish, gardener to J. Downing, Esq., The Shrubbery, Enfield, was third, all showing healthy well-flowered plants. With a collection of Primulas, Mr. G. Braid, Winchmore Hill, was second to Messrs. Cannell & Son, Swanley, with good samples.

In the amateurs' class for twelve Primulas Mr. A. Carter was first with excellent plants of double varieties. Mr. A. Newell, gardener to Sir E. Saunders, Fairlawn, Wimbledon Common, was second, and Mr. A. Ives, gardener to J. C. Jukes, Esq., Hope House, Winchmore Hill, was third. Well-berried Solanums were shown by Messrs. P. Cornish, W.

Kemp, and H. Williams & Son, who gained the chief prizes, the plants being arranged in the centre of a long table between the rows of Chrysanthemum stands. Horticultural sundries and artificial manures were exhibited by Mr. H. G. Smyth, 21, Goldsmith Street, Drury Lane, Mr. B. Field, and Mr. W. Colechester. Mr. W. Holmes, Hackney, contributed a group of foliage plants, chiefly Palms.

Messrs. Sutton & Sons' group comprised 420 plants of Primulas and Cyclamens, and several varieties were certificated, as noted under the Floral Committee. A silver-gilt medal was awarded for the collection.

FLORAL COMMITTEE.—Present: Messrs. E. Sanderson, R. Ballantine, W. Holmes, R. Dean, G. Gordon, L. Castle, C. Gibson, G. Stevens, R. Owen, &c. The Chrysanthemum novelties were not numerous, but first-class certificates were awarded for the following:—W. G. Drover (Messrs. W. & G. Drover), a large Japanese that has been shown several times before and found too coarse, but it was in much better condition this time; and Governor of Guernsey (T. S. Ware), a decorative variety with pale yellow flowers, very free, and naturally late. A primrose sport from Meg Merrilies, shown by Mr. Kipling, was approved by some, but it was desired to be sent again.

The other certificates were awarded for Cyclamens and Primulas—namely, Cyclamen May Queen (May), a variety with large flowers, and hard rounded petals, white, crimson at the base; Cyclamen Queen of Dwarfs (Sutton & Sons), white, free, and dwarf; Cyclamen White Butterfly (Sutton & Sons), of spreading habit, but dwarf, very free and graceful; Primula sinensis Giant Red (Sutton & Sons), very large single variety, with finely formed flowers and light eye; Primula Picotee Edge (Sutton & Sons), neat single white flower, edged pink, very pretty and distinct; Primula Miss Cannell (Cannell & Sons) a large single flower, massive, white and blush tinted, very handsome; and Miss Eva Fish, certificated on the previous day at South Kensington. Sutton's Fern Leaf Scarlet Primula was commended.

FRUIT FORCING.

VINES.—*Early Houses.*—These will now require great care in ventilating, so as not to admit draughts of cold air, which injure the foliage. Disbud and tie the shoots down before they touch the glass. In stopping do not confine to any given number of joints beyond the bunch, but extend it so that an ample and even supply of foliage will be insured, but do not crowd the house with more foliage than can be fully exposed to light. Remove all superfluous bunches, overcropping and overcrowding of the foliage being most adverse to satisfactory results. When the flowers are open maintain a temperature night and day of 70° to 75°, and a rather drier atmosphere, not allowing the fermenting materials to decline at this critical stage, but preserve a good heap of Oak leaves and stable litter in the reserve ground to admit of a supply being obtained as required.

Early-forced Vines in Pots.—As soon as the fruit is set attention should be given to thinning, commencing as soon as the berries are fairly swelling, watering copiously with liquid manure, keeping the evaporation troughs charged with liquid manure and damping available surfaces with the same in the afternoon. Encourage growth above the fruit, yet only as much as can have exposure to light. The soil should be surface-dressed with short manure, and when roots are emitted freely from the "collar" some turves may be placed around the rims extending a couple of inches over the inside of the pots and over them, so as to lie on the fermenting bed of leaves. The temperature should range from 65° to 70° at night, 70° to 75° by day, and 80° to 85° from sun heat, admitting air from 75°, and closing early, so as to raise it to 85° or 90° with sun heat, damping available surfaces at closing time, or early in the afternoon. Syringing the foliage ought not to be practised, as there is always danger of the water leaving a deposit on the berries, which spoils the appearance of otherwise well grown and finished fruit.

Houses Started at the New Year.—The Vines ought to have the inside border thoroughly moistened by repeated waterings or liquid manure at a temperature of 90°. It is more conducive to a speedy and good break than anything short of the employment of fermenting material, which not only affords warmth but gives ammonia-charged vapour highly conducive to rapid vegetation. The outside borders should have a good supply of fermenting material, and if this may not be done owing to the scarcity of material, afford a good supply of dry litter or fern so as to modify in some measure the chilling tendency of cold rains or snow. Sprinkle the Vines frequently, maintain a temperature of 50° to 55° at night, 60° to 65° by day, ventilating freely above 65°. The rods and canes of young Vines should be slung in a horizontal position to secure a regular break.

Houses of Thick-skinned Grapes.—These may now be removed to a dry room, where they will keep quite as well as if left on the Vines, but the bunches with as much wood attached as can be spared, and place the stems in bottles filled with soft water, each containing a few pieces of charcoal. The bottles should be fixed in an inclined position so as to admit of the bunches hanging clear of the sides, and they may

be as far apart as not to allow the bunches to touch each other. Keep the temperature of the room at about 45°, examining the bunches occasionally for decayed berries, which should be carefully removed. The Vines should then be pruned, dressing the cuts with Thomson's styptic or patent knotting, and the house thoroughly cleansed. Air should be admitted freely in favourable weather, seeking to give the Vines as long and complete a rest as possible. Where the borders are not satisfactory lift the roots and relay them in fresh compost, and where the Vines have inside and outside borders the renovation may be accomplished without loss of crop by renewing the former one year and the latter the next.

FIGS.—Early-forced Trees in Pots.—The growth being now somewhat advanced the temperature should be increased to 60° at night and 65° by day by artificial means, and 70° to 75° with sun heat, commencing to ventilate at 70°, closing at 75°, and if the temperature rise 5° to 10° it will be an advantage provided it is due to sun heat. Avoid a high temperature by artificial means, as the sturdier and shorter jointed the young shoots can be kept the greater will be the chances of a satisfactory early crop. The trees and house will need to be syringed twice a day, in the morning and again at closing, but avoid a confined saturated atmosphere in dull weather. As the fermenting materials settle firmly about the pots add more fresh leaves, bringing them nearer to the rims of the pots, taking care that the heat about them does not exceed 70° to 75°. Water the trees as required with weak liquid manure, and place some turves about 2 inches thick, grass side downwards, as already advised. These should be watered with weak liquid manure so as to keep them moist, filling the space between the turves and stems of the trees with decayed manure.

Fig Trees to Ripen Fruit in May.—The house containing planted-out trees would be started at the new year, or there should be no further delay. The border being thoroughly watered, repeating so as to insure its thorough moistening, after which the surface may be mulched with short manure about 2 inches thick, placing it rather thicker near the stem so as to encourage the roots to extend. The surfaces of the house and trees will require an occasional syringing, the night temperature being 50°, and 55° from fire heat by day, and from 60° to 65° with sun heat, ventilating freely from that temperature. The mulching should be kept well moistened.

PLANT HOUSES.

Lapagerias.—Most insects that infest plants will attack these useful greenhouse climbers, and if mealy bug establishes itself upon them it is the most difficult of all to eradicate. To do this is not the work of a solitary season, for *Lapagerias* are the most difficult of all plants to clean. Mealy bug in a small state gets behind the buds on the main stems, which are generally protected with a sheath of dead matter. The plants must be taken down and this removed, and the bug dislodged by the aid of a brush over a tank containing a strong solution of Fir tree oil, lemon oil, or some other equally useful insecticide. After they have been dressed with a brush they should be thoroughly dipped. After they have been trained on the roof, or even before, they should be syringed with petroleum and water, one ounce of the former to a gallon of the latter. This may be practised at intervals of a month, by which means, in time, they will all be destroyed. Where insects do not exist the main work will consist in the regulation of the shoots under the roof where they are grown. Although these are shade-loving plants their shoots should not be crowded thickly together to prevent ripening, or they will not flower satisfactorily. If the border in which they are growing is full of roots top-dress them with decayed manure or give them a good dressing of artificial manure on the surface. Manure is seldom applied to these plants, but after the borders become full of roots they are greatly benefited by such applications.

Passifloras and Tacsonias.—These should be liberally thinned and pruned back at the present time. If too much wood is left in them they become crowded before the close of the growing season. If treated judiciously during the resting period, thinning during the season of growth will not be needed except in solitary cases. After severely pruning them, the house in which they are growing may present a rather bare appearance, but this can be remedied by training a number of the growing shoots to the pillars and wires supporting them until after growth has commenced. If infested with insects strong solutions may be safely used after they are pruned, and this is the only chance of cleaning thoroughly plants of this nature. They cannot be done with any degree of satisfaction during the season of growth without destroying the picturesque appearance they should add to the structure in which they are grown. Top-dress the borders if needed with manure and loam in equal proportions.

Tecomas.—These are not such rapid-growing plants as the preceding, and therefore do not give such labour in keeping them within bounds. All that is needed is slight thinning to prevent overcrowding and the regulation of their shoots. Clean the plants if they need it, and top-dress the border in which they are growing.

Clematis indivisa lobata.—Where the shoots crowd one another weak unripened ones should be removed. Pruning should be deferred until the plant has flowered. Aphides and scale are the worst enemies this plant has to contend against. The former is readily destroyed by slight fumigations, and the latter with the petroleum solution advised for *Lapagerias*. Top-dress the border if it needs it, but be careful not to give too much water at this season of the year. Where deciduous *Clematises* are grown indoors prune closely those that flower on young wood, while those that flower from ripened wood should merely have weak ends removed and growths that are likely to crowd the plants.

THE BEE-KEEPER.

PRACTICAL BEE-KEEPING.—No. 27.

A STOCK of bees when in a normal condition will at once destroy a stranger queen; a stock deprived of its queen either by death or the interference of the bee-keeper will show an equal antipathy and dislike to a substituted mother unless special measures are taken to overcome their prejudice. Bees, it is well known, are endowed with a wondrous instinct, and the fact that they should be so utterly unable to comprehend the value of a queen entering the hive after the death or removal of their former sovereign is an emphatic proof of the essential difference between instinct and reason; a queen entering the hive by chance might not unfrequently be the means, and the only means, of saving the stock from destruction, and yet the bees themselves at once destroy her. At certain periods, therefore, when the bees are—either owing to the time of the year when the old queen dies or owing to her sterility for some days before actual death—unable to raise a successor, the death of the queen will, unless the bee-keeper holds out a helping hand, entail the total destruction of the colony. Yet on the other hand instances have been adduced in which stocks, deprived of their queen by her death at a time when there were no eggs in the hive and no larvæ young enough to be used for queen-raising purposes, have made most extraordinary efforts to obtain a successor, and in one case it is asserted that the bees of a queenless stock stole worker eggs from another colony. This, however, is by the way. Enough has been written to show the bee-keeper that when introducing queens he is under the necessity of combating by some means this spirit of hatred to a change of dynasty if he desires to effect his purpose with certainty and without incurring needless risk.

The introduction of queens to stocks which have thrown off swarms, and giving royal cells to stocks, have been already discussed, and it is not to them that we now refer. The general principle upon which the bee-keeper works when introducing queens by means of any of the various kinds of cages available for the purpose is that the queen being thus confined for a certain period in the hive, and yet out of reach of the bees, she gradually loses her peculiar scent and gains confidence, while the bees also become accustomed to her presence and fondle her with their antennæ, thus becoming by degrees friendly, and in the course of some forty-eight hours in the majority of cases willing to receive and welcome her as reigning queen. One of the oldest and most useful cages for the purpose is the ordinary pipe cover cage, which is fastened on to a comb by simply pressing its sides or edges into the cells until the midrib is reached, or at any rate until it is firmly fixed and does not prevent the combs from being brought into their ordinary position. The old queen must in any case be first removed, and all royal cells should be carefully excised; the new queen then being caged on one of the central combs containing a little honey, upon which she may feed when necessary. In thirty hours afterwards the cage may be removed, and unless the bees show signs of attacking her the hive may be closed and the success of the operation is practically assumed. If, however, signs of anger are manifested a confinement lasting about half of the former period will probably induce the most angry stock to lay aside all feelings of anger and distrust, and the desire of the bee-keeper will thus be accomplished.

The other cages are used in a somewhat similar manner, but are in some respects superior. These cages allow the queen to be removed without disturbing or removing any of the combs. The cage, being inserted between two centre combs, is kept in position there until the time—from twenty-four to thirty hours—arises when the queen is to be let loose from her confinement. This is done by merely pressing a wire or flange, as the case may be, which opens a

small door at the bottom of the cage, and allows the queen to enter the hive without further disturbance. Of this description of cage the "Raynor" is perhaps as useful as any. The method of using cages of this description is to first imprison in the selected cage for a period of twelve hours, the queen removed from the stock, then take her away with as little disturbance as possible, by allowing her to come out through the door at the top of the cage—using a little smoke if necessary—next placing the queen, which it is desired to substitute for her, in the cage in her stead, and leaving the stock quiet for another twenty-four hours, when by pressing the wire at the top of the cage the bottom door is opened and the queen descends into the hive, and is generally received and allowed to reign in peace. In every case it is decidedly advantageous to feed gently any stock which is being requeened, taking care that the queen is able to get free access either to the feed-bottle or to the honey in the cells to which her cage is fixed or adjoins.

Mr. Cheshire, however, prefers the "Alley" cage to the "Raynor," and states as his reason one which bears the imprint of sound common sense, and that is that in the "Raynor" cage "the queen has, if surrounded by angry bees, no spot where she can for a moment remain without attempted attack, and although the wire cloth is fine—about fifteen meshes to the inch—no sooner is the foot set down than one of the mob is struggling to seize it, necessitating perpetual movement. Feeding is impossible under the circumstances, to which he attributes his not infrequent losses when he gave the 'Raynor' cage a fair trial now many years ago. With the 'Alley' cage, however excited and unfriendly the stock, the queen on any part of the circumference of the hole is beyond the touch of her enemies, so that she can rest and sip at her candy if she will."

Having no personal experience in the use of the "Alley" cage, it may be as well to follow the example of Mr. Cheshire in his excellent work, and give Mr. Alley's own description of it, which in "Bees and Bee-keeping" is as follows:—"Take a block of wood 3 inches long, 2 inches wide, and half an inch thick, and bore through it a 1¼-inch hole, half-inch from one end. Then cut the slot or mortise from the hole to the end of the cage or block, being careful not to cut out more than enough to allow the bees to pass through after the wire cloth is fastened on. Now cover both sides with fine cloth, cut the tin rest 1½ inch long and three-quarter inch wide, and fasten it to one end of the cage by driving a nail through the centre of it and into the block, which it will hold between the frames."

Sufficient has now been said to explain the methods of introduction by eaging. There are, of course, many more kinds of cages, each one differing in some respects from the other, but the "Pipe Cover," "Raynor," and "Alley" cages are fairly representative of their different classes, and are most generally in use. Occasionally it is necessary to cage a queen, and especially a virgin, for twelve, and occasionally for twenty-four or even thirty-six hours longer than under ordinary circumstances. If a great uproar is noticed at the entrance to a stock soon after a queen has been released, there is more than ground for suspicion that the queen is enfeebled and in danger of being killed by the too close, yet not loving embraces, of her rebellious people. The stock should then at once be examined, and the queen re-caged for another period. The time is fast approaching, and for all practical purposes has already come, only bee-keepers are at present rather too conservative in their ideas to adopt it and to realise its full value; when bees may successfully be induced to accept a queen introduced by the "Direct Introduction" method; a plan which has the advantage of simplicity, and will in a very short time effect a revolution in the methods of introduction at present practised. In the next paper this method shall be discussed, together with certain means other than caging which are occasionally adopted when circumstances happen to be favourable for their use. I must, however, decline to be dragged into the controversy which has lately been carried on respecting the author of this new method;

but must ask those readers who think that the credit lies with a certain individual, and also those who think that another person should have the praise, to leave for the moment such vexed questions, and only endeavour, without apportioning praise or blame to either side, to grasp the main principles upon which it is necessary to work if success is to attend their efforts.—FELIX.

TRADE CATALOGUES RECEIVED.

- E. J. Jarman, Charl, Som rsetshire.—*Catalogue of Choice New Seeds for the Kitchen and Flower Garden.*
 Wm. Paul & Son, Waltham Cross, Herts.—*Catalogues of Seeds and Garden Sundries.*
 T. S. Ware, Hale Farm Nurseries, Tottenham.—*Catalogue of New, Rare, and Choice Flower Seeds, Gladioli, Begonias, Gloxinias, &c.*
 Little & Ballantyne, Carlisle.—*Seed List, 1888.*
 Barr & Son, 12 and 13, King Street, Covent Garden, London.—*Descriptive Spring Catalogue of Choice Seeds for Flower and Kitchen Garden, 1888.*
 Arthur Robinson, 8, Leadenhall Street, London, E.C.—*Illustrated Seed Catalogue, 1888.*
 J. R. Pearson & Sons, 2, Exchange Row, Nottingham.—*Descriptive List of Garden Seeds, 1888.*
 Dobbie & Co, Rothesay, N.B.—*Catalogue of Seeds and Plants, 1888.*
 Benjamin Soddy, 243, Walworth Road, London, S.E.—*Spring Catalogue for 1888.*

 Kent & Brydon, Darlington.—*General Seed Catalogue.*

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Gas Tar in Plant Houses (*Forbes*).—It is injurious to plants whether applied to hot-water pipes, walls, or stages, and you had better not be tempted to try the experiment.

Cement for Pipe Sockets (*S. Oates*).—We have seen pipes jointed with cement with the most satisfactory results. They were fixed twenty years ago, and there has not been a leak nor a crack in one of the joints. Hempen yarn was first placed firmly in, following with cement, but not filling quite flush with the outside.

Rival Chrysanthemum Shows (*A. L. II.*).—Our space this week was filled to overflowing when your letter arrived, and as negotiations may possibly be in progress during the week its insertion in a subsequent issue might be untimely. We trust a decision satisfactory to all parties may be arrived at without further public discussion.

Heating Glass Structures (*Cambridge*).—If you send a plan drawn to scale of the house to be heated, showing also the position of the existing boiler, stating its character, size, and length of pipes attached, indicating also the configuration of the ground between the two houses, we think we shall be able to afford you reliable information. No charge is made for answering questions in this column on any subjects on which information is desired.

Chrysanthemums for Decoration (*II. II. C.*).—The following are suitable for greenhouse decoration, and with good culture make fine specimen plants, bearing good sized blooms when one only is allowed on each stem:—Incurved—Mrs. G. Rundle, Mrs. Dixon, Mr. G. Glenny,

and Lady Hardinge. Japanese—Madame Lacroix, Madame Bertie Rendatler, La Nympe, and Source d'Or. Reflexed—Dr. Sharpe, Chevalier Domage, Mrs. Forsyth, and King of Crimson. Plants are grown with from twenty to 100 stems and blooms, according to the skill displayed in their culture. Mr. E. Beckett gives the requisite details in a paper, which will appear in the Journal. He is a very able cultivator of Chrysanthemums.

Rhododendrons (E. G. O.).—The dictum that "Rhododendrons will not grow without peat" is the reverse of well founded. We have seen peat carted long distances for these shrubs, and it was afterwards found that some planted in the ordinary soil of the shrubbery borders grew better than those in the peat beds. They will grow in loam that does not contain much lime, and if the subsoil is not dry; but peat, leaf mould, cocoa-nut fibre refuse, and even sawdust, are all good for incorporating with heavy lands for these beautiful evergreen shrubs. Rhododendrons are often injured by digging amongst them ruthlessly, thus destroying the fine fibrous roots that usually form near the surface of the ground. Top-dressings of loam and the ingredients indicated are excellent for Rhododendrons.

Winter Dressing Vines (F. J.).—It is a good plan to wash the rods after pruning. The loose bark should be removed, any that comes away readily, but there should be no attempt at scraping. Wash the Vines in the first instance with a softsoap solution, 4 ozs. to the gallon of water, using a brush; then dress with a mixture of softsoap, 4 ozs. to half gallon of water, a like quantity of tobacco juice from the manufacturers, a quarter of a pint of spirits of turpentine, with as much flowers of sulphur added as will form a cream, brushing this well into every angle and crevice, being careful, however, not to injure the buds, and yet dress the Vines in every part. It will destroy every insect that infests Vines, and is good against mildew.

Page's Champion Auricula (Florist).—No doubt, as you suggest, we could find something about this variety on consulting "old books." As an example we turn to "Gossip of the Garden," and in a description of Auriculas in 1861 find this paragraph:—"Page's Champion.—Londoners are justly proud of their two green edges, this and the Duke of Wellington. Very showy they both are, and this is something better than showy. Still, it is far from perfect—like every other green edged Auricula. Why cannot they be brought as near perfection as the greys or selfs? Fairly circular, never flat in the pip; edge a pure vivid green, lighter than Colonel Taylor or Freedom; colour light reddish violet that commonly darkens as it grows older; paste circular and good; eye circular, of a dark lasting cowslip, with anthers slightly above the surface; excellent trusser; and lasts in bloom as long as any. Foliage good, curly, green."

Artificial Manure for Fruit Trees (J. F.).—All the advertised manures are good for fruit trees, as they contain the different food constituents properly blended, and it is impossible to say that one is better than another for any particular soil, and the absence of an analysis of it, and for practical purposes that is not necessary in such cases as yours. Apply the manures according to the instructions accompanying them, giving a little more or less according to the weakness or vigour of the trees. Crushed bones are good, applying about a pint to every square yard, and pointing in lightly. But why not make your own manure? Save the bones of the house, put them in a cask packed in wood ashes. They will dissolve and be a superphosphate, to which you can add an equal quantity of soot, and apply a good handful to every square yard of ground occupied by the roots in early spring, lightly pointing in, and repeat after the fruit is set, not neglecting to give water and to mulch with grass or litter in dry weather.

Applying Fowl Manure (E. B.).—Fowl manure being very powerful should not be applied too liberally, about 6 tons per acre being a sufficiently heavy dressing for ground to be cropped with vegetables, and is best applied shortly before the crops are sown or planted. For garden crops we use it at the rate named—viz., 2½ to 3 lbs. per square yard with very satisfactory results. It is applied to the surface evenly and pointed in with a fork lightly. For flowers it is not advisable to give so heavy a dressing, as it sometimes proves too powerful for the delicate and moderate growing kinds, promoting luxuriance of growth not favourable to the production of flowers; therefore we think it best to give a light dressing about February, and again in June to plants that have been planted in autumn or are permanent, in each case pointing it in lightly. For ground intended to be planted with flowers it may be applied just before planting, pointing it in with a fork, following with a light sprinkling between the plants a little before they come into flower, or when they are showing the flower buds, giving at the same time a good watering if the weather be dry. It is assumed the manure is dry and mixed with sand or road grit used. If the manure is un-mixed it must be used in lessened proportion. Being rich in ammonia it should not be left on the surface of the soil, as the ammonia will be rapidly evolved and pass away. It should be kept dry, and not placed thickly so as to heat before it is used.

Amaryllyis (Sprekelia formosissima) (R. S.).—This, the Jacobæa Lily, is very beautiful. Its fine crimson flowers are produced in early summer before the leaves. The plants should be well supplied with water during the period of growth, alternating with liquid manure so as to produce vigorous leaves, keeping the plants in a very light position in order to a thorough solidification of the growth and perfection of the bulbs. When the foliage gives indications of ripening lessened supplies of water should be given, and when the plants are at rest little will be required. They succeed admirably in a compost of good fibrous

loam, leaf soil, and sand in equal parts, affording pots twice in diameter that of the bulbs, or if more than one are grown in a pot allow corresponding space, and in potting bury the bulbs in the soil level with the neck. If they have a greenhouse temperature it will be ample, but they will succeed in a light cool stove. They should be potted before they push fresh growths. If you wish to grow the plants outdoors choose a well drained, dry, and warm position near a wall, using good loam, leaf soil, and sand in equal parts, loosening it fully 18 inches deep. Place the bulbs from 6 to 8 inches deep, surround each with sand, and then cover with the compost, pressing it rather firmly about them. The best time to plant is in spring before the flower stems are sent up, when they begin to make roots. During growth in dry weather afford water or liquid manures. They should not be again disturbed for years, they will have established and form splendid masses of blooms in suitable positions.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*T. Tatham*).—The large Apple is Orange Goff, the small one we do not know.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*G. F. B. Spalding*).—*Odontoglossum Inslcayi*. (*W. R. T.*).—1 and 2, *Laelia anceps* varieties, both good, but the former especially very dark coloured. (*Inquirer*).—1 and 2, *Polypodium aureum*; 3, *Asplenium longissimum*; 4, *Polystichum aculeatum*. (*N. B.*).—1, *Primula sinensis alba plena*.

LAMBING TIME.

THE near approach of the lambing season once more leads us to call special attention to certain matters in connection with it to which it is desirable all due care should be given, in order that there may be as little loss as possible either of ewes or lambs. It is our own practice to turn in the tups to the flock about the end of August, so that the lambing season shall begin by the third week in January. We thus secure a fall of early lambs to be sold as lambs early in June, or as hoggets by the end of July. In order to ensure this much care is given to the selection of both ewes and tups, and we have reason for satisfaction with our selection of half-bred Suffolk ewes and pure Hampshire town tups. The result of this cross is a hardy sturdy progeny of quick growth and early development; but everything possible is done to promote healthy growth, and we begin giving lamb food as soon as the lambs can eat it.

Before entering farther upon the treatment of lambs, let us turn our attention to that of the ewes now. Since Christmas the ewes have been in rather large folds upon a 30-acre pasture held specially in reserve for this season of the year. After the hay-making last July growth was so much retarded by drought that when rain fell autumn was already upon us, and though the grass then grew freely enough it was left untouched for the ewes to have the benefit of for a month previous to and during the lambing. A belt of trees around the pasture affords sufficient shelter; the pasture is well drained and firm, and the herbage abundant. Let it not be thought that because sheep are hardy and bear much exposure with impunity that they are not much benefited by shelter. Pregnant ewes especially should have shelter, be kept quiet, and be carefully fed. We shall give no roots of any kind this season till the lambing actually begins, and then the ewes will have a certain quantity of Mangolds daily. Our dietary since Christmas has been as simple as sound—chopped Barley straw with a few Oats in the troughs, Pea straw in cribs and racks, and the grass. The shepherd has had many a hint from the horsemen that he ought to be having some hay for the ewes, but we answered his request for some that we should probably use no hay for the flock this winter, as we have plenty of Pea and Oat straw, and it is our intention to sell the whole of the hay. We may explain that the horsemen's advice about the use of hay was not altogether disinterested, for they like to be able to get some for the horses to rack up with at night. We, however, insist upon the use of straw chaff, and we know full well how wholesome and nutritious really good straw is. With our large stacks of Barley straw we have no occasion to touch any of the hay, of which we have an ample store of some 250 tons, which a little later on should realise some £900 or £1000, and prove a real help to us in our struggle with difficulties arising from the poverty of the farms which fall upon our hands one after another.

On the day of writing this article we saw two ewe flocks on different farms both folded upon white Turnips. There had previously been a frost of several days' duration, a thaw had set in, and the poor sheep evidently had some difficulty to wade through the sea of mud in which they were apparently kept continuously. We saw this with regret, knowing as we do from dearly-bought experience how severe is the strain upon the ewe's frame as it struggles to withdraw its feet from the sodden soil. A

ewe requires from 20 lbs. to 24 lbs. of food daily, and if the bulk of it consists of a mass of half-frozen Turnips day after day, the loss of heat caused by the consumption of such cold watery food proves so injurious, that abortion and the death of the ewes not unfrequently spreads like an epidemic through the flock. No doubt dry food in troughs tends in some measure to counteract the baneful effects of the Turnips, but it cannot prevent mischief. We have both white Turnips and Swedes, but neither will be touched till the lambs are taken upon them with the sheep. If we were short of grass now we should certainly turn to the Rye, which is such a full and forward plant that it would afford excellent grazing for the sheep. We know that many farmers are at their wit's end to find food for the stock this winter, yet there were ample opportunities last autumn for the sowing of green crops, and it certainly shows great want of forethought and care where this was not done. The short crop of hay and roots upon so many farms was like a danger signal for the coming winter, and we took care to keep the number of our sheep well within due bounds, and at the same time did all we could to secure plenty of green crops for spring use. If we should have a late spring the struggle will be a severe one, and it will probably lead to the premature disposal of many a flock.

(To be continued.)

WORK ON THE HOME FARM.

More than ordinary attention has been giving to the rearing and disposal of pigs by us since we ceased keeping bullocks in quantity, and it is one of the matters in which a remarkable improvement has been effected upon all our farms. We have just now a grand lot of what are technically known as "jointers"—i.e., fat hogs about half grown, which realise about £3 a piece at market. A batch of some twenty-eight have been lately consuming three sacks of ground Oats daily, and remarkably well have they thriven upon this food too. Oats are so cheap that we find it answer well to purchase imported Oats to grind into meal for pigs, for, as we have previously explained, a sack of Barley is worth two of Oats and something more, and therefore we certainly cannot afford to grind Barley for pigs. But we were seriously informed that nobody in East Anglia ever heard of fattening pigs upon oatmeal, and we had to insist upon attention being given to our instructions for doing so. Pigs are prolific animals, and every sow should yield at least twenty pigs yearly, so that the two farrows of a sow may always be considered as being worth from £20 to £60. Need we wonder that one of our tenants who keeps thirty or forty sows is now able to pay labourers with "pig money?" Just look at the figures, for they are sufficiently important to be worthy of it. Forty sows should bring 800 pigs yearly, which as jointers at £3 a piece are worth £2400. Surely it will be conceded that there is some profit in this transaction? Yes, we may be told, and some risk too. We grant it, but hold that the risk sinks to a minimum under the exercise of careful management. It by no means answers to breed jointers only; a brisk trade in porkers of 50 lbs. weight is far more profitable if a farm is within fifty or sixty miles of London, but the larger pigs make the best manure, and are often kept on for that purpose. In making calculations of profit and loss a reasonable margin must always be allowed for some failures, but careful selection and management go far to ensure success. It never answers to keep an inferior breed of pigs, nor is it necessary to give fancy prices in order to procure a really useful class of them. Every locality has good pigs if they are only sought for, and with a little care really good animals may be had.

REMARKS.

- 1st.—Fine and bright and very cold, especially in the morning.
 - 2nd.—Dull early; fine bright morning; damp afternoon; rain in the evening and night.
 - 3rd.—Fair morning, except for slight fog, with a little sunshine; dull afternoon.
 - 4th.—Overcast all day.
 - 5th.—Overcast early; fair day with glimpses of sun.
 - 6th.—Cloudy and rather dull, with rain in the evening.
 - 7th.—Fine and pleasant, with occasional sunshine.
- Rather sharp frost on the first two days, but on the whole a very average week alike as to pressure, temperature, and rain.—G. J. SYMONS.

PRUNING AND TRAINING
PEAR TREES.

IN these days of high pressure and keen competition, when much besides gardening is often expected from the gardener, it is of the greatest importance that the various departments of labour for which he is responsible should be reduced to a system, and also that that system be of the simplest nature possible consistent with remunerative returns. There are few gardens of any extent where it is not found necessary to leave many important operations to subordinates, and sometimes even to labourers of no gardening experience; and what aggravates the evil, these gardens are often expected to compete with those where nothing but skilled labour is employed and gardening exclusively pursued. Under such circumstances a simple method, which may be easily explained, and as easily comprehended by the inexperienced, is imperative, not only for securing the best results, but for diminishing the risk of bad workmanship.

Does it not often occur that much important work is left undone, which of course will tell its own tale, because the head gardener has not time to do it himself, neither has he those about him whom he can trust to do it for him? Disadvantages, however, there always will be more or less in gardens, and it is not these that I wish to make prominent, but only to point them out to show the importance of having easy-to-be-understood rules for the guidance of assistants; not that it is possible to unswervingly follow hard-and-fast lines in gardening, for with the best of rules very much must be left to the discretion of the operator. Much more might be said on this point, but my purpose is rather to give a practical example of the benefits arising from a simple system when applied to the training and pruning of fruit trees, more especially to pyramid, bush, and standard Pear and Apple trees, as these are the forms of trees most frequently treated in a haphazard way.

I am well aware that in most gardens fruit trees of all forms are trained on some system, and beautiful they are in many places, even when void of leaves; but this does not alter the fact that in many gardens, if there be a system, it would defy description, and that the trees would be far more remunerative if left entirely to Nature. What a beautiful object is a well-trained pyramid Pear or Apple tree, either in bloom or laden with fruit; and yet how seldom, except in first-class gardens, do we meet with a fair sample from which one could expect to gather well-flavoured fruit?

Not long since it was my lot to take in hand some so-called pyramid Pear trees. They were pyramids with a vengeance, especially after they were pruned, which had been done for more than ten years every autumn with Box-shears, and consisted in cutting off all summer growths as close to the old spurs as possible, all of which were clustered at the top of the branches, for the inside spurs had died years ago from want of light and air. Now here is a case to the point where every possible chance of fruit was sacrificed to mere shape of tree, and how a gardener could expect to supply his master's table with good fruit whilst pursuing such a system is a problem I could never solve. How these trees were brought into a fruitful condition, and our simple method of keeping them so, may be worth relating, especially as the principle may be applied to all fruit trees that bear their fruit on spurs.

They were allowed their own way until August, by which time they had thrown out a mass of strong shoots from 1 to 2 yards

long. As is often the case with pyramids, the main branches had been left much too close, and they had been allowed to branch several times, until they had become a tangled mass of main branches. Our first pruning operation consisted in sawing off about half of the branches close to the main stem, so that those remaining should be from 9 inches to 12 inches apart. We next cut off furcations close to the remaining branches, for we wished to have undivided branches, which with judicious management should be clothed with fruit spurs throughout their length. Cordon training and pruning is simplicity itself, and we aimed at treating each branch as a simple cordon, so that our pyramids should really be compound cordons, and we are well pleased with the result, for each branch being well away from its neighbour the sun and air act equally on their entire length, ripening the spurs and fruit which cluster round them so that they resemble ropes of Onions. It must not be fancied, however, that this desirable condition can be brought about in one season; it will take two or three years of careful treatment both of root and branch. Besides thinning the branches and cutting off all furcations, the current year's side shoots were cut back to about 4 inches if they exceeded 6 inches in length, if not they were left alone. Nothing more was done to them until early in October, when they were carefully root-pruned in the following manner:—

As these trees had been severely pruned and produced little but strong shoots for the past ten years, and as we also had so severely thinned their branches, root pruning was of the greatest importance to bring them into a fruitful condition. They had sent strong wood-producing roots far into the subsoil, so that unless these had been severed the trees would have produced a mass of strong unmanageable shoots. A trench was opened 18 inches wide and 3 feet from the bole of the trees. All fibrous roots, which were very scarce, were carefully preserved, but all strong roots were cut back as close as possible without reducing the ball of earth too much, not merely round the sides, but they were thoroughly undermined, and many of the trees replanted. After thoroughly mixing four wheelbarrows full of fine ballast and two pecks of half-inch bones with the soil which came from each tree it was well rammed back round them. Four inches depth of half-decayed stable manure was then laid on the surface over their roots, and they were securely tied to strong stakes driven into the ground in a slanting direction, so as not to pass through their roots. The leaves flagged very much on some of the trees, but they were supplied with warm water and syringed on dry days, which caused them to stiffen, and with few exceptions they fell off in a natural manner. This operation had the desired effect—viz., preventing wood growth, and clothing the strong shoots made the previous summer with spurs from top to bottom. If the few small shoots along the old branches do not exceed 4 inches in length they are let alone, for being low down they will not develop into strong shoots, but gradually turn into fruit spurs—that is, so long as the main branches be not cut back; but if, as is often the case, they are cut back, what would have been fruit spurs will be converted into wood growth, strong or weak in proportion as the main branches be shortened. The second spring after root pruning the trees formed one of the finest sights I ever saw, for with few exceptions they were covered with flowers nearly the entire length of the branches. They ripened good crops of fruit, but owing to sharp frost and cold winds whilst in flower more than three parts of the flowers never set, which, of course, saved us the trouble of thinning the fruit. The trees have since been lifted and planted in another part of the garden, when it was found that the roots had become a perfect mass of fibres.

The same simple system is adhered to not only with these, but with bush and standard Apples and many other fruit trees—viz., of treating each branch as a simple cordon, allowing them to extend unchecked, which acts as a safety valve by carrying off surplus sap in the right direction. It will be found, however, that if they can be trained into a fruitful state very little dangerous growth will be

made ; but if there be, recourse must be had to careful root-pruning, which will never fail to preserve balance of the trees. Strong, unfruitful growth is the indication for root-pruning, for that proves there are a superabundance of strong wood-forming roots, which if well cut back will be converted into fibrous fruit-spur-forming roots.

To form handsome pyramids it will be necessary to begin with maiden trees, and if for small gardens preference should be given to those grafted on the Quince stock. It should be cut back to within a foot of the ground, which will cause it to break strongly. From four to six of the best placed shoots should be selected to form the future bottom branches, and one for a leader. These should be encouraged to grow as strongly as possible, allowing no furcations on any of them, but let each branch be considered as a simple cordon. It is of the greatest importance to get the bottom branches well advanced before more are started, so that if they have not made good progress the first season they should be allowed another year's growth before more branches are formed ; indeed, this applies to all forms of fruit tree training. If the bottom branches are not thoroughly established when the tree is being formed, especially in trees with undivided stems, they will in after years gradually become weaker and in time die. This arises from the fact that the sap has a strong tendency to fly to the top of the tree ; but if while the tree is being formed it be made to flow into the bottom branches and thoroughly develop them before other branches are formed, the sap will ever after flow through and duly nourish them. Should it be decided not to form new branches the second year the leading shoot must be shortened to within 3 inches of the previous year's cut, and when it breaks in spring select the best placed shoot to form the new leader. Some gardeners cut off about a fourth of the branches, but they will give much less trouble and be clothed with fruit spurs in less time if left alone, for then the sap will find an outlet in lengthening the branches instead of producing a host of shoots along them, which requires very carefully handling, or it will be several years before they give place to fruit spurs. The third year the leading shoot should again be cut back to within 14 inches of the previous year's cut, which will cause it to throw out numerous shoots, from six to eight of which should be selected for another set of branches and a leader, and so on from year to year until the tree be fully developed.

Of course some shoots will be found on the main branches, but they will not be of a strong troublesome kind, all of which if they exceed 4 inches, should be shortened to that length in August, and in winter all should be shortened to 2 inches. The tree being once formed can be easily kept furnished with fruit spurs by the simple method already described, but that, of course, owing to late spring frost, does not always insure a crop of fruit ; but such a tree will always be of interest to a gardener, and generally so to his employers, even if inclement weather does destroy the blossom, because it will be seen that the barrenness is not the fault of cultivation, but of a calamity beyond the cultivator's control.—
J. H. W.

HORTICULTURE IN 1887.

I HAVE already taken one look backward in my retrospect of the Rose in the past year (to which, by-the-by, I would refer your correspondent, Mr. Raillem as to my opinion of the new Roses), and now purpose taking a somewhat wider sweep, and looking at the past year in its bearing on our favourite pursuit, as I have been accustomed to do in previous years. I think that when we get to the threescore years and ten we are more concerned with looking forward ; the port seems nearer, while the long stretch of sea behind us seems more and more undefined. Still we must look back if only on this, as on other things, to encourage us to more vigorous efforts for the future.

As far as the weather was concerned it was probably one of the most trying seasons for gardening that we have for some years experienced. The late spring frosts that have been so usual for some years came to us as usual, although we had hoped to have escaped them owing to the long severe weather in the winter ; but notwithstanding all this, we might have "weathered the storm"

had it not been for the prolonged drought which was felt all over the country, and which sorely taxed the energies of the gardeners and the constitution of the plants. Week after week went by, and still no water. Happy were they who (like myself) had access to a plentiful supply ; but in many places it was deplorable to witness the havoc wrought by it. Where bedding out was still the main chance the result was deplorable, the plants never seemed to move, and had a miserably stunted appearance. In the vegetable garden Peas were infested with mildew, Lettuces ran off to seed, Turnips were sown over and over again, and yet came to nothing in the end. The small fruits were abundant, but Apples and Pears felt the drought very much. Nor was this all. We had in many parts of the country, and more especially here in Kent, on the last day of August, one of the most destructive gales we have experienced for years—the flowers battered to pieces, and the gardens and orchards were strewn with Apples and Pears. To such an extent was this the case, that in one celebrated fruit garden in our county the gardener told me that where he expected to have gathered 150 bushels of King of the Pippins he should not gather one bushel. We, however, anticipated a fine autumn. In this again we were disappointed. Not only did St. Luke not bring us his "little summer," but we experienced in the second week in October a severe frost that ate up everything, killed off our Dahlias, made our Fig trees shed their leaves, and utterly ruined the bloom of our out-of-door Chrysanthemums. Nowhere, I believe, was a decent bloom cut. To many this entailed a most serious loss. Where blooms are cut for the London market, and plants are grown extensively for that purpose, one grower in the neighbourhood of London growing two acres for that purpose, that frost causing him a loss of close upon £500. On the whole, then, I think that we must look upon the Jubilee year as about one of the worst for gardening that we have had for many years.

The Jubilee year of Her Majesty's reign has made itself felt amongst horticulturists as amongst other people, and Jubilee memorials have been established in many places. The most notable, as far as we are concerned, has been, however, the establishment of the Gardeners' Orphanage Fund originated by Mr. Penny, gardener to H.R.H. the Prince of Wales at Sandringham, and very effectively piloted by Mr. George Deal. Everyone must wish it well, and it is earnestly hoped that it may not interfere with the efficiency of the Royal Gardeners' Benevolent Institution. There is fear of this, for it has been found that the gifts to Jubilee celebrations have interfered with ordinary contributions, and therefore we must hope that in this case Peter may not be robbed to pay Paul.

The year has not been a remarkable one for new plants, whether introduced from abroad or raised in our gardens at home. Of course there have been novelties, for we could not live without them, but nothing very startling. Orchids, which have been the source from which we have had our greatest wonders of late years, do not seem to have supplied us with any startling novelties such as have marked previous years. Orchids have unquestionably not only held their own, but more, and increased in favour with those who have means at their disposal to indulge a somewhat expensive hobby, and which has oftentimes to be carried on with much inconvenience, the heated atmosphere of the East India and other Orchid houses inducing rheumatic twinges to mar the pleasure of the amateur. Every season brings forward some new growers who have joined the band of lovers of this most marvellous genus, while we may with justice say that the two other most popular flowers are the Rose and the Chrysanthemum. Of the former I have already written, and of the latter one can only say that each year seems to add to its already widespread popularity. The number of Chrysanthemum societies has wonderfully increased, and as it is a flower within the reach of all, and one that will accommodate itself to the requirements of "town life," and comes to cheer us in the depth of our dark and dreary winters, we may rejoice in its increased culture. Each year, I think, sees the incurved varieties decreasing and the Japanese increasing in favour ; indeed we are likely to be inundated with a quantity of worthless varieties, one grower, M. S. Délaux, having announced a hundred, while Mr. Cannell and others have been importing from Japan, and others again from America, so that the revision of our lists will be a difficult matter by-and-by. I was going through my own small collection to-day, which does not comprise above 100 varieties of the different classes, and it was an exceedingly difficult matter to say which were to be eliminated. There is, especially in the Japanese, so much variety both of form and colour that it is difficult to discard them ; it must be done, however. The Begonia has advanced in size, but it is questionable whether this enhances its beauty, nor do I think it will ever rank as a popular flower in the sense that it will be grown in collections as Zonal Pelargoniums, Fuchsias, &c., are cultivated. They have been successfully used for bedding out.

The favour with which herbaceous and alpine plants have been

received of late years has in no way diminished during the past year, and although it has been a most trying one in many situations, and we hardly at present can estimate the extent of our losses from the drought, yet great progress has been made. In all directions we find amateurs entering into the new pastures opened out for them, and many have felt how valuable they were during the past dry season, for where many others failed, and the vases would have been empty or nearly so, those who had herbaceous plants to go to could always find something pleasing, and oftentimes novel, while at many exhibitions throughout the country groups of them, and collections of their cut flowers, have attracted a large number of visitors, and encouraged many to begin their culture. It now becomes a question, What is to be considered an herbaceous plant? Do bulbs come under that designation? It seems, for instance, rather out of place to see a large plant of *Lilium auratum* figuring amongst them as a hardy herbaceous plant, but definitions are funny things, and I leave this thorny question for the present.

The depression which has rested on the whole commerce and agriculture of the country has had a very deteriorating effect on many of our large places. The staff of gardeners has been reduced, gardens left in untidiness, and in many instances sale of produce carried on to a considerable extent. I was in one place last summer which used to be a grand show place, and one I had often desired to visit. How woeful was my disappointment! Houses in ruins or pulled down; gardens littered and ill-kept, and everything looked at in a commercial point of view. Nor was this to be wondered at. When the able and intelligent gardener went there twenty years ago he had twenty-three men under him, now he has four! This, I very much fear, is a sample of what is going on around us, and I think no one can regard the process without great regret for what is taking place. These large places formed some of our best schools for gardeners, and it will be a great pity if they should cease to exist. The question as to the equity of proprietors disposing of their surplus produce has been much debated, but personally I do not see why a gentleman should be thought mean if he disposes of surplus Peaches any more than of his surplus Shorthorns or Berkshire pigs. He is not regarded as a butcher if he does the one, why should he be called a market gardener if he does the other?

The death-roll has not been so large this year as in some previous years, nor have those who are gone from us occupied very prominent positions. It is many years since Lord Hawke gave up exhibiting. He used at one time to be the great amateur Hollyhock grower, and his flowers were looked for with anxiety by those who cultivated that stately autumn flower, but when the mysterious disease attacked it he became more engrossed with another favourite flower, the *Gladiolus*. This he had already cultivated successfully, but the failure of the Hollyhock incited him to a more extended culture, and his flowers were looked for with great interest and a considerable amount of fear by those who were his antagonists. He never undertook anything that he did not carry out with energy and success. Mr. Kinghorn, one of the gentlest and most amiable of men had, from his delicate state of health, been but little seen latterly. He was a man of sound judgment, quiet, but not easily moved from a position he had once taken up. Amongst gardeners Mr. Z. Stevens of Trentham has passed away—and so the world goes on. There is one lesson among many we all have to learn on looking from year to year at the lists of those who have gone from us—viz., how very soon we are forgotten. We fancy sometimes, What a blank when such a one is gone! Just the blank that the sea leaves on the shore when the receding wave lays it bare; but the next wave soon covers it again. And so it is with us all; we must work for love of the work, and fulfil it in our day. Of all idle things, that which is the idlest is to think of what will be said of us when we are gone. We shall be forgotten; and in the emphatic words of the old Book, "the place that knew us shall know us no more." And so my brothers and sisters in the craft, let us work cheerily on, rejoicing in a pursuit so full of calming and restful thought, and look forward (forgive a parson) for the true Garden—the Paradise of God.—D., Deal.

CONSIDERATIONS AS TO EARLY AND LATE POTATOES.

EARLY POTATOES.—Potatoes are of first importance in Ireland as a general crop; but before coming to that it may be well just now to refer to preparatory considerations affecting early varieties. The weather has been singularly mild since Christmas, so much so that there seems some risk of starting into premature growth owing to the atmosphere being almost at saturation point for some weeks. For frame culture this would be no inconvenience, as they might now be placed in at any time with a fair expectation that sufficient sun and light can be had to mature the haulm later on, without

which tubers are insipid. The question has often been discussed whether the tubers or "sets" should be cut. Every such query must be decided on its merits. If a number of stalks and a number of small tubers are desired, do not cut; if the reverse, as is customary, divide according to size and number of eyes. There are other reasons for doing so, but at present I pass on.

Those who have a warm southern border with a wall behind may do well, if they want very early Potatoes, to start the "sets" slowly any time now according to requirements, say in shallow boxes of sandy soil, and subsequently lift into the furrows as you would Peas. If the soil is naturally cold and wet this would be time lost as well as the "sets" and vexatious disappointment, as when transplanted growth would cease and the fibrous roots rot. Two capital applications for almost any soil and any variety of early Potatoes are newly slaked lime and rather fresh stable manure. The lime in that state is loose and friable, and kills larvæ, grubs, and the eggs of insects—benefiting the subsequent crop also—while the stable manure, somewhat fresh, warms the soil. If cold and sodden the tender forced rootlets in the early spring are more injured than benefited thereby. In fact, no manure would be more desirable. Now is the time for the amateur and gardener to turn such considerations over in their minds; no writer can do more than mention general principles, particular cases differing in essentials.

As to the best early varieties, the old Ashleaf Kidney (Myatt's, Veitch's, or Rivers') is now run hard in the race for priority and popularity by Carter's First Crop, and by the recently certificated Snowdrop, all kidney shaped. If an early round is desired, after many trials and many years' experience I have found nothing to equal Carter's Eight Weeks, that very nearly will be found to merit its name. If quality is a secondary consideration, Early Rose, Racehorse, or Excelsior should get a preference, as the yield is heavier.

GENERAL CROP POTATOES.—Last year's experience of the field crops has been very singular, owing to the persistent and almost continuous drought in the south of Ireland—the north had several inches more rain—growers were speculating on having no Potato crop as late as August. The clay was then actually hot, and after some heavy showers tubers began to form with extraordinary rapidity. Fortunately with me, and I may say the greater part of Ireland, the field Potatoes had formed no tubers up to that time, so there was virtually no "supertubering," a subject of much importance discussed recently by Mr. Laxton, Bedford, who takes much interest in raising new varieties. Another peculiarity of last season, and for which you must go back to 1843, the year (and subsequent ones) of the famine and total blight, there was no Potato disease last year. I must specially draw attention to this matter, as I think it has not been sufficiently noticed, and this observation applies to all varieties sent me for trial by the most noted growers of England and Ireland. Up to the present moment of last year's crop in any part of Ireland I have been in, from Clare to Dublin, from Cork to Wexford, I have not seen a diseased Potato. I say diseased advisedly, as I mean affected with the peronospora blight or "murrain." Of course I have seen a limited number of decayed ones—quite a different matter. Now this disease is a fungus, and moisture is necessary to its propagation, or even existence at a certain period. But there was no moisture and no disease at that period, so I am tempted to ask you and fungologists what they think of the country being finally rid of the Potato disease? I am proceeding on the supposition that the experience of other growers last season and up to the present is like my own and those I have discussed the matter with. The importance of this point, in its bearing as the future prosperity of the country, leaves me only space to refer nominally to certain varieties I grew.

The quality of almost all varieties was good. Of new ones I may name Carter's King of the Russets and Carter's (Bennet's) Surprise, which I find the Royal Horticultural Society also gave first-class certificates to after testing at Chiswick. Sutton's Abundance, Seedling, and Twenty-one, owing to the drought, I am growing this season again. Mr. Laxton sent me ten varieties rather late; all were free from disease, but the best, everything considered, were Reward, Bouncer, and Bedfordshire Hero. Mr. Inglis has a capital Potato in White Fortyfold. Of older varieties I will at present merely name them as I found in the order of their merit—Reading Hero, Cosmopolitan, Beauty of Hebron (second early), Scottish Queen, Emperor, Carter's Freedom (new), Champion, Magnum Bonum (heavy crop), and Vicar of Laleham.—W. J. MURPHY, Clonmel.

READING RUSSET POTATO.—We grew Reading Russet Potato for the first time two years ago, and were so pleased with it that we grew it more extensively last year, but the quality was not nearly so good, and the cracking mentioned by "G." was very prevalent; in fact, all our Potatoes cracked a good deal last year, but none so much as Reading Russet. I attributed the cracking to the heavy

rainfall about the middle of August following a long period of drought. Our best Potato is still Schoolmaster, and our "seed" of this variety has been unchanged for eight years. White Elephant is dry and mealy with us, but lacks the flavour of Schoolmaster.—E. B.

DISAS.

THE admirable article contributed by "O. T. C." in the Journal on page 3 describing his method of growing the charming *Disa grandiflora* should be acted upon by those who have previously failed to grow it successfully.

I have seen the magnificent specimens at Chatsworth and Blenheim, and at the last named place there is certain evidence that the plants do suffer from exposure to a few degrees of frost. The plants occupy large pans, and during the summer months they are grown in a frame placed under a north wall. One of the lights happened to have a broken square of glass immediately above one of the Disas, and the unexpected early frost blackened some of the growths, which still show, and will do for some time, the effects of that night. During the months of last April and May several other species of *Disa* were introduced by Mr. James O'Brien. Some of them came under my charge; and being anxious to succeed in cultivating them, I commenced experimenting with various composts. Too much loam is decidedly harmful, and should only be used sparingly, and that fibrous. As the Disas require abundance of water during growth the potting material should be loose, so that water can pass freely through. Anything approaching stagnation is fatal to them. Sand and dung—I used dried cowdung—can also be dispensed with, all that is required being good fibrous peat and live sphagnum in equal quantity, with plenty of rocks broken very small.

After potting the plants soon began to show signs of activity, and during the hot weather were placed outside over a narrow stream in a shady part of the garden. *D. cornuta* was potted singly in 4-inch pots, and grew very strong, throwing up spikes of bloom 16 inches high. One of these was awarded a botanical certificate in August last by the Floral Committee of the Royal Horticultural Society. *D. Herschelli*, with grass-like leaves, has made tubers as large as the imported ones, and ought to bloom this year. *D. graminiflora* and *D. spatulata* has similar foliage, and have formed large new white tubers. *D. sagittalis* in habit of growth resembles *D. grandiflora*, but the flowers are white and mauve. The latest addition is one sent by Mr. O'Brien as a new species, the flowers of which are described like *Laelia autumnalis* in size and colour, with the habit of *D. grandiflora*.

Our plants were housed early in September, and have since occupied a shelf in the cool house close to the ventilators, where frost is only just excluded, and since then the soil has gradually been allowed to become dry. I have been examining the tubers, and find them as mentioned and very firm, and a few are commencing to grow again.

LEADEN LABELS FOR ORCHIDS.

Many gardeners have experienced the disadvantages of the ordinary wooden label for recording the names of their Orchids. Often when they have been in use for a year or more the pointed end decays, and is easily broken off and lost. If the lower part is left in the pot it will cause fungus to appear, which soon spreads through the compost and proves hurtful to the plant.

I have adopted for some years a simple and useful mode. By cutting lead strips according to the size of the pot, and having a set of letters and numbers, I punch the first letter of each name with a number underneath. In a register I have the full name and corresponding number, with the name of the person or place from where it was obtained, together with the date, all on one page, and on the opposite or blank page, using the same number, I am able to make any remarks concerning the plant, which would be inconvenient to write on a label even if a durable one. After the impression is made on the lead, which is cut tapering, the pointed end is put inside the pot and bent outwardly over the rim, where it is securely held in position and is practically indestructible. For baskets and blocks a square piece is cut with a hole bored to admit a wire passing through for suspending. They are neat in appearance, and anyone with a fair knowledge of Orchids can generally recognise the species or variety by the letters, which would be diffi-

cult sometimes if numbers only were employed. It also enables a grower to keep a correct list of worthless varieties or any that may die.—G. W. C.

FACTS ABOUT GRAPES.

(Continued from page 5.)

MRS. PEARSON.

ALTHOUGH of the same parentage as Golden Queen it is totally distinct from it. Golden Queen inherits the strong growth of Ferdinand de Lesseps, but Mrs. Pearson more resembles the Alicante, being less robust and very prolific. It also produces prettier well-shouldered bunches, the berries being round, and if well grown, of a rich amber colour. In common with the Ferdinand de Lesseps and the Strawberry Grape, it has a peculiar sweet musky flavour, and quite a powerful aroma, which can be observed in passing the Vine. Being an excellent keeping Grape, a newly discovered property, Mrs. Pearson may yet become a popular companion for the Alicante and Lady Downe's. It succeeds admirably under the same treatment as these receive, setting quite as freely, and finishing off well without much fire heat. Mr. Goodacre at Elvaston Castle was one of the first to give both this and Golden Queen a good trial, and this season has had Mrs. Pearson exceptionally fine. When well grown, and bottled and stored in a cool dry room, it will keep better than Alicante, and quite as long as the Museat of Alexandria. It forces fairly well, and if not quite so early as Foster's Seedling or Buckland Sweetwater, is quite as reliable, and decidedly superior in quality.

MUSCAT OF ALEXANDRIA.

Having repeatedly tried, and seen others try to grow this fine Grape in a mixed house of varieties requiring little or no heat to bring them to perfection, I have been obliged, reluctantly enough, to advise others not to plant it unless they can give it a fair amount of heat from first to last. The very finest Muscats, notably those at Longleat, are grown in a compartment, or houses, entirely devoted to them, but very good examples are frequently forthcoming from houses of mixed black and white late varieties, and in all probability Mr. W. Taylor will yet prove that it is possible to have them extra good from a mixed house. In his case the Muscats occupy the sunniest side of a span-roofed house, and consequently get much more light and sunshine than do the black varieties on the cooler side. All cannot imitate this practice, but as there is usually a warm end to most vineries, it is here where the Muscats ought to be planted. A careful use of the ventilators may further serve to keep the Muscat end warmer than the rest of the house, and well-finished Grapes be the result. Although a high temperature at flowering time may be safe, and even beneficial, in a large house, it is by no means necessary or advisable in small vineries. Plenty of pollen may be distributed, and yet a good set not effected, owing to the weakly character of the flowers. An extra high temperature has a weakening effect, and is positively injurious to Vines not in robust health. Avoid crowding the laterals so as to admit plenty of light to the bunches, and this strengthens them, and largely contributes to both a good set and finish. When at Gunnersbury House in October, Mr. Hudson drew my attention to the superiority of the bunches of Muscat of Alexandria in a house where a rather low temperature was maintained at flowering time. In one house the temperature was kept 70° and upwards night and day, but the result was not nearly so good as in the next division, where the night temperature ranged from 60° to 65°. Without a great expenditure of fire heat Mr. Hudson obtained capital Muscats which promised to keep well. In our case the temperature of the Muscat house cannot be kept much above 60° in the night time, and a good set is the rule.

Speaking from experience, having made plenty of blunders, I am of opinion that there are two primary causes for so many failures with this Grape—viz., overcropping and crowding. Naturally it is of free growth and very prolific, young well-ripened canes being almost certain to develop numerous extra large bunches. Six bunches are frequently left where three or four would be ample, and the consequence is a serious check from which the Vines rarely recover. Neither the young nor newly renovated Vines ought to be heavily cropped, nothing being gained by it, but on the contrary loss results. Every strong rod should have a roof space of nearly or quite 4 feet, whereas there are plenty of vineries I could mention where they are disposed more near 2 feet apart. Given good room the bunches are thick and well-set; crowded, nothing but spindly thinly berried bunches can possibly be obtained, these presenting a very poor appearance either on the Vines or the dessert dishes. I prefer to have the Muscat of Alexandria on its own roots, but find it makes a capital stock for any other variety worked on it.—W. IGGULDEN.

"STONELEIGH," BARKBY, NEAR LEICESTER.

WHEN spending a day or two of the Christmas holidays with friends near Leicester, and having previously heard from various sources of the exceptionally fine Chrysanthemums which have this season been grown at the above address, I took advantage of the opportunity afforded me to call and see what remained of them at so late a date as Christmas week, feeling sure that if the proprietor, W. Billson, Esq., was as much an enthusiastic lover and grower of the flower as I had been told he was, I should be quite certain of a genial welcome, and in this I was not at all mistaken. I was fortunate in finding Mr. Billson at home in more senses than one, as I found him in his garden busily employed along with his gardeners in cutting down and clearing away those of his favourites of which the flowers were quite gone. The gardener, Mr. Bolton, is a quiet, unassuming, but skilful and painstaking young man, who has already made his name known at both the summer and autumn shows of the district, and is likely to make it much more widely known in other towns and districts in future seasons. Mr. Billson himself is evidently a true gardener at heart, with a love for the work, but being closely engaged at all except holiday times as the head of a business firm, he has little opportunity for indulging in his favourite occupation.

The first object of interest to me being the Chrysanthemums, I was conducted through the several houses which they have occupied during the flowering season, and although by far the greater portion had been cut down and cleared away prior to my visit, there was still a sufficient number left to prove how fine had been the collection when at its best. The total number which had been grown during the past season was slightly over 700 as standards for exhibition blooms. Some very fine blooms were still left of such late varieties as Hero of Stoke Newington, Princess Teck, &c., with the remains of what had once been grand flowers of Queens and Empresses (I was told that they had had Golden Empress measuring 17 inches over the bloom). The plants were all robust, with stems like walking sticks and large leathery foliage. I asked if any cutting back or topping had been practised, and was told not, but that the treatment adopted in this respect had been that recommended by Mr. Molyneux, except that the varieties Eve and Mabel Ward had been allowed to grow unstopped until the first bud was produced, which was destroyed, and the three breaks formed immediately below this being then taken on for producing crown buds. From the two varieties above named I was told very good flowers had been obtained by cutting back to produce early breaks. Although allowed to grow thus freely and unchecked abundance of good early flowers were obtained, and at the Leicester Chrysanthemum Society's Show, held so early as the 4th and 5th November, nearly all the first prizes offered in the open classes were awarded to flowers from this collection. Again at Loughborough they were equally successful, and also again much later at Leeds. It had been Mr. Billson's intention to compete at the Sheffield and West Riding Chrysanthemum Society's Show for the large silver cup and money prizes given for forty-eight blooms, and his entry was duly made, but unfortunately his gardener was prevented by illness on the day of the Show from competing.

Early propagation appears not to be practised. At the time of my visit only a portion of the stock had been taken, and those very recently, and as the system adopted is that of putting about four cuttings in each pot (60's) and plunging the pots in cocoa-nut fibre placed openly on the side stages in a cold vinery, the free ventilation of which causes the cuttings to flag seriously, it is likely it will be a considerable time yet before any have formed roots. Mr. Bolton, however, attributes a large amount of his success with them to the fact that when they commence growing freely in the early spring they are pushed along very rapidly and yet sturdily in a very fine range of lean-to pits or frames running along and attached to the south-east side of a range of span-roofed houses. Frost and damp are kept out of these pits by wooden slides set into the walls, separating them from the houses, which can be opened or closed at pleasure. The floor of the pits is also sunk considerably below the ground level, and the plants are so arranged as that their heads are always near the glass, sinking the pots lower as they grow, and giving always free ventilation, thus securing a strong and sturdy growth in the early stages of the plant's existence, a point undoubtedly of great importance to ultimate success. A few of the varieties which have been exceptionally fine, as described to me by Mr. Billson and his gardener, are Golden Empress, Comte de Germiny (each of these I was told had measured 17 inches over), Lord Alcester, John Salter, Mr. Bunn, Jeanne d'Are, Hero of Stoke Newington, Criterion, Baronne de Prailly, Boule d'Or, Belle Paule, Madame C. Audiguier, and Meg Merrilies.

Chrysanthemums are far from being the only plants well grown, the culture of Tea Roses in pots being also a specialty; but as I have dwelt at length upon the former subject not much can now be said concerning others. I found, however, that one large span-roofed house which had been filled with Chrysanthemums during their season had recently been entirely cleared and cleaned out, and was then full of large, strong, and healthy bunches of "Teas" in pots, just breaking freely into growth, and from which a fine crop of bloom may be expected in about two months hence. I was told by the gardener that thirty dozen flowers per week were cut last season for a considerable time from the first week in March onwards. In another large span-roofed plant stove were some very good specimen foliage and flowering plants which have already made their mark at the Leicester Abbey Park summer shows. Amongst them I noticed handsome specimens of Bougainvilleas, Allamandas, Stephanotis, Crotous, Anthurium Veitchii (twelve fine leaves), A. Sanderianum (a fine piece), and Dracæna Lindenii, 4 feet high, finely

coloured; also a number of very large specimen Adiantums, the best being farleyense, Mooreanum, gracillimum, and cardiochænum.

In a conservatory adjoining the residence I noticed well-grown Primulas, also Camellias, Azaleas, &c. The kitchen garden is extensive, and is well stocked with healthy fruit trees, also some fine Hybrid Perpetual Roses. The house is a very commodious and substantially built red brick structure, commanding some beautiful and pleasant views along the Valley of the Soar, and is about four miles from Leicester.—W. K. W.

EVENTS OF THE WEEK.—There are few strictly horticultural events of importance this week beyond the usual auction sales. The scientific societies' meetings are now frequent; the Royal Society has a meeting on Thursday, 19th inst., at 4.30 P.M., and the Linnean Society on the same day at 8 P.M. On Wednesday, 25th inst., at 8 P.M. the Society of Arts also has a meeting.

— THE ROYAL HORTICULTURAL SOCIETY.—As already stated, the annual meeting of this Society will be held on February 14th next, the following being the names of Fellows nominated for the Council:—Sir Trevor Lawrence, Bart, M.P., Robert Hogg, L.L.D., F.L.S., Professor M. Foster, F.R.S., D. Morris, M.A., F.L.S., W. T. Thiselton Dyer, C.M.G. F.R.S., A. H. Snee, William Lee, Col. Beddome, George Paul, Harry J. Veitch, Sydney Courtauld, E. G. Loder, Rev. W. Wilks, Baron Henry Schröder, and G. F. Wilson, F.R.S. Messrs. Morris, Snee, Paul, Veitch and Wilkes will take the places of Major Mason, Mr. W. Haughton, Hon. and Rev. J. T. Boscawen, Col. Trevor Clarke, and G. Maw. As officers the Council recommend the following:—President, Sir Trevor Lawrence, Bart, M.P.; Treasurer, D. Morris; Secretary, W. Lee; and Auditors, Messrs. John Lee, Wm. Richards, and H. Turner.

— A FEW packets of the manure spoken of by "Dum Spiro Spero," on page 559 of our last volume, have been received at this office, and will be sent to applicants in the order of their applications on receipt of 3d. in postage stamps to pay for postage.

— WE have received Mr. Shirley Hibberd's GARDEN ORACLE, which has attained its thirtieth anniversary. Its appearance is no doubt well known to all gardening readers, and when we say that the present issue is in no way inferior to its predecessors we need say no more.

— A CACTOPHILE writes:—"It may interest some of your readers to know that a CACTI SOCIETY has been instituted on the Continent. It is entitled the *Vetplantenkring*, and the meetings are to be held once a month at the Tivoli Rue du Pelican 82, Antwerp, the Secretary being M. J. Havermans, Rue Jesus 46, Antwerp."

— WE learn from the *American Gardeners' Monthly* for the current month just to hand that MR. CHARLES H. MAROT, well known as the publisher and proprietor of that periodical, and of numerous gardening works, died on December 21st last in Philadelphia in his sixty-second year. Mr. Meehan states that he had been associated with him for a quarter of a century, and that he was much respected.

— IT is with great regret that we announce the death of MR. MCLAREN, which took place on Friday evening last, after a long illness. The deceased was gardener at Farnborough Hill, Hants, the seat of the ex-Empress Eugénie, where he was much respected by all with whom he came in contact. The deceased was gardener at Farnborough Hill before the Empress acquired possession; therefore his acknowledged abilities have stood him in good stead during the alterations effected there since.

— "AN AMATEUR FLORIST" writes:—"In the subject JUDGING BOUQUETS, recently discussed at some length in this Journal, all the correspondents, but especially 'A Learner,' Mr. Chard, and Mr. Garner have done good service by their useful remarks. I am glad to find that 'Learner' was not actuated by any desire to lessen the credit due to other successful exhibitors. This is a paltry feeling, and the true manly spirit is when fairly defeated to make an extra effort for victory on

another occasion. Rivalry when confined within proper limits is invigorating and beneficial to all. After what has been advanced no doubt some societies will exercise more care in the revision of their classes for bouquets and in the appointment of judges."

— MR. MARK LONGHURST, 18, Church Road, Hove, informs us that the dates of the BRIGHTON AND HOVE CHRYSANTHEMUM SHOW are fixed for the 13th and 14th of November next. Schedules will be ready the first week in March.

— "T." writes, in reference to *STACHYS TUBERIFERA*—"I was pleased the correct name has appeared, as I have good reasons to believe they have been grown in this neighbourhood (Bickley) during the past season, and have the reputation of being a most delicious vegetable, but erroneously named Crasie's. Would anyone kindly give cultural details or the best time to plant them?"

— AT a meeting of the ROYAL BOTANIC SOCIETY, held last Saturday, Mr. John Birkett in the chair, Dr. Prior exhibited specimens of the sweet acorn called Bellotas, of which great quantities are brought into the markets of Northern Africa and Spain during the autumn months, and are eaten raw, boiled, or roasted, or made into bread by the inhabitants.

— THE WEATHER IN THE NORTH.—"B. D." sends this note on weather in the north for the past week:—"A week of open, dull weather, latterly colder, with wind from N.E., except on morning of the 13th, when we had 2° of frost, with a good deal of rime. The temperature has ranged from 34° to 45°. The barometer, steady at 30.4 for some time, remains firm. The buds of Roses are swelling; a Tea on a wall shows half an inch of growth. Auriculas have made a decided start."

— THE WEATHER IN DECEMBER.—Mr. J. Mallender sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR DECEMBER, 1887.—Mean temperature of month, 36.8°. Maximum on the 2nd, 53.4°; minimum on the 12th, 22.6°. Maximum in the sun on the 2nd, 95.8°; minimum on the grass on the 28th, 14.5°. Mean temperature of the air at 9 A.M., 36.3°; mean temperature of soil, 1 foot deep, 37.5°. Nights below 32° in shade eighteen, on grass twenty-five. Sunshine, total duration in month, forty-eight hours. We had eight sunless days. Rainfall total fall 1.01 inch. Rain fell on nineteen days. Wind, average velocity 11.5 miles per hour. Velocity exceeded 400 miles on five days, and fell short of 100 miles on three days. Approximate averages for December:—Mean temperature, 37.2°. Rainfall, 2.03 ins. Sunshine, 52 hours (six years). The first three weeks were unsettled with large and sudden changes of temperature. The last ten days were anticyclonic with dry and rather cold weather.

— THE METEOROLOGICAL SUMMARY FOR 1887.—The same correspondent submits the undermentioned record:—Mean temperature, 46.6°. Maximum, 85° on July 3rd; minimum, 12.3° on January 7th. Number of frosts in shade 103, on grass 178. At 9 A.M. temperature of air, 47.3°; mean temperature of soil 1 foot deep, 47.2°. Sunshine 1420 hours, or 32 per cent. of possible duration. We had sixty-six sunless days and ninety-six bright days. Rainfall, 15.95 inches. Rain fell on 161 days. Maximum fall on Oct. 8th 0.62. Wind, average velocity 9.3 miles per hour; twenty-seven days with more than 400 miles, and fifty-seven days with less than 100 miles. The mean temperature is lower than any of the previous eleven years, except 1879, though the last two years were nearly as cold. This is mainly due to the very cold nights throughout the year, as even in May and June they were only just up to the average. The daily range is very large. The rainfall is about 36 per cent. below the average, and is much less than any year since our record commenced in 1875. The sunshine is larger than any of the previous six years. The proportion of N. and N.E. winds is larger than usual.

— AT the meeting of the Horticultural Club on Tuesday the 10th inst., Mr. Drury read a paper on "PER SALTUM" VARIATION IN WILD FERNS, and after drawing attention to several examples of sudden wide variations in cattle and sheep, such as the Niata cattle and Aneon sheep, in which cattle with bulldog features, and sheep of turnspit character, had originated suddenly from ordinary breeds, he proceeded to illustrate and remark upon a large number of equally abnormal forms of Ferns which from time to time had been found wild in Great Britain under circumstances, which, as he pointed out, could only lead to the assumption that they were the direct offspring of the common Ferns,

amongst which they were discovered, no intermediate forms existing likely to be progenitors. To illustrate his remarks he exhibited a large series of very beautiful Nature prints, executed by Col. A. M. Sones of Clifton, and kindly lent for the purpose by Mr. F. W. Stansfield of Sale, and proceeded to argue, that in view of the great number of these curious forms which had been discovered, and the immense amount of patience which Fern-hunting necessitated, it was a legitimate assumption that the tendency to vary under natural conditions must be as great as under cultivation, where everything was in favour, instead of against any peculiar sport being discovered. An animated discussion followed.

— THE RAINFALL IN 1887.—Mr. A. Pettigrew, Cardiff Castle Gardens, Glamorganshire, sends his observations on the rainfall for the past year, stating that the rain gauge is 1 foot above the ground, and 38 feet above sea level:—January, 2.93 inches; February, 1.35 inch; March, 2.58 inches; April, 1.45 inch; May, 2.10 inches; June, 0.61 inch; July, 1.53 inch; August, 3.51 inches; September, 4.12 inches; October, 2.76 inches; November, 3.45 inches; December, 3.28 inches—total, 29.72 inches. The greatest fall in twenty-four hours was 1.50 inch on August 16th, and the smallest 0.44 on April 26th. The most rainy days occurred in January—viz., twenty, and the fewest in June—viz., five, the total number of rainy days being 160.

— MR. ROBT. SCOTT, gardener to Ed. Priestman, Esq., Moorfield, Manningham, Bradford, writes:—"We have a plant of *POINSETTIA PULCHERRIMA* planted out in our stove here. I send you a specimen of the heads it produces. It is quite common here to have them branching down the stem. I have cut them with as many as ten branches. Our plant a month ago was extremely beautiful. I consider those sent now are past their best, and some of the largest have been cut, but there are still many equal to those sent on the plant. It carries about eighty heads." The specimens received were very handsome, the largest head measured 18 inches across, the broadest bracts exceeding 3 inches in diameter.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—JAN. 10TH, 1888.

PRESENT:—Mr. F. P. Pascoe, Vice-President, in the chair; Messrs. Boulger, Lyneh, Smith, O'Brien, Michael, MacLachan, Ridley, Murray, Morris, Smece, Wilson; Profs. Church, Scott, Ward; Drs. Lowe, Masters, and Hon. Sec., Rev. Prof. G. Henslow.

Hybrid Rhododendrons.—Messrs. Veitch & Sons sent five hybrids between East Indian forms, interesting as showing the effects of colours. The crosses were as follows:—1, Female, *Rhododendron jasminiflorum*, from Malacca (white); male, *R. Curtisi*, from Sumatra (small and scarlet). Hyb., scarlet corolla, a little broader than that of the male parent. Effect: male transferred colour and form; female had no effect. 2, Female, *R. jasminiflorum* (white); male, *R. javanicum* (orange yellow). Hyb., *R. j. carminatum* (bright red). Effect: male transferred the red colour, but the white female eliminated the yellow. 3, Female, *R. "Maiden's Blush"* (very pale pink); male, *R. Teysmanni*, from Sumatra (palish yellow). Hyb. *R. "Primrose."* Effect: yellow male transferred colour, unaffected by female. 4, Female, *R. "Princess Alexandra"* (large and white); male, *R. Curtisi*. Hyb., *R. "Eclatant,"* bright red. Effect: male transferred colour, female imparted size. 5, Female, *R. "Monarch"* (a hyb. from *javanicum*, but of a more pinky tinge to the orange); male, *R. Malayanicum* (very small, diam. $\frac{3}{4}$ in., but bright red). Hyb., "Little Beauty" diam. $1\frac{1}{2}$ inch, bright red. Effect: male transferred red, and eliminated the yellow. The general results observable are—1, The prepotency of the red male flowers and the impotence of white females to affect the offspring. When yellow is present—e.g., in orange, then either white or red can eliminate it (Nos. 2 and 5). The "Princess Alexandra" (female white of No. 4) arose in a similar way. A cross between the larger-flowered *R. javanicum* (orange) with the smaller, *R. jasminiflorum* (white), gave rise to Princess Royal (rose), the yellow disappearing. A further cross of the last with the parent, *R. jasminiflorum*, now eliminated the red; the offspring, however, retained the form and large size of the corolla of Princess Royal and *R. javanicum*. Mr. O'Brien observed that a similar elimination of yellow had occurred in Begonias, for *B. Sutherland* (orange) crossed by *B. parvifolia* Dredge (white) had given rise to a red flowered offspring. *Abutilons* afforded another instance.

Rhododendron Carringtonia.—Baron von Mueller sent a description of this new species, which occurs on almost inaccessible declivities of Mount Obree, at elevations of 6000 to 7000 feet. The corolla is white (from Viet. Naturalist, Nov., 1887).

The Silver Fir (Abies).—Mr. Plowright sent the following communication with specimens:—"The extreme tip of the branches of the Silver Fir are often found bare of leaves and variously swollen and distorted. This condition has been assumed to be the result of injury from their having been bitten off by squirrels or other animals. In the specimens sent herewith, which have been given to me by Mr. H. Munro

of Cleveland, Lyme Regis, the mischief is caused, not by animals, but by a fungus, the so-called *Peridermium columnare*. Robert Hartig worked out the life history of this fungus in 1880. He found that the *Æcidium columnare* A.P.S. is a heterocicmal fungus, the teleutospores of which occur upon *Vaccinium Vitis-Idææ*, and are known to mycologists under the name of *Calyptospora Goeppertiana* (J. Kühn). The *Calyptospora* is not a British species, so that it is difficult to account for the presence of the *æcidiospores*, R. Hartig, Forst und Jagdzeitung, 1880. "Lehrbuch der Baum Kraukheitlu," p. 56 to 61, t. ii. Prof. J. Kühn has, however, recently repeated Hartig's cultures with this result. He finds that there are two *Æcidia* on the Silver Fir, the true *Æc. columnare* of Abertini and Schweitz, which has for its teleutospores *Calyptospora Goeppertiana* and another *Æcidium* much resembling *Æc. columnare*, but with a different life history. This *Æcidium* he proposes to call *Æc. pseudo-columnare*, and it is most probable that the fungus which has injured the accompanying shoots of Silver Fir is Kühn's plant."

Potato with Incarcerated Beetle.—Mr. Maelachlan exhibited a Potato perforated and with a large internal cavity. A predaceous beetle, *Pterostichus madidus*, had somehow entered and apparently could not escape. The lining of the cavity, which had seemingly been excavated by some animal, was provided with a strong layer of cork cells.

Aluminium in Plants.—Prof. Church called attention to the fact that though large percentages of this metal are well known to exist in Lycopodiaceæ, it was not hitherto suspected to be general in flowering plants. A Japanese chemist having discovered it in *Rhus Vernix*, &c., in the gum of the laequer resin; Prof. Church examined Cherry tree gum, gums arabic, tragacanth, &c., and found traces to be invariably present. In the "Analyst" for January it is stated that it is also invariably present in the gluten of Wheat, in this case as a phosphate of alumina. It does not occur in association with the starch. From the precautions taken it could not have been due to the millstones. In all cases it is probably accidentally absorbed by the roots and plays no part in vegetable physiology.

Orthesia insignis, "Coccus" on *Strobilanthes*.—Mr. Morris exhibited specimens of this newly discovered "bug," on *S. conspidatus*, from the economic house at Kew. It has been described and figured in the "Journal of the Quek. Mic. Club," vol. iii., p. 169. Mr. Michael observed that its habits did not agree with those of cecidi of which the larvæ lie dormant beneath the parent, but the young were always very active. The genus was, in fact, on the border of the coccidæ, and its nearest ally was *leeria*. A discussion followed as to the nature of the secretion of wax. It is generally believed to be renewed, the length of the secretion depending upon the age of the insect. Mr. Browne, in the paper alluded to, says it is spreading, and is now found on *Scutellaria*, &c., in the adjoining house at Kew. Mr. Lynch added that apparently the same species attacked *Acanthaceae* plants as well.

Clerodendron, n. sp.—Mr. Morris exhibited shoots of a new species received from Sir J. Kirk from Zanzibar. It is remarkable for having the basal parts of the leaves much thickened and curved for the purpose of support. The upper half of the petiole carrying the blade can oscillate, and becomes detached. It does not appear to be sensitive, but resembles the hooked peduncles of *Uncaria* and stipules of *Dipladenia*.

Monstrous Pears.—Mr. Henslow exhibited three forms of abnormal Pear growths, which appeared to explain the true nature of the fruit. The first was the "Bishop's Thumb Pear," which consists of a succulent rod-like structure, presumably of an axial character alone. In the second a branch bore two or more irregular whorls of leaves with hypertrophied and partly coherent petioles. This case, which does not appear to be common, seems to suggest that the upper part of a Pear—corresponding to the whole of an Apple—consists of the hypertrophied bases of the sepals. The figure of an Apple with so-called "interrupted growth" in "Teratology" (p. 327) would therefore receive its interpretation in that the lower part is axial and the upper foliar. The third case represented a more complete fusion, in that the successive whorls were all welded together.

Dr. Masters describes this form as follows:—"The axis dilates to form the lower fruit without any true carpels being produced, but at its summit a whorl of leaves (sepals) is formed. Above these another swelling of the axis takes place, also without the formation of carpels, and this, it may be, is terminated in its turn by a branch producing leaves."

Judging from the last specimen Mr. Henslow was more inclined to regard this "succession of pseudo-Pears" as whorls of leaves with hypertrophied petioles rather than as axial. This view was confirmed and accepted by Mr. G. Murray.

The fruit of a Pear, therefore, would seem to be axial below—*i.e.*, from its tapering point up to the base of the carpels; but foliar from thence upwards to the summit. Apples, therefore, would have no truly axial part at all.

Plants Exhibited.—Mr. R. J. Lynch brought the following from the Bot. Gard. Cambridge:—*Vanda concolor* ("Bot. Mag." 62, 3416); *Cymbidium sinense* ("Lodd. Cat." 37); *Moricandia* (*Orychophragmus sonchifolia* ("Bot. Mag.," 6243); *Acacia platyptera flore pallido*, and "Miss Hope's" Wallflower, a monstrous form, upon which Rev. G. Henslow undertook to report.

Pomegranate (English).—He also showed a small fruit, about 1½ inch diameter, grown on the walls of Emanuel College, Cambridge.

NEWTON'S SYSTEM OF GLAZING.

I HAVE seen various modes of glazing, but for strength, lightness and economy combined this stands foremost, but requires bringing more prominently into notice to be more extensively employed.

Fig. 5 gives a side view with the glass in position; the iron bar is galvanised, making it almost imperishable. The corrugation underneath

Fig. 5.

gives strength and lightness, and causes moisture condensed thereon to run down on the under edges.

As will be seen in fig. 6 they are provided at E with condense spouting, which carry off the water to the gutter outside; the glass resting on a separate rebate enables anyone to remove easily any dirt or grease that may accumulate in the channel, rendering the house free from drip. Paint and putty are entirely dispensed with, the glass being held securely in position at the bottom at B with a lead clip, which prevents any possibility of slipping down the roof. At C is a copper spring that allows for expansion and contraction; both these are fitted in holes punched in the bar, and the latter are bent to the size of the house required. These are only a few of the advantages.

Mr. A. H. Smec, who was appointed with Mr. James O'Brien on a Subcommittee to report on it for the Royal Horticultural Society, thought the most practical way would be to have a roof fixed in his own garden, and a Pine stove was selected for the experiment. This being heated by

A, Iron Bar. B, Lead Clips. C, Copper Springs. D, Glass. E, Condense Gutters.

a large hot-water tank, it can be imagined there is great condensation and formerly too much drip, but that is overcome now. Another house of equal size was glazed at the time with wooden bars and the glass bedded in putty, using the same material outside, and the first cost of this was about the same as the other. I have visited places where there are larger houses than this on the same principle, and in each case they give perfect satisfaction. I have no motive in recommending this system beyond making it known to the readers of the Journal who, contemplate building, how well it has answered in Mr. Smec's garden. It is patented by Mr. Edgar Newton, Hitchin.—G. W. CUMMINS.

IMPRESSIONS AND OBSERVATIONS.

WE live in a world of change, with a constant hankering after something fresh, and as there is nothing like frankness I may as well say at the outset that I am taking advantage of the new year, if not to turn over a new leaf, at least to change both the head and tail of a few jottings that may from time to time appear on matters of current interest. Being extremely sensitive and sympathising with human frailty, and having thought I discerned a shadow of it now and then, the substance of which appeared to indicate that my assumption of the philosophic pen name, "A Thinker," was a little presumptuous, I cast aside the distinctive pseudonym as I would cast off an old hat, for what may happen to be under it remains the same; and now whoever the cap may chance to fit can put it on.

I OUGHT in courtesy to acknowledge several inquiries as to my health and whereabouts that have found their way to my den. I am thankful to say I am no worse than I ought to be if I had my deserts for all shortcomings, and grateful that notwithstanding them I am permitted to take a turn at the wheel—wheelbarrow if you like—at the commencement of the year. As to where I am just now and where I have dwelt during the last fifty years, or what I have done, or am supposed to have done, in a past generation, is for present purposes, perhaps, immaterial; still if the curiosity of any reader of an inquiring turn of mind should desire those particulars and adduce a good and sufficient reason for their possession, he can have them by post. An arrangement of this kind may possibly avert the recurrence of past misunderstandings and slight mistakes.

BEING happily in charity with all men at the beginning of the year, and desirous of continuing in this placid frame of mind, I will try and be modest and unassuming; but with all my care may fail, as others have failed before me in practising what they preach. But I am not going to write in fear and trembling, nor suppress my opinions on subjects that may come to the front. I shall ignore all individualities in my observations, and know no rank nor class. Matters, not men, will be the leading idea, though sometimes they get so mixed as not to be very easy to separate. I hope all this is consistent with modesty; if it is not I cannot be modest, and there ends the matter—that is, as the theatrical people say, the prologue, and now for the “patter.”

MY first impression is that we have begun the new year well. A buoyant feeling of hopefulness pervades the editorial address for the reasons stated therein. Gardening is not going to recede but advance; public interest in horticulture is not destined to contract but expand. I am as confident of this as I can be of anything that is coming to pass. The difficulties that have been encountered have sharpened endeavour, and the greater and better the supply is of that which is essential to life—food and refreshment, the outcome of the soil, with the beauties of Nature as developed by skill—the more surely will a demand for them be created. I heard something like a groan the other day because plants had to be sold for half a crown now that would have realised half a guinea a few years ago; but what of that? The person who sold a hundred in one day, as he did, would not have sold a dozen if half that number in the palmy days he seemed to long for. When tea was 6s. a pound it was no better for the dealers, and when newspapers were half the size and twice or thrice the price they are now, it was no better for the vendors. On the contrary it was worse for them and for everybody. Such are my impressions of the editorial; but I must pass on.

“A YORKSHIRE AMATEUR,” who writes like a clergyman, follows with greetings, thoughtful and kindly. He recognises the facts of life, and more—reminds us of the Great Beyond. There are moments of sadness in the life of everyone; but then comes, as he shows, the sunlight on the page. May it be a happy omen to him and to all who love their gardens and do what he urges—their duty. Our friend informs us he is in gardening patter a Rose man. It is an honourable designation, and possibly no section of the community than the Rose-loving section, scattered as its constituents are all over the land, has done more to foster a taste for gardening. Many a plot previously dismal, little more than a weedy waste, has been by the influence of good examples made bright and sweet with what is and will remain the national flower—the Rose. May the year be a great Rose year, and all who strive to make it so reap reward for honest endeavour in the good work.

THEN our good adviser tells us to cultivate the virtue of kindness in our little controversies, and not to use verbal brickbats for arguments. Very good. I hope we shall not, nor what is less vulgar, perhaps, though not more admired, seek a vulnerable point in the armour of a supposed enemy for shooting a dart, scarcely visible in transit, but which wounds him for whom it was intended. To speak the plain truth, however, I have observed persons who do not pretend to like literary combats enjoy them immensely when out of the fray. But they may easily continue too long and grow too severe, friendly though the combatants may be personally. I have often thought they understood each other, and were merely playing before the public. I am at any rate in the happy position of not having, to my knowledge, lost a friend nor made an enemy in a few literary skirmishes in which I have been engaged. We cannot be always digging and delving, or “singing sweet songs of love” to each other, but must have our little fracasos to sharpen the wits, like sparkling wine. But we may all remember, and we ought to hear steadfastly in mind, the great truth brought before us so opportunely, that “a soft answer turneth away wrath.” I suspect, however, it is in the nature of our race to be combatant; anyhow there is always a crush in Parliament when a “row” is expected, and we ought to find the best of natures there.

NEXT a great gardener speaks, a man of whom British horticulturists ought to be, and are, proud—Mr. David Thomson. I have had the pleasure of seeing him at home in the “old Duke’s time,” when the noble demesne of Drumlanrig was nobly kept. It was a treat to see the gardens then, and whatever changes death may have wrought, the chief centre of interest to gardeners remains in the man (though some lesser souled than he would object if so described) who has done so much with spade and pen to improve the craft that he adorns. Like a veteran he stands back on a point of vantage and surveys the field. To see the extent of a wood we must get from amongst the trees. Recognising the mighty strides that have been made in his time in the domain of gardening, he has faith in its future extension. So have I. Remedies are found for ills by thrifty, prudent, and enterprising nations, and peace brings prosperity, of which gardens are sure to have a good share in this land of gardens, Great Britain, and let us all in one deep wish and prayer add, Ireland. I thank you, Mr. Thomson, for your cheery contribution, and should like to whisper in your ear, Write again.

POSSIBLY, however, even a gardener so eminent, and with such a wide range of experience, may fancy he does not know what to write about. Let me reproduce a text. “It is sad to see the public tendency to prefer mere size to quality, for in the markets all good qualities must go to the wall in favour of size.” Nor does this apply to fruits

alone, but to vegetables; nor to markets alone, but to shows. It is “sad to see” leading prizes awarded to Potatoes unfit to form part of a respectable dinner. Brussels Sprouts will be spoiled if a reaction does not soon set in, and Onions in the form of flat-footed monstrosities are on the road to ruin. Seedsmen cannot be blamed, as they must meet the demand for big things, but judges at least should give due weight to quality. Not long ago a prize was very nearly awarded to Potatoes averaging more than a pound each, when the third judge put in an emphatic “No,” remarking “if you honour such coarse tubers, and condemn the smaller, and obviously superior, what do you think the character of the show will be next year?” They saw the point, and were glad they escaped making a great blunder. The multitude, no doubt, must have bulk, as much as can be had for money, but the majority of gardeners do not cater for the multitude, and many of them, if not most, grow the produce of gardens too big by half.

“O. T. C.” (page 3), writes well, on what is not often written about by a master of its culture, that gorgeous terrestrial Orchid *Disa grandiflora*, and the extract from Dr. Harvey in which its natural habitat is so vividly described is highly suggestive and instructive. I have seen plants apparently quite happy in handlights, with the lids propped up in a damp position on the north side of a wall in summer, also in the little greenhouse of an amateur, facing north from which frost was only just excluded in winter. “D., Deal,” and Rev. F. Tymons have also told us how they succeed with this plant, which is not difficult to manage when its requirements are understood, and the citation on page 3 makes these clearer than I have hitherto seen. The best *Disas* that have come under my observation were near a tank at the end of the Heath house at Chatsworth, “between a door and a ventilator,” just as described in the notes of your correspondent, who perhaps has seen them too. There are blue *Disas* now, I believe, but I have not seen them; perhaps somebody can tell us something about the new comers.

WHOEVER penned the article on “Melon Growing Made Easy” (page 5) is, I venture to say, a worker. There is no flourish about him. You may almost see “P. D. T.” carrying out the details he points out, with good crops at the end. Such practical notes are of real service to many, for the inexperienced are always with us taking the places of others who have passed to higher grades, and it is hoped they always will be, for armies can only be kept at the full strength by the accession of recruits.

AND now I come to my old friend, Mr. Iggulden. His “Facts about Grapes” have been throughout sensible and good, but I am lucky enough to find a little to differ about in his notes. He says, on page 4, that “Alicante is superior to Gros Maroc as usually met with, Gros Colman and Alnwick Seedling.” That is not quite my experience. Gros Maroc varies greatly, and is not, as a rule, so good as it looks. I have tried samples of all the Grapes named from three districts lately. The Gros Colmans in each were superior to either Alicante or Gros Maroc, and so was Alnwick Seedling. I have only once found this inferior to Alicante from Vines in the same house, but it cannot be compared with it for easy culture, and as a late Grape for untrained amateurs. By far the best Gros Colmans I have tasted this year and much superior to any Alicante I have tried, were grown at the West Lynn vineyard. Mr. Iggulden does not appear to have a very high opinion of Golden Queen. I know only of two gardeners who grow it well—Mr. Allis at Old Warden, and Mr. Wallis of Keele Hall. Mrs. Pearson, to my mind, is far in advance of it. Mr. McIntosh has it fine at Duneevan every year, where it ranks among the best in his good collection, and now Mr. Goodacre speaks a strong word in its praise, and a Grape, I fancy, cannot be very bad that he calls good. But I see the “facts” are not finished, therefore I will say no more on Mrs. Pearson at present; but just one more word about Alicante. I think it is a good variety for bad Grape growers, though many good ones produce it grand in appearance and even fairly good in quality, though in that respect I am not able to regard it otherwise than a second or third-rate Grape.

I PASS the Orchids with the remark confirmatory of the observations of “J. J.” that more Orchids are ruined by overpotting than by any other mistake in management, except a want of cleanliness, and I do not think that such names as Mrs. Gamp and Mrs. MacMuggins are appropriate for this aristocratic race of plants. If *Oncidium Jonesianum* had been named in “popular” fashion it would be *Oncidium Rev. Mr. Jones*—the clergyman who flowered it, and this would scarcely be more euphonious and suitable than the latinised appellation. But perhaps I may be prejudiced in this matter through my aristocratic tendencies, which I have tried to shake off, but they were renewed the other day through dining with a noble lord, and I fear I shall not be quite myself again till I have done a little digging.

I COULD say much about woods and plantations, having had a few scores of thousands of trees through my hands and watched them grow into money. Mr. R. Parker has placed his finger on a great blot in the management of many estates, or rather two blots—1, neglect in planting; 2, what is perhaps still more sad to see—ruined plantations through want of timely and systematic thinning. Similar neglect is painfully flagrant in many shrubberies where evergreens and ornamental trees have been purchased at considerable cost, only to be spoiled. A reformation is greatly needed in the planting and management of trees and plantations. Vast tracts of land now profitless might bring in a

substantial return in a few years if properly planted and the trees not left to ruin each other through overcrowding.

SEVERAL letters have appeared denoting a little uneasiness among gardeners, while some of the "heads" do not seem to be altogether comfortable. It is no use mincing matters nor attempting to hide existing facts. There have always been a few greedy and exacting gardeners out of the many who are just the reverse, and there have always been namby-pamby youngsters who think they "do all the work" while everybody else gets all the plums and the praise. I could relate some rather curious experiences on this subject. I have heard of one generous member of the craft winning a valuable cup and a good round sum giving the money to his youthful helper; and of another—well, I will not say just now exactly what I have heard about him—but to put it mildly, he does not treat his subordinates with half the consideration that his master shows towards him. In my opinion, and I have had experience on both sides of the question, when a gardener is allowed to make all he can at shows, and keep it, he should not press on his assistants too hardly nor work them excessively in season and out of season for his own profit, and these in turn should not indulge in "great expectations," but be content with a little of the encouragement that may and should be given, and which in many cases is readily granted in some form or other, this at the same time stimulating to further effort and sweetening labour. This is a subject on which very calm reflection is needed on both sides, and each should endeavour to grasp all the circumstances of the case, then act in accordance with the spirit of the grand old rule, the fairest and the most just that can be adduced, of doing unto others as you would have them do unto you. If the men could think the matter over fully from the master's standpoint, and the masters look at it from the men's position, no harm could be done, while there would at least be the possibility of good resulting.

JUDGING from what is not infrequently heard, I think I must be a little differently constituted from some who have a good desire to share in the literature of gardening, inasmuch as while they "cannot find anything to write about," I can find a great deal more than I can deal with. Here I am, not half way through one issue of the Journal, and must stop my pen, even with one of the best articles before me—that on packing fruit by Mr. Pettigrew. It is rare indeed to find a subject, however ably handled, exhaustively treated and leaving nothing more to be said. Thought gives birth to thought, and mind influences mind, impressions being formed either in harmony with or antipathy to those recorded, for reasons which if adduced would add to the common stock of knowledge. But this cannot be done without effort, at least I cannot "knock off" a series of notes, however simple they may be, without some deliberation, and I only regret that more cannot be given very often for reducing their crudity. I am not a believer in the "born genius" theory. With the exception of about one in ten millions a man is what he makes himself, whether a genius or a fool, or the impersonality of any grade between, and there is not an intelligent aspirant who reads these notes who cannot, if he tries, not fitfully, but perseveringly, soon reach what many a ripe gardener has attained—a higher grade in the ranks, the fighting ranks if you will, of the army of horticulturists, than is occupied by—and here is the new and neutral sign manual for 1888—SPECTATOR.

P.S. — In reference to the observations of a leading gardener on page 27 last week, and my thoughts thereon, let me say that I have often noticed when a judge in summing up a case highly compliments one of the advocates at the outset, the flattered man is almost sure to lose in the end, and therefore I shall not be surprised if I have to play second fiddle to this same leading gardener before the year is out. Let us hope we shall both, and all others, keep in tune.—S.

HYBRIDISING AND CROSS-FERTILISATION. CARNATIONS.

REFERRING to your report of the American Commission at Chicago on the above subject, which appeared in your issues of the 15th and 29th ultimo, Mr. C. T. Starr speaks of the Carnation in particular and his experience in cross-fertilisation in America, allow me to confirm some of his notes as to the same work on this side the Atlantic. Following upon the scientific researches of Professor Charles Darwin and the hints given in that able work of Dr. J. E. Taylor's "Flowers, their Origin, Design, &c.," I noticed the most able natural fertilisers of the Carnation are the humble bees (*Bombus terrestris*). It seems as far as I have noticed that the hive bees have not power sufficient to open the petals to get to the nectaries. Whether the night moths (*lepidoptera*) work these flowers with their powerful long proboscises or not I have not been able to ascertain, but it is evident to me it would require more than the strength of the hive bee to do so. It is certain that after the visit of the humble bee to a flower it is no use for show, for it makes a hole in the centre, disarranging the petals so much that they cannot be re-arranged by dressing. Having raised twelve seedlings of some merit during the last five years from purchased seed, and having a dark crimson "Gipsy King" of a strong robust constitution, smooth, stout petalled, very floriferous, and throwing grass so early that layers struck as soon as flowered in August may be bloomed as early as the end of November under glass, equal to the summer bloom; I made this the male and took "The Governor" as the female

plant. Three days after fertilising I found the petals of the female beginning to curl, and they soon became disarranged, and having concluded that they were no longer needed, the power of the sap having been diverted to the growth of the seed and supplying nutriment to the ovaries, I removed the petals, a few daily, soon leaving the seed pod freed from any material likely to cause it to damp; on the other hand I left a few others with the petals in them. The result was that the pods of the latter damped, but the others soon developed into large pods of seed. I gathered six pods of this same cross on the 1st October, three of which I fertilised on one division of the pistil, and the other three on both, and these I am keeping distinct, as I anticipate a different result. I sowed the seed after exposing it three days on a sunny shelf, and in four days after sowing I was surprised to find nearly every seed had germinated, and have now nearly 400 plants, 2 inches high, pricked off into boxes and placed on a top shelf near to the glass in a cool house, where they continue strong and sturdy. I intend potting singly in February and removing to a cold frame, and expect them to bloom from August to October this year. This would bear out Mr. Starr's experience, except that I am in advance of Mr. Starr by four months, and I may add the experiment was upon plants in the open ground and not under glass. The result I shall be pleased to send you in September, and by then be able to accord a cross with "Mary Morris," a plant raised last year, just bloomed, deeper in colour, larger, and of the two more robust. I append a few short notes as to growth, &c., for amateurs.

HOW TO GROW AND SHOW CARNATIONS AND PICOTEEES.—*Soil*.—Stiff loam or decayed turf three parts, leaf mould one part, mix road grit or coarse sand to render it open.

Potting.—Pot in the above, keep them in a cold frame during winter, giving air in open weather, plant in border (or shift into larger pots) in April.

Staking.—Use two sticks, tie round same with bast, resting the stem between.

Water.—They should never want water. In dry weather water twice a day (if needed). In continuous dry weather put a little moss or cocoa-nut fibre refuse round the roots to produce continual humidity.

Manure.—When buds are forming the only manure should be liquid from sheeps' droppings or cowdung twice a week. Avoid all artificial manures. These and strong liquid make the colours run.

Preparing for Show.—Preserve a leading bud, pinch off second and third so as to force strength into first bud. If buds begin to split, cut the calyx down slightly at each division to help equal bursting.

Dressing.—But little is needed to a good flower. The guard petals should be flat, smooth, and flower round, the others should be arranged evenly to overlap the divisions of the under ones. Bone tweezers are best for this purpose, which should be made warm as the dressing is done.

Quality of Flowers for Show.—1, Roundness. 2, Smoothness of petal. 3, Even colour. 4, Brightness of colour. 5, Depth of flower. The inner petals should be well up.

Showing.—Show on cards 3 inches in diameter, with round holes cut to the centre. Some put a second ring not quite so large, and cut in slits in the centre, and this if forced up over the lower part of the calyx will set the flower up off the box. Flowers should be equal in size (if possible), the largest (if any) in the back row. The box must be made sloping 4 inches high at the back, 3 inches at front, holes for cups 3½ inches apart each way. Arrange the colours so that one does not mar the others.

Crossing.—If in pots, these should be at least 6 inches over. If out of doors in border (it is best to have some of both), see that the ground is turned in winter to be seasoned by frost and mix in leaf mould, cow dung, and road grit or burnt ashes (or turf if the ground is light).—W. GILBERT, *Bishop's Waltham*.

WHITE CUCUMBER.

I BEG to bring to your notice a white Cucumber, which I have grown this last summer. It is known that the Vegetable Marrow will produce both green and white fruit from the seeds of a green fruit, or *vice versa*; but I am not aware that this peculiarity in the origin of different coloured fruits has been shown to occur in the Cucumber plant. But this last summer, as I have said, I had the satisfaction of seeing the seeds of a green Cucumber give rise to plants which bore white and green fruit; and the following are the facts connected with that occurrence.

For several years I have grown the long prickly Cucumber out of doors, and have obtained seed for the following year. In 1886 the seed was obtained as usual; but the plants springing from it yielded this last summer both green and white fruit in about equal proportion, and of equal size. I allowed one of each kind to ripen, and with the seed of the white one I shall experiment next season to see whether the plants will yield only white fruit, or mixed white and green fruit, or whether the fruit will revert to the original type—the green Cucumber.

Probably this sport of Nature may not be new to you, though it is uncommon to me; but I forward to you some seeds of the white sort, by which experiments can be made by anyone who has an interest in watching the result.—GEO. VINER ELLIS.

WILLIAM ALLEN RICHARDSON.

IN reply to "A Lady Gardener" I may state that this Rose does well under glass early in the season. It grows well, even luxuriantly, and flowers freely whether forced or allowed to come into flower naturally in a cool house. Well ripened plants by gentle forcing can be had in bloom from the middle of February. It does well grown in pots either trained under the roof, or the strong shoots trained round five stakes placed round the sides of the pot in autumn. If the last method is practised after strong shoots issue from the base after flowering the old wood can all be cut away and the young ones trained under the roof until they are ripe. They can then be placed outside & cured to a wall or fence until they have been exposed to frost, which will induce complete rest. It will do splendidly planted out, and the flowers early in the season will last longer fresh in water than those of any Rose I know.

The plants purchased now will not do for forcing. They should, whether planted out or grown in pots, be brought forward into growth under cool conditions. To start them in heat or attempt to force them the first season will ruin them. We presume those purchased will be plants lifted from the open ground. Planting out is strongly advised, if practicable, to keeping them in pots. In the latter they are confined at their roots, and naturally decline in vigour after a few seasons even under the best of treatment, unless they are transferred annually into larger pots.—W. B.

FORCING ROSES.

I AM glad to see in to-day's Journal a column specially for Roses. Though I have long grown in quantity Roses at all times of the year, yet, like "A Suburban Amateur," I much wish some really able Rose forcer, from large experience, would tell us in "our Journal" all about how Roses should be and can be best grown in December, January, February, March, and April; including the best and most practical kind of house and heating arrangements.

I have been a diligent reader of our Journal for seventeen years, and whilst I readily admit more valuable practical knowledge of Rose-growing has been given to the world in it during that time than all other papers put together, yet I wish to say but little on the subject of forcing Roses has been given.

The four papers in *Garden Work*, given last year, were good, and amongst the best available, but "our Journal" should give us something fuller and more exhaustive than those or of anything now published.—S. S., *Herts.*

ROSE QUESTIONS.

I AM much obliged to those correspondents who have written in answer to my last letter, and have a few words to say in reply. Mr. D. Gilmour is an enthusiastic patron of the seedling Briar, and he advocates what was quite a new idea to me when I saw his article in the "Rosarian's Year-Book," I mean cutting off the tap root even before the seedling is budded. In my innocence I thought the great, if not the sole, advantage of the seedling Briar as a stock was the possession of a tap root. If this has to be cut away in order to make it root horizontally like the cutting, I am even more inclined than before to give my preference to the latter. For what advantage under these circumstances has the seedling? "Its greater vigour," says Mr. Gilmour. But with me cuttings of the same age have made as much top and more root than seedlings; however, I have never tried the plan of depriving the latter of their tap roots. I wonder, by-the-by, whether anyone has tried the seedling Manetti.

Mr. Gilmour says, "The greatest merit the seedling has is that it is grown from seed, seedlings being as a rule more vigorous than cuttings." If I may quote from the "Year-Book," he there explains this statement thus:—"The cutting is part of a branch cut from a tree, and made to root by a certain course of treatment. The seedling is a perfect plant grown from the seed of the wild Rose." Now it is, I think, an interesting question whether the statement that a seedling is a more perfect plant than a cutting, is much more than sentiment. I think most people would say that there is at least something of truth in it, and that all plants are likely to suffer from too much or too long continued artificial propagation. They would probably point to the unhealthy constitutions of the Ribston Pippin Apple or Moorpark Apricot as instances of this, and if rosarians, would perhaps bring forward the alleged tendency to canker in *Maréchal Niel*, and the slow degeneration of other Roses, such as *Prince Camille de Rohan*. But these arguments would not apply to the Briar, which is only occasionally propagated in an artificial manner, and I think a majority would say that for all practical purposes the cutting Briar would be as perfect a plant as the seedling, especially if the latter were deprived of its tap root.

I do not know whether it is fair to allude in this place to another statement in the "Year Book" by Mr. Gilmour on this subject. My hear y apologies to him, if I am "not in order." He therein says the seedling Briar does not make suckers, "at any rate, not to anything like the extent, or the half of it, that the cutting does. . . . The

cutting is full of eyes to start with, and will anybody attempt to argue that the boys who are employed in nurseries to do this kind of work can remove the eyes from the cuttings so well and so completely as to make cuttings equal to seedlings, which latter have no eyes on their roots at all?" That boys are fallible is an axiom well understood by gardeners and most people. The farmers in this part of the country have a saying that "A boy is a boy, two boys are only half a boy, and three boys are no boy at all," the meaning of which, of course, is that when boys get together they are sure to play and "humbug." But is it not a little "rough" on Briar cutting to say that it is subject to suckers because boys are not trustworthy, and because some people neglect the good old adage, "If you want a thing well done do it yourself?" Many thanks, however, to Mr. Gilmour for his notes, which are always interesting.

I am extremely obliged to Mr. Worthington G. Smith for his kind answer to my query. I did not know that mildew was ever invisible in its summer stages. The case which I had in my mind of *Rose* mildew in a greenhouse was this: In April, 1886, I moved a *Maréchal Niel* standard which had stood out all the winter, and was pruned to within an inch or two of the stock, with no leaf remaining, into a house where, to the best of my knowledge, there had been no Roses before; it made three long shoots during the summer, on which I never saw a sign of mildew, and I often examined it. Towards the end of next March mildew appeared where there had been a little too much ventilation. It looked as if it had come in through the shutter, but if the simple spores are sometimes invisible to the naked eye, I suppose mildew was present during the previous summer, though undetected.

Many thanks to "S. C. B." for his recommendations of preparations against mildew and thrips. I thought I had explained that the varieties which with me are spoiled by thrips are just those which are equally damaged by the clearest water when once they are in bloom, and therefore nothing liquid can be used. Preventive measures against mildew and thrips are what we want.—W. R. RAILLEM.

THE CATALPAS.

THE majority of hardy trees grown in this country possessing any floral beauty produce their flowers in early spring, and the ornamental shrubs cultivated here are mostly similar in this respect, so that by midsummer there are few attractions left in gardens where trees and shrubs are valued. The Catalpas, however, provide a much later floral display, and if for this alone, they would be worthy attention; but they possess several other good qualities, such as flourishing near towns, possessing a remarkably strong vitality, being of quick growth, and with their broad fresh green leaves are really beautiful for their foliage, and useful as shade-affording trees. They certainly also have a few defects, but they are chiefly experienced in northern or exposed situations, and in the south many handsome specimens may be seen that for half a century have been amongst the most admired occupants of gardens.

CATALPA BIGNONIOIDES.

The tree so generally known as "the Catalpa" is now recognised by authorities under the above title; the name *C. syriaca*, which is also widely used in nurseries and gardens, having been formerly given to the same tree, and is now ranked as a synonym of *C. bignonioides*. The adoption of these two names has caused some confusion, and even now it is not uncommon to find them classed as distinct in trade lists. Some of the earlier writers referred this tree to the genus *Bignonia*, to which it is closely related, and it was consequently described as *Bignonia Catalpa* in several botanical works. It appears, however, that the same designation has been conferred upon at least two other species—namely, *C. Kämpferi* and *C. speciosa*, the former by Kämpfer and Thunberg when describing the plants of Japan, and the latter by writers on the North American Flora.

Catalpa bignonioides is an old inhabitant of English gardens, as it was introduced by a Mr. Mark Catesby from Carolina in 1726. It is faithfully described by Phillip Miller, and it was included in the Kew collection at the time Aiton published his "Hortus Kewensis." The tree is a native of Georgia and neighbouring States, but it was early and extensively planted for ornamental in the towns of the northern States as far as Massachusetts, and is now a common tree over a wide area. Loudon in referring to it says, "The French of Upper Louisiana call the tree Bois Shavanon from its being found in abundance on the banks of the Shavanon now called the Cumberland;" but as will be noted farther on, Dr. Engelmann considers this term was applied to *C. speciosa*, and had a different origin. In the southern counties of this country and on the Continent the Catalpa grows as rapidly as in its native land, quite a good sized tree being formed in ten or twelve years, and this has recommended it to many planters. Another advantage is that it succeeds in damp situations where some Conifers and other trees will not exist, but with the common Birch, Poplars, and Willows it flourishes admirably. A waterlogged soil is not suitable for it, but it does not object to abundant moisture where there is

a good natural drainage. In deep alluvial soil it makes most vigorous growth until a height of 30 or 40 feet is attained, and

branches, but the curious part of it is that a previous stem nearly as large had been produced, and from some accident it had to

FIG. 7.—CATALPA BIGNONIOIDES.

after that it becomes more spreading and bushy owing to the production of numerous strong lateral branches.

A tree in my garden at Merton is one of the oldest specimens I have seen, although it is not of remarkable size. It is about 40 feet high, with a stem 2 feet in diameter at the base and widely spreading

be cut down close to the soil; a shoot from this was, however taken up and has now for many years attained its full size. The tree thus had two lives as it were, and probably dates from some time in the last century. This Catalpa produces its leaves very late, and they are rarely fully out until the end of

May. They are also destroyed by the first severe frost, and in the past autumn both it and an old Mulberry were almost denuded of their leaves in one night. The largest leaves are 1 foot long by 8 inches broad, heart-shaped, and tapering at the tip, of a peculiarly bright fresh green, quite distinct from the majority of deciduous trees, and in contrast with a dark *Pinus* and *Arbor-Vitæ* the tint is very striking. The flowers are produced very freely every year during August, and they are occasionally followed by long narrow pods 8 inches to a foot in length, but this rarely happens except after a hot summer. Strangely enough the tree did not bear one fruit last year, although the season was so favourable; perhaps it was too dry. In some gardens this *Catalpa* bears its fruits more frequently, certain peculiarities of situation no doubt helping it. In the United States the fruits often remain on the tree until the following spring.

When in flower the tree is very handsome, the large panicles being borne in great numbers, and for a fortnight or more these expand in succession. The corollas are peculiarly crumpled, with spreading lobes and a short inflated tube, white with yellow lines in the throat, and numerous small violet or purple dots, which give it a beautiful appearance, something like the spotted *Gloxinias*. The calyx has a dark purplish tinge, the pedicels being similar, and they serve to show up the flowers still more. The illustration (fig. 7) represents a panicle of ordinary size, many exceeding it in length, and with larger individual flowers. They are almost useless for cutting, as they last but a short time when placed in water.

The tree is almost solely planted here for ornamental purposes, and a moderately sheltered position should be chosen when possible, as the leaves, being of delicate texture, are soon torn and injured by wind. The wood being very brittle, the branches are soon broken and the symmetry of the tree completely spoiled. In the south it is rarely injured by frost, but the previous season's growths if unripened are occasionally killed. Owing to its starting so late in the spring it usually escapes the frosts that are often so disastrous to fruit trees. The wood is very light, but when matured and well seasoned is said to be durable, and large numbers of trees have been planted by the railway lines in North America to furnish timber. Judging by the wood produced here, however, it would not be expected to be of much use, as it is extremely brittle and pithy. The bark is of a corky nature, grey, or almost white, and it is said to possess some medicinal value. One curious character is the freedom with which shoots are produced from all parts of the old branches or stems when cut back or injured in any way.

The variety of *C. bignonioides* named *aurea*, which is remarkable for its rich golden leaves, has come into notice of late years, and is one of the finest ornamental foliage trees we possess. Throughout the summer, especially in warm bright seasons, the leaves assume a golden hue that is most effective amongst variegated or green-leaved shrubs or trees. Last season I saw a large quarter of young specimens of this variety in a nursery near Richmond, and the unusually rich colour was very notable. Though not frequently seen in gardens it has been in cultivation for over eighteen years, as a certificate was awarded for it by the Royal Horticultural Society in 1870.

CATALPA SPECIOSA.

Most of the other *Catalpas* are but little known in English gardens, but *C. speciosa* is so nearly related to *C. bignonioides* that it was long regarded as that species, and it may possibly be still found in some collections under that name. It is regarded as the representative of the better known tree in the valley of the Mississippi, and Dr. Engelmann has said that the French settlers called it Shawnee Wood (*Bois Chavanon*) after the Indians in that district. It was first brought prominently into notice as a distinct species in 1853 by a Dr. Warder, and it was then propagated extensively by Messrs. John C. & E. Y. Teas of Indiana. It is more erect in habit than *C. bignonioides*, equally quick in growth, and flowers several weeks earlier. Fruits have been produced as much as 20 inches in length, but they are usually much shorter. The flowers are whiter than those of *C. bignonioides*, and their handsome appearance led to the adoption of the name *speciosa*.

CATALPA KÆMPFERI.

This is the Japanese tree already mentioned as being described by Kæmpfer under the name *Bignonia Catalpa*. By some it is regarded as a geographical variety of the American species, but it is very distinct in habit, being dwarfer, more bush-like, with lobed leaves. The flowers are also smaller, yellow spotted with red, but they are fragrant. It was introduced from Japan in 1862, and is figured in the "Botanical Magazine," t. 6611. Sir Joseph Hooker there states that it was discovered by Kæmpfer in 1693, and introduced into Belgium by seed in 1849. It has proved perfectly hardy, and though not attaining the stature and size of leaf and flower of *C. syriaca* (*C. bignonioides*), it is a most welcome addition to

the tree flora of Europe, being easily propagated by seeds, which have been ripened on the Continent and by cuttings. *C. Kæmpferi* is often found under the name of *C. Bungei*, a very different tree, not hitherto introduced into Europe, which is a native of North China, has a much larger flower, and pods 18 inches long.

CATALPA BUNGEI.

A dwarf-growing tree from North China, described as having lobed leaves and yellowish flowers spotted with red, borne in a raceme. This rarely exceeds 10 feet high, and a variety with very diverse leaves is named *heterophylla*. It is evidently a near relative of *C. Kæmpferi*. *Catalpa Pottsi*, said to be from Mexico in 1851, with pink flowers, I do not know, and the two stove species, *Catalpa longisiliqua* or *C. longissima*, and *C. microphylla*, from the West Indies, are rarely seen out of botanical collections.—LEWIS CASTLE.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE annual meeting of this Institution was held at Simpson's, in the Strand, on Friday last, the 13th inst., when the chair was occupied by Harry J. Veitch, Esq. With a few preliminary remarks the following report was read to the meeting:—

REPORT OF THE COMMITTEE OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION FOR THE YEAR 1887.

It is with infinite satisfaction that the Committee present their report for the year 1887, and they sincerely congratulate the subscribers on the great success that has attended their labours during that time.

During the year fourteen pensioners have died, five leaving widows, and these having been found worthy, and having in every way complied with the rules, were, in accordance with Rule 7, placed on the pension list in succession to their late husbands.

This being the year of Her Most Gracious Majesty's Jubilee, it was, after very mature deliberation, determined by the Committee that some steps should be taken to mark that auspicious event, and it was eventually arranged that a special Jubilee grant of £5 should be made to each of the pensioners and each unsuccessful candidate at the last election, and that a special appeal for this object should be made to the public and the horticultural world. This appeal, your Committee are pleased to say, was nobly responded to, more particularly by gardeners, to whom special collecting cards were issued, resulting in a clear sum of £677 12s. 2d. This with the donations, &c., received at the annual festival have enabled the Committee not only to pay the largest amount ever distributed in pensions—viz., £2124 10s., but also to make the proposed Jubilee grant, amounting to £655, without trenching on the reserve fund.

This has been, with one exception, the most successful year on record, and the Committee have to return their best thanks and acknowledgements to Baron Ferdinand De Rothschild, M.P., who so kindly presided at the anniversary festival on the 29th June last, who, by his influence and his eloquence, added to his liberality and that of his friends, so materially assisted in securing a very large subscription list, and making the festival one of the events of the season.

It is with infinite satisfaction that your Committee have to announce that the Right Hon. Joseph Chamberlain, M.P., most kindly consented to succeed Baron Ferdinand De Rothschild as chairman at the festival when held in the ensuing summer, and they have reason to believe that with such a distinguished President the festival will be a grand success.

The number of pensioners on the list is 114 now, this day increased to 126.

After the report was read the following resolutions were adopted:—

I.—It was moved by Mr. B. Wynne, and seconded by Mr. A. F. Barron, and carried unanimously, That the Report of the Committee and statement of the accounts of the Institution as certified by the auditors now read, be received and adopted, and that the best thanks of this meeting be given to the Committee for their able management of the Institution during the past year.

II.—Moved by Mr. John Lee, and seconded by Mr. W. Roupell, That Mr. Harry J. Veitch be elected the Treasurer, and that the thanks of the meeting be presented to him for the great interest and trouble he has taken in the affairs of the Institution during the past year.

III.—Moved by Mr. W. Richards, and seconded by Mr. John Lee, That Mr. N. Sherwood, Mr. John Roberts, Mr. John Laing, Mr. A. F. Barron, Mr. Geo. Woodgate, and Mr. Henry Tillman be elected on the new Committee.

IV.—Moved by Mr. Webber, and seconded by Mr. Richards, That Mr. John Lee, Mr. J. F. Neston, and Mr. Jesse Willard be re-elected auditors.

V.—Moved by Mr. Watkins, and seconded by Mr. Woodbridge, That Messrs. E. Tidswell, James Webber, E. W. Cathie, George Mouro, and William Richards be appointed arbitrators.

VI.—Moved by Mr. John Lee, and seconded by Mr. Watkins, That Mr. Cutler be re-elected Secretary.

VII.—In consequence of four vacancies having occurred in the list of pensioners since the voting papers were issued, the Committee recommend that after the pensioners for whom the election has been called have been elected, the four next highest on the poll shall be declared elected. Mr. H. J. Veitch proposed, and Mr. Woodbridge seconded the adoption of this suggestion, which was agreed to unanimously.

VIII.—The Committee also recommended that Elizabeth George, Patrick John Haraby, and Caroline McElroy, being in distress and having complied with the regulations, should be placed on the pension list, in accordance with rule 6, without the trouble and expense of an election. Mr. Veitch moved and Mr. Watkins seconded this proposition, which was adopted.

IX.—Moved by Mr. A. F. Barron, and seconded by Mr. Monro, That the best and grateful thanks of this meeting be presented to Baron Ferdinand de Rothschild for his great kindness in presiding at the last Anniversary Festival, for the able and eloquent manner in which he advocated the cause of the Institution, and for his liberality and that of his friends upon the occasion.

It was unanimously resolved that a grant of £10 be made to the widow of Charles Osman of North Wootten, Sherborne, who died only a fortnight before the election, and who, if he had lived till then, would have been certain of success.

The total number added to the pension list was twelve—namely, the three mentioned above and the following—Thomas M. Wall, Matilda Charlton, Charles Papworth, James Ewing, William H. Head, Elizabeth Horton, Henry Meeham.

In reference to the proportion of the working expenses to the amounts paid in pensions the following figures are interesting. The per-centage of working expenses was in 1861, 26.6, the pensions paid being £739; in 1866, 26.9, pensions £739; in 1871, 22.4, pensions, £824; in 1876, 21.2, pensions £986; in 1881, 19.5, pensions £1200; in 1886, 14.8, pensions £1950; and in 1887, 15.8, pensions £2779.

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.

NEW SERIES.—No. 6.

A MOVEMENT for planting trees about our towns is one of the favourable signs of the time, and owing to the changes that occur in the metropolis, many opportunities offer for the introduction of trees or shrubs along roads, in odd corners, and vacant plots turned into gardens. Perhaps those concerned in this limit themselves too much to a few species, as witness the abundance of Planes of the Oriental and American varieties, though many other trees will thrive in London smoke nearly or quite equal to these. But now we are improving somewhat the London atmosphere, its fogs are less frequent than they were; one thing, however, against the vegetation is, that through the extensive digging and boring that has gone on, especially about the central dis-

tricts, the numerous springs have been dried up that our ancestors found favourable for their orchards and groves outside the city walls. The yet existing names of Moorfields and Finsbury testify to the moist character of old London; even when the Mansion House was erecting early in the reign of George III. the builders were impeded by such a flow of water that piles had to be driven to get a foundation. It is worth remembering that the site was once that of the Stocks Market, so called like the adjacent church, from a huge pair of stocks close by, and which at first a meat market, became after the great fire a market for herbs, roots, and fruits. It was, in fact, the parent of the present Farringdon Market. Within the walls of the Bank of England a garden yet remains that was formerly the burial ground of the Church of St. Christopher-le-Stocks. It has two trees, and is planted with evergreens, which, when their enclosed situation is considered, look fairly healthy. It owns two Limes, not very aged, but interesting as being probably descendants of older trees that once grew here, for on this ground, or somewhere near, tradition says there was formerly a rookery in the heart of the City. For the sake of variety some of those in charge of the small open spaces of London have introduced pigeons and monkeys, and one clergyman has asked a scientific journal whether a rookery could not be started in a garden he has charge of. Rooks, like most birds, are fond of their own choice in the matter, but the circumstance that extinguished the rookeries about London was the building over the fields, this depriving them of their subsistence; and this difficulty remains still unless rooks could be fed like tame birds.

On the west side of the Bank of England, enclosed by a high wall, a straggling group of Elms, tall, but of moderate girth, look down upon Princes Street, with its rush and roar by day, and its contrasting stillness at night. These are in what is left of the Grocers' Garden, which it is likely once extended from Old Jewry to Lothbury. Even in the eighteenth century enough of the garden ground remained to furnish citizens with a pleasant evening stroll. Other City Halls had their gardens in days of yore. One much famed, yet extant but reduced sadly, is that of the Drapers', between London Wall and Throgmorton Street. It was part of the garden of Cromwell, Earl of Essex, and the Drapers' Company when they acquired it laid out the plot with walks, planted rows of Limes and Elms, also put up "pavilions," and for centuries the ground was open to the public. An old author mentions it as commanding fine views of the hills and woods about Highgate. In 1888 we find the diminished space shut in by tall buildings, but Limes and Elms are still to be seen, and there are shrubs scattered over small beds, in which, during summer, plants are put; but, of course, during January the ground appears dreary. A fountain which is kept playing sounds singular amid the busy hum of the talk and traffic just outside.

Finsbury Park is one of the recently formed parks, with an extent of more than a hundred acres, but it is a long way from Finsbury. North of London Wall there is a densely populated district at present poorly off for recreation grounds, but Finsbury Circus and its Square, which might delight the thousands of children who are now obliged to play in courts and gutters, are jealously closed except to a privileged few. It is to be hoped the Public Gardens Association will succeed in getting these and some other suburban spaces at the north made free to the public. The Circus is one of the metropolitan gardens that are of oval form, and it is a fair example of one laid out in the Georgian style; trees far too numerous to favour the growth of flowers, yet picturesque, because they have not been extensively clipped for years. None very venerable, the older being Hawthorns, Limes, and Poplars, the locality, once fenny, and still rather moist, suits the last. Though it encloses only four acres, by his arrangement of the paths and shrubberies the projector managed to give the impression that the space is much larger; it is below the level of the adjacent ground. Finsbury Square beyond is about half as large again, but contains a less number of trees, none as old as its formation, which was just a century ago. Here are a few specimens of the Bladder Senna, which might be more frequently planted in London gardens. We are now close to Bunhill Fields, so called from the largest of three fields belonging to Finsbury Farm. Another was named Mallow Field, from the familiar wild plant growing freely there. Bunhill, if not at first "Bone-hill," as some think, might have been thus styled, for it had been a place of interment before the Stuart times, when the present ground of about seven acres was formed. Interesting, certainly, as an historic spot, but though it is reckoned as one of the City recreation grounds, it possesses few advantages, save that of being an open space free to the sky. It is too crowded with monuments of all sorts to allow of its being properly laid out as a garden, though a number of small beds have been made here and there amongst the tombstones and the dank grass. The number of shrubs is small, but there are some avenues of trees shading the asphalted walks, probably planted since Her Majesty's accession; the older trees, of which there were a few, have been removed. A less space adjoining, also a part of the Bunhill Fields, is the Artillery Ground, long reserved for military exercises. At one time, so one author tells us, the ground of the Artillery Company was called Tassel Close, from the "tassels" grown there for the benefit of cloth-workers. These, of course, were what we now style "Teazels," the heads of *Dipsacus fullonum*, and still applied to the like use. An ancient thoroughfare near this space is Cherry-tree Lane, perhaps a reminiscence of the nursery and garden owned by John Milton, temp. James I., and which was south of the Old Kent Road.

Hoxton, to the north, is still badly off for open spaces. Our forefathers knew it as Hogsdon, and at one time it was a resort on account of a mineral spring of some supposed virtues. Its squares, Hoxton and

Charles, are scarcely three acres together, and even these are closed at present, but it is hoped they may shortly be opened to the public. Both contain a few trees; the most notable one in Charles Square is an old Lime with a forked trunk. About this square are scattered relics of ornamental stonework, which look like part of an ancient arch. Hoxton Square has two rather fine specimens of the Weeping Ash. This, unlike most squares about London, is higher than the roadway, so better drained, but like its neighbour needs replanting. A little further north is the churchyard of St. John's, Hoxton, surrounded by Planes and Elms, and opened a few years ago as an experiment, but owing to the injury done by some uncultured juveniles not much has been done yet towards a floral display. This is an acre in extent, literally, a "God's Acre."—J. R. S. C.

THE PROPAGATION OF SMALL FRUITS.

THERE are few operations connected with gardening which delight amateurs more than the art of propagating. Apples and Pears afford a grand field in this respect, but they are too difficult to graft or bud to be successfully accomplished by all amateurs, and the next best fruit trees to them are Gooseberries, Currants, and small fruit bushes generally. The present is the best of all times for attending to the matter, and in dealing with the most popular kinds I will begin with

GOOSEBERRIES.—I need say nothing on the excellency of this well-known fruit. It is a general favourite. It should be grown in every garden without exception, and it is in the most of them, but in many cases the old worn-out bushes might advantageously be supplanted by new young and vigorous bushes. Old bushes may bear profusely, but the fruit is invariably small and deficient in flavour. If the very best flavour is desired and fruit of the finest size required, strong healthy trees only will produce such. I would never approve of propagating or perpetuating an inferior variety. The best do not require any more space or culture, and those who grow only inferior varieties stand greatly in their own light. In selecting cuttings the young growths produced during the last summer are the best. They must be straight, or nearly so, and strong. Examine the bushes before pruning is commenced, and cut out the shoots which it is noticed will make the best cuttings. If the cuttings cannot be made and inserted properly at once do not keep them out of the ground, but tie them in a bundle and insert them several inches in the ground cut ends downwards. There is then no danger of their shrivelling. Allow all the spines to remain on, but take every bud out from the bottom half way up the stem or more. If the cutting is a foot in length, which is a good size, the buds may be taken out to a distance of 9 inches up the stem. This will allow 3 inches of stem to be put in the ground to root, 6 inches as a stem to the bush, and 3 inches to branch out to form the head. If possible no cutting should be less than 1 foot in length, and they may be 15 inches or 18 inches, the extra length being added to the stem.

A rather light sandy soil is the best to root them in. The ground should be dug and made very smooth on the surface, a line then being placed across it and the cuttings dibbled in along this. A distance of 6 inches or 8 inches between the cuttings and 15 inches between the rows will be found suitable, the soil being trodden firmly on each side of the rows after the cuttings have been inserted. Throughout the summer the Dutch hoe should be run between them occasionally to keep the weeds down. Apart from this they require no farther attention. Probably every one will not root, but if treated as here suggested I could guarantee nine to root out of every dozen. If they do well the first year every alternate one may have to be lifted from the cutting rows during the succeeding winter, and some will fruit in the second and all in the third year.

RED AND WHITE CURRANTS.—If anything, Currants are more easily rooted than Gooseberries. They are certainly more comfortable to handle, and all the cuttings should be selected with the greatest care. In length they should be much the same as the Gooseberries, and the buds must be removed as in their case, as unless they are taken out on the part that goes underground and forms the stem they will shoot and form green twigs when growth begins, and this is not desirable. As a rule, we continue with our Currant cuttings after the Gooseberries, and the same soil and after treatment suits them all.

BLACK CURRANTS.—These are also treated like the above, but they are hardly so free in rooting, and where old bushes exist that have become a close mass of shoots from the ground they may be dug up, the young shoots with roots attached selected as new plants, and if placed in good soil they will bear some fruit the first year and a great deal the second. This is a quick way of raising a stock of Black Currants, but it is a mistake to insert old divisions to become new plants, and where young growths cannot be secured with roots the cutting plan ought to be practised.

RASPBERRIES.—Though not so generally grown as the Gooseberries, they should be seen in every garden. They have an advantage over all other small fruits in growing well and fruiting freely in cool shady spots, where other fruits would not be profitable, and this is a point in their favour which should not be overlooked. I have seen many capital crops secured from them when growing against shady boundary walls in small gardens, and they also do wonderfully well under the partial shade of tall-growing Apple, Pear, and other fruit trees. When Raspberries are planted at first they are only small as a rule, with one or two stems, but after a year or two these throw out side suckers which grow up to young plants at a distance of 6 inches or more from the

main root, and it is these which should be dug up and replanted to form young or new plantations. In this way there is no time lost in raising a new stock of Raspberries, because the young ones taken off and replanted now or at this season will bear a considerable quantity of fruit the first summer. This is the only way of propagating Raspberries I have practised, and I can assert it is easy and effective.—J. MUIR, *Margam Park, Port Talbot.*

SHOWING—OWNERS' CLAIMS.

MANY letters having lately appeared in your paper anent Chrysanthemum shows and prizewinning thereat, written from the gardeners' standpoint, I venture to pen a few lines in the interest of a class now almost consigned to oblivion—to wit, the gardeners' employers. I notice that a general feeling of regret, in which I heartily join, was expressed, that, on account of his employer's decease, the gardener who staged the winning stands for the 1886 challenge cup at Hull was ineligible for the competition last year. I also notice that some of your correspondents, from whose views I emphatically dissent, stated that this gardener had a perfect right to exhibit in the class last year. It must be borne in mind that not the gardener but his employer is the owner, and therefore exhibitor, and that on the employer dying his ownership necessarily ceases, which would effectually prevent his late possessions being exhibited as still belonging to him, and most certainly they are not the property of the gardener.

It is, I think, a pity that under the lead of, I believe, the National Chrysanthemum Society, the employers' names should be now so generally eliminated from the prize list. In olden times the prize card used to run "Exhibited by A. Blank, Esq.; gardener, William Hobbs; now, on the contrary, one reads, "Exhibited by Mr. Williams Hobbs, gardener to A. Blank, Esq." When the prize list appears in print Mr. Blank's name has vanished utterly, and Mr. William Hobbs stands forth in solitary grandeur thus, "first prize W. Hobbs" (I refer to the official prize list of the National Chrysanthemum Society November Show, as it appeared in the form of an advertisement). This change is spreading, two Chrysanthemum Societies that I know of having altered the wording of their prize cards this year. The entry forms as a rule contain a stipulation that the exhibits must have been in the possession of the exhibitor for a certain time; this is complacently signed by the gardener, heedless of the fact that he possesses not even a particle of the soil in which the intended exhibits are grown; but having posed as the possessor of the exhibits, he also appears as the exhibitor, and eventually annexes the prize money, carefully avoiding, as appreciatively alluded to by one of your correspondents, any competition where the prize happens to be a cup, for fear his employer may so far forget himself as to put in a claim to it. Now I venture to state that in no other species of competition is the owner such a nonentity as in a Chrysanthemum Show. If my thoroughbred wins the Derby neither my trainer nor jockey is alluded to as the owner; if my yacht wins a Queen's cup my captain is not singled out as the possessor of the fastest yacht afloat; if my hunters win prizes at a horse show, my Herefords at a cattle show, my retrievers at a dog show, my game cocks at a Poultry show, my name appears in the prize list as their owner; but should my Chrysanthemums win a prize at a flower show, the prize list contains my gardener's name and not my own? This glorification of the gardener, who has done no more to deserve such honour than any of the other "heads of departments" whose charges have competed with success, it is hard to justify. To neither the employers, whose millions bring the highest honours within the reach of the head of his regiment of gardeners, nor to the exhibitor whose personal care and handiwork enable his one man to achieve success, can this state of things be gratifying; it may be so to the gardener himself, but I should doubt if in the long run he does not find it bad policy.—WRAITH.

CHALLENGE TROPHIES.

MY thanks are due to "A Liverpoolian" for trying to correct my memory in reference to a trophy being offered at Liverpool on the same conditions as those at the other places. I was apprised of the error into which I had fallen by my friend Mr. Mease on Monday the 9th inst. At the time of writing I was under the impression that the first cup given by Messrs. J. Williams & Co., Mount Pleasant, was competed for on those conditions. If I am not mistaken it was first offered to the Committee on those terms with other conditions that need not be entered into here, and was finally given without restrictions. It was the discussion that took place over the matter that led me astray. I should have corrected the matter when reverting to the subject of "challenge vases," which I intend doing. While I am anxious to be correct, the slight mistake made does not alter in the least my arguments against the unpopularity of these large restricted vases. I observe with satisfaction "Beverley's" note, and hope exhibitors and others will pass their opinion on the subject. I wrote purposely to draw out the opinion of others, and the Secretary of the Hull Society has done the

same. This is the time to discuss the subject, so that managers of shows can form a just estimate how far their efforts in taking a foremost position in offering "cups" are appreciated, or will be when the time of exhibition arrives. If good substantial prizes are offered, and the competition is poor or only second rate, not only is the committee disappointed, but the public as well. I wonder how many of those who have competed for "challenge trophies" will do so again; and it is indeed questionable if we have heard the last of those that have been won.—WM. BARDNEY.

ANNUAL DINNER OF THE PORTSMOUTH CHRYSANTHEMUM SOCIETY.

THIS took place at the "Royal Albany" Hotel on Friday, the 13th inst. F. Power, Esq., the popular Secretary, presided, the vice chair being occupied by G. Ellis, Esq.; they were supported by Sir W. D. Kirg, J. Moody, Esq., W. P. Winter, Esq., W. Kimber, Esq., R. Barnes, Esq., &c. Letters of apology were read from Sir F. Fitzwygram, M.P., The Mayor of Portsmouth, and Aldermen Whitcombe and Baker. Amongst the successful growers of this favourite flower who were also present we noticed Messrs. Kimber, Collins, Molyneux, and Drover, &c. The loyal toasts having been duly honoured, Sir W. King proposed in felicitous terms the toast of the evening, "Success to the Portsmouth Chrysanthemum Show." He stated this was the third dinner he had attended, and it afforded him much pleasure to briefly notify how each season had been more successful than its predecessor, for though the Society had given nearly £130 in prizes at its last Show, yet they still had a balance in hand of £121 15s. 1d. He was pleased to learn that the Committee thought of keeping the next Show open for three days. There were 160 subscribers, which no doubt would soon be doubled, and in a few years he was sure they would rival many of the large shows near the metropolis.

The Chairman, in responding to the toast at some length, said they had received the support of some of the very best growers in England, such as Messrs. Molyneux and Drover, and they intended to try the experiment of having the Show open for three days this year, and by offering valuable prizes they hoped this new departure would make the Society's next Show more successful than ever. Messrs. Molyneux and Drover responded on behalf of the growers, the former remarking that he feared the three days would be a mistake; however, that was for the Committee to decide, and suggested the offering of a prize less in value than the cup but higher than any money prize the Society has hitherto offered. Mr. Drover coincided with Mr. Molyneux's views in regard to the three days, and advocated the Society holding an additional show the week before Christmas. Messrs. Barber and Chatfield responded for the amateurs. Mr. N. Fuller, Idsworth Park, responded for the Judges. Messrs. Power, Collins, and Penfold responded to the toast of the Committee.

CHRYSANTHEMUM MADAME PAGES.

MESSRS. J. R. PEARSON & SONS send us from Chilwell blooms of the white Japanese Chrysanthemum Madame Pages. This variety is stated to be invaluable as a late bloomer; it is a strong grower, reaching the height of 6 or 7 feet. The plants are grown in 8-inch pots, are stopped twice. It is very prolific, producing on an average eight or ten sprays similar to the one enclosed. When disbudded it produces as many substantial blooms, which are useful examples for wreaths or crosses or any other floral decorations. The variety is evidently a very useful one, a small Japanese, free, pure white, and suggestive of another good late variety, Princess Blanche.

SHEFFIELD AND WEST RIDING CHRYSANTHEMUM SOCIETY

THE third annual dinner of the above Society was held on Wednesday evening, January 11th, at the "Clarence Hotel," High Street, Sheffield, and was the largest gathering of the kind the Society has yet held. Between sixty and seventy of the patrons and members were present. The after proceedings were presided over by C. E. Jeffcock, Esq., Vice-President, in the unavoidable absence of the President (Mark Firth, Esq.). The usual loyal toasts having been proposed from the chair, Mr. Jarvis, one of the Hon. Secs., gave "The Army, Navy, and Auxiliary Forces," which was responded to by J. P. Jeffcock, Esq., Lieutenant 19th Hussars. "The President and Vice-Presidents" was proposed by Mr. John Haigh, and given with musical honours. The Chairman responded in a very happy speech, which created much enthusiasm. Referring to the rapid growth and success of the Society, he said much of this was due to the energy which had displayed in the Society's interests by the Hon. Sec., Mr. W. K. Woodcock. He was pleased also to find how thoroughly Mr. Woodcock's work had been appreciated by the Committee and members of the Society generally, and he had great pleasure in presenting to him a purse of gold, which had been subscribed by the Committee and members. Mr. Woodcock in returning thanks said that he felt very deeply this latest instance of the kindness and good feeling towards himself, and which had taken him by surprise. It was not, however, the first by very many of the promoters of their kindly feeling he had experienced, and instanced as a very striking one the fact that when at the recent annual meeting and a section of officers he had expressed a wish to resign the office of Hon. Sec., on account of the work pertaining to such office pressing too heavily upon the limited time at his disposal, two prominent and efficient members of the Society, Messrs. J. W. Jarvis and J. W. Needham, had at once volunteered to undertake the whole of such work as joint Hon. Secs., conditionally that he would withdraw his resignation, and which under such circumstances he had felt himself bound to do.

The toast of the evening, "The Sheffield and West Riding Chrysanthemum Society" was next proposed by E. H. Wake, Esq., who in an effective speech which was frequently applauded spoke of the great pleasure which the success of the Society had afforded him during the past season. It had very largely increased its lists of patrons and members, and was able to show a balance on the right side financially. Mr. W. K. Woodcock responded. Mr. J. Shipman proposed, "The Patrons and Subscribers," which was responded to by C. H. Firth, Esq. The other toasts on the list were, "The Nurserymen and Non-Competing Exhibitors," proposed by Mr. G. S. Stocks, and responded to by Mr. W. Shaw.

"The Officers of the Society," proposed by Mr. Allison, responded to by Mr. J. G. Newsham, and "The Hostess," proposed by the Chairman, responded to by Mr. Jno. Haigh, on behalf and by request of Miss Telfer, the Manageress. Special prizes amounting to a total value of over £40 were promised during the evening to be added to the Society's schedule for the next show, to be held November 16th and 17th, 1888. The donors and amounts were:—Mr. H. Broomhead (Hon. Treasurer), silver cup, value £15 15s.; Mark Firth, Esq. (President), £5; C. E. Jeffcock, Esq. (Vice-President), £5; A. Wilson, Esq., £5; Mr. Edge, £2; Mr. Holden, £1; Ditto, £2; Mr. Wilkinson, £3; Mr. Webster, £3; Mr. Allison, £1; Messrs. Fenton Bros., Silversmiths, amount not stated.

NEW VARIETIES.

Now—"when the hurlyhurly's done, when the battle's lost and won"—is the time to exchange notes on the newer kinds, so that additions may be made to an already extended list. Such notes we think will prove interesting to and help to guide those among the great army of Chrysanthemum lovers who cannot visit the exhibitions and see the novelties for themselves. Anything of merit in the way of new flowers is now sure to be found at the National and such shows as the Crystal Palace. To my mind the most remarkable circumstance connected with the incurved class is the rapidity with which the variety Princess of Teck is producing new sports bearing a family likeness. A year or so ago we had but two, it now wants that number only added, and they will be able to say with the tribe of "queens," we are seven. Taking form of flower, smoothness of petal, and habit of growth, this handsome group of "Tecks," were it not for the drawback of coming rather late for the shows, would undoubtedly be rivals to that grand type of which Lord Alcester is the leading flower. The Princess herself we compare to the most perfect of all Dahlias, Mrs. Gladstone, and who can help admiring a well grown specimen of the Hero of Stoke Newington? Mrs. Norman Davis is a valuable acquisition, and another year, from plants struck in a cool manner and not forced into flower, may not be so variable, many of the blooms as shown being as bronzy as they were golden, and out of character as regards florets. Lord Eversley will be sought after by all who desire neatness and delicacy in an incurved flower, as also will the latest of the sports, the bronze Charles Gibson. The comparatively new bronze Queen of England we saw in rare form on one occasion this season at a local show. Its florets were as perfectly arranged as, and in other respects equal to, a good Lord Alcester; seen in such trim it is a gem. With all regard for the skill of the producer we should call it the result of one of those unaccountable accidents that we wish would more often occur in our own case, especially with that Japanese beauty Belle Paule. For three seasons we have had it and grown it a variety of ways, but at yet have not had a presentable flower. This by the way. One "sport" we know of that has appeared this season on a plant of Prince of Wales, which, if it retain its character, will be a fine addition. The florets are so multiplied that it reminds one of a dark rose-coloured Princess of Wales. In his interesting retrospect, page 464, last vol., Mr. Molyneux writes—"I am inclined to think that some new incurved varieties may be brought to light during another year as the result of this season's tropical summer. I have noticed that an unusual number of florets have been found in all incurved blooms this season, probably the result of extra ripening of the wood. This may then be the means of producing new and varied forms in the section to which we have so few additions—the incurved. Assuming "sports" are meant we fail to understand how an extra number of florets in blooms grown this year can be conducive to the increase of "new and varied forms" during another year, and have observed that sports appear more frequently on plants grown in a more natural manner than those subjected to such "generous" culture as is necessary for producing blossoms for exhibition. In this view we are supported by the above writer himself, for on page 57 of his book "Chrysanthemums and their Culture" we read—"The present general system of growing Chrysanthemums for the production of large blooms is not favourable for increasing the number of new varieties by sports as the side shoots are taken off the plants as they grow, and it is from these side shoots, when they are allowed to develop into flowers, that the largest number of sports appear."

The new Japanese make a goodly list, and among them are improvements that will rank with the very best of the class. The importations of Messrs. Cannell, Swanley, from Japan must be mentioned first. Connected with these we are pleased to know the glaring error whereby the stand of grand flowers exhibited by Mr. Martin, West Hill House Gardens, Dartford, was left out of the running for the Jubilee prize at the Aquarium Show has been set right. No little comment was caused by the prize cards being placed as they were, and we do not think judging by ballot will be very extensively adopted at Chrysanthemum exhibitions. To say the least, it is an unnecessary innovation.

Edwin Molyneux is a grand flower, quite worthy of its name,

colour a rich combination of deep crimson and old gold. Mr. and Mrs. H. Cannell are two superb sorts, the former a nobly built yellow, and the latter a creamy white of handsome proportions; these three varieties will help to win in many a future floral fight. C. Orchard, something like Comte de Germiny in colour, but flatter in build, and Mr. Wellam, a white with bright rose splashes, must also be added to all collections. The value of these importations make one hope the energetic firm above mentioned will secure for us all that "white elephant" among Chrysanthemums—we mean the "blue" variety, the charms of which are said to be gazed upon only by a few favoured worshippers in Japan.

We have not seen Avalanche, but a new one that can win premier honours, as this did at the late Portsmouth Show amongst so many beauties must be a gain indeed. Edouard Audiguier in form, colour, habit of growth, and constancy is first class, and is already a favourite. No one seems to have grown it so well as its introducers, Messrs. Davis and Jones. That winner of so many certificates, Ralph Broeklebank, a light yellow sport from the well-known Meg Merrilies, needs mention only, although "Meg" is not the style of bloom to our taste comparable to the best of all Japanese varieties, Mdle. Lacroix. The white of this fascinating flower may not be like that of Elaine, "pure as the driven snow," but its graceful and captivating form make it "a thing of beauty and a joy for ever," while the plant is sure in producing its charms and is of easy culture. Carew Underwood, sported from Baronne de Prailly, is a variety of great excellence, of a lively colour of bronzy red, and in all ways equal to its parent. Florence Perey, sent out last year, is an elegant pure white variety, with thread-like florets, very large and full from early buds. Mrs. J. Wright is another white which gains in favour as it becomes more widely known, and like the foregoing produces the finest flowers from crown buds. Were it not for its early character Phœbus would make a telling variety on an exhibition stand; however, it must be grown for the richness of its yellow and for the grace of its form. We find it lasts a very short time in perfection. In Gloriosum we have a large flower in the way of Soleil Levant, but finer, although the colour is less bright and striking. Roi des Japonaise, a useful addition, opening bright orange red in colour, and when fully developed fading at the tips of florets a deep yellow. Mdle. Blanche Pigny was seen this year in many stands, and will gain in popularity, notwithstanding that we have so many good whites in the field. The flower is well formed and of good substance. About the best of the French introductions of the present year is Mr. Garnar. Its florets are drooping, the flower full and clear, bright yellow in colour. Duke of Berwick will make a handsome exhibition bloom, colour white tinted rose with thread-like florets. Hamlet, salmon red, is also well worth growing. To judge the per-centage of "wheat" we find among the French "chaff," it may be mentioned that the last three are selected from about 100 new varieties; still, in justice to them, a few more may turn out good after a further trial. Our raisers across channel are evidently taking the tide at the flood, which, we are told, leads on to fortune.—H. SHOESMITH, *Saltwood, Hythe.*

CHRYSANTHEMUM CULTURE.

[A paper read by Mr. Edwin Beckett, gardener to H. H. Gibbs, Esq., Aldenham House, Elstree, before the last monthly meeting of the St. Albans' Horticultural Society.]

As the Rose is considered to be the queen of the summer flowers, which undoubtedly it is, so I claim for the Chrysanthemum the title of queen of the autumn flowers, and no plant in cultivation has made such rapid progress during the last few years as this. The Chinese, or incurved section, was introduced from China somewhere about the year 1764, but it seems to have found but little favour till within the last twenty or thirty years. Now nearly every town holds its annual exhibition. As a mark of its increasing popularity, mention may be made of this year's Portsmouth Show, where, during the last three hours of the second day, no less than 8109 visitors paid for admission. And this is no exception, for wherever good exhibits are brought together, as a rule, they are well patronised. The later introductions from Japan have had much to do with this. They have such a striking appearance, the diversity of form and richness of colour making them most welcome during the dull months of November and December. They are also very easily grown. Anyone possessing a small garden might have a rich display in autumn, and Chrysanthemum growing, when once taken in hand, will not easily be given up. It is not always those possessing the best means who obtain the best results; the flower must be carefully studied, tenderly cared for, and success will follow in nine cases out of ten.

Having met with a fair amount of success, both as a cultivator and exhibitor, I will now proceed with what I believe to be the best mode of cultivation, and will first deal with plants grown for fine flowers. From the middle of December to the first week in January I consider to be the best time to commence propagation. As there are so many varieties cultivated, it is necessary for the beginner to make a selection of the best and most popular sorts before starting, which is easily done by noting down at the exhibitions those varieties generally staged by the most successful competitors, and I would advise growing only a limited number of sorts, according to requirements, two or three each of the best, rather than a host of uncertain varieties. I have tried several methods of striking, but have found the safest and best way is to devote to them a light or two of a pit divided by a temporary wooden partition, with hot-water pipes running through filled with finely sifted coal ashes as near the glass as the pots will allow. I much object to cold frames,

although I am aware that many growers recommend them, for the reason, that owing to the bad weather we are likely to have at this season, it is necessary to keep them closed and covered, perhaps for weeks together, hence the cuttings must suffer from damp, and at the same time remain in almost dormant condition. To obtain satisfactory results, the plants should be kept in a healthy condition from the time the cuttings are inserted until the flowering season comes round. The soil to be used should consist of equal parts of light fibrous loam and leaf mould, with a good addition of sharp silver sand. Use large 60-size pots with a little moss or rough loam placed over the drainage to keep it clean and sweet. Fill the pots moderately firm, and place a little silver sand on the top. Insert four cuttings in each, which must be cleanly cut, and not rooted suckers, choosing the most sturdy; label, water, and place them in the pit already prepared. For a few weeks they will require but very little attention, except a sprinkle most mornings when the weather is bright.

Some sorts will be found to root much more quickly than others. These should be taken out as they commence starting into growth, and placed either in a cold frame or on a light airy shelf in the greenhouse. The whole stock should be ready for transferring into large 60-pots by the end of January or the first week in February. Arrange them in a cold frame facing south on a bed of coal ashes. The soil for this potting should be the same as before advised. Thoroughly water in, and keep them close for a few days, taking care to protect them from frost. Ventilate freely as the plants commence growing, and remove the lights on all favourable occasions during the day. Nothing tends to strengthen and keep them in good health like fresh air. By the last week in March they should be ready for 6-inch pots. The soil now should consist of two parts of good fibrous loam, one part well-decayed horse or cow manure, one part leaf mould, with a good addition of coarse sand and a few half-inch bones. Place a neat stake to each plant, and return them to the cold frame, treating them as before mentioned. At the end of April, if the weather is favourable, move them outside to a sheltered position, the foot of a south wall or fence will suit them admirably. Let them stand well clear from each other on slate or boards to keep the drainage perfect.

The final potting should be made the first or second week in June. I recommend 8-inch pots, which are large enough for all kinds, but a few of the strongest-growing may be placed in 10-inch pots. The compost for this potting should be three parts best loam, one part decayed manure, with a good addition of bonemeal. Drain well, using a thin layer of fibre taken from the loam over the drainage, which should be clean crocks and half-inch bones. If the soil is in a good state it is impossible to pot too firmly, using the potting stick freely, securing them with a longer and stronger stake before leaving the potting shed, and take them to wherever they are intended to remain for the summer months. The most suitable and convenient place, if to be had, is an open and airy position by the side of a walk where they get the full benefit of the sun during the whole day, and if neatly arranged and kept tied, they are far from being unsightly. Make them secure against the wind by driving in strong stakes a short distance apart, straining wire or strong string to fix the plants to. Syringe freely every fine afternoon. As the plants advance in growth, and as the pots become filled with roots, liquid manure must be applied at every other watering. Attend to thinning out the shoots, allowing but three or four to a plant, according to their strength and variety.

Taking the buds is a source of great anxiety even to the most experienced cultivators, as sorts differ so much as to the time it takes them to expand. Experience alone can make one perfect in this, but generally for those that are required about the middle of November, I have found the last week in August to the second in September the best time. From three to six flowers must be left if extra large blooms are desired, and the central bud always to be left. Disbudding should be performed by a steady hand and keen eye. A small pointed stick is what I use, taking them away when the buds are large enough, exercising great care not to damage the remaining bud. By the first week in October all should be safely housed, and when first taken in allow them as much room and air as possible. As they get acclimatised they may be stood as closely together as the pots will allow. When water is required always apply it in the morning. A little fire heat in damp cold weather will greatly help to improve the quality of the flowers, particularly the Japanese, and with a little top ventilation will act as a preventive against damping.

(To be continued.)

UNDER GARDENERS AND EXHIBITORS.

THERE are no doubt good and bad gardeners, but if we are to believe all that some of your correspondents say on this subject it would point to the fact that they are most extortionate men. My experience enables me to entertain quite a different opinion. I have served under several, and as a rule I have found them just and even generous. I am inclined to think the instances which "A Lover of Fairplay" has mentioned about young men having to pay their own expenses when assisting at flower shows are very rare. At the same time, a young man who is thoroughly interested in his work, and who keeps his eyes open, may find many a show worth paying a reasonable fare to see, and may be materially benefited by it in the future. As to night work, I think a man who objects to working an hour or two in the evening at a busy time, or to prepare for exhibitions, cannot enter into his work with the will and energy that is required to make a competent gardener of the present

day. The men who most object to it are not those who devote their spare time to study, but rather those who spend their time in idleness or questionable pursuits. I do not say this is always so, but generally speaking it is, and I fully believe the same rule applies to those whose lamentations are so loud at not receiving their share of prize money. Those who do least towards preparing things for show expect as much or more than those who do most.

It would seem by what an "Under Gardener" says that he considers it unlikely for a man to become a thorough gardener if he serves in places where exhibiting is carried on to any great extent. This I consider a very erroneous idea. Supposing a few things are grown superlatively well, as he terms it, is that any reason why everything else should of necessity be badly grown? I say, Decidedly not. Again, supposing in the early part of his career he was to serve a term where fruit-growing was the chief feature, in fact, grown well for showing, the next change he made—I think it good for a young man to change—was to a place where plants were largely grown also for show; does he mean to say that a man of that experience would not be as likely to prove as good an all-round gardener as one who had always lived in places where things were grown in just a presentable condition only? I think the former would be likely to prove the better man of the two.

Let us see, too, if there are not some other advantages likely to be gained by assisting a gardener in a subordinate position. I do not suppose there are many of us who always wish to remain subordinate. Then, who is the man most likely to assist you in gaining a responsible situation? The head gardener, as a rule. Which will he use the most influence for, then—the man who has assisted him to the best of his abilities, or the one who when asked to give a little extra help has either grumbled, or did it with a frown and in a manner which made his help worse than his absence would have been? Perhaps when he does gain that goal of bliss which an "Under Gardener" seems to think a head gardener's place is, it may happen his employer will be wishful for him to become an exhibitor, when he will probably find the knowledge he had previously gained in that respect as an assistant of great value to him. Supposing a head gardener does get the benefit of exhibiting in a pecuniary sense, as well as the bulk of congratulations, he has the greater portion of the anxiety in preparation, as well as the disappointment and expense if failure. One could hardly expect every friend of an exhibitor to come and congratulate each assistant that he may have at a show, and perhaps totally unknown to him. No, "Under Gardener," I cannot agree with you that exhibiting is detrimental to young men, quite the reverse; and if they are not to any great extent financially benefited by it, they can if they choose benefit in a way which is worthy of greater efforts than the majority of young men are willing to put forth in that direction. Many a man worthy of the good position he holds owes it to the fact of having lived in places which have become noted for their exhibits coupled with the influence of the gardener whom he helped to the best of his abilities.—ANOTHER UNDER GARDENER.

young growth closely spurred back, but we prefer the plan of leaving a number of young shoots untouched, these usually fruiting to their entire length. Black Currants also bear fruit on the young shoots; thinning out and foreshortening the straggling branches in order to keep them within bounds is all that is necessary. Young trees need not be cut back after the second season, as these are constantly pushing young shoots. Fully formed Red Currant bushes, too, have all lateral growth spurred back to the main branches, and the leading shoots freely shortened back. Young bushes to be cut rather hard back, and the centres kept clear till such times as a good head is formed. The leading branches must be shortened back to a length of about 6 inches at each pruning, in order to clothe them with fruiting spurs.

CORDON APRICOTS.—This termed is employed for want of a better one to describe a system of training Apricot trees that ought to be adopted in gardens where they are apt to die off wholesale. We prefer the fan-shaped trees, but when these suddenly lose one or more of the main branches they are disfigured for life, and, what is still more regrettable, other limbs soon follow suit. A wall can be most quickly furnished by trees trained with one main stem, the fruits being borne on the branches laid in right and left and treated very similarly to a Peach tree. The start should be made with well-ripened maidens, these being planted in fresh loamy soil not less than 6 feet apart, and trained obliquely in order to prevent the top of the tree from growing more vigorously than the lower branches. Cut them back to a length of about 2 feet, lay in side branches thinly, and one central shoot to continue the stem. Each winter the leader should be lightly shortened, and more side branches and a leader laid in during the summer, in which manner quite a high wall may be furnished in about four years. The trees being planted against a sunny wall and the subsoil well drained, the young shoots laid in thinly will usually flower and fruit freely the following season, and may then be cut out and their places taken by other growths purposely laid in during the summer. If they fail to fruit during the first year save them to the next.

PRUNING THE GRAPE VINE.—Plenty of good Grapes were ripened in the open air last season, and the wood also is much better ripened than usual. It is a mistake to closely prune them, for if spurred back as closely as those rods under glass, many of the laterals will fail to show bunches. Where possible lay in short lengths of young and well-ripened rods, as it is these that give the best bunches. This can frequently be done without destroying the old rods, the simplest plan being to tie a number of laterals along the rods or very near to them, these being replaced next season with other young rods reserved for that purpose. The spurs on permanent rods ought to be fully 12 inches apart. If it is decided to spur back the laterals cut to a plump bud, or say at the second or third joint. Permanent rods ought to be disposed 2 feet apart, and all should be securely fastened to the walls or trellises at the present time. No skinning or cleaning is necessary, but if mildew is troublesome dress them with a mixture of liquid clay, Gishurst compound, and sulphur. It is useless to attempt fruiting Grape Vines on other than hot sunny walls or roofs.

FRUIT FORCING.

PINES.—*Fruiting Plants and Starters.*—Those should now have a mean temperature of about 70°, varying it 5° according to external aspects, admitting air at 80° with sunshine, but not lowering the temperature, allowing the heat to rise to 85°, closing the house at 80°. Syringe all available surfaces twice every day, but do not syringe the surface of the bed between the plants. Avoid dense steam produced by syringing highly heated hot-water pipes. The plants also should be syringed occasionally early in the afternoon when the axils of the leaves become dry.

Starting Plants for Successional Fruiting.—About the commencement of next month (February) another supply of Queens should be started to supplement the supply of fruit from those plants which are already introduced for that purpose. Beds having hot-water pipes beneath them can soon be prepared for the reception of the plants, but it is not the case where fermenting materials alone are employed, hence the subject is mentioned now so that the matter may be seen to at once, and 85° to 90° of bottom heat secured by the time required. When plants which have been kept somewhat drier are to be started see that the balls of the plants are made thoroughly moist, so that with the extra warmth root-action may commence at once.

Successional Plants.—A night temperature of 60° to 65°, and 5° less in severe weather will be suitable for those, and 5° to 10° in the daytime according to external conditions. Keep the plants rather dry at the roots, but not excessively so, and when water is considered necessary give it thoroughly at a temperature of about 80°. Suckers should have a temperature of 55° to 60°, 60° to 65° by day from fire heat, and 10° more with sun heat.

CUCUMBERS.—The night temperature should be maintained at 65°, allowing 5° more in mild weather, whilst it may be 5° less on cold nights, 70° to 75° by day and 80° to 85° with sun heat. When the external air is mild a little ventilation may be given at 80°, closing before the temperature is reduced below that degree, so as to raise it to 90° or 95°; but if the external air is cold, although the sun shines, it is better to allow the temperature to advance a little beyond the above limits than to admit cold air, which injures the foliage, also causing the fruit to become stunted and to curl at the end. Plants in bearing will require to be examined about twice a week, removing all weakly and exhausted growths, reserving as much of the young bearing wood as is necessary to fill the allotted space, stopping the shoots at one or two joints beyond the

WORK FOR THE WEEK.

HARDY FRUIT GARDEN.

PRUNING FRUIT BUSHES AND PROTECTING THE BUDS.—But for the birds now is the best time for completing the pruning of both Currants and Gooseberries. The latter, however, are so liable to be stripped of the greater portion of their buds by bullfinches that many defer pruning till the spring, and we have known cases where market growers do what thinning is necessary when the fruit is large enough for picking. The more dense the growth the less likelihood of the buds being cleared off wholesale, but delaying pruning was of little avail last winter. The best course to pursue is to either prune the bushes, and then coat them with thin lime water and soot water applied through a syringe, or dusted over them when wet, or else to tie all the principal branches and young shoots up into a conical heap. Unless the bushes are very stubborn two men with gloves can so dispose the branches with the aid of tar twine as to make them almost impenetrable by birds, only a few of the outside buds being taken. The bushes are opened out just as the buds are bursting. Where this plan is tried light crops are the exception. If the bushes are coated with lime and soot this must be renewed whenever it is washed off by rains. Where a framework to support wire netting is erected over a quarter of fruit bushes, the ends at least should be moveable, so as to admit birds between the flowering and ripening periods, otherwise caterpillars do more harm than birds. Now is the best time to put up such permanent protections, and it should be kept closed in all the winter and spring. When pruning Gooseberries the best course is to lightly thin out the old wood and some of the young growths, and remove all that are near the ground. Young bushes to be cut freely back and the centre of those of erect habit kept open till such time as a good head is formed. Wall and trellis trees to have leading growths laid in wherever there is room, and all lateral growth spurred back to the main branches. The bushes also may have all

fruit. Young plants just coming into bearing should not be allowed to bear too soon, and by no means be overcropped. They are greatly assisted by removing the male flowers (also surplus female flowers) as they appear. The supply of moisture both at the roots and in the atmosphere must be governed by external influences. Syringing should not be practised over the foliage, except a light sprinkling in the early part of bright afternoons, damping the floor moderately at about 8 A.M. and 2 P.M. Encourage the roots to spread on the surface of the bed by adding a little lumpy loam from time to time, with which may be incorporated a little well decomposed cowdung or fresh sweetened horse droppings. Keep a sharp look out for aphides, and fumigate several times moderately and consecutively rather than once severely. Cauler is not uncommon at this season of the year; fresh slaked lime rubbed into the affected parts will arrest its progress. If mildew appear dust with sulphur.

Raising Cucumber Plants in Frames.—The greatest mistake is commencing too early. The materials are either not obtainable or they are not forthcoming in sufficient quantity to make up beds and continue the heat in them by linings, so as to keep the plants in progressive growth during weather that cannot be relied upon as assisting by sun heat; consequently those not sowing seed before the beginning of February cut fruit quite as early as some do with an inadequacy of heat-furnishing material by sowing at the new year. The material for making up the bed for raising the seedlings being in a fit state for turning over and mixing with leaves, so as to induce a sweet regular heat, a site for a bed should be chosen with full southern aspect, and having shelter to the north, as that of a hedge or wall. If the ground be rather higher where the bed is to be formed than the surrounding ground all the better. Beat the dung and leaves well down with a fork as the work proceeds, making the bed about 5 feet high at the back and 4 feet 6 inches in front, which will allow for settling, as it will do about a third. A few Pea sticks placed across and along the bed at intervals not only prevent overheating, but admit the heat from the linings being conveyed to the interior of the bed. For early work we have used frames with double sides with advantage. They are formed by placing an inner lining of half-inch boards 9 inches less in depth at the back and 6 inches less in front than the box, nailing strips of wood an inch wide and thick on the inside of the box, and then the boards which form an inch cavity all around the inside of the box, and thus top heat is furnished.

In about a week the heat will be up. Level the surface of the bed, replace the box, and put in sufficient sweetened dung to raise the inside to within 4 inches of the top of the inner frame or cavity, placing sawdust, dry leaf soil, or spent tan on the dung for plunging the pots in. For raising the plants 3-inch pots are half filled with light rich loam, placing one seed in the centre of each pot, covering with fine moist soil, so that no water is required for the germination of the seed. Space is thus left in the pots for top-dressing, which is preferable to potting the plants. A square of glass placed over the pots will hasten the germination, but it must be removed as soon as the plants appear. The plants from a sowing made early in February in the manner described will be ready for planting early in March, and will afford fruit nearly as soon as those from a sowing made early in January.

MELONS.—Add a little soil as a top-dressing as the plants grow, having them near the glass to prevent drawing. Keep a sharp look out for slugs. A ring of soot or lime placed round the plants will generally preserve them, but means should be employed to entrap the slugs. For frame culture seed should be sown early next month. The bed as described for raising Cucumbers is suitable for Melons, and should be made forthwith, unless one be made for Cucumbers, which will answer the same purpose for raising Melons. Soil should be placed under cover, so as to become dried preparatory to forming it into ridges in the Melon house. Good loam rather strong than light is suitable for Melons, and if it has been laid up in ridges so as to reduce the turf it will be in a fitting state for the purpose. If deficient of grit add a fifth of road scrapings, and if not calcareous a similar proportion of old mortar rubbish. If there is need to add manure nothing is better than fresh horse droppings. The composition would in that case be four parts of loam, one part each of horse droppings, road scrapings, and lime rubbish.

STRAWBERRIES IN POTS.—When the plants commence flowering admit air freely, remove the weaker blossoms, and when the pollen is ripe brush the flowers lightly with a feather. After the fruit is set thin them to about half a dozen, more or less according to the variety. Whilst the fruit is setting 50° to 55° will be sufficient heat artificially, advancing to 60° to 65° with sun heat, but after the setting is effected remove the plants to a house with a temperature of 60° to 65° artificially and 70° to 75° by day, supplying liquid manure until ripening commences, then employ water only and sparingly. See that successional plants do not require water and are not brought forward too rapidly in the early stages. If there be any trace of aphides fumigate moderately, taking care to have the plants perfectly clean before they come into flower.

CHERRY HOUSE.—Beyond the necessary care in watering trees in pots and syringing the house with attention to ventilation, there will be little work at present, the temperature being kept at 40° at night, 45° to 50° by day by artificial means, ventilating at 50°, and allowing a rise of 10° to 15° from sun heat with full ventilation, closing at 50°.

PEACHES AND NECTARINES.—**Earliest Forced Trees.**—Continue to fertilise the blossoms, using a camel-hair brush or feather, which is more effectual than shaking the trellis. When the fruit is well set syringing may be resorted to both morning and afternoon, but in dull weather syringing in the morning will be sufficient, damping the house in the afternoon, it being important that the foliage be dry before

nightfall. The water employed must be of the same temperature as that of the house, the inside border being kept well supplied with water. Disbudding will soon require to be attended to, but it must be done carefully at this early season, it being better to remove a few shoots daily from a tree than many at a time at distant intervals, which last practice gives a check to the roots and is not favourable to the swelling of the fruits. The night temperature may now be maintained at 55° to 60°, 60° to 65° by day, 5° less as the minimum when the weather is severe and dull, admitting a little air at 65°, not allowing an advance over 70° without full ventilation, closing at 65°, always excepting a small space left at the top constantly.

Second Early Forced Trees.—Syringing must cease for trees started at the beginning of the month, when the blossoms show colour, but damping every available surface in the morning and afternoon must be practised, for though a confined atmosphere is not favourable to Peaches in any stage of their growth, a dry atmosphere is equally pernicious, promoting excessive evaporation, the blossoms equally with foliage and fruit being invigorated by atmospheric moisture, provided it is not stagnant. See that the border is in a thoroughly moist state, and make a close scrutiny of the trees for aphides. If there be any, fumigate the house on two or three consecutive evenings moderately, which will be sufficient to keep the pests under until the fruit is set. In case of an excess of blossom buds, and they are very abundant in our case, and promising, draw the hand the contrary way of the growth along the under side or back of the trellis, so as to reduce the number of the bloom buds, which will increase the vigour of those best situated, and tend to a more even and better swelling of the fruit after setting.

Late Houses.—We should again urge the necessity of completing the pruning of the trees at once, dressing them with an insecticide, and tying the shoots to the trellis, the borders being forked over, but not disturbing the roots, any loose surface soil removed and fresh loam supplied, an admixture of wood ashes a fifteenth part, and a twentieth of half-inch bones being beneficial. If the borders are at all dry they should be given a thorough watering. Those, however, that have moveable roof lights will not require any water, the soil being in a thoroughly moist state from rain, and the shoots are kept in a condition by the air moisture unfavourable to evaporation, so that the trees not only have thorough rest, but the buds are prevented falling (a consequence mostly of deficiency of moisture at the roots). With the trees exposed we have not experienced any loss of buds, yet they may fall from other causes, such as over-maturity, or imperfect formation through attacks of parasites, and deficiency of aliment and assimilating power, resulting from too crowded a condition of the foliage.

PLANT HOUSES.

Marantas.—Repotting should be done at once where needed, so that the plants will have a chance of establishing themselves again before the sun has much power. If they are left till about the middle or end of the following month the sun often proves too strong for them, and they flag severely. These plants will do in the same pots for years provided the drainage is good and the soil about their roots in a sweet condition; but the liberal supplies of water needed during the growing season soon renders the soil unfit for them. They unquestionably do best when they are repotted annually. When turned out of their pots and the drainage removed the old soil should be worked from amongst the roots by washing it out in a tank of tepid water. This necessitates the plants being allowed to drain for some hours before they can be repotted. Many of the varieties do well in a compost of fibry loam, one-seventh of manure, charcoal broken according to the size of the plants and pots, with an addition of coarse sand. Others do better in rough peat, the fibrous portion of loam only, and charcoal in lumps. After potting plunge the plants where a night temperature of 65° can be maintained, syringe them freely, but water with great care until their roots are active. The pots used should be liberally drained.

Alocasias.—These may also be top-dressed or repotted if they need it, so that they will become established and be growing freely before the season is too far advanced. Those potted last year in peat fibre and lumps of charcoal freely intermixed should have the soil in good condition at their roots. They will only need the removal of the surface, top-dressing with rough material composed of peat, loam, and manure, which will induce the formation of roots from the stems, and thus add to their strength before the season is over. Those needing potting should have all the soil washed from their roots and fresh supplied. Drain the pots liberally, and cut off the lower portion of the stems if the crowns cannot be placed on a level with the rim of the pot. It is a mistake to elevate them much above the rim, for top-dressing cannot be well carried out after a season's growth. Sphagnum moss in the compost, except for covering the surface, should not be used, it decays too quickly, and assists the decomposition of the other ingredients of the compost, rendering annual potting a necessity. If good peat and charcoal only are used they will last well for two years. Destroy any red spider that may be on the foliage by sponging, and treat in other respects the same as advised for Marantas.

Anthurium Andreanum.—All plants that need repotting or top-dressing may be done at once. This, as well as *A. ornatum*, *A. Ferriense*, and others do equally as well in loam from which the soily portion has been removed, charcoal and sand freely added as what they do in peat. Sphagnum moss, except for the surface, has long since been discarded as a requisite for these plants. They may not grow quite so rapidly in loam as what they do in a moss and peat mixture, but the growth is sturdier and the plants do not need cutting down so fre-

quently. They flower equally as well, if not better, and the flowers are brighter in colour. Those that are top-dressed may have a little manure applied to the surface. Plants that have grown too tall may be cut down. The heads will root freely if placed in the propagating frame in brisk heat. Every portion that has a sound eye upon it will make a plant. The old stool should be allowed to break, and frequently half a dozen or more shoots will issue from it, and the result is a splendid plant by the end of the season. After it has broken into growth the soil may be shaken from its roots and the plant placed in a smaller pot. Be careful to warm the soil thoroughly before these plants are repotted.

*Bignonia*s.—Both evergreen and deciduous varieties must be well pruned, and from the former all unripe ends may be removed, except where the extension of the plants are needed. Treat in other respects the same as advised for Tecomas.

Cobaea scandens.—This and its variegated forms are such luxuriant growers that unless they are severely pruned annually and occasionally during the growing season, they smother all smaller-growing climbers that are near them. If well reduced in size they will in a very short time furnish the space allotted them with clean healthy foliage, which is preferable to leaving a large mass of old foliage upon the plants. As a rule, these grow in a very small quantity of soil without being top-dressed or fed during the season of growth.

Plumbago capensis.—Whether grown in a pot and trained upon a trellis, or planted out and trained to a pillar in the greenhouse or conservatory, they should be well pruned back. If a succession of bloom is appreciated place one or two of the plants that have enjoyed a good season of rest in an intermediate temperature until they break into growth. They may afterwards be top-dressed or repotted as the case may be. If any old foliage is left upon the plants be careful that no red spider exists upon them. It will increase rapidly with increased heat, and soon devour the young tender foliage after the plants have started into growth. If syringed with the solution advised for *Lapagerias* it will destroy any insects that may be upon them.

THE BEE-KEEPER.

THE STEWARTON HIVE. FOREIGN RACES OF BEES.

In reference to this subject the following letter has been received, the reply to which is made the text of this article:—

"I am obliged by your last letter, to which I have delayed answering, as I thought you would be busy at the moors. As to your kind offer of the Syrian bees, I have a lively recollection of your description of their behaviour and the way they stung you awhile ago, and would not risk such an experience myself on any consideration. I am far from having the patience of Job, and suffer much when stung, so I hope you will not send me Syrians if they are dangerous and only fit for an expert. I trust you understand that I intend and wish to pay for what I obtain. I shall be very glad to take advantage of your offer to feed the bees, and perhaps you will kindly inform me whether the hive you propose to send is a frame hive, or of what description. Reading your description a few weeks back in the *Journal of Horticulture* of the strength your stocks attained when in full working order (requiring four body boxes) set me thinking whether the time has not come for a modification of the Stewarton pattern hive. Your skill, experience, and thorough knowledge of the subject gives your judgment great weight, and I shall be glad if you will consider the following points:—

"1, The foreign races of bees, such as the Syrian, Cyprian, Carniolian, &c., are much more fertile than the blacks, and consequently require much larger hives for their successful management.

"2, The Stewarton in its dimensions and form is an old hive, and was constructed to meet the requirements of the black bees, there being no others kept in Scotland then.

"3, Although the Stewarton is the very best hive for a moderate swarm, yet it loses that proportion which is one of its great recommendations when it becomes necessary to use four body boxes and five or six supers for one stock, as you have had to do—53 inches high with a base of only 14 inches appears to me to be an error.

"4, The octagon is the best form of hive after the circular (which is out of the question for wooden hives), but the proportion between base and height should be considered, and therefore as the size of the hive as a whole requires to be increased the base area must likewise be increased.

"5, I would therefore suggest that the Stewarton pattern hive should be increased in diameter to something like the enclosed plan. This would give ten bars instead of nine in the body boxes, and eight in the supers instead of seven, with only a fraction less than 2 inches each. It is not a perfect octagon, but the corners are cut off so as to allow the six centre bars to be full size. The internal superficial area will be increased from 160 square inches as at present to 215 square inches, or about 33 per cent., and three body boxes will contain about 3900 cubical inches, equal to four of the present size.—F. J. J."

[1, "F. J. J." is quite correct, all the foreign races of bees mentioned are more prolific than the common black bee, and require much larger hives, and in many instances different treatment. The failure of many

bee-keepers is owing to their persistency in keeping their bees in too small hives, which results in want of bees to gather honey, the evil being further aggravated by excessive swarming and the deposition of queens at an improper time, and often where it is most important, that swarming should not take place.

2, The Stewarton hive is practically unlimited in its capacity, as any number of divisions may be used suitable to strength of stock and fertility of queen, no matter what the breed may be. Since the days of "Bee Robin," who was both bee-keeper and joiner, many makers of the Stewarton hive were not bee-keepers, having but an indefinite knowledge of bees and bee-keeping, sent out these hives incomplete as is in some cases done yet, and without proper instructions, often none at all, hence so many failures. Then, for some years past, manufacturers not up to the making nor working of these hives, found it answered their purpose better to make square ones, recommending the latter and condemning the former without the knowledge of its merits.

3, When a Stewarton hive attains to the height of from 4 to 5 feet its weight is a sufficient guarantee that it will not topple over unless in an extremely severe storm that may occur during the honey season. We have never experienced storms at home that capsized hives during summer. Sometimes I have stretched guy cords as a precaution, but never saw the use of that. It was different, however, at the moors: having to contend against both winds, stray cattle, and sheep, and being often confined to little space, I used to place my hives in threes upon notched crossed stands, and lashed the hives to these so that they stood secure. These stands were made from five pieces of timber about 4 inches broad, one piece long the other short to suit the size of the hives, are notched together forming a right angle, then three shorter pieces are notched into the ends, forming a triple stand similar to the notched stands sold by dealers as the "cheapest, best, and simplest kind of stand ever invented." It has been used here by me for upwards of thirty years, and I had them in use in my apiary in 1875, when the person who claims the idea visited me before he invented the said stand. Probably the visit to me helped him in that as it did on the same occasion when comb foundation was condemned by him and his companion as worthless. I relieved them both of that notion.

It will be observed a stand of that description prevents the hives looking all in one direction, but if one is made to look due east, another may look south-east, and the third one may look due south. I have had my hives in fours, but it was objectionable owing to the impossibility of standing behind all the hives when manipulating. The triple stand has not that objection, and the hives can be lashed to it and together to prevent capsizing as easily as if it was a quadruple stand.

4, This seems a reasonable suggestion in theory, but not in practice. The increase of one bar only adds greatly to the superficial measure, thereby detracting from the properties of the original form of the Stewarton hive for profitable working. I had a number of such hives made, but as they disappointed me I gave them all away. Clumping hives in threes as described overcomes the difficulty and danger of capsizing.

5, The great difficulty bee-keepers have to contend against is our variable climate, hence also is the difficulty of having hives exactly to our mind. The hive as suggested is exactly similar, except the angles, to those I parted with. In some seasons they eclipsed the original form of hive, but were oftener a failure; they do not winter the bees so well, nor are they so well adapted for supering as the narrower and more compact form. It takes a long series of years to arrive at a proper conclusion what form a hive should be, as well as the mode of management. In some seasons a very indifferently managed apiary will give large returns, and when this occurs the bee-keeper jumps to a conclusion, based upon imperfect ideas and opinions, which his injudicious treatment (although once in a time fortunate) was sure to be disappointing and unprofitable in the end, arising through a misunderstanding that led to success. We do not require to go far to seek truth to support that statement. We have only to turn our eyes to much of the bee literature for ten or twelve years past; there we find leaders jumping from one style of hive and system of management to another, thereby leading people into expenses and disappointment. But at last, as the truth is forced upon them, another change is made; but lo! what do we find? Instead of either hive or system of management being new, it is but an appropriation of old ideas. The truth of the above has only to be searched for in older literature, and will give the reader a glimpse into the unfairness and injustice of some of our great bee-men of the present day.—A LANARKSHIRE BEE-KEEPER.]

Creek Road, Deptford, S.E.—*Vegetable and Flower Seeds, 1888.*
Biddles & Co., Loughborough.—*Illustrated Catalogue for 1888.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Primula sinensis variety (T. F.).—The variety of which a flower is sent is an excellent one, and more nearly resembles Princess of Wales than any we know, though it appears quite distinct from that. The flower is massive, 2½ inches in diameter, of a soft, clear pink colour, and a bright pale-green eye. It is well worthy of preservation and increase.

Glass for Greenhouse (G. R.).—You had better have 21 oz. glass, not lighter, and for ordinary purposes of growing plants and flowers for sale third quality will answer, though a grade higher, or "seconds," is better, and necessarily a little more costly. It has been recently advertised by Mr. J. B. Robinson, Moor Lane, Cripplegate, London, who will supply what you require.

Mushrooms (W. B. R.).—Answers in this column are only intended for regular subscribers, and to such they are freely given and as fully as is requisite to be useful. That is general information. To answer your questions fully would cost ten times more than the charge for the paper; therefore they are answered briefly. 1, Not with good materials in the hands of a competent man; 2, Not if the whole is much broken; 3, Advertise.

Imperator Potato (J. B. Hythe).—There is little doubt but that this is one of the best Potatoes for market during the winter and spring months. It is correctly described on page 510, December 15th, 1887, and the tubers are of very good quality. It will grow in any soil in which late Potatoes usually thrive, but if very rich or much manure is used many of the tubers are apt to grow too large. It is found by experience that less manure suffices for producing a good yield of marketable tubers of Imperator than for most other late varieties. It will be extensively planted this year in some of the large Potato growing districts in the north of England.

Purple Laburnum (J. H. V.).—As a rule the racemes of the purple are not so long as those of the best of the yellow Laburnums, but are often produced in clusters; and still smaller clusters of buff-coloured flowers are also like to issue from the trees. We once planted twenty-four trees, and only one of them bore purple flowers exclusively, and though these were of a fair size they did not equal those of the Wistaria, and were duller in colour. We do not consider the purple so effective as the yellow, but it is more rare. A deciduous flowering tree for arresting the attention of passers-by, excluding as you wish Cherries, Hawthorns, and Peaches, is *Pyrus Malus floribunda*.

Forcing Asparagus (H. A.).—The subject has been frequently alluded to during the present forcing season, and possibly you may find the information you require on page 435, the issue of November 17th, 1887. All you have to do is to pack the roots closely together before they get dry on any moist base, resting them on a layer of soil and covering them and the crowns with any light compost, such as leaf mould, giving a good watering. They grow quickly with a bottom heat of about 80°, and top heat of 60° or 65°, affording produce in about a fortnight. Roots should be put in at intervals of about a fortnight for maintaining a regular and prolonged supply. A pit in the stove will be very suitable, where the growths can have light.

Daphne Dying (A Taunton Subscriber).—The cause of death is apparent on an examination of the plant sent. In the first place the stock was faulty, not clean, healthy, and, to employ a grafter's term, "kind;" and in the second place the union of the scion with it was not good, and the descending sap could not pass down below the junction, but exuded there, forming a large callosity. If this had been buried in the soil roots would in all probability have issued from it, and supported

the plant at least for a time, but it is scarcely likely it would have grown into a healthy specimen. The top of the stock ought to have been cut slantingly up to the base of the scion, nor left flat and square for holding and absorbing wet, thus causing decay.

Raising Conifers from Seed (W. M.).—Seed gathered in the autumn and sown in the open ground in sandy soil during fine weather in March will germinate in a few weeks; but any of choice varieties is best with the protection of a light frame, sowing in a mixture of very sandy loam and leaf soil, taking care that it is kept uniformly moist, and to afford adequate ventilation when the seedlings appear for keeping them sturdy. We do not know to what species you refer under the name of the "Welsh Pine," but possibly some of our readers may be able to distinguish the tree thus named; or if you send sprays and a cone we may perhaps be able to identify the species. The popular name cited is, we think, local. An agent to whom you may apply is Mr. C. Bates, 24, Mark Lane, and R. Silberrad & Son, 25, Savage Gardens, E.C.

Vine Roots Decayed (R. W.).—We remember receiving and examining some Vine roots a few weeks ago, but received no letter referring to them. These may or may not have been yours. We could not find any traces of the phylloxera, and we thought the roots had come in contact with some corroding substance in the soil. We have seen good and not ill effects from the use of Beeson's manure, though it would no doubt be a mistake to use it in excess; but so far as we know it is safe when the instructions of the vendors are followed. Not knowing the weight of the quantity used we can scarcely form an opinion of its possible effects in your case, but should not think it was the cause of the damaged state of the roots, assuming those we examined were sent by you.

Chemical Manures for Fruit Trees (W. J.).—Of the ingredients you name 2 cwts. each muriate of potash, superphosphate of lime, steamed bone flour and gypsum would form a good mixture for applying to the soil for the support of Vines and fruit trees generally, dressing with sulphate of ammonia subsequently if needed, its quantity being regulated by the condition of the trees or Vines, an excess causing exuberant and sappy growth. If mixed with the other kinds ½ cwt. would be ample. You will not err by using muriate instead of nitrate of potash to garden or farm crops. Having regard to the outlay invested in both, the former has proved the more satisfactory in many experiments, though possibly there may be a few exceptions not known to us.

Fungus in Vine Border (A. W. C.).—The fungus is common in leaf soil containing woody matter, such as the twigs and branches of trees, also in spent tan, and its presence in the Vine border may be due to the pieces of laths introduced with the lime rubbish. You cannot do better than proceed as you are doing—i.e., removing as much of the decaying woody matter and white fungoid mass as possible, being careful not to injure the roots. Dusting with fresh slaked lime will be highly beneficial alike in hastening the decay of the woody matter and converting the nitrogenous substance of the fungus into nitrate of lime, which will act beneficially on the Vines. You may also add dry wood ashes to the lime, an equal proportion of each, applying the mixture as the renewal of the soil is effected; thereby potash will then be afforded, which with the fresh soil cannot prove other than advantageous to the Vines.

Seeds Required for Garden Plots (B.).—The following seeds and space the quantities named may occupy has been determined by experiments, the seeds being good and uniformly covered at a proper depth in suitable soil:—Asparagus, bed of 15 square yards, ½ pt.; Beans, Broad, per row of 80 feet, 1 qt.; Beet, row of 50 feet, 1 oz.; Broccoli, per 4 square yards, ½ oz.; Brussels Sprouts, per 4 square yards, ½ oz.; Cabbage, bed of 8 square yards, ½ oz.; Carrots, drill of 120 feet, 1 oz.; ditto, bed 12 square yards, 1 oz.; Cauliflower, 4 square yards, ½ oz.; Celery, 4 square yards, ½ oz.; Cress, 3 square yards, 1 oz.; Endive, 4 square yards, ½ oz.; Kale, 4 square yards, ½ oz.; Kidney Beans, row 80 feet, ½ pint; Leek, 2 square yards, ½ oz.; Lettuce, 4 square yards, ½ oz.; Mushroom, 7 square yards, 1 bus.; Onions, 9 square yards, 1 oz.; Parsley, row 80 feet, 1 oz.; Parsnip, drill of 200 feet, 1 oz.; Peas, early, row of 60 feet, 1 pint; Peas, large, late, row of 80 feet, 1 pint; Potatoes, row of 30 feet, ¼ pkt.; Radishes, 4 square yards, 1 oz.; Savoy, 4 square yards, ½ oz.; Spinach, 10 square yards, 1 oz.; Spinach, drill of 120 feet, 1 oz.; Turnip, 4 yards square, ½ oz.

Pruning Peach Trees (F. J.).—It is better to arrange the main branches wide enough apart to permit a selection of the summer growths being laid in between them, not topping them till the beginning of September, if then; but disbudding is essential to prevent overcrowding, or the foliage of one shoot materially overlapping and shading the others. The growths then ripen and triple buds form nearly their entire length, the centre one being a blossom bud. The requisite number of shoots should be laid in annually, and no more, to permit of much of the wood that has borne a crop being cut out after the fruit is gathered. The process has been plainly described many times in our "Work for the Week" column, and not long ago. It will be referred to again in time to be of service. Peaches are pruned in the spring, the spur system answering fairly well in very favourable positions, but we do not remember having advised you to adopt it. Prune to triple buds, if any, on ripe wood when the blossom buds show colour. Undoubtedly chemical manures are good for lawns, so is soot. If you mix superphosphate of lime and sulphate of ammonia at the rate of 4 lbs. of the former to 1 lb. of the latter, and sprinkle about 2 ozs. on each square yard in February, it will do your lawn good. The formula to which you refer

has been so often given that we must leave it to our correspondent to give it again when the subject comes under discussion in the ordinary course of routine.

Inarching Alicante on Foster's Seedling Vine (B. K).—The inarching of Black Alicante on Foster's Seedling will tend to an earlier maturing of the Black Alicante, which will succeed in the same house with Black Hamburgs where artificial heat is employed at starting and during the early stages of growth, also during the ripening period, should the weather at that time prove unfavourable to the ripening process. There is no better keeping Grape for growing in the same house with Black Hamburg than Black Alicante, its quality being generally superior to Gros Maroe, which, however, is a very "showy" Grape, and would no doubt succeed well on Foster's Seedling, ripening with the Hamburg; but Black Alicante requires a little more time to mature. Lady Downe's will also succeed along with Hamburgs, but it is liable to scald unless kept rather warm and freely ventilated towards the close of the stoning period, being safe from that scourge after the Grapes commence ripening. It is the best of all long-keeping Grapes, and is decidedly superior to any late, thick-skinned varieties except Mrs. Pinee, which, grown well, which it seldom is, is first-rate in quality. For your purpose we advise Black Alicante. It would be best to inarch a young cane of Black Alicante on to the Foster's Seedling, preferably to a good lateral near the bottom of the Vine rather than on the old wood. Victoria Hamburg is synonymous with Frankenthal, which is very much confounded with Black Hamburg, indeed many of the so-called Hamburgs are Frankenthal. It is a very good Grape, than which no better evidence is needed than yours—viz., "I have had good Grapes from the Vines every year." It would be well to allow both the stock and scion to start into growth before inarching, especially the former; indeed, you may erop the Foster's Seedling this year, but keeping the laterals well in hand, encouraging growth in the Black Alicante by permitting its laterals to remain, cutting away the Foster's Seedling so soon as the erop is out. The union will be effected in about six weeks after inarching. You would find Barron's "Vines and Vine Culture" valuable for reference, and it can be had from this office, price 5s.; post free 5s. 3d.

Improving Neglected Garden (R. S. O).—You could not have done better than in sparing no pains in eradicating the weeds, it being an essential in good husbandry that the resources of the soil be reserved for useful erops. The couch and bindweed should be forked out, and then there is a prospect of the soil being utilised—giving a good return as it always does for intelligent cultivation. Burning the weeds and returning the ashes to the soil will have an improving tendency through acting mechanically on its texture, and also as manure. The trenching would also tend to improve the soil's texture. There is no fear of the dung applied in the trenches being lost—it failed in being appropriated last year through the drought. We presume the good soil has been kept near the top, or, at least, the soil has been well mixed. In trenching the mistake is sometimes made of burying the good surface soil under poor and stubborn material. In that case either much manurial matter must be applied to get it into heart, or long exposure is necessary to bring it into a fit state for erops, but we note none of these defects in your method, and think the procedure you have followed upon certain to bring its reward in due season. In the absence of manure you may have recourse to nitrate of soda, muriate of potash, and superphosphate. Of nitrate of soda 1½ ewt., nitrate or muriate of potash (the latter preferably) 1½ ewt., superphosphate of lime 4 ewt., would be an excellent dressing for one acre. They should be procured separately, and mixed as required, applying just prior to putting in the erops. A pound of nitrate of soda, the same of muriate of potash, and 2 lbs. of superphosphate will be suitable for a rod (30¼ square yards). The quantity is heavy, but yours is a particular ease and needs more radical treatment than had the soil been in fair heart. You can supplement those by dressings of soot after the erops are fairly established, applying a peck per rod, or 40 bushels per acre, employing it during moist weather, one application being sufficient for each erop. As your soil is strong, mulching with anything calculated to prevent evaporation, such as grass mowings, &c., will be useful for such erops as Peas, &c., indeed anything to which moisture is an essential. Such soils are liable to bake and crack under powerful sun.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (J. R.).—1, Cox's Orange Pippin; 2, Blenheim Pippin; 3, Flanders Pippin; 4, Mère de Mènage; 5 and 6, Not known.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed 'horists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. A correspondent whose name has been mislaid sends long fronds of the following Ferns:—1, Asplenium diversifolium; 2, Nephrolepis tuberosa; 3, Polystichum aculeatum; 4, Polypodium aureum. (R. S. T.).—A good variety of Dendrobium nobile. (W. P.).—1, Anthurium Schertzerianum; 2, Asparagus plumosus; 3, Rhododendron javanicum. (J. L.).—1, Cypripedium venustum; 2, Tylda Madame Heine; 3, Selaginella uelcinata; 4, Adiantum amabile; 5, Adiantum assimile; 6, Selaginella caulescens.

COVENT GARDEN MARKET.—JANUARY 18TH.

MARKET quiet, with good supplies.

LAMBING TIME.

EARLY or late lambing is very much a matter of expediency, for there are local circumstances which must always be taken into account. A fine batch of forward fat lambs ready for market a week or so before Easter is always profitable; certain butchers and salesmen must have them at any price for fashionable customers, and they often realise double the price of lambs sold a few weeks later in the season. This is a matter, however, somewhat outside the general question, for if farmers generally were to press Easter lambs upon the market, prices would certainly come down. Shelter

and food are perhaps the two most important factors worthy of attention as affecting final results. Given enough of both we cannot well have lambs too early, but our system of flock management must be well digested and our plans elaborated for the entire year.

We saw a large flock of ewes a few days ago upon an absolutely bare pasture, where they were having trough food and Mangolds, but they could get no grass, for the herbage was eaten off closely, and the ewes had evidently been on short commons. If this was the case at the beginning of January, what will it be if we have a late spring? Why, the flock will either have to be sold outright, or both ewes and lambs will be very low in condition. We have a large surplus quantity of Mangolds, and we have ample reason to expect 20s. a ton for them by the end of February, when many a flockmaster will be eager to buy. Anything like a fair profit upon the progeny of underfed ewes is a very doubtful matter, or rather we should say is not doubtful, for we know it is not to be had. Again we say, if the animals of the farm are to be bred profitably they must be well fed from the birth. Let any of our readers having a flock look closely into the condition of it, and if it proves to be too numerous for the means at their disposal there should be a reduction in the number when it can be done without a serious sacrifice. Season after season do we see ewes with very young lambs sent to the auction mart to be sold for what speculators care to give. The loss upon such a transaction is greatly to be deplored, because it might so easily have been avoided by the exercise of a little forethought.

There can be no doubt that many farmers are much concerned just now about the provision of food for the flock, and it is equally certain that many of them have an ample store of food by them of which they do not avail themselves simply through ignorance of its value.

Roots, roots, is their cry for sheep food in winter, yet we know by analysis that straw contains twice the proportion of fat and flesh-formers to that contained in any root crop, and we have only to chaff it to render it suitable for sheep food. If we have occasion to render the dietary a little more nourishing, a moderate addition of Oats will answer the purpose admirably, for, subject to the crucial test of analysis, Oats are known to contain at least ten decimal parts more of fat and flesh-formers than the best linseed cake. If, then, we require a perfect nourishing sheep food we have only to chaff unthreshed Oat sheaves, and we have it. In point of fact both economy and utility tell us to mix some chaffed Barley straw with the chaffed Oats to avoid waste by the use of too nutritious food. Why will farmers continue running up heavy cake bills when they have it in their power to avoid them? Why, also, should an undue proportion of farm land be under roots? It is well known that root crops are exceedingly costly and speculative, and if we can avoid much of the outlay hitherto incurred in the cultivation of such crops we are bound to do so. So many bullocks and sheep and so many acres of roots has been an article of faith with farmers for a long time. We may now advantageously discard the bullocks and dispense with two-thirds of the roots. Only let us take care to increase the acreage of pasture and green crops sufficiently to insure enough green food at all seasons of the year for the sheep, and then with plenty of the trough food we recommend we may very well dispense with most if not all of the roots.

The lessons of adversity are teaching us many useful things. We may fairly claim to be successful in farming even now, but we are not content with bare success, and are constantly on the alert to effect really useful reforms in our practice. The present lambing season is certainly an opportunity for doing so, and we intend taking the dietary of the lambs entirely into our own hands. We have shown that it is our practice to begin giving the lambs some trough food as soon as they can take it, and we intend trying a mixture of coarse Oatmeal and bran, with a slight addition of salt at the outset this season. All that the lambs require is sound,

finely divided, nourishing farinaceous food, and by the aid of a little common sense we think a farmer ought to be able to prepare such food from home-grown produce. It is claimed for special mixtures that they possess important medicinal properties which tend to keep the lambs sound and healthy. We know that a little Fenugreek imparts a savoury aromatic flavour to such mixtures, and we strongly suspect that some such addition is all that specialists use in the way of drugs.

(To be continued.)

WORK ON THE HOME FARM.

So far the winter has proved to be favourable for work on the land. But little snow has fallen, frost has not been severe, and the land is not sodden by rain, so that ploughing has gone on with but little intermission save when the horses have been required for the carting of corn. For us this is most fortunate, as in addition to our ordinary farm work some three hundred acres of exhausted land came upon our hands at Michaelmas, and we have still got much of it to plough. We have, however, finished ploughing the home farm, and have sent off all the horses and ploughs thence to help plough the poor land. Unfortunately for us this poverty-stricken farm is also very foul with couch grass, and our work upon it this year will be of an arduous nature. It is almost disheartening to have to take such land in hand, more especially for us, as we had just got the farms in hand into good order, and they were showing a handsome margin of profit. Landlords' farming is often spoken of by tenant farmers as certain to fail, and we shall have something to say about that very soon. We as a landlord's agent have proved farming to be so profitable that it is a moot point whether to let any more farms at the very low rents now offered by prospective tenants. This thought occurs to us with especial force just now, as we have had the accounts of all the farms under our care balanced, and we find a decided improvement during what has been termed the worst year that farmers of our day have known.

Our readers know full well how we have repeatedly pointed out for their guidance what to avoid and what to do in farm management. We now mention something of the result of our work to show how thoroughly in earnest we are, for before all things we are bound to be practical, and we cannot afford to indulge in untried theories which may or may not succeed under the test of practical application. With bad or good land we have done all we could to turn it up roughly to the action of frost, snow, rain, and wind. We began doing this immediately after harvest, and when the winter corn was sown the ploughing was pushed on as fast as possible, but we could not get all of it done before the end of the old year as we so much wished to do. We have said that the land is not sodden by rain; in proof of this we may mention the fact that soil ploughed a few weeks ago has quite recently been thrown into ridges without any difficulty.

THE HESSIAN FLY AND ITS PARASITES.

OBSERVATIONS upon the Hessian fly, so-called, or properly *Cecidomyia destructor*, made in North Britain, brought to light the fact that it has not reached our island without being accompanied (or followed) by several of its minute parasitic enemies. Probably it is in some measure due to the proceedings of these that it has not extended itself over a larger area in those districts where it first appeared. One of the most curious facts is, that these parasites have been verified as occurring in Russia chiefly, at least four of the species; the fifth has been recorded in America, but in Germany also. This rather supports the theory that the recent visitation came to us through imports from Russia.—ENTOMOLOGIST.

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude, 111 feet.

REMARKS.

8th.—Generally overcast, but fair at times.
 9th.—Thick white fog except at mid-day.
 10th.—Fog more or less all day; dense till 11 A.M., and very dense in the evening.
 11th.—Dense fog all day.
 12th.—Fog, dense at times in the morning; fair afternoon.
 13th.—Overcast day, slightly foggy at times.
 14th.—Dull, with varying fog.
 A very dull and rather foggy week, with very high barometer, and, of course, little wind, and equable temperatures. No rainfall but deposition of wet and dirty fog.
 —G. J. SYMONS.

GARDEN PRODUCE.
SIZE v. QUALITY.

NO, Mr. "Spectator," I will not take the text you have selected for me, but will take one from your own book—"Many if not most gardeners grow the produce of gardens too big by half." The charge of mine to which I am referred for a text was preferred more against the public taste for things merely large; his charge is against gardeners for making an ideal of large productions instead of finer qualities. This charge may have a double meaning, or may be interpreted in two different ways. Either your correspondent means that we grow certain varieties of fruits and vegetables over-luxuriantly, or that we select the largest varieties and reject the smaller, or it may embody both these assertions. Perhaps he is correct. In many cases he may have hit the mark correctly.

Beyond all doubt size in the vegetable and animal kingdoms has an imposing, and it may be said a captivating, effect on many minds. More particularly is this the case in regard to such objects as become the special care of the cultivator and feeder, who naturally enough likes to see and cultivate things that are given to develop into all the sizes they are capable of. Fostered by public demand, exhibitions, and commercial success, beyond all question size in fruits and vegetables, instead of quality, and at the expense of it, has been too much the aim. In the markets of our great consuming centres size and appearance bring much better prices than the highest order of quality weight for weight. This of necessity compels the grower for market to go in for size if he is to hold his own in the scramble for existence—a fact that does not say much for refinement of taste on the part of consumers.

Anyone who in October prefers to give, say, 3s. 6d. per lb. for Gros Colman Grapes, and will not buy fine Black Hamburgs when to be had for 2s. 6d. or 2s. per lb., is surely to be pitied either for the poverty of his taste or for his ignorance. Gros Colman, especially at the time named, is not in the running with the Black Hamburg for all that is fine in quality, yet this fine old Grape and all other first-rate blacks are being fast driven out of the markets by Gros Colman. The latter when grown in high Muscat temperature and allowed to hang on the Vines till January, or, better still, February, is a good and pleasant Grape, but not equal in flavour to thoroughly ripened Lady Downe's at the same date, yet in the markets Gros Colman brings nearly double the price realised for the more modest-looking Lady. This craving for mere size and show leads me almost to exclaim in irony, "Where ignorance is bliss 'tis folly to be wise." In this matter the evil is not by any means confined to market growers and buyers. There have been far too many of the coarse sorts planted and grown by gentlemen's gardeners for nothing else than for the size to which either the berries or bunches attain. Horticultural societies have fostered and aggravated this malady by offering handsome prizes for mere weight and for collections of eight to twelve sorts of Grapes. No doubt this has been done to please the public eye, but it is not a sound education. Hence there is to be met with far too much space little better than wasted in the production of tasteless monsters, while the smaller and finer sorts have been in many cases all but hustled out of numbers of vinerias. It has been no uncommon sight to see such as Raisin de Calabre, Syrian, and Gros Guillaume, and similar sorts planted and trained 5 to 6 feet apart, and allowed to carry a very few bunches each, simply for the sake of producing an abnormally large bunch or two to figure in a collection or get a prize for weight and gull the public, and it is feared

in some cases the Judges too. More than double the weight of Muscats, Hamburgs, and Lady Downe's, and other good sorts could have been produced in the space thus little better than wasted.

Not long since a writer—if I remember correctly in these pages—had the hardihood to put forward Gros Maroe as a formidable rival in quality to the grand old Black Hamburg. My judgment is sadly deficient if this Grape has a single quality except colour and size that brings it within miles, so to speak, of Black Hamburg, and it is almost a sin to name it as a rival anywhere in any way except on the market stall, and to get 6d. or 1s. more per lb. The same may be said of Cooper's Black, which, if not identical with Gros Maroe, is very like it. Both, it must be granted, are beautiful to look at, and that is about all that can be said for them. The large-bunch-producing whites stand in the same relation as to merit to Muscat of Alexandria and others of that type as the large blacks do to Black Hamburg, and it is a pity that horticultural societies have not the courage to check the growth of such coarse sorts from gentlemen's gardens. Here is a work for the Royal to take up that is surely worthy of it. After all the test of skill does not lie in the direction of coarse monsters. Muscats and Black Hamburgs and a few others are the real tests of skilful culture. The whole thing is a mistake. Let our fine varieties be grown to their largest size in bunch and berry, and no great fault need be found with the result. But even in their case moderate sized bunches are far and away the more useful for family service, a greater number of medium bunches being preferable to a lesser number of larger ones.

Before quitting the subject of Grapes I would say that in keeping Grapes for my own taste or that of a particular employer I would avoid cutting and bottling them. This system is much practised now. No doubt it is a convenient one, but that is all that can be said in its favour. The extent to which Grapes lose flavour under it is enough to condemn it root and branch. The effect produced is very much like what the Highlander considers is produced in his whisky by adding cold water to it. The advocacy in some quarters of ripening Grapes in a low temperature is another method of spoiling good Grapes—aye, and Vines too. If a Grape is wanted of high quality and to keep well let the temperature be high, within certain limits, of course, to the finish in conjunction with a circulation of air. Such treatment produces a Grape entirely different in texture and in flavour, and as a consequence in keeping qualities.

The Grape has been thus dwelt upon, because what in this question of mere size is applicable to it applies to most of the products of our gardens. The mistaken craze for size and appearance is carried too far. This refers to nearly all other fruits—Melons, Pines, Peaches, Figs, Apples, Pears, Gooseberries, Strawberries, &c., the smaller varieties of which are, as a rule, the best, and where there is an exception it only proves the rule. It applies not altogether to large sorts, but to abnormally large examples of smaller sorts. I was very much struck this winter in comparing the flavour of some very large Apples with that of medium-sized ones of the same sorts that were grown two or three hundred miles further north. The latter had the much better flavour, were more solid and crisp. The more spongy texture of the very large ones was very conspicuous. The difference was as striking as that between the Chesterton yellow Turnip and the Aberdeen short top yellow. The former is what we in the north call "bosse" or "fosey," while the latter, though less bulky, is far more solid and heavy, and of course better. Speaking of these Turnips, I saw at an agricultural show in September the first prize awarded to the Chesterton, while Aberdeens were placed second on no other ground than a point or two of size. On being cut open the absurdity was patent to all. As well place a west Highland ox second to a shorthorn for quality of beef.

There is much to justify the remarks not only regarding Brussels

Sprouts but other vegetables as well. The absurdity of the preference for mere bulk is far too prevalent. Large Brussels Sprouts are invariably loose and deficient in quality, and surely to the eye, of nice appearance. They are not solid enough to begin with, and when cooked there is no getting the water out of them without squashing them out of shape in the process. The smaller bullet-like sprouts boil as whole as a Potato, are easily dried without smashing them, and are of much milder flavour. The most perfect forms of this fine green that I have met with are the "Northaw" and "Ne Plus Ultra." Their stems are densely set with solid sprouts about twice the size of a marble. Large Beets, Celeries, &c., are invariably coarse. The smaller sorts of Cabbages are also the best. As a blanched or hearted Cabbage what can be finer than Chappel's Colewort?

Potatoes are also mentioned. For a special object, and by command, I have probably grown the largest Potatoes of some sorts that have ever been produced. I have had bushels of Walker's Regent over 2 lbs., and one tuber 4½ lbs., but I have no hesitation in saying that the usefulness of the Potato, for human food especially, is in inverse ratio to its size. The chief secret of having the finest Potatoes in the finest possible condition on the table is to have them properly cooked. They should be cooked in their jackets. The larger ones should be rejected and the smaller ones preferred, because in cooking a large Potato properly to its centre, the outside and best part of it is spoilt. Besides this, all large Potatoes deteriorate towards their centre. A friend in writing to me a few days since, referring to the absurd craze for size, says:—"I was very much struck by what Mr. Charles Van Geert of Antwerp said to me two or three years since when admiring the pretty little even-sized Potatoes that came to table, none of which was larger, and some smaller, than a hen's egg. I asked him what variety it was, as I had noticed them wherever I had been in Belgium. He said they were just the same as we had in England, only the small ones were sorted out. Then he added, What you give to your pigs we eat, and what we give to our pigs you eat." Now if what has been remarked above about the relative cooking and other qualities of large and small Potatoes be correct, the Belgians are right and we are wrong. If the raisers and exhibitors and vendors of the deluge of huge worthless Potatoes that have been showered on us of late years had directed their energies to quality and moderate size, and if judges had set their face in the right direction, we might have been better off to-day. Not one of twenty of these monsters is fit for human food, and our very oldest are yet the very best.

Nothing stems the craze for mere size in fruits and vegetables more effectively than having to meet the demands of a first-class French cook, backed by the refined tastes of a nobleman and lady. The gardener who has to do with such soon finds out that monsters will not suit. I remember some very large coarse Celery being once sent from a distance to a cook I served for many years to show him how much larger it was than a fine type of Incomparable White which was exclusively grown to meet his wants. The former soon found its level at his hands.

The Scotch have a saying that "Gude gear is pit up in wee booke," and the rule holds the field. It is true of fruits and vegetables just as it is true of beef and mutton. The larger, as a rule, the more coarse and deficient in flavour are the products of the animal and vegetable kingdoms.—D. THOMSON, *Drumlanrig*.

"TURNER MEMORIAL" PRIZES FOR 1888.

An idea prevails that the prize money available from this fund should be set apart to give prizes for florists' flowers only. This is an error. The expressed wishes of the Committee were, that as the late Mr. Turner had a mind in active sympathy with every branch of horticultural work, and had introduced new varieties of fruits and vegetables as well as flowers, prizes should be given for fruits and vegetables. Acting on this assumption the Trustees have decided to give a fresh prize of £10 at the Grand Yorkshire Gala, York, 13th to 15th June, for a collection of ten distinct varieties of fruits. The Society will give £5, £3, and £2, as second, third, and fourth prizes. At the Crystal Palace,

on October 11th to 13th, the following prizes for twelve dishes of vegetables, distinct—first prize £4, second £3, third £2, fourth £1. These prizes are open to gentlemen's gardeners only.—JAS. DOUGLAS, *Hon. Sec. to "Turner Memorial" Fund.*

DEATH OF MR. JOHN DAY.

ON Sunday, January 15th, died a distinguished amateur orchidist, Mr. John Day of Tottenham, and numbers of horticulturists besides those specially interested in Orchids will learn the news with deep regret. For many years Mr. Day devoted himself earnestly to the cultivation and study of Orchids, during which time he formed a most extensive and valuable collection that was famed throughout Europe for the number of varieties it contained. All who had the pleasure under the guidance of the proprietor of inspecting the houses crowded with choice Orchids prior to the great sale will not readily forget the quiet enthusiasm with which he regarded his plants. It will be in the memory of many that the principal collection was sold in 1881 in four portions, realising a total of £7000, amongst which the celebrated *Cypripedium Stonei platytenium* was sold for 140 guineas, with many other valuable plants that were confined to the Tottenham collection. Since then Mr. Day has devoted his attention to a few plants, but has been a frequent visitor to all the leading trade and private collections of Orchids around London, and has sketched some hundreds, probably thousands, of the most notable Orchids he saw in his travels, filling about fifty large books, a collection in its way scarcely less remarkable than the plants he formerly cultivated. Mr. Day had also travelled in India and South America and the West Indies, both as an observer and a collector, by which he gained much information that he not only utilised himself in the culture of Orchids, but which he was also always ready to communicate to his friends. In a general way he was reserved, and of late years did not enjoy good health. Innumerable plants have been named in his honour, also after his sister, Mrs. Wolstenholm.

WARNE'S ORCHID PROTECTOR.

One of the troubles of an Orchid grower is to prevent slugs, ants, woodlice, and other insect pests reaching the plants, injuring young flower spikes, or disfiguring expanded flowers. When pots are placed directly on the shelves this is not readily accomplished, even when the stages themselves are isolated by means of saucers of

Fig. 8.

water surrounding the supports, but it is far better to isolate the plants individually. Then if proper care has been exercised in examining the peat, moss, and crocks before using them, there will be little difficulty in keeping such enemies at a safe distance. A capital contrivance for the purpose is the saucer and stand shown in fig. 8, which is manufactured by Mr. Conway G. Warne, Weston-super-Mare, and which has been patented. As will be noticed, it is of similar design to that employed in Mr. W. Lee's Orchid houses at Leatherhead and illustrated in these pages a year or two since, but it differs in an important particular—namely, the centre is hollowed so that water can pass freely from the pot placed upon it, and when pots are stood upon a perfectly flat smooth surface there is always a danger of interrupting the drainage. The saucer is filled with water, serving as an effectual barrier to most insects, and further affords a constant supply of moisture, which evaporating steadily beneath the foliage is very beneficial.

DENDROBIUM STRATIOTES.

Of the numerous *Dendrobiums* now in cultivation perhaps there is scarcely one to equal *D. stratiotes* in singularity of form and distinctness of colouring. Last September a plant was shown at South Kensington from the Burford Lodge Gardens, Dorking, that indicated the peculiar characteristics of the species in a remarkable manner, and it then formed one of the most prominent features of the meeting. The specimen had a short raceme of four flowers, as represented in the woodcut (fig. 9) which faithfully portrays their

strange formation. In most Orchid flowers, when the sepals and petals are not of equal size, the latter are the larger, but in *D. stratiotes* the sepals are four or five times broader than the petals, much shorter, and white. The petals, which constitute the most curious portion of the flower, are very narrow, ribbon-like, of a greenish tint, and regularly twisted in a spiral fashion. The lip is three-lobed, the centre one being much the most prominent, ovate in form, pure white, with a few deep purple irregular veins, the side lobes being marked with a few parallel streaks of a similar colour, and lead into a short conical tube or spur. It was introduced to Belgium a year or two since by one of Mr. Linden's collectors in the Sondaic Archipelago.

LÆLIA GOULDIANA.

At one of the sale rooms recently I saw some plants in flower of this new and beautiful *Lælia*, and though it is a near relative of *L. autumnalis* and *L. anceps*, it is readily recognised as quite distinct when compared with them. Upon the same occasion Mr. F. Sander pointed out to me the rare *L. Crawshayana* and

rare plant he found to his disgust that a snail had made his breakfast off the plant—a most expensive breakfast, many will say. I would advise Orchid growers to give the slow-worm a trial. They can be purchased from any dealer in wild animals.—ALEXANDER PATERSON, M.D.

CYPRIPEDIUM SANDERIANUM.

WE learn that Mr. William Bull, King's Road, Chelsea, has lately purchased a plant of *Cypripedium Sanderianum* for £300, and it is said that the same plant was purchased by its recent owner a few years ago for 50 guineas. This is the largest price recorded as having been paid for one Orchid.

LÆLIA ANCEPS BARKERIANA.

By this post I am sending a spray of this beautiful *Lælia*, which my employer, W. H. Watts, Esq., considers a decided advance upon the ordinary forms of *L. anceps*, an opinion upon which I am sure you will agree. Still, the various shades of this popular Orchid from the richly coloured *L. a. Barkeriana* to the palest forms are not to be despised, and are well worthy of cultivation. If we take

FIG. 9.—DENDROBIUM STRATIOTES.

L. furfuracea, which, with the three named above, form a group of five handsome allies, and it afforded a good opportunity of comparing them. *L. Gouldiana* was found in a collection of Orchids in the United States during a recent tour there by Mr. Godseff, the representative of the St. Albans firm, and it was very properly suggested that it should bear his name, though it was ultimately named *Lælia Gouldiana* in honour of Mr. Jay Gould at the desire of Messrs. Siebrecht and Wadley of New York. The flowers are remarkable for their deep crimson colour and beautiful shape, the petals being very broad and quite rhomboidal in form. The colour is uniform throughout the sepals, petals, and lip, but there are some slight variations in which the throat of the lip is lighter or nearly white. It is a grand winter flowering Orchid, and will become a favourite in many collections.—LEWIS CASTLE.

BRITTLE SNAKE IN THE ORCHID HOUSE.

THE brittle snake (*Anguis fragilis*, *Lin.*), or the slow-worm, is a native of Britain, common in England, not so common in Scotland. When full grown it is about 12 or 13 inches long and generally of a dark glossy colour, moves slowly, and has a beautiful snake-like head with keen piercing eyes, is perfectly harmless, and can be made a pet. I find this snake a grand assistant to the green tree frog in the Orchid house, as its principal food is snails. All Orchid growers hate snails, as they destroy flower spikes and young pseudobulbs. Some years ago a friend of mine purchased a rare *Phalæ-nopsis* for 10 guineas. Next morning when he went to look at the

into consideration the time (midwinter) and freedom of its flowering, simplicity of culture, and price at which it can be procured, this Orchid must commend itself to all in possession of a stove or intermediate structure.—A. R. COX.

[The variety named is well known as a handsome and rare one, the flowers before us showing the rich colouring admirably.]

CROPS THAT PAY.

WE seem to have been congratulating ourselves that the good old ship of horticulture was making steady but certain progress. Upon reflection, I think it may be said we have made a move onwards; but nevertheless we have been too apathetic, while the cultivators of other countries had their eyes turned to the future, and patiently plodded on, preparing themselves to supply our markets with fruits, flowers, and vegetables. Years of depression have not had the stirring effect amongst home cultivators that we might desire, for still foreigners supply our markets with the produce of the soil in much larger quantities than formerly. Something seems to be radically wrong, for the impression is firmly established that "nothing pays." Is the land worse than formerly, or is it incapable under good and intelligent cultivation of yielding the same as it did years ago, or is it that those who cultivate it have grown slothful and indifferent? Not long ago bad seasons were to blame, and now explicit reliance seems to be placed on the

reduction of rent as an amendment for all the evils that have been lately hoisted before us. The land is as good as ever, and speaking generally no better can be found in any other country. Its resources only want developing. In many cases I firmly believe that if cultivators had the land for nothing they would fail to make it pay. There is prosperity still in store for many tillers of the soil if they could only be induced to bestir themselves to greater diligence and energy; in a word, to turn over a new leaf in the management of land and cropping. I am not alluding to farmers in particular, but to all tillers of the soil, whether they term themselves agriculturists or horticulturists. I see an Agricultural Education Bill is projected to provide for teaching the principles of agriculture and for the provision of school gardens for the illustration of those principles, the subjects to be taught including grafting, pruning, fruit, flower, and vegetable growing. So far so good, but while these principles are being instilled and take permanent effect, there is ample time for many by their own efforts to rise to a prosperous condition, or, on the other hand, to be ruined by neglect.

If we try to see how matters stand at present, to what conclusion can we arrive if we glance at the returns of our agricultural imports that have been issued for the past year? We have to pause before we can say that we are making progress, at least in the production of vegetables. We imported more by £133,143 worth last year than was the case in 1886. Are we to draw the inference that we have been producing less than formerly? or shall we take the more hopeful and perhaps reasonable view of the case, and say that the public demand for vegetables has increased so enormously? I should say this is the right view to take, and I believe the increase will go on steadily—especially if trade continues to prosper—then why not prepare in earnest to meet from our own land this increasing consumption? The question that it is natural to ask is, How do we know that the increased consumption of vegetables will continue? No fear need be entertained on this score, or even in disposing of the produce if good and of the right kind. If we suppose that it does not increase there is ample scope for cultivators to meet the demand that already exists, for we paid away last year for these articles the enormous sum of £600,882. I think it is high time we stirred up to greater effort those engaged in husbandry, and I do not know a more suitable place than our Journal in which it can be done.

While the impression so largely exists that "nothing pays" it is my intention, with the Editor's permission, to remove if possible these erroneous notions how it can be accomplished by growing "crops that pay." Mushroom growing has been urged as a profitable concern to the successful grower, and its claims cannot be too forcibly pressed to the front, as it is one of the most remunerative crops that can be grown. They can be grown to realise a good return to the grower at a much less price than can now be obtained for them in the market. This is a good time to make beds, and those who know nothing of the business should study Wright's "Mushrooms for the Million," and if the details there given are intelligently carried out and added to or modified according to circumstances none need fail. My crops, by information gathered from that source, paid the rent and labour, besides clearing the cost of the manure, which will materially reduce the cost of other ground crops by applying it instead of having to buy fresh. But it has been said, If more start growing them you will not make so much out of them. I shall just make the same, for this is easily done by increasing the number of beds. At present there are more consumers than there is supply, consequently they are imported from France. If they are cheaper more will be consumed; the supply may be in our own hands, and the grower as well as the consumer will profit by increased production.—MARKETER.

SIX GOOD PEAS.

THERE is no vegetable that commands more attention for summer cultivation than Peas. So anxious are many to possess them that the days are counted from the time the seed is sown until the first dish is gathered, and this is not confined to large gardens, but amateurs, and even cottagers, have all a desire to secure early Peas. From May until October Peas afford a never-failing topic. If we go into a garden in May one of the first questions asked is, "Have you gathered Peas yet?" Farther on, when the hot dry weather of July and August is apt to interfere with the success of many crops, the question is, "How are your Peas?" and later still when the days are shortening and the cold nights are staying the progress of vegetation the question is still, "Have you any Peas?" and from beginning to end the important question as to which are the best varieties for a long and good succession is freely discussed. This is a point that is forced on all; and although it is not unseasonable to speak of it when the Peas are being inspected in the rows or tasted on the table, it is now at the commencement of the sowing season that the matter may be

discussed with great advantage. All kinds of vegetables have multiplied at an extraordinary rate during the last twenty years, and none more so than Peas. In a list before me, a good and trustworthy one from Messrs. Barr & Son, the number of varieties of Peas offered is just sixty, and I almost tremble to think of what will be said of the fifty-four that my heading excludes, but for all that I am not afraid of stating what I regard as six good Peas; and although these are some of the newest my selection has been made from over fifty, and the weeding out has been done without fear or favour.

Carter's Lightning is said to be the earliest Pea. I can verify the assertion, and therefore begin the season with it. It is a compact robust grower, attains a height of 2½ feet, or 3 feet if grown in very rich soil. The pods are produced in multitudes about 3 inches in length each, and they are crowded with Peas of fine flavour. They fill quickly, and prove very remunerative and acceptable as a first crop. Probably some may think if it is only ready from six to ten days before Harbinger, Ringleader, and other better known Peas, it is not much to speak of. I am of a different opinion, as even a week advance in the time of having Peas in the market or on the table makes a wonderful difference in the price and the appreciation of this choice vegetable, and apart from its unique early character, its other points are decidedly good. We put it down as a May Pea, and come to

Veitch's Prodigy as a June variety. This Pea has two good parents, one being Giant Marrow and the other Stratagem, and it is therefore not surprising that it has come to the front as a Pea of the finest quality. It is a second early. It is a robust grower, and runs up to about 5 feet in height. Its pods with remarkable freedom, and each pod contains from eight to ten Peas. Being wrinkled Marrows they are grandly flavoured, and in all points Prodigy is a fine second early Pea.

Webb's Wordsley Wonder is our favourite for July, or indeed for a general main crop. No fault can be found with it. Probably no Pea was ever subjected to a more rigid trial all over the country, and the result was all in its favour. I have grown it here from the first. It is a blue wrinkled Marrow, grows to a height of 2½ or 3 feet at the most, and is more prolific than any Pea I ever saw. It has a capital constitution, is thoroughly adapted to contend successfully with the warmest and driest weather, and as a table or show Pea it will hold its own against all comers. Some varieties have a bad fault of forming good Peas in the middle of the pod, but fail to fill at the points; this deficiency is unknown in this variety, as the pods fill from end to end in a most satisfactory manner. Had these notes been confined to one Pea, Wordsley Wonder would have been the one selected.

Telegraph is a well-known variety. It has been out for years, and has done excellent service in thousands of gardens. It grows to a height of 6 feet or more, and its stature is rather against its culture in the hands of those who are badly off for stakes, but it produces many handsome dark green pods, and the flavour of the Peas is excellent. It is a main crop variety, and well merits being included in all lists of six good Peas.

Veitch's Perfection has stood the test of many years, and all who have grown it cannot help asserting that it is a good Pea. It is not so prolific as some, but it grows compactly, and the flavour is delicious. It may be sown to bear freely in September, and while it will not display any deficiencies in the garden, it is certain to give the highest satisfaction on the table.

Sutton's Latest of All Green Marrow.—Very late Peas should be grown in every garden. When they can be secured in October or later they are as much valued as very early in the season. I could name many with pretensions to be late, or the latest, but in my opinion the one named above is not only a good Pea, but the best of the late varieties. It is 3 feet in height, and very productive as a late Pea. It is dark green in the colour of the leaf, the pods are the same, and they swell and fill more freely at the end of the season than any other. Its extremely hardy character is a strong point in its favour, and as to the flavour it is first-rate, indeed as a late Pea I consider this variety to be unique. Considering that Peas are so generally grown, and all can readily note their qualities, some of your readers may be inclined to give their opinion of these or other varieties, and I have no doubt their remarks will prove highly interesting.—J. MUIR, *Margam, Port Talbot.*

KENNEDYA MARRYATTE.—Though an old plant, this is not by any means frequently seen in gardens. At the present time we have a plant trained to the rafters of a conservatory, the shoots being allowed to droop over the side stages and path to the lengths of 3 or 4 feet. These are now crowded with bright red flowers, and have a beautiful appearance, the foliage also being distinct and pleasing. When it can be induced to grow freely this plant needs but little attention beyond a good pruning every season and keeping it clear of insects, such as mealy bug.—M. A.

PREPARING MARECHAL NIEL FOR FORCING.

WHATEVER may be the defects in the constitution of this popular variety it is one of the most valuable that can be grown for supplying flowers early in the season. For this purpose the plants must be well and strongly grown, and thoroughly ripened early in autumn. Immature wood will not produce good blooms early in the year, the eyes from which they should issue very frequently result in nothing but growth. This is often due to raising the plants too late in the season, and then subjecting them to close treatment, which fosters luxuriant growth at the expense of solidity.

Plants of this variety that have been grown under greenhouse treatment during the past season have plenty of wood upon them that will be suitable for cuttings. Twiggy side shoots strike with greater freedom than shoots of stronger growth, but the latter are preferable, for they grow strongly when rooted, while the others cannot probably be induced to make a strong shoot before the season is over. Shoots that are half ripened are the best, and these may be had in quantity near the extremity of shoots that have scarcely yet ceased to grow. The cuttings only need two joints, one to be placed in the soil and the other to be left just above it. They may be inserted at once in 7 or 8-inch pots, well drained, moderately thick together, in sand, which is better than a mixture of soil and sand, because the roots can be disentangled without breaking them, which is not the case when soil is used, even if it has been sifted. After insertion they should be well watered and covered with a bellglass, then placed in a temperature of 65°. If the pots can be plunged in a warm bed so much the better. In three weeks or a month the young plants will be ready for potting singly into 3½-inch or 4-inch pots. This must be done carefully and every root preserved, or growth will be seriously checked. At this potting equal parts of loam and leaf mould with a little sand added should be employed for them.

The pots should be replunged, in fact plunging must be carried out the whole of the season if practicable, or until they are started in their flowering size. The slight warmth they will receive from below will be advantageous to them. When once started in their flowering pots such assistance is not needed. Where accommodation of this nature does not exist they can be grown very well without, but their progress in the early stages will be slower.

When the young Roses are about 1 foot high it will be necessary to shift them into 6-inch pots and supply each plant with an upright stake. One-third instead of one-half leaf mould only should be used this time, and one-seventh of manure may be added. By the time they have filled these pots with roots they will be about 3 feet in length. From these they should be transferred into 10-inch, using the same soil as before, only add one 6-inch potful of soot and the same quantity of bone meal to each barrowful of the soil needed.

When established in these pots they must be carefully and gradually hardened to cool treatment, for any check will be injurious. Frequently at this stage strong shoots will issue from the base, which should be encouraged, for shoots of this nature will soon outrival the others, and often travel a length of 20 to 25 feet before the end of the season. These are the shoots that result in excellent plants for forcing, and will mature sufficiently to flower satisfactorily if trained close under the roof of a light and airy house. During the time these shoots are in rapid growth weak stimulants may be given, or better, and safer still, a little artificial manure applied to the surface at intervals of about three weeks.

To insure their starting well and freely when introduced into the forcing house they should be taken outside about the end of October or early the following month, and tied to a wall or fence to prevent their being broken. If practicable plunge the pots, for while it is beneficial to subject the shoots to a few good early frosts there is no advantage gained in allowing the soil in the pots to become frozen. This is the easiest and most certain method of inducing the plants to rest completely for a time.

Those who have not practised this method of forcing rest upon the plants will be surprised how much easier forcing operations are rendered afterwards. We will leave the plants outside, and the details necessary for their preparation and forcing until another issue.—N.

ROSES IN WINTER.

A "SUBURBAN AMATEUR" will find no difficulty in obtaining Tea Roses in winter provided he has space to grow them. We have a great demand for them all the year round, more so in winter than other seasons, and never fail to produce them by following this rule. The last week in July or the beginning of August we report in a compost of light loam, wood ashes, and a liberal sprinkling of sand. The roots of established plants are reduced and returned into the same sized (clean) pots. Young plants are given a slight shift without disturbing the roots. They are placed in a partially shaded position, and kept sprinkled, the hotter the weather the oftener syringed, till root action commence, then exposed to full sun to secure well-ripened wood. All flower buds are kept pinched off, and in September we prune them. A few are stood

on one side, and a slight rest is given by withholding water for a week or two. The first week in October they are taken into a gentle heat, and soon commence expanding their buds; in a month's time other plants are taken in. These have supplied us with flowers since the beginning of November, and at the present time are full of buds, which promise to give a few daily for the next six weeks. Others are served the same for a continual supply.

Judicious watering is absolutely necessary. If allowed to get dry or too wet, the foliage assumes a sickly colour, and disappointment follows. Occasional sprinklings with Clay's fertiliser assist the plants greatly. Ventilate on all favourable occasions, but avoid cold draughts, or that terrible pest mildew is sure to make its appearance, which must be immediately checked. Prevention being better than cure, we boil 2 lbs. of soft soap in 4 gallons of soft water fifteen minutes, and mix 1 pint of the solution with 4 more gallons, and syringe on twice a week, or oftener if necessary, sulphur making an unsightly appearance; gentle smoking will destroy all aphides.—G. K.

ROSE-GROWING FOR BEGINNERS.

IN compliance with the request of several correspondents Mr. D. Gilmour has published the series of articles that appeared under the above heading in this Journal last year in the form of a manual. It consists of eighty-four pages in a stout gay cover, and will meet the wants of many who desire plain information on the cultivation of Roses. The work has been issued for some weeks, but a copy has only recently come to our hand. It is published by Mr. William Cate, Bouverie Street, London.

THE SEEDLING BRIAR.

I AM glad to see the subject of the seedling Briar as a stock for Roses is being well discussed in your columns. I certainly cannot think that it is good for the seedlings to have their tap roots cut, as they appear to me to be one of the great points in favour of this stock. During last summer I had an opportunity of observing two large quarters of Roses, one worked on Briar cuttings, the other on seedling Briars, and although not far from each other, those on the latter were the most continuous bloomers, and appeared to suffer less from the intense drought than those on the others. I think this is a fair argument for the retention of the tap roots of the seedlings, as in a season like the last they are better able to procure moisture by striking down deeply than roots running near the surface. I think there is no method of growing Roses by which such a continuance of flowers can be obtained as the one in which Roses are budded on the seedling Briar, and for that reason I strongly recommend them. I do not see any advantage in growing Briar cuttings. They are certainly not cheaper to procure, and if one is ever so careful the suckers will come, and much more frequently than on the seedling Briar. What splendid Tea Roses can be obtained on this stock. The colours and quality of flower altogether are much finer than when grown in any other method, with perhaps the exception of standards.

Another great point in favour of the seedling Briar is that Roses grown on them are better and more plentiful in autumn than those on Briar cuttings, Manetti, or standards. This I have proved for some years. I have cut Roses from seedling Briars in October, when there was scarcely one to be found on any other stock.

There is another matter which I think might be discussed advantageously in "our Journal," and that is, What is the best height to have our standard Roses? Are not 2 to 3 feet stems tall enough? For my part I prefer to see Roses on 2-foot stems than the most ungainly objects on 4-foot stems one so often meets with. And, again, one is more likely to get the varieties he prefers from the nurseryman on a short stem than he would if ordered on 3½ to 4-foot stems.—ROSIERISTE.

[We have several other articles on Roses, for which space cannot be found in the present issue.]

USEFUL POTATOES.

AT one time last season the prospect of a Potato famine was a contingency seriously contemplated, and very few of us were prepared for the agreeable surprise in store for us. Instead of few or no Potatoes being obtained quite a good average weight was lifted hereabouts, but whether the quality generally is equally satisfactory is very doubtful. With us it is not, neither in the case of those lifted before supertubering was far advanced, or those dug much later on. Ours on the whole stood the drought remarkably well, and had I been a little sharper in lifting or drawing the haulm a fairly heavy crop of good tubers would have been secured. Unfortunately it did not need a soaking rain to start the second growth, and the character of the whole crop in many instances was changed as if by magic. Before the change to showery weather not a few cultivators were complaining that many of their Potatoes had formed much more haulm and roots than usual and scarcely any tubers. If these had lifted when we did in order to avoid having a mixed crop of tubers they would not have secured a tenth part of the crops that eventually resulted. Large breadths were growing strongly both above and below ground, when the early frosts cut them down, and then a lot of tubers that I saw lifted resembled the much rubbed early crops annually sent to the markets.

With so many new and old varieties in cultivation, numbers of which are more or less worthy of a trial, it may at first sight appear a difficult matter to decide which are the best, but if we pass over the showy section and come to the really useful Potatoes the weeding out process is by no means hard to accomplish. White Elephant has stood out pre-eminently good. It was never good with us. Hereabouts it is in the cottagers' gardens, where it is mostly grown, and this season it yielded very heavy crops of extra large tubers. Five solid tubers, 1 lb. in weight, were plentiful enough, and a few were forthcoming weighing 2 lbs. and upwards. All were of fairly good quality, and altogether it may be classed as a fairly reliable sort for hot or shallow soils and dry seasons.

Idabo, a rather ugly rough-coated white round, also crops heavily, keeps well, and is of excellent quality. Its disease-resisting qualities have yet to be tested, but it is worthy of a trial by those who do not care for appearance so much as uniform good quality. It is of fairly vigorous habit, and reminds me of the "Irish Lumpers" of my boyhood days.

Village Blacksmith scarcely comes up to the high character given it. With us it grows very vigorously, but does not crop so heavily as anticipated. The tubers are round, fairly shallow eyed, remarkably rough coated, and cook very satisfactorily. I should say it will prove disease-resisting and evidently will thrive under the same conditions as best suit the Scotch Champion. A trial may well be given it.

The Dean, a blue round, is not a good cropper here, but the tubers grow to a large size. Both this and the foregoing keep well, but I am of opinion it will never become generally popular. Vicar of Laleham though largely grown is not reliable as a disease resister, and on heavy soils especially is apt to be poor in quality. Cosmopolitan apparently likes a hot and dry season, for we never had it so good either as regards the weight of crop or size, shape, and quality of tubers, but it is much liable to disease, and even this season we found several affected. For this reason I cannot recommend it unless a good exhibition kidney is needed.

Cole's Favourite, a white kidney grown here for the first time, yielded exceptionally heavy crops of medium sized very handsome tubers, and these were of excellent quality. It is a second early, and forms sturdy branching haulm. This season I intend to plant it extensively, and strongly recommend others to do the same. A grand dish of it was exhibited at Taunton last autumn, and in competition is hard to surpass. Sutton's Seedling again proved very serviceable, and ought eventually to become a favourite with market growers. It does not form a great amount of haulm, and matures a heavy crop of large handsome tubers sufficiently early to admit of an early clearance—a decided gain to those who double crop their ground. Abundance belongs to the disease-resisting class, and requires plenty of room and manure, for which it amply repays. Chiswick Favourite, white round, with rather deep eyes, forms sturdy haulm and crops heavily, the quality being also good. We have grown it for three seasons with highly satisfactory results, and can therefore strongly recommend it for the main crop and late supplies. Chancellor, a large and handsome white kidney, also does well and is a good companion for the last named. It forms plenty of haulm and promises to be disease-resisting.

Of better known varieties, Reading Russet, second early, red round, is one of the most popular. It forms good sturdy haulm, always crops heavily, the tubers being handsome and fairly good in quality. Lady Truscott is a good white companion for it. Schoolmaster seems to have collapsed, and very few now cultivate it. Covent Garden Perfection is largely cultivated by a friend of mine, who considers it excellent for the second early supplies, but with us it was much liable to disease, and very rarely fit to eat. Pride of America, Snowflake, Triumph, Adirondack, and those of Yankee origin generally are useless in a wet season, being only profitable and good in quality on light soils and during a season somewhat similar to that last experienced.

The Ashleaf section may also be briefly dismissed. The true Old Ashleaf is the best for pots, frames, and early borders, no other variety yielding such a good crop in proportion to the smallness of haulm formed. It is fit for lifting before the tubers are fully grown. Veitch's Improved Ashleaf everybody is acquainted with, this being the most generally grown for the earliest supplies. This, besides being good when lifted early, also keeps well, and is one of the best for planting extensively in gardens where double cropping has to be closely practised. Myatt's Ashleaf, if obtained true to name, is also to be strongly recommended, as it is fairly early, heavy cropping, and good in quality, also keeping good till mid-winter.

Having commented on the comparatively new varieties, as well as older favourites, we must not omit the invaluable disease-resisters. Sooner or later the time will come when these will again be in the ascendant, and immunity from the disease must not make

us forget what sad havoc it may again work among the Potatoes. Fortunately the varieties that do well in a bad season are equally trustworthy under more favourable conditions—that is to say, they will repay for good culture at all times. Scotch Champion is yet the favourite here, and if ever superseded, it will be by the seedling raised from it by Mr. Laxton of Bedford, this apparently possessing all the good qualities of the Champion, and being, in addition, more shallow-eyed, and therefore much less wasteful. It is handsome enough for exhibition, and cooks beautifully. Scotch Champion has been, and still is, very good, this being what we send to the table up to midwinter. To follow this we have Magnum Bonum, but I am sorry to find this is not so uniformly good as usual. Supertubering did not spoil the quality of the Champion, but it has injured the Magnums. The latter stood the dry season well with us, and produced quite large tubers. A good round companion for it, if the Champion is objected to, will be found either in Abundance or the Reading Hero.—W. IGGULDEN.

EUCHARIS CULTURE.

FEW sights are more familiar when visiting gardens than to see in some out-of-the-way corner of the stove or forcing pits a number of overpotted sickly looking *Eucharis amazonica*. In most cases a great amount of labour has been bestowed upon them, but all to no purpose. "The mite has attacked the bulbs, and they will never be any good" is the remark that is sometimes passed about their condition. Now, if there is really such an insect I have never yet made its acquaintance, so that I may be pardoned for doubting its existence. But it was not to argue this point, an accomplishment which is decidedly not my forte, that I write this, but to state an easy method which I have seen successful in restoring plants to vigorous health after years of languishing. At any time when a gentle bottom heat can be obtained shake the plants out of their pots—they ought to be dust dry at the time, otherwise they cannot be shaken out clean—placing the bulbs in separate sizes for potting. Then have some pots of convenient sizes, thoroughly well drained, and over the rough material which protects the crocks sprinkle a good dash of soot. Pot them firmly in a compost of about equal parts of peat and loam of a sandy nature—if not a little can be added—and enough soot to show itself all through the compost. Water slightly and plunge the pots, or place them on the top of the hotbed. For a time they ought to be shaded rather heavily, which may be loosened as the plants seem to require it, but they ought never to be full in the sun. Keep the heat up to about the ordinary stove temperature. It is surprising how little water the *Eucharis* requires at any time, and it is far better practice to err in giving too little than too much.

I do not say that this is an infallible remedy, but I have seen it give such satisfactory results that it may be found worth trying. I think that a little soot agrees with the *Eucharis*, at least I attribute a great part of my success in their culture to the judicious use of soot water. When once established they may be grown in the same pots for many years with its assistance, and except to increase the stock they are better kept away from the potting bench.—M. D.

STACHYS TUBERIFERA.

THIS plant has attracted some attention as a new vegetable, and inquiries are becoming frequent respecting its qualities and the method of cultivation adapted to its requirements. Reference has been repeatedly made to it under the name of *Stachys affinis* or *Choro-Gi*, and with the former name it was exhibited at South Kensington last December by Mr. A. G. Hookings, gardener to Sir H. Thompson, Moulsey. There seems to be a little uncertainty respecting its true name, but several leading botanists regard it as quite distinct from the true *S. affinis*, and have adopted the title *S. tuberifera* as more appropriate. It is of similar habit to many species of the well-known genus *Stachys*, but is chiefly notable for the large number of small, spirally shaped, fleshy tubers produced on the roots round the base of the stem. Plants of moderate size bear some scores of these, and consequently it is very readily increased. The tubers are light, and contain a very large per-centage of water, being suggestive in texture and taste of the Jerusalem Artichoke, though some have also compared it to Salsafy. They contain, according to analysis, nearly 20 per cent. of starch, and upon this their value as a vegetable mainly depends, though owing to their small size they are not likely, unless greatly improved, to become of much commercial value.

The plant grows freely in ordinary garden soil that is not very heavy, but prefers a light, rich, and moist soil. The tubers should be planted in narrow shallow trenches, and covered 3 or 4 inches deep with soil, and may be assisted in dry summers with occasional supplies of water. One disadvantage is that the tubers will not

keep long after being lifted from the ground, but soon shrivel, and the only way is to lift them as required for use. In France, where it has been grown for market, it has proved quite hardy, and it has also been found hardy here in warm situations. Several methods of cooking have been tried, such as baking, frying, serving in soups, and as sauce, but these could, no doubt be considerably extended.—C.

FREESIA REFRACTA ALBA.

THIS beautiful plant seems to be gaining popularity, and there is no occasion for wonder that such should be the case. It is easily grown, free-flowering, lasts well in a cut state, and can be had in bloom from November up to March and April, a period when white flowers are most acceptable, especially when possessing an agreeable perfume. My method is to pot the bulbs about June into 5 or 6-inch pots, six to ten in a pot, and about an inch below the surface of the soil. The compost used is loam, leaf mould, a little dried cowdung, and a sprinkling of sand. After potting, they are watered and placed on the border of a vinery, or in any position affording an intermediate temperature, together with moisture and shade, until they have commenced growth. They are then brought out and placed in a cold frame, or even outside, where they remain until the end of September, by which time they have made sturdy growth. A few pots are then introduced into a little heat for early flowering, and the rest are kept in a cool greenhouse temperature, from whence a few can be removed into heat as occasion demands. For a late supply to come into bloom about March it is not advisable to pot until September, and with perfectly cool treatment, and keeping them close to the glass, they will come into bloom without any forcing about the time mentioned.

A great point is to have the bulbs well ripened. To insure this, the plants after flowering are placed in a sunny position near the glass, duly attended to with water until the leaves have died, and then allowed to remain perfectly dry until the bulbs are shaken out for repotting. A single pot will frequently treble its produce of flowering bulbs in one year, so that a stock is quickly raised when required.—J. C. A.

WINTER AND SPRING CABBAGES.

AFTER Brussels Sprouts perhaps no green vegetable is in so much request at this season as good young Cabbages, and to obtain these in quantity is one of the difficulties many young gardeners have to contend with. Formerly London or Rosette Colewort was the sort mostly relied upon for this purpose, but in the neighbourhood of towns and the majority of localities in the north this sort has the great drawback of having the edges of its leaves injured by early frosts, and thereby rendered comparatively useless. Thanks to those who are ever on the look-out for improvement, we have now several varieties of good hearting Cabbages that meet all the requirements of the important demand. For the past three or four years we have found Ellam's Dwarf Early Spring a most serviceable sort. It is of a close compact habit of growth, with very few outside leaves surrounding a conical-shaped heart, which in the winter never become solid enough to be white, and is hardy enough to stand ordinary winters without having the edges of its leaves browned. When cooked it is tender as Spinach, and flavour excellent, the ideal of what an early Cabbage ought to be.

Laing's Early Matchless is another very fine winter Cabbage of the old Early York type, and when better known will doubtless find a place in many gardens.

Veitch's Earliest of All is also an excellent early, coming quickly into use, and deserving further trial. We make our first sowing about the 20th June, and the young plants are ready for transplanting about the second week in August in an open situation after a crop of Peas or Potatoes have been cleared away. Here they are planted in rows a foot apart and 9 inches from plant to plant. Two more sowings are made about the end of June and 10th July, but on no account must the young plants be allowed to get spindly. From the three sowings we grow about 5000, and are never a day without young Cabbages from the end of November until far into spring. Many people make a mistake in planting winter Cabbages too far apart, because when not close enough to steady each other the wind plays sad havoc amongst them.—JAMES McINDOE.

CHRISTMAS ROSES.

ALLOW me to say a few words in support of Mr. Hilton's remarks on Christmas Roses in the Journal of January 12th. About the first week in November we took up three dozen clumps of *H. niger* and *H. niger major*, potted them in 24's, 16's, and 12's, and stood them in cold frames; then about a fortnight afterwards

we put half of them in a warm pit, and had them in bloom about December 10th, and have had them flowering until January 14th. They have proved very satisfactory, as they can be used for vases, table decoration, bouquets, or buttonholes. They look very pretty associated with Holly berries. I filled some soup dishes with wet sand, covered the sand with moss, then made holes with a little stick, and inserted the blooms alternately with bunches of Holly berries, putting a fringe of Maidenhair round them. They look very pretty arranged like that, and the wet sand keeps them fresh for a week. We had some very fine flowers on *H. niger major*, but it does not bear half so many as *H. niger*. I counted three dozen blooms on a plant in a 16-size pot of the latter variety. We shall plant them out again as soon as they have hardened a little in cold frames. Kindly insert this my first article.—J. ETTLE.

THE MYTICUTTAH.

THIS is a new pruning implement that has been recently perfected by the Standard Manufacturing Company, Derby. Some years ago the same company introduced the standard tree pruner, which has proved of great service in lopping and pruning tall trees, the implement combin-

Fig. 10.

ing lightness with strength. The myticuttah is on the same principle, but of the length of hedge-shears, and though much lighter will sever branches ten times stronger than any ordinary shears can remove. It is a small implement of great power, easy in action, and will be found serviceable in thinning fruit and other trees and bushes, of which so many are in need of assistance in the manner indicated. We have tried the new implement and find it answers its purpose well. It is represented partially open and closed in the engravings.

PLANTS AND FLOWERS IN THE HOUSE.

THERE is no diminution in the quantity of these employed for house decoration, but, on the contrary, their use for lending a finish to the furnishing of apartments seems to be on the increase. It is perhaps hardly the gardener's work to arrange plants and flowers so as to aid the general good effect of a room. In many cases, however, he has to do so, and the study of the subject becomes necessary. The one fact he must always bear in mind is to subordinate the plant arrangements to the permanent occupants.

In large apartments a few very large plants will be more in keeping than a number of small ones, and no plant should be placed where by any chance it will be in the way. Exactly the same remark applies to the employment of cut flowers. For large rooms use substantial vases and fill them with flowers and foliage of massive and striking appearance. At the same time it is quite admissible to adorn some particular table with a small plant, but it

must be of merit in itself, and also with small vases of cut flowers, but the flowers employed should, like the plants, arrest attention by some merit of their own. To particularise somewhat. We use for the larger public rooms specimen Palms, such as *Latania borbonica*, a grand decorative sort; *Chamærops excelsa*, also fine; *Chamædoreas*, &c. Crotons are good, also large *Dracænas*, tall Bamboos, and any handsome foliaged plant. Flowering plants include free-grown specimen *Chrysanthemums* of the type of Simon Délaux, Elaine, Peter the Great, &c. Tall *Fuchsias* are very good; so are specimens of *Celosia pyramidalis*, a grand decorative room plant which stands very well. *Statice profusa* is not easily injured. Large plants of double Ivy-leaf *Pelargoniums* are useful, but require light to stand well. *Azaleas* and *Rhododendrons* are very suitable. *Richardias*, on account of their foliage being so striking, are extra good. Another season I hope to have *Cannas*. *Liliums* are indispensable, but the scent of *L. auratum* in some cases is offensive in rooms. However, nothing can be more beautiful than the common *L. candidum* in a large mass. Of small plants the choice ought to be limited to good *Dracænas* or *Crotons*, well coloured variegated *Ficus elastica*, the variegated Pine Apple and *Yucca filamentosa*, well-grown Ferns, of which nothing surpasses the common Maidenhair. *Platynerium alicorne* also does well, and of green foliage plants nothing is better than *Aspidistra lurida*. *Cyprus alternifolius* from seed, and *Asparagus plumosus nanus* are also useful. Amongst flowering plants *Hyacinths*, *Tulips*, almost all kinds of *Narcissus*, *Lily of the Valley*, *Solomon's Seal*, *Chinese Primulas*, *Cyclamens*, *Statice profusa*, *Carnation Souvenir de la Malmaison*, *Mignonette*. Some of the hardier Orchids are suitable plants which I recall to mind as good for finishing a table.

For furnishing tall glasses at present we may employ spikes and foliage of Pampas Grass, both excellently effective; *Richardia* spathes and foliage cut with long stalks. Late *Chrysanthemums* are also good cut in bunches with stalks from 18 inches to 3 or 4 feet in length. During the time of *Chrysanthemums* nothing can be better than these. It does not matter how large the flowers may be if they are set in freely with long stalks and as much foliage left as possible. Varieties of the type of *Gloriosum* with narrow florets stand much longer than the broad and close petalled varieties. *Gladiolus* cut foliage and spike are grand. Many of the large *Irises* are fine, using some of their foliage with them. *Cactus Dahlias* and some of the self *Dahlias* are also good. Occasionally used are side shoots of *Hollyhocks*, and tall *Michaelmas Daisies* cut in long pieces are very effective. *Liliums* are of course a host in themselves, two or three good spikes cut with long stalks well furnishing a large vase.

In arranging flowers they may either be set in just a few good pieces with foliage, or if a very massive arrangement is wished for more tall flowers may be used, and a few on shorter stems with plenty of foliage, set in lower and outside these. These remarks apply to vases standing 4 to 6 feet in height. The same class of flowers may be employed for glasses 18 inches to 3 feet in height, but as a rule such tall stems as advised above may be dispensed with. In the shorter glasses we can choose from a much wider class of flowers, as, for instance, just at present nothing prettier need be wanted than a few stems of the rose-coloured *Begonia semperflorens*, not merely the flower stems, but the entire stems glossy foliage and all. *B. Carrierei* and the white *B. semperflorens* are also suitable. Mixed glasses may be prettily arranged with a few spikes of *Zygopetalum Mackayi*, *Phalænopsis*, *Cœlogyne*, or *Calanthes*, an odd bloom of *Lilium Harrisii*, and a few leaves of *Aspidistra*, *Croton*, or *Calla* giving each bloom spike or leaf a clear space in itself. In summer *Iris graminea* is a most useful plant, its foliage mixing well with *Gladiolus* and many other flowers, while it stands exceedingly well. Single *Dahlias* constitute pretty arrangements alone. The foliage and flowers of *Solomon's Seal* are extra fine. Few flowers are more useful, because so effective, as are *Pyrethrum uliginosum*, white Sweet Sultan, and *Chrysanthemum maximum*. *Salpiglossis* form by themselves a quaint and pretty arrangement.—B.

(To be continued.)

PRIVATE VERSUS TRADE GROWERS.

IN his admirable retrospect of "Horticulture in 1887," "D., Deal," alludes to one very important matter in these terms:—"The question as to the equity of proprietors disposing of their surplus produce has been much debated, but personally I do not see why a gentleman should be thought mean if he disposes of surplus Peaches, any more than of his surplus shorthorns or Berkshire pigs. He is not regarded as a butcher if he does the one, why should he be called a market gardener if he does the other?" If it were a question of surplus only the matter might be regarded in a little different light from what is now by those most deeply concerned; but when, as is the case nowadays, we have gardeners to noble lords issuing catalogues, just as those in trade do, the time has arrived for speaking out on the subject. The "mean" part (if

any) of the transaction comes in at this point, that such private growers are not put on the same footing with regard to assessment of rates as the less favoured, in this respect, trade growers and nurserymen. There would appear to be an injustice here, though possibly it may not be discernible by your esteemed correspondent above referred to.—JUSTITIA.

GROS COLMAN GRAPE

MR. J. H. GOODACRE having sent us an excellent photograph (by Mr. W. Winter, Derby, of a bunch of Gros Colman Grape, we have had it reproduced by a process that displays the faults equally with the merits of the subject. As many of our readers who have seen the best examples of Elvaston Grapes [at exhibitions know, the bunch and its berries are not so large as some that have been staged, but our page did not permit of a larger, and the present one suffices for showing a fair sample of the work of the cultivator. The Grapes were covered with a dense bloom, some of which, as will be seen, has been rubbed off, and in that respect the bunch is faulty, and it also contains a few small berries towards the top; still, with all its faults, the bunch is creditable to the grower, and is such that not a few persons would be satisfied with as representative of their crop of this handsome Grape. Accompanying the photograph was the following cultural note. We have another communication from Mr. Goodacre on "Fallacies in Grape Culture," with which all cultivators may not perhaps entirely agree, but for that article we cannot find room at present.

GROS COLMAN when well grown is the handsomest of all black Grapes. When grown with fire heat and allowed to hang on the Vines a couple of months after the fruit is coloured the flavour is not so bad as is frequently represented, and it is probable that this variety is destined to be more extensively cultivated than all other Grapes put together; the appearance is so grand that it more than counterbalances any little deficiency of flavour. We are told that Grapes are grown to eat, and in my case they are also grown to look at, and I find a keen eye is quite as difficult to satisfy as a keen palate. At the present time good "Colmans" are realising considerably more money in the market than any black Grapes.

The accompanying photograph represents what can be grown without much difficulty. The bunch is one of fourteen cut from a Vine the weight of the crop being 40 lbs. Some of the berries are 5 inches in circumference, and are fairly well coloured. Last year the same Vine carried seventeen bunches, the berries larger and much better in colour. Why this should be so I am unable to judge, unless the excessive heat of last summer ripened them prematurely.

The Vine in question is growing near a water tank, which some of my friends consider the secret; but when this tank was kept full the berries did not colour, so the last two seasons it has been kept empty, with more favourable results. The Vine is planted in pure loam from a hill side, not a particle of any other ingredient being used with it. We start the Vines early in March with fire heat, and commence thinning these "Colmans" almost before the flowers expand. We give a few good soakings of weak liquid manure from the farm, the first when the berries are the size of peas, the last when they show signs of colouring. About four doses are sufficient for our very stiff soil. In another vinery Gros Colman colours as black as jet without fire heat, but they lack sweetness and are not relished like those grown with fire heat.

In writing the above, I hope I have succeeded in my endeavour to avoid self-exaltation, but it is difficult to stop all the holes in one's coat; be that as it may, no notice will be taken of pseudonyms, but all *bona fide* inquirers will be gladly answered by—J. H. GOODACRE, *Elvaston*.

UNDER GARDENERS AND EXHIBITORS.

YOUR correspondent, "An Under Gardener," argues well for under gardeners, but I cannot help thinking he is giving us the darkest side of the picture. When a subordinate I have frequently had to assist in exhibiting, and on two notable occasions was not permitted to leave the group of plants we had staged until the show closed at 9 P.M.; but if my memory serves me truly, I raised no objection to my task, considering myself amply repaid with the insight I received in staging plants and many other things, not including the valuable lessons I had learnt in the gardens on growing for exhibition. Your correspondent does not think this experience valuable—he may one day have a different tale to tell us—being under the impression that gardeners who grow for exhibition are only men "who can grow a few things superlatively well." Now that I contend is an erroneous idea, for in good exhibition places is

FIG. 11—GROS COLMAN GRAPE, GROWN BY MR. J. H. GOODACRE

generally found the best all-round gardening, competing as they do in all classes. I may be met with the rejoinder that under gardeners, being generally restricted to one department for a given time, have no facilities for acquiring experience in other branches; if so, I reply I have never known the head gardener who, if his men conducted themselves aright, did not give under gardeners the opportunity of passing through all the departments, remaining in each for a year, and longer, if they choose to stay. "Under Gardener" is strangely reticent ament the suggestion of "A Head Gardener," that when the value of prizes taken will not cover expenses, will the young men contribute towards doing so? For in many cases when shows are at a great distance the prize money is not nearly sufficient for that purpose; in such cases it may be seen at a glance they compete for the post of honour and not for the mere value of the prize. To their credit be it said gardeners as a rule are not so mercenary as your correspondent represents them to be. Finally, he raises objections to the concluding remarks of descriptions of gardens in horticultural papers because the entire credit is given to the head gardeuer, while none is given the assistants; and who, permit me to ask, is the credit due to, if not to the head gardener? Without assistants I admit he could do but little; but who is responsible for all the garden contains? Who directs the work of the gardeu in its proper course? Even though he may do no manual labour he works harder with his brains than all his assistants combined. His life is doubtless imagined an enviable one; take my word for it that his bed is not all Roses, but composed largely of thorns. In conclusion, I would advise "An Under Gardener" to bear his troubles like a man, and not get up an agitation among his colleagues, and remember that if he does his work willingly he will at some time receive his reward, when I hope he will not forget his motto, "Do as you would be done by;" also bearing in mind that much as he may object to extra work without tangible acknowledgment that there are numbers of young gardeners waiting for places, who would accept the post without hesitation. Dissatisfaction will injure his reputation eventually, and though he may consider this fault a small thing he must remember his own words, "Life is made up of small things."—R. WELLER.

RANDOM NOTES.

LAST September, when visiting Trentham Hall Gardens, I was much struck with the splendid health of the numerous cool Orchids, especially the *Odontoglossums*. Though rather late in the year to see many of the latter in bloom there were still some fine varieties in flower. A photograph taken when the *Odontoglossums* were in bloom was shown me by Mr. Blair, and it made me wish to see the house when in full beauty. The spikes were enormous, and the individual flowers all that could be desired in regard to size, shape, and markings. Mr. Blair is not easily satisfied as regards the quality of the *Odontoglossums* he grows, and only the first-rate forms are to be found in the collection he cultivates so well.

General gardening is well carried on at Trentham, and large quantities of fruit, plants, and cut bloom, all of good quality, are produced in the numerous houses. Not content with the already large amount of glass at Trentham, Mr. Blair was having some more large houses erected at the time of my visit. A beautiful drive of five miles or so in company with Mr. Blair brought me to Keele Hall, where much to interest and instruct was to be seen. The view from the gardens is most extensive and beautiful.

Another day I had the pleasure of visiting Eaton Hall, the princely seat of the Duke of Westminster, near Chester. The glass houses at Eaton are very numerous and of the most substantial construction, no expense having been spared. Large quantities of all kinds of fruits, plants, and flowers are here grown, and Mr. Selwood is evidently quite prepared at all times to meet the great demands on the resources of the gardens that are made by the hospitable and wealthy owner of this most splendid place.

A day was also spent in Liverpool and vicinity was well repaid by a hearty welcome and much kind treatment received from Messrs. Ker. Mr. Ker took me to see the firm's well-stocked houses and nursery grounds at Aigburth. Here amongst other things excellently grown, I took especial note of some houses of *Cyclamens*, large numbers of strong and short-jointed pot Vines, and a house of *Crotons* that could not be surpassed for health and colour. I felt quite repaid by the sight of this grand collection of *Crotons*, and would have liked to have spent a much longer time in admiring them.

At Mr. Heine's residence in Manchester a wonderful collection of specimen Orchids is to be seen. At the time of my visit there were not many in flower, as most of the blooms had been cut a few days before and exhibited at the Flower Show held in connection with the Great Exhibition in Manchester. Anyone who saw the stands of Orchid trusses that Mr. Heine exhibited at that Show will not forget them in a hurry. They were superb, and a crowd was continually round them. For luxuriant health the Orchids at Mr. Heine's are remarkable. Enormous plants of almost every good variety of the various branches of the Orchid family are here grown, and all flourishing in grand style. The only thing I saw amiss was that the houses were not by any means numerous enough to hold the plants in such a way as would enable one to see them to full advantage. The collection would easily fill nearly as many houses again and then not be too thinly disposed. Mr. Cragg seems thoroughly at home in Orchid culture, and may well be proud of the grand collection.—J. T.

POINSETTIA CULTURE MADE EASY.

At this time of year many gardeners will have a number of Poinsettia plants which have flowered, that they will feel inclined to throw away; if these are kept in some shed or greenhouse until next spring where the frost is excluded they may be turned to good advantage for next winter's floral display by a very simple and easy method. Let them retain all their old growth till about the end of the second week in May, and then cut them well back, and let them still remain where they have been wintered. By about the end of May they will have begun to grow again. Then shake them out of their pots and plant them in a sunny outdoor border, putting some leaf soil around the roots of each plant. About the third week in August lift the plants carefully and pot them. Place them in a cold pit or frame, and keep them close and shaded from the sun for a week or so, then gradually give air and light. Grow them in the usual way, and there will be no lack of scarlet bracts for Christmas and New Year decorations.—C. DENNING.

THE SEED SUPPLY.

PERHAPS there are few greater mistakes, and they occur every year, than deferring the ordering of seeds till the last moment, or until the time has arrived for sowing, and when the ground and weather are favourable for the work. Experienced gardeners who are free to act in providing garden requisites take care to have everything in readiness when the moment for action arrives; but many owners of gardens who give personal attention to these matters cannot of necessity perceive the importance of early action in providing seeds. These cost no more to purchase early than late, and further, the earlier the application the better the choice. By waiting till the actual time of sowing the weather may change and be unfavourable for weeks by the time the seeds arrive, late crops or lost crops being the unpleasant result. Though the operatives in seed warehouses work almost night and day in the execution of orders that arrive in shoals during bright weather in spring, they cannot all be completed and dispatched with the expected promptitude; and it would be to the advantage of all concerned, purchasers and vendors, workers in the garden and the warehouse, if seeds were more generally ordered a few weeks before they are required for sowing, thus insuring their being ready to hand for the gardener to take advantage of opportunities, which are often of very short duration, for placing them in the ground at the proper time and under the best conditions for insuring a good return in the form of thrifty plants and satisfactory crops. There is danger in delay in this matter, as hundreds of gardeners, of whom I am one, know to their great disappointment.—A. D. M.

MEMORIES OF A TOUR.

MARGAM.

I HAVE been interrupted in jotting down a few memories of South Wales, with the inevitable result of some of them becoming obscured and others vanishing, but a few cannot be easily obliterated. I suspect no wandering gardener could enjoy a day or two's rest with Mr. J. Muir at Margam and forget everything that was seen there, and particularly the hospitalities dispensed by the presiding genius of the lean-to house. The "lean-to," let it be said, is not a vinery, but the gardener's cottage, which in some far past years was erected against a lofty wall which appears to have been built for displaying on the other side, facing the pleasure grounds, some fine examples of Inigo Jones' architecture. But I have made a mistake, not about the house, but the resting. I cannot conceive it possible that Mr. Muir will allow anyone to "rest" long. Strong, active, energetic, accustomed to rush to and fro, up hill and down, over some hundreds or thousands of acres of land in his charge, he seems able to laugh at fatigue, and to rejoice in seeing a fellow mortal seeking rest, "done up" with his exertions. No, I shall not forget Margam. Seeing a stiff and foot-sore pilgrim, he proposes a remedy in this wise, "Come on, I want to go to some men where you hav'n't been yet; a short walk will do you good, it's only just over there." If anyone is tempted to go "just over there" at Margam he will perhaps find a four or five miles journey before he gets home again, the leader going as if he were fetching a doctor, and without a spark of pity for the panting victim he has allured limping along beside or behind him. We get back to the lean-to, and he says to the weary one, "Now you go in and have a good rest while I go round the garden." A "good rest!" In ten minutes he is back again dragging us out—for Mrs. Tourist has to go this time—"You must go up the hill or you will not see Margam at all; it's quite easy, I am sure you will like it." After making us feel as if he had a hydraulic lift to hoist us up in comfort, he prevails, and we enter the wood, for it is a wooded hill, and now commences this easy promenade. We twist about along the mountain side, now stumbling over a boulder, next getting entangled amongst brackens and Brambles, anon slipping into a rabbit hole, then resting on a prostrate tree, and so we struggle on higher and higher. "Only a few inches more," says the tempter, "and we shall be above the trees." And so we persevered and had a reward. We look down on the mansion, a great pile with its lofty central tower when viewed from the base, but now resembling a game-keeper's lodge with a rather prominent chimney, and the eye sweeps across the Vale of Glamorgan from the Severn to the sea. It is a splendid panorama. We thread our way down the pathless slope, and instead of taking us to the lean-to, we are adroitly led into a garden, and after shouting for a fork as if there were a lion

in the path, the man of energy commences tearing up "Laxton's Potatoes." The crops of several of them were remarkable; a few tubers of one of the varieties, No. 8 I think, were cooked, and the quality equalled their good appearance. But I do not like trials under numbers neither in private nor public gardens. Describing the varieties is very much like writing in the dark, so I will say no more about these novelties; but while on the subject of Potatoes may remark on the crop of Adirondack, then just dug, and that would at the least equal 20 tons per acre, and probably 25 tons, of fine pinkish rough-skinned tubers.

The kitchen garden of 4 or 5 acres was as well cropped with as fine a lot of vegetables as could be desired, Leeks and Laxton's Czar Kidney Beans being of enormous size, while fruit both on wall trees and as bushes was abundant. The glass structures are ancient, mostly flue-heated. They are not grumbled about, but made the best of in producing a good family supply of Grapes, excellent Pines, various decorative plants, and Tomatoes. The crop of these in a lean-to house was worth more than the structure if all had been sold. The variety most grown was Webb's Sensation, a wonderful crop of grand fruits. This has been described as synonymous with the Stamfordian and some others. All I have to say on that point is, I have seen what was named and grown as Stamfordian at the least a hundred times in different

chapter-house pillars still solid, Gothic windows still in order, and trees growing out of the top of some of the walls—fancy all this diversity, this blending of architectural with arboreal beauty, and a crude idea may be formed of the attractions of Margam. The church in the grounds is also a notable feature, as it is part of the abbey of the Cistercian monks, founded by Robert Earl of Gloucester in 1147. Now go on still further eastward and through the vista formed by noble trees you see the mansion on the rising ground beyond, and reach it by an ascent of broad and high flights of steps at intervals on the way. It is a stately building with a lofty central tower and a terraced garden in front. It was erected by the present owner about fifty years ago. Through the kindness of Mrs. Gittens, the courteous housekeeper, we were favoured with a "peep" inside, and found evidence of wealth and taste, without glare and glitter, in keeping with the fine exterior and grand surroundings. The genealogical stained glass window in the hall, divided into twenty circular memorial compartments, giving the names, births, and deaths of the several owners from John Mansel in 1100, through eighteen generations to the present owner, is unique. It shows that the male line of the family terminated with Lord Mansel in 1661, thence the great possessions passed by marriage into the Talbot family, the present head of which, C. R. Mansel Talbot, Esq., M.P.,

FIG. 12.—THE ORANGERY AT MARGAM.

places, but never saw it like the large and perfectly smooth fruits at Margam. In the same house were some red and yellow-shaped Plum-shaped varieties from Messrs. Sutton & Sons, the fruit hanging in long clusters, and in the raw state the flavour surpassed all others. Such fruits would make beautiful dishes on a dessert table, and could not well be excelled for salads.

Well as what may be termed the supply department of Margam is conducted, the pleasure grounds, fine and beautifully situated mansion, with a magnificent background of Oak-clad hills, rising abruptly to a height of 600 feet, must leave the deepest impress on the mind of the visitor, whoever he may be. There is a natural grandeur about these wooded heights that cannot be described, while the dressed grounds at the foot, half a mile or so long, but not of great width, are beautiful by, so to say, their irregularity. There has been no levelling to destroy the undulations of the lawn, and magnificent deciduous trees and splendid evergreens and flowering shrubs seem as if they had sprung up naturally just in the right places. Fancy Sweet Bays 50 or 60 feet high and more in diameter, Camellias nearly as high, Tulip Trees 70 or 80 feet high, handsome Conifers here and there, bold clumps of American Azaleas, numerous huge masses of Hydrangeas 2 or 3 yards high and of twice that diameter, weighted down with the load of flowers, some pink and others of deepest blue; then at one end of the grounds an Orange grove, the trees throwing their fruit-laden branches over your head; more towards the centre the finest orangerie in the kingdom, and a grand feature of the grounds whether the fountains near it play or not; then onwards and eastwards a romantic ruin the well-cared-for remains of the home of the monks of old, the massive

being eighty-five or eighty-six years of age, with a step as firm and eye as clear as ever; but his only son died, and was mourned by all around, a dozen years ago. Miss Talbot is the good genius of the home now, her only sister living being married to Mr. J. Fletcher, of Salton, N.B. Mr. Talbot, as is generally known, is the father of the House of Commons, of which he has been a member for nearly sixty years. Mr. and Miss Talbot usually arriving home from their yachting cruise towards the end of September, Mr. Muir endeavours to have the flower beds on the terrace attractive then; and the large masses of Sedum spectabile and the most useful yellow Chrysanthemum, Felicity, produced, with the relief afforded by Perilla and margins of Golden Feather, an excellent effect.

But we must return to the orangerie. It has been represented in the Journal, but there have been several yearly additions of new readers since then who will be glad to see what the building is like, and those who have seen it before will admit it is worth seeing again. It is upwards of 350 feet long, 30 feet wide, and 24 feet high; the trees, which are in large tubs, being arranged in it in October for the winter, and placed in the garden in spring. Several of them are 300 years old, the ship that was bringing them as a present to Queen Mary or Queen Elizabeth, being stranded on the foreshore, became the property of the Mansel family. They are in the best of health, and there is no fear of their suffering through want of attention in Mr. Muir's keeping. He was drying Tobacco in the orangerie in September, and in November I had a sample, manufactured from it by Mr. Wills of Bristol, in the form of cigars, cigarettes, shag, and birdseye, as good probably as has been made from home-grown "leaf;" but in no form could the produce

compare in quality with that grown in the more favourable climes of southern latitudes, and I have yet to be converted into the belief that Tobacco growing will be a commercial success in this country.

Orange, Lemon, and Lime trees of great age and size cover the back wall of a long lean-to house in the pleasure grounds, the body of the house being occupied with Camellias, also old and large, yet vigorous, many Tea Roses being grown in the same structure, and at one end as healthy a plant as has been seen of *Magnolia fuscata* in a pot in a shaded alcove, from which it is never removed. It flowers profusely, and fills the house with fragrance. At the opposite end of the house *Solanum jasminoides* is established, and grows right through the roof, its flowers hanging down in wreaths, and of a size I have never seen equalled, nor had Mr. W. Watson of Kew, who was my co-admirer of it, and who pronounced Margam as his ideal of a garden. It is a grand old place without a doubt, and Mr. Muir, as its manager, is the right man in it. His duties, however, extend far beyond the garden, and in an important work he has scored a triumph, in clothing with vegetation some 2000 acres of sand blown from the beach into a long and broad range of hills, but ever shifting and eating up the land. He has stopped it, and I, for the present, must stop too.—A TOURIST.

THE CAULIFLOWER SUPPLY.

A GOOD Cauliflower supply is appreciated in most establishments, but in dry and hot seasons like the past many of the plants have an annoying tendency to "button," especially where the ground is poor or not deeply worked. On light land a deeply worked and well-manured soil is essential, for if the season should prove dry a collapse is certain if the above conditions are not secured. During the past season we were rather fortunate in our supply, and especially so from the commencement of September onwards. These were grown on ground that had previously been occupied with Celery, and as this had been well manured and worked it was in good condition for the crop. Many failures are due to the young plants not being properly prepared in the first instance. The seed is often sown too thickly and the plants spindle before being pricked out, and are then pulled up and planted with a dibber, leaving the fibrous roots behind, thereby losing time and often courting failure. I have great faith in sowing the seed thinly and pricking out the plants when large enough into a frame, and into good loam that will hold together, and manure, say equal parts of each, which will cause the roots to become fibrous and plentiful. When planting time arrives each may be taken up with a good sized ball and planted with a trowel, when after a good soaking of water they will barely feel the shift.

I am very much averse to planting Cauliflowers on the level. In all cases we cut out a deep drill as if for Potatoes, which gives shelter, especially so in the case of the early supply; they also have the benefit of the water direct to the roots as well as rain. When the plants are about half-grown the ridges may be levelled in with the hoe about the stems, which keeps them firm. When planted on the level and earthed up very little water reaches the roots. These drills are also very useful for the second supply, as if the season should prove dry these require occasional soakings of water, and if at command liquid manure or sewage.

Eclipse and Veitch's Autumn Giant are grand Cauliflowers, one succeeding the other if sown at the same time, but in many districts they are sown too late to grow to any size or do much good before the frosts come. For our earliest supply we depend upon Early Dwarf Erfurt, Early London, and Large Asiatic, which succeed one another. The seeds are sown thinly on a west border the first week in September, and when large enough are dibbled out into a cold frame about a foot from the glass. There they remain through the winter, receiving air on all favourable occasions, and being protected from frost. Early in April they are planted out, the Early Erfurt on a warm border for the early supply, and the others for the main supply in the open. If handlights are at command these could be placed over a part of the early ones, which will hasten them on. To succeed these, about the middle of February a little seed is sown thinly in a box and placed in a slight warmth. A vinery just started will do admirably, and as soon as the seed germinates the box is placed in a cool house close to the glass or in a cold frame, but take care to protect from frost. This will cause the plants to become sturdy. When ready these are pricked out into a roughly made frame 4 inches apart and 6 inches between the rows, and as they become established are ventilated freely and hardened, taking care to protect from frost. When ready they are planted out. Eclipse, Autumn Giant, and Veitch's Self-Protecting are the main autumn varieties. The seed is sown thinly in boxes and treated precisely as the former, but the plants are allowed a little more space when pricked out. When ready for planting a thorough soaking of water is given the night previous. We allow 30 inches between the plants in the rows, and 2 feet 9 inches between the rows. Of course showery weather is the best time to select for planting them out, but last season that was out of the question, and

they only had a thorough watering at planting time and about twice afterwards, though they did remarkably well. The ground was kept well stirred with the hoe. I ought to have mentioned that we had a sowing of Veitch's Self-Protecting the first week in April in the open border. These were planted out when ready, and came in very useful about the middle of November up till nearly Christmas. If the weather had been severe these would have been lifted and planted in pits.—A. YOUNG.

YELLOW SPORT FROM MRS. HEALE.

IN answer to "An Exhibitor," I wish to state that we hold here, where it originated, the entire stock of that beautiful variety, which received a first-class certificate at Bath, November 9th, 1887. The colour is a deep primrose. I must also state that it is not in commerce at the present, and will not be this season. The stock being very small we intend growing it again before finally disposing of it. I am highly pleased that "An Exhibitor" has taken the trouble to make inquiries, as he evidently knows the value of the sport.—F. R. HAYES, *Gardener, Woodville, Kneighley, Yorks.*

CHRYSANTHEMUM GOLDEN GEM.

THOSE of my brother gardeners that have not yet had the above variety in addition to their Chrysanthemums would do well to obtain it. For the decoration of house and conservatory it is highly valuable throughout January, being of a robust dwarf habit, retaining its foliage well to the time of its flowering. Those who have grown it well are most thankful for its production by Mr. Owen, the Floral Nursery, Maidenhead, who has it in its true character.—H. VICKERY, *Huntsmoor Park, Iwer, Bucks.*

A CATALOGUE OF CHRYSANTHEMUMS.

It is announced that the National Chrysanthemum Society intends undertaking the production of a Catalogue of Chrysanthemums during the present year, and if they do it is to be hoped the task will be performed in such a way that it will be useful to growers and creditable to the Society. What we require is an authoritative list as full as possible that we can turn to as a reliable guide, and this could surely be accomplished by the Society named better than by any other. To ensure its success it must, however, be the work of the whole Society, and not the production of two or three members, utilise as far as possible the information obtainable from all the members of the Society, and then, with a good system of condensation and arrangement, a standard work of great value will be produced.—M. N. C. S.

SECRETARIES JUDGING AND SHOWING.

SOME attention has been called to the fact that the Secretaries of Chrysanthemum and other societies occasionally either exhibit or assist in judging at the shows under their management, and I should like to know the opinion of some of your readers upon the subject. There is no question that in the majority of cases the gentlemen who perform the very arduous duties of Secretaries are above any suspicion of unfairness, but their position necessarily gives them such opportunities for knowing who are the exhibitors of the particular produce to be judged, also the number of competitors in the several classes, that their acting in any way outside their strictly official duties is apt to give rise to unfavourable comments. The question is, whether it is desirable, in the interest of horticultural societies, that Secretaries should either compete or judge at their own shows.—A PROVINCIAL EXHIBITOR.

EXHIBITING CHRYSANTHEMUMS.

It is possible that "Wraith," in your last issue, may represent the feelings of a few gentlemen, but I am persuaded he does not represent those of the majority. Some do not like to see their names associated with every insignificant prize their gardeners may win, and rightly regard competition at shows as an encouragement to those who are working for them. If an owner desires his name to appear no sensible gardener would wish to suppress it, and the rule adopted by most societies is to give on their prize cards the names and addresses as they are received on the entry forms. That is the practice with the National Chrysanthemum Society, and official lists thus prepared at special request have been occasionally supplied to one of the gardening papers for gratuitous insertion as an advertisement.—A MEMBER OF THE NATIONAL SOCIETY.

CHRYSANTHEMUM EXQUISITE.

I SHOULD be glad to know whether any readers of the Journal who have grown Chrysanthemum Exquisite have found it to be fragrant. In consequence of this variety being mentioned in the Journal last spring as a scented one I procured it, but have not found a vestige of scent. Most of the fragrant Chrysanthemums appear to lose their odour after they are about half expanded. Mrs. Langtry, however, and probably other single varieties, are exceptions to this.—R. FALCONER JAMESON.

IMPRESSIONS AND OBSERVATIONS.

I DID not finish my self-imposed task last week of glancing through the first January number of the Journal and jotting down a few impressions, the result of reading the different articles. The subject of packing fruit, which was "mentioned," is one of great importance, and is only referred to now for making an observation founded on experience. The best of fruit may be spoiled by bad packing, and its value brought down 500 per cent. in twenty-four hours. Some time ago I was prospecting a very large house and very fine crop of Black Hamburgh Grapes. These were grown by an amateur purposely for sale, and he was then selling the fruit in his district for 2s. a pound. At that price it paid him very well, but he anticipated a fall of 6d. a pound, and as he had observed the Covent Garden Market prices, and thought his Grapes as good as any he had seen in London, resolved to send a large consignment there. I endeavoured to dissuade him, pointing out the liability to injury in transit and a possibly overlaid market bringing down values, but all I could do was to induce him to make his first consignment smaller than he projected; and as I knew to whom he was sending the Grapes—a fruiterer of high standing, dealing direct with consumers, there was no difficulty in arranging that I should see the cases opened; indeed, the consignee was only too glad for me to do so. It was a sorry sight to see the "rubbed" and shaken Grapes, some having been broken, and the whole having a bedraggled appearance. Would I give 6d. a pound for them? was the question asked, and only a negative reply could be given. "In this case," remarked the fruiterer, "I will not offer a price, but as the lot is small will have the Grapes sorted and make the best of them, sending the man the money in full and request him not to send me any more Grapes." The best were sold for 6d. a pound, some for 4d., and some were unsaleable. The fruit could have been sold for 1s. 6d. a pound at home. The best Black Hamburghs in the same shop with these damaged Grapes were being sold for 2s. The loss indicated was caused wholly by bad packing, as thousands of pounds are lost yearly in the transit of tender fruit long distances to its destination. Old hands do not make such blunders, and if Mr. Pettigrew's article on page 8, and this comment thereon, with the example given, lead to greater care in the work under discussion we shall not have written in vain.

I CAME across an old story the other day of a Scottish "daft" breathlessly running, as he explained to an interrupter, to the funeral of his relative Lord Somebody. On being told his lordship was alive, Joek observed, he "didn't care for that, there were sax doctors at him, and he would be deid before he (the daft) got to his journey's end." That is the gist of the tale as I remember it. It reminded me of the doctors who have been consulting over the case of the Royal Horticultural Society and prescribing accordingly. It must be supposed that "Dr. Masters' Committee" have been instrumental in nominating the four gentlemen, whose names are published on page 41, for filling the vacancies of the retiring members of the Council; at least, if they have not done so, they have done nothing that the public yet know about. Let it be assumed that all the nominees are fit and proper persons for the position to which they are introduced, as others might be who are passed, then we find three out of the four of the nominees for the Council also members of the Consultative Committee, which looks very much as if they had been engaged in nominating one another. The interesting lesson to be learned from the results of the deliberation of the Council's advisers appears to be this—If you wish to push yourself into prominence take an active part in passing resolutions and getting on a reforming Committee.

WITH a sincere wish for the prosperity of the Royal Horticultural Society, and doing my little best to assist by adverse criticism and otherwise, I am very far from satisfied with the constitution, as proposed, of the new Council, and, so far, fail to see that the special committee have done an atom of good. The "trade" is represented on it, it is true, or one section of the trade, for the two nominees are not only both nurserymen, but practically London nurserymen. The country trade is ignored, the important manufacturing trade is ignored, the seed trade is ignored, and the great body of professional gardeners is ignored. Whether this is the result of the action of the Council or of their advisers, or both, matters not; the fact remains that the Council is not fairly representative; and I do not hesitate to express an opinion that I am positive is shared by many, that it would be better to have no traders in the governing body than to have such a one-sided arrangement as is proposed. One representative of London and one of provincial nurserymen, one of the seed and one of the manufacturing trade, with two professional gardeners of good standing, leaving nine seats for independent gentlemen of business capacity and scientific attainments, including Dr. Masters and Mr. Hibberd, would be a much better balancing of all the interests that are identified with the work of which the Society is, or ought to be, the head, and by which it should be supported. A high policy of excluding professionals, or a liberal policy including all the branches, would be intelligible, and either one preferable to the half-hearted scheme that is indicated in the nominations that will only satisfy the minority. The support of the majority is wanted, and this cannot be had without securing their sympathy. The gardeners of the kingdom may be the best helpers in advancing the interests of the Society and gaining for it supporters, or the reverse. Many will be sorry to see their existence is not recognised in the projected scheme of remodelling the directorate, and it is a pity they were so carefully

excluded from the Consulting Committee that was proposed and appointed in December. This is all I have to say this week, and it is perhaps as much as is wanted.—SPECTATOR.

EVENTS OF THE WEEK.—The following are the principal meetings during the week, from January 26th to February 1st. Thursday, 26th inst., Meeting of the Royal Society at 4.30 P.M.; Friday, the 27th, The Quekett Microscopical Club at 8 P.M.; Saturday, the 28th, The Royal Botanic Society, Regent's Park, at 3.45 P.M.; Wednesday, February 1st The Society of Arts, at 8 P.M.

— THE schedule of prizes of the GREAT YORK GALA for the current year's June exhibition is just issued, and over £600 is offered in prizes. For Roses in pots and for cut blooms £123 is offered, about £50 for Orchids, which include special prizes from Messrs. Backhouse and Son, £104 10s. for the various classes of Pelargoniums, £60 for fruit, including good prizes for a collection, and special prizes for Pansies, Violas, double and single Pyrethrums, &c.

— WE are requested to announce that Her Majesty's First Commissioner of Works has entrusted MESSRS. OAKSHOTT & MILLARD, Seedsmen to the Queen, Reading, with the order for supplying Grass seeds for the Royal parks.

— THE WEATHER.—"P. D." sends this note on the weather in the north from the 16th to the 23rd January. "A variable week of frost, fog, and fine weather. The bat was flitting about on the evening of the 16th. Frost occurred on nights of the 18th and 19th, when 9° and 2° were registered, followed by a dense fog on the afternoon and night of the 20th. The 22nd was a really fine day with west wind; bees were enticed out here and there by the sunshine. Snowdrops in bloom." In the neighbourhood of London the weather has been dull, with little sunshine until Monday, which was a clear bright day. The temperature has varied from 28° to 40° at night.

— ON Saturday last the heads of departments and clerks engaged at MESSRS. WEBB'S ROYAL SEED ESTABLISHMENT, WORDSLEY, STOURBRIDGE, had their usual annual banquet at the Mitre Hotel, Stourbridge. About fifty were present, and after justice had been done to the excellent repast provided, Mr. J. P. Hitchings was, in the absence of the principals, voted to the chair, and an enjoyable programme of vocal and instrumental music was gone through. The toast, "Success to Messrs. Webb & Sons," given by the Chairman and responded to by Mr. Berrington, was enthusiastically received.

— MR. E. BUTTS, Leigham Court Gardens, Streatham Hill, writes:—"Permit me to add a few words to your very brief notice of MR. MCLAURIN'S death. He was for upwards of thirty years gardener and manager of the outdoor department generally on the Farnborough Hill estate. For nearly a quarter of a century he was the trusted servant of the late Thomas Longman, Esq. After that gentleman's death the estate passed into the hands of the ex-Empress Eugenie, Mr. McLaurin still retaining his post and enjoying the same confidence as with his former employer. During Mr. McLaurin's stay at Farnborough Hill the gardening part of the establishment underwent a complete change; new grounds were laid out a new kitchen garden was made, and a new range of forcing houses erected. Few men in a similar position enjoyed more respect than Douglas McLaurin, and with him passed away a fine type of a man. In his young days Mr. McLaurin passed some time in the Sheffield Botanic Gardens (I believe under Mr. Marnock), and also at Putteridge Park, under the late Mr. Robert Fish."

— BOUQUET JUDGING AND EXHIBITING.—A correspondent writes—"I think 'A Learner,' Mr. Chard, Mr. Garner, and 'Amateur Florist' will be pleased to learn that chiefly owing to the articles on bouquet showing lately published in the Journal, the Committee of the Richmond (Surrey) Horticultural Society have fixed the size of bouquets at the forthcoming Summer Show on July 4th as not to exceed 18 inches. Also 'A Gardener' will be glad to know that out of the two classes

previously open to all comers they have reserved one class for gentlemen's gardeners and amateurs only, and the Judges will have instructions on the day of the Show to strictly adhere to this rule and attend to other minor details."

— WE are requested to announce that Mr. C. P. Kinnell (hitherto sole partner in the firm of CHAS. P. KINSELL & Co.) has admitted into partnership his brother, Mr. John Kinnell. The style and title of the firm will remain as heretofore. Mr. John Kinnell has been actively associated with the business for the last ten years, and will continue to devote his entire services to the new firm. The offices are 65A, Southwark Street, London, S.E.

— BIRMINGHAM GARDENERS' ASSOCIATION.—At the fortnightly meeting of the Association, January 17th, several new members were elected, and Mr. John Pope, nurseryman, Birmingham, read a paper on "Florists and Florists' Flowers," the Auricula, Pansy, Tulip, Pink, Ranunculus, Carnation, and Picotee coming under review, and their properties pointed out. It was a very interesting paper and led to an animated discussion. On the 31st inst. Mr. W. Wildsmith of Heckfield will read a paper on "Flower Gardening."

— A FOURTH edition of Mr. Lewis Castle's "ORCHIDS: THEIR STRUCTURE, HISTORY, AND CULTURE," is being prepared, and the work is also being translated into French and German on the Continent.

— SETTING GRAPES.—Mr. Stephen Castle writes—"In reply to Mr. Taylor I only wish to say that I very willingly accept his fuller explanations. I did not object so much to the starvation theory itself as to the evidence by which it was supposed to be supported. My Vines flower for the most part in May and not in April. 'Proprietor' rightly says that I followed in all respects Mr. Taylor's own recommendations for applying lime, as given in 'Vines at Longleat.' Mr. Taylor replies so too. In the case quoted from 'Vines at Longleat,' an unusually heavy dressing of lime was given while the roots were active, but heavy feeding followed. So also at West Lynn."

— A MEETING of the Committee of the GARDENERS' ORPHAN FUND was held on Friday night last at the Caledonian Hotel, Adelphi, London. Present—Mr. G. Deal (in the chair), and Messrs. Barron, Wynne, Woodbridge, Goldring, Williams, Bates, Herbst, Nicholson, Wright, Richards, Roupell, Dean, Laing, Cannell, and Head. Gratifying progress was shown, as since the last meeting contributions were received from nearly 200 persons, through local secretaries, including £25 from Lord Ravelstoke, £10 each from the Baroness Burdett Coutts and Colonel Page, £5 each from the Leeds Paxton Society and the Bradford Gardeners' Mutual Improvement Society, with other sums that will be announced in our advertising columns. The total sum promised amounts to £1400, of which £1034 15s. have been received. A vote of thanks was recorded to the local secretaries for their effective co-operation. It was decided to hold the committee meetings on the last Friday in every month, at which any of the local secretaries who could make it convenient to attend would be cordially welcomed. Forms of applications for candidates, contract, and nomination, as prepared by the sub-committee, were passed, and in due time may be had from the general or local secretaries, applications for the benefits of the Fund to reach Mr. Barron not later than April 23rd; the annual general meeting and election to be held on Friday, July 13th, at the Cannon Street Hotel. A most hopeful tone pervaded the meeting, and with the continued efforts of widely scattered friends in support of the Fund, it cannot fail to become a great and important institution, fraught with much benefit to the children of misfortune for whose succour it is established. Through a clerical error a correspondent referred to the Fund, in an article in the Journal last week, as the Gardeners' "Orphanage," which implies the erection of a building, and we are desired to state that there is no intention whatever to apply the money subscribed to any such purpose.

— A LONDON evening paper has the following note on COLLECTING DAFFODILS:—"Lovers of Daffodils will be pleased to know that, encouraged by the success of his visit to Portugal last spring, Mr. Barr proposes to start early in February for a real Daffodil hunt through Northern Spain. He will ransack the mountains from San Sebastian to Vigo, and doubtless settle some vexed questions in regard to the Narcissi of the Peninsula. He may have some adventures too. Last year he was kept in view for some time by the Spanish police, and was within

an ace of being arrested in mistake for the Republican chieftain, Don Ruiz Zorilla, there being probably in all the world no two individuals more utterly different in tastes, manners, and appearance than the great revolutionary bourgeois and the distinguished British bulb-collector."

DESTROYING INSECTS.

MESSRS. CORRY, SOPER, FOWLER & Co. have sent us samples of their new Lethorion or vapour cone that they are now advertising as a certain method of destroying insects without injuring the most delicate plants. The contrivance is quite new. A small bottle is enclosed in the cone, and when the top of this is lighted the fire gradually spreads downwards, till the heat is sufficient for diffusing the contents of the

Fig. 13.

bottle in the form of vapour. We lighted a cone in a basement of our office, but the action of the fire was so slow that we felt a little disappointment and "left it to go out." Half an hour afterwards about fifty men were coughing and sneezing, for the vapour found its way everywhere, and there was a general expression of opinion that if there were any insects on the premises before none could be left alive after this experimental fumigating. The Lethorion appears worth trying for the purpose for which it has been devised.

CERTIFICATING OLD FRUITS.

I WISH you would dissuade members of the Fruit Committee of the R.H.S. from bringing forward for certificates stale subjects long in the hands of the public. The one good of certificates is to guide the public as to the merits (and then only as to appearance and flavour) of sorts not yet distributed. When distributed the public can judge much better for themselves. On January 10th a first-class certificate was given for Royal Medlar. This was described in the catalogue of the late Mr. Thomas Rivers for 1856 as "a new sort from France." The same description remained in his catalogues till his death in 1877, and was continued afterwards. On August 6th, 1887, a first-class certificate was given for Pear Mdle. Solange, which had been a considerable time in the hands of the public. The wonder is that a certificate was not also given to the universally grown Gooseberry, Red Champagne, exhibited by the same firm on the same day. Neither Medlar nor Pear was either raised or distributed by the firms which brought them before the meeting.

The Committee of the 1883 Apple Congress, for some inscrutable reason, out of all the Apples exhibited selected Grenadier and Bramley's Seedling for certificates. These had both been for a considerable time in commerce; in fact, of Grenadier I had at that time forty-three trees not less than ten years old planted out in an orchard. Royal Medlar, Mdle. Solange, and Bramley's Seedling I had, at the time they were certificated, grown for several years. Such being the case I think I should be wrong not to draw attention to the subject. If the certificate is accorded to the fruit only, and not given to the exhibitor, it would show backwardness on the part of the Royal Horticultural Society in finding out the merit of a first-class fruit which has been not less than thirty-one years in the country.—PHILOMELOS.

TROPEOLUMS.—When these are used as climbers they should be renewed annually by young plants. If old ones are retained they often become dirty, and are rendered unsightly nearly all the season by the old foliage turning yellow. Clean healthy plants may be retained for a time until young ones are ready to take their place. In a temperature of 45° to 50° they will not be long before they flower profusely, and where the flowers are appreciated they will be useful for cutting. If young plants were not raised in autumn and wintered in small pots, select healthy cuttings and insert them in sandy soil in small pots and root them in a temperature of 60°. As soon as they are rooted subject them to cooler treatment, or they will grow weakly.—B.

WORK FOR THE WEEK.

FRUIT FORCING.

VINES.—*Earliest-forced Houses.*—The earliest Vines will require careful attention now. Remove all loose and duplicate bunches, thinning the berries as soon as they are well formed. If there is no fermenting material in the house charge the evaporation troughs with liquid manure, or 1 lb. guano to twenty gallons of water, and the borders and other available surfaces may be sprinkled with the same at the time of closing the house or early in the afternoon. Where results are of more consequence than appearance a portion of the fermenting materials may be removed and the whole of the inside border surfaced with thoroughly sweetened dung from the stables, which should be turned over several times before it is introduced, or the ammonia will be too strong for the tender foliage, which may, however, be obviated by admitting a little air by the top lights to allow any excess of steam to pass off, as it will in a day or two. The inside border before being covered with the sweetened stable litter must have a good supply of tepid water, not exceeding 90°. This with the leaves in an active state will incite root-action, and the berries will swell freely. Avoid cold currents of air, also steam arising from highly heated pipes, both being prolific of rust. The heat of fermenting material on outside borders must not be allowed to decline, but should be renewed as required. Where no fermenting materials are used care should be taken to prevent the roots in outside borders becoming chilled by cold rains or snow, having wooden shutters or tarpaulin so disposed as to throw off the rain or melted snow. Attention will be required in tying the shoots and in stopping the laterals. It is assumed the shoots have been stopped two or more joints beyond the fruit. Where the space is restricted they may have been pinched to one or two joints, and in any case the axillary growths may be stopped at the first leaf, and to one leaf afterwards as fresh growth is made. If this is likely to interfere with the principal leaves the axillary growths may be rubbed off except from the two lowest leaves, those above the fruit being stopped to one joint. It is of the utmost importance that the principal foliage be fully exposed to light and air, overcrowding and overcropping being highly prejudicial; at the same time very close stopping is not to be recommended where there is room for extension, as an increase of foliage promotes corresponding root-action, therefore preserve all the foliage consistent with its full exposure to light.

Early Forced Vines in Pots.—Afford copious supplies of tepid liquid manure. Thin the bunches somewhat freely, so as to induce larger berries, not, however, going to the extreme of making the bunches loose, though that is better than small berried clusters. The temperature should be maintained at 65° at night, falling to 60° on cold mornings, 65° to 70° by day, admitting air at 75°, increasing the temperature with sun heat to 80° or 85°, closing the house at 80° with a prospect of an advance to 85° or 90°, at the same time damping the house. Damping is also necessary in the early part of the day. Great care is necessary in ventilating. During such weather as we have lately experienced air should be admitted in moderate quantity, a little at a time, so as not to reduce the temperature much, but to prevent its rising suddenly.

Houses in which Vines are in bloom should have a steady night temperature of 65°, 70° to 75° by day by artificial means, and 5° to 10° more from sun heat. Muscats 5° higher all round. Black Muscat and other varieties liable to set indifferently may be assisted by tapping the bunches every day, or more certainly by applying ripe pollen, drawing a brush lightly over the bunches. A constant circulation of dry warm air is conducive to a good set, and it is advisable not to stop the growth closely during the setting period.

Vines Started Early in the Year.—Syringe the rods twice a day until the bunches are formed, when it is best discontinued; but maintain atmospheric moisture by damping the paths and borders three times a day. Increase the temperature to 55° at night and 60° to 65° by day, with an advance from sun heat to 75°, with ventilation in accordance with the state of the external air. Avoid damping the hot-water pipes when they are highly heated, the steam arising therefrom being very different from that given off by cooler surfaces. Keep up a supply of ammonia in all the houses by turning over the fermenting materials and adding fresh horse droppings, or if this be objected to the house may be sprinkled with liquid manure, the evaporation troughs being kept filled with the same. Ammonia vapour not only aids the growth and texture of foliage, but is inimical to red spider.

Houses for Affording Ripe Grapes in July.—Start the Vines not later than the beginning of next month. There is no need to cover the outside border with fermenting material, but a covering of leaves or litter is necessary to prevent chill. A bed of fermenting material inside the house conduces to a good break by securing a uniform moisture. Syringe the rods three times a day, maintaining the temperature at 50° at night, and 65° by day with sun heat. Water inside borders with liquid manure at 90°, and repeat as necessary so as to bring the soil into a thoroughly moist state.

THE FLOWER GARDEN AND PLEASURE GROUND.

Tuberous Begonias.—Late in January or early in February is the

best time for sowing the seed of Tuberous Begonias. Not only does such minute seed germinate more surely when sown before much hot sunshine and drying winds are experienced, but an early start insures the requisite strong growth before bedding-out time. Fill well-drained pans with light sandy compost, make the surface fairly firm, smooth, and level, cover with silver sand, and moisten thoroughly through a fine-rose pot. When dried somewhat, or say in the course of three hours, sow the seed evenly and carefully, dust a little dry sand over the seed, but do not bury it deeply. Cover closely with a square of glass, and plunge the pans in a gentle hotbed. If shaded, or closely darkened, no water ought to be needed till the seed has germinated. It is the careless watering that is often to blame for failures to raise seedling Begonias, this dislodging the seed when perhaps just on the point of sprouting. Dryness may end equally bad, and if the surface needs moistening at any time, whether before or after germinating, it is most safely accomplished by partially immersing the pans in a tank or pail of tepid water. As soon as the seedlings show themselves thickly all over the pan, gradually dispense with the shading, and wait till rough leaves are formed before pricking off into pans of fine soil. Strong tubers intended for bedding out may be examined and cleared of any decaying stems, but they ought to be kept cool and rather dry for at least another two months.

Lobelias.—Excellent and very reliable strains of bedding Lobelias are sold by the principal seedsmen, and seedlings being much more easily obtained than are plants from cuttings, are now usually solely relied upon. *L. Erinus* *erecta* and *speciosa* are good, and *pumila* *magnifica* can also be recommended, these being the most dwarf. Various shades of colour can be bought, but as a rule a good blue is the most serviceable and effective. The Lobelia seed again is very small, and we prepare the pans, sow the seed, and otherwise treat it much the same as advised in the case of Tuberous Begonias. The seed being new and sound will all germinate, and when sown very thickly the seedlings are liable to damp off wholesale. Better, therefore, to sow the seed thinly in two or three pans rather than crowd it together into one. The seedlings ought to be well exposed to the light, and set on a shelf in a lower temperature for a time prior to pricking off. Old plants kept for the purpose of affording a supply of cuttings or for division should be kept in a rather cool house or frame, or otherwise the tops will be spindly, as well much given to flowering. Examine them frequently, and remove any decaying portion, or this will quickly spoil the whole plant.

KITCHEN GARDEN.

THE FIRST CARROT CROP.—If early Carrots are appreciated there will be a general desire to have them ready for drawing as soon as possible. When about the thickness of one's thumb in March or April they are delicious, and all who can muster a hotbed and frame may have them ready then. They are easily grown. A thick substantial hotbed should be formed, place a frame on this, and then fill 8 inches or 10 inches of soil. This should be prepared for the Carrots. Ordinary garden soil will do for part of it, but it should be mixed with a quantity of sand and a little decayed manure. A quantity of soot should also be mixed with the soil before putting it into the frame, as it would never do to go to the expense of preparing a bed and then allow the roots to be destroyed by grubs, but the soot will keep them away. Make the soil firm and smooth, and sow the seed carefully broadcast. As a rule we cover the seed with sand to the depth of 1 inch. Do not give water, as the moisture from the manure will be sufficient. Should much frost come protect by covering the glass lights. The young plants will be visible in a fortnight or so, and then they may be ventilated a little on fine days. French Horn is generally regarded as the best early Carrot, but Sutton's New Early Gem is superior.

BROAD BEANS.—These are not so extensively grown as Peas, but the majority of garden owners desire a few early dishes, and as they grow freely without heat in the open, and come in at a time when early vegetables are not plentiful, a few rows always give satisfaction. For exhibition and main crop Webb's Kinver Mammoth is unique, but it is not so early as Early Mazagan, and a row or two of the latter should be sown for a first crop. We have sown our early Peas on a south border in rows 8 feet or 9 feet apart, and placed a row of Broad Beans between them with good results, and they may also be sown by themselves in any warm corner. From one to two pints of seed will make a good plantation. The ground may be heavy, and it should always be rich. Do not sow deeper than 4 inches below the surface.

THE BEE-KEEPER.

PRACTICAL BEE-KEEPING.—No. 28.

The simplest methods of performing necessary manipulations are ever the most valuable. The saving of time is of itself no inconsiderable matter, and if to simplicity of method is added certainty of success the bee-keeper must indeed be happy. The weary work of introducing queens by the ordinary method is too uncertain to give anything but anxiety to the amateur bee-keeper. Success does generally result if the manipulation is properly performed, but

there is just too much uncertainty on the point to make the operation pleasurable. As in all other manipulations, so when the "direct introduction method" of giving new queens is practised care must be taken not to deviate from instructions until by experiment a better way has been found of achieving a like result. If a bee-keeper tries the direct introduction plan, and neglects to do as his instructions tell him, he must in the first place not expect to succeed, and in the second place must when he fails blame himself and not the method. Amateur bee-keepers, as a rule, are too apt to do as they think best without having sufficient knowledge on a subject to think rightly. It is well for a man to think, but before he can do so he must have a knowledge of the subject upon which he wishes to think, otherwise he may discover that, though in the abstract a man may, knowing nothing, yet think seriously, but in the concrete he must before thinking out any particular subject have a sufficient knowledge upon which to base his thoughts. Those who desire to succeed will first try the method, following closely the instructions given by those who have pursued it with success, and will then—having succeeded—endeavour if they think it possible to simplify the method by such plans as may suggest themselves; and after putting their ideas into practice and finding them an improvement will no doubt be kind enough to give to those who have less of the experimentalist about them the result of their trials and the means by which those results have been achieved.

To introduce a queen by the direct method the following points need attention:—

- 1, Removal of old queen.
- 2, Confinement of new queen alone and without food for thirty minutes previous to introduction.
- 3, Keeping the queen warm during such confinement.
- 4, Not introducing her till dark.

There is no special time for depriving the stock of the queen which it is desired to supersede. It may be done at any time during the day upon which the new queen is to be introduced. The operation should be performed with as little disturbance as possible, and the stock must be allowed to become quiet again as soon as possible. The confinement of the queen for thirty minutes, keeping her during that time alone and without food, seems essential to success. Whether by such confinement the queen loses her peculiar scent, or becoming more quiet is less excited when allowed to run into the stock, or by abstinence from food becomes more agile and moves about the combs more freely, and therefore apparently with greater confidence, seems hardly decided, but that in some way this solitary confinement does exercise an influence either upon her conduct when introduced to the stock or upon the conduct of the bees when she is introduced to them there can be but little doubt. During this period of restraint the queen must be kept warm. This point needs no explanation, for it is self-evident, knowing what we do about queens, that a chill contracted just prior to introducing her to a strange stock would be in every way detrimental to her, and probably cause the bees to reject her; and even if they received her amicably she would herself have sustained an injury from which she would in all probability never wholly recover. The fertility of the queen is, I believe, often reduced by chills suffered during the winter months. This seems to be especially the case when stocks are weak. In no other way can certain failures in queens be accounted for. The queen must not be introduced until dark, and then the introduction must be done as quietly and with as little disturbance as possible.

Mr. S. Simmins in his "Original Non-Swarming System," gives a very succinct and good chapter on this subject, from which a few quotations shall be made. "Upon receipt of a queen, go to the hive and remove that one to be superseded (or otherwise). At dusk take the new queen quite alone. After keeping her so for not less than thirty minutes previously, but quite warm, and moreover without food meanwhile, lift quilt at one corner, drive bees back with very little smoke, and then permit the queen to run

down. Close the hive, and make no examination until after forty-eight hours. Leave the operation until so late that a lamp is necessary." He adds, "It matters not as with the original method whether the old queen has been only just removed or if the hive has been long queenless, the new queen will always be accepted." Every bee-keeper may give this system of introduction a trial, and from my own experience such a trial will—if strict adherence is given to the instructions—end in success.—FELIX.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Books (J. P.).—If you mean Sweet's "Hortus Britannicus," it can only be obtained from second-hand booksellers, but may be occasionally met with for a few shillings. Johnson's "Cottage Gardener's Dictionary" will be much more useful to you at the present time. It can be obtained from this office, price 7s. 6d., post free 8s.

Furnace not Heating (Subscriber).—Your letter will be fully answered next week.

Kew and Chiswick Gardens (J. G.).—The young men employed in these Gardens as students are required to have had several years previous experience in gardens or nurseries and to be of good character. Particulars can be obtained on application to the Curator of the Royal Gardens, Kew, or to Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick.

Fuel (Inquisitive).—We do not quite understand to what you allude under the name of "burgy," but many persons who have tried different kinds of fuel find a mixture of small coke and coal, the latter being known as slack and breeze in different localities, as economical and profitable as any for the different forms of saddle boilers. We have found no fuel give more heat for the same outlay than the mixture indicated, and you may safely try it for your boiler.

Horticultural Society (Old Subscriber).—It is impossible for us to form an opinion of a Society which has been brought before you as "limited, and shares so much each," without seeing a prospectus. We are pleased to observe your desire to "help gardeners," but trade societies are usually formed to benefit the shareholders. There are benefit and provident societies that are real helps to gardeners, their widows and orphans, and all or any of these are glad to receive subscriptions to the funds from persons able and willing to contribute.

Celery—Naming Exhibits (J. R. W.).—We are not able to give the address of Mr. Wright "the raiser of several specimens of Salary;" but possibly some of our readers can identify the raiser of the varieties of Celery to which the name mentioned is attached. Specimens at shows should be named, and care exercised in spelling the names correctly; as to the alternative of marking the specimens "unknown" where the condition is published in schedules it should be enforced, and if not enforced discarded as a useless redundancy.

Red Spider on Vine Rods (A Learner).—The buds as well as the rods and canes, in fact every part of the Vines, may be dressed, and the mixture being used with care and judgment will not injure the buds provided they are quite dormant. Winter dressings will not render the Vines proof against red spider. The pest must be prevented by painstaking culture, and prompt remedial measures must be taken whenever it appears.

Eucharis not Flowering (Idem).—It is a mistake to rest the plants by keeping them in a dry and too low temperature, as it has a weakening tendency. We find the best results follow from encouraging the plants to make and complete a good growth and still continue them in the same temperature but with lessened supplies of water, yet to prevent much limpness of the foliage. Under this treatment the plants flower successively throughout the year. The only precaution necessary is to keep an eye on them, and when they commence throwing up their foliage and flower scapes to apply water freely and feed liberally, continuing this until the growth is perfected.

Tennis Lawn Mossy (W. H. A.).—Lime will destroy moss, but we should use it along with wood ashes, the lime freshly slaked and the wood ashes dry. Half a bushel per rod will be sufficient, or a peck of each. It should be distributed evenly, and before applying it would be advisable to scratch the ground well with an iron rake, clearing off the moss disturbed. It may be done from now to March in mild weather,

the earlier the better. If you require a better growth of grass, apply a dressing of decayed manure or compost a short time after using the lime and wood ashes, or apply soot during moist weather when the grass begins to grow. A peck per rod is a sufficient dressing.

Nitrate of Soda and Sulphate of Ammonia (North Herts).—As a rule the former is somewhat quicker in its action, the latter a little more lasting in effect, but the results are not uniform in all seasons, and on differing crops and soil. Speaking broadly, nitrate of soda is the more effective in dry soils and seasons, sulphate of ammonia in cold soils and in wet seasons. It is impossible to indicate the quantity best to apply, as this must be determined by the fertility of the soil and the condition of the crops. An ounce of either sprinkled on a square yard of ground and hoed in, also watered in dry weather, would be a good dressing, and better results might be expected to follow with twice the quantity of superphosphate of lime added to your Roses and Strawberries. You cannot make a mistake by trying both the nitrogenous manures, as they will stimulate growth, and you may then find which is the better for your soil and purpose.

Yellow Picotees (T. Wood).—They are certainly not a "new race." We have known them for thirty years at least, and remember some seedlings raised by Mr. Richard Smith of Witney that caused somewhat of a sensation at the time. In searching for a reference to these we find that after the death of Mr. Smith in 1860 his stock was placed in the hands of Mr. J. D. Hextall, who further alludes to the section as follows in "Gossip of the Garden," page 257, vol. vi. (1861). "My own acquaintance with the yellow Picotée extends as far back as 1824. I found a coloured plate of a bloom given in 'A Treatise on the Pink Carnation,' &c., by Thos. Hogg, a high authority in those days. Its singularity attracted my attention, and I obtained a dozen varieties from Mr. Hogg as a trial; but in a wet season, and with plants of German origin from a climate warmer and drier than our own, and the stock not sufficiently acclimatised, it was no wonder I did not then succeed. A few years afterwards I procured some of the best English raised ones I could obtain, and have continued to grow them to the present time, adding from time to time the new ones sent out by Mr. May, Mr. Bragg, and others, but must confess they have fallen short of my wishes. It remained for a veteran amateur, by a dozen years of unwearied scientific hybridisation, to accomplish that which had been attempted with less success by professional growers. Mr. Smith's memory will for many years be perpetuated by his labours. There can be no doubt that the introduction of these seedlings, of such superior quality and stamina, will greatly tend to the future popularity of the class, and if persevered in as they deserve to be, and a fair proportion of encouragement given to them, that they will add a new and attractive feature to the future exhibitions of the National Carnation and Picotée Society."

Forcing House Arrangements (Cambridge).—It is not necessary to have the partition; indeed, it would be alike objectionable from a cultural and economic point of view. A propagating frame could be made to rest on the slates or covering over the hot-water pipes in the bed, and with cocoa refuse for plunging the cutting pots you will have all that is required for the successful propagation of most plants. It would be most desirable to have both sides the house arranged as shown on the east side in the plan, having the two 4-inch pipes for bottom heat forming a chamber by covering with slates, and with cocoa refuse the arrangement would be complete, as it would form a moist medium for standing pots upon, or for plunging such as it is deemed advisable to afford bottom heat. For so narrow a house side ventilation is not necessary, but it should be provided in the roof at the ridge. The side walls we should have reduced to 4½ inches, four courses of bricks from the top, which should—i.e., the four courses of 4½ inch—be built in cement. This would form a ledge on which two rows of 4-inch pipes, a flow and return over each other, could be placed, and would give all the top heat necessary. The pipes on the roof are not necessary for the forcing house. The hot-water pipes for top heat will be quite right in the troughs, and adopting our plan you will only need a board the depth of the pipes to keep the plunging material away from them. A shelf over them might be useful for small plants, but it must not rest on them, being fully 6 inches from them, so that the heat may rise freely, in fact it would be better without it. A frame on the west side would be useful. It would be best heated with hot-water pipes. A 1½-inch or 2-inch flow and return would be ample for a frame 6 feet wide inside. We have heated them very successfully by fixing the piping beneath the bearing pieces or rafters, one pipe at the lower part and the other near the middle of the slope of the roof.

Fruit for Strong Soil (New Subscriber).—If you cannot make the clayey soil more open by additions of lime rubbish, sand, or gritty matter of any kind, you should collect a little of the freest soil you can find to place in actual contact with the roots, fresh roots not forming quickly in cold heavy land. If you could char or partially burn some of the soil, it would improve it considerably for fruit culture. Both orchard standard, and bush or pyramid trees would answer, and it is for yourself to choose which form you prefer. The latter take up the least space and bear the soonest, but eventually, and in the course of years, the former give the most fruit with the least trouble in pruning. You do not say whether you wish to grow dessert as well as culinary Apples: if you wish to do so, Irish Peach, Devonshire Quarrenden, and Cox's Orange Pippin are good; Duchess of Oldenburgh, Wormsley Pippin, and Blenheim Pippin are good for both dessert and cooking, the first being the best for bushes, the last for standards. Stirling

Castle, Small's Admirable, and Lane's Prince Albert are good for bush trees. Of Pears Williams' Bon Chrétien, Beurré d'Amanlis, Louise Bonne of Jersey, Fondante d'Automne. Doyenné du Comice and Bergamotte Espere are good growers and bearers of excellent fruit. Denyer's Victoria is one of the most profitable Plums, but if you want a variety for succession Rivers' Royal Prolific, The Czar, White Magnum Bonum, Victoria, Pond's Seedling and Grand Duke will be useful. You do not state your wants very precisely, so we give the best reply we can under the circumstances. The sooner you plant the trees the better, but the soil must be in a dry and friable condition, not wet and adhesive when the work is done. Spread the roots out straight, cutting off any broken ends and cover with crumbled soil 4 or 5 inches deep, and if when all is finished the trees are on mounds 3 or 4 inches above the general level of the ground they will be better than if planted level in your cold heavy soil. Stake to prevent their being blown about, and if convenient spread a layer of 3 inches of littersy manure on the soil over the roots and a foot beyond their extension. The trees should be pruned soon after they are planted, shortening the wood made last year to half its length, more or less, due regard being paid to the symmetry of the trees, also thin out any misplaced or overcrowded growths altogether, following in regard to the disposition of the branches the routine described on page 37 last week.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (P. H. Wright).—1, Walsgrove Wonder; 2, Lady Henniker; 3, Grecnup's Pippin.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (A. B. C.).—Cupressus sempervirens stricta. (Surrey Gardener).—Yes, your plant is the true Freesia refracta alba. F. Leichtlini is not so pure, being of a creamy yellow tint. The Epaeris is miniata splendens. (W. R. S.).—1, Kennedy's Marryattæ; 2, Cypripedium insigne Maulci; 3, Lælia albida. (P. A.).—1, Libonia floribunda; 2, Peristrophe speciosa; 3, Acacia platyptera; 4, Erica melanthera.

COVENT GARDEN MARKET.—JANUARY 25TH.

MARKET still very quiet with supplies falling off.

LAMBING TIME.

No flock of ewes, however carefully they may have been selected, can pass through the lambing time without some risk of—we may say some loss. A flock of young ewes will sustain few losses, but yet there will, even in such a flock, be a few delicate animals, and some will prove troublesome—some die. It is obvious, therefore, that all possible precaution should be taken beforehand to prevent such losses, and much may undoubtedly be done to that desirable end.

We have devoted our first two papers chiefly to remarks upon the dietary of pregnant ewes, just because experience has shown that careful feeding has very much to do with successful lambing. Shepherds will assume a profound air, and assure one that a certain daily quantity of roots before lambing are essential for the ewes' safety. The aim of most shepherds is to induce one to regard their calling in the light of a "mystery;" but we long ago resolved to ascertain what were the requirements of sheep and how best to treat them both at lambing time and at other seasons of the year. We thoroughly recommend young farmers especially to take a flock in hand for a year or two themselves, and learn thoroughly the management of ewes, lambs, hoggets, and crones. Once acquired, such knowledge will prove invaluable for life, and we hold that no farmer is really competent to control shepherds till he has practically become a shepherd himself. Acting upon this conviction we insisted upon our own boys helping with all details of flock work when they became our assistants, with the result that one of them has already made his way to the honourable position of assistant agent in the management of two large estates, and depend upon it he will eventually be all the better manager for having held the plough and helped care for the sheep.

Our work of preparation for the lambing consisted of having a warm snug fold made with hurdle set in a double line wide enough apart to admit of plenty of straw put in closely between them. In addition to this outer enclosure there are numerous cribs around the inside of it, formed of thatched hurdles at the sides and for the roof. There are also divisions of thatched hurdles intersecting the interior, so as to break the force of the cold winds and to render the entire fold as snug as possible. Close by the fold is the shepherd's portable hut on wheels with a rude couch and fireplace inside it. Such shelter we consider essential, and we certainly have no sympathy with those flockmasters who provide no shepherd's hut because they think he may get inside and neglect the sheep. We know it for a fact that this harsh treatment is enforced by more than one owner of large ewe flocks, and we know also that they are wrong. To insist upon a shepherd being out with his flock through the long nights at this season of the year without reasonable provision for his comfort is absolute cruelty, and we

should say it would lead to negligence rather than the exercise of vigilance. We do not make much provision of drugs and nostrums for the ewes. A few packets of Epsom salts, a bottle of castor oil, a large bottle of Calvert's carbolic oil and a syringe, some ergot of Rye, sweet spirits of nitre, and some brandy are all we require.

WORK ON THE HOME FARM.

We have certainly been highly favoured with fine weather for bringing up arrears of work upon the land this winter, and up to the time of writing this note have been able to keep the ploughs going notwithstanding that we have had some sharp frosts. Most anxious have we been to do all we could before snow locks up the land and prevents such work from being done, for our work of bringing poor farms into good order is an arduous undertaking in which we have to make every stroke tell. Withal it is most interesting work to watch the change from poverty of condition and lean crops to fertility, plenty, a bountiful yield, and a profit upon our labour. We do not speak rashly in this matter, for year after year we have farms falling in under the agricultural depression, and we have to take farm after farm from the incompetent hands of bankrupt farmers, and to render them really fertile, clean, and profitable to the owner of the land.

In this work we should like to proceed with deliberation, to drain, clean, and manure in due sequence of order, but the imperative necessity which exists to get something out of the land even during the first year compels us to make the best of things and to drain and manure for as speedy a return as may be. Faulty practice is it we know to crop land that is foul with perennial weeds. Well, we will have the drills wide apart to give free scope for the use of horse and hand hoes, but we will apply an extra dose of manure to enable the land to bear its double burden of corn and weeds, and once we get the corn off next harvest up comes the land to be got as clean as possible in autumn.

We are already at work upon our scheme of manuring for the year, for we have to give much thought to this work, and to thoroughly digest the whole matter beforehand in order to ensure the timely and correct use of the manures upon each farm. Our root crops will this year be materially reduced, for the cultivation of such crops is an expensive affair, and we only need them for sheep, as we have practically given up keeping bullocks for making farmyard manure.

OUR LETTER BOX.

Intercropping on Fruit Farm (Four Tower).—Your new farm is a veritable Kentish fruit plantation, and we warn you not to exhaust the generous soil by trying to get too much out of it. Bush fruits at 6 feet apart will soon require the whole of the space, and the spreading roots must not be destroyed or broken at all, and therefore as you find them making way through the soil it must be left altogether undisturbed, and not broken up by ploughing or digging. For the first two years while the bushes are small you might have two rows of Beans down the centre of each 6-foot alley, grinding the Beans and cutting the stalks into chaff for horse food. In the 24-foot alleys your plan of growing Tares is a good one, provided you keep them full 5 feet from the fruit trees. Eventually you will find it answer best to fill the entire space with bush fruits or Strawberries, and to purchase food for the horses. You require no seed drill for so small a farm. Any handy man can sow you Tare seed broadcast, but you must have a small harrow to cover it with. We are intimately acquainted with your soil, and you may like to know that under good cultivation some years ago Black Currants in your locality yielded a crop of 16 quarts per bush. We mention this in order to show you that fruit-growing should be your chief aim.

REMARKS.

- 15th.—Fine, but gusty, and rather bleak.
 - 16th.—Overcast all day.
 - 17th.—Cloudy morning, fair afternoon, bright evening and night.
 - 18th.—Cloudy all day.
 - 19th.—Dull with high fog.
 - 20th.—Fine and bright, but with slight fog.
 - 21st.—Very wet morning, damp all day with no sun; moonlight after 11 P.M.
- A cloudy and somewhat dull week, generally dry, and practically free from fog. Temperature about 3° below the average, and nearly 4° below that of the preceding week.—G. J. SYM NS.

FLORAL DECORATIONS.

DISCUSSIONS on horticultural topics can be rendered very profitable to readers as well as the disputants when the sole object is the elucidation of some difficult point, and the desire of those engaged in it is not to prove themselves right and others wrong, but to find the truth. Within such limits there is ample room for the courteous expression of different opinions, and much good often results from a consideration of a matter from opposite standpoints. During the past few weeks floral decorations at exhibitions have been discussed by several correspondents in this Journal, and, as announced last week, advantage has already been taken of it in the framing of schedules for the current year. The Richmond Horticultural Society (Surrey) has set an excellent example in this respect, and it is reported that the enterprising Honorary Secretary (Mr. J. H. Ford), supported by a thoroughly practical Committee, contemplate some other alterations in their arrangements for the present year that are likely to still further increase their popularity.

There can be no question that, in fairness to all exhibitors, schedules cannot be too clearly worded, and, as regards the size of bouquets, much latitude has been allowed to competitors, with the result that there has seemed to be a general struggle which should show the largest, and the real objects of such classes have been lost sight of. Why the enormous bouquets sometimes seen at exhibitions and in florists' shops find admirers or purchasers it is difficult to understand, but it is probably in the same way that large fruit and vegetables find favour with some. A bouquet of medium size can be rendered as tasteful a combination of flowers as the most exacting could wish to see, and what advantage is gained by using twice the number of flowers? Too often the only results are an increased cost, and a huge production that is almost fatiguing to look at. Some of the finest bouquets of many hundreds that have come under my notice were not the most elaborate, in which the striving for effect was apparent; but those, composed with a kind of careless grace, good flowers only being used, and these with judgment, so that while their individual characters were not lost they were not sufficiently prominent to mar the general effect.

The separation of gardeners' and amateurs' classes from those devoted to the trade florists is a step in the right direction where sufficient competitors can be obtained to make an adequate display. It is correctly said, however, that gardeners can learn much from professional florists, and this they no doubt have done. Perhaps, however, they can learn just as well without having to be constantly contented with second and third prizes, as they are usually placed at a great disadvantage when competing with a trade grower having an almost unlimited command of choice flowers. Florists, like other human beings, are fallible, and they sometimes make mistakes that gardeners need not wish to follow. For example, in one of the leading florist's shops in Covent Garden market recently, there was displayed a very elaborate bouquet of white Camellias, Eucharises, Christmas Roses, Roman Hyacinths, with graceful spikes of Lilies of the Valley freely and well arranged; in fact all that could be desired, except in one particular, which, to my taste, effectually spoiled it—namely, four large sprays of *artificial* white Lilac were inserted. Whatever could have prompted such a positively hideous production cannot be imagined, and happily such instances are rare, though florists may find some excuse for eccentricities in the variable tastes or peculiarities of their customers.

Still the combination of artificial with real flowers in such a way is painful, and it would be as appropriate and agreeable to have a few wax models stationed in an assemblage of young and beautiful women.

Wreaths and crosses are now greatly in demand, and some of the trade florists derive a good portion of their business from the production of them. The spathes of *Richardia aethiopica* are extensively employed for this purpose, but they are often too numerous, and impart a heavy effect that is very undesirable. For decorative purposes generally they are very useful, either cut or on the plants, especially where large spaces have to be filled, but they might be frequently dispensed with altogether in wreaths. There are plenty of white flowers to select from that are much better fitted for the purpose, and the peculiar heavy white of the *Richardia* spathes contrasts unpleasantly with the purity of the old double white *Camellia japonica*, the Christmas Roses, and Lilies of the Valley.

Sprays of flowers for ladies, and buttonhole bouquets for gentlemen, are usually the most satisfactory at exhibitions and in the florists' shops, because they are marked by the greatest simplicity. Very few flowers are employed, and consequently more care has to be exercised in their selection or combination. In the case of ladies' wreaths there has been a tendency to increase the size unduly, but even in those the flowers require to be used with care.—C.

THE CULTURE OF HARDY FRUITS.

THE Apple, I consider, may fairly claim the first place amongst our hardy fruits. Being indigenous to this country it can be cultivated with considerable success, and no other kind of fruit tree affords so lasting, and so generally useful, a supply of fruit, for with a suitable selection of varieties a supply may be had the whole year round. Its usefulness for culinary, dessert, confectionery, and cider-making purposes is too well known to need comment. A suitable selection of varieties is of vast importance, as some well-known varieties succeed in certain localities much better than others, therefore it is an advantage to be well acquainted with the varieties that are found to succeed best in the neighbourhood. It is also necessary to bear in mind the kind of trees taken in hand, and the purpose for which they are required, and the kind of stock they are worked upon. For small gardens, where space is limited, and numbers of different varieties are required, it is necessary that the trees must be of small stature; therefore trees worked upon dwarfing stocks are preferable, otherwise much labour has to be spent upon them in root and branch pruning to keep them within the limited space allotted to them. In many instances, too, much is expected to be produced from a given space of ground. It is not uncommon to find fruit trees surrounded with crops of vegetables close up to their stem, drawing away the food which should go to support the trees, and necessitating stirring the soil far too deeply for the full benefit of the trees, and is the cause of depriving them of their most important roots. I can fancy what a first-class Grape-grower would say to anyone recommending digging, a spade deep, the surface of a *Vine* border, and yet how frequently do we find the ground immediately around the roots of hardy trees dug the full depth of a spade, and then it is wondered that trees do not bear satisfactorily, and that they grow so strongly. The cause in their unsatisfactory condition in this respect is not far to seek, for with the annual cutting off of their most important roots (those just below the surface of the ground) they are left to derive their supply of food from thick roots placed deep down away from the immediate influence of the warmth of the air, thereby causing them to produce a superabundance of gross unripened wood, which usually proves unfruitful, ultimately cankers, and is one of the causes of branches dying back.

When trees are planted sufficient room must be allotted to them

for their future growth, both root and branch, and they should be so placed that the soil once properly prepared for their reception by deeply working it (and if an old garden, a good portion of maiden soil may be placed round the roots of the trees when planted), after which no further disturbance of the soil will be needed beyond lightly pointing over the surface, or hoeing to keep down weeds. When planting is being done, the soil, if in a suitable condition, should be made very firm about the roots, which is conducive to sturdy growth. Give a mulching of rather long manure over the roots, and renew this annually, but when the trees get into a bearing state the mulching should be of a more stimulating nature—that is, if the trees do not grow quite so strongly as desirable.

Pruning must be regulated by the strength of the trees. If strong shoots are cut hard back they will only grow the stronger the following season; if only slightly shortened they will form fruit buds two-thirds the length of the shoots, and when once they are in good fruiting condition the growths may be shortened more freely without fear of their becoming too strong. Allow full space for the branches, so that the sun has access to the centre of the trees to colour and flavour the fruit. The bush form of tree appears the most natural for the Apple, and, in my opinion, the most profitable; and if they can have a portion of ground allotted for their entire use it is very much better than dotting them about all over a garden, where they very much interfere with the rotation of crops and the cultivation of the ground. In large gardens the borders at each side of the principal walks are generally devoted to fruit trees, and then sufficient space is left for vegetables without interfering with the trees. But even in the case of large gardens one frequently sees fruit borders occupied with herbaceous plants as well; but it is not at all times the fault of the gardener for cropping the ground at which should be occupied by the roots of the trees. I lived with a lady once who used to look upon the outside borders of the vineries, which were occupied with Vine roots, as a waste piece of ground, and, notwithstanding an explanation of the evil result, insisted upon having the borders filled with herbaceous plants, and yet at the same time first-class Grapes were expected. I am here going a little astray as regards hardy fruit, but only to illustrate what are some requirements.

The Pear is scarcely less useful than the Apple, for, with a suitable selection of varieties, they can be had over a considerable portion of the year, and the treatment of the one is to a great extent applicable to the other; but in some instances the protection of a wall is almost indispensable in the colder districts for some varieties of Pears to enable them to attain the highest perfection, and it is preferable to have a limited number of well-known reliable sorts to form a good succession than to have a vast variety of sorts which ripen simultaneously and are inferior in flavour. Severe pruning in a young stage should be avoided, for in allowing more extension than is sometimes adopted the trees come into bearing more quickly and fill the space allotted to them in much less time than when they are cut back hard. Ample space for the branches must be allowed, whether standards, pyramids, espaliers, or trained to walls in the various modes. Care is necessary and judgment is required in gathering the fruit; if gathered too soon they invariably shrivel, the late varieties requiring a long season to mature, so should be allowed to remain on the trees as long as possible. On walls the fruits in good season generally set very thickly, and it is advisable to thin the fruits considerably, or the strength of the trees is so taxed that they cannot bring the crop to perfection.—W. SIMPSON, *Knowsley*.

(To be continued.)

GARDEN SPECIALTIES.

THERE are perhaps but few gardens, whether they are under the care of the professional or the amateur gardener, where there are not among their numerous occupants specialties in some form or variety; and indeed a garden would be considered of little interest

if it contained no cherished favourites that would be deemed worthy of some extra cultural attention. Orchids form a specialty with some, while Grapes find many enthusiasts; the outdoor flower gardener selecting perhaps Roses, hardy herbaceous plants, &c.; the fruit grower devoting his extra attention to Apples, Strawberries, or Peaches. There is abundant scope in any branch of gardening for the exercise of individual tastes, and this is almost or quite as marked among cottagers as it is with professional gardeners.

In this, as in most districts, each garden seems to have provided some object that claims attention in a more or less marked degree, those of Park House, Kingsclere, the residence of J. Porter, Esq., claiming premier honours in point of specialty. In this garden Orchids are being made the prominent feature, and although it is not as yet in possession of a representative collection, still it is on a fair way towards attaining that end. At present there are no Orchid houses proper, the plants requiring warm treatment being grown in mixed stoves or forcing houses, while the cooler Odontoglossums, Masdevallias, &c., occupy positions in cool houses or pits. It is intended shortly, however, to erect some houses for the convenience of these choice exotics, then additions will be made both in point of numbers and variety. Mr. Porter is a great admirer of this class of plant, and spares no expense in extending his already interesting collection.

At the time of my visit there was a fairly good show of Orchid bloom, and a promise of a richer display later on, there being numerous spikes of flowers advancing among the various species grown. Some plants of the popular *Laelia anceps* were carrying several spikes of their richly coloured blossoms. *L. autumnalis* was almost past, but had been very showy and useful. Very noticeable was the almost pearly white *L. albida*, this being greatly valued as a buttonhole flower on account of its delicate primrose scent. *Calanthes* have also proved useful, and afforded abundant material for cutting purposes. Of *Oneidium erispum* there was an extra fine variety. The same remark also applies to *Odontoglossum erispum*, a small plant being furnished with flowers of a very superior form. There is a good number of this valuable cool Orchid, and their flowering is looked forward to with great interest. They being obtained from several trade sources are expected to furnish some distinct forms, those already in flower being very dissimilar. *O. Rossi majus* has been in perfection for three months, and is still fresh. *Oneidium ornithorhynchum* also forms an interesting and pretty spike.

Cypripediums in flower are represented by the old and indispensable *C. insigne*, some of these having been expanded since early in November. *C. Boxalli* is another favourite, this being remarkable for its apparently highly polished surface. Among other Cypripediums noticed, some of which were in flower, others in bud, were the choice *C. Spicerianum*, *C. Lawrencianum*, *C. Harrisianum*, and *C. Stonei*. Mr. Norris, the gardener, has been very successful with *Dendrobiums*, many of the varieties having made excellent growths, and are promising a rich display. Space will not allow of the mention of many, but such as *D. Wardianum*, *D. primulinum giganteum*, *D. Devonianum*, *D. Dalhousianum*, *D. thyriflorum*, and *D. crassinode Barberianum* might be named among many others of perhaps equal merit. In addition to those already enumerated there are numbers of others, the whole of which are in capital health, under the same atmospheric conditions provided for other plants.

In another house there are some good Tree Carnations in variety, these, too, being highly valued, and are in good demand for buttonhole purposes, several of Mr. Turner's latest introductions from the Slough nurseries being among the collection, the best of which includes Col. Cox, Countess Howe, Coronet, and Madeline. Of older sorts mention might be made of the following—Andalusia, primrose, bright; Phœbus, scarlet; Brunette, maroon; La Belle, white; Whipper-in, scarlet, with darker stripes; and Incomparable, buff, scarlet edges, very fine, these all being sorts of the very best quality. Border Carnations and Picotees are grown in goodly numbers both in variety and quantity, these two sections providing flowers the whole year without any break in the supply.

Roses, too, are treated in much the same liberal manner, all the best and most popular varieties being represented, the H.P. section predominating. These receive liberal treatment, and are grown in a specially prepared border, and during the Rose season large quantities of blooms are gathered almost daily, many of them being of exhibition quality. These, together with the Orchids and Carnations, form a trio of choice plants worthy of being made a specialty, and although they are in a measure expensive in the first instance, yet they give a good return for the outlay in obtaining and providing for them.

Although I have thought to mention these three distinct classes of plants only as specialties, it does not by any means exhaust the list of other plants grown in varying numbers. In the stoves may

be seen a very good assortment of material grown to supply choice table and other plants, while Violets, and the usual florist flowers, such as Cinerarias, Primulas, Calceolarias, Gloxinias, &c., are each represented in fairly good quantities. Chrysanthemums number about 300, these being grown to supply large blooms principally, but due provision is made with regard to flowers for cutting, as there is a good demand at all seasons.—W. S., *Kingsclere*.

THE CULTIVATION OF ZINNIAS AND OTHER ANNUALS.

PROCURE seed of double Zinnias from a reliable house, sow it at the right time, and give the plants about half the attention required to prepare Zonal Pelargoniums for bedding; plant them in a well prepared bed by themselves, and they will repay the cultivator with a rich and continuous harvest of bloom, by the side of which Pelargoniums will be tame and carpet bedding flat. Not only so, he will be able to "cut and come again," for few flowers last so well when cut as Zinnias, as if arranged so as to take off their rather stiff formality they are very effective for dressing flower stands.

At first sight it seems surprising that plants of this nature are not more largely grown, but is it not a fact that many beautiful easily grown plants and flowers have often to give place to those which are much more difficult and expensive to grow, but which, in many cases, are far less effective and profitable? The reason is not far to seek, for it is often because they are easily managed that they are left to themselves until what should have been a grand display becomes an eyesore, such as a Zinnia, for instance, with a small solitary flower on the top a thin nearly leafless stem, which requires a stake to prevent it falling.

We have every phase of bedding here—carpet, sub-tropical, succulent, ribbon borders, mixed beds, &c., but although all of it did well last season none was so much admired as a bed of Zinnias; indeed, although they were far less trouble and expense to prepare we had nothing to equal them neither for use or beauty. The seed was sown on a slight hotbed April 11th, the plants were pricked off into a cold frame May 12th, and planted on a large circular bed 6 inches apart (they should have been 9 inches apart) June 9th, where from the first week in July they formed a rich mass containing many shades and colours of bloom.

For the guidance of beginners I will give more detailed instruction on the cultivation of Zinnias, which may be safely applied to many beautiful annuals. Those having frames or other means of protection should make a slight hotbed with leaves or well sweetened stable manure the first week in April. The frame may be placed on the bed as soon as made, and 6 inches of compost, consisting of equal parts loam, leaf mould, and sand, laid over the bed inside the frame, and should be well pressed down. Draw drills 3 inches apart and 1 inch deep, in which the seed should be thinly sown and covered with fine light soil sifted for the purpose. If each colour be kept separate and duly labelled it will be of great advantage, as then the colours can be more artistically arranged in their permanent quarters. The light should be kept closed until the seedlings appear through the soil, when on every favourable opportunity they must have a little air until they are in rough leaf, after which on warm days take the light off, the object being to produce strong stocky plants. Through April and May, however, we often have hot sunshine with a cold wind. On no account must the light come off on such occasions, but give a little ventilation, or if very rough and cold keep the frame closed. Plenty of air will get under the glass to prevent injury, but if the sun be very hot a slight shade will be better than admitting the cold wind. Set the frame on a hard base, put in 2 inches of leaves and 9 inches of the following compost—three parts loam, one part leaf mould, one part Mushroom bed refuse, and one part sand, thoroughly mixed and pressed down firmly. Carefully prick off the seedling plants into this frame 4 inches apart. Give a good watering with warm water through a rose can. Keep them close and shaded from sunshine for a few days, then give a little air, gradually increasing it until the light can be taken off through the day, which may be done in about fourteen days after pricking off. The last week in May the light should be left off day and night, always remembering what has been said about cold winds, for they sometimes pay us their unwelcome visits far into June.

The first or second week in June, according to the weather, the plants should be transferred to their flowering quarters, which to do them justice must be a well manured deeply dug bed, but of course plants prepared as above will make a grand display in mixed beds on borders if not too much smothered by other plants. Give the plants in the frame a good watering a few hours before taking them up; they will then carry good clumps of earth, and may be transplanted without any check if carefully done. Plant them 9 inches apart, arrange the colours according to taste, and give a good water-

ing to settle the soil round their roots; the cultivator will then, in due time, be rewarded with a rich and continuous display of large flowers and a general effect such as is seldom produced by plants requiring a more troublesome and costly preparation. If 3 inches of cocoa-nut fibre or the sifted material of a spent Mushroom bed be laid over the soil it will keep the roots cool and moist, save much watering, and benefit the plants considerably.

Those not possessing means of protection may grow Zinnias by sowing the seed thinly in pots the last week in April, keeping them in a warm room with plenty of light, and when through the soil place them out in warm favourable weather, taking them in at night. Make a rough frame by nailing together four boards 18 inches wide; two of the boards may be 6 feet long for the sides and two 4 feet long for the back and front of the frame, and then proceed with soil, &c., as already advised, but in the absence of lights to cover the frame nail a few strips across the top and cover with mats, bags, or anything to keep out the cold at night. With a little care equally good plants may be grown in this way, only they will not commence flowering so early by two or three weeks. The following annuals may be grown to perfection if treated according to the above directions, only being for the most part hardier they may be planted out earlier, and the smaller growing ones closer together:—Asters, Ten-week-Stocks, Helichrysums, Salpiglossis, Petunias, Phlox Drummondii, and Portulacas, all of which will richly reward the cultivator if liberally treated.—J. H. W.

EARLY PEAS—SOWING IN TRENCHES.

EARLY Peas are a consideration where a constant supply of vegetables is required all the year round. Some gardeners sow in the open ground in November for early use, others raise them in the spring under glass, and then plant them out in the open ground when the weather becomes favourable.

Peas raised under cover are often more forward than those sown in the autumn. They can be sown in pots, boxes, or turves. We generally procure a sufficient number of turves cut for the purpose about 12 inches long, 3 inches thick, and 6 inches wide, place them grass side down in a vinery, then make holes in them about 1 inch apart with a small dibble, sow the Peas, and cover them with fine soil. Mice should always be guarded against. When the Peas have made about 1 inch of growth the turves are removed to a cooler house or pit, placed as near to the glass as possible, afterwards admitting plenty of air when the weather permits.

In due time they are planted in shallow trenches which have been made ready to receive them, a little soil being drawn to both sides of the row, and the Peas staked at once. It is a good plan to stick in plenty of small branches in order to protect them from cold winds. Early varieties should be sown. American Wonder is good, being of compact growth.

Last summer will long be remembered as a very hot and dry one. Main crop Peas with us would have been a total failure if we had not sown in deep well manured trenches, as our soil is naturally dry. We form trenches about 1 foot deep, put in the bottom a good layer of manure, with a sprinkling of soil on the surface; and after sowing the Peas cover them at least 3 inches deep with soil. In summer water is given to them without waste, the water going direct to the roots.

Our object in covering the Peas with so much soil is to prevent the sun drying the soil at the roots too soon. If after a few good waterings the rows are mulched with manure they will grow and yield a good crop, while others sown on the level ground are scorched. Stratagem Pea does not do well with me. I have tried it with plenty of manure and with a moderate quantity, in shallow trenches and deep ones, but the pods always appear stunted and prickly, somewhat like a ridge Cueumber. I do not know the cause of this. G. F. Wilson is a grand Pea for dry soils and seasons. It is also a good flavoured Pea. I intend to grow it more largely in future.—G. GARNER, *Amberwood Gardens, Hants*.

WINTRY WEATHER.

FICKLE though our climate is, the month that has just closed has perhaps exhibited more than the usual variations of temperature, the most marked feature of January being perhaps the dense fogs which prevailed for nearly a week. Very little snow fell, and on the whole there was little rain. Here and there during the month, and notably on Monday the 23rd, came a day of rare softness, when the air was besides full of sunshine. The thrush piped in early morning, and the larks in the open soared high and sang loudly. Between the 24th and the 25th strong winds swept from the north-west. The 27th was fine but cold. Towards afternoon the weather was unusually bright, when just at sundown, while a vast portion of the sky was perfectly unclouded, a great and sudden darkness

came on. It was a snowcloud sweeping swiftly out of the north. Daylight was in a moment gone, and one was almost bewildered by the unexpected obscurity. Not much snow has fallen, however, indeed the covering is all too scanty. Farmers and gardeners desire more moisture. Spring flowers are well to the surface. Here and there some Snowdrops, Winter Aeonites, and the dead time is past. Every day one expects something to appear. The gardener's eye is always watchful; the gardener's heart always hopeful.—A. M. B., *Mid Lincoln.*

CYPRIPEDIUM SAUNDERSIANUM.

THE *Cyripedium* which was noted last week as having been purchased by Mr. W. Bull for £300 was inadvertently given as *C. Sanderianum*, but it should have been *C. Saundersianum*, a quite distinct and very remarkable hybrid. It is, however, so scarce and so little known that it deserves a special descriptive and historical note. I have been favoured with most of the particulars by Mr. R. H. Measures, Mr. F. G. Tautz, and Mr. W. Bull, who are, I understand, the only possessors of this *Cyripedium* in England.

It appears to have been raised about twenty years ago by Mr. Wm. Marshall, now of Auchinraith, Bexley, and recently elected on the Fruit Committee of the Royal Horticultural Society, but he was some years ago a member and Chairman of the Floral Committee. Nothing certain seems to be known respecting its parentage, but it is thought that *C. Schlimi* or *C. Sedeni* was one of its parents. In the leaf it resembles *C. Sedeni*, but it is not so free in growth or flowering as that, for though it has been cultivated so long flowers have been seldom produced. According to the descriptions given by those who have seen the flowers it must be one of the most handsome yet obtained. The general colour is said to be a fine "mauve purple," the dorsal sepals white with green and purple stripes, the petals broad spotted with purple on a white ground.

Mr. Marshall's plant was purchased by Mr. W. Bull, and subsequently sold to Mr. W. Lee, of Leatherhead in the autumn of 1883 for £50 on the condition that when it could be divided a side break should be returned to him. A year or so afterwards this was done, a second break having then been produced, which was obtained by Mr. Bull, the original break being purchased for £100. One of these went to enrich the valuable collection of *Cyripediums* in the possession of Mr. F. G. Tautz, Studley House, Hammersmith; the other was secured by a firm in Ghent. The latter was shortly afterwards sold to M. Jules Hye of that city, who is well known as an admirer of the *Cyripediums*. He divided it, and one of the plants was obtained by Mr. R. H. Measures, The Woodlands, Streatham, in exchange for some of his choice plants. The original plant at Downside flowered in 1886, and was then described under the name *C. Saundersianum* in honour of the late Mr. Wilson Saunders. This is the plant transferred to Chelsea, and now divided into six pieces.

Mr. R. H. Measures, has kindly favoured me with the following note:—"Referring to our conversation at Protheroe's, *re* *Cyripedium Saundersianum*, I find it was actually raised by Mr. Marshall of Enfield, Middlesex. Its parents are *Schlimi* and *caudatum*. From the habit of the plant I should think *Schlimi* is the seed parent. The plant is what we call a difficult one to grow. I remember a conversation I had with Mr. Lee, and his telling me that it had bothered him considerably, until at last, finding an insect somewhat resembling a small beetle, he attributed to this the apparent blemishes in the leaves, thinking the insect fed on them. This could not have been so, as the plant afterwards (and at other places) showed the same defect of foliage. When Mr. Marshall's collection was sold the seedling went into the possession of the Royal Horticultural Society, and was at South Kensington some time between 1866 and 1869. When the Royal Horticultural Society's collection was sold the plant was lost sight of by me, but I believe it passed into the hands of Mr. Saunders, and was by him named '*Saundersianum*' (but of the naming I am not sure). From Mr. Saunders I believe it went into Mr. Bull's nursery. There appears to be some confusion as to its being sold to Mr. Lee. I had it from Mr. Bull himself that he presented it to Mr. Lee, owing to Mr. Lee being so greatly struck by its beauty, but from Mr. Lee I understood he bought it with other plants. At any rate it passed into Mr. Lee's possession and there flowered, a flower being sent

to Professor Reichenbach, who described and possibly named the plant. At the commencement of last year I believe Mr. Bull bought a portion of the original plant back from Mr. Lee, and sold one part to Mr. Massarel, the well-known Ghent orchidist, who resold it at considerable profit to M. Jules Hye Leysen, who divided the plant, keeping one portion himself, the other portion coming, in exchange for another rare *Cyripedium*, to me. One other portion of the original plant went to Mr. Tautz's well-known collection, the price paid indicating the estimation in which Mr. Bull and Mr. Tautz held it."

It will be seen that there are a few minor differences in the accounts obtained, but they are worth placing on record in reference to such a valuable plant.—L. CASTLE.

ORCHIDS AT FOREST HILL.

THE following Orchids are in flower just now at Messrs. John Laing & Sons' Nurseries, Forest Hill, London, S.E.—viz., *Calanthe Veitchi*, *Cattleya exoniensis*, *C. Trianae*, and *C. Trianae-delicata*, *Cyripedium Boxalli*, *C. Dominicanum*, and *C. insigne*, *Dendrobium Ainsworthi* (fine), *D. infundibulum*, *D. fimbriatum*, *D. heterocarpum*, *D. nobile*, *D. eœrulescens*, *D. pendulum*, *D. Pierardi*, *Dendrochilum glumaceum*, *Lycaste Skinneri*, *Masdevallia ignea* (Patersoni), *M. polysticta*, *M. tovarensis*, *Odontoglossum Alexandræ constrictum*, *O. grande*, *O. Lindleyanum*, *O. Rossi majus*, *Oncidium cucullatum*, *O. Forbesi*, *O. ornithorhynchum*, and *Pilumna fragrans*.

ORCHIDS AT STUDLEY HOUSE, HAMMERSMITH.

THIS collection has been previously noted in this Journal, and is especially remarkable for the large numbers of *Cyripediums*—some 200 varieties—it contains with many rare and beautiful forms in excellent condition. On a recent visit I found the following, amongst others, in flower:—*C. nitens*, a cross between *C. villosum* and *C. insigne* Maulei; the dorsal sepal is in the way of Maulei, but larger; the petals wavy, light brown, very glossy. *C. Hartwegi*, beautiful rose colour, in the way of *C. Roezli*. *C. Argus Moensi*, very fine, being heavily spotted with dark purple spots, the dorsal sepal white, with green lines and spots, not so large as on the petals. *C. Ashburtoniæ* var. *calospilum* is the best of the *Ashburtoniæ* group; the dorsal sepal large, white, tinged with green and veined with purple; the lip pale purple tinged with yellow and slightly blotched with purple. *C. Petri*, beautiful, figured recently. *C. Marshallianum*, said to be the only plant in the country, the result of a cross between *C. concolor* and *C. venustum*, the parentage being very noticeable; a distinct variety. *C. insigne* var. *sylhetense*, shorter in the pouch, and more thickly and largely spotted than in the type. *C. Tautzianum*, a charming and distinct novelty, described in the Show at South Kensington on the 19th inst., when it received a first-class certificate, and was described in this Journal. The handsome *C. venustum* was represented by some well grown and vigorously flowered examples. Amongst miscellaneous Orchids in flower we noted the old but still good *Ansellia africana*. It is seldom seen so well grown as we saw it here, and is worth, therefore, putting on record. *Zygopetalum Mackayi*, another old favourite; *Odontoglossum Inseayi leopardinum*, choice; *Lycaste lanipes*, *Dendrobium bigibbum*, &c. The condition of all plants is most creditable to the gardener, Mr. C. Cowley.—B.

ORCHIDS AT TILGATE, CRAWLEY.

AMONG the other gay and choice occupants of the stoves and greenhouses at the above beautiful estate of J. H. Nix, Esq., the Orchids are not the least conspicuous. The select collection of *Cattleyas*, *Lælias*, *Dendrobiums*, *Cyripediums*, *Calanthes*, &c., look full of vigour and furnished with stout growths or flowers in various stages; more especially is this notable in the *Odontoglossum* house. There are about one hundred plants, chiefly of *O. Alexandræ*, *O. Pescatorei*, and *O. triumphans*, with stout bronzy green pseudobulbs and healthy green foliage that are quite in character with the strong fleshy roots and stiff flower spikes bearing from nine to eighteen flowers on a spike. In the collection is a plant of the very beautiful *Pilumna fragrans*, valuable at this time of the year for its highly perfumed and pure white flowers, the throat only having a slight circle of orange, which adds to its beauty. For buttonholes or sprays it would be well adapted, being of a useful size and pure colour, with a sufficient length of flower stem. All the plants are potted in a mixture of chopped sphagnum, peat fibre, and charcoal, the pots being previously half-filled with broken clean crocks. Under the open latticed stages on which the plants are stood are cement tanks the whole length and width of the stage, which forms a receptacle for the rain water from the roofs and is used for watering the plants. The cement path is also constructed to hold about 2 inches of water, and a latticed grating is laid over it to walk on. The evaporation from these tanks forms the element

that these plants enjoy during their growing season, but there are waste plugs constructed so that the water can be let out when the house is required to be drier in the winter season. The temperature is never allowed to go below 48° or 50° in the winter season. Should a plant be making a new growth while it has a flower spike, the latter is removed to throw all the energies of the plant into the new growth. The marvellous development of these plants that were only small imported pieces three years ago is proof that the construction of the house and the treatment they receive is another instance of the thoughtful work and intelligent skill displayed by Mr. W. Jordan, the gardener, in everything he takes in hand.—C. O.

PLANTS AND FLOWERS IN THE HOUSE.

(Continued from page 66.)

AMARYLLISES cut with the stem the full length are grand for large glasses. So also we occasionally cut trusses of Eucharis and Imantophyllum with long stems, and all these should stand clear of every other flower or leaf. Small vessels of glass or metal are very pretty set about tables. It is the worst taste to crowd these; a few sprays of Lily of the Valley with a leaf or two, a good specimen bloom of a Chrysanthemum, one or more good Roses, or a spray or two of any Orchid, with an accompanying spray of Maidenhair Fern or Asparagus is all that is wanted. When flat dishes are used we like to fill these with whatever is employed. Almost any kind of flower is admissible so long as it is not tall. In arranging them we use nothing but water to keep the flowers fresh, but fill in with some green material, such as Box, sprays of Myrtle, scented Pelargoniums, &c., Roses, Chrysanthemums, Eucharis, Orchids, Tulips, Pelargoniums, Ivy-leaf especially, Chinese Primulas, common Primulas, Polyanthus, Auriculas, Camellias, Snowdrops, Crocuses, &c., being all admissible. If very choice flowers are used a good spray or two of Maidenhair Fern, put in after the flowers have been arranged, and standing boldly out from among them, gives a good finish. Certain Grasses, bits of Bamboo, the leafage of the flowers employed, &c., may all be used, but never in excess.

In small rooms, especially those with low ceilings, small plants and the smaller flower glasses should be used. In cases where groups of plants are wanted one can hardly have too many Maidenhair Ferns. *Isolepis*, *Ficus repens*, and *Panicum variegatum*, *Bambusa Fortunei variegata*, small plants of *Asparagus tenuissimus*, and *A. plumosus*, and *Cyperus alternifolius* are also useful. If flowering plants are scarce these can be used as a full groundwork, and just a few plants in flower dotted among them. Indeed in any case it is well to avoid making groups heavy with many large plants.

But when we have all arrangements of plants completed there are numerous little points to be observed in order to keep them in health and make flowers stand as long as possible, and in providing a continuous supply. If plants were merely taken into a room for a day or two it would not matter so much, but when they are kept there for many weeks then it is necessary to pay particular attention to see they do not suffer. If a room is kept only moderately warm there is little fear of harm, but when they are kept hot the plants in dark position suffer very quickly. Of course often changing is perforce the rule in such cases. All plants taken into rooms should be in good health (that is a first principle), clean, no insects present, and the roots healthy and active. Water should be given before it is placed, and afterwards keep the soil moist and never on any account allowed to become dry. In order to use as little water as possible, and make sure that it quickly goes through the soil, we have for the past year or two used warm water for all house plants. An occasional syringing with warm water and soap or sponging the leaves with the same mixture will keep the plants free from dust, make them look fresher, and be better for their health.

Flowering plants should be selected which are not quite as far in flower as they will be. This applies to all kinds, Dutch bulbs, Lily of the Valley, &c., as well as others. When it happens that no plant will be tolerated in a room which is declining ever so little in beauty, the force of so selecting fresh young specimens will be more readily understood. With regard to cut flowers. It is of the utmost importance, in order to keep up a continuous supply of good flowers, that the proper stage to cut them should be understood and acted on. If, for instance, a number of Pelargoniums only half developed in the truss were cut, and others were on the plants fully developed, the result would be that the latter would be past before using, and those cut too quickly would be wanted later on, when they would be quite as good. But further, supposing the Pelargoniums cut were the only ones to be had, there might be some other flower developed to its utmost extent, and which required cutting, and thus the same effect would ensue. Of course there is the alternative of drafting them into cooler drier

quarters, but where an establishment is in full swing, and the most wanted out of everything, it does not pay to stop a growing plant when it happens that the more growth it makes the more it flowers. Placing flowers in water during winter is not a good way to keep them—that is to say, if they are expected to stand any time in vases. It is much better to put them into a perfectly cool room, either in a nearly close tin box, or if not to be kept long they may lie open. Of course every flower will not keep in this way, but very many do. When used, the end of the stem is cut off and the flower treated to a little warm water, but in all cases it is best to cut from the plant as wanted. For keeping flowers fresh and good nothing excels pure water in the vessel in which they are arranged. The latter must be kept perfectly clean, not only on account of its appearance, but also on account of the flowers. Deep stemmed glasses are easily cleaned by means of brushes on flexible wire stems, the upper portions being rubbed with a sponge or a cloth. The water used should not be too hot, lest the glass should crack. When well cleansed rinse in cold water. Dry the outside with a proper cloth, fill with sufficient lukewarm water, and then arrange the flowers. The next day the glass will require filling with water. Flowers should not stand longer than a week without re-arranging. The stems of good flowers should be washed in warm water, a portion cut off each, the glass again cleaned, and fresh water supplied.—B.

MUSHROOM HOUSE WITH A GLASS ROOF.

MUSHROOM houses in many instances are not what they ought to be in private gardens, and the gardener is blamed for any deficiency in the supply of this delicious esculent, therefore any hints that may be of use are worth recording. The roof of our Mushroom house being in a bad state, we thought of renewing it, and the question arose as to how it should be done. Having carefully read the practical treatise on the cultivation of Mushrooms by Mr. Wright, we thought a departure might be made with safety. Taking as our guide what Mr. Wright in the above treatise calls the easiest of all systems of culture, pages 75 and 76, in a Melon or Cucumber frame we put on a glass roof, using quarter-inch rolled plate glass in large sheets 4 feet 6 inches by 1 foot 3 inches, with a 6-inch lap, two of the sheets being used as ventilators, the framework being galvanised T iron. The house is of the usual description, a lean-to behind a north wall with the beds in tiers of slate slabs, supported by cast iron and heated by a flow and return pipe placed in or under the cast-iron pathway.

On the 17th September we spawned our first bed; this came into bearing in six weeks. On October 17th a second bed was spawned, and this came into bearing in seven weeks. On November 16th we spawned a third bed, and this also came into bearing in seven weeks. The quality was about what is usually found in private gardens, as you will see by the seven I enclose to show you the average quality, as we gather them every morning. I may mention the beds are 20 feet long by 3 feet wide and 1 foot deep at the front, sloping to 1 foot 6 inches at the back, with a slight covering of stable litter on each, which answers two purposes, keeping both moisture and temperature at a regular point.

I will now tell you why we decided on using glass. We only require a supply of Mushrooms six months in the year, the house being empty and useless the other part—at least four months; that is what we will call under the dark system. Now, I think we can make the house useful during these four months, besides being better adapted for forcing such things as Rhubarb. Asparagus and Seakale we find succeed in the same house in a part specially darkened. All things considered, we think we have made a decided improvement, and we shall be very pleased if any of your readers are able to pick what Mr. Eggnlden calls a "wrinkle" out of the above narration of facts.—A. HAGGART.

[The Mushrooms received were very fine indeed.]

SIZE VERSUS QUALITY.

WHILE this question is under consideration it would be a step in the right direction if other authorities would follow the example of your able correspondent, Mr. Thomson, and record their opinions thereon, in order that a right conclusion may be arrived at as to what should be a standard of quality. If this could be accomplished it would be a boon to many. I think the most glaring instances of size being preferred to quality is to be found at the Scotch shows. For example, at the last Edinburgh International the first prize in the big Grape class was awarded to huge unripe exhibits, while the third prize in the same class was awarded to as neat a collection as one could wish for, every bunch of equal size, varieties of good quality, perfectly ripe, and without a blemish. In this case I knew neither judge nor exhibitors, yet I felt more dissatisfied with this

colours and habit. A dwarf race has now been formed with large flowers having exceptionally broad petals, and the varieties of this section possess considerable decorative value. Some flowers of these were shown at South Kensington by Messrs. H. Cannell & Sons, Swanley, last year, and they call attention to some of the varieties in the cut (fig. 14) kindly lent us by that firm. The colours vary from deep crimson and scarlet to orange and yellow, either self-coloured or spotted and streaked with other tints, giving them in some cases a very unique ap-

pearance. The safe packing of all soft fruits; and last, but not least, because the "sweet" or "fusty" smell which is always present is most objectionable. Mr. Pettigrew says some gardeners of considerable experience use dry moss or paper shavings. It certainly would be interesting to know why Mr. Pettigrew prefers hay, which is all the more to be regretted, seeing that he has spared no pains in describing the entire arrangement of the box referred to that has always been such a success. But in case the box should be turned upside down in its transit, "which is by no means an unheard-of occurrence," I am unable to see how Grapes could escape being crushed by the weight of Pines, Melons, Cucumbers, &c., being

FIG. 14.—NEW CANNAS.

pearance. The foliage also differs, bronze, purplish, dark and light green tints prevailing. A long list of new varieties is given in Messrs. Cannell's "Floral Guide."

PACKING FRUIT.

THIS is an operation most gardeners have to perform, and success often is as varied in packing fruit as in cultivating it. The hay process recommended by Mr. Pettigrew, page 8, is one I have known the last forty years, and have long since discontinued it, for two reasons—first, because it is of a flexible nature and not elastic, which is so essential in

suddenly placed on them. Evidently Mr. Pettigrew's boxes have always travelled right side up, which is most creditable to the officials on that particular route.

Again, referring to Mr. Pettigrew's mode of Grape packing, I fail to see how the bloom is preserved. The large bunches we find are first placed in the four corners of the box and then wedged in with smaller bunches, covering them with paper, and on the paper a layer of hay; yet, strange to say, Mr. Pettigrew's Grapes always look as fresh after the long journey as if they had been newly cut from the Vines. I must plead ignorance as an excuse for my inability to catch the secret of this success, as I have yet to be convinced that "anything" touching the

bloom of Grapes can preserve it. Mr. Pettigrew's partition box and materials, hay excepted, for Peach packing is excellent, but his mode of rolling the Peaches in the material, and then dropping them into these compartments, is quite novel to—R. W.

EVENTS OF THE WEEK.—To-night (Thursday), at 8 P.M., the Linnean Society will hold a meeting at Burlington House, Piccadilly, at which it is announced that Harry J. Veitch, Esq., will contribute a paper on "The Fertilisation of *Cattleya labiata* var. *Mossiae*." Mr. H. F. Blanford will also have a paper on "The Ferns of Simla." The Royal Society meets on the same day at 4.30 P.M., and the Society of Arts on Wednesday, the 8th inst. The usual Orchid sales will be held in the Cheapside Rooms on Friday and Tuesday, and at Covent Garden on Thursday and Wednesday.

— REFERRING TO POINSETTIAS PLANTED OUT, "A. H." says:—"I am very pleased to notice that at least one other person has a Poinsettia planted out. Ours has only been planted three years. The first year we cut a head that measured 22 inches across, composed of eighty bracts."

— THE WEATHER IN THE NORTH.—"B. D." writes:—"The weather was very mild up to the afternoon of the 26th ult., when frost set in, 3°, 8°, 12°, 6° of frost being recorded on the last four nights. During the night of the 24th the thermometer in the open stood at 47½°. The eclipse of the moon was observed throughout in a cloudless sky. A snowstorm was pretty general over Scotland on the same day, drifts of 6 feet and upwards being reported from some of the N.E. counties. On the 30th ult. in South Perthshire the ground was thickly covered with snow, and frost was somewhat keen." In the south of England the weather has been variable, several sharp frosts alternating with rain, sleet, and very little snow.

— WE learn with a deep regret, which will be shared by many persons in this country, that PROFESSOR ASA GRAY, a botanist of world-wide fame, died on January 31st, at Boston, Massachusetts. This gentleman was born at Paris, in the State of New York, on November 18th, 1810, and was educated for the medical profession, but applied himself closely to botanical studies, to which he has devoted his whole attention since 1831. In 1864 his herbarium amounted to 200,000 specimens, which with a library of 2200 botanical works he presented to the Harvard University. He was for ten years President of the American Academy of Arts and Sciences, and was subsequently elected to the same position in connection with the American Association for the Advancement of Science. He was also correspondent and honorary member of numerous scientific societies in Europe. His botanical works include several admirable popular treatises that are distinguished by a singular lucidity of expression, and his "Flora of North America" is a most valuable work of reference.

— WE also regret to announce the death of Dr. J. T. IRVINE BOSWELL, which took place on the same date—namely, the 31st ult.—at Balmuto, Fifeshire. Dr. Boswell was for many years Curator for the London Botanical Society, and lecturer at the Charing Cross and Middlesex Schools of Medicine; but his chief fame as a botanist was derived from the fact that he re-wrote "Sowerby's English Botany," a most extensive work in twenty volumes, and which occupied his attention for twenty years.

— WE learn that Messrs. Sutton & Sons' useful work, the "CULTURE OF VEGETABLES AND FLOWERS FROM SEEDS AND ROOTS," has been awarded the first order of merit and highest prize medal as a horticultural book at the Adelaide International Exhibition, making seven similar awards to the exhibits of the firm at Adelaide.

— MESSRS. J. VEITCH & SONS, Kings Road, Chelsea, have received the following letter from Mr. H. E. Kennedy, The Gardens, Downton Hall, Ludlow, Salop, which they forwarded to us as requested:—"I have this day sent two flowers and foliage of a plant of *Cineraria* growing in

an 8-inch pot, the seed being supplied by you last year. The foliage measures 17 inches in diameter; one flower being 2¼ inches across, the other 2½ inches. Is it a common occurrence to see them so large? It is not only one plant, for I have three dozen in flower. I should be glad if you would forward them to the *Journal of Horticulture* office if you think it is worth while doing so. All the people that have been here, including gardeners, say they never saw such foliage and flowers on *Cinerarias* before. I may also state that the plants are from 2 feet to 2 feet 9 inches across, and are grown in 8-inch pots." The flowers sent were of rich colour with very thick florets, and the leaf of wonderful size.

— THE LIVERPOOL HORTICULTURAL ASSOCIATION held their ninth annual meeting on Saturday evening last. Towards the close of the proceedings a lively discussion arose between Messrs. Bardney and Cox. It appears that the Society's receipts for the last year or two have slightly fallen off, while the amount in schedule of prizes has been increasing. To remedy this Mr. Bardney very prudently spoke in favour of a more economic schedule. Mr. Cox in a very energetic manner defended and upheld the Committee in providing so liberal a prize list, and was sure that the course taken was a wise one for the welfare of the Society. The question, no doubt, will be brought forward at the next meeting.

— No. 13 of the KEW BULLETIN for January was recently issued, and contains a continuation of a subject introduced in the November number last year—namely, "Colonial Fruit." The Colonies under consideration are Victoria, South Australia, Western Australia, Tasmania, New Zealand, Cape Colony, and Mauritius. Lists of fruits grown in these countries, and in some cases the local prices, are given. Thus, in the case of South Australia a list of twenty-seven fruits is supplied, with the times when they are in season, the relative quantities and prices. For example, Grapes are said to be in season from January to May in unlimited quantities, at 7s. 6d. to 10s. per cwt.; Apples, January to October, in larger quantities, 2s. 6d. to 5s. per bushel; Apricots, December to January, unlimited quantities, 16s. to 24s. per cwt.; Pears, December to July, 3s. to 6s. per bushel; and Peaches, December to February, 16s. to 24s. per cwt.

— MR. JOHN F. PASCOE furnishes the above particulars, and he further mentions in reference to the export of fruit to this country from Australia that "A bushel of Apples costing in Adelaide 4s., sent to England in the ordinary way would have to realise nearly 9s. to pay the shipper net cost. To give an example. Per Orient steamer 'John Elder,' I sent last year to the Colonial and Indian Exhibition fifty cases of fruit, which realised £55 3s., a good price, and ought to have shown good profit; but the expenses were—Commission, &c., on sale by commissioners, £33 15s. 4d.; freight and incidental expenses, £7 14s.—total, £41 9s. 4d., or, deducting the cases £2 10s., a balance of £11 3s. 8d. from the sale total—about 4s. 6d. per bushel. Considering this lot consisted of the choicest samples obtainable it certainly gives very little encouragement." There is something extraordinary about the commission charged in this case, and over 60 per cent. is what few salesmen would have the audacity to charge. Those who remember the fruit market at the exhibition mentioned will also remember that the charges were very high.

— KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.—We are informed that at the recent meeting of the above Society it was unanimously resolved to offer another challenge cup, value 25 guineas, with the usual money prizes.

— MR. W. DYER, Park House Gardens, Edgbaston, Birmingham, the well-known specimen Chrysanthemum grower, desires to state that he has found Wood & Sons' liquid manure powder of service to his plants.

— A LIST of seeds for the year 1888 has been issued from the CAMBRIDGE BOTANIC GARDEN containing the names of those in stock for exchange with other botanic gardens, as well as the names of plants of which seed is required. The list fills fifteen closely printed pages, and the plants are arranged under their natural orders.

— WRITING in reference to OUR BENEVOLENT INSTITUTIONS, "D. S." makes the following suggestion:—"I should like to suggest to the committees of every horticultural society in the kingdom, that special effort should be made by each society to help the funds of the Gardeners' Orphan and the Gardeners' Benevolent Societies. Even an

annual subscription from each would do a world of good, but many societies have goodly sums of money in hand, and could well spare £5 or £10 to those most deserving charities. Individual members also can do the orphan fund especially a great service by collecting small sums and transmitting them to the Secretary. Mr. Hughes, the Secretary of the Birmingham Chrysanthemum Society and the Birmingham Gardeners' Association, has a collecting box in which donations from a penny upwards are welcomed, and he has already remitted to the Secretary a good sum of money collected in this way. In these times of depression generally, and in gardening especially, the calls upon these two charities will grow rapidly, and it is therefore most desirable that increased funds should be possessed by the executive of these Societies, and I think that if a special appeal was made to each horticultural society in the kingdom, stating what each was doing, so that the matter may be brought before each Committee, that good results would follow."

— MR. RICHARD GILBERT is a very clever man, and almost merits a free advertisement for the following trite observation. He writes—"My advertisement last week, and Mr. D. Thomson's leader, will hand down the *Journal of Horticulture* to posterity?" How very fortunate for the *Journal*, and, shall we add, Mr. Gilbert?

— MR. OBADIAH KING, Secretary of THE MAIDENHEAD HORTICULTURAL SOCIETY, informs us that the annual Show is fixed for Thursday, August 16th, 1888.

— A WELL-KNOWN north of England naturalist, MR. J. D. SIDALL, OF CHESTER, has recently been lecturing in Wakefield, and has given much satisfaction to the numerous local gardeners and naturalists who attended his fluent and interesting extempore discourses. Mr. Siddall has made a special study of the Foraminifera of the River Dee, and we remember a year or two since seeing a microscopical slide he had prepared containing 150 distinct species in the space of about a square inch. A lecture was also devoted to the Canadian Water Weed, the *Anacharis*, which was discussed very fully. He mentioned as an example of its rapid increase that 3000 tons were dragged out of a loch near Glasgow, which had been cleared a year previously. Mr. Siddall stated that the chief reasons why the plant increases so rapidly here while it advances but slowly in America, are that the currents of the rivers are much slower here than there, and also contain much more refuse or pollution. He thought it would gradually die away and disappear.

— GARDENING APPOINTMENT.—We are pleased to be able to announce that Mr. C. Orchard, late of Coombe Warren, Kingston-on-Thames, has been appointed bailiff of the estate of The Brading Harbour Company, St. Helens, Isle of Wight. His address will be Bay View, Brading, Isle of Wight.

THE HOLLYHOCK.

THE Hollyhock has recently been written about in the *Journal*, its return to the front rank of florists' flowers being prophesied, and I am quite prepared to predict the same thing. In some districts really good Hollyhocks are shown annually, but unfortunately not from the gardens of many cultivators. It would have been a great pity indeed if those majestic flowers had been allowed to die out of cultivation, for to my mind they are the most attractive and beautiful the autumn brings us. Thanks, however, to the energy and skill of some horticulturists who have taken them in hand, they are saved from the dying out process. We happen to have one of these men in our district—namely, Mr. G. Finlay of East Layton Hall, who has certainly the best Hollyhocks I have ever seen. He has been at work with them about eight years, and has wrought wonders in obtaining new and excellent varieties. I had the pleasure of seeing his plants in bloom last year, and what a marvellous sight they were! The colours ranged from a white to the deepest of crimsons and purples, some of the flowers measuring 8 inches in diameter without the guard petals. Mr. Finlay has a few excellent seedlings, and has a good stock of three of his best, which I believe he intends sending out next autumn—namely, *Pride of Layton*, a beautiful deep salmon coloured variety, of splendid form and robust constitution; *John Finlay*, a very large and especially deep flower, of a dark red colour, devoid of salmon tint (which is unusual in Hollyhocks), this is a variety of great merit, also of vigorous constitution. The third is a pink of the most perfect shape and lively colour. It is a rosy pink, lighter towards the base of the flower. There are a few more excellent seedlings, but as yet not a large stock of individual sorts. I should say Mr. Finlay

has twelve seedlings in his possession that would surpass any other twelve Hollyhocks in cultivation. The *Layton Hollyhocks* are famous wherever they have been shown, which is not a few places, as Mr. Finlay has won about fifty first prizes and only one or two seconds. The much-dreaded Hollyhock disease once found its way into the *Layton* collection and made great ravages one summer, but he set to work and completely overcame it in a very short time. The process, too, is very simple, yet effective, and I daresay Mr. Finlay would describe it if desired to do so.—F. M.

[We shall be glad to publish a note from Mr. Finlay on the subject.]

NATIONAL CHRYSANTHEMUM SOCIETY.

JANUARY 31ST.

THE annual general meeting of the above Society was held at "Anderton's Hotel," Fleet Street, on Tuesday last, when there was a good attendance of members. The Vice-President, R. Ballantine, Esq., took the chair shortly after 7 P.M., Mr. E. Sanderson being unavoidably absent, the Treasurer, J. R. Starling, Esq., and the Hon. Secretary, Mr. W. Holmes, with others, being present. Mr. Holmes read the report for the past year, of which the leading points were as follows:—"The result of the operations of the National Chrysanthemum Society for the past twelve months may be truthfully recorded as that of an unqualified success. Good and useful work has been accomplished in each of its departments, while its finances have been equal to the heavy strain imposed thereon. The September Show was again considered both good and interesting, although the early varieties of Chrysanthemums do not as yet seem to have taken a very firm hold of popular favour. Dahlias and Gladioli, however, formed as before a very attractive display. Of the November fête too much can scarcely be said. It was in every respect the largest and most attractive exhibition ever yet held under the auspices of the Society. The buildings were well filled during each day, while in the evening the crowds were enormous, no less than 10,000 persons (exclusive of staff entranees) passed through the turnstiles on the first day of the Show. The January Show was vastly superior to that of any preceding year. Chrysanthemums were largely staged, although as yet the object of the original promoters of the midwinter Show has not been largely fulfilled by the introduction of many naturally late-flowering Chrysanthemums. The Floral Committee steadily carried on its work during the season, and its decisions in every instance carefully debated.

"The business meetings of the Society will for the future be held at 'Anderton's Hotel,' Fleet Street, the Society having outgrown the accommodation of its old quarters, and Fleet Street being considered to be more central, and consequently more convenient, for its members generally. The Committee desire to tender their very hearty thanks to all donors of special prizes, and especially to the Trustees of the Veitch's Memorial Fund for the liberal grant of medals and cash during the past season."

The balance-sheet was next read, from which it appears that about £700 have been received and expended during the past year, leaving a small favourable balance besides the reserve fund, which Mr. Starling stated now amounts to £78. Subscriptions were received from 432 members, but the number has been considerably increased at the last two or three meetings. Both the report and the balance-sheet were unanimously adopted, and votes of thanks were accorded to the Auditors.

The Hon. Secretary announced that Lady Lytton, The British Embassy, Paris, had signified her willingness to become a patroness of the Society, a number of Fellows and members were elected, and the Wimbledon, Tooting, and Pembroke Societies were admitted into affiliation. The next business was the election of officers, the following being unanimously returned:—President, E. Sanderson; Vice-President, R. Ballantine; Treasurer, J. R. Starling; Hon. Secretary, W. Holmes; and Auditors, Messrs. Crane and Drain, jun. In accordance with the rule passed at a previous meeting one-third of the General Committee retire annually, but are eligible for re-election. The following were elected to fill the vacancies thus caused, and who retire in 1891—namely, Messrs. W. Blake, F. Bingham, Lewis Castle, W. Davey, F. J. Long, J. Newton, R. Nichols, R. Payne, R. E. Reeve, J. Udale, J. Williams, and H. C. Wildman. It was proposed and adopted that the Floral Committee should be elected at the first General Committee meeting, that it shall consist of fifteen members, and that one-third of these shall retire annually. Liberal special prizes from Messrs. Sutton & Sons, Brading, Wood & Sons, Wood Green, and H. Cannell & Sons, Swanley, were then announced to be offered at the November Show.

Several projects for the present season next came under consideration, and the first was a proposal that the Society should hold a provincial show in the north of England, concerning which Mr. Holmes read some correspondence that had passed between himself, Mr. Morton of Darlington, and Mr. E. Mawley, Hon. Secretary of the National Rose Society. The general feeling of the members present was in favour of the idea if it could be carried out without incurring any material financial risk, and it was ultimately resolved to refer the matter to a Sub-Committee, comprising Messrs. Bevan, Castle, Gordon, Dean, and Rundell, for full consideration and to prepare a report to be submitted to the General Committee. Until this matter is settled it was felt that the dates of the Society's shows could not be all fixed, but it was decided that the November Show should be held on the 7th and 8th of that month.

With reference to the proposed revision and extension of the catalogue there was a short discussion, some members thinking a select list was required, and others, who appeared to be in the majority, thought it should be rendered as complete as possible. This also was finally referred to a sub-committee, consisting of Messrs. Castle, Gordon, Wynne, and Harman Payne, who will prepare a scheme for the consideration of the General Committee.

It was decided that the representatives of affiliated societies should be entitled to only one vote whether they represent one or more societies, and Mr. Rundell earnestly pressed for a definition of the term amateur that would admit a number of growers who cannot compete with any chance of success under the present arrangements. He thought an amateur might be defined as one who "does not employ skilled labour, and who does not sell plants, cuttings, or flowers."

ROSES FOR A COLD WALL.

I WAS very pleased to see that the Journal has devoted a special column to Rose-growing, and I should be obliged if some of our Rose-growing friends would give me a list of the twelve best Roses for planting on a wall facing east and north-east, somewhat exposed. I wish to have this wall covered with Roses soon as possible. Would your readers suggest any evergreen creepers as nurses to the Roses? I enclose a list of eleven, and shall be glad to see opinions on them:—Bessie Johnson, Charles Lefebvre, Madame Berard, Belle Lyonnaise, Countess of Oxford, Aimé Vibert, Céline Forestier, Victor Verdier, Dundee Rambler, Gloire de Dijou, and Bouquet d'Or.—A. J. BROWN.

MEMORIAL TO THE LATE M. FRANCOIS LACHARME.

M. LEVÊQUE, on behalf of the Committee in Paris and Lyons organised for the purpose of raising a memorial at the grave of this noted Rose grower, has asked me to distribute some circulars, inviting the co-operation of English Rose growers. Naming the request to some members of the National Rose Society it was suggested that it would be a graceful act if the contributions of the English growers took the form of a medallion with an English inscription on the tomb or monument, and on conveying this suggestion to M. Levêque, he writes that they would gladly accept such a contribution, and would give the English memorial a place of honour. Either Mr. D'Ombrain or I would be happy to receive any contributions to this fund, which I need hardly recommend, so well was Lacharme's name known to all rosarians. Subscriptions of 5s. to 10s. would suffice for all that is necessary.—GEORGE PAUL.

ROSES UNDER GLASS.

If the unripe ends of shoots have not been removed from Maréchal Niel, Rêve d'Or, William Allan Richardson, Reine Marie Henriette, and others of similar habit of growth that are trained under the roof of greenhouses and other cool structures, it should be done at once. Growths that are too weak to flower may also be removed, for they only have a tendency to crowd the plants and no advantage is gained. Train and regulate the shoots, and, if aphides exist upon them fumigate the structure with tobacco until they are destroyed. If completely eradicated at this period they will not give much trouble when the plants come into flower. Red spider is also very likely to exist upon some of the old foliage, and if this is the case it must be destroyed, or it will prove troublesome the whole of the season. Annual attacks of this insect are often due to their existence on the plants at the commencement of the season being frequently overlooked, and with increased heat their injurious effects are quickly visible. Wash the plants thoroughly with a solution of softsoap one ounce to each gallon of warm water, in which has been stirred a 2-inch potful of sulphur. This can remain upon the plants, and will do them no harm until the season for syringing freely arrives.—B. L.

BUDDING ROSES ON THE SEEDLING BRIAR.

I INTEND budding a few hundred Roses on the seedling Briar as recommended by Mr. Duncan Gilmour in his little work ("Rose-Growing"). The seed was sown the early part of January in the ordinary way, and the box was placed in a good position in the Rose house where the seed will germinate very gradually. The varieties which I wish to increase are chiefly Teas, and will be dwarfs for pot work; and as I am not quite certain which is the best plan to adopt in getting the Briars in the best state possible by the time the operation will have to be performed, I should be glad if Mr. Gilmour would be kind enough to state in the column you devote to Roses whether the Briars produced from this seed if brought on under favourable conditions will be ready for budding by July next, and the best plan in managing the Briars, whether to grow and bud them in pots or plant them out in well prepared ground, and if planting the Briars out should be advised the most suitable time to have the work done.—R.

PEAS AND POTATOES.

Now so many are busy preparing their seed lists perhaps a few words in addition to the contributions of Messrs. Iggulden, Muir, and Murphy in the last two issues of our Journal may be acceptable. Regarding Mr. Muir's selection of six Peas, I cannot find fault with Lightning and Prodigy, for I have grown neither, but I certainly think Duke of Albany is preferable to Telegraph. I have grown both for several years, and have now discarded Telegraph as being not so good a bearer, not so good quality, and also not so good looking as Duke of Albany, which I have found succeed both in heavy and light soils. Another thing to be considered also is that Duke of Albany is a better show Pea. Wordsley Wonder I am trying this year, and am glad to find Mr. Muir bears out what I have heard from others as to its good qualities. Veitch's Perfection is indeed a good Pea, but is surpassed to my mind by Sutton's Satisfaction. The Peas are truly immense, and when cooked make a very good looking dish, and they do not belie their appearance or name. I wanted to harvest some seed, but I could not save them from the pot, for no other Pea would satisfy the household powers. Another Pea which I found to be a great bearer with high quality is Duke of Connaught, early, and it continues a considerable time in use.

Mr. Iggulden likes Village Blacksmith Potato, but I can see nothing good in it. I have grown it on light and on heavy land, and liked it on neither. Its appearance is not in its favour, and if cooked in their jackets the Potatoes are very apt to fall to pieces when taking off the very thick skin. I have not found it a great bearer, although the haulm has been rampant. I must say a word for my favourite Vicar of Laleham, for I have always found it of good quality, and it suits me better than any other because, although floury, it does not break, and I never knew it to be diseased. Cole's Favourite I do not know, and perhaps Mr. Iggulden will favour us by telling us where it is procurable, and I shall then be pleased to try it on his strong recommendation. Reading Russet is a good Potato in all points, but I have found it sometimes crack very badly indeed, as noted by your correspondent "E. B."

Mr. Iggulden ignores three of the best Potatoes—Victor, which I have found best of all for frame culture and early work; a kidney with a beautiful skin, short haulm, and of good quality. Beauty of Hebron, which I always find of good quality (and its price in the London markets, although it has a coloured skin, shows how it is appreciated), is also a great bearer, and the haulm not being too strong does not exhaust the land. The third Potato, to which I would draw Mr. Iggulden's attention as worthy of a trial, is Duke of Albany, which has the advantage over Beauty of Hebron of a white skin. It is a seedling from that variety, and is in all points identical except of better quality. Sutton's Nos. 36 and 44, now Satisfaction and Masterpiece, were very satisfactory, and the latter being very late in starting into growth will be found very useful for late planting without a loss of vigour.

I strongly agree with what Mr. Thomson says as to size in Potatoes. I strongly object to large Potatoes, and always choose medium-sized. I might say small, Potatoes for my table, finding the smaller the Potato the better the quality. What is wanted is a variety that will bear a heavy crop of medium-sized tubers with few chats, having a dwarf but not tender haulm. This is what I want to obtain, but what so far I have found unprocurable.—H. S. EASTY.

OXERA PULCHELLA.

FROM Pendell Court Gardens, Bletchingley, specimens of rare and beautiful plants are occasionally sent to the meetings of the Royal Horticultural Society at South Kensington, but no exhibit from that establishment recently has attracted so much attention as the flowering shoots of Oxera pulchella shown on January 10th this year. There was no hesitation on the part of the Floral Committee in awarding a first-class certificate for it, and the honour was so well merited in this case that it could not be subjected to the criticism sometimes considered necessary. New flowering plants of really sterling merit are too seldom brought into notice now outside the numerous Orchids, and such an addition as this is therefore all the more welcome.

Oxera pulchella is a handsome climbing plant of the natural order Verbenacæ, related to the Clerodendrons, and is a native of New Caledonia, where it was found during La Pérouse's voyage. A plant was flowered at Pendell Court in December, 1886, and this has flowered freely again this year, as the specimen exhibited well indicated. The plant is a strong climber with smooth bright green elliptical opposite leaves, and the flowers are borne in dense pendulous axillary cymes. The corollas are white, broadly funnel-shaped, with two long stamens and a greenish white calyx of four sepals.

Mr. Frank Ross, who has charge of the Pendell Court Gardens, has obligingly furnished the following cultural particulars:—"The Oxera is

will not injure it. Train it on the glass end of a house up a rafter, or along the ridge of the house, say where there is a lantern top, as these

FIG. 15.—OXERA PULCHELLA.

an extremely free-growing shrubby climber, producing immense cymes of white flowers usually about Christmas. They are freely produced, both axillary and terminally, on the ripened wood. Therefore, to secure the proper ripening of the wood the plant must be afforded plenty of light; indeed, it cannot have too much, even full exposure to the sun

are the positions which would suit it best. Our plant, both this and last year, had by far the finest flowers on the glass end of a cool stove, where the temperature during winter is kept at about 55° to 60°. A fair degree of temperature such as I have mentioned is necessary to flower it, although the plant will live through the winter in ordinary

greenhouse temperature; but under such treatment we failed to flower it, and it was not until it was moved to its present position two years ago that anything satisfactory was done with it. It flowered the following year and again this year about the same time—Christmas. It is by no means particular as to soil, but a good friable loam seems to suit it best.

“It is easily propagated in the usual way, either by cuttings or seeds, which, judging from what I have seen of it, are produced rather freely; but cuttings inserted round the edges of a pot in sandy soil and placed in a propagating frame root in a few weeks, and if potted and liberally treated may be expected to flower in about a year, much depending on the time of year at which the cuttings were inserted. As far as I am aware, this is the first and only plant which has flowered in England—possibly in Europe—and is not yet, I believe, in the trade; Sir George Macleay having brought the plant to England when travelling abroad a few years ago.”

ROYAL HORTICULTURAL SOCIETY.

JUDGING from the various expressions of opinion in the Journal and other channels of information, as well as from other sources, an undercurrent of dissatisfaction exists on the nominations for the new Council, or some of them, and it is not improbable that some opposition candidates will be run at the forthcoming meeting. One is heard of who has only quite recently been made a Fellow, as if for the purpose of his elevation, while another is not a Fellow, though possibly he may be enrolled at the next meeting. We shall see. One of the gentlemen already nominated is also a very new Fellow, and has done nothing for the Society in the past. So long as the Society does not include among its older supporters gentlemen who are competent to serve on the Council, whether as amateurs, tradesmen, or gardeners, they must of necessity be sought for outside; but surely, as a matter both of justice and policy, old supporters, if equally competent with new comers, should be entitled to the first consideration in the filling of vacancies. I am one of those who cannot understand how persons can join any Society for the purpose of getting placed into positions which they covet. If I were to join to-day, and be placed in office to-morrow so to say, I should feel, even if I had no wish for the distinction, that the public would regard me as taking a step for my own exaltation, instead of being animated with a desire to support the Society. Having been a Fellow of the Society a few months I am free to speak on this subject, and should certainly object to be placed on the Council to the exclusion of competent persons who have been supporters of the Society for years. Holding these views I shall not give my vote to anyone who has only quite recently joined the Society, as though he may have not done so with the object of personal distinction he could still have joined before and given himself a better claim, in my opinion, to the suffrages of the electors.—A NEW FELLOW.

PRIMULA SINENSIS CULTURE SIMPLIFIED.

THE PLANTING OUT SYSTEM.

In drawing your readers' attention to the above system of treating Primulas through the summer, I do so with a desire of urging others to try the plan themselves. Having placed a few dozen plants outside at the end of last June, which were lifted at the end of September, with the result that they have flowered profusely since the last week in October, I can with confidence recommend this mode of growing Primulas, particularly to amateurs who wish to retain old plants another season. I would advise those who possess plants that will be flowering from now to May to plant them outside in June; such will not need much hardening previous to being planted. If they are planted about 2 feet apart in a position rather shaded, not under trees, but with a few hours' sun on them through the early or latter part of the day, it would be of benefit rather than otherwise. Those desirous of giving the plants a little fresh soil when they are planting might do so with advantage, but it is not really necessary, for they will grow in any good garden soil. If fresh soil be used the finer the better, for then the soil adhering to the roots can be readily removed when they are lifted without injuring the plants. I have several plants that had the soil removed from the roots until they could be placed in 5-inch pots.

I intend sowing seed early in March, with a view of having the plants ready for planting out in cold frames in June, where they will remain until the autumn. I believe this idea will answer, and will commend itself to those who have to provide a large number of plants for decorative purposes. Not half the work will be required when they are planted out in frames as when they are grown in pots through the summer. I find the young plants always do well in their early stages, when they are growing in pans and boxes; therefore, I think they will do well when planted out in frames for three or four months through the season,

and at a time when gardeners are fully occupied. If this method of planting the old Primula plants outside was to become adopted there would be a great many more growers of this most beautiful plant. If they could be purchased in May or June, and treated in the manner described above, I think those not even possessing a cold frame could have them flowering through the autumn and winter. Seed sown in the autumn would produce plants readily for placing outside in May and June following. If growers of plants for sale were to find there was a demand for them at the time indicated I am sure they would soon avail themselves of the opportunity and be in a position to supply plants at a reasonable cost.—T. F. B., *Lancashire*.

[The specimens with others that were received in September afford ample evidence of the success of the simple method of culture described.]

A GOSSIP ABOUT ORCHIDS.

[A paper by Mr. Lewis Castle, read before the Chiswick Gardeners' Mutual Improvement Association, January 25th, 1883.]

THE title of this paper was chosen with the express object of avoiding any expectation of a formal or elaborate essay, and to permit a gossiping discourse on matters orchidic, with an occasional straying into bypaths, and perhaps a little horticultural moralising on the way. If I can thus provide you with a few subjects for reflection, and sundry hints of general applicability, it is of course all you desire and all I can undertake this evening, not because the subject is limited, but because it is so wide that it would only be possible to deal thoroughly with one portion or to glance hurriedly over it generally, and the latter course is preferable, as we can thereby avoid many technicalities that are apt to become tiresome. We will therefore proceed to a few considerations respecting

ORCHIDS AS GARDEN PLANTS.

Orchids unfortunately have many defects, and the greatest of these to the minds of some very worthy and thoroughly useful persons is that their economic value is extremely small. They do not contribute anything to the necessities of life, and with the exception of the exquisite vanilla flavouring to please the palate occasionally, those who derive a large portion of the pleasures of their existence from eating and drinking obtain so little from the Orchid family that they can afford to despise it most vigorously. We are told that utilitarianism is the order of the day, and very rightly too, but with many this also seems to mean a dreary kind of puritanical existence, the abolition of refinement, and the general assumption of corduroy vestments. Then, again, we cannot look to Orchid culture for a remedy in the prevailing agricultural depression, nor can we from a commercial point of view claim for Orchids the financial advantages of the humble Mushroom as depicted in the inimitable Wrightian style. They are rather more expensive to grow than Cabbages or Turnips, and lastly, they constitute the favourite hunting grounds of many voracious and prolific insects.

Such are the principal defects of the Orchids as garden plants, and having given them their full weight it may be worth while to see what can be set off against them. As civilisation advances and wealth accumulates in any country, demands arise for what are termed luxuries—*i.e.*, something outside and beyond what is essential to the mere preservation of life. These modes of disposing of surplus pecuniary possessions of course vary greatly with the dispositions of the fortunate individuals who, luckily for the other portion of the community, are generally desirous of doing so. In old countries or prosperous new ones the better form of this is seen in the patronage accorded to the arts and sciences, and in this country the exceptional development of horticulture has been entirely due to the same cause. In the United States of North America the increase of capital has also resulted in a wonderful advance in horticulture, and it seems that our cousins are surpassing us in real gardening enthusiasm as they already have in some other matters. Is it, therefore, surprising that a share of the attention of the wealthy should be devoted to plants, and amongst them especially to Orchids? In provincial gardens the first requirements are good supplies of fruit and vegetables, then come the plants, and in not a few establishments where decoration is largely carried out this is now a highly important department. Around large towns it often happens that fruit and vegetables can be purchased more cheaply than they can be grown in gardens, and then the owner delights himself with his Roses, Chrysanthemums, hardy plants, or Orchids, according to the length of his purse and his own partialities; or perhaps he is a man of large sympathies, and then they all come in for a share of his regard. It consequently happens that suburban gardens abound in examples of good plant culture, while for general “all-round” establishments we must usually go to the provinces. In the former gardens we find the greatest extension of Orchid culture in recent years, successful merchants and “City men” have taken them in hand as their especial favourites, and collections have multiplied with surprising rapidity. Regarding Orchids simply as luxuries there have been substantial reasons for this popularity, as no thoughtful person with the smallest capacity for appreciation of the beautiful in Nature could fail to admire their strangely handsome flowers, singular formation, varied and rich colours. A more intimate acquaintance with and extended knowledge of them invariably develops that admiration into a kind of enthusiasm such as distinguishes all true horticulturists, and which some petrified persons, wrongly named utilitarians, are incapable

of experiencing. The man who has no love for flowers or music, or who does not feel a thrill of satisfaction and an exaltation of the mind in contemplating a beautiful landscape, is a near approach to a soul-less creature.

But Orchids are more than mere luxuries, for they comprise some of the most useful plants that can be grown for durability of their flowers and decorative value. Take, for instance, such an old favourite as *Dendrobium nobile*, which stands unrivalled for beauty of flowers, floriferousness, and ease of culture. Another old inhabitant of our houses, *Cypripedium insigne*, the flowers of which will last for weeks when cut, is a similar example. The graceful *Calanthes* of the *Veitchi* and *vestita* types are almost indispensable, together with the lovely *Lælia autumnalis* and *L. anceps* for winter use, while *Lycaste Skinneri* and a host of grand *Cattleyas* furnish floral charms that cannot be over-rated. Some of the crimson coloured *Cattleyas* are now great favourites for table decoration, as under artificial light their marvellous colours are seen to perfection, possessing a richness that is quite unique in the floral world. For bouquets and buttonholes the exquisite *Odontoglossum* of the *crispum* type are general favourites, and the supplies of these now sent into the London flower market would have been considered extraordinary a few years ago. When market growers take a plant in hand it is certain that no fantastical qualities have caused them to do so, but it affords a proof that a demand exists which is difficult to satisfy. There are now hundreds of houses devoted to *Odontoglossums*, and in some extensive nurseries they may be seen in hundreds of thousands planted out in the side beds and watered with a hose, like bedding plants.

This brings us to another part of the subject, which deserves a few observations—namely,

ORCHID GROWING.

Whenever plants of any kind have just come into notice there has always been a tendency to exaggerate the difficulties attending their culture, and if one or two people become fairly successful they attained a proportionate degree of fame.

In what might be termed the early days of modern horticulture there was not the same readiness to communicate for the general good the experience thus gained as there is as at the present time. Cultural secrets were often guarded as jealously as possible, and, as in a few very rare instances, they are even now. Happily, however, the horticultural press has assisted in dissipating such prejudices, and encouraging a true freemasonry amongst gardeners. Until quite recently the culture of Orchids was regarded as of exceptional difficulty, but many have helped to prove that such ideas are completely erroneous, and the only danger now is that growers may go to the opposite extreme and become careless.

The chief key to successful Orchid growing is close, thoughtful observation, and the same key will be found an exceedingly useful one in every department of the gardener's art whatever a man's experience or position may be. General rules can be readily furnished, but the success or failure of their application must depend upon individual experience, which will modify them according to the varying circumstances under which they may have to practise. I am familiar with many examples of able cultivators who have made considerable fame in one garden by their successful productions, but who, when removing to other localities have for a time completely failed in the culture of the plants they had made a special study, until they had become accustomed to the peculiarities of their new situation. In a somewhat similar way we find an Orchid or some other choice plant thriving in one garden, while perhaps in a neighbouring place it is never satisfactory. Even in the same establishment and in one house there are certain situations which seem to suit some plants better than others, and which can only be discovered by a man who takes a sincere interest in his work, and who watches his charges closely.

An instance of this is afforded by the lovely *Vanda cœrulea* which is found in many gardens, but too seldom in its best condition, and as the result of his large experience Mr. B. S. Williams says that it is most strange in its likings and dislikings, sometimes succeeding in a warm house sometimes in a cool one, and the only way when a place is found that appears to meet its requirements is to let it remain there.

We often wish that collectors and travellers who have such exceptional advantages for noting the local surroundings of Orchids in their native habitats would favour us with more particulars than they do. This could easily be accomplished without betraying the exact whereabouts to rival trade collectors, and it would be an immense assistance to cultivators at home, who often have to sacrifice some of their plants in experimental search for the right conditions to provide.

In his most entertaining book of travels, "The Himalayan Journals," Sir Joseph Hooker has given a very interesting reference to the plant just noted—viz., *Vanda cœrulea*, which is worth repeating. It is as follows:—"Near the village of Lerna Oak woods are passed in which *Vanda cœrulea* grows in profusion, waving its panicles of azure flowers in the wind. As this beautiful Orchid is at present attracting great attention from its high price, beauty, and difficulty of culture, I shall point out how totally at variance with its native habits is the cultivation thought necessary for it in England. The dry grassy hills which it inhabits are elevated 3000 to 4000 feet: the trees are small, gnarled, and very sparingly leafy, so that the *Vanda* which grows on their limbs is fully exposed to sun, rain, and wind. There is no moss or lichen on the branches with the *Vanda*, whose roots sprawl over the dry rough bark. The atmosphere is on the whole humid, and extremely so during the rains; but there is no damp heat nor stagnation of the air, and at the

flowering season the temperature ranges between 60° and 80°. There is much sunshine, and both air and bark are dry during the day. In July and August during the rains the temperature is a little higher than above, but in winter it falls much lower, and hoar frost forms on the ground. Now this winter's cold, summer's heat, and autumn's drought, and, above all, this constant free exposure to fresh air and the winds of heaven, are what of all things we avoid exposing our Orchids to in England: it is under these conditions, however, that all the finer *Orchidææ* grow."

One evident requirement of *Vanda cœrulea* is plenty of light, and Mr. J. Godseff, who has lately been travelling in the United States for Messrs. Sander & Co., tells me that he saw some hundreds of plants of this *Vanda* in the house at Mr. W. S. Kimball's establishment, Rochester, New York, with a profusion of fine blue flowers such as are never seen in this country. Under a clearer sky the colours of most Orchid flowers are much more intense than here, and this is seen even in Belgium, and some well-known varieties or hybrids would be scarcely recognised as seen there, so much richer do the colours become. These facts point to the necessity of admitting all the light possible to plants grown in our thick atmosphere, but even this has led to extremes and bad results.

Diffused light is what is required, and shading cannot be altogether dispensed with in the summer under any circumstances. Of course most *Odontoglossums* and other cool house Orchids always require protection from the direct rays of powerful sun, but some experiments have been tried with *Cattleyas* and other tropical Orchids that have been rather discouraging to growers. I remember visiting a private collection of Orchids in the north of England a few years ago which contained some remarkably fine *Cattleyas* and *Lælias* with leaves almost as hard as leather, of a dark bronzy green colour in some cases. The plants were exposed to an unusually free ventilation, and were very rarely shaded, indeed I believe for some time it was dispensed with altogether. The plants flowered in an astonishing manner, and during several seasons they came under my observation were extraordinary in that respect, but a short time afterwards they were sold, passing into the hands of several growers, and in my wanderings I have found them in widely separated gardens both north and south. All alike had found they were seriously defective in the number of roots, and some have since collapsed even under the best management. This rootless condition might be attributed to several circumstances, but the most probable seems to be that the continual exposure to bright sun, combined with a very free ventilation, had necessitated such frequent and excessive supplies of water that the roots had been gradually destroyed. It seems strange to talk about giving an Orchid too much water, but it can be done under such conditions, and it is an atmosphere regularly charged with moisture that is chiefly required to meet the demands of the plants in the hottest weather, rather than frequently deluging the roots in the pots with water. Ventilation in suitable situations might be much more liberally provided than is usually the case with advantage, and a little morning and evening sun is beneficial also, but the results I have seen do not encourage the adoption of a general system of non-shading.

In the flowering of Orchids, which is apparently so greatly encouraged for a time under the system already described, there is also another point worth consideration. It is an extremely weakening process, and small plants of anything choice should not be allowed to retain their flowers long, nor to expand many, or they are apt to terminate their existence rather abruptly, and it is not agreeable to see a few £5 or £10 notes vanish in this way. *Phalænopses* in particular are very liable to flower abundantly for a year or two, which the delighted owner regards as a convincing proof of his cultural skill, and then they sink into a rapid decline, or dwindle for several years before they recover. The fogs which play such havoc in town and suburban gardens save the lives of many weakling *Phalænopses* by destroying the flowers which their owner cannot bring himself to voluntarily sacrifice. But with many Orchids the flowers last nearly as long when cut and placed in water as when remaining on the plants, and there is then no excuse for allowing them to suffer. There is another part of the subject to which I wish to devote a few remarks—i.e.,

ORCHID GROWERS.

A week or two ago a writer contributed to one of the gardening papers a letter containing an expression that is very much like a deliberate slander. Referring to the constitution of the Floral Committee, he remarks concerning the orchidists that "the bulk of these know little and care less about other flowers." Either this writer knows very few orchidists, or his mind is clouded with very dense prejudice, and strangely enough in the same letter he pays a well deserved compliment to one of the best examples that could be adduced in controverting his statement—viz., Mr. James Douglas. I have a wide circle of Orchid-growing friends and acquaintances, and respecting nine-tenths of them that assertion is absolutely without foundation. There has always been an ignorant prejudice against specialists of all kinds, and it is only the advancing knowledge of the present time, with the corresponding development of wider views that is dissipating this. Young men would do well to remember the aphorism, "Know something of everything and everything of something." It is advantageous, indeed essential, to have as wide a general knowledge as possible, but to give any man a chance of excelling in these days he must descend to the minute details in some one study or branch of his business and become a specialist. This is necessary, not only for individuals, but for the benefit of society, as it requires a life's study to master any particular subject now; the accumulated knowledge of centuries has often to be analysed before a

student can do much as an original investigator. In horticulture we have abundant examples of specialists who are also first-rate "all round" gardeners, and a few visits to the gardens managed by such men would be sufficient to remove the antiquated prejudices that some people possess. Mr. E. Molyneux, for instance, has made his fame as a Chrysanthemum grower, but all who have visited Swanmore Park or seen his vegetable, fruit, and plant exhibits at shows can testify to his abilities as a thoroughly practical cultivator. Mr. J. Douglas is another example of a similar kind. As already noted, he has long made a special study of Orchids, but after an hour or two in the Great Gearies Gardens a visitor would think that their superintendent made a specialty of everything under his charge. The same could be said of many gardeners who have made specialties of fruit or vegetables, such as Mr. McIndoe, Mr. Hunter, Mr. Goodacre, Mr. Woodbridge, and scores of others who are very far from being one-idea men.

Even amongst amateurs themselves, who might naturally be expected to be more entirely devoted to particular hobbies, plenty of instances could be given of gentlemen, and ladies too, who, while selecting one class of plants for an especial share of their attention, have yet an extended interest in plants generally. Baron Schröder is well known as a distinguished amateur orchidist, but he is almost as partial to his Rhododendrons and other outdoor plants, and he knows them as well.

My experience is that the men who are contented with mediocrity in everything are not the men with the largest minds, nor do they, as a rule, attain to the best situations. It must not be thought that I advocate all young gardeners becoming orchidists, but if a young man has a partiality for any one branch of his business let him give his best attention to it, while not neglecting the other essential parts, and the probability is that he will excel. He, however, is a happy man who is prepared to adapt his specialty to the varying requirements of the circumstances by which he may be surrounded in different situations. The fact is that the additional exertion needed to master any subject must invariably have a beneficial effect on the mental powers generally, for the mind requires training and developing as much as the body. Rest assured that when the acquirement of knowledge and self-improvement by working, reading, and thinking is earnestly regarded as a duty by young men, they will soon find that it also constitutes one of the chief pleasures of life.

FLOWERING BOUVARDIAS WITHOUT ARTIFICIAL HEAT.

THAT Bouvardias are accommodating plants as well as being very choice when cut flowers are in great demand admits of no doubt, but when a good supply of flowers can be had without the aid of artificial heat to flower the plants in, Bouvardias are doubly valuable, particularly to those who do not possess a large amount of glass room. The large-flowered white variety, Humboldti corymbiflora, produces an abundance of fragrant flowers during September and October, when other flowers are becoming scarce; add to this the bright scarlet variety elegans and the delicate pink of Vreelandi, and you have varieties sufficient for an early supply of these useful flowers. The next question which suggests itself is, Where are these plants to be flowered without heat?

If plants of these varieties are on hand, having flowered last season, these should be at once cut down to two or three eyes if the plants are young, otherwise cut to one eye if the stock plants are old ones and freely furnished with branches. A vinery or Peach house just started is a capital place for them, as the moisture and daily syringings assist the Bouvardias to break freely into growth, or failing these a Cucumber or Melon house will suffice. To increase the number of plants cuttings should be inserted singly in small pots when procurable, those about 2 inches long taken off with a heel answer best. A brisk bottom heat and the protection of handlights or a propagating frame are the best means of procuring quickly struck plants. The soil best suited is equal parts of peat, loam, and leaf soil, with a liberal use of sharp silver sand. When roots are formed and growth commences ventilate gradually, as the plants are liable to flag if exposed suddenly to the air. Remove them when ready to a shelf or position close to the glass in a temperature not less than 60° by night, with a rise of 10° during the day. When the plants are 4 inches high pinch out the point of the leader to induce the formation of side shoots, and shift the plants into larger pots as required. Gradually harden them until they can be placed in cold frames toward the end of April. The stock plants should be shaken out of the old soil just before growth commences, replacing them in pots into which the roots will go comfortably, using soil composed of two parts peat, one of leaf soil, and one of loam, with a dash of finely ground bones and some sand. Pinch the points out of each shoot when 2 inches long. Harden them similarly to the younger plants.

The next consideration is the position they are to occupy during the summer, and to flower in later on. We plant ours in pits following a crop of Potatoes, by levelling the soil which contains a plentiful supply of decayed leaves; adding a small portion of peat and some bone dust we get a compost which suits them well, and they grow vigorously and flower freely. Much depends upon the growth made by the white variety for the future flowering. The stronger the growth in reason the finer the trusses. Plant sufficiently low in the pit to allow of a free growth, so that the points of the shoots will not rub against the glass, or they are more liable to be destroyed by early frost in October, this is why pits are better than cold frames. The middle or end of May is a good time to plant them, allowing sufficient space between them, and

as the current year's plants will not make more than half a dozen shoots from the bottom this will guide the planter as to the distance. The growths should not be topped more than twice, or succeeding growths will not be so strong. Keep the pit nearly close for a few days until new roots are formed, and shade from bright sun until growth is fairly started. Admit air gradually as growth advances until the lights can be removed. Give the plants a vigorous syringing every afternoon; supply water freely to the roots, which may be supplemented when the flower buds appear by liquid manure not too strong. If black aphides attack the points of the shoots, as they sometimes do, dust the parts affected with tobacco powder in the afternoon, and syringe off in the morning. Repeat this in a day or two until the plants are clean. Towards the end of August place on the lights, giving abundance of air, gradually reducing it as the flowers expand and the nights grow colder. Towards the end of September cover the lights with mats to protect from early frosts. The centre or extreme point of each branch will produce the first blossoms. If care be exercised in cutting the blooms side growths will be produced freely, which will in turn flower abundantly. By this treatment of the plants in pits of this character we have been able to cut flowers freely until the middle of November in a mild autumn.—E. MOLYNEUX.

OUR NATIVE FERNS.

I WISH to say a few words on the above plants, and I for one am much obliged to those friends who have been the means of reminding the lovers of Nature's beauty that there are in the British Isles plants of such beauty, and we have them in such variety that they appear as if intended to suit all tastes. The distinct varieties may be counted by hundreds, and I believe I am within the bounds of truth in asserting that no other country with only nineteen genera of Ferns and only forty-three species possesses so many distinct varieties as the British Isles. Yet these beauties of our native land seem to be far from attracting that share of attention they ought, and in our estimation deserve to do. No doubt there are some reasons for this, and I am rather inclined to think one is to be found in the non-appearance month after month of any reference to them or their merits in such journals as yours and others. We see one or two advertisements, but seldom a word to commend them to the public. I hope you will pardon me if I suggest that a short paragraph in your valuable paper two or three times a year would not be out of place, and no doubt would be acceptable to many of your friends. I can speak for myself that the first thing I look for in the Journal, or any other horticultural paper, are the Fern notes. I was much pleased recently to learn that a bequest has been made to the Royal Gardens at Kew. A gentleman at Usk bequeathed 4000 British Ferns, representing over 1000 named forms, so that those who have the opportunity of visiting those gardens will have the gratification of seeing and judging for themselves the merits of our native Ferns.

I will now refer to several other causes which I think have helped to put our native ferns in the shade of late. Mr. F. W. Stansfield says some years ago classes specially for British Ferns were not uncommon in exhibition schedules; but these are in many schedules now supplanted by the extremely indefinite hardy Ferns, a term so vague that disputes as to its meaning are as common as exhibitions, and I endorse Mr. Stansfield's opinions. But they suggest something further to my mind. I would ask, How much has bad judging had to do with the present way of scheduling Ferns? for I can assert from my own experience that that few who are called in to judge in these parts know the difference between hardy exotic and British Ferns, and this explains to my mind the reason for schedules being altered to hardy instead of British Ferns and exotics. Then again, supposing there are twelve plants staged as hardy, and half of them are exotic, how many judges are there who could tell whether the exotic plants were hardy or half-hardy? I rather fancy, if put to the test, they would be found wanting. I would suggest that such a state of things ought to be altered, so that the public may know when they are looking at a class of plants whether they are British or foreign, and I believe by so doing we should increase the knowledge and love of our native Ferns in no small measure.—J. EADON, *Heeley, Sheffield.*

UNDER GARDENERS AND EXHIBITORS.

I HAVE read Mr. R. Weller's letter with great interest and pleasure, and beg to assure him that it is a matter of great regret to me that I am unable to look at this subject through his eyes. He will, I know, excuse me when he reflects that dulness of vision was a characteristic infirmity of an illustrious namesake of his own—the immortal Sam of Pickwickian fame. I am, however, shocked and grieved to find that I, an obscure under gardener, am classed by Mr. R. Weller with professional agitators. Alas! in the words of the great poet, "To what base uses do we come at last!"—AN UNDER GARDENER.

As your correspondent, Mr. R. Weller, states, "Under Gardener" certainly does not put the dark side uppermost, and perhaps goes a little too far in his opinion of head gardeners, but at the same time I believe that many young men really have cause to grumble a little at the way they are treated. Perhaps "Under Gardener" is one of the unlucky ones, but I believe that many head gardeners are very kind to their young men, and I when such is the case there is much more encouragement for

a young man to do his best, and even if he does do a little extra without getting paid for it he ought not to grumble. I have only been in one place where plants were grown for exhibition, and in that I found it something similar to what is spoken of by "Under Gardener." Upon two occasions we have had to change our clothes and set to work on Sunday afternoon, about 4 o'clock P.M., and keep at work till about 10 P.M., then be up again by 4 A.M., and not be able to go to bed again till about midnight. For this we received nothing, but I should have been very well satisfied if, after doing my best and seeing my companions do the same, I could only have seen that the gardener was pleased with us; but this was not the case, for if only a leaf was out of place it was an opening for fault-finding, and on one occasion he went so far as to say that we did all we could to hinder him from getting prizes. I can assure you that this was far from being the truth, for it used to be a matter of competition between the three of us in the bothy to see which could get up his plants the best and secure the most prizes in our several departments. The shows were all within a reasonable distance, and I am well aware that the prizes left £3 to £5 clear when everything was paid. I do not wish to say that that is the case with all, for there are not a few instances where the prize money comes a long way short of the expense, and then I think it would be very unreasonable of young men to get anything even for overtime; but I do think that in cases where anything is cleared, the young men should be paid for their overtime, and receive some encouragement for their exertions, if only a pleasant word of recognition. The gardener we all know is responsible for everything in the garden, and has to work his brains very hard to please, but if the young men did not also work their brains as well as their hands in doing their best to aid him, he would come far short when the day of the exhibition arrived, anyway this is the belief of—A FOREMAN.

THE NATIONAL SOCIETY'S PROPOSED PROVINCIAL SHOW.

A DESIRE has been expressed by several northern growers that the National Chrysanthemum Society should hold a provincial Exhibition this year, and the idea has been favourably received. Suggestions from exhibitors and the secretaries of societies in the north of England, indicating the encouragement that may be expected, would however be useful in furthering a consideration of the matter, and any communications forwarded to me, addressed to this office, will be brought before the Committee.—L. CASTLE.

SHOWING—OWNERS' CLAIMS.

I VERY much dislike to enter a controversy under the protection of a *nom de plume*, and I think I have only once before done so, and then it was not assumed for the purpose of sheltering myself, but to prevent the possible identity of another person whose private actions were made the subject of public discussion, but as "Wraith" has adopted a *nom de plume* I will follow his example. If "Wraith" will disclose his identity I will do the same, because I think the proper names of the writers are the best proof of good faith in controversies, but are not necessarily require to ordinary articles.

"Wraith" enters the list as a champion of employers, and suggests if gardeners' names must appear in reports of horticultural shows they should be given in this way—"Twenty-four Chrysanthemums, incurred, distinct.—First, A. Blank, Esq. (gardener, Hobbs)." That is, we are told, as it ought to be, and gardeners must know their places. I fear you, Mr. Editor, are not entirely free from blame in this matter, for it has been stated in leading articles that in the ranks of gardeners are to be found men of considerable education, men of refinement, men of great business capacity; and on page 1, January 5th, 1888, are these words—"Some of the most intellectual of gardeners are the most energetic workers, and the best painters amongst them are at the same time well in the forefront amongst the most successful Grape-growers and general cultivators of the generation." Surely there is a mistake somewhere. Men such as you describe are surely entitled to the usual courteous prefix of Mr. when mentioned in print. Perhaps it may be well not to dwell long on "jockeys," who, as "Wraith" perhaps knows, do not hob-nob with the rich and the great, do not receive high retaining fees, or handsome presents into the bargain if they win, so we return to the gardeners. In the future their names must not appear. Reports of shows will then stand thus—"Plate of Onions.—First the Duke of Ramsgate, the Onions were well grown with very thin necks, and His Grace must have been most assiduous in pinching them. Celery, two sticks.—First the Marquis of Willerford, this was of excellent quality and showed careful management on the part of his Lordship in the earthing-up process. One Red Cabbage.—First Ephraim Snooks, Esq., this was the largest specimen we have seen, Mr. Snooks must have bestowed a considerable amount of labour and time in the application of liquid manure, which, we fear, he would at times find somewhat offensive."—PHANTOM.

CHRYSANTHEMUM PROPAGATION.

NOTHING succeeds like success, and in the propagation of Chrysanthemums, whatever method may be adopted, if the end is thoroughly satisfactory, we are quite justified in pursuing that course which has led to those results. In a recent issue of the Journal, on page 41, I notice "W. K. W." writing of Mr. Billson's garden near Leicester, speaks of the Chrysanthemum cuttings being struck in a cold vinery and were flagging "seriously." It must be gathered from this remark that "W. K. W." is no believer in this system of propagation, and I know he is supported in this view, perhaps, by the majority of cultivators. This would appear sufficient evidence to at once condemn the practice; nevertheless, that this cold and prolonged system of propagation has its advantages I am quite convinced. The excellent blooms obtained by Mr. Billson is sufficient proof that the flagging was not "serious," and quite justified Mr. Bolton—I beg "Wraith's" pardon, Mr. Billson—in persisting in a course which has led to such good results. Our own cuttings have been struck in a somewhat similar way for several years past. Ten or a dozen cuttings are placed in a pot, and then stood on a ledge in the front of an orchard house, from which frost can be excluded by hot-water pipes. On all occasions, except when frost prevails, the ventilators and doors are thrown open, and as a consequence of such extreme exposure the cuttings flag considerably; but on dry or sunny days they are sprinkled with the syringe, no fear being entertained of damping in this airy structure. Very slowly but surely do they form roots, after which they seem to grow away with a freedom and sturdiness which could not be surpassed by plants which had been struck in a close or warm atmosphere. Again, the small space occupied by the cuttings for two months or more, and the little labour attached, must be advantageous to the amateur, and also the gardener with limited assistance. I should state, however, that I insert the bulk of our cuttings from the 4th to the 20th of December, any that are compelled to be inserted towards the end of January or in February are placed in heat.—A. R. COX.

SWEET-SCENTED CHRYSANTHEMUMS.

THAT sweet-scented varieties of Chrysanthemums will form an interesting class when their numbers increase admits of no doubt. Taking the family of Chrysanthemums generally the odour emitted from both the leaves and the flowers is anything but pleasant, in fact most people consider them disagreeable. It is not generally known that some possess a fragrance similar to Violets, which is much appreciated. In my opinion the fragrance of the single pale pink variety, Mrs. Langtry, is much more pronounced and agreeable than that from any other variety. One or two plants of this will perfume a whole house if the plants are grown in "bush" fashion, so that numbers of blossoms are developed at the same time. At present I do not know more than four varieties which are scented. Now that they are being taken in hand more generally for cultivation, and as prizes are being offered specially for this class, we may expect shortly to see more varieties added to the number. I will describe the sorts I know to be fragrant.

Progne, a small flowered, rather tall-growing variety of the reflexed type when cultivated in the manner generally adopted for the growth of large blooms, the colour is amaranth and scented like Violets. Dr. Sharpe, also reflexed, magenta colour. Little or no scent is emitted from flowers of this variety, which are produced from grown buds, and are consequently large and oftentimes early; even if they have any it does not last long, but when grown with a view to produce a number of blossoms on each plant, as this variety readily does, the scent is much more pronounced. The single variety, Mrs. Langtry, already referred to, is dwarf in habit of growth, branching freely and flowering abundantly the whole length of the stems. Dick Turpin, Anemone Pompon, has brightly coloured ray florets and deep yellow scented flowers, highly perfumed, dwarf and stocky in growth; this variety succeeds well grown either in pots or planted at the base of a south wall; in the latter position its blossoms last a long time in perfection.

A few cultural notes will perhaps be useful to some. Cuttings should be inserted at once, choosing stout suckers, either singly or two in a 3-inch pot. When the plants are 4 inches high pinch out the point of each to induce side branches. Select about three of the strongest of these, removing any others. When those retained have grown from 4 to 6 inches long pinch out the points again. From these new breaks select six of the strongest shoots. After stopping the shoots no other pinching will be needed. These may be allowed to grow, and will in time produce a plentiful supply of flowers. The two reflexed varieties should have some of the weakest growing branches removed from the lower part of the main stems. Thinning the flower buds also will induce a fuller development of the flowers, but in the case of the single variety and the Anemone Pompon, all branches proceeding from these after the six branches are selected should be allowed to grow and all bloom buds develop. The colour of Dr. Sharpe and Progne will be richer if later produced flower buds are retained for flowering. The soil used for potting should not be too rich, nor the pots too large where space is a consideration. Mrs. Langtry and Dick Turpin may be grown two plants of each variety in one pot. The pots at each potting should be a trifle larger, say 4 inches, 6 inches, and 9 inches in diameter.—E. MOLYNEUX.

SPORT FROM MRS. C. CAREY.

MESSRS. H. CANNELL & SONS, Swanley, send us flowers of a bright yellow sport from Mrs. C. Carey with flat florets of a very clear and

pleasing tint. In the style of the flower it is suggestive of the variety from which it has been obtained.

CHRYSANTHEMUM FLORETS.

IN reply to Mr. Shoemith's remark, page 52, respecting an error in my article on page 464 last vol., it may be explained that what I had intended to say was that I had noticed an unusual number of seed or tubular florets in incurved blooms this season. This is of course an approach to the single condition, and it will probably make the matter clear to your correspondent.—E. MOLYNEUX.

HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY.

THE annual general meeting of the members of this Society was held at the "Station Hotel" on Friday evening, 27th January. Mr. R. Falconer Jameson (Chairman) occupied the chair, and there were about forty members present.

After the minutes of the last meeting had been adopted, the annual report was presented. The balance sheet showed that the total receipts of the year had been £681 14s. 1d., including £30 8s. 5d. balance in the bank at the beginning of the year on the current account, and £200 on the cash deposit account. At the close of the year the current account showed a balance in hand of £29 13s. 4d., and a deposit of £150. The amount of members' subscriptions was £110 8s., and the amount given by the Society in prizes was £178 9s. 6d. The Chairman proposed the adoption of the report and balance sheet, and Mr. Bohn, in seconding this, said that the £50 which they had spent over and above their income this year was, to a large extent, accounted for by the annexe to the Artillery Barracks, which they erected for providing extra accommodation for the public at their annual Show. The fact that they had not so many visitors at their Show was accounted for by the other attractions that there were in Hull. The quality of the flowers, however, was far superior to that of the previous year. He hoped that next year they would have flowers equally as good, and that they would be able to show them a more favourable balance sheet.

The election of officers was next proceeded with. Mr. C. Judge proposed and Mr. E. Harland seconded the re-election of the Chairman (Mr. R. F. Jameson), which was carried. Captain Brodrick, Mr. Geo. Bohn, Mr. A. W. Stanley, and Mr. J. Hornsey (Chairman of the Hull Amateur Floral and Horticultural Society) were appointed Vice-Presidents. Messrs. C. Judge and R. W. Judge were re-appointed Hon. Treasurers, Messrs. E. Harland and J. Dixon were re-elected Hon. Secretaries, and Messrs. T. G. Milner and James Abercromby as Auditors. The following gentlemen were voted to form the Committee:—Messrs. F. W. Jameson, E. T. Sharp, E. Goddard, W. S. Brodrick, W. Wheatley, J. H. Fisher, W. W. Cogan, H. Robinson, F. W. Holder, O. Hillerns, Cottam, and Captain Wellsted. A vote of thanks to Mr. R. F. Jameson for presiding concluded the proceedings.

The annual report stated that the Show was visited by 9000 persons, who, by a well-arranged system of circulation, were accommodated without any inconvenient crowding. Some considerable cost was incurred by providing an annexe to the Artillery Barracks, so as to give more room for the Show, but this extra cost was, unfortunately, not recouped to the Society by the extra number of visitors who came, and, unless a large increase of annual subscriptions is made, the Committee cannot recommend their successors to incur the expense of a similar building for the next Show. There was a great advance in the general excellence of the exhibits in the local classes, showing that the Society is fulfilling the object for which it was formed—viz., to encourage and promote the cultivation of the Chrysanthemum in this district.

CHRYSANTHEMUM MDLLE. CABROL.

THIS in my experience is one of the best of all for producing late blooms, and I do not know any variety of which the blooms remain fresh and good upon the plants for so long a time after opening as this. I had good blooms of it opened in the latter half of November which were cut beautifully bright and fresh the first week in January, and some on later plants opened second week in January are now very beautiful, and would, I believe, last throughout February. It is one of the most beautiful of the new class of Japanese Anemones, and as a cut flower for table decoration is, I think, unsurpassed by any owing to its extreme lightness and elegance.—W. K. W.

PORTSMOUTH CHRYSANTHEMUM SOCIETY.

WE understand the above Society is preparing a schedule in which prizes to the value of £200 will be offered, in addition to a cup value £25. A three-days show will be held—namely, on November 7th, 8th, and 9th. From the balance sheet for the past year it appears that there is a favourable balance of over £120, and that upwards of 8000 persons paid for admission in three hours on one day when the charge was 1d.

JAPANESE CHRYSANTHEMUMS FOR EXHIBITION.

WOULD any grower kindly name the best nine large Japanese for exhibition?—AN ANXIOUS INQUIRER, *Carlyon*.

CHRYSANTHEMUMS AT STONELEIGH.

IN my notes at page 41 on the Chrysanthemums grown during the past season at the above address a mistake occurs in the middle of the second paragraph which alters the meaning. It is stated that the

varieties Eve and Mabel Ward had been allowed to grow unstopped until the formation of the first or July bud, the three breaks immediately below this being taken on for producing crown buds. What I should have said was that all the varieties grown were treated as recommended by Mr. Molyneux, except only those two varieties, which were stopped early to induce early breaks. In the fourth paragraph of the same notes, speaking of Roses, my remark on the healthy bushes of "Teas" in pots reads healthy "bunches."—W. K. W.

CHRYSANTHEMUM CULTURE.

[A paper read by Mr. Edwin Beckett, gardener to H. H. Gibbs, Esq., Aldenham House, Elstree, before the last monthly meeting of the St. Albans' Horticultural Society.]

(Continued from page 52.)

I WOULD draw some attention to the dwarfing or cutting-down system which in some localities is practised rather largely, and for some purposes is useful, especially where dwarf plants are desirable; but from my own experience I do not advocate it, for the reason that the blooms lack depth and finish. When practised the plants should be grown on in the usual way until the commencement of June, then cut back to within 4 inches of the pot; after this keep them moderately dry until they begin to break, thin out the shoots, leaving three or four of the strongest, and treat in the usual way.

In the production of dwarf-trained specimens the principal points to be aimed at are fine quality flowers, good foliage, and neat training. Strong plants should be selected early in February. Place them near the glass in a moderate temperature. When about 6 inches high pinch out the points, shifting into 6-inch pots as they commence growth to break, still keeping them in the same temperature. When becoming established remove them to a cold frame. When the shoots are long enough training should be commenced; fix a wire under the rim of the pot, gently pulling down the shoots until they are in the required position. Admit air on all favourable occasions, syringe the plants early in the afternoon as required, transfer them into 8-inch pots, tying down the shoots as before, hardening the plants so as to fit them to stand out of doors early in May, selecting a sheltered but light position, and if the weather be frosty they must be protected by light canvas. The second week in June they should be shifted finally into 12-inch pots. Stand them on slates a good distance apart. A wire hoop painted green placed round them 6 inches from the pot is the best means of training the shoots; on all fine days syringe in the morning and again in the evening. Stopping the shoots should be discontinued by the first week in July, or poor flowers will be the result if left later. They should be placed under glass about the same period as previously mentioned, also being staked before the flowers are too far expanded. Willow sticks painted green may be used, as they are light and of neat appearance, a point always to be aimed at. Weak liquid manure in all stages of growth will greatly assist these, increasing the strength as the pots become filled with roots. The above remarks in all cases apply to the large flowering sections—viz., incurved, Japanese, and reflexed. Anemone-flowered and Pompons for fine flower are best struck in February, and stopped once or twice during the spring. Disbudding must not be practised to such a large extent as in the case of large-flowering sorts, but a moderate thinning will always repay.

Many kinds of liquid manure have been advised, but I have found none to suit them so well as the following:—In a large tub or cistern place one bushel of soot tied securely in a thin bag, one barrowful each of cow and horse manure, fill with soft water, stir the whole before using and strain through a half-inch mesh sieve, dilute to the colour of weak tea, and recharge when the strength becomes exhausted. Occasionally give the plants a change of guano water or Wood & Sons' universal liquid manure powder; this is undoubtedly a first-class stimulant both for foliage and flowers. The two latter must be applied with great care and discretion or damage may be done.

The diseases and enemies of the Chrysanthemum in some seasons are very numerous, and the past season has been by no means an exception. I have always noticed there are more blind and deformed buds after a long spell of hot dry weather, and mildew is sure to make its appearance, notably so on some varieties more than others. As a preventive dust occasionally with flowers of sulphur. When in a young state the common green aphid is often very troublesome, attacking the points of the plants. Strong tobacco water is the safest and best remedy, dipping the plant thoroughly, syringing two hours after with soft warm water. Earwigs are also troublesome pests from the time the buds are forming until the flowers expand, doing great damage to the florets as they unfold; these must be watched for night and morning. Bean stalks cut in lengths of about 6 inches make capital traps placed among the plants and blown into a pail of hot water every morning. The earwigs are easily dislodged; I have seen as many as a dozen blown from one stalk. Another insect, commonly known as the jumper, does a lot of mischief to the young points and buds. I know of no remedy for this except killing with the thumb and finger. But the most destructive of all that I have met with is an insect which in its young state resembles black aphid, becoming a light green, and at this stage travels round the shoots very rapidly when disturbed, and when full developed turns to a soft brown fly, which must be caught and killed. Dust the points occasionally with tobacco powder during the season.

This concludes my short treatise on the Chrysanthemum. There are so many classes and different methods of growing it would be quite impossible to go further into details.

WORK FOR THE WEEK.

FRUIT FORCING.

FIGS.—Earliest Trees in Pots.—The trees started in November for affording ripe Figs early in May will be throwing out fresh roots plentifully, the bottom heat being kept steady at about 70° to 75°. Bring up the fermenting materials to the rim of the pots, and instead of allowing the roots to come over the top of the pots to ramble unchecked into the fermenting material, place pieces of rich turf of good size round the rims to keep the roots near home and to induce sturdier growth. Maintain a good moisture in the atmosphere by syringing twice a day and damping as may be required in bright weather. Admit a little air at 70°, increasing it with the temperature; close at 75°, and if the temperature rise to 80° or 85° from sun heat it will be an advantage. See that there is no lack of water at the roots. The drainage being good there is little danger of giving Figs too much water, many crops being lost by the soil being kept too dry. The temperature in dull weather must be kept at 60° to 65°, 55° to 60° at night when the external air is cold, but 5° higher when the weather is mild. Dishudding will need to be attended to as growth advances and gross shoots stopped, but the finest Figs are borne upon extensions.

Early Forced Planted-out Trees.—The trees planted out in inside borders and started early in the year will, if the borders have had repeated waterings at a temperature of 85°, be starting into growth, and may have the night temperature to 55°, 60° to 65° by day from fire heat, with an advance from sun heat and free ventilation to 70°, or even 75°. Syringe twice a day as before advised, and see that the borders are thoroughly moistened. If the trees are weak a thorough soaking with liquid manure, not too strong, at a temperature of 85° to 90°, will assist the growth.

VINES.—Eyes and Cut-backs.—Eyes may now be inserted, using pots pans, or square pieces of turf. Select firm well ripened wood, filling the pot or pan with rich friable loam, inserting the huls with a pinch of silver sand half an inch beneath the surface, plunging the pots, &c., in a bottom heat of 80°. Cut-backs should be placed in a house where they will have a temperature of 60° to 65° at night, and 70° to 75° by day. When they have started into growth shake them out and return them to the same size of pot, using good friable loam, and give a moist and rather close atmosphere until re-established, when they should have a position near to the glass, so as to insure sturdy, short-jointed thoroughly solidified growth.

PINES.—Fruiting plants and starters, which will now be throwing up fruit, should have a mean temperature of 70°, varying it 5° according to the weather, admitting air at 80° with sunshine, but not lowering the temperature, allowing it to rise to 85°, closing between that and 80°, and if it rise somewhat after closing it will be advantageous rather than otherwise. The plants recently started into fruit will, if in good condition at the roots, produce strong suckers. When the suckers are large enough to handle, all except one to each plant must have the growth checked by taking out the centre. To supplement the autumn potted plants select others which have been wintered in 7 or 8 inch pots, choosing the most vigorous. Those remaining may be reserved until the general spring potting, when they can be shaken out and treated similarly to suckers. Good fibrous loam with the turf well reduced, placed under cover to become dried, is a suitable compost. Drain the pots well, dust soot or dry wood ashes over the crocks to exclude worms, and ram the soil firmly round the plants, keeping them well down in the pots to admit of copious supplies of water being given when necessary; 10-inch pots are suitable for Queens, and 11 or 12-inch for those of more robust growth. A temperature of 60° to 65° will be sufficient for these plants, also those potted last autumn, and about 85° bottom heat. Plants in beds about to be started into fruit must not have the heat at the base of the pots over 90° or 95°, or their roots will be injured. If sufficient fruit be started to meet the requirements, later successional plants that have not been subjected to a high temperature may be advanced slowly, they with autumn-rooted suckers requiring careful watering, especially where the heat at the roots is supplied by fermenting materials.

KITCHEN GARDEN.

PEAS.—All good kitchen gardeners are annually striving to have their first dishes of Peas ready as soon as possible in the spring or early summer months, and they cannot be ready too early or in too great a quantity. The seed we sowed in the open ground in November has germinated freely, and the young plants are now about 1 inch in height. We would rather have them this height now than 6 inches high, as the dwarf plants are rarely injured by wind or had weather, but the tall ones are very liable to be damaged before March is over. We have almost ceased sowing Peas under glass with the object of forwarding them, as they suffer so much as a rule when transplanted that those sown in the open ground often surpass them. Those who have not sown Peas in the open in January need not be afraid to do so. They are rarely

injured by the weather, and we advise every garden owner to make a good sowing at once. For private consumption two or three rows will be enough at a time. Some may say, "Oh, my garden is too small to grow early Peas well." Nothing of the kind. It is not a question of extent of land in their case, and we would undertake to have them ready as soon in a piece of 10 square yards as 10 acres. Carter's Lightning is one of the earliest Peas, and its qualities are first-rate. Sutton's Ring-leader is much superior to William I. For all Peas sown at this time in good ground should be selected, and in a position well exposed to the sun. A dusting of soot will benefit those through the soil, but do not render them tender with too much protection.

KIDNEY BEANS IN POTS.—Kidney Beans can only be grown at this time by those having glass houses. They require considerable space and heat to produce them in quantity in the early spring months, and they cannot be profitably grown as a market crop except by those who have special facilities for their culture. A number of dishes may, however, be grown in an early vinery or any warm pit, and the cultivator may be assured they will be much valued on the table, as Kidney Beans in March or April are a delicacy. A good variety for forcing is Cooling's Ne Plus Ultra. Fill a number of 3-inch pots half full of good soil, place six or eight beans in each, cover over with more soil, and place them in a temperature of 65° or 70°. Here they will germinate in ten days, and they should then be supplied with water, and kept in the light. As soon as the plants are 6 inches high they should be transferred into 6-inch or 8-inch pots. If the first size is used put one pot of the small plants into each, but if 8-inch pots are used two or three of the small ones may be turned into this. Use a mixture of rough loam and manure in potting, and make it firm. Water sparingly until they begin rooting, and as soon as they begin growing again water freely, and do not allow the temperature to fall below 65°.

EARLY RADISHES.—These are easily grown on a hotbed. They are sometimes sown amongst other early crops, but we do not approve of this plan, as Radishes make a good many leaves and often hinder their own development or their companion crop. The best way of growing them is to make up a slight hotbed and sow them under a frame on this. One ordinary light will be sufficient to begin with, and the seed should not be sown too thick. French Breakfast is still the earliest of all, and they are very acceptable in their tender young state.

LARGE LEEKS.—"How do you grow those monster Leeks, and when do you sow them?" were questions put to us last August by a gardener who was admiring some specimens 3 lbs. in weight each. Our reply was, "There is no secret in their culture, but they must be sown early;" and that is so. Indeed, all who wish to have very large Leeks in summer should sow a pinch of seed in a box now. If given good soil and a temperature of 65° they will do well for a time, and we will write about them again when they demand attention.

PLANT HOUSES.

Heliotropes.—Heliotropes trained upon walls or pillars should be thinned and pruned without delay. If all the growth made is laid in they become too crowded before the season is over, and small trusses of bloom result. Liberal thinning will cause strong growth, and consequently fine trusses of bloom; White Lady is one of the best for purposes of this description. Top-dress the soil in which these plants are growing with equal portions of loam and manure.

Abutilons.—Where these occupy positions as climbers they may be liberally thinned, and the shoots shortened back. With these, however, it should be determined whether the bloom will be required or not, for with increased light and heat they will flower again freely. If a judicious system of pruning is not practised they soon outgrow the space allotted them. Where a succession of flowers is needed pruning should be done at various periods—that is, as soon as those pruned back break into growth and commence flowering others should be done. The growing ends removed will root freely if inserted singly in small pots and plunged in the propagating frame in a temperature of 65°. Aphides and scale are the worst enemies to these plants; the first is destroyed by fumigating with tobacco smoke, and the latter can be eradicated by the petroleum solution if used at the rate of 3 ounces to 4 gallons of water after the plants have been pruned. If used on the plants while in active growth it invariably turns many of the leaves yellow.

Anthurium Scherzerianum.—Plants that have been resting in a temperature of 50° to 55° may be introduced into the stove or any structure where the temperature ranges about 10° higher. In this temperature they will soon start into activity and produce their brilliant scarlet spathes. Top-dress with rough peat and moss any plants that need it, while those that require larger pots or the renewal of the compost about their roots may be done just as the roots are starting into growth. If this work is delayed until new roots have been formed it is impossible to remove the old soil from amongst them without seriously injuring them. The best and easiest method of removing the decayed soil is to wash it out in tepid water. The plants should be allowed to drain thoroughly before they are repotted. The pots or pans used should be liberally drained, and the compost, which should consist of fibry peat and charcoal in lumps, should be carefully worked amongst the roots. The plants must be lowered into the pots as much as possible, and the soil slightly raised above the rim. It should not be too high, ample room for top-dressing another year being left. Those still in an intermediate temperature must not have too much water, or else their roots will decay instead of remaining fresh and plump. A long succession of blooms may be had by introducing a few plants into the stove at intervals of a month.

Gardenias.—Young stock rooted in August or September should be placed into 5-inch pots without delay. Use a compost of rough peat and loam in equal proportions with a liberal addition of sand. Where it is difficult to obtain good peat leaf mould may be used instead. They will do well in rich loam and sand, but in a young state they make greater progress in a lighter mixture. Place the plants after potting in a close moist atmosphere where the temperature can be kept about 65°. In this heat established plants will swell their flower buds rapidly. Avoid feeding them with strong stimulants, which has a tendency to cause the flower buds to become deformed. Strong insecticides and over-watering will bring about the same results.

Caladium Argyrites.—Well grown plants are not only handsome for decoration in 4 and 5-inch pots, but the foliage is charming in a cut state for associating with flowers for the embellishment of vases. If the tubers have been preserved in the soil in which they were grown last year they may be shaken out and started in boxes of light sandy soil. Directly the tubers commence growth pot them singly according to their size. To do them well they must not be over-potted. It is better to repot them on after they have filled the first size with roots.

Begonia nitida.—Plants of this and its variety rosea that are in 3-inch pots may be placed at once into 5-inch. Pot firmly to prevent them running up tall in a mixture of good loam, one-seventh of manure, and sand. If kept for a time in a temperature of 60° they will soon commence to flower.

Begonia Ingrami.—Those that have been wintered in 2-inch pots may be placed at once into 4-inch size. Where there is a good stock of these plants pinch the shoots of half of them, selecting the smallest plants for the purpose, while the remainder may be allowed to extend, and in a short time they will be ready for the stove. Cut back plants that have been doing duty more or less all winter, and insert a good batch of cuttings. These will root freely enough if inserted in sandy soil in pans and placed on a shelf where the atmosphere is moderately dry. The old plants of *B. Knowsleyana* may also be cut back and the necessary cuttings inserted.

Begonia weltoniensis.—This variety, with others of a similar nature, may have their old branches well shortened back. The soil may be shaken from their roots and the plants repotted in fresh, and then started into growth in a temperature of 50°. If water is applied carefully there is no need to delay potting until after they have broken into growth.

THE FLOWER GARDEN AND PLEASURE GROUND.

Verbenas.—Seedling Verbenas are not suitable for forming neat edgings or for a band or mass of one colour, being of too vigorous habit and much mixed. At the same time they are very effective for mixed beds, and also for borders. Many very pretty varieties are included in a single packet of seed. If the seed is new it germinates quickly, but if old it may be several weeks before it starts. Sow in pans of light sandy soil, cover lightly, and moisten carefully. Then plunge the pans in a rather brisk bottom heat, cover with a square of glass, and shade heavily till the seedlings appear. Keep the latter growing in gentle heat, and when of good size prick out into pans or boxes of light and fairly rich soil. When tall and strong enough, the tops of these seedlings may be taken off and struck, plants thus obtained not growing so rankly when planted out. *Verbena venosa*, an old-fashioned and useful border or bedding plant, may also be raised from seed, but root cuttings afford the best plants. Stock plants of named Verbenas should still be kept in a cool house, pit, or frame. When placed early in heat they are apt to get infested with insects, and the cuttings are also hard and wiry. Strong sappy cuttings are the most easily rooted, and these only develop into healthy plants. They may be struck in quantity as late as May.

THE BEE-KEEPER.

PRACTICAL BEE-KEEPING.—No. 29.

QUEEN INTRODUCTION.

CONTINUING my remarks on this subject from page 74, last week, it was not my intention to allude to any other method of introduction, but when reading Mr. Simmins' "B" method, it struck me that it might, in certain cases, and under some circumstances, be very useful. It must be understood, however, that I have no experience of the plan in practice, and must therefore rest content in giving Mr. Simmins's own words without comment. "When a queen is received, at once make up a nucleus to receive her; form a strong colony, take one frame of hatching brood with adhering bees, and place in a nucleus hive, say 14½ inches by 4¾ inches, by 9 inches deep inside, then shake off most of the bees from another comb into such small hive, and on either side of the one containing brood place one comb of honey. Close the entrance with perforated zinc, and place on top a sheet of straining cloth tacked to a simple

frame. Thus securely confined, and having ample ventilation, they are to be taken into a warm dark room. In a few minutes, finding themselves confined and queenless, a great uproar will be heard. Now slide frame of strainer cloth just off one corner and let queen run in, keeping bees back with little smoke if necessary. Close again, and let them remain indoors until the third day, when stand out where desired. After a day or two give another frame of hatching brood, which repeat at intervals of seven days, or as often as they appear able to cover more combs until well established. In this case the bees are reduced to exactly the same conditions as the recently confined queen."

The advantage of being able, by some one of the methods described in this and the preceding paper, to supersede and introduce new queens is very great. In some apiaries this power is abused. Bee-keepers of a certain stamp are never content to leave well alone. No doubt it is most proper to attempt to improve, but it is wise to leave "well" alone until there is a fair prospect of making it "better." Stocks are disturbed too often; queens are superseded at all seasons, sometimes necessarily, but more often without good cause. A bee-keeper is often—especially in his early years, when he is buying experience at the usual dear price—fidgetty, and wants to be "doing something." He cannot understand that his interference may not only not benefit a stock, but may actually retard it, and in some cases ruin it. Let such bee-keepers think twice before destroying a queen in order to supersede her! If they are sure that the manipulation is a wise one, taking everything into consideration, it must be done without delay, whatever the time of the year may be, "unless it is in the coldest months;" but where possible all re-queening should be done either in early spring or in late autumn. Nothing is then lost, but much is gained. The danger of purchasing queens without proper precautions has already been alluded to, and no further comment is therefore necessary. Every bee-keeper should at least make a trial of the direct introduction method, but it will be advisable to do so on a small scale. Success will give confidence, and confidence having once been secured, the "cages" and other paraphernalia to which we have been accustomed will be swept away and consigned to the sea of oblivion.—FELIX.

BEEES WEARING OUT AT THE HEATHER. RIPENING HONEY.

SUFFICIENT has been said on the above both by "A Hallamshire Bee-keeper" and myself. Your readers have had our opinions and experience, so I do not think prolonging of the discussion would be advantageous, but I will touch a salient point or two of "A Hallamshire Bee-keeper's" assertions. First, in regard to bees dwindling at the Heather, "A Hallamshire Bee-keeper" seems to misunderstand what I meant by "I have witnessed hives at the moors having nearly all their bees lost, but not by working on the Heather, but by some occult influence of Heather or season I cannot explain." The explanation of the above is the bees died from some cause, not by working upon the Heather, nor by flying out at unfavourable times, nor by being lost on their homeward journey, but the bees died within their hives and were thrown out, and in some seasons I have witnessed bins of dead bees lying at every hive equal to ordinary swarms, and when neither robbing nor fighting had taken place either. Can "A Hallamshire Bee-keeper" help to explain? I cannot, and in all other respects my opinion is still the same as I have previously stated. In regard to bees dwindling there is still much to learn. Judicious crossing is the antidote to weak constitutions, but what about nocturnal enemies to bees? I have never observed a single line upon that, unless it was the toad. Is there no creature that preys upon bees after we bee-keepers are sound asleep? I am inclined to think there is. This year when heaps of drones were lying dead in front of the hives at dusk not one could be seen at sunrise. I saw no hedgehogs, but will they confine their appetite to dead ones only? I know something of their carnivorous and insect-eating propensities, and what a number they could consume at one meal, and how easily the bees would be caught during a honey glut. Then the wagtails during the day consume many dead ones, and probably living bees too. For a number of years (at the moors) I have observed on the tops of the hives large quantities of droppings, composed wholly of digested and semi-digested bees, and judging from the size of these the animal could not be less in size than a large owl. Is it possible this is an enemy to bees hitherto unsuspected? Whatever it is that eats bees at the Heather there need be no question but that many are eaten by enemies unknown to us, but which we should endeavour to find out.

I trust these remarks will make things clear to "A Hallamshire Bee-keeper."

BEES CHANGING THEIR WORKING GROUND.

I cannot alter my opinion regarding bees changing their working ground frequently at different time of the day, suitable to the flow of honey, for I have witnessed the phenomenon so often. In regard to bees working only when the sun shines, there is much truth in that, but still our finest honey days are when the sun is obscured behind a sultry and peculiar haze with a temperature of 65° to 75° Fahr. As the sun brightens it often brings along with it a parching drought that puts an end to all honey gathering, often for the season too. Honey under a bright sunshine is usually most plentiful when the temperature is not higher than from 70° to 75° in the shade. The time bright sunshine is most beneficial to bees is during the spring months, and for a few days before the sultry honey gathering ones which often precedes a thunderstorm and ends the honey season.

As already stated I will not prolong the discussion, but will, for the benefit of your readers, explain that honey unsealed may be ready for sealing to-day, but if the interior of a hive is cooled to a low temperature the honey therein may contain much water to-morrow. The same thing in addition to losing its flavour occurs when kept any length of time exposed to the atmosphere, hence one of the reasons honey deteriorates in quality when put through a ripening process.

Many modern innovation and invention for the management of bees are hindrances rather than otherwise. To wit, the feeding or "pick-nicking" bees in the spring with sweetened water wears out the bees, and other mischief follows. If bees are in search for water they will not provide themselves with it from that sweetened with sugar, but while flying long on the wing in the intervals of sipping it they discharge the water, retaining the sugar only. This act of the bees is easily observed by placing yourself so that the bees are between you and the sun. A proof that bees do not depend on water for breeding purposes from honey is the fact when honey is most plentiful, and breeding going on briskly, the marshes and water resorts are more frequented by bees than when honey is scarcer.—A. L. B. K.

TRADE CATALOGUES RECEIVED.

Samuel Yates, 16 and 18, Old Millgate, Manchester.—*Seeds and Garden Requisites, 1888.*

Hogg & Wood, Coldstream-on-Tweed.—*Garden Seed List for 1888.*

Vilmorin, Andrieux, & Co., 4, Quai de la Mégisserie, Paris.—*General Catalogue of Seeds for 1888.*

TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Subscription for the Journal (F. Walker).—The amount received will insure the Journal being posted to your address at the antipodes till January, 1889, or for eleven months from the date of the

present issue. We are sorry that an occasional number should fail to reach its destination, but on the whole we have few complaints on the subject from subscribers in Australasia.

Cucumber Root Disease (R. T., Oporto).—It is quite probable your plants are attacked with the disease that has been illustrated in our columns by Mr. W. G. Smith, and for which a solution of salus applied to the soil has been recommended by him as a preventive. We understand, however, that salus is not now prepared for sale. Roast the soil so as to destroy all germs, moistening it before using. This scorching does not impair, but rather increases its fertility.

Camellia Buds Falling (R. S., Southampton).—There is no doubt whatever that the dry heated air from the hot-water pipes is the chief cause of the evil; it is possible, too, that the plants in pots do not have the support they need, and a gentle stimulant such as soot water might be beneficial. If the stage is of open latticework you would do well to cover it with something that would hold a layer of gravel, and by keeping this moist and syringing the pots occasionally the flowers of the Camellias would probably expand.

Peaches for Planting (G. A.).—You cannot do better than plant the Nectarine you name, Pine Apple. If you want a succession of Peaches, plant Grosse Mignonne, Bellegarde, and Barrington. If you plant Royal George it would ripen before you had finished gathering Grosse Mignonne. Alexandra Noblesse is a splendid Peach, but tender in the skin, and is easily damaged; at the same time it is rather shy. Dymond is an excellent Peach, but not better than Royal George. If you could place the last-named at the coolest portion in the house, then we should prefer it to Bellegarde, for the flavour is superior.

Clematis Jackmanni (A. R.).—We think you had better not prune your plant until March. It is not at all uncommon for the first early growths to be killed or seriously injured by sharp frosts; and if you cut back the stems now the back buds will be forced into growth the sooner, possibly to be injured, whereas by allowing the first growths, now pushing, to expand they will take the sap, the lower buds remaining dormant the longer. Towards the end of March, or when severe frosts are no longer expected, cut back the shoots to the prominent buds on the stems, not below them, and these will start strongly, and flowers will be produced abundantly in due season. The extension of the early growths to which you refer will not weaken the plant, but incite root action ready for supporting the later growths when the first are removed in pruning.

Unripe Vine Wood (S. K.).—The laterals you have sent are not only immature, but essentially weak, and indicate that the Vines are in a very unsatisfactory state. The composition of the border does not appear to be faulty, but either some mistake has been made in respect to insufficient pruning after planting, or in heating and ventilation. What length were the canes when planted, to what extent were they shortened, and what length and strength of growth did they make the first season? If you answer these questions, and indicate the time of starting the Vines, the temperature maintained, and the general routine of management pursued, we may perhaps be able to give a more definite reply on the subject, at present we are not in possession of information that is necessary for answering your letter satisfactorily to ourselves. If there has been no mistake in management we should be inclined to suspect the presence of the phylloxera, but have not sufficient grounds.

Successful Tree Planting (C. B.).—While we congratulate you on your success, we are scarcely in a position to say it is unprecedented, because we have not known a similar number of trees of the same age removed under exactly the same conditions as to soil and weather influences. Speaking generally, we think there are many gardeners who could transplant the same number of trees successfully. We, however, print your question as the best means of eliciting the required information. "At the end of 1886 and beginning of 1887 I prepared and planted ten and a quarter acres with standard fruit trees, ranging from five to nine years old—Apples, Pears, Plums, and Damsons, in all 710 trees. Notwithstanding the very hot, dry, trying summer for newly planted trees, not one has died, but all are healthy and strong, and the root action all that could be desired. The only watering during the hottest time was to twelve large trees that looked sickly, but these recovered their healthy condition. I should like to know if my success is unprecedented." What have gardeners and tree planters to say on this record of good work?

Roses for the Neighbourhood of a Town (Mum Grower).—You cannot do better than plant the following H.P.'s—Général Jacqueminot, scarlet crimson, splendid in the bud; Louis Van Houtte, reddish scarlet, heavily shaded with purple, a grand dark rose; Madame George Paul, bright rose, heavily shaded with violet purple; Prince Camille de Rohan, dark maroon crimson, one of the finest of dark Roses; Abel Carrière, purplish crimson, with violet and black reflection; Mons. Boncenne, intensely rich crimson. Tea varieties; Gloire de Dijon, fawn tinged with salmon and rose; Grace Darling, base of petals creamy white, deeply tinted and shaded pinkish peach, full, very free; Madame Lambard, salmon pink, shaded rose, given to sporting, sometimes the blooms are of a rich peach colour, at others of a coppery hue, and occasionally these two features are distinctly prominent; Etendard de Jeanne d'Arc, cream, changing to pure white, very full; Marie Van Houtte, yellowish white, slightly shaded rose; and Rubens, white, delicately tinted with rose. Procure strong and especially well-rooted plants, even if you pay a little extra for them, weak and ill-rooted plants not gaining strength near towns in the same way as in country gardens.

Furnace not Drawing (*A Thirty-years Subscriber*).—Something is radically wrong with the way the flue from the boiler furnace enters that of the part underground, or in the flue itself. We had a similar case to deal with only a short time ago. Our conservatory boiler—a wedge saddle—had its flue and chimney near the conservatory, a new chimney having been made expressly for it since the boiler itself would not draw, as the old "flue has to pass under ground for a long distance" before the smoke reached the chimney. The new chimney was both "a nuisance and an eyesore." We had the boiler reset, and only took the simple precaution to assure the flue, as it left the boiler, having a gentle rise into the old underground disused flue. The fire being lighted, all the smoke came out at the furnace door—even the ashpit. There was the usual twitter, "I told you so,"—indeed, so said everybody; and, as often happens, everybody was wrong. We had taken the precaution to put in a soot door at the bottom of the chimney shaft, and, opening this, the smoke came out freely. Nothing was wrong with the flue, but for a time the smoke would not ascend the upright shaft. We introduced some straw into the chimney through the soot door, and tried to light it with a taper, but the flame of the taper was soon extinguished. The flue had been full of foul air, and no wonder, as it had been disused; but it was stated to be damp, and would never draw. We let the smoke come out of the soot door, and lighted the straw outside, but it would not draw through the soot door up the chimney—in fact, the issuing smoke from the flue put out the flame; but the putting out was only making way for the ascent of the smoke through the escape of the foul air by the soot door. After a time the chimney drew so well that it took the smoke and flame of straw 3 feet outside the soot door—roaring like a furnace, and the soot door being shut has not smoked since. In hope of being of service, we think the experience worth recording. How it may apply to your case can only be determined on the spot. We should certainly try something before going to the expense you suggest. If you suffer from down draught, perhaps a cow—a spinner—on the chimney would make all right; but we apprehend the fault lies in the boiler flue not having sufficient "rise" into the underground one. If you look through the advertisements of the present and a few back numbers of the Journal you will find gas-heated boilers that may be useful should you decide to employ gas. Provision must be made for the exit of fumes, a small pipe sufficing, and receptacles are necessary for collecting the moisture that is produced by the consumption of gas.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*Lady Gardener*).—*Garrya elliptica*. (*W. B. R.*)—1, A good variety of *Cœlogne cristata*; 2, A variety of *Dendrobium nobile* resembling one called *cerulescens*; 3, *Sophranitis grandiflora*. (*T.*)—*Pteris longifolia*.

COVENT GARDEN MARKET.—FEBRUARY 1ST.

No alteration to quote this week this week with the exception of Cobs, for which there is scarcely an inquiry.

WINTER FOOD FOR SHEEP AND CATTLE.

MUCH nonsense is written about a mild winter affecting the price of food for the animals of the farm, and we must own to a feeling of wonder that writers upon agriculture should allow themselves such latitude, but it has become so much a habit with many literateurs to impart a tinge—often something more—of sensationalism to their work that mere force of habit may perhaps be pleaded in extenuation of what in our opinion is a lamentable fault. A late autumn or early spring does undoubtedly afford the grazier much valuable food, but a few weeks of mild weather during midwinter have no appreciable effect upon growth, and certainly contribute nothing to our store of winter food.

A short crop of hay, and very generally an equal falling off in the root crop, have straitened the means of so many farmers, that it cannot fail to prove useful if we invite attention to the provision of winter food in view of some degree of future improvement in practice. A light land farmer whom we met recently was loud in praise of his stack silage. We entirely agree with him that ensilage affords a much larger bulk of wholesome nourishing food than can be had from hay or straw, and it is in the power of every farmer to make such provision of it as he require irrespective of climate or weather. Prejudice has kept many a man from trying his hand at making silage, but enough sensible men have now taken the matter up in real earnest to induce others to follow, and ensilage has taken its legitimate place among the regular operations of the farm. The best raw material for silage is any forage growth which can be had before it has gone beyond the flowering stage. Seed development makes such heavy demands upon the economy of every plant that a heavy per-centage of nutriment is absorbed from leaf and stalk, which becomes proportionately less valuable for feeding purposes, no matter how it may afterwards be prepared for storage or use. Dealers in such nostrums as cattle spice tell us that by scattering a certain quantity of it among such inferior forage we render it both palatable and nourishing. Do we? Really, it might be expected that even such men might give farmers credit for the possession of sufficient intelligence to avoid the waste of money upon their so-called specifics; yet the lamentable fact remains that money is so spent, even under a heavy depression, which should render everyone careful to avoid mistakes.

We have repeatedly called attention to the value of unthreshed

Oats when chaffed with the straw, and we again strongly recommend it as one of the very best articles of winter diet for cattle, horses, and sheep. There is, however, much difference in the nutritive properties of such straw, some having twice the feeding value of other straw. The least nourishing and most indigestible straw is that from poor land, and which has become dead ripe before harvest; the best is from rich soil, and which was mown immediately after the grain passed out of the milky stage. By the term of milky stage we mean when a white milk-like juice can be squeezed out of the grain; when this is at an end the grain is sufficiently developed for harvesting. Very hard, dry, over-ripe straw contains so much woody fibre that it has a low feeding value, and makes a heavy tax upon an animal's digestive organs. We altogether object to having food pass through its stomach undigested, as such straw often does, just as uncrushed Oats pass through the bowels of old sheep, horses, and cattle. As a case in point, we may mention that of an old horse sent from the home farm as a garden horse. Our orders that it should have all its food chaffed or crushed were disobeyed, and we at length discovered that the poor animal, though consuming much food, was being slowly starved. It was at once replaced by a younger horse, and subsequently recovered health and vigour so as to be really useful upon the farm.

Next in general value to Oat straw when chaffed we may place Bean straw, which is richer in digestible constituents, and is more nutritious than any other. Then comes Pea and Barley straw both which, when chaffed, should have the pods and grain chaff mixed with it, as being much more nutritious than the straw itself. We have in recent articles explained how highly we value unchaffed Pea straw for the ewes. In either form it is most useful and we may mention that a flock of healthy young ewes have recently been having chaffed Pea straw with some Oats in folds upon a stout piece of Mustard, to be followed by a crop of Barley. Meadow hay is generally held in reserve for the dairy cows when there is such a herd, not simply for its nourishing properties, but rather because it is so sweet and wholesome that it imparts no unpleasant flavour to the butter at this season of the year. For other purposes as hay can be dispensed with, and it should at any rate be kept untouched as long as possible, either to be turned to under the difficulties of a late spring for a most welcome and valuable supply of nourishing wholesome food, or if not wanted to be sold, and so contribute something towards the Lady Day rent.

WORK ON THE HOME FARM.

Gladly do we record the fact that the whole of our ploughing in arrears is finished, and that the sowing of Peas and Tares has already been done. Wheat is a strong full plant; so, too, are winter Oats and Beans. We feel hopeful now that there will be no serious loss among Beans such as happened last winter, and with a fair seed time for spring corn we hope to have a full plant upon all our farms this year. Given this it shall be our endeavour to render every crop as vigorous and productive as possible. Our arrangements for the application of chemical manures are now under consideration, for we hold that in order to render farm crops profitable now the soil must contain an ample store of manurial constituents, and the plants of the farm, just like the animals, must be kept going in unchecked vigour from the first. We must have quantity in combination with quality if we would hold our own under foreign competition. The fertility of the soil must be fully sustained, and every perch of farm land rendered productive of a profitable crop. Such a standard is undoubtedly a high one, but we cannot rest content with anything short of it. Why, indeed, should we? Dire necessity is teaching us most valuable lessons of thrift, perseverance, and energetic action, and anything like easy-going action in farming practice is altogether a thing of the past.

Glad are we to find more attention being given to dairy farming, for it is a standing reproach to the British farmer that importations of butter, condensed milk, and eggs have reached such huge proportions. Success with either dairy produce or poultry is simply a matter of detail. Eggs and chickens are always a saleable commodity, and first-class butter soon commands a first-class price. It takes some little time to establish a reputation for dairy produce. Once gained it has only to be sustained in order to render it fully profitable. But a farmer must not leave this important matter to the sole management of his wife or servants, he must see that the cows are well bred, well tended, and that the land affords an ample store of the best food for them. We have now plenty of Rye for cows to graze, and the effect upon the butter is almost equal to that of grass in spring.

BRITISH CULTIVATION OF TOBACCO.

AN adjourned conference, presided over by Sir E. Birkbeck, was held recently at the Salisbury Hotel, for the purpose of forming an Association for resuscitating and encouraging Tobacco cultivation in England, Scotland, and Ireland under profitable conditions. The report of a Committee previously appointed, presented by Mr. Kains-Jackson, stated that the East and West India Dock Company have offered free storage in London for the present year where Tobacco can be prepared to compete for the £50 prize offered by the London Chamber of Commerce. The samples grown in Great Britain have been remarkably free from damage, the injury done by insects being insignificant; but out of sixty-four varieties tried opinion favoured only about six as being suited for home cultivation. The Committee were of opinion that, all things considered, the experiments were very satisfactory and encouraging, and that Tobacco cultivation in England, Ireland, and Scotland might be easily carried out and become a profitable British industry which in the course of time would probably be taken up by tenant farmers in suitable districts. The Chairman stated that letters on the subject had been received from Lord Walsingham, Lord Torrington, Mr. Mark Stewart, M.P., Mr. Coiman, Mr. E. Beck (Prince of Wales's agent), and others. One question, he said, would be whether the Treasury would allow the Association to issue licences for growing Tobacco in the United Kingdom; another whether a deputation should ask the Chancellor of the Exchequer to allow a drawback, or whether there should be a duty of so much per acre. Mr. Sharman, of Messrs. Carter & Co., stated that the firm had received nearly 400 letters on the subject, and that Tobacco had been successfully grown in Wales and in Ireland. Mr. Wright, of Sales, Pollard & Co., said that English manufacturers generally would be glad to take the matter up, and that his firm had purchased Lord Walsingham's Tobacco. On the motion of Mr. Hastings of Devonshire, seconded by Mr. Sharman, an Association was formed, and it was further resolved that Sir E. Birkbeck shall be Chairman, and the following gentlemen members of the Council: Lord Walsingham, Mr. W. L. Wigan, Mr. Kains-Jackson, Mr. E. J. Beale, Mr. Mitchell-Henry, Mr. J. Sutton, Mr. Veitch, Mr. Mark Stewart, M.P., Mr. C. H. Sharman, and Mr. Faunce De Laune, with power to add to their number. It was also agreed to ask Lord Harris to become President. In the course of conversation it was stated by Mr. Lewis Morris, of the London Chamber of Commerce, that Tobacco from the South of Europe can be delivered in England at 3d. per pound, and with this British Tobacco would have to compete. A specimen of the latter, grown unsheltered in a 20-acre field, was shown to him and declared to be serviceable Tobacco for pipes. Sir Spencer Wilson said he had some difficulty in getting rid of his stock, and that his farm was visited twenty-four times by the excise-man. A vote of thanks to the Chairman terminated the proceedings.

MUCH attention has been drawn to Tobacco culture in this country lately, and an Association has been formed to promote the interests of those engaged in the work, but British farmers will be wise to pause before they engage in an undertaking of such very uncertain character. Apparently the most that the advocates of home culture can state in its favour is that a working man's Tobacco of medium quality can be produced here, and this would have to compete with continental grown Tobacco of a generally superior character that can be purchased at 3d. per lb. Some home-grown Tobacco has been sold at as low prices as 1d. and ½d. per lb., and such imaginary prices as 6d. to 8d. per lb. cannot be realised.

The methods of preparation also are not well understood, and much of the quality of Tobacco is dependent upon its due ripening, drying, or fermentation in the leaf before it reaches the manufacturers' hands. I have lately had samples of Tobacco, cigars, and cigarettes from two sources given me for trial, and though they had been carefully manufactured and were rather taking in appearance, they were distinguished by a flat herby taste or an unpleasant scorching effect on the tongue and throat. During the past thirty years I have frequently grown Tobacco in gardens, but it was always useless for all purposes except ordinary fumigating in plant houses.—AN OLD GROWER AND SMOKER.

THE above was crowded out of our columns last week, and in the meantime we have received the following report of an interview on the subject of Tobacco culture in this country with Messrs James Carter and Co., by a representative of "Barker's Trade and Finance":—

TWO YEARS' EXPERIMENTS.

"What judgment have you formed," asked our representative of Messrs. Carter & Co.'s manager, "upon the experiments of the last two years?"

"We have established this, at all events," was the reply, "that Tobacco can be grown in this country as a profitable farm crop. Our first experiments were made in the spring of 1886, at Holloway Farm, at the foot of Bromley Hill, in Kent. We got our first crop promptly into market, and it was purchased in the month of December of the same year by Messrs. Cope, of Liverpool, and we hope to be able to show the manufactured article from Messrs. Cope at Wednesday's meeting, January 18th. Last year we planted an acre of Tobacco upon the same land, being determined to ascertain whether Tobacco can be grown for successive years upon the same ground. All that we did was to apply about ten cartloads of farmyard manure, some ashes, and 5 or 6 cwts. of special artificial manure. The result was a success, notwithstanding that a portion of the land was more or less overshadowed by trees, and

the soil of a shallow and light description. The summer months last year were remarkably deficient in rainfall, and this had the effect of diminishing the average weight per plant. Then again, in August and September there was a considerable rainfall, accompanied by cold nights, just at the time when warm weather was needed; while on the 1st of September there was a gale of unusual severity, which destroyed not only Tobacco but other growing crops. These facts, and the probability of early frosts, show that it is not safe to leave the Tobacco plants upon the land after the 15th of September. In our judgment neither the season of 1886 nor that of 1887 was as favourable for Tobacco cultivation as we could desire; but the experiments which we carried out simultaneously with Lord Walsingham, Sir Edward Birkbeck, M.P., and Mr. Faunce de Laune, have, nevertheless, been so successful that next season they are likely to take place upon a considerably extended scale."

THE BEST VARIETIES.

"What varieties of Tobacco do you think most suited to the English soil?"

"Well, the experiments this year were made with no fewer than sixty-four varieties which we obtained from every possible Tobacco-growing country—from the United States, from China and Japan, from Turkey, and from many other places. As a result, we are of opinion that the kinds best adapted to our English summer, and calculated to give the largest return, are the Big Frederick, the Kentucky, the Connecticut, and a 'Havana' Tobacco which reaches us from America. The average weight (green) of the Big Frederick was about 1 lb. 11 ozs. per plant; of the Kentucky, 1 lb. 9 ozs.; of the Connecticut, 1 lb. 10 ozs.; and of the 'Havana,' 1 lb. 7 ozs. Other varieties ranged from 8 ozs. to 1 lb. 5 ozs. per plant. Allowing the full acre to have been occupied with the varieties of which we took special notice of weights, the number of plants would be 4840, and the gross weight 2 tons 14 cwt., or in round figures 6000 lbs. As the plants shrink from 60 to 65 per cent. in the process of drying and stripping from the main stem, there should remain about 1500 lbs. of Tobacco as the produce of 4840 plants. This quantity, calculated upon a sale price of about 6d. per lb., would show a return of upwards of £40 per acre."

AN ESTIMATED BALANCE SHEET.

"We have," continued Messrs. Carter & Co.'s manager, prepared a number of balance sheets, which we think fairly show the figures as they would affect the farmer. Let us take that relating to the Big Frederick Tobacco, which is an early kind, a strong grower, and one specially suited to our English climate. On the credit side of the account we put the sum of £50 from the sale of 3000 lbs. of Tobacco at 4d. per lb., which is the lowest price which Tobacco of average quality is likely to fetch. Then come our expenses. We put the rent of an acre of land, with buildings and incidental charges, at £3; we allow for ploughing and harrowing, for farmyard manure and guano, for the plants, for pruning, topping, and other manual labour; for cutting and carting, curing and stripping, sorting and packing. We figure out all these charges in detail, upon the basis of our own experiments, and we find the total expenditure of the farmer upon this acre of land would be £24 17s. 8d., giving him a profit of £25 2s. 4d. This, he it remembered, is for a crop which can be grown on the same land year after year."

FURTHER EXPERIENCE NEEDED.

"Have you any reason for discouragement?" asked our representative.

"No, we can scarcely say that," was the reply. "Our great difficulty consists in want of experience. All those who have experimented with Tobacco have, of course, obtained the services of skilled Americans to assist in the preparation of this English-grown Tobacco, but there are certain circumstances, climatic and otherwise, which make a different course of proceeding to that followed in the States necessary in this country. No doubt, however, we shall get over these troubles, particularly if the present experiments are continued on a larger scale. They would, of course, be greatly developed if the Government could be induced to place as few impediments as possible in the way of the cultivation. Our personal experience is that the Inland Revenue authorities are most desirous of helping us as far as is consistent with the regulations. But they are bound down by red tape, and to such an extent that it is almost a wonder the growers and the Government representatives get along so comfortably as they do. If we produced ten times as much Tobacco as we now do it would not interfere with the Revenue, and therefore it is a little difficult to see why such a fuss is made about it. One of the things we need is a simple method of dealing with the refuse. The stalk of the Tobacco plant, for example, has no commercial value yet we cannot burn it till the Excise officers come along and give approval to the operation."

A CENTRAL BONDED WAREHOUSE.

"Do you not think that, under some well-defined scheme, the Customs difficulty could be very much modified?"

"Yes; and on that point I have made a suggestion which is likely to be adopted. It is that there should be established—say in London—a bonded warehouse, to which the Tobacco from various farms might be sent, and where the whole of the stages, from the curing to the putting of the article in the market ready for the smoker, might be gone through. Or, if it is more desirable, there might be a number of bonded warehouses in the Tobacco-growing districts, where the plants could be sent by the farmers, and where the curing could take place. In this way the labour of the Excise officials would be diminished, while the

farmer would be sure that his produce would be properly treated. It does not matter very much to the dairy farmer whether he sends away milk, or milk in the shape of cheese. In the same way, if the farmer can only protect himself, it will not matter whether the Tobacco leaves his premises in a cured state, or just as it is taken from the field. I ought to have said before that in the most favourable localities in the United States the crop is not always a success. Therefore it is reasonable to suppose that there is always a possibility of an increased value being obtained for the English crop, by reason of the occasional short deliveries from abroad. Though we may not have the high degree of summer heat or persistent sunshine peculiar to some countries where Tobacco is largely grown, yet we are happily more or less free from the tornadoes and hailstorms that frequently devastate the Tobacco crops in America and elsewhere."

A CHANCE FOR A COMPANY.

"How do you think the farmer could best be helped?"

"The best way would be for the Tobacco-growers to unite with capitalists in forming a syndicate, the members of which work together to the promotion of a common end. Not only might further experiments be carried out under their auspices, but when the industry has developed it would offer important advantages, not only as to the curing of the crop and the preparation of it for market, but for generally upholding the right of Tobacco cultivators to get a fair remuneration for their outlay. If a syndicate were established in the way I suggest, and operated upon each year's crop, with the aid of specialists trained for the purpose, there is no question that some excellent English Tobacco would be produced, which would run the imported article very hard. I do not assert that the farmers of Kent and Norfolk are going to turn out Tobacco equal to the finest Havana leaves, but they will undoubtedly produce a valuable article which will largely enter into consumption."

THE TOBACCO DUTIES.

"What is the object of your conference?"

"We shall probably arrange for a Bill to be introduced into Parliament, with a view to making the cultivation of Tobacco more easy. The measure will most likely aim at removing some of the existing regulations, which are frivolous and vexatious, and at obtaining for a certain number of years a rebate, say of 6d. or 1s. a pound, upon the duty paid on English-grown Tobacco. This slight advantage to the home grower ought to put him on his legs. Parliament, we think, will be inclined to look the more favourably on the proposal because it is in Ireland that the cultivation of Tobacco will probably be on a more extensive scale than anywhere else in the British islands. Experiments have recently been made in Dublin county with the result that the samples of Tobacco produced were highly spoken of by leading manufacturers in Dublin. The soil seems well suited for the growth of the plant. It looks, therefore, as if Tobacco cultivation is going to be a good thing for the Irish people as well as for the English farmer. So far, of course, there has been no money made by those who have carried out the experiments, nor is it likely that there will be until a syndicate takes the matter in hand and develops a promising new industry for the British agriculturist. So far as we are concerned—and we are sure we can say the same of others who have made experiments simultaneously with ourselves—it has been a labour of love. We shall only be too glad if, by any effort of ours, we have helped to draw attention to a source of wealth which has for many years lain dormant, chiefly for fiscal reasons, but which is certainly capable of being revived. Briefly, the question is this. We consume annually some 50,000,000 lbs. of Tobacco. Are we to grow some of it ourselves, as we unquestionably can do, or shall we continue to buy it entirely from abroad?"

REMARKS.

22nd.—Dull and damp all day.
 23rd.—A lovely spring day.
 24th.—Fair morning; bright afternoon and evening.
 25th.—Dull and jampearly; fine and generally bright day; gale at night.
 26th.—Gale all day, abating in the evening; morning dull and damp; afternoon generally bright; clear evening and night.
 27th.—Fine, bright morning; cloudy afternoon, with showers of rain and sleet; bright evening with one or two squalls of rain, hail, snow, and sleet.
 28th.—Fine and bright throughout, lunar eclipse, well seen except at intervals between 10.30 and midnight, when fleecy clouds drove across.
 Temperature warmer than last week and above the average. Rainfall still deficient.—G. J. SIMONS.

PLAIN WORDS TO SOME
GARDENERS.

NO one can follow the career of a gardener for thirty or forty years without becoming acquainted with the educational status of a great number of fellow workers in the craft. Letters of various kinds from various men are received during that time, all indicating the capacity of the writers as correspondents. In several instances marked improvement will be apparent after a lapse of years, showing plainly the results of persevering endeavour in the important work of self-improvement; but in many others there is no appreciable advance on the original low standard of bad writing, bad spelling, and bad grammar. It is lamentable that this should be so, but it is a fact, and it is better, in the true interests of the gardening community, that this should be brought to the surface than ignored as if there were no grounds for the allegation.

That there are well educated men in the ranks of British gardeners goes without saying, and not a few of them have acquired their attainments mainly by their own exertions after their short term of schoolboy life ceased; and this fact renders it the less excusable on the part of others whose lethargy or misapplied time have unfortunately dragged down the average educational standard of gardeners to such a low level. It is nothing less than pitiable that more pains are not taken by illiterate men who have managed to get enrolled in the ranks of professional gardeners to improve themselves in writing and plain education. Not in penmanship alone are so many deficient, for that is perhaps the smallest fault, but carelessness, not to say slovenliness, of expression and outrages in spelling are more to be deplored. How so many men of good appearance and general conduct fail to see their shortcomings in the very rudiments of education is almost astounding. Many readers of these lines must have heard expressions of surprise from educated persons that gardeners with whom they have come in contact—men of fair competency in their calling, respectful in demeanour, and some of them almost dandies in appearance—should betray their scholastic ignorance in a five minutes' conversation; but when this is stereotyped on paper in the form of letters to friends or employers, orders to seedsmen and nurserymen, or in the naming of flowers or other exhibits at shows, the illiteracy is intensified, and in far too many instances deplorable.

The most common excuse on the part of men of "no education" is that it is "not their fault, as they had no schooling." It is certainly not the fault of a man that his parents could not, or did not, send him to school when he was a boy; but it is his fault most decidedly that he did not himself strive in advancing youth and early manhood to spell correctly and write an intelligent letter; and there is positively no excuse for exhibitors at shows making such flagrant and often ludicrous blunders in nomenclature as are so obtrusive and humiliating, for the correct spelling of every name is to be found in catalogues. These names are read over and over again in print, yet when written down are tortured into something of which every gardener ought to be ashamed.

It is quite true that such lazily illiterate men seldom rise to good positions. One here and there may get hoisted above his fellows by a fluke; but in fair open competition he must be left at the bottom of the ladder to grovel along as best he can, grumbling out a lifetime because his 'abilities' are not recognised, for the fact cannot be disguised that those who know the least think the most of themselves. Many a valuable appointment has been lost by the

misspelt ill-expressed letters of applicants, and many a one gained because of the intelligence displayed by candidates seeking to fill good vacancies in the gardening world.

It is a rule with gentlemen who advertise for gardeners to first cast aside all letters that are obviously written by men who have made no serious endeavour to educate themselves; and it is a rule with nurserymen, too, and other persons who are applied to to supply gardeners, to send the best educated men and otherwise qualified to the best places. This is only natural and right—natural because the patron of a gardener will not incur the risk of receiving a notification of this kind from a customer or friend—"William Hobbs you sent me is a good worker, but very ignorant; he cannot write a label fit to be seen, much less a letter to me when I am from home;" and right, because the man who strives the most earnestly to fit himself in every way for an important charge is the most deserving of advancement; and, moreover, the gardener who educates himself, as not a few of the best have done in grammar, spelling, composition, and other necessary attainments, cannot do so without acquiring information bearing directly on his calling, for when once a course of evening improvement is resolutely pursued the mind is led on step by step from subject to subject, never resting content but ever searching for knowledge, and its possessor of necessity becomes a better gardener and more accomplished man. Much more might be said on this subject, and perhaps will be said by some well qualified correspondents, for it is undoubtedly important, and for various reasons has scarcely had the prominence accorded to it that it fairly demands.—EXPERIENTIA DOCET.

CROPS THAT PAY.

I HAVE said Mushrooms pay, and advised the preparation of the manure and the making of beds at once. I did so because I prefer to obtain manure after Christmas rather than earlier in the season, then make the beds as early as the material can be prepared. I have an object in this, and it may be of advantage to others, and that is the reason I allude to this crop again. There is a tendency in the neighbourhood of towns to use "green food" for horses during the summer, and often well on into the autumn, and the manure from horses fed on this material takes too much sweetening to be agreeable, or to be certain that the crop is going to be a success instead of a failure. Manure that is offensive when the beds are made up is not in the condition in which the spawn will run. The man who can make a good hotbed can make Mushroom beds from which a paying crop can be obtained. Selfishness must be abandoned, for it is the reverse of economy to make the beds too small, thinking of saving outlay in manure by so doing. Such beds cool too quickly, which often means failure. On the other hand they must not be too large, thinking to snatch a "big" yield with but little trouble, for instead of the crop paying it may fail. Extra large beds (I mean too wide and too high; they can be as long as the cultivator wishes) often heat too violently and kill the spawn.

I wish to make my notes as seasonable as I can, and therefore will try to start with those that need first attention. "Do Lettuces pay?" said a neighbouring farmer early last spring when I was busy putting out some thousands of young sturdy plants; "Don't they?" was the rejoinder. He watched them with evident interest, and I tried to induce him to try a few this year by detailing the method I was pursuing. But he has not done so, and I am afraid it is such "dilly dallying" that lands us in the deplorable condition I pointed out in my first article, and makes room for the foreigner to supply our markets. Early Lettuces, if well and quickly grown, are a very remunerative crop. Bear in mind, intending growers, that Cabbage varieties only pay very early before Cos varieties find their way into the market. When once the Cos, or "London Lettuce" as it is called, is in, no matter where it is grown, finds its

way into the market it is difficult to sell the Cabbage, however good or well grown it may be. Hardy Hammersmith and All the Year Round are the two grown. I place very little dependance in these, and only regard them as a catch crop. Those who have sheltered positions, and who reside in moderately dry localities, may do very well with them. I have given up autumn planting, simply because all the plants died. The plants are kept in frames and placed out at the same time as the Cos Lettuces, but the former are planted so that we are certain of a remunerative crop from the ground if we miss the market. Those who go in for marketing must watch the market, for it is no use going with Cabbage Lettuces when somebody else is taking Cos Lettuces. This means 4d. a dozen, perhaps 2d., while your neighbour realises a shilling from the same extent of ground, and with the expenditure of no more labour. I have been caught napping, and selling at the lowest price very soon taught me to watch the market and mend my ways. How I did so will be detailed, but it necessitated some outlay, which I managed to recover the first season, and was very well paid into the bargain. There is no better variety to grow than a good selection of Paris White. Hick's Hardy is hardier, but it needs tying, no small objection for those growing for the market. Veitch's Cos is a favourite, and may take the place of Paris White when the seed is cheaper. But those who want it do as I have done—buy a packet of seed, and if it meets with approval select some of the best and save the seed. Those who wish to make the most of things will be wise in saving the seed of any variety that suits their purpose.

Cos Lettuces to pay should be grown 1 foot apart each way. At a shilling a dozen they pay well, and the grower will not lose much if he has half that price later in the season. Those that have not sturdy plants in a frame to start with may sow at once in boxes in heat if they have glass, and then prick them off into frames; or better still, make a hotbed roughly, place 2 inches of soil over it, and then sow the seed. Do not sow too thickly, and then from this position they can be planted out. Those sown in autumn are pricked out at this season of the year singly into frames, home made, no matter how rough they are—a little protection only is needed.

For these early crops of Lettuce it is natural to ask whether we plant large plots close together, a foot apart in the row and between the plants, and our answer is, Not generally. Although some are grown on this principle, another crop always follows. The best and most convenient method is to plant in rows 2 feet apart, and 1 foot between the plants. Between these French Beans are sown, and when the Lettuces are removed they occupy the whole of the ground. Between young Strawberry plantations we always take Cos Lettuces early in the season. The early crops are planted so that they can be followed by others. Lettuces may be sown until the end of the first week in June, at intervals of three weeks from the time they are first sown outside. At one time we only grew early ones, and left later crops in the hands of others, because we thought they might miss by bolting during hot dry weather. But now that we have south borders and north borders in what was once an open field we manage to have good crops that pay from the north borders during hot summer weather. Our latest crop is from a south border. Our early Cabbages are taken from a south border planted between early Potatoes 2 feet apart. One word more—to grow good Lettuces quickly the ground must be fertile and well manured.

I had not started marketing long before I found that not only must I have Cabbage Lettuces earlier to pay, but Potatoes also to equalise the price of this crop if possible, and to have some of the "plums" I thought foreigners, or somebody else, were getting by supplying the market before I was ready. I was not content with 5s. a hamper (a hundredweight) down to 3s., when somebody else was getting from 8s. to 10s. for the same weight. I also wanted to grow Tomatoes, and had no favourable position outside. At last I succeeded, but how I managed to do so must form the subject of my next contribution.—MARKETER.

THE CULTURE OF HARDY FRUITS.

(Continued from page 78.)

THE Peach and Nectarine, as far as cultivation is concerned, may be classed as one fruit, both requiring the same treatment. Of late years the Peach out of doors has been to a great extent very much neglected, and through a variety of causes, but chiefly the unfavourable seasons for some years past, there has been partial or entire failure of the crops. Where good cultivation has not been neglected a fair measure of success has been obtained, which shows conclusively that the bad seasons we have experienced of late years are not altogether the cause of failure. That some places are more favourable for their successful cultivation than others cannot be disputed. Some are naturally well suited to their wants, while others are not, and require to be made suitable if success is desired. The requisites are a well drained substantial soil, a south, south-east, or south-west aspect, a good wall, and a border of about 5 feet well raised up well mulched with manure. The shoots must be thinly disposed, the leaves free from all insects, and the blooms protected from frost, then a good crop of fruit might be annually expected from the greater portion of the country. Glass copings were at one time considered favourable for protection, but the trees are often better without them.

The Plum, Cherry, and Apricot require similar treatment, the Apricot needing the warmest aspect, but all the stone fruit appear to do equally well in the same kind of soil, and that which is rather heavy and contains lime naturally, or which has had it applied, seems to be the best suited to their wants, with the borders kept well mulched and not disturbed in any way after the trees are planted. The wood as it is made should be allowed ample space to receive full share of light, and crowding of the branches and shoots should at all times be avoided. Some think the more shoots the more fruit, but such is not the case, and the contrary is mostly the result. The Morello Cherry is often seen thickly nailed to the walls, and frequently half the fruit falls during the stoning process. Although the Morello bears mostly on the young shoots they should not be deprived of sufficient space. I have seen trees that have been tied year after year each shoot over another until the wall even in winter time was scarcely visible. What a fine cover for insects! The fruit when too thick on the Plums and Apricots must be duly thinned, especially the larger varieties of Plums, if fine fruit is desired.

The Strawberry is an important fruit in most gardens both for dessert and preserving, and is generally fairly well cultivated; and like most other things there is more ways than one of attaining the same end in its successful culture. To obtain good results the necessary labour must not be neglected in the first place. The Strawberry requires a good soil, which should be dug 2 feet deep, adding as much manure as will form a good coating in each trench as it is turned over, and previous to planting should be made very firm. Strong runners layered into small pots and planted out as soon as well rooted make good plants and fruit well the following season. In transferring the plants to their permanent quarters see that they are previously well watered, and in planting the soil should be well rammed with a blunt stick round the plants, and a hollow space be left round each plant to hold water that may be applied after planting if needed. The distance apart can be regulated by the strength of the variety and the kind of soil they are planted in. After planting no disturbance of the soil must take place other than by hoeing to keep down weeds, all runners to be removed as they appear if not wanted. Early in the winter, as soon as frost renders wheeling on the ground an easy matter, a good mulching of long stable manure should be given them, which will answer more purposes than one. I invariably find the finest fruit is produced on maiden plants, and if a plantation is made annually no difficulty will result in obtaining good fruit. In growing specially for preserving the small fruiting sorts it is not necessary that recourse be had to such high culture, as it is a waste of time in trying to grow small varieties to a large size. Small berries with firm flesh are those which are held in the highest esteem for preserving purposes. On very light ground Strawberries (if very fine fruit is required) must be planted annually, as they do not, as a rule, produce such large fruit unless extra means in the shape of watering with liquid manure is bestowed upon them.

The Raspberry is highly esteemed in most gardens for various purposes, and generally succeeds in most soils, but, like the majority of fruits, pays for good culture. Once the ground is properly prepared it need not be moved again after the canes are planted. When planted, the canes should be cut down near to the ground. Various ways of supporting the canes are adopted, but the best way is to have two wires along each row, fastened to stout posts, and if the canes are tied to these, about 9 inches apart, they will have ample room. As soon as the fruit is gathered, the canes that have borne fruit, together with the surplus young ones,

should be cut out, which will give those that are left more room and enable them to get thoroughly matured. A good mulching of manure should be given annually, the old being removed previous to adding the new. The young canes left for fruiting should be shortened according to their strength, and duly tied to their supports, or the wind may snap them off.

The Currant, Red, White, and Black, have their various uses, and are not difficult to cultivate, but where they are judiciously attended to better results are obtained. Whether grown as bushes or trained to walls, the Red and White sorts should be kept to rods far enough apart to admit light to the fruit, the young shoots should be pinched in summer and spurred back in winter; the Black, which has its fruit chiefly on the young wood, requiring only to be kept well thinned out to prevent the branches getting too much crowded together.

The Gooseberry should be treated in much the same way as the Black Currant, as I believe more fruit can be had than by spurring the shoots, and as a portion of the crop is usually taken in a green state the trees are not as a rule overtaxed. The caterpillar plays sad havoc with the trees at times, and requires to be looked after or much mischief is done. I have known the cuckoo to materially assist in this matter. If trees are planted against walls the rod system, kept spurred, answers best, for when the rods are well secured to the wall the spurring back is a simple matter.

The Fig forms a good addition to the dessert where it is successfully cultivated, but it does not succeed in all parts of the country out of doors. They require an extra moist soil to grow in, and plenty of sun to ripen both fruit and wood. Short-jointed wood should be encouraged all over the tree and allowed plenty of room, keeping all small, useless shoots cut out, and the strong ones leave their full length, as it is at the point of these that fruit may be expected.—W. SIMPSON, *Knowsley*.

PLANTS AND FLOWERS IN THE HOUSE.

THE DINING ROOM.

ONE feature in decorating dinner and breakfast tables, which is very satisfactory, and a long step forward, is the simplicity which is now permitted, and not only permitted, but I may almost say, sought after. Before beginning to write this I had the pleasure of arranging a table laid for fourteen persons, yet I carried the whole material, plants and flowers, in a small basket. The arrangement of the table was thus—a tall seven-branched candelabrum in the centre, with two smaller candelabra at each end. Between the plates, &c., and the candelabra were dessert dishes, one dessert dish on each side, opposite and between the middle and end candelabra, with a dish at each end corner. In the middle of the table, just clear of the centre candelabrum, and between the first-noted dishes, a silver vase with a tall *Dracæna* was placed on each side. Round the base of the middle candelabrum a group of plants was arranged, comprising two Grasses and two plants of *Asparagus*. The open spaces were then filled with fronds of Parsley—so good, however, as to be like a beautiful *Todea*, then five small Maidenhair Ferns, in thumb pots, were set amongst these; a little *Selaginella* lightly covered any bare portions. Four or five crimson Tulips dotted amongst as many *Chrysanthemum* blooms, and some sprays of *Coronilla glauca* running to the cloth completed this portion. A small group at each side was then arranged between the end candelabrum and the silver vase with the plant. These were composed of small plants (in thumb pots) of *Cyperus alternifolius*, the pots hidden among *Selaginellas* and a few crimson Tulips and white *Chrysanthemums*. On two occasions in December very large blooms of *Chrysanthemums* were used. In one instance light coloured varieties, and in another dark ones. The light blooms had a ground of dark velvet, the dark ones yellow plush. About twenty to twenty-four blooms sufficed for a large table, a few good fronds of Maidenhair Ferns being the only other material used. The effect in both cases was really excellent, the more effective of the dark kinds being *Cullingfordi*, *Jeanne Délaux*, *Triomphe de la Rue des Châtelets*, a very soft and pleasing shade; and *Janira*, which shows crimson by candlelight. Of the light sorts, *Snowstorm*, *Fair Maid of Guernsey*, *Gloriosum*, *Golden Empress* and *Bronze Queen* were finest. The flowers we cut with good stems and foliage, so that there was no waste with them. One good feature with large *Chrysanthemums* is that they are altogether free from that coarseness of appearance which some people find in large Dahlias. I am sure that large *Chrysanthemums* have only to be tried as cut flowers to be appreciated.

Another pleasing arrangement we had lately was composed of small leaves of *Rex Begonias* laid on the cloth and flowers of *B. semperflorens* and *B. s. rosea* laid on each leaf, draping these with a small piece of *Adiantum gracillimum*. In autumn we had some arrangements with berries, the common *Barberry*, *Snowberry*,

Elderberry, *Rose heps*, *Haws*, *Hypericum*, *Winter Cherry*, and *Sea Buckthorn*. As an example—some long drooping shoots covered with bright *Barberries* were inserted among the branches of the candelabra and drooped over and twisted round the stalk; a few of *Snowberry*, and a very little *Elderberry* were added. Round the foot of the candelabra large bunches of *Elder* were disposed with a good quantity of its foliage. Among these sprays of *Snowberry*, and perhaps a few *Rose heps*. Single berries of *Barberry* and *Elder* were placed here and there on the cloth, but so as to appear to have dropped from the candelabrum. The smaller candelabrum was treated in the same manner, but with less material. In other cases merely a few haws and foliage, with *Rose heps* also with foliage, were laid on the cloth. The fact is, flower and fruit and foliage are all so beautiful that we may arrange them as we please, and we can hardly fail to make them acceptable. At the same time it must be conceded that when elaborate arrangements, and only the “best” flowers are permitted, we are forced to come to the conclusion that there is much labour expended, great expense in waste of flowers involved, and no better, nor perhaps even such good effects secured as the result. Who would not rather attack and rob some hoary *Beech* of his copper leaves, or trim some coloured foliage off his *Carrots*, or even, if need be, select a few claret-coloured *Vine* leaves, and make sure of giving equal satisfaction with employing some of his most cherished blossoms? It only remains to add that it is of absolute importance that thorough cleanliness is observed in all the work in connection with table decorating. Not a speck of dirt should be left on the cloth, nor for that part, on the carpet either. And when glasses are in use they ought to be kept perfectly clean, and the clearest water only used.—B.

EUCHARIS CULTURE.

YOUR correspondent, “M. D.’s,” estimate of the cultivation of the *Eucharis* in this country is sad, and depressing to reflect upon. He writes, “Few sights are more familiar when visiting gardens than to see in some out-of-the-way corner of the stove or forcing pits a number of over-potted sickly *Eucharises*. In most cases a great amount of labour has been bestowed upon them, but all to no purpose. The mite has attacked the bulbs, and they will never be any good.” A melancholy statement this. But there is good cheer in store, as “M. D.” informs us he “writes to tell his readers of an easy method which he has seen successful in restoring plants to vigorous health after years of languishing.” With reference to the mite, it seems your correspondent is of a doubting cast of mind, and has no hesitation in boldly asserting, “If there is really such an insect (as the *Eucharis* mite) he has never yet made its acquaintance,” and asks to be “pardoned for doubting its existence.” It is quite possible that “M. D.” has never seen the *Eucharis* mite, but it would not alter the fact that it does exist if he were never to see it.

It is some four years since I first saw the mite in question, and I have no wish to see it again. I ordered a dozen flowering bulbs of *E. candida* from a well-known nurseryman, and after keeping them for a year they seemed to make little progress in growth, although they had the same treatment in every respect as the large plants of *E. amazonica*, which are not placed in an out-of-the-way corner here as described by your correspondent, but grown in the centre of a large span-roofed house, where they receive abundance of light from all sides. I had the pots taken out of the house and the bulbs shaken out of them for examination, and it did not require a very keen eye to see that they were infested with mite. I was afraid if I kept the bulbs to experiment upon in killing the pest it might find its way to the healthy plants of *E. amazonica*, and I gave orders for them all to be taken to the stovehole and thrown into the furnace.

There is something remarkably strange about the culture of the *Eucharis* without taking the mite disease into consideration. I know several places where it grows well and flowers freely without any very particular attention being paid to its culture. I also know other places where it will not thrive and grow satisfactorily under any kind of treatment. As an instance of this, I know a friend, who is reckoned one of the best gardeners in the country, yet, with every appliance for good culture, he could not get his *Eucharises* to grow vigorously, although he tried every method he could possibly think of, and it could not be said that his plants were placed in out-of-the-way corners, or received bad treatment, as they had a house entirely devoted to themselves. My late foreman, who lived at the place once, told me that he had seen more flowers at one time on a single plant here than he had seen the whole houseful of plants produce during the three years he was there. The plants in question were potted in different kinds of soil, plunged in bottom heat and unplunged, shaded, &c., but still they would not grow satisfactorily.

Your correspondent, "M. D.'s," easy mode of procedure, or rather the method which he has seen successfully adopted to restore languishing plants to vigorous health, is as follows:—"At any time when a gentle bottom heat can be obtained, shake the plants out of their pots—they ought to be dust-dry at the time—placing the bulbs in separate sizes for potting. Pot them firmly in a compost about equal parts of peat and loam of a sandy nature, and enough soot to show itself all through the compost. Water slightly, and plunge the pots, or place them on the top of the hot-bed. Keep the heat up to about the ordinary stove temperature. It is surprising how little water the Eucharis requires at any time, and it is far better practice to err in giving too little than too much." The above is the sum and substance of "M. D.'s" advice in restoring languishing plants to vigorous health. I must confess that I fail to see where the "better practice" comes in, or how languishing plants can be restored to vigorous health by giving too little water, and would advise all who grow Eucharis to err neither in the one way nor in the other, but to give the plants sufficient water at all times when they require it.

The Eucharis plants here must differ very much from those "M. D." writes about, as they "require" and receive a good watering three times a day during the hot weather in summer, and a heavy watering every day during the winter. They are never allowed to become dust-dry at any time, or indeed anything approaching to it. The plants receive the same treatment all the year round as regards heat and moisture, and are never subjected to a lower temperature, or allowed to become dry at the root. They are grown in heavy yellow loam, with no other mixture except a little leaf mould, river sand, and charcoal, and they grow remarkably strong in this, producing leaves from 2 to 3 feet in length, and they flower abundantly two or three times during the year. I think many people err in potting the plants too often and in too light soil, resting them in a low temperature, and in not giving them sufficient water when they require it.—A. PETTIGREW, Cardiff.

EARLY MELONS IN POTS.

THIS mode of culture is perhaps not practised so much as it ought to be, especially by those who wish to obtain early fruits of medium size, and who have only a small space allotted to them for that purpose. We practised it here for the first time last season, and as the result was most satisfactory we intend doing so again this year. The seed was sown at the same time as that of the Melons planted out, and the seedlings were grown under the same treatment as recommended on page 5. We employed ordinary Seakale pots, these being preferred on account of their depth, as when placed on the pipes close to the path they elevate the plants nearer to the glass. By following this system we were able to obtain from one plant two fruits weighing 2 to 3 lbs. each, and occupying the small space of one wire about 3 feet long, and a little earlier than these planted out.

The pots were filled with the same compost as recommended on page 5, and made firm, care being taken that they were well drained with clean crocks, covering them with some good decayed manure, the pots being left about three parts full, for I consider that the roots being confined in such a small space they require a little extra encouragement in the way of a top-dressing when their fruits are swelling. In a few days, when the roots were found to have passed through to the sides of the 5-inch pots, they were planted, making the compost firm, and leaving a small mound around the stems. A stout stake was placed in the pot and secured to the wire it was intended to train them to. All side shoots were pinched off to one leaf from the stem up to the one nearest the wire. They were then allowed to grow, and the leader trained along the wire until it reached the next plant, and then it was pinched out. As soon as two flowers were open together they were fertilised, and as the fruits commenced swelling liquid manure was supplied, and a dressing of rich compost was applied, the growths being stopped at one leaf past the fruit, also picking off all flowers as they appear, as this greatly helps the swelling of the fruit. On several of the plants we succeeded in procuring a second crop of small fruits, all being of first-rate flavour. Sutton's Imperial Green Flesh and Thames Ditton Hero proved most valuable for this purpose.

I would like to add a few remarks here about syringing Melons, as this should at all times be done with great care, always taking the weather into consideration. On a fine morning, and the day likely to prove sunny, syringe freely, the water being at the same temperature as the house. If in the morning the temperature is found to be rather low, syringing should be delayed until it has risen to its proper height, as if done when at a low temperature it is likely to cause a chill to the Melons and produce decay in the growths. If this happens, the affected parts must be rubbed with

quicklime and soot, or it will quickly spread, and probably cause the ruin of the plant. Melons should never be syringed so heavily in the afternoon when closing the house, and then only on bright days, but take care to well damp the floors and walls in the afternoon and evening, so as to cause a moist atmosphere, or otherwise insects will soon become troublesome.

I have often seen it advised to dry Melons when ripening their fruit, thereby causing the loss of most of the foliage. This I do not agree with; that method, as I think, instead of adding to the flavour it takes it away. I like to give just enough water without manure to keep the foliage from flagging, and then expect my fruit to be of a good flavour. I may add that we grow Melons and Cucumbers in the same house here, and with success, always choosing the sunny side for the Melons, and of course the Cucumbers get the most syringing. In my reference to hotbeds on page 5, the width should have been stated to be 2 feet wide.

In conclusion, I wish to thank "Spectator" for his kind remarks on my scribbling (page 44). I assure him that if I can prove of service to some of my fellow workers, the object I aim at will be accomplished, which will well repay—P. T. D.

VANDA TRICOLOR.

I FIND this beautiful species of easy culture, no Orchid in our collection being more so in fact. My first pair of plants came from Drumlanrig, and were fairly strong well rooted pieces. They have been in our possession for about six years, and during that time the stronger of the two has only missed flowering once. Each is now strong and healthy, and in addition to the annual growth of a few good leaves, several suckers are pushing from the base. A third plant has been added to our number, this being about 40 inches high and very robust. Strange to say it has never flowered, and in all probability that is the reason we got possession of it. What this Vanda appears to require to root in is either a perforated pot or basket filled with large pieces of charcoal, broken crocks roughly broken, brown fibrous peat, and sphagnum in about equal proportions. Such a mixture is not easily soured, and the coarse roots ramble among it at their will. It is immaterial whether a surfacing of sphagnum is given or not, but our plants thrive as well without it as others seem to do with. No drying is ever attempted, the plants simply receiving water when they appear to need it, or much the same as the majority of ordinary pot plants are treated. Many succeed in raising fine healthy plants, but cannot get these to flower, simply owing to keeping them in a very high temperature. Even the ordinary plant stove is too hot for them, as I found on placing a plant with the Cattleyas for a time. It grew strongly, but refused to flower. Where ours succeed is on the front staging of a fernery, this being covered with thick rolled glass, and also freely shaded during the hottest part of the year. The temperature during the winter ranges from 50° to 60° by day and frequently as low as 45° by night. This just suits the Vandas, these giving two or three strong spikes of flower each season, usually in the spring. Very beautiful they are, too, and, kept in the house where grown, they retain their beauty for several weeks.—W. I.

DENDROBIUM HILLI.

THIS is an evergreen Australian species named in honour, I believe, of Mr. C. G. Hill, Arnot Hill, Nottingham, who possesses a very fine specimen. It is similar in style of growth to *D. speciosum*, but the pseudo-bulbs are much longer. Two remarkable plants are at present in flower in Mr. C. M. Major's conservatory at Cromwell House, Croydon, under the management of Mr. W. Wright. They are grown in large baskets with peat and sphagnum, and during the period of growth they are subjected to a fair amount of heat and moisture in the stove, after which they are well rested in a cooler and drier atmosphere. The growths made last season now measure 18 inches in length and are 7 inches in circumference, producing on each three long and graceful racemes averaging sixty blooms each; the sepals and petals are creamy white with a throat of the same colour and spotted with purple.—G.

LÆLIA ANCEPS SANDERIANA.

THERE would appear to be varieties of this extremely beautiful Orchid. Two such are now flowering in the fine collection belonging

to A. Wilson, Esq., of Westbrook, Sheffield, and both are very beautiful, but distinct from each other. The finer of the two is a noble specimen about 30 inches across and has produced five flower spikes, one carrying five flowers and the remainder four each. The individual flowers measure 5 inches in diameter, are very stout in texture, the petals $1\frac{1}{4}$ inch broad, and the colour of both petals and sepals of the purest waxy white. The lip is of large size, the colour a white ground pencilled with crimson in the throat; the column a pale primrose yellow, and a small blotch of magenta at the tip.

The other variety is also very fine, but not quite equal to the foregoing. Flowers from this plant were a year ago sent to Reichenbach, and were described by him as an extra good variety of *L. anceps Sanderiana*.

In the same collection as the foregoing are many other good Orchids now flowering, amongst them being a very fine plant of *Cattleya Trianae alba*, with extra large flowers beautifully fringed and of the purest white throughout, except a faint tinge of yellow in the throat. The following were also in flower:—*Cypripedium acanthum superbum*, most richly coloured and having two flowers on one stem; *C. Boxalli*, a large plant with nine flowers; *C. Lawrenceianum*, *C. Haynaldianum*, and a unique variety of *C. villosum*; *Ada aurantiaca*, with six flower spikes; *Oncidium cheiroporum*, very pretty and sweet scented. *Odontoglossums* were numerous, including some fine varieties of *O. crispum*, *O. Pescatorei*, *O. Inslayi leopardinum*, *O. Halli*, and others. A plant of the latter was carrying eighteen flowers on one very long spike. Other Orchids were *Masdevallia Lindenii superba*, *Vandas tricolor* and *suavis*, *Cymbidium giganteum*, *Dendrobium Wardianum* and *nobile*, the latter densely bloomed large specimens 3 feet in diameter, and a number of plants of the pretty orange coloured *Lælia harpophylla*.—W. K. W.

ORCHID FLOWERS.

FROM The Grange Gardens, Carshalton, we have received a few flowers of the following useful winter-flowering Orchids:—*Cælogyne cristata maxima*, large, pure white, with a golden centred lip; *C. Lemoniana*, with a spike of seven flowers, pure white, with a lemon centred lip; *Lælia anceps* in three varieties, all very good, but one especially rich both in the sepals, petals, and lip; *Dendrobium Wardianum* is represented by several varieties, differing considerably in the size and colours of the flowers; *Phalæ-nopsis amabilis Dayana* has the two lateral lobes of the lip heavily streaked with crimson at the base and a few similar dots in the two lower sepals; *Odontoglossums* are represented by *O. Rossi majus*, very strong and of dark colour, four flowers to a spike; *O. odoratum*, large and well coloured; *O. Sanderianum*, lighter in colour, with a white lip, but equally as fragrant as *O. odoratum*; the pretty *O. Oerstedti majus*, one very fine single flower, and two flowers on one stem; and *O. madrense*, which has been in flower for three months. There were also flowers of the interesting *Helcia sanguinolenta*, with narrow brownish mottled sepals and petals, and a crisped lip streaked with purplish crimson on white; and the neat but not showy *Lycaste Sinceana*.

FREESIAS GROWN FROM SEED.

AFTER reading your notice in the *Journal of Horticulture*, January 26th, your readers may be interested to know how easy it is to grow the *Freesias* from seed and to flower them within the year. On receiving the seed it was sown late in January, and the pan placed in heat. When the seedlings appeared they were pricked into pans and grown near the glass in an intermediate house. When large enough the little bulbs were placed in 5-inch pots, the compost being loam, leaf mould, and silver sand. Plenty of sun and air were admitted, and the plants were in flower before Christmas, but have bloomed more freely since, and are still beautiful. Bulbs potted in January, 1886, flowered a week later, but were stronger. The flowers of the seedlings were not pure white, but all deliciously scented.—EDWIN PRICE, *Gardener, Lower Soughton*.

SIX GOOD ONIONS.

THE friend who suggested to me that "six good Peas" would be an interesting subject to readers of the *Journal of Horticulture* has caused me to think that a selection of six of the best vegetables in general classes would help to reduce the hosts of varieties to a serviceable limit, and Onions are my second topic. I know thirty varieties of Onions, or perhaps I had better say Onions under thirty names, and the best of them may be included in six good varieties. Cultivators, almost without exception, have a hankering after large Onions. I daresay if anyone advertised an Onion that would attain a weight of 6 lbs. or 8 lbs. the stock would be exhausted by return of post; but although very large Onions are attractive for

exhibition, medium sized bulbs are the best for keeping and the most acceptable in the kitchen. Indeed for profit and satisfaction I would rather have a crop of bulbs averaging in weight from 6 ozs. to 8 ozs. than others weighing from 14 ozs. to 20 ozs.

WEBB'S BANBURY.—I have grown varieties annually under the name "Banbury" ever since I was responsible for the production of a supply of Onions. Some I have found globular, others conical, straw coloured, red, and white. The true Banbury is rather flat with a good round shoulder, a very small neck, and of a clear straw colour. They grow very uniform in size, yield a great weight to a given space, and are in season from July to March. The selection offered as Webb's Banbury, which I have had from Wordsley, Stourbridge, for the last ten years, is the finest and most profitable type I have ever been able to procure, and as a main crop Onion I know none to surpass it. Years ago I asked a friend of mine, previous to an important exhibition, "Would a dish of spring-sown Onions count as much in a collection as a dish of autumn sown?" The reply was "Yes, if they are good." I then staged a dish of typical Banburys, was successful, and since then the same thing has been repeated, as quality often counts more than mere size. But at the same time the attention given to some sorts to bring them up to 1 lb. or 20 ozs. would bring Webb's Banbury uncommonly near these marks.

TREBONS.—This is a good type of Onion. It is quite different from the preceding. It is very conical in form, and tapers sharply from the root to the widest part and again to the stem. When true it is a pretty Onion and bears heavily. In an ordinary way the bulbs will average 8 ozs. or 9 ozs., and by a little extra attention they will weigh 12 ozs. and 14 ozs. It may be sown in either autumn or spring, and in both cases it is sure to give satisfaction. I have sometimes seen it much mixed, many bulbs being white and others red or purple, but the true colour is a clear straw, and those who keep it perfectly true would find their labours much appreciated.

JAMES' LONG KEEPING.—I freely include this variety, because it is the best keeper of all Onions. You may do as you like with some sorts and find it impossible to keep them sound until April, but in the case of James' it is the easiest of matters to keep them sound and good as late as May, and they fill the gap in the supply which is apt to occur from the time ordinary sorts are finished until the autumn-sown ones are ready. It is not a show Onion, neither would I grow it for autumn and early winter use, but for spring and what might be termed early summer it is excellent, and in keeping qualities it may be said to be unique.

NEW QUEEN.—I name this for two reasons. It is the quickest in growth of all varieties, and in cases where Onions are scarce in spring it may be sown and grown to come in before all others. It is very useful in June and July, or from the time the last of the spring Onions are finished until the new crops come in. Its other good point is that it may be used for pickling, and on this account it may very well be included in all collections.

VEITCH'S MAIN CROP.—This is the newest Onion I have named and it has proved so good as to merit being named and recommended here. It is very globular, and appears to be a cross between a flat variety and one conical in form. It grows freely, bulbs well, is exceedingly true in form and colour, and is a very heavy cropper. Grown with about twelve others it was distinct from them all, and the quality was so good as to attract general attention.

GIANT ROCCA.—This is undoubtedly the best variety for sowing in the autumn for the main crop of this class. It is well known and need not be described at any length; but although many have been recommended as being superior for autumn sowing I have not found them so, and for table use or exhibition the Giant Rocca still stands at the top of the list.—J. MUIR, *Margam, South Wales*.

THE NEWCASTLE AUTUMN SHOW.

WITH somewhat questionable taste Mr. Goodacre, in the *Journal* for last week (see page 82), attacks some of the fruits exhibited in the collection of fruit that won the Jubilee prize for fifty dishes at the Newcastle Show last August, and holds up to derision "Warner's King" Apples and "Green Citrons." Being present at the Show I took particular interest in these huge collections, especially in the first prize lot, but failed to see either Warner's King Apples or Green Citrons. Is Mr. Goodacre not mistaken in this matter? Beurré Diel there certainly was in Mr. Hunter's collection, and such Beurré Diels too as one rarely meets with, weighing some 18 to 20 ozs. each. These I have seen growing at Lambton in an early Peach house, therefore were not the despicable things Mr. Goodacre makes them out to be. We do not always see ourselves as others see us, and upon looking over Mr. Goodacre's collection that was awarded the third prize I was much struck with what appeared to me to be three dishes of Louise Bonne of Jersey under as many different names. No. 1 was the genuine Louise, as one would expect to find it at the end of August when grown out

of doors in the midland counties. No. 2 was a larger and finer-looking fruit that had apparently gone through some preparation for the occasion, while No. 3 was a dish of very small Pears, and almost unrecognisable. I am not the only person who noticed these Pears, and freely commented upon them at the time. Can Mr. Goodacre give satisfactory proof that the eight dishes of Pears in his collection were distinct varieties? One thing there can be no doubt about—viz., that the market value of Mr. Hunter's dish of Beurré Diel was worth more than all Mr. Goodacre's eight dishes put together, at least such is the opinion of—AN OLD HAND.

EVENTS OF THE WEEK.—Tuesday next, the 14th inst., will be an important day at South Kensington. The Fruit and Floral Committees of the Royal Horticultural Society meet as usual at 11 A.M. in the Conservatory, but at 3 P.M. the annual general meeting will be held in the East Crush Room of the Royal Albert Hall. The principal business will be to receive the report of the Council and Auditors, elect Council and officers, and the election of new Fellows. On the 13th inst. the National Chrysanthemum Society will hold a meeting at Anderton's Hotel, Fleet Street, to consider the proposals respecting a provincial show this year and the production of a catalogue of Chrysanthemums. Sales of Orchids will be held at Protheroe's Rooms, Cheapside, on Friday and Tuesday, and at Stevens' Rooms, King Street, Covent Garden, on Thursday.

— **THE WEATHER.**—"B. D." writes—"The week commencing the 30th ult. began with wintry weather, and ends with spring-like mildness. Frosts of 6° to 8° and snow showers marked the first four days, since then the thermometer has stood on two nights at 45°. Spring flowers have made a leap during these last three days, and now Snowdrops, Crocuses, Hepaticas, and Primroses may be seen in bloom. On the morning of Thursday last about 5 o'clock a somewhat alarming shock of earthquake was experienced in many districts in Scotland, most violent in the line of the Caledonian canal." On Thursday morning in the neighbourhood of London the frost was severe, 12°, 14°, and 16° below freezing point being recorded. Since then the weather has been much milder and more open with several bright sunny mornings.

— "DUCKWING" writes—"Now that everyone is writing about the relative merits of NEWER VARIETIES OF PEAS, it may be worth mentioning that of the eight or nine varieties which I grew last year, so remarkable for drought, the only one which produced a good crop was the old Oxford Tom, the seed of which I bought from a cottager."

— WE have received the first part of a re-issue of "CASSELL'S POPULAR GARDENING," of which we have previously spoken in approving terms. To those who do not already possess this useful book, the present is a favourable opportunity for them to begin taking it.

— MR. B. S. WILLIAMS, Upper Holloway, sends blooms of PRIMULA SINENSIS MAGENTA QUEEN, a new variety being sent out this year. The flowers are of excellent shape and substance, the colour being a rich rosy magenta. It is an effective and handsome variety.

— MR. J. TRESEDER writes on PACKING FRUIT:—"I have read your correspondent "R. W.'s" criticism on Mr. Pettigrew's method of packing mixed fruits, which he finds fault with, but he advances no theory himself on the subject, and it certainly would interest the readers of the Journal to know the method "R. W." adopts, and the material he uses in packing his fruits after an experience of no less than forty years."

— *The Kew Bulletin* for February is devoted to SEEDS OF HERBACEOUS PLANTS, and it is stated that "these seeds are available for exchange with colonial, Indian, and foreign botanic gardens, as well as with regular correspondents of Kew. But the seeds are for the most part only available in moderate quantity, and are not sold to the general public." About 3200 names of species and varieties are given, nearly eight pages out of twenty-five being occupied with the Compositæ. The authorities for the names are given, together with the native

countries and the principal synonyms. It constitutes a useful reference list.

— FROM M. Maxime Cornu of the PARIS MUSÉUM D'HISTOIRE NATURELLE we have also received a list of seeds, which comprises in seventeen large pages over 5400 names of Ferns, Grasses, and miscellaneous plants. More than 180 Ferns are named of which spores are in stock, presumably for distribution to other botanic gardens. The botanical authorities only are given with these names, though "Bot. Reg." and "Bot. Mag.," which appear connected with some names in this way, seem rather curious. In noticing Mr. R. I. Lynch's list of seeds from the Cambridge Botanic Gardens recently it might have been stated that about 1400 species and varieties were enumerated.

— THE ROYAL SOUTHAMPTON HORTICULTURAL SOCIETY have issued their report for the year 1887, of which the following are the chief points:—The past year has not been so prosperous for the Society as the Council could desire, the many calls upon the public and the counter attractions in connection with the Jubilee celebrations no doubt materially affecting both the subscriptions and the attendance at the shows. The principal reason for the decrease in the receipts is, however, more immediately due to the railway company failing to run the usual excursions to Southampton on the August Bank Holiday. On former occasions these excursions have brought many thousands of visitors into the town. The Council have, therefore, little doubt that by this omission on the part of the Company the Society lost from £80 to £100. The shows of the Society last year fully maintained their reputation, both by the extent and the excellence of the specimens exhibited. At the Summer Show the fruit exhibits were pronounced by the judges and the horticultural press to be the best seen at any provincial exhibition last season. Considering the Society had to depend entirely upon local support, as already explained, the attendance on the two days, over 20,000 persons, is evidence that the Society's Great Summer Exhibition and Fête still retains its popularity as the event of the year. The Autumn Show, with the exception of the afternoon of the first day, was very well attended, considering the very unfortunate weather, and the exhibition, although held upon an early date, was one with which the Council had every reason to be satisfied, both as regards the entries and the quality of the fruit, flowers, and birds shown. The next Summer Show is fixed to take place as usual on the August Bank Holiday and the Saturday preceding it, and the Autumn Show on the 6th and 7th of November, provided the funds at the disposal of the Council warrant the latter being held. The Council cannot conclude this report without alluding with the deepest regret to the death of their late greatly respected colleague, Mr. W. C. Westlake. The active interest which that gentleman took in the welfare of this Society will cause his loss to be greatly felt. The Right Hon. Baron Montagu having expressed a desire to be relieved from the office of President, through ill health, the Council has obtained the sanction of W. H. Myers, Esq., J. P., of Swanmore Park, to allow his name to be placed in nomination for the office. Mr. Myers is well known as a successful exhibitor, especially of Chrysanthemums, at the exhibition of this and other societies.

— GARDENING APPOINTMENTS.—Mr. E. Shephard, late head gardener to the Misses Bannerman, Roden Hall, Wellington, Salop, has been appointed head gar'ener to N. Eckersley, Esq., Standish Hall, Wigan, Lancashire; and Mr. R. Sharpe succeeds Mr. Raffill as gardener at Low Hill Gardens, Bushbury, Wolverhampton.

— CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On February 22nd E. W. Badger, Esq., Birmingham, will deliver an address "On the Advantage to Gardeners of a more thorough Knowledge of the Science as Contrasted with the Art of Gardening." The same gentleman has also kindly promised to discuss later on the most important question of the raising hardy fruits, Apples and Pears particularly, to bloom later than most of our existing kinds do, so as to escape or minimise the effects of our late spring frosts. The latter subject will chiefly consist in the presentation of two ideas—(A) That most of our hardy fruits bloom at a time when spring frosts prevail, and are rendered barren for the year because the frosts destroy the year's promise. (B) That the obvious remedy is to commence at once, and by systematic hybridisation with the right kind for male and female parents to originate sorts as good as we now possess, which will bloom a little later, and so run less risk of damage from the late frosts.

— A MEETING of the ROYAL METEOROLOGICAL SOCIETY will be

held at 25, Great George Street, Westminster, on Wednesday, the 15th instant, at 7 P.M., when the following papers will be read:—"Electrical and Meteorological Observations on the Peak of Teneriffe," by the Hon. Ralph Abercromby, F.R.Met.Soc.; "Rainfall of South Africa, 1842-1886," by W. B. Tripp, M.Inst.C.E., Fr.Met.Soc.; "Some Methods of Cloud Measurements," by Nils Ekholm. The Council this Society have also arranged to hold at the same place on March 20th to 23rd next, an exhibition of apparatus connected with atmospheric electricity, including lightning conductors, photographs of lightning and damaged objects. The Committee will also be glad to show any new meteorological instruments or apparatus invented or first constructed since last March, as well as photographs and drawings possessing meteorological interest.

— THE schedules of the ROYAL BOTANIC SOCIETY'S SHOWS, REGENT'S PARK, in the present year are now issued, and contain liberal provision for plant exhibits. The Spring Shows will be held on March 21st and April 18th, the prizes ranging from £3 to 10s. for bulbs and forced plants, eighteen classes being devoted to the first Show and fifteen to the second. The Summer Shows are fixed for May 16th and June 30th, thirty classes being enumerated for the former and fifty-eight for the latter, which besides plant classes includes twelve for cut flowers and sixteen for fruit. At the June Show some alterations have been made in the classes for Orchids; thus, there are now two for twelve exotic Orchids from nurserymen and amateurs, two in the same way for collections of Dendrobiums and Cypripediums, and one open class for a collection of Masdevallias. These may be expected to form very interesting features. At the May Show there are also classes for Cattleyas and Lælias, and at each Summer Show a class is devoted to greenhouse Rhododendrons.

— CALLICARPA PURPUREA.—"J. H. L." writes: "Mr. Miller, gardener to Lord Foley, has this useful though rarely seen berried plant in profusion in the well-kept greenhouses at Ruxley Lodge. He recommends the following mode of culture:—Cuttings should be struck of the old cut-back plants in the spring and treated the same as a Fuchsia. Pot in a compost of loam and peat and a little sharp sand. Place the young plants in house or pit at a temperature of 70°. They should be constantly pinched back, and no shoots forgotten, until the beginning of August. Give them plenty of air, but more especially when they are in flower."

GARDENERS' ORPHAN FUND.

FOR the information of your correspondents who evince so warm an interest in this fund, and to whom I feel deeply grateful, I shall feel obliged if you will kindly allow me to state that the question of money boxes was considered at the last meeting of the Executive Committee, with the result that sample boxes are to be presented at the next meeting for approval. A number of boxes of the approved pattern will then be ordered for distribution among such of our friends as will kindly undertake the charge of them.—GEO. DEAL, *Chairman*.

AT the annual meeting of our Chrysanthemum Society, held on Friday night last, it was resolved to arrange for a concert to be held on April 5th in aid of the Gardeners' Orphan Fund. If the committees of other societies in the country should think of assisting in the matter, I shall be glad if they will communicate with me on the subject.—A. J. BROWN, *Lindfield, Sussex*.

[We are glad to observe the Lindfield Society is in a sound financial state, and to learn that it will be well supported. We also readily publish the above resolution formulated by our correspondent.]

A LITTLE CHANGE.

HAVING been engaged in trade for several years, and by, I trust, fair dealing and fair advertising, established what is regarded as a good business, I can afford to allude to what are known in the circle as "puffing pars." The public form a true estimate of "news" which they see clearly enough is "supplied." These "little pars" were novelties once, but the market has been overstocked and the game is played out. But even yet they are "sent round" now and then, and one creeps into print here and there—a mere flash in the pan—for it is clear enough the shot has been withdrawn, because the flashes are not alike in all the papers that let them off, and does this not betray the hollowness of the whole thing?

When I see these "little items" I am always reminded of Bob Sawyer's method of advertising as described in "Pickwick." "Don't you see," said Bob, "he goes up to the house, rings the area bell, pokes a packet of medicine without a direction into the servant's hand, and walks off. Servant takes it into the dining parlour; master opens it and reads the label—draught to be taken at bedtime—pills as before—

the powder. From Sawyer's, late Nockemoff's. Physicians' prescriptions carefully prepared, and all the rest of it. Shows it to his wife—she reads the label; it goes down to the servants—they read the label. Next day the boy calls. Very sorry—his mistake—immense business—great many parcels to deliver—Mr. Sawyer's compliments—late Nockemoff. The name gets known, and that's the thing, my hoy; bless your heart we have one four-ounce bottle that's been to half the houses in Bristol and hasn't done yet." Dare you insert this, Mr. Editor?—PROVINCIAL.

[Certainly; why not? You evidently think it as interesting as some other paragraphs, and if it pleases you it may please others who like "a little change" in literary fare.]

ERICA ODORATA.

ONE of the pretty spring-flowering Heaths that are now too seldom seen in greenhouses is *Erica odorata* represented in fig. 16. The

Fig. 16.—*Erica odorata*.

flowers are bell-shaped pure, white, gracefully supported on slender foot-stalks, and possessing a delightful fragrance which has been compared to "a compound of Roses and Honeysuckle." It is an old inhabitant of English gardens, having been introduced in 1784 by Mr. John Wedgewood, but though usually found where collections of hardwood plants are prized it is now comparatively scarce. It is, however, well worth the attention of cultivators.

IMPRESSIONS AND OBSERVATIONS.

IN devoting a few moments' consideration to some points recently advanced in the Journal, I do so in response to wishes that have been expressed, and in this instance my subjects have been chosen for me. The first on which observations are requested is that of noble and other owners of private gardens competing with market gardeners in catering for the multitude of consumers of produce, which both class of traders grow for sale. I will try to look at the matter calmly and without prejudice, but at the same time shall be obliged to call a spade a spade whosoever may be its user, and in doing so shall have to admit myself a

supcrannuated cattle drover before I am douc, and if I am not ashamed to admit this I do not see why anyone who is a market gardener should object to be called one.

THE paragraph to which my attention is directed is the following—“Personally I do not see why a gentleman should be thought mean if he disposes of his surplus Peaches any more than of his surplus short-horns or Berkshire pigs. He is not regarded as a butcher if he does the one; then why should he be called a market gardener if he does the other?” Most certainly a gentleman should not be considered “mean” for selling food produce that would be otherwise wasted. I could tell of a nobleman who sells his surplus fruit and vegetables and devotes the whole of the proceeds to hospitals. It is to the advantage of the community that private garden crops should be sold, because not only is much labour thereby employed in the production, but consumers are better supplied with what they require at the cheapest rate, as the greater the supply the lower the market rates must be. But while I would do the fullest justice to noble sellers, and claim for them the freest action, it is impossible not to distinguish between those who make selling a secondary matter, a prevention of waste, and those who convert their gardens into trade establishments with the object of gain. And even then I would not object if these were placed on an equal rating assessment with cultivators whose livelihood depends on their work; but I cannot recognise the principle of fair trading when one grower for market is rated at from 100 to 200 per cent. higher than another, and I know that industrious men have been crushed out of competition through having to work against gentlemen on unequal terms. I remember “D., Deal,” once scoring a strong point when he submitted that a grower of florists’ flowers was no longer an amateur when he published a catalogue of plants for sale, but must then be regarded as a nurseryman. The proposition was unanswerable. I have before me a trade catalogue, issued from the gardens of a nobleman, from which gardens not only seeds, but all the flowers, fruit, and vegetables that can be raised, are sold. It is a trade establishment or nothing. Why, then, should not its owner be called a seed dealer and market gardener?

It is well known that ladies of distinction conduct dressmaking and millinery businesses in London, and are not ashamed of their calling. Why should they be? It is at least as honourable as the useless frivolities of life that many engage in as befitting their circumstances; as honourable, too, as it is for their lords to engage in banking, coal dealing, and other trades. No one objects to this, because it is fair trade, and their competitors are not handicapped in towns by accidental conditions.

BUT to go into the country. Is a gentleman who sells farm stock and produce a butcher? He would be if he killed his shorthorns and pigs and cut them up for sale; but if he only rears and grows them, as he has every right to do. I take it he is not a butcher, but a farmer. And many a high bred gentleman does not object to be so called. We read of one of the kings of the realm rejoicing in the appellation of “Farmer George.” One of the best farmers I have known and best of men was a country vicar, and he had the word “Farmer” attached to his name on his carts. Once he sent me with a man to drive some cattle a few miles to one of his friends. The man—that is, the drover in chief, for I was a small subordinate, was a thirsty specimen of humanity and did not like returning home without a drink, while he scarcely dared to ask for one. However, he started, but suddenly turned round while within ear-shot of the master and shouted, “If you please, sir, if the vicar should happen to ask what sort of beer you keep, what am I to say, sir?” What could the master say under the circumstances, but “Come back and try it?” The man’s point was thus gained at that end, but there was the other. Fortunately the vicar was in the way on our arriving home, and we were greeted with a hearty “Well, you have got back, and what did Mr. Blank say?” “He asked me what sort of a farmer you was, sir, and I hope I didn’t make a mistake, for I told him you had six quarters of Wheat an acre in one close, seven in another, and eight in another.” The Vicar paused, then replied, “You told him quite right, go in and have some supper.” So, as my chief said, all came right at both ends. I fear some of my friends will think I have had a “queer bringing up;” and it is true I have had varied experiences, with not a bad memory, and I cannot forget this good vicar farmer. He was rich, and farmed with a high motive of showing what could be done by superior culture and the free yet judicious employment of labour. His farm was a model, as clean as a garden, and his exact accounts showed it was profitable. He is long since called away. The parish remains with the same acreage, but not half so many men are employed on the farms, and it is questionable if they yield half the amount of produce they did when the vicar led the way so nobly. He was a devoted parish priest and proud to be a farmer. I have seen a nobleman, too, indicate his calling as a farmer on his farm vehicles. Why, then, should a gentleman who makes all the money he can by the sale of fruit and vegetables object to be called a market gardener? I cannot see that one vocation should be more undignified than the other, and I think whoever is ashamed of either should retire from the business.

BUT I have the suggestion of “meanness” to deal with, and this can best be done by relating an episode from life exactly as it occurred. It shows the difference in “feeling” upwards of forty years ago and now. Then trading by persons of rank was done clandestinely, now it is conducted openly, and few persons will doubt which is the better way. A

change was made in the garden of a territorial magnate. All the produce that could be raised and spared was to be sold. A greengrocer was engaged to fetch the “stuff,” and none was to be sold to anyone else, but he must not come on the premises till seven o’clock at night, and must be off them by half-past five in the morning in summer; and in winter the time was half an hour before and after working hours. I do not know why the rule was imposed, but I know it was strictly enforced for a few years, then broke down. One Saturday morning the greengrocer took away all he could do with, and at night I was sent to borrow a horse and cart, as our own would not do. Two men and a boy were sent to the market to sell new Potatoes, Strawberries, &c., against the greengrocer, and were instructed to call at the best houses. I was the boy, and got lost in the crowd. It would seem as if pride were ingrained in my constitution; at any rate, I was ashamed of my work, shirked it, and got what was known in those days as a “good jacketing.” That was the “meanest” act I have seen in connection with selling produce from a private garden. The author of it was not disclosed. Some thought it was the steward, who was known as a “sharp” sort of person, others the gardener, and others again the men who prevailed on him to let them earn a shilling or two by the huxtering; but no one suspected the owner of the garden of this peculiar method of trading, the worst feature of which was borrowing the cart as a mask for the whole transaction. I remember it well for the reason named—the “jacketing.”

My friends must wait as patiently as they can for references to other subjects they wish me to dwell on, for if I start now there is no telling where I may stop, and it is easy to have too much of a bad thing.—SPECTATOR.

FLORAL DECORATIONS.

THE leading article by “C.” on the above subject last week reviews the questions previously discussed in the Journal. Being somewhat of an enthusiast in floral decorations generally, I have been glad to see the matter taken up by the Journal, and also that some of the committees of societies are acting upon the suggestions. I have often wondered there has not been more written about it, as there is a very wide scope in matters of taste, as people seldom agree at once or even after a good deal of discussion as to what is the correct thing. The bouquet mentioned by “C.” I should say had been made to order, as I cannot understand any practical florist committing such an atrocity. The proper place for real Lilac would be in rather medium size sprays round the outside of the bouquet drooping a little over the paper. I have heard of a fashionable lady entering a ballroom with a large bouquet of Richardia spathes, and I told someone of the circumstance, and they exclaimed, “How beautiful!” Not long ago I saw an exhibition bouquet at a local show, by which I mean one not for competition; it was made in a very loose style, not very bad till the centre was reached, then a large Richardia stood about 6 inches clear of the other or surrounding part of the bouquet. It was a bridal bouquet, and I unfortunately made a laughing remark to my neighbour, and was caught in the act by the proprietress, who said, “Do you know that style is to be the taking one of the future?” Then I thought tastes certainly differ. Fancy a Richardia in a bridal bouquet! but I am of the same opinion as “C.” that these eccentricities in bouquet making are brought about by the peculiar tastes of different customers. I had on one occasion a special order for a bridal bouquet not less than 2 feet in diameter. I pointed out to the lady the enormous size it would be, but all to no purpose. It was a grand bouquet composed of Eucharis, Gardenias, white Roscs, Lily of the Valley, white Azalca, white Cyclamen, white Heath, and studded with single flowers of Cologyne cristata, interspersed with the Lily of the Valley, but much too large and weighty for a lady to carry. I could have made as handsome a bouquet with half the flowers, but of course I had to obey orders. I avoid using white Camellias in bouquets as much as possible, as they are injured by the least touch of anything hard. I use them in wreaths, as they look well if put into use at once, which in wreaths or crosses is generally the case. I am also of the same opinion as “C.” that Richardias should be used sparingly, say one in the centre of a cross and three at the most in a wreath without special orders to the contrary.

I should like to suggest that if gardeners wish to excel in bouquet making they should not be content with defeating their fellow gardeners, but to try hard to lower the colours of the florists who exhibit in the neighbourhood, and not to mind a first or second failure, but to persevere. Fortune favours the brave, and the fiercer the fight the greater the honour. I should like to ask “C.” if he does not agree with me that of late years too much importance has been attached to the first prizes at exhibitions. I do not mean that any exhibitor should not aim higher than second or third, but that when obtaining either of those places he should be encouraged rather more than it has been the custom of late, as often and often there is not much difference, if any, between the first three exhibits. I am not alluding entirely to floral decorations, but other exhibits also. I cannot help thinking if, “Well done; persevere!” was said to the unsuccessful sometimes, it would stimulate him to greater exertion, whereas in the reverse case he would perhaps give up in despair.

I should like to have someone’s opinion as to dinner-table decorations. I have watched them year after year for a long time, and have often thought that an improvement could be made. Nothing has been introduced at any time better than the stands that are met with at exhibi-

bitions. The single centre tubes, with the three small tubes on triangle wires, if lightly filled with flowers, do not obstruct the view across the table, and afford an interesting feature to the guests. The upper parts of the stands will be attractive also, whereas in the flat stand system there is much less variety. I was once fortunate enough to have a private view of a dinner table laid out for Royal visitors, and thought I was going to learn something, but was rather disappointed to find in the centre of the table an oval dish or bowl all crimson Roses and Maidenhair Fern. The ends were round dishes or bowls filled with all Gloire de Dijon Roses and Maidenhair Fern, and I think the specimen glasses contained red and cream Roses alternately. The whole was taken in at one glance, and again I am bound to say tastes differ.—A. B.

PREPARING AND FORCING MARECHAL NIEL.

CONTINUING my remarks on this subject from page 63, it may be said that the plants were left outside secured to a wall or fence, from this position being carried to the shed, and the unripe ends of the shoots removed—all the pruning that is needed at that period. Remove the surface of the soil and supply equal proportions of loam and manure. Arrange five stakes round the sides of each pot and train the plant to them, but it will not be necessary to have the stakes more than 18 inches or 2 feet high at the most. They should then be placed in a cool airy structure from which frost only is excluded. While in this position the soil must not become dry, in fact in no stage of growth, or the roots will suffer severely. Even in this position they will quickly display signs of starting. The buds on plants housed about the middle of December have shoots from half an inch to an inch in length, and they have occupied a position in a cool house from which frost has scarcely been excluded.

Perhaps the best of all methods of forcing early is to make up beds of leaves in a house that can be devoted to these plants. If plunged, or even stood on the surface, the gentle heat the leaves afford is ample to start the plants without the aid of heat from the hot-water pipes or even the use of the syringe. The moisture that rises from the leaves is ample for them until the flower buds show. This method allows the plants to be arranged close to the glass, which is a decided advantage in early flowering. Such arrangements are not within the reach of all, and it may be done well by starting them in vineries or Peach houses. *Maréchal Niel* naturally flowers early under glass, even with cool treatment, and is therefore one of the best Roses that can be grown for the purpose. It produces its flowers from the eyes on both sides of the shoots of the previous season's growth, and therefore has only a few inches of growth to make before the flower buds are visible and commence development. Until they attain this stage the temperature at night must not rise above 50°, when it may be gradually increased to 55°, not exceeding this except on very mild occasions, when it may with safety be allowed to rise 5° higher. If they are forced out in strong heat the flower stems are weak and the flowers small and colourless. Give no ventilation during the early forcing of these plants, in fact not before April—that is, when the plants are growing under warm genial conditions. It is almost impossible to admit air early in the season without cold draughts striking upon the tender foliage of the plants, and therefore subjecting them to an attack of that most dreaded pest, mildew.

When the flower-bud shoots are about 2 inches in length the roots will be active, and tepid water only must be given, and a little artificial manure applied to the surface of the soil two or three times between this stage and the development of the flowers. Plants such as have been described will often produce as many as forty creditable flowers within fourteen months from the time the cuttings are inserted.

Some may think the plants are rendered useless after they have been forced early, but such is not the case if they have been well cared for. Later forced plants, by the time the flowers have expanded, have strong growths springing from below the soil or from the eyes just above it, but this is seldom the case with those that have flowered early in February. If these are kept in the temperature advised for a time after flowering they will not be long before the shoots are visible. Do not cut the plants down directly after flowering, for this proves a severe check to the roots, and the growths made after will rarely attain more than a yard in length. After the shoots from the base are extending freely, say 18 inches in length, the whole of the previous year's wood may be cut away. They will now extend rapidly, and when about 3 feet high they may be placed into pots 2 inches larger. The old roots need not be disturbed farther than the removal of loose surface soil and the drainage from the base. These plants, if encouraged by heat for a time, will make two or three good shoots this season which will be ripened sufficiently soon to flower a month earlier, or by the middle of January. After this season's forcing these plants are thrown out, except one or two perhaps that start away freely a little later in the season, and are retained for a large plant or two. They do not, however, give the same satisfaction as younger plants, unless they are shifted into larger pots, which are too large for moving about conveniently. Lamarque, William

Allen Richardson, and the old *Gloire de Dijon* succeed well grown on this principle. *Reine Marie Henriette* is beautiful in the bud, but it is too shy to pay for growing early in the year.—N.

A ROSE DAY FOR GARDENERS.

WE beg to call attention to our plan of a Rose day for Torquay to raise funds to help in various ways gardeners who may be in distress. The desire is, if funds come in, to assist gardeners whose bad state of health renders a change and rest necessary, in coming down into Devonshire for a few weeks. Dr. Ramsay of Torquay, whose generosity to gardeners is well known, will assist us in getting the use of a sanatorium on special terms, and he would look after the men medically and we secretarially free. It is thought that where the gardener is too poor to pay even the low terms charged for board and lodging and fare down we could, with the assistance of the man's master, pay for this necessary cost, and he would have comfortable rooms for a few weeks, plenty of good food, companions amongst his brother gardeners, and the sea air and breezes of this lovely place. Will you help in this good cause by ventilating the matter in your valuable paper?—CURTIS, SANFORD & Co.

NEW FRENCH ROSES OF 1887-88.

WHEN I sit down to analyse a list of new French Roses, I can imagine faintly what a gold-digger feels when he sits down before some tons of quartz which he knows must be crushed before he can get the precious metal—he may have a great success, or he may draw a blank; it may be the means of setting him up in the world, or it may end in vanity and vexation of spirit. If he hears that the "claim" has had a good report, that many before him have obtained much from it, he is the more encouraged in his arduous work; but if, on the other hand, he knows that nothing valuable has ever come from it, it is with anything but a light heart that he ventures upon it. And so it is with the Rose lists. The number shows no diminution, the descriptions are as glowing as usual, all the superlatives at the disposal of the writer are as freely used as ever; over and over again are we entranced with the — description; but then, alas! comes the damping thought—Ah! Mons. A. has said the same thing every year, and yet I have never got much from him worth having. I see here, however, a Rose which comes from what I know to be a good claim, and I may find a nugget in this new one. It is surprising how hopeful rosarians are, and although they have often had to take the bitter pill of disappointment, yet are they prepared for another trial dose. I suppose a man, after having bought a Rose, budded it, and increased his stock, feels a certain sort of tenderness towards it. He first begins to think, Well, it is not quite as good as I thought it was at one time, but I hope it will do. But it gets no better, and finally he is compelled to get rid of it altogether.

Messrs. Ketten, E. Verdier, and others have taken the trouble to get together the lists of new Roses. From it I gather that of the two classes which most interest us, Hybrid Perpetuals and Teas and Noisettes, there are thirty-four of the former and twenty-nine of the latter. Time was when half a dozen Teas was considered a good supply for the fifty or sixty Hybrid Perpetuals. Now we see them approximating one another very closely. It is an instance again of the law of supply and demand. The increased estimation in which the Tea Rose has been held of late years has led raisers to endeavour to add to the beauties we already possess, and although it is very difficult to beat some of those we already have, yet we now and then do get a beauty. *Madame de Watteville*, *Madame Cusin*, and *Princess of Wales*, &c., are proofs of this, although an immense quantity of useless lumber has also been brought forward.

As usual *Nabonnand* heads the list in Teas and Noisettes, sending out ten of the whole number, while he has also one in the H.P.'s. We are so accustomed to get so much chaff and so little corn from this raiser's productions that we cannot look forward with any great expectation to what he may have for us this season, but here they are:—

NABONNAND.

AGATHE ROUX.—Globular flowers, delicate rose colour, good form.

CLAIRE JOUBERT.—Large; orange yellow, not very full; petals large; blooming in clusters.

EDOUARD PAILLERON.—Large petalled Rose; shaded coppery rose, reverse darker.

JEANNE CUVIER.—Flower shaded deep rose.

MISS LIZZIE.—Flowers pale yellow, passing to white.

BARONNE DE HOFFMANN, N.—Flowers shaded coppery red, base yellow; a rampant grower.

COMTE GEORGE DE ROQUETTE BUISSON, N.—Flowers imbricated; of a bright shaded rose colour.

L'IDÉALE, N.—Medium size; yellow and metallic red in colour, with touches of light gold.

MADAME JULES FRANKE, N.—Flowers of pure white changing into yellowish white; a strong climbing variety.

TRIOMPHE DES NOISETTES, N.—Colour bright rose; medium size; nearly full.

BERNAIX.

DUCHESSÉ D'ANERSTADT.—Bright golden yellow, deeper at the base; petals large; habit climbing.

SOUVENIR DE MADAME MÉTRAL.—Good form; flowers light cherry red colour, good shape, brightened with crimson and vermilion; climbing habit.

VIVIAND MOREL.—Crimson and deep scarlet, brightened with carmine and shaded with rosy yellow. How utterly hopeless it is to imagine what flowers can be really like from such descriptions as these.

PRIES.

CLARA PRIES.—Creamy white, yellow in the centre. As a seedling from Madame Berard it is evidently one of the Gloire de Dijon race, of which we have had an abundance, but none to excel the parent.

BEAUVILAIN.

Like the preceding, the name of this raiser is new to me, and we have therefore no idea what his Roses are likely to be. Apparently he hails from near Bourdeaux, a good locality for seedling Roses.

ÉLIE BEAUVILAIN.—Flowers imbricated; white, shaded satiny rose, copper coloured at the base, veined with red; a climbing Tea.

GLOIRE DE LIBOURNE.—Imbricated flowers of a deep canary colour; a climbing Tea.

MADELAINE BEAUVILAIN.—Flowers imbricated; clear yellow, base copper coloured, slightly tinted with rose; a climbing Tea.

These three Roses seem, as far as description goes, to be of the Gloire de Dijon, and I fancy that anyone who grows that Rose largely might readily find blooms to correspond to these descriptions.

SOUPERT ET NOTTING.

COMTESSE ANNA THUN.—Orange yellow; flowers cupped.

MADAME MAX SINGER.—Medium size; clear yellow, shaded with orange; centre golden yellow.

THERÈSE LAMBERT.—Rose colour, with yellowish red at the base and orange in the centre.

REBOUL.

ÉLIZA REBOUL.—Flowers moderate, eup-shaped; outer petals white, centre canary colour; moderately vigorous; fatal defect.

SOUVENIR DE GÉNÉRAL CHARRETON.—White, slightly edged with pale rose; centre rose shaded red, yellow base.

LACHARME.

HENRIETTE DE BEAUVAU.—This Rose will be cherished as the last one sent out by François Lacharme. It is said to be large, globular; colour clear yellow. I know the old gentleman expressed in strong terms his opinion of this flower, and I hope it may be a credit to his judgment.

GUILLOT, FILS.

MADAME HOSTE.—Flowers composed of large thick petals; yellowish white, deep yellow at the base. This sounds well.

COCHET.

MADAME PHILEMON COCHET.—Medium size; cupped; rose colour, salmon white at back of petals, slightly suffused with bluish violet.

DUBREUIL.

PRINCESSE DE SAGAN.—Flowers medium in size; cupped shape; velvety crimson, shaded black purple and amaranth.

PERNET, FILS.

MADAME JOSEPH GODIER.—China rose, tinted with carmine, shaded with canary red.

PERNET, PERE.

TRIOMPHE DES NOISETTES.—Nearly full, blooming in clusters; colour bright rose. Climbing variety.

MOREAU—ROBERT.

L'ABONDANCE.—Medium size; pure white, slightly rosy on opening; blooming in clusters from fifty to a hundred. What use this is, except as something in the style of Félicité perpetuelle, I cannot see.

I shall next come to the Hybrid Perpetuals, which are not nearly so numerous this year.—D., Deal.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

So much advice has been given to the ruling powers of this Society lately that it seems almost superfluous to add anything to what has already appeared; however, my interest in the Society, and the desire that it shall gain the position it should occupy, are so great that a few words may be admissible. An important step is about to be taken in the election of several new members on the Council, and, like myself, many are awaiting the result with considerable curiosity. If a strong, united, and thoroughly horticultural representative Council be elected a large number of new supporters will be gained, as a reformed policy will no doubt result. I am confident that some of the older and proved friends of the Society could from their long practical experience aid considerably in the reorganisation of the Society, and at the same time perhaps the energy of younger Fellows could be utilised. In any case, if the members elected have not the full confidence of the horticultural world, alterations in arrangements and tempting programmes will have but little effect.

No one who is familiar with amateurs, gardeners, and nurserymen throughout the kingdom can fail to be aware that the interest felt in the Royal Horticultural Society's proceedings and success is much less than it should be, and no one equally familiar with the Society itself can ignore the fact that they have only themselves to thank for this apathy. There is, however, a strong horticultural enthusiasm prevailing throughout the country, and there is no reason whatever why the "Royal" should not attract a much larger number of supporters than it has at present. With a representative Council, a vigorous and generous policy, and lower terms of membership a successful start on a new career might be safely anticipated.

The fair representation of horticulture could be effected in this way. Six of the members should be amateurs, three members of the trade (nurserymen and seedsmen), three gardeners, and three members of the Press (editors or proprietors). Two of the first named and one each of the others should retire annually, but be eligible for re-election. Then as to alteration in the membership, the Fellows' subscription of two guineas could remain unaltered, and for that they should have two transferable tickets; a membership of one guinea has been proposed and might well be adopted, giving one transferable ticket and voting powers. For gardeners half a guinea is the highest subscription that is likely to give any satisfactory returns, and it would be unnecessary that they should have voting powers, as probably but few would avail themselves of it. But gardeners generally might be given a voice in the management of affairs by permitting all local societies affiliated to the "Royal" to send one delegate each, who, whether members or not, should be entitled to vote on all occasions. The question of electing associates has been raised, but it is a difficult one, though for my own part I think it could be accomplished by allowing gardener members to elect a certain number annually from their own body, such associates to have full voting powers.

The garden at Chiswick could be rendered much more useful with an increased outlay in experiments and testing, but the results must be published promptly to serve their purpose. A monthly record of the Chiswick trials would keep the work of the Society constantly before the public, and be valuable to thousands of persons. The metropolitan meetings must still be followed out, but the shows can be left to other societies at present. Still, the conferences and congresses, which have proved so successful, might be advantageously continued and extended. Some of these suggestions could no doubt be improved, but they are contributed with the earnest wish that whatever course the Society adopts it will be speedily raised from its present depressed state.—AN OUTSIDER.

LAPAGERIA ROSEA AT COVENTRY.

THE gardens of James Marriott, Esq., are situated in Queen's Road, Coventry, a few minutes' walk from the London and North-Western station, and close to the nursery establishment of Messrs. Perkins and Sons. Plants are well grown in Mr. Marriott's garden, and some of them have appeared formidable rivals in competition with Mr. James Cypher's and other noted exhibitors at the best of the midland summer shows, including Shrewsbury, August 17th and 18th last year; also at Bath Floral Fête, and obtained valuable prizes at the Derbyshire Agricultural and Warwickshire Agricultural Societies. It was at Sandy Show, August 26th, where the splendid specimen *Lapageria rosea*, fig. 17, was awarded first prize in a collection of ten stove and greenhouse plants. It is grown in a tub, and the measurement is 7 feet 8 inches high and 5 feet through, and at the time bore 300 expanded blooms. A good plant of the white variety bids fair to become as large before long. A *Stephanotis* growing in a 14-inch pot is about 4 feet high from the rim of the pot and 5 feet 8 inches in diameter, and had on 580 trusses when shown; this is grown in the intermediate house. *Ixora salicifolia*, sometimes difficult to manage, is represented by a large and vigorous plant.

Various houses are filled with Ferns and Palms, *Eucharis* and *Paneratiums*, *Crotons* and *Dracenas* both being well coloured, and other plants all suitable for exhibition and home decoration. *Allamanda cathartica* is valuable as a winter blooming plant, and *Rhododendron*

Duchess of Edinburgh is nearly always in bloom. Heaths and other hardwooded plants occupy a house to themselves, a low span-roofed structure about 40 feet long by 12 feet wide. The plants are arranged

well and flower satisfactorily, the useful *Oncidium flexuosum* is 4 feet through and produces plenty of flowers for cutting. A very dark form of *Sobralia macrantha* has over 200 growths. Cattleyas and

FIG. 17.—A SPECIMEN LAPAGERIA.

on a border of ashes close to the glass, with a free circulation of air among them. All the best varieties are grown.

Orchids receive a good share of attention. The cool house is filled with healthy *Odontoglossums* and *Masdevallias*. *Phalenopses* grow

Laelias look well, *C. Dowiana*, *C. Eldorado*, *C. Wallisi*, *C. Sanderiana*, *C. superba*, with *C. Mossiæ* and *C. Trianæ* are among the best. *Laelia anceps* and *L. a. morada* are flowering well. The collection is rich in *Dendrobiums*, one plant of *D. clavatum* has twenty new growths; *D.*

Dalhousicanum and other tall growing species have done equally as well, and *D. japonicum* and *D. Jamesianum* in cooler quarters bear evidence their treatment is understood. There are many other Orchids worthy of notice, and another visit will be paid later on when more are in bloom. Grapes, Peaches, and Pines are rather extensively cultivated, and the management of the place reflects great credit on the painstaking gardener, Mr. W. Finch.—G. W. CUMMINS.

NATIONAL AURICULA, PRIMULA, CARNATION, AND PICOTEE SOCIETIES.

THE following are the annual reports and balance-sheets issued by the above Societies for the past year.

NATIONAL AURICULA AND PRIMULA SOCIETY.
(SOUTHERN SECTION.)

REPORT FOR THE YEAR 1887.—The Committee have much pleasure in reporting to the subscribers of the continued prosperity of the Society.

The Exhibition held on April 26th, under the auspices of the Royal Horticultural Society, was as good as any previously held. The competition was very keen in the principal classes for Show Auriculas; there were in Class A no less than six competitors; in B, seven; and in C, six competitors. The classes for single plants were also well filled with specimens of a high order of merit.

The best thanks of the Committee are due to the Trustees of the "Turner Memorial" fund, who gave £5 in a class for Show Auriculas.

Extra classes were provided for Alpine Auriculas, and it is desirable that a larger competition should be promoted in this section.

Gold-faced and Fancy Polyanthuses, and Primroses were well and numerous shown.

The species of Primulas formed a most interesting feature of the exhibition. Extra prizes had also been provided in this class, and although an excellent display was made, it is desirable that more exhibitors should come forward to claim the prizes.

New exhibitors and new members were added to the list last year, and it is very desirable that a still further increase may be made next year. There is practically no limit to the work yet to be done. The Committee may venture to hope that each member will try to add one more for next year. As conclusive evidence that the work of the Society has been well directed, it is sufficient to state that no less than ten first-class certificates were awarded to Show Auriculas in the various classes last year. This is a sufficient answer to those who believe that the Auricula has been developed to a point beyond which substantial progress cannot be made. The fact ought also to be recorded, that a new member, Mr. White of Killingworth, near Newcastle-on-Tyne, was awarded the premium prize for the best Auricula in the exhibition.

For ten years the exhibitions have been held at South Kensington, in conjunction with the meeting of the Royal Horticultural Society; but it has not yet been decided where to hold the exhibitions for next year.

Owing to this uncertainty, an increase in the funds may be necessary, and the Committee confidently appeal to the subscribers to give the Society their best support as heretofore. Schedules will be prepared and issued as soon as it has been decided where the exhibitions are to be held.

NATIONAL CARNATION AND PICOTEE SOCIETY.
(SOUTHERN SECTION.)

REPORT FOR THE YEAR 1887.—The Committee have to report very considerable progress for the past year. New subscribers and exhibitors have come forward, and, as will be seen from the financial statement, there is a considerable balance on the side of the Society. The exhibition was held on July 26th, under the auspices of the Royal Horticultural

Society; and although all were agreed that the past season was not altogether favourable to the Carnation and Picotee, there was little falling off in the quality, and none at all in the number of exhibits. The Picotees, flaked and bizarred Carnations, were but little below the high-class quality of the national exhibitions, and a few new ones were exhibited, first-class certificates being awarded. The class for self Carnations and Cloves showed considerable improvement, and the number of exhibitors was larger than usual, no less than twelve exhibitors contesting for one set of prizes. Two first-class certificates were awarded to seedlings in this section.

The yellow-ground Picotees are also in the line of progress, some very notable improvements having been made in this class, to some of which the Society's first-class certificates of merit have been awarded. During the past season some yellow self varieties of a deeper colour than any seen hitherto were exhibited at the Society's exhibition.

The best thanks of the Committee are due to the Trustees of the "Turner Memorial" Fund, who give a series of prizes to the amount of £5.

The Committee are at present unable to state where the exhibition for 1888 will be held; under these conditions increased support from the subscribers may be necessary, and the Committee, as in the case of the Auricula Society, confidently appeal to the subscribers to give the Society their continued support.

Schedules of prizes will be prepared and issued as soon as the necessary arrangements can be made.

HARDY FRUIT AT CULZEAN CASTLE.

It is well known to readers of the Journal that Mr. David Murray, head gardener to the Marquis of Ailsa at Culzean Castle, Maybole, Ayrshire, is a good all-round practitioner. His Grapes and other hothouse fruits invariably occupy prominent positions in the prize list at the Edinburgh shows; and although hardy fruits and vegetables have not been often shown both are, nevertheless, cultivated extensively and well in Culzean Gardens. A first-rate Onion raised within the last couple of years is also being sent out this season for, we believe, the first time. The method of procedure followed by Mr. Murray and other good fruit growers is to lift or root-prune a given number of wall and other fruit trees which show signs of exhaustion every autumn until they all have been operated on, and the desired results in way of good crops during ordinarily favourable seasons are thereby secured. A trench about 2 feet wide and 3 feet deep is opened at say 3 feet from the stems of the individual trees, the soil is then, by the assistance of five-pronged steel forks and shovels, carefully worked out from under and about the roots. The latter are shortened a little, removing any damaged or strong roots having a downward course, afterwards, assuming that the drainage is perfect, the soil good, and the roots within the proper distance (5 or 6 inches) of the surface, replacing the soil, working it well among the roots in doing so. But on the other hand, if the cause of unsatisfactory results is traceable to the trees having been planted too deeply on a heavy wet soil they are taken up bodily with care. This done the wet ungenial soil is removed, sufficient drainage being placed at the bottom of each hole to prevent the possibility of the roots of the trees when replanted being at any time submerged. The trees are then transplanted in the best prepared soil at command—a compost consisting of four parts sound loam and one of mortar rubble and wood ashes—spreading the roots over the soil with a slight inclination downwards, and covering them 5 or 6 inches deep with the mixture indicated, following this with a mulching of short dung. The branches of the trees being tacked loosely to the walls until the soil in which they are planted has settled down, an allowance of 3 or 4 inches above the ground line being made for this purpose in planting.

A plan Mr. Murray has adopted for several years is to plant young trees in any open space that can be spared for the purpose, giving them good soil to grow them in for two or three years before transplanting them where they are to remain, making good sized pits and putting about 14 inches thick of road metal in the bottom, making the surface of the metal smooth with lime rubbish before putting therein the necessary complement of soil in which to plant the trees. This, Mr. Murray says, he finds to be much better than flagstones or concrete. Standards, pyramids, and espalier fruit trees are treated in the same manner before they bear well, and as the result of this treatment the fruit is improved in size and quality where there is a very bad cold clay subsoil. The trees, too, are the picture of health during the summer and autumn months, the foliage being quite free from blight, and ripens quite differently from that of trees having their roots down in bad soil. The leaves fall naturally, whereas trees that are in bad condition keep green until they are forced off by the frost, showing that the wood is not ripe and a bad prospect for a crop of fruit the following year.

The subject of root-pruning, lifting, and transplanting fruit trees with a view to promoting fertility, and afterwards maintaining the said trees in a fruitful condition, is not exhausted yet, and its importance in a commercial point of view is sufficient reason for the matter treated of being discussed for the benefit of all fruit growers. In support of this assertion I will quote Mr. Murray's own words, which afford conclusive evidence on this point. He says, "Just take into consideration the great number of fruit trees that is pruned and nailed from year to year that never yield a shillingworth of fruit in return. This happens more frequently in districts having a bad wet subsoil;" adding, "I know many large gardens in which this state of things is allowed to go on from year to year, expecting a crop of fruit without ever making any effort to get the trees in a bearing state, they very likely being in the same positions in which they were planted as maiden trees." Unfortunately, Mr. Murray's experience in this respect coincides with that of many other gardeners similarly situated.

As soon as the crops have been taken in the autumn is undoubtedly the best time to operate on fruit trees which exhibit signs of exhaustion, or, worse still, have annually failed to yield satisfactory results; nevertheless, we unhesitatingly recommend everyone having trees in the undesirable condition just referred to to set about the work of restoring or promoting fruitfulness in the trees in the manner indicated as soon as possible, so as to get the operation completed before the sap rises. In the case of old stunted trees, root them out and consign them to the fire heap, planting in their stead young healthy trees. Should the prepared soil in which the trees are transplanted be moderately dry, and in the absence of rain at the time the work is being done, give sufficient water to each tree to settle the soil about the roots. Such trees planted as indicated, provided they are afterwards treated with ordinary skill in the way of disbudding, pinching, and training the shoots, giving liberal supplies of water at the roots during a dry summer and keeping the foliage free from the attacks of red spider and aphid, seldom fail to yield good crops of fruit of first-rate quality. Such at any rate is the experience of Mr. David Murray, and no doubt of many other gardeners who have adopted a like method of procedure, including—H. W. WARD.

CULTIVATION OF THE CROTON.

[A paper read by Mr. W. W. Pettigrew before the Young Men's Mutual Improvement Society, Castle Gardens, Cardiff.]

AMONGST ornamental fine-foliaged stove plants the Croton stands in the first rank for the rich colour and gracefulness of its leaves. Most varieties differ so much in habit as to make them well adapted to be grown in great numbers together without looking in the least monotonous. Indeed to grow them to anything like perfection they should have a house to themselves. Few plants are more beautiful when well grown than a collection of Crotons when the sun is shining upon them. The large dark-red foliage of Baron James de Rothschild, the rich golden bronze of Queen Victoria, and the large golden-blotched leaves of Morti, blended with the pale yellow and green foliage of variegatus, and the stiffness of these taken off by the graceful drooping foliage of such varieties as interruptus, interruptus aureus, linearis, Weismanni, Cyrus, chelsoni, aureo-punctatus, Princess of Wales, elegantissimus, Warreni, and many others, is a sight to be remembered by all interested in the cultivation of fine-foliaged plants.

The Croton belongs to the natural order of Euphorbiaceæ, and is a native of the East and West Indies, South America, and several other places. It was introduced into Britain during the last century, but since then the varieties—thanks to the energy of hybridisers—have increased to hundreds. The culture of the Croton is comparatively easy, yet it is seldom seen in its best condition. It is now nearly eighteen months since I was entrusted with the management of the Croton house here, and since then I have endeavoured most carefully to carry out the instructions I received, and note the treatment which suited the plants best, and everything I mention in this paper regarding their culture is from my own experience.

To perpetuate a variety of any plant it must be propagated by cuttings, buds, or grafts, as those raised from the seed rarely come true. As a proof of this I may mention that I have at present six seedling Crotons, from 4 to 5 inches high, raised from one of the narrow-leaved varieties, and not one resembles the parent plant, and no two of them are alike. They differ much in the colour and shape of their leaves, and also in the habit of their growth. Some have narrow leaves of different shades of colour, while others have broad green leaves with no signs of variegation whatever.

Crotons can be propagated at almost any season by inserting strong cuttings of half-ripened wood in small pots in a soil or composition made of equal parts of loam, leaf mould, and silver sand, and plunged in a gentle bottom heat until they are rooted. During this stage the cuttings should be dewed over the foliage with a fine-rose watering pot every day to keep the leaves fresh and to prevent red spider attacking them. When the cuttings are sufficiently rooted, which will take from three to six weeks according to the season, they are shifted into pots a size larger, using the following compost—three parts good fibry loam, one of peat, one of leaf mould, a good sprinkling of Thomson's Vine and plant manure, and about a third of the whole of sharp river sand, which will keep the compost fresh and porous. The plants are then placed in the stove close to the glass, where they will receive as much light and sunshine as possible. As the plants increase in size they are shifted into larger pots, always using the same compost as that just mentioned.

Great care must be exercised in watering the plants. The soil should never be allowed to become too dry or too wet and sodden, or the roots will be injured and decay, and the plants will suffer in consequence. The roots of the Croton are soft and spongy, and are therefore liable to damp off if the soil becomes wet and sour on the one hand, or too dry on the other. Great care and attention should therefore be paid to watering at the proper time and in sufficient quantity to keep the plants in a healthy growing state.

It has been truly said that one of the secrets of success in the cultivation of any plant is the frequent and judicious application of manure. This is especially so with regard to the Croton. The great amount of foliage which a large and healthy plant has to roush soon extracts all fertility from the soil in which it is potted. It is quite different with plants growing in the open air. The soil in which they are growing is always receiving, more or less, natural manures from the rain, for rain and snow never fall to the earth without carrying fertilisers with them. As a matter of course plants grown under glass receive none of these, consequently if they are to be grown successfully manures must be applied artificially, and in greater quantities to large plants that have filled their pots with roots and are growing vigorously, than to those whose growth is at a temporary standstill. The fertilisers applied to the Crotons here are Thomson's Vine and plant manure, liquid cow manure, and soot. The first of these is used as a surface dressing, and the soot and cow manure are mixed together and used when watering.

Crotons are subject to the attacks of several insect-pests, but the worst I think is red spider. If once this has possession of any plant its health is ruined in a short time, and the leaves fall off one by one, completely disfiguring it if the spider is not checked at once. The yellow varieties I find are more subject to its attacks than any of the others. The best plan is to give the plants a thorough, and individual, syringing as soon as the pest appears and wash it clean off. But prevention is better than cure, and I think if the syringe was used judiciously every day red spider would be kept under.

Thrips are also great enemies to the Croton; if once they get on a plant the leaves are soon disfigured and ruined, no matter how excellent the treatment may have been. A sharp look out should be kept at all times for this pest, for, unlike red spider, its effects on the plant are not seen all at once, and it is only by close investigation that its presence is discovered in its early stage of development. To get rid of thrips we have two methods—the first is by fumigating the house with tobacco paper, and the other by syringing the plants with a decoction made from tobacco paper mixed in water. The first of these methods is the easiest though the least effective in getting rid of the pest, and the most detrimental to the health of the plants. Many of the thrips fall off the plants and bury themselves in the soil, and remain comparatively uninjured, and by-and-by they ascend the plants again. The smoke is detrimental to the Croton to a certain degree, as I find after the house has been fumigated three times in succession to kill the thrips that many of the leaves fall. Therefore syringing is the most effectual in killing these pests, and it is not in the least injurious to the plants. The only objection to syringing is that it entails a great amount of labour in carrying the plants outside to the open air, and shifting heavy plants loosens the stakes and makes them a little unshapely for the time. Small plants are dipped in the tobacco juice decoction without any trouble.

Scale is another pest which sometimes infests Crotons, but it is easily killed by syringing with a little petroleum mixed in water and kept in perpetual motion while being applied to the plant. Mealy bug can be destroyed in the same way.

I have said nothing in this paper about draining, potting, stopping the shoots to make well-furnished bushy plants, or about heat, moisture, and the ventilation of the house. The pots here are thoroughly cleaned and well drained for all plants that have to be grown for any length of time in them, and in potting the plants are placed a little lower than they were in their previous pots to cover the top of the ball. The soil is pressed firmly down, and when finished sufficient space is left at the top of the pot for watering. The plants are trained with as few stakes

as possible to put them in shape, and the strong shoots stopped shortly before they begin to grow in the spring, to make them branch out and furnish the plant with fine leaves from top to bottom. The temperature of the house is kept at 70°, and it is ventilated when the heat rises above that degree in sunny weather, and it is allowed to rise to 80° or 90° with air in the summer time. When the plants are growing they require abundance of water. They are syringed twice a day, and the bed and path damped frequently during the day.

UNDER GARDENERS AND EXHIBITORS.

CHEER up, under gardeners, don't look so gloomy because you are not complimented by all and sundry regarding the skill you have shown in the cultivation of some special plant, fruit or flower that has been under your own devoted care. Bear in mind that the merits of a good man will not be overlooked, although at the time they may be but little talked of. By the time you want to make a change to better your position, you will, if deserving, receive a certificate from your commander-in-chief, which will stand you in better stead than all the paltry compliments which some of our brethren seem to attach so much importance to. The man who pays attention to his duties and takes a thorough interest in his employment is very seldom overlooked by his superior officers.

Now, do not imagine when I mention taking an interest in the profession that I am an advocate for working extra time systematically without remuneration, but I think there are times when every young gardener who has real interest in his business will not grumble to go out an hour or two in the evenings if he sees that some important work wants doing, whether or not he receive remuneration for his extra services. I know some gardeners who expect their assistants to work overtime every night all the summer without the least encouragement, but rather instead a continual growling. Such men ought not to receive any extra labour from subordinates.

Some of your correspondents try to make out that in the majority of places where exhibiting is carried on under gardeners receive no remuneration to repay extra labour and expenses incurred in taking exhibits to and from the shows. I quite believe there are some such places, but I am confident they are in the minority. Where such a system does exist there is ample room for dissatisfaction on the part of under gardeners; but if under gardeners are to rank for an equal share of praise and prize money in the times of success, and then stand out altogether in the hour of defeat and allow the head gardener to defray all expenses, then the time will come when, instead of our ambition carrying us to a head position, we shall prefer to remain subordinates.

I have been brought in contact with many exhibitors, but there was not one amongst them who did not give his assistants ample remuneration to cover all show expenses. For two years I was under one of the principal exhibitors in the north and was always honourably treated. I did not expect to have an equal share either of money or praise, but was always delighted to think that a little exertion on my part was appreciated by one who did not forget me when he had a chance to further my interests for a higher situation.

Some are also inclined to think that places where exhibiting is carried on are detrimental to all round practical knowledge. With those I again disagree. Are we to ignore the hundreds of establishments which have proved to the horticultural world their superiority in the culture of all round garden produce? I say, No, but ought rather to be looked at as models in the gardening world.—J. E. M.

Mr. GOSCHEN'S advice to the Aberdeen students may be equally acceptable to many of our own fraternity, and his remarks apply with equal force to those whose complaints have been published in this Journal the last few weeks under the guise of "Under Gardeners." When he says, If a man is anxious to succeed he must study for the love of learning, and not for the sake of gain, and to put their whole energy in their work, for unless they do this they are doomed to disappointment, and are found the most discontented with their lot. Surely these remarks strike hard those who seem to begrudge any little extra exertions their employer may require of them, fearing it might benefit the employer more than themselves. The reason for this is difficult to imagine, for are not their interests identical? for I doubt if the one could make much progress without the aid of the other. How easy it is to apply every exertion to any little pet hobby of our own, how assiduously we work until our end is accomplished. Now where is the difficulty to apply a little of the same energy for the supposed benefit of others, which in the case of gardeners are one and the same? I think the difficulty will be found in the disposition.

Mr. Goschen alludes to the high class education in the commercial schools of Germany, and regrets the same schemes are not practised in this country, but I question if the benefits would be as great as expected, for cultivation seems to injure our disposition for work.—J. H. GOODACRE.

DAFFODILS IN POTS.

HAVING grown these for early work in great numbers I am well able to endorse the opening statement of Mr. Calthorpe, at page 82, where he says, "these are not grown nearly as much as they deserve to be." Your correspondent appears to have experience of Daffodils going blind, at the same time attributes the fact to a rather strange cause. During the

planting season—*i.e.*, from September to November, we frequently turn out a few "rogues," which at that busy time are thrown into the "mixed boxes" to await attention. If taken from a quarter where the best are planted they are in time replanted, but if not they are thrown away. I have experiences of the latter which include many varieties, lying in a heap the whole of the winter exposed to all weather, and having several inches of new roots upon them when upturned, still making efforts to grow, and curiosity has led me to try what they are capable of enduring; the results I will in due time record. Some Tenby Daffodils, however, which had escaped notice when they were picked up, and which were discovered in December last when planting other things, I have put in boxes and pots, and these have since flowered well, notwithstanding that they were on the surface for nearly five months fully exposed, and from the manner the majority perfected their flowers one would imagine that their culture had been the best throughout. Certainly the flowers had been previously formed in the bulb, and all that remained was to bring them out. This could hardly follow if, as your correspondent imagines, exposure to light should cause them to go blind. I do not see how the light would affect them, especially when they were only left under the ashes till "well rooted," which they would be in four or five weeks after potting, and the growth still under the surface. Had Mr. Calthorpe allowed them to remain till now covered with 3 inches of ashes, I do not think he would find them above it. I am of opinion that we must seek in another direction for the cause of blindness, and would suggest that the pots used by your correspondent are much too small. Imagine three fair-sized flowering bulbs of double Daffodils in a 4-inch pot. Such a statement makes one inquire—first, where are the bulbs? secondly, where are the roots these would form? and thirdly, where is there sufficient soil in so small a compass for their sustenance and development?

Two other causes of Daffodils going blind are subjecting them to the hottest sun after being lifted, and packing them too closely together before being fairly dried, which causes sweating. Either of these as well as giving them too much heat very early in their season will cause the flower buds to go blind in the bulb. All the Daffodils after the opening of February will endure a much stronger temperature than that given by Mr. Calthorpe with impunity, at least so far as flowering them is concerned, but before that time they should be kept as cool as possible, for although they are to be had in flower much earlier than the present time, it is only done at great risk and frequent heavy losses. Apart from this fact I hardly see the need of them while Chrysanthemums can be had in quantity, and also any colour, though perhaps the tone of colour which we find in these Daffodils is not easily matched and is eagerly sought for.—J. H. E.

I QUITE agree with your correspondent, Mr. J. A. Calthorpe, page 82, that these are not grown nearly so much as they deserve, and as there are many varieties greatly admired when seen flowering in the outdoor borders, it does seem a mistake not to prolong their season of enjoyment. It is easy enough to have them in flower early in January, and we find it possible even some days earlier still. We quite agree that too great heat is not so well for them, but the well-known Tenby variety, provided the pots are well filled with roots to begin with, will stand very well in 55° to 65° of heat without drawing, provided it is kept near the glass up to the point of one or two blooms just opening, then moved into a cooler place for a few days before being taken in for house decoration. We are always glad of this variety as soon as we can possibly have it in flower. We place seven bulbs in a 32-inch pot, and the wonder is that gardeners do not grow this variety a great deal more than they do. We like to have a few pots also in our plant house arranged among Hyacinths and other things. Then, too, how seldom we meet with that pretty little variety, minor or nanus, which can be had in flower soon after Christmas, and when frequently called upon to furnish a quantity of cut flowers for small glasses on the dinner table this variety is most useful.

In regard to covering bulbs with coal ashes after being potted, there seems to us to be only one advantage as against fresh fallen sweet leaves—namely, that you can leave the bulbs longer under them than under leaves, the ashes not crippling the growth like leaves; but as this can easily be avoided, we much prefer leaves, and to get a good pressure we lay heavy boards over the leaves, otherwise a quantity of leaves would be wanted to get the weight required to prevent the bulbs rising out of the soil while making their roots.—T. S.

THE LIVERPOOL HORTICULTURAL ASSOCIATION.

THE short report of the annual meeting which appeared in your last issue commenced and finished with the close of the proceedings, and must convey the impression of a conflict of opinion between two of its members rather than a summary of the general proceedings. At the previous annual meeting, held on January 21st, 1887, the Treasurer's financial statement showed a balance to the good of the Society of £549 16s. 4d.; the statement of accounts for the past year, however, are far less satisfactory, the balance being £340 18s. 6d., or a loss on the year's working of £208 17s. 10d. The Spring Show was fairly satisfactory, proving a gain of £17 8s. 9d. on the corresponding Show of 1886. The Summer Show was very unsatisfactory, the loss being £147 1s. 11d. as compared with that of 1885. The Autumn Exhibition was equally disappointing, and proved a loss of £72 4s. 10d. compared with the Show of 1886. The amount collected in subscriptions is £564 18s. 6d., or £26 5s. less than in 1886.

After the adoption of the report and balance-sheet, and a vote of thanks to retiring officials, the election of officers for the present year took place, which resulted in the re-election of Fletcher Rogers, Esq., as Hon. Treasurer; Mr. G. Blackmore, Sub-Treasurer; Mr. E. Bridge, Secretary; Mr. J. Kelly and Mr. J. Peers, Auditors; while Messrs. White, Bennett, Jellicoe, Rimmer, Turner, Wilson, and Cox were re-elected members of the Committee; two new members being added in Mr. D. Lindsay and Mr. Bryan.

Mr. R. W. Ker then proposed that the sums of £3 and £2 be granted as donations to the funds of the Gardeners' Royal Benevolent Institution and the Gardeners' Orphan Fund respectively; this being carried unanimously.

Mr. Bardney, in order to reduce the expenses of the Society, next proposed that the amount offered in prizes for the three Shows of 1888 be reduced to the extent of £157—viz., £17 Spring, £105 Summer, and £35 Autumn Exhibitions respectively. To this Mr. Cox moved an amendment that the subject be left in the hands of the Committee, which was carried by a majority of two to one. A cordial vote of thanks to Mr. White for presiding brought the meeting to a close.

The Committee have already arranged for three shows as usual, the amount offered in prizes being about the same as last year. The Spring Show, as already advertised, will be held on March 21st.—A COMMITTEEMAN.

[Other Horticultural Societies with a favourable balance in hand may imitate the excellent example of the Liverpool Association in contributing to the funds of the Institutions mentioned.]

DATES OF CHRYSANTHEMUM SHOWS.

A CORRESPONDENT suggests the desirability of our publishing dates of fixtures of shows where such have been decided, as he thinks this might guide other Societies in their fixtures, and to some extent avoid "clashing," though that is difficult with so many exhibitions occurring within a month. If secretaries of shows will favour us with a postcard of their dates for the present year, whether they have been previously intimated or not, we will insert them as suggested.

CHRYSANTHEMUM GROUPS.

NOTHING adds more to the attractions of a Chrysanthemum Show than groups of Chrysanthemums interspersed with foliage plants, and yet I am surprised to find that out of about forty societies whose schedules for last year I have been looking through, only seven societies allow foliage plants to be used in arranging groups.

The Chrysanthemum plant alone is not well adapted for the formation of artistic groups, although for staging as cut blooms it is unsurpassed. But what can be more beautiful than groups of Chrysanthemums relieved with handsome foliage plants and surrounded with a bordering of Ferns and other dwarf plants? Such plants show none of the stiffness and want of grace of Chrysanthemum groups alone. Their unsightly sticks and stems are effectually hidden, and their formation, whether the shape be circular, square, or semi-circular, provide great scope for the display of taste and judgment. In order to maintain the distinctive character of the Chrysanthemum show all other flowers, also berries, should be rigidly excluded. As societies will soon be arranging their schedules I offer this suggestion as a means of increasing the attractiveness of their exhibitions.—EDW. HARLAND.

SHOWING—OWNERS' CLAIMS.

I HOPE the letter of "Phantom" will not cause "Wraith" to omit the letter *i* in his *nom de plume*, but it certainly does seem to me to be inconsequent and illogical, and during the reading of it I found myself once or twice repeating one of the sentences—"Surely there is a mistake somewhere."

I did not gather from "Wraith's" letter that he objects in any way to the prefix of "Mr." to the gardener's name. I understood him merely to be contrasting the old form of exhibition card with the modern one, and agree in almost every respect with the subject of his letter. No employer worthy of an honest man would object to the titles of common courtesy being applied to his gardener however humble his position might be, but it is apparently this supposed objection which has raised the ire of "Phantom" in all the first part of his letter. If not, what has the truth that some gardeners are men of refinement and education to do with the fact that the flowers they exhibit belong to their employers? "Phantom" says later, . . . "we return to the gardeners. In the future their names must not appear. Reports of shows will then stand thus," &c., which he has no doubt made very amusing. But if it be asked, Who has suggested that gardeners' names must not appear? it must be answered, Nobody but "Phantom" himself in the words quoted. He has himself raised a phantom for the purpose of demolishing it, not a difficult task.

"Wraith" wrote to complain of employers' names being omitted,

and a very just complaint in my opinion, and "Phantom" writes to show how unjust it would be to omit gardeners' names, which no one but himself had suggested.—W. R. RAILLEM.

I DO not exhibit very much, but when I do I certainly like to have my master's name on the cards, and always send his name with the entries. In 1887 I exhibited at three shows in the north, and in no one instance was his name on the cards. In the papers reporting the shows his name, of course, never appeared, and I must say that if we were in changed positions I should not like to go round an exhibition and see my own produce shown without the slightest notice being taken of my right in it. It so happens that poultry, horses, cattle, &c., are shown from the same estate, and the owners' name is the only one mentioned in these cases. I do think this is a matter requiring to be remedied.—B.

RALPH BROCKLEBANK.

I HAVE (Feb. 3rd) sent herewith two Chrysanthemum flowers—one of Meg Merrilies and the other the golden sport from it, Mr. R. Brocklebank—to show the adaptability of these varieties for late work. They are, as you will, see terminal flowers from disbudded plants.—T. WINKWORTH, *Childwall, Liverpool*.

[The flowers were very fresh and good for the time of year, Ralph Brocklebank especially so.]

CHRYSANTHEMUM PROPAGATION.

I HAVE several hundreds of Chrysanthemums inserted in cold frames exactly like Calceolarias, Violas, and other hardy plants of that type. These are, of course, cuttings which were taken early. Those who do not require to grow exhibition blooms may use a considerable freedom in the methods of propagation. We have repeatedly struck stock in a hot propagating house, and never saw any bad effects follow. Last season I was obliged to strike between two and three hundred in this way, and some of them turned out as well as those that were struck earlier and cooler. I allow myself considerable latitude throughout with regard to these most useful flowers, and find one method of treating them just as good as another.

I have not seen gloriosum set down as worth growing for its scent. Here it is decidedly honey-scented. It is also one of the very best for decorative purposes in a cut state, though it must be grown on the single stem principle in order to have fine blooms.—B.

JAPANESE CHRYSANTHEMUMS FOR EXHIBITION.

FOR the information of "An Anxious Inquirer" I give the names of varieties which in my opinion are the best nine varieties of large Japanese for exhibition, adding also their colours. Madame C. Audiguier, deep mauve; Belle Paule, white edged with rosy purple; Boule d'Or, yellow and bronze; Jeanne Délaux, dark velvety brown; Edwin Molyneux, purple, crimson, and gold; Mr. H. Cannell, soft yellow; Mrs. H. Cannell, snowy white; Fair Maid of Guernsey, white; Triomphe de la Rue des Châlets, salmon red. If nine varieties are required for exhibition it would not be wise to depend upon that number only for supplying the necessary blooms, as all varieties do not succeed in the same season; therefore it is better to allow a margin by growing more than are really required. At the least three or four varieties should be added to the number already given. Criterion, amber; Mdlle. Lacroix, white; Ralph Brocklebank, primrose yellow; Mrs. J. Wright, white. Avalanche is a very fine white variety, but as it is so scarce at present it is perhaps not wise to give it a foremost position in a list of varieties for fear of disappointment to those wishful to cultivate this sort.—E. MOLYNEUX.

MR. H. LOWMAN also gives the following names of nine good Japanese varieties worth growing:—H. Cannell, Avalanche, W. G. Drover, E. Molyneux, Carew Underwood, Ralph Brocklebank, Mrs. H. Cannell, Maggie Mitchell, and Boule d'Or.

CHRYSANTHEMUM PROPAGATION.

I WAS pleased to read the note under the above heading by Mr. A. R. Cox on page 91. As a well-known successful cultivator and exhibitor, the opinions of Mr. Cox will carry much weight with many readers, and justly so. Nevertheless, as he surmises, I do not believe the mode he advocates and practises to be the best possible. The mode I have found most simple and successful for the last four or five years is to place four or five cuttings in each pot, and to place the pots inside small single-light frames, which are quite cool, excepting that they are placed inside a freely ventilated Peach house, from which, as in the case of Mr. Cox's house, frost is excluded by hot-water pipes. The frame lights are slightly tilted almost from the first, and the condensed moisture is wiped off them each day. Under this treatment the cuttings never flag, are about one month in forming roots, and there are scarcely any losses. I do not think I have this season lost more than 5 per cent. of all the cuttings inserted. I certainly cannot suppose flagging can be beneficial, and it must cause the cuttings to be a longer time in producing roots than when such is prevented.—W. K. W.

CHRYSANTHEMUM ROSEUM SUPERBUM.

PERMIT me to write a word in praise of this excellent Chrysanthemum. We have had it in flower here since the second or third week of November. For cutting it is invaluable, and is much appreciated arranged with Maidenhair Fern. We cut the last of it on the 4th inst.

for the dining-room table. It is rather a tall-growing variety, but if grown on the cut-back system it can be had dwarfier.—G. HILTON.

EXHIBITION CHRYSANTHEMUMS.

I SEND the results (tabulated) of the Chrysanthemum competitions of the past season. It is compiled on the same lines as the one you published last year, and commences with the Southampton Show, November 2nd. Even a cursory glance will demonstrate what considerable changes in the relative positions of the various kinds have taken place during 1887.

Among the incurred Empress of India still leads, but only in conjunction with Lord Alcester, which occupied seventh place last year; having ousted Golden Empress, this latter variety retiring to fourth place, where it now ties with Queen of England, which has advanced one place. Lord Wolesley's record is disappointing, but Alfred Salter jumps from the sixteenth up to the seventh place. Hero of Stoke Newington rises ten places, while Empress Eugenie wins more than double the number of prizes in 1887 than it did in 1886! Nil Desperandum, on the other hand, experiences "a heavy fall," securing only six prizes against twenty-seven in 1886. I will not go further through the list; your readers can make their own observations and draw their own deductions, which will doubtless vary greatly. I may, however, point to the rapid rise to fame of Bronze Queen and Mrs. N. Davis, neither being prizewinners in 1886. Last year, however, they took eleven and five prizes respectively, being the only new incurred varieties which have come to the front at all.

Position in 1887.	Position in 1886.	INCURRED. First Fifty Prize-winning Varieties.	Number of Prizes.	Position in 1887.	Position in 1886.	JAPANESE. First Fifty Prize-winning Varieties.	Number of Prizes.

Among Japanese the most remarkable change of fortune is to be found in the case of Belle Paule, which stood fourteenth on the list in 1886, but in 1887 yielded only to that grand old favourite Madame C. Audiguier. Jeanne Délaux, however, ties with Belle Paule, while Meg Merrilies runs it very close. Mlle. Lacroix, Comte de Germiny and Peter the Great recede considerably, though the greatest "backward-ation" is to be found in Japonaise, with only thirteen prizes last season against thirty-four in 1886. I may just mention here that during the southern shows Val d'Andorre seemed likely to secure premier honours, but as the season advanced this fine variety ceased to advance in favour.

Perhaps the most astonishing fact to notice in connection with the past season has been the rise of Ralph Brocklebank from 0 in 1886 to fifteenth place in the 1887 list, while Edwin Molyneux, a still newer variety, has already won four prizes. Madame B. Pigny, Martha Harding, and Carew Underwood also stand well. But with these few exceptions that vast crowd of new varieties brought out with such a flourish of trumpets in 1886 have failed as prizewinners, and have probably ere this been consigned to their proper place, the rubbish

heap! Duchess of Albany and Bertie Rendatler, you will notice occupy exactly the same places as last year, a coincidence which also occurs amongst the incurred in the case of Mr. Brunlees.—B. D. K.

SIZE VERSUS QUALITY.

I AM very much obliged to Mr. Goodacre for so strikingly corroborating the observations made by me on this subject, and if he will read again he will find I did not, as a rule, condemn the growth of fine sorts to their full dimensions. When I said "Muscats and others of that type," the reference is wide enough to include Canon Hall, and also the Duke of Buccleuch. As I said, where there are exceptions they only prove the rule. Surely Mr. Goodacre would never suppose that I could class the grand old Royal George Peach among the large and coarse varieties, such as Lord Palmerston and Barrington. I must say that I do not admire the taste that would prefer a pumpkin-looking Melon, 20 lbs. weight, in the dessert in preference to a moderate sized fruit. If Mr. Goodacre's twenty pounder be as fine in flavour as, say, Imperial Green Flesh or Golden Perfection Melons it is such an exception as I have never met with, and even if it be, would not five 4 lb. fruits be more desirable for family use? Many families would not allow a Melon of such size on the table. I am afraid it would be stale by the time it was all eaten.—D. THOMSON.

KITCHEN GARDEN.

THE WEATHER AND THE CROPS.—The weather has been seasonable, with frost and snow, and although these are not favourable to the advancement of kitchen garden crops or work, all vegetable gardens will be benefited by them. The soil works beautifully in March after a February frost, and where all empty quarters have been dug roughly over the surface will now be receiving as much benefit as if it was dressed with some artificial fertiliser. The application of manure should be pushed forward, all trash and refuse burned, and the ashes placed on the soil. Vacant quarters undug may be turned deeply in open weather, as in all probability they may still be favoured with sharp frost.

FORCING.—As a rule a great effort is made to have a quantity of forced produce in at Christmas, but after that the supply is apt to lessen, and in many cases this will not give satisfaction. Choice vegetables in the dead of winter are always acceptable, and so they are in the spring months, as February and March are periods when the supply of open air vegetables are often more scarce than in December and January. We would therefore urge cultivators to force all they can at this time. Do not rob the Asparagus beds by lifting more roots for forcing than can be spared, but do not fail to force all surplus ones. Every root of Seakale may be forced that is large enough to bear this operation, as it can always be planted afterwards to grow and become useful again. Rhubarb may also be forced in quantity. Do not lift the roots now, but cover them with pots, boxes, or casks, and fermenting material. Keep up a supply of Mustard and Cress, and fill all available spaces with Kidney Beans.

TOMATOES.—The open air culture of Tomatoes is becoming more common every year. Those who try them find they succeed better than they expected, and their culture is so easy in the open and the crop so heavy that they soon insure for themselves extended favour. It is essential that the plants be raised early and have them well advanced in size for planting out in May. We have known good plants turned out then produce ripe fruit by the end of June, and continue bearing heavily until cut off by frost in early winter. We therefore recommend seed to produce plants for the open to be sown at once. If a pinch is sown in a 6-inch pot many plants will be produced that will soon gain size when repotted singly or put into boxes a few inches apart. These plants should not be hurried; they are much better when kept in a temperate place and grown sturdily, as then they do not receive any check in being transferred to the open. Spindly plants are never satisfactory. We have raised some capital plants for the open air by taking cuttings from the early fruiting plants, and if these are rooted in March they will be found to do well.

POTATOES IN FRAMES.—No matter what the weather may be, we never think of planting Potatoes in the open until March. Good weather might tempt some to put them on in February under the protection of a wall, but the growth is seldom rapid or satisfactory, and we always have more from a March planting than a February one, but early Potatoes may always be had in quantity from frames, and all structures of this sort may be filled with them. As a rule they are grown on hotbeds, and many are of opinion that early Potatoes can only be had by the aid of such; indeed, they never think of planting unless they can put them on a hotbed, but their culture might be greatly extended in frames without hot manure. A hotbed always causes Potatoes to make much top growth; in fact, this is so luxuriant in some cases that it almost prevents the tubers gaining any size, but if the Potatoes are planted in the frames without manure this will not happen, as they are not forced

into unnatural growth. If some good rich soil is put into the frames to about the depth of 1 foot, and the sets planted 15 inches apart and 6 inches deep, they will produce a fine crop and be ready for use some weeks before any planted in the open. In dealing with first crop Potatoes none but the earliest should be planted, and these are all of the Ashleaf type. At present we are filling twelve lights with them.

VEGETABLES FOR FIRST CROPS.—We can see it is not likely to be a very grand spring for raising young Cauliflowers and Brussels Sprouts in the open for the first crops, and an early supply of all sorts should be raised under glass. It is astonishing what can be done with frames in this way, or indeed a few boards and glass lights. If a slight hotbed is formed, a rough frame put on the top of it, and a layer of good soil put inside, a capital place for raising early vegetables is at once formed. We have just sown two lights of Cauliflower, one light of Brussels Sprouts, one light of Lettuces, one light of Celery, two lights of Radishes, and one light of early Cabbages in this way. The young plants will soon appear, and by carefully ventilating them on fine days and covering them in frosty nights they will grow so hardy and sturdy that many of the largest will be transferred direct from the frame to their bearing quarters early in April. Where frames are not available, a pinch of seed may be sown in a box of the vegetables named except the Radishes, and an attempt should be made to have some in as soon as possible, as plants raised under protection are always in advance of those in the open air.

FRUIT FORCING.

VINES.—*New Borders.*—The soil for new borders should now be prepared, and the best for the purpose is the top 3 or 4 inches of a rich pasture of a friable nature, neither very light nor very heavy. As that is not always obtainable light loam may have an addition of clay marl, and heavy loam an addition of old mortar rubbish, about a sixth in each case. To good friable loam add a tenth of old mortar rubbish broken small, removing every particle of wood, as laths, &c. To all add a twentieth part of the bulk of charcoal, and a fortieth part each of crushed bones and calcined oyster shells. Chalk is also a good application to light soil. If the soil be poor a fifth part of short fresh stable manure or horse droppings may be added, otherwise manure or vegetable refuse should not be added, manure in most cases being best applied as a mulch. In preparing the border, which may be proceeded with as the weather permits, bear in mind that no fruit tree requires more copious supplies of water when in growth than the Vine, and at the same time is more impatient of stagnant water; hence drainage should receive first attention, and instead of excavating, concreting, and cementing, keep the border well elevated as far as circumstances admit. Employ 3-inch drains, with proper fall and outlet. Provide a foot of drainage, the roughest at the bottom and the smallest at the top, which last preferably may be old mortar rubbish. If the border is intended for early or late Vines allow a sharp slope to the south for the purpose of throwing off the wet by shutters or other means. The best time for planting Vines is from April to June inclusive, and those intended to be planted at that season should now be cut back to the length required and be placed in a cool Peach house or pit to start into growth, and the new shoots are 2 or 3 inches long shake out the plants and plant them in the permanent borders. A 6 feet width of border will be sufficient in the first instance. Where the Vine roots are to have the run of both inside and outside borders they should be confined inside, not making the outside border until the Vines are thoroughly established.

Early Forced House.—The Vines in flower must have a temperature of 60° to 65° at night and 70° to 75° by day artificially. Keep the atmosphere somewhat drier by free ventilation, leaving a little air on at night, yet keeping the floors sprinkled three times a day during bright weather. Any shy-setting Grapes may have the pollen distributed by brushing them with a camel's-hair brush. Stop the laterals at the first leaf, and keep those stopped to one joint throughout the season, but those beyond the bunch may be allowed to make two or more joints before stopping them, provided there is space for the full exposure of the foliage to light and air. Avoid overcrowding the foliage; it is better to reduce the laterals than do that.

Houses Started at the New Year.—The Vines are in leaf and showing fruit. Dishud when it is seen which shoots are likely to afford the best bunches. One bunch on a spur is as much as is likely to finish satisfactorily, but if there be space, the spurs being widely distant along the rod, two shoots may be left, it being clearly understood that only one is to be allowed to carry fruit, the duplicate only remaining until choice can be made of the best, and in case of two shoots being left one ought to be near the main rod, so as to keep the spur as short as possible. Weakly Vines, however, may be given more latitude, so as to secure stouter wood, larger and plumper eyes, and better bunches in future. See that outside borders are sufficiently protected to prevent chill by heavy rain or snow.

Houses to Afford Grapes in July and August.—The Vines must now be started. Damp the roots three times a day and every available surface. A temperature of 50° at night, 55° by day, and 65° from sun heat is suitable until the buds begin to move. Bring the inside border into a thoroughly moist state by repeated supplies of tepid water or liquid manure. Afford outside borders sufficient protective material to prevent chill.

Ripe Grapes.—Avoid fire heat as much as possible in the Grape-room, admitting air to prevent an accumulation of moisture, replenishing the latter with clear soft water as required. An equable temperature of 45° is most suitable.

CHERRY HOUSES.—These are not nearly so common as they deserve to be, indeed there is no fruit so esteemed at dessert as this most agreeable fruit. A lean-to house erected against a wall with a south aspect is suitable for Cherries, and it need not be more than 6 feet in width. The back wall can be covered with trees, and the front to a height of about 6 feet with trees on the Mahaleb stock. Provide ventilation at the bottom and top of the house, and the front roof lights be movable. The border should be inside, though the roots may have access to an outside one, thoroughly drained to carry off superfluous water. Good loam rather strong is most suitable, adding about a sixth of old mortar rubbish and a fifth of road scrapings, increasing the grit if the soil be too aluminous. Trees from the open wall between four and six years trained, if carefully removed to the house come into bearing at once. Water them well to settle the soil about the roots, and ventilate freely, syringing in the morning and again early in the afternoon, employing fire heat only to exclude frost; but when the trees are fairly in growth let the day temperature from fire heat be 50° to 55°, rising to 60° to 65° from sun, increasing the ventilation at 55°, and close at that temperature, leaving, however, a little ventilation on day and night, 40° to 45° at night from artificial heat will be sufficient. May Duke, Black Tartarian, Elton, and Governor Wood are suitable for forcing.

THE FLOWER GARDEN AND PLEASURE GROUND.

Propagating Dahlias.—As a rule plants with one single stem or those struck the same season are the best for planting, one strong branching stem being preferable to several weakly ones proceeding from an old stem and tubers. Any old roots that have been stored, if set on the inside border of an early vinery or Peach house and covered with soil, will soon give plenty of cuttings, or they may be packed in boxes and set on a gentle hotbed, where they will grow more rapidly. When the shoots are about 3 inches high take them off with a heel and dibble them singly in the centre of 2½-inch pots filled with sandy soil, and plunge in a gentle hotbed. Tops of shoots will also root readily if similarly treated, but they must be taken off before the stems are hollow, or they will not strike. When rooted they ought to be gradually hardened off, and will be greatly improved by a shift into 5-inch or larger pots. Dahlias, notably the single varieties, may also be raised from seed. Sow this now in a pan, and plunge in a mild hotbed. The seed germinates readily, and the seedlings may be pricked off either singly in small pots or thinly in boxes, in which they may remain till bedding-out time.

Dahlias worth Growing.—With so many superior varieties to select from, it is unwise to keep any that are not first rate. Many of the single-flowering varieties are very handsome, some of the best being Alba or White Queen, Avalanche, Canary, Cetewayo, Cicero, Evening Star, Firefly, Gracilis superba, Harlequin, Mary Anderson, Miss E. Terry, Paragon, Rotundity, Rose Queen, Scarlet Defiance, Sunset, Terra-cotta, and Yellow Gem. For affording abundance of pretty little white blooms Pompon Guiding Star or White Aster is to be commended, while the Cactus-flowered section comprise several popular varieties of great value to those who require many cut blooms. Juarezi, tall-growing and very showy; Constance or Ariel, white and very serviceable; Mrs. Hawkins, pale yellow, much admired; and Mrs. Tait, white with fimbriated edges, are all worthy of a place in every garden. Glare of the Garden, both crimson and red, are of dwarf habit and very free; and Cochineal, of much the same habit, is of a richer colour and more attractive than either of them. If dry roots of any of these can be bought procure them at once and start propagating.

PLANT HOUSES.

Adiantums.—Where well hardened fronds are in demand the whole of the year it will be necessary to forward plants into growth by placing them in a temperature of 60°. Directly they are starting transfer all that need it into larger pots. In doing so the roots should not be disturbed further than is necessary to remove the old drainage. If the plants already occupy as large pots as it is intended to grow them in, the plants may be cut into two, and then potted into the same size as they were originally growing in. This operation does not injure them seriously, in fact they quickly recover and soon grow vigorously. It is a mistake to cut them up severely for the purpose of increasing the stock, in fact the system cannot be too strongly condemned. The plants are weakened in time by the constant removal of their fronds, and in order to keep a stock in the most robust health a few should be raised by spores annually, which permits plants declining in vigour to be thrown away. Repot young stock without disturbing the roots. Spores may be sown at once on the surface of pots or pans filled with loam and peat in equal proportions, with sandstone or bricks broken fine freely mixed. Nothing is gained by the surface being made too fine. After sowing water with a fine-rose can and cover with a square of glass. The great object in achieving success is to place the pots or pans in a warm position where a uniform temperature and moisture can be maintained without having to water the surface constantly. This is best achieved by plunging the pots to the rim in moisture-holding material, and then covering the glass with damp moss. When the fronds of *Adiantum cuneatum* are required for cutting, the plants should be potted in three parts of good fibry loam and one part of leaf mould, this being rendered porous by the liberal addition of sand.

Davallias.—Repotting all plants that need it should be done directly they display signs of growth. It is a mistake to delay repotting these plants until the sun gains strength and renders heavy shading necessary long before it would otherwise need to be applied. These plants do not care for a deep rooting medium, but enjoy liberal

surface room upon which their rhizomes can creep. Pans are the most suitable, and these should be liberally drained. Very few of the varieties need potting below the rim of the pans, in fact only those that do not creep. Use for a compost rough fibry peat and loam in equal proportions, to which should be added liberal quantities of coarse sand and charcoal in lumps. Nearly all Davallias do well in baskets and add materially to the attractiveness of any structure in which they may be suspended. *D. Mooreana* creeps rapidly round the sides of a basket, and the same may be said of *D. dissecta*, *D. bullata*, and others. Many of the smaller growing species are admirably adapted for cutting, and when grown in quantity yield abundance of fronds that are highly prized, for they arrive fresh and last a long time in that condition after undergoing a railway journey of several hundred miles.

Polystichum proliferum.—This is a grand Fern for decorative purposes in from 2 to 5-inch pots. It is readily increased by keeping two or three plants in pans and pegging down the mature fronds, all down the centre of which quantities of young ones are produced. Those pegged down in autumn will be ready for cutting off, for all the young ones are rooted. Transplant them into pans or boxes until they are ready for placing into pots. If two or three are planted together instead of singly the plants are fuller and more beautiful when they attain a decorative size. When grown singly the plants are too thin for many purposes.

Pteris tremula.—Transfer small plants from 2 into 4 or 5-inch pots, in which they will make handsome decorative Ferns. For a variety of purposes they are beautiful in a small state. Sow spores, and treat them the same as advised for *Adiantums*.

Lomaria gibba.—This is one of the most attractive Ferns in a small state for decoration. Place those in 3-inch pots into others 2 and 3 inches larger. If spores are sown at once and the young plants afterwards grown on in heat they will be excellent by autumn in 5-inch pots. The same may be said of *Blechnum corcovadense* and *Nephrodium molle*; the latter when growing freely must not be grown too warm, or it will certainly be attacked by scale.

THE BEE-KEEPER.

NOTES ON BEES.

EARLY ACTIVITY.

On a mild day in January, with a temperature of 54°, the bees were out in myriads, and by ten in the morning, to prevent their leaving the garden, I gave them a supply of both water and pea meal. Before my hand was withdrawn from the feeder the bees were in working upon it. Most of the hives carried a great quantity of it, as they also did of water, carrying at both at 4.30 P.M. when getting dusky. The day being so exceptionally fine I remained mostly outside, watching and enjoying the movements of the bees as also the flowers. So great was the growth on that day, Snowdrops that were barely peeping through the ground in the morning were up half an inch or more at night, and Rose bushes were pushing forth their buds. But what was even more interesting than all that was the enormous number of young bees upon the alighting boards and taking short flights.

Hives that I mentioned in an article in December as having turned out the last of their drones on the first day of that month were still clearing them out on that eventful day. The hive that I mentioned having the appearance of breeding much at the same date, and supposed to have a young queen, fertilised as late as the 27th October, has turned out exactly as I supposed. So numerous are the young bees that the hive is already perceptibly increasing in strength, and should the breeding continue at the same rate for a month or two longer it will be necessary to enlarge the hive. What was even more interesting than so many young bees were the drones flying out and in without the slightest interruption. Whether these were young or old ones I do not know.

Altogether this hive has had no parallel in all my experience. It was my best hive during last summer, and was the weakest one throughout the whole of the winter and spring months, and located in a Stewarton hive of the old type, wrapped in a piece of old sacking, over which a piece of inodorous felt is tied, and on the top a few pieces of carpet. A piece of semicircled galvanised iron placed over all sends the water off, keeps all dry, and the bees comfortable; the cheapest and best of all coverings. Plenty of food, pollen, and a young fertile queen at the head of plenty of bees are

the best stimulants and the only ones bee-keepers should attempt to provide their bees with. To prevent over-propolising, the hives should be made tight, and all superfluities, such as excluder zinc, should be kept out of the hive.

How this hive, so far advanced now, will turn out during summer, I know not, but I have every faith that my weakest nuclei will perhaps surpass my present very populous hives, as they have almost invariably done in past years. I certainly do not over-estimate the ulterior advantage of the present advanced state of some of my hives; still there can be no doubt in the minds of reasonable persons, that hives of such a nature, in the hands of bee-masters who are situated in early districts, must be a decided advantage. Then what a world of troubles and disappointment are disposed of in the proof, to those who have been taught that to be successful with bees a certain but great amount of manipulation and artificial work were necessary with bees before they would even respond to the dictates of Nature. Happily for bee-keepers the whilom pupils are becoming teachers, by and through observations made, demonstrated to them from living proof, contrary to what they, in their novitiate days, had been taught.

WINTERING BEES.

I have more than once in the pages of this Journal shown that in this country the best and safest mode of wintering bees with the least amount of trouble, was to leave the bees alone on their summer stand, and with the same dress or covering. To imitate Continental or American bee-keepers in this, or to offer advice to them on the subject, is, in my opinion, assuming too much. The Syrian bees excepted, I have never known bees suffer much from a low temperature, provided they had the opportunity shortly thereafter of airing themselves in a clear atmosphere and the ground free from snow. It is the latter that depopulates our hives, which judicious ventilation and confinement prevent. A protracted season with a very low temperature tell sadly against the bees. But in reality how seldom does this occur. I have never, in all my experience, known bees to be kept within doors throughout November or January. In December I have, but never saw November or January pass but the bees had an airing on one or more days. When bees are kept in confinement during the winter months it matters not what the day is after being set at liberty the bees will be out and fly. That would be all very good if a proper day could be decided upon for their release, but unfortunately in this country the weather is so variable and treacherous that a fine morning is often followed by a cold day, and often till far on in the spring, when it proves fatal to thousands of hardened bees. The longer bees are confined in hives the less able they are to stand the vicissitudes of the weather when liberated. Bees which have been kept upon their summer's stand, after the first flight (which often takes place in January), are more able to fly out and return to their hive than before. It is therefore evident that a flight in January conduces more to the health of the bees and their preservation than if they had been confined in any cellar or structure whatever built expressly for preserving bees. Owing to the loss of bees that in many cases and seasons that is sure to take place after confined bees are liberated, not speaking of the extra expense and trouble involved in preparing a cellar, placing the hives therein, and thereafter returning them to their original stands.

Bees commence breeding soon after the shortest day, and as that proceeds the desire to fly out becomes greater every day, and they cannot be kept healthy unless when in a semi-listless state at a temperature of about 45°. Neither need the fact be overlooked that bees when kept in confinement are as sensitive to the change of temperature outside as if they stood there, and when the temperature rises confined bees will assuredly become active and restless, which tends greatly to aggravate abdominal distension, encouraging incipient disease, which may in all probability render every hive confined unprofitable.

Looking at it from every point of view I can see no advantage to be gained by wintering bees in cellars of any construction. Doubtless some may attribute profit in summer to wintering bees in cellars, but I am inclined to think that it will end very much in the way that stimulating feeding and spreading brood has done, and those who advocate it now or are experimenting on old plans will be the first to denounce the practice, and probably claim the ideas of others following the more natural plan of letting bees have their liberty throughout the year.

YOUNG QUEENS.

The hive referred to in the foregoing as breeding so much is one of the best lessons that a bee-keeper could have, and a good proof of the value of introducing young queens at intervals throughout the season. I have frequently pointed out the great advantage of introducing young queens early in July to all stocks intended for the Heather, as well as the importance, showing the advantage to be derived from joining two or more stocks together when at all practicable. But I am afraid enough has been said upon the caution required to maintain the strength of the stock when an unfavourable change of weather takes place. Although a young queen deposits many eggs, and it is for that purpose the introduction of young queens at that season is advised, so that there will be many bees hatching out some time before the Heather is in bloom and able to carry in much honey when it is to be had. But although all that is done and the hive full of brood and promising in every way, a wet day or two may (and frequently does) cause the bees to draw every egg and unhatched bee in the hive, to prevent which the bee-keeper must be on the watch, and should an unfavourable change come feeding must be resorted to.

Naturally a change to a new place encourages breeding, but at that season a few wet days encourages the drawing of brood, which nothing can restore to the loss of all possible after honey gathering. The bee-keeper should therefore be impressed with the above fact, and never allow his bees to start drawing brood at any time before the honey flow. The weather experienced at the moors is more often of a backward nature than otherwise, and often a week at the close of the Heather is all the bees ever get. Two things are therefore necessary—viz., to have all hives prepared with bottom feeders for that and every other emergency, and be sure to be liberal with the syrup and in time before brood drawing commences. Those who have not their hives provided with bottom feeders should take the hint, and remember not to be too late in feeding, because there is no remedy if neglected, and there can be no honey without bees.—
A LANARKSHIRE BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books on Orchids (*H. G. A.*).—There are several works on Orchids, but they differ greatly in price, some of the best being those illustrated with coloured plates. The following may be mentioned as likely to suit

you:—"The Orchid Growers' Manual" and "Orchid Album," published by Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway. The "Manual of Orchidaceous Plants," published by Messrs. J. Veitch and Sons, Chelsea. Burbidge's "Cool Orchids" (Allen & Co.); and Castle's "Orchids, their Structure, History, and Culture," published at this office, and of which a fourth edition is now in preparation. You ought to succeed with the aid of these works and the instructions supplied in this Journal.

Carpet Bedding (*E. W.*).—You can obtain all the particulars of the work you name by writing to Mr. A. Graham, Garden Superintendent, Hampton Court Palace, Kingston-on-Thames.

Primula Flowers (*F.*).—The colour is bright but evidently variable, yet not so rich as other varieties in cultivation that have also much larger flowers. Your variety is doubtless worth growing for home decoration, but we are not able to say it possesses any particular commercial value.

White Cineraria (*T. S., Aberdeen*).—The flowers are not developed, and although we cannot regard the variety as a "weed," we have seen many better than this promises to be. We do not suppose it will have any commercial value, though it may be acceptable for home decorative purposes, especially as, so far as we can judge, the plant appears to be dwarf in habit and floriferous; but the flowers are defective as regarded from the florist's standard of excellence.

Ammoniacal Liquor (*Subscriber*).—This is not of uniform strength and value, consequently a fixed quantity of water cannot be stated as generally suitable. We have used large quantities of gas liquor mixed with about six times its volume of water, and it improved the pasture to which it was applied; but the liquor was produced on the premises and had neither to be bought nor carted very far, or so much of it would not have been used. You had better try a few experiments at once with the liquor diluted at the rate of from four to ten times its volume, and note the results before its general application.

Large Beetle (*W. O., Manchester*).—This is one of the larger aquatic British beetles, *Dytiscus marginalis*, a carnivorous insect both in its mature and larval stages, but though passing its life chiefly in ponds or ditches, as a beetle, it takes occasional excursions upon land. It is not in any way destructive to plants, and its presence under the floor of a greenhouse seems difficult to account for. The likeliest explanation is, that it had somehow been brought to the place as a larva or grub, had then gone underground and changed to a chrysalis, but on becoming a beetle it died imprisoned, being unable to extricate itself.

Woodlice in Mushroom Beds (*T. C.*).—We know of no better plan than that of Mr. R. Parker, as described on page 116 of "Mushrooms for the Million." It consists in placing dry old dirty and decayed boards face to face under the covering of the beds. The woodlice crawl between them, and the boards are taken with the lower edges pressing against each other, trough fashion, and the contents jerked into water. Thousands of woodlice have been caught in that way, and large houses and beds cleared of the pest. New and smoothly planed boards are useless for the purpose, for the simple reason that the insects cannot crawl between them. Mr. R. Holmes, who is one of the best Mushroom growers in the kingdom, and who has grown several tons, has found this method of eradicating woodlice perfectly satisfactory.

Cutting Down and Renovating Camellias (*A Hampshire Subscriber*).—No plants endure cutting better than these. You may cut them down as close as you desire, and then, if the root-action is even fairly good, and the plants are kept in a warm house and syriaged frequently, young growths will issue from the old wood freely. If they are cut down entirely, as if pruning a Rose tree, and the roots are much crowded or in inert soil, they may have a great part of that soil removed, reducing the old balls considerably, and giving them a fresh sweet compost of turfy loam and peat in equal parts, and a plentiful admixture of silver sand. By carrying out this practice many tall and unsightly Camellias have been transformed into dwarf bushes bearing healthy foliage and fine flowers. You may cut them down whenever you can afford brisk heat with moisture to induce them to break freely.

Pruning Clematis—Dissolved Bones (*F. I.*).—Clematis pruning was described on page 95 last week, which you would no doubt see after sending your letter. Dissolved bones are more speedy in effect than either steamed or ground bones, as by the action of sulphuric acid nearly all the constituents of bones are converted into soluble compounds, and are at once fitted to become the food of plants, hence the value of superphosphate as manure. Next comes bone dust, which produces effect sooner than crushed or half-inch bones in consequence of the speedier decomposition. Steamed bones are very valuable on account of the organic matter not being extracted as in boiling, and they are speedy in effect and durable. You will not err in using bone dust. The other, however, can be had through any agricultural or horticultural manure dealer.

Chemical Manures (*North Herts*).—The addition of either nitrate or muriate of potash could not impair, and might probably improve, the mixture for your soil and purpose. Of the two forms of potash the nitrate is the more costly and possibly effective, but many experimentalists have found the muriate the more economical. The quantity of fertilisers to apply profitably can only be determined by the condition of the soil as to fertility. Assuming yours is poor rather than rich you may apply 2 ozs. each of the two mineral ingredients at once, pointing them in, then following with a sprinkling of nitrate of soda or sulphate of ammonia in showery weather when growth fairly com-

mences; but strong applications of these induce the growth of leaves at the expense of flowers and fruit. Possibly an ounce to the square yard would not be excessive in your case, but you had better exercise judgment in the matter, and we think you will not make any serious mistake.

Unfruitful Trees—Root-pruning (J. G.).—Thousands of large trees bear no fruit because spring frosts destroy the blossoms. The question in your case is whether the trees blossom or not, and this you do not mention. However, you cannot err by removing the suckers that spring up, separating them close to the roots. The dying of the branches suggests that the soil may be wet, therefore the wood does not ripen. If water stands within 3 feet from the surface the land needs draining to more than that depth. The extent to which the roots of trees should be cut depends entirely on the character of the wood. If it is luxuriant and blossomless, then the trees should be well undermined, starting them 3 or 4 feet from the stems, and cutting off the roots that strike downwards, reserving all of a fibrous nature and laying them in fresh soil as near the surface as is convenient, mulching with manure to prevent the roots drying in summer. If the growth is short and stubby, blossoming freely, such root-pruning would do harm, though the old soil might be removed from the roots, adding fresh of a loamy character, and covering it with a thick layer of manure to be left to decay. This would stimulate root action, then better and healthier growth would follow. Some varieties of Plums and Apples are naturally shy, while others are abundant bearers.

Unheated Peach Houses (C. V.).—There is grave danger in forcing the blossoms out early of their being ruined by after frosts with no blinds for protection. It is not wise to forward the blossom in the way you describe—viz., “keeping the house close for the past two or three weeks;” indeed, the house should be kept open, so as to retard the blossom as much as possible. We have a house of similar length. The lights are off, and will remain off until the middle of March, unless the weather prove unusually mild, and so accelerate the blossom as to cause it to show colour, when the lights will be put on, in order to keep it dry and insure immunity from damage by frost. The difficulty is to keep back the blossom until about April, when we usually have weather that enables frost to be excluded by early closing the house and maintaining a dry atmosphere. After setting and the weather becoming warmer much can be effected in accelerating the ripening by judicious early ventilation—moderate ventilation during the day, so as to secure a good heat, and early closing so as to husband the sun heat—securing a long day's work. Fruit can be had ready for use full three weeks before the same varieties are ripe grown outside. If fruit is wanted at the earliest period very early sorts should be grown, but these are not equal to the succeeding kinds in size, colour, and quality.

Cool House Orchids (J. P. C.).—We should not advise you to undertake the culture of cool house Orchids in a “hotbed and a greenhouse,” as you will probably fail, and it is very discouraging to amateurs to find some of their valued plants dying after they have been in their possession a month or two. Greenhouses suit but few Orchids, and even for them they require a special preparation. Some of the hardy Orchids and *Disa grandiflora* can be grown in this way, but *Odontoglossums* would not succeed long in an ordinary greenhouse. They require a constantly humid atmosphere and protection from the direct rays of the sun, while the usual occupants of greenhouses need liberal ventilation, a drier atmosphere, and will endure much exposure to sun. To ensure satisfactory results you must either devote a portion of the house to the Orchids, separating it from the other part by a glass or wood partition, or you must give up the other plants. When you have arrived at a decision on these points we shall be able to give you some further information. When Orchids are in flower less moisture is necessary in the air, as the flowers are liable to be spotted and damp. The plan of standing the pots on inverted saucers in zinc trays is a good one in several ways, as it not only ensures a regular supply of moisture, but prevents the attacks of slugs, woodlice, &c., which are apt to be troublesome.

Planting Marechal Niel Roses (S. S.).—Although we should foresee no difficulty in securing at least three main growths from healthy and well-managed plants established 3 feet apart, you can accomplish your object equally well by planting 2 feet asunder. When the plants are vigorous more than the desired number of shoots will probably start, and the removal of the least suitable will then be necessary. If one here and there should be extra robust, taking a very decided lead of the others, its point may be nipped off, choosing the most suitable of the growths succeeding for extension with others that were not topped. You cannot expect absolute equality in the strength of all the shoots, nor is it necessary, though the less the disparity the better. Proceed on the lines indicated, topping the shoots as they reach the top of the house, and there will be no difficulty, with good management, in covering the roof with wood that will produce flowers in abundance. When the object is to establish strong permanent plants, and these have long shoots when planted, they should be cut down to good buds near the base of the shoots after the upper buds have pushed an inch or so. Many *Marechal Niel* Roses are ruined by allowing them to bear all the blooms possible the first season and before the roots are plentifully and actively working in the soil. Secure strong root action the first year, and strong growth will follow. If the plants are dug from the open ground they cannot well be too closely pruned soon after planting, because in that case the roots will have been, of necessity, mutilated, and the tops must be shortened correspondingly to restore the lost balance between root and branch.

Span-roofed House (J. E.).—The site appears a good one and the arrangement for stokehole admirable. We should have the house 12 feet wide, the side walls 3 feet high above the ground level, 9 inches thick to within three courses of bricks of the top, which should be 4½ inches and built in cement, by which you would gain 4½ inches on both sides inside. We should have side lights about 2 feet high, and made to open the entire length, being hinged at the top, and opening outwards from the bottom by crank and lever movement. The house would therefore be 5 feet high at the sides, and it should be about 8 feet 6 inches high in the centre from the floor to the ridge. On the south-east side have top lights 2 feet wide running the whole length of the house, and raised by crank and lever movement similar to the side lights. The end next the stokehole may be a blank wall, and if you could arrange to have a potting-shed over the boiler, a door leading from the greenhouse, it would be a great convenience. Have the path 2 feet 6 inches wide up the centre, with open lath stage on both sides level with the top of the recessed brickwork, the wall forming rests for the stage on that side. Two rows of 3-inch pipes on each side would be required for heating, and should be placed beneath the staging but clear the floor. On one side you could arrange to have a bed of about 4 feet in length and the width of the stage walled all round, and the hot-water pipes going through it; they being covered with boards would form a chamber, and covered with a frame would make an excellent place for raising plants from cuttings. Slates would be better than the boards, and they should not be placed quite close, but have slight spaces between to let water pass away. The cover on the bottom of the frame should be level with the stage on which the frame—about 9 inches deep in front and 1 foot at back—should rest. Let the south-west end be glazed down to the level of the brickwork at sides, having corresponding brickwork at the end to that of the sides. A small boiler would meet your requirements. The pits would be very useful for hardening off plants.

Repotting Stephanotis and Camellias (F. G.).—A pot 2 feet in diameter is large enough for a fine exhibition specimen *Stephanotis*, and as your plant is at present established in such a pot, yet needs repotting, you may safely reduce the mass of soil, disentangling some of the roots, in the meantime washing the pot well with hot water, and it will quickly dry for using again. But we should not ruthlessly chop a slice off all round the ball of soil as you propose, but pick out the soil with a stick, and preserve all healthy roots, removing sufficient of the old soil to enable a good quantity of new being placed under, around, and over the roots and soil as reduced. Drain the pot well, and mind the old soil is not dry in the centre, nor should it be very wet. Let the fresh compost be of a turfy character, and composed mainly of fibrous loam and peat, the former preponderating, with some broken charcoal and sand added to ensure porosity, and if a tenth part of dried cow manure, crushed into small particles, be added, it will improve the compost, as would a twentieth part of bonemeal. Press the whole down into a firm yet slightly elastic mass, leaving a space of 2 inches from the surface of the soil to the top of the pot for subsequent top-dressings, and holding sufficient water for passing through the entire mass of soil; be careful, however, not to overwater at the first, but rather keep the plant fresh by syringing frequently, and shaded as may be needed in bright weather. Still water must be given before the soil gets dry, withholding it so long as it remains decidedly moist, remembering that extremes of both dryness or wetness will check free root-extension into the new soil. If you make no mistake in carrying out the work of reducing, repotting, and subsequently watering, your plant will thrive. It will be better plunged in gentle bottom heat, the temperature of the house ranging from 60° to 85°. The same mixture will be suitable for the *Camellia*, and any inert soil may be removed from the roots, only placing the plant in a pot just large enough to enable fresh soil being conveniently packed round the roots. Exercise good judgment in watering, syringing more or less freely according to the weather, also the temperature in which the plant is placed, from 50° to 65° being suitable for inducing free yet healthy growth, though the plant will grow very well, though more slowly, in a cooler house.

Vines not Thriving—A Mistake (S. R.).—We fail to find evidence of the presence of the phylloxera on the roots sent, but they are almost in as bad condition as if they had been attacked by that pest. We should uproot them and procure fresh Vines, shortening now, and planting in spring as advised in “Work for the Week” of the present issue, and in soil similar to there described. You now tell us you buried “some legs, &c., of horses in the border;” but you “do not think the Vine roots have got down to them yet.” If they had we presume you would have attributed their condition to the carrion. Why, then, have you placed it within their reach? If you have been a reader of the *Journal* for many years we are astonished you should bury “legs, &c., of horses” in the border; and if you have not long been a subscriber so much the worse for yourself. Whether the roots have reached the poison or not, we suspect they have scarcely moved since they were planted, or rather it is certain that many of them have moved backwards. A few may have extended somewhat, but only sufficiently to prevent the Vines dying. After your admission we have lost confidence in your Vine border; but even assuming it to be good where the Vine roots are, your treatment has been faulty, and in one important particular different from what we have many times advised. It is the reverse of good practice to plant Vines in the autumn and force them into action in February in a temperature of 55° to 65°. That is the way to drain the rods of sap before it is possible for the roots to move for absorbing nutriment to sustain the growth; indeed, we suspect the roots were

drained as well as the rods, hence their miserable condition. The Vines ought not to have been forced into growth at all, but on the contrary kept cool and the buds dormant as long as possible. By the time of starting naturally, or with little or no artificial heat, the border would have been at the same time warm enough for inciting root growth with the expansion of foliage, and the soil and management being good, stout canes would have followed and ripened in the autumn; but as stated in the instructions to which you have referred, spring, after growth starts, is the best time for planting Vines, shortening them several weeks previously, or if not shortened removing the swelling buds from the upper portion of the rods down to where the leading cane is desired to start from, and as a rule the lower this is the better will be the growth if it starts from a good and well developed bud. We are sorry for your failure, but if you proceed intelligently on the lines indicated you will have good canes in the autumn. You will only lose time by attempting to restore the present Vines.

Heating Houses (J. D.).—A check end saddle boiler, as you prefer that form, will answer well. No. 2, 36 inches long, 20 inches wide, and 18 inches high, all outside measure, would be capable of heating the piping you will require, which is shown by the direction of the arrows on the plan, and where those only go to the end of a structure it must be understood that the returns are under or beneath the flows. The flow main would leave the boiler at A, pass into the span-roofed house at J, and across the end inside to I. Along both sides the house two pipes will be necessary for top heat—viz., a flow and return over each other, and an H-pipe with throttle valve at C, and a throttle valve at D, both on the flow and return, so as to shut off the heat from the second compartment, or D E, opening the throttle valve in the H-pipe when the second compartment is not on, and closing it when the valves in D E are open or heat is wanted in the second compartment as well as the first. The flow is taken across the end beneath the pathway to I, from I to H, where is an H-pipe similar to C, and valves at G similar to D. At the end of the second compartment the pipes for top heat return by a syphon, where must be an air pipe, E and F. It is not necessary to have any pipes across the end M, and the bed there is not a good arrangement. For bottom heat you will need a flow and return in each bed, similar arrangements being made at the end K for the water to return by having a cross-pipe with throttle valve, open when the second compartment is not wanted heated, and the valves on the bottom heat pipes in that compartment are closed, but closed when the heat is wanted therein, the valves at L being open. Similar arrangements will need to be made at O as regards the cross-pipe and valve and the valves at N as are made at K and L. The bottom heat pipes need only have a slight rise, the flow to E, where must be an air pipe, and the return should have a corresponding decline from that point. Similar remarks apply to the other side of the bed as regards the rise and fall of the flow and return pipe, also air pipe at F. By this arrangement you can heat the two compartments of No. 2 separately or together. No. 1 will be sufficiently heated by a flow and return pipe. With a valve at S on the flow, and another at R on the return, the heat will be shut off. The flow is shown along the front and the return by the side of the pathway. Across the end U to T a cross pipe will be needed, and on that a throttle valve; open when heat is not wanted in the second compartment, closed when heat is needed in the compartment. Valves will be needed at V and W in the second compartment, and an air pipe at the highest point—viz., Y, the return pipe being taken across to X. The pipes in all cases should be 1-inch, and the boiler should have a feed cistern in the stovehole, and it should be so fixed that it will only about three parts fill the flow pipes for top heat when cold so as to leave space for the swell of the water when heated, or a swell cistern should be provided; but by allowing space at the air pipe end of the highest pipes—i.e., top heat ones, the pipes being about three parts full, there is no need of the overflow cistern, which, except in large arrangements, is neither desirable nor necessary. You can grow Mushrooms in lean-to frames either under glass or with wood shutters outside either No. 1, or No. 2, or both, the lines 3 feet from the walls of the span being intended, we presume, to represent the position for the beds, and also that at the back of the lean-to, the latter being an excellent place for growing Mushrooms in summer. You will require your plan back, and can have it by sending a stamped directed envelope addressed to yourself; and if you find some of the letters indistinct you will perceive it is the result mainly of your not having drawn the plan to a larger scale.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (J. J. M.).—1, Gloria Mundi; 2, Northern Greening; 3, Golden Reinette.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (A Young Gardener).—1, an immature frond, quite unrecognisable; 2, Onychium japonicum; 3, Adiantum pubescens; 4, Asplenium proliferum; 5, Nephrolepis exaltata; 6, Aspidistra lurida variegata. (G. H.).—1, A variety of Croton, but it cannot be determined; 2, A Bamboo, perhaps Bambusa Fortunci; 3, Panicum variegatum; 4,

Cœlogyne ocellata; 5, Tradescantia variegata; 6, Ficus Parcelsii. (R. W.).—1, A fine variety of Dendrobium Wardianum; 2, Odontoglossum madrense; 3, Cœlogyne Lemoniana.

COVENT GARDEN MARKET.—FEBRUARY 5TH.

No alteration this week.

SEED TIME.

Most welcome are the frost and snow which lock up the land and cover winter corn so snugly as we sit down to write this article. Nothing could possibly be more opportune than a spell of hard weather just as arrears of ploughing have been finished, for it will sweeten and shatter the soil so as to insure a fine seed bed, and with mild dry open weather towards the end of the month the sowing of spring corn will probably be done quickly and well. In view of the probability of such a seed time it will be well that

due care should be taken now to have seed, implements, and manures prepared for the work.

Before all things we must see that the seed is pure, clean, and of the best sorts for our land. At one time farmers generally were very remiss in this matter, the seed corn often being mixed, foul with weed seeds, and inferior in other respects. The yield was of course proportionately inferior, but prices before the depression set in were so high that even such slovenly practice on the land was profitable. Glad are we to know that a much greater degree of attention is now given to seed selection; in point of fact we have reason to believe that many farmers have rushed to another extreme, and have given extravagant prices for special strains of seed corn, without that previous high cultivation of the soil which is so necessary to its profitable culture. The very fact of the purchased seed being superior to home produce is sufficient to show that it was grown in superior soil, and must be sown in equally good soil to yield a crop of equally good corn. Nothing can surely be more patent, and yet we know that it is often overlooked, with the inevitable result of failure and loss. By all means let us have good seed, but we must also have clean, dry, fertile soil, and every other condition of high culture, for if one thing be wanting all our efforts for success or improvement will be in vain.

We hold that corn-growing may still be done profitably in this country under the best combination of science with practice, but we know there are others who boast of the teachings of long experience in support of their views that corn-growing has ceased to be profitable. Quite recently we saw a statement which went to show that Wheat cannot be grown at present prices without a clear loss of £2 17s. per acre. To prove this figures were given, but we never saw a more glaring example of the truth of the axiom that figures may be made to prove anything. Rent and taxes were put at £2, labour at £7, and manure at £5 12s. per acre. Now we think this statement to be altogether false and misleading, for we can certainly afford to strike off half the amount of the labour item, and feel assured that our Wheat will be well cultivated, harvested, threshed, and delivered. Then as to rent. Why, in the great corn-growing district of East Anglia the reduction of rent has been so great that £1 an acre is considered to be the average, including tithes, parochial rates, and the tenants' income tax under schedule B. It is true the rent of some farms near to large towns runs higher, but we can go as far as 30s. an acre for them, and yet grow Wheat at a profit. The most preposterous item is that of £5 12s. for manure, but we must explain that this amount is intended to apply to farmyard manure. Compare this with the last manure recommendation circular of the Sussex Association for the Improvement of Agriculture by Professor Jamieson, which shows that enough pure chemical manure for an autumn and spring dressing can be put on rail in London at a total cost of 31s. per acre. The formulae are as follows:—

Per acre in autumn—Half cwt. nitrate of soda, quarter cwt. steamed bone flour, quarter cwt. mineral superphosphate. In spring—Half cwt. nitrate of potash, 1½ cwt. nitrate of soda, quarter cwt. steamed bone flour, half cwt. superphosphate. But then, if farmers will not learn that chemical manures answer better than farmyard manure, why we can only say they deserve to fail. We intend using for our spring corn muriate of potash on an 80 per cent. basis, and we are offered this at £8 7s. 6d. per ton; nitrate of soda at £9 5s. per ton; bone flour at £5 10s., and superphosphate at £2 10s. Such low prices of these excellent fertilisers is certainly a matter for congratulation, and we shall turn them to full account by giving both winter and spring corn a liberal dressing, as we strongly recommend our readers to do. The manures should be procured at once, but they should not be mixed till a few days before required for use. Then either sow them broadcast and give the land one turn with the harrows before the drill, or if you have an excelsior drill, the manure and seed can be sown by one man and a pair of horses at the same time. We strongly recommend

this drill as one of the best labour-saving appliances we have. Compare it with the old drills requiring three horses, two men, and a boy to sow the corn, another man to broadcast the manure, and another to follow him with the harrows.

WORK ON THE HOME FARM.

The lambing is going on very well, we are glad to say, but care has to be taken not to expose the lambs to the cold weather, and they are kept in snug quarters in the large fold. We have reason to suppose that an overdose of ergot of rye caused the death of one ewe. This may be cited as an instance of the folly of trying to force Nature. When an animal is long in labour help must be given, but care should be taken not to attempt forcing natural effort by very strong doses of ergot. Do not suffer the lambs to be exposed to cold cutting winds, for if they are so exposed serious losses will be the inevitable result. Many lambs die when left out in a cold bleak fold at night, and we cannot wonder at it, but we do wonder how anyone with a grain of common sense can let them be so exposed. There can be no excuse for this, for if only a double row of hurdles is made around the fold, and the space between them filled with straw, there is shelter at once, and straw and hurdles are to be had on every farm.

Glad are we to say that at the last meeting of our local farmers' club we were able to induce several of the members to promise to try oatmeal as a substitute for barley meal for pigs. Such meetings are capital occasions for an interchange of ideas and discussions of important points of practice. Among other matters we recently called attention to the best way of laying down land to permanent pasture, and that is a detail of spring work of which many men are ignorant, and we purpose again calling special attention to it in this Journal shortly. We have recently heard farmers loud in complaints of the scarcity of food on their pastures, and we know some who have already had to feed off their Rye; yet we know that if only the pasture received due care and the requisite amount of cultivation it would not be bare even now. That is the point we wish to enforce, that every part of a farm requires culture, and none of the land should be left without its due share of annual care. Sustained fertility can alone insure full crops. To maintain this we must store the soil regularly with plant food so that it can never become exhausted. We shall then have an early and late growth so robust and sturdy as to suffer very little from unkind seasons. Severe drought must, of course, affect pasture, but it is the poverty-stricken neglected pasture that invariably succumbs to drought first.

MESSRS. SUTTON AND SONS' PUBLICATIONS.—The result of experiments with artificial manures on permanent and temporary pastures at Dyson's Wood, near Reading, have been published, and throw fresh light on this all-important subject. In instituting these experiments, Mr. Martin J. Sutton in co-operation with Dr. J. A. Voelcker has rendered great benefit to all who are engaged in the cultivation of the soil; and we strongly recommend "The Dyson's Wood Experiments" to their serious consideration. A new and "Popular Edition" of Mr. Martin J. Sutton's "Permanent and Temporary Pastures" has been issued, and a copy is before us. It is a cheap reprint of the original edition, with plates of the Grasses uncoloured, and will be found useful to those of limited means.

OUR LETTER BOX.

Hen Dying (*W. Raynor*).—We are unable to account for the death of the fowl, but will hand your letter to the Editor of *Poultry*, who may possibly be able to formulate an opinion on the case.

REMARKS.

29th.—A little snow after 9 A.M., and damp for an hour or so, then bright sunshine for a time; fair afternoon, clear moonlight night.
 30th.—Generally fine, with some sunshine. Snow in evening.
 31st.—Very wet till 11 A.M., then cleared and bright for two or three hours. Shower about 5 P.M., and damp evening.
 1st.—A sprinkle of snow in the early morning; beautiful day, but the ground remaining white in the shade; clear cold night.
 2d.—Fine, but slightly foggy and cold.
 3d.—Cloudy morning; fine afternoon with some sunshine. Much warmer.
 4th.—Fine and pleasant and very mild; overcast evening.
 A very changeable week with great variations of temperature, but as a whole decidedly cold. Temperature 4° below the average, and nearly 8° below that of the preceding week.—G. J. SYMONS.

THE ROYAL
HORTICULTURAL SOCIETY.

CONSIDERABLY more than ordinary interest attaches to the meeting that was held on Tuesday, and which is reported on another page. As the last annual meeting of the Fellows held at South Kensington it must be regarded as an important event in the history of the Society, as important, indeed, as that at which it was determined to establish the Society in the then great centre of the fashionable world. Objections were urged against that step at the time in these columns, and it was strongly opposed as likely to end in failure sooner or later. It was not difficult to foresee that a conflict of interests must arise between what may be fairly described as a policy of gaiety and that embodying the legitimate claims of horticulture. That is precisely what occurred; and while South Kensington has not gained by the alliance that was effected with Her Majesty's Commissioners as trustees of the estate, the Society was brought to the verge of ruin. Its independence was sacrificed on the altar of fashion, to which it was bound; but the cords are cut at last, and it escapes, weakened, but not abandoned.

Now that a new course is determined, it would be most unwise to ignore the lessons of the past; and it will not be disputed that the most momentous of all of them is that of incurring obligations disproportionate with the means provided for meeting them. The great mistake that stands out clear has been that of discounting the future. It has been felt that something must be done from time to time, and something has been done, but with no certainty that the action would bring the hoped-for results, and too often these were not realised, but, on the contrary, greater difficulties arose and had to be encountered. Enthusiasm is an admirable quality, and no great successes have been won without it; and the same may be said of enterprise, but the former must be tempered by sound judgment, and the latter based on sound principles, or the ultimate issue may be the reverse of that anticipated. A throw of the dice may bring fortune or may bring ruin, this last being immeasurably the greatest contingency.

The Royal Horticultural Society has a long, if chequered, history, yet notwithstanding adverse circumstances that have impaired its influence and crippled its action, it has been of great service to the world of horticulture. More than any other agency it has stimulated the taste in gardening that has been established during the period of its existence, and this in turn has created a home industry which, in its entire scope and nature, is unequalled in any country beyond the seas, though in all of them, where the art of gardening is practised in its highest forms, its influence has extended beneficially. Under its charter it must be managed wholly in the interests of horticulture, and no one on its governing body can derive any personal advantage from the position he occupies. It is, if any institution is, the representative head of practical gardening in these realms, and as such should be placed in a position worthy of its name and nation. This can only be accomplished by a wide extension of popular support, and to command this support its affairs must be very judiciously managed by representative men. Though at present in a transition state, the Society has many friends, well-wishers, and anxious helpers. This has been shown by the committee that was recently formed, and which was made representative solely with the view of devising means and making provision for its future working; and the suggestions and recommendations of this committee will doubtless

receive, as they deserve, the most careful consideration of the Council.

This important body, as will be observed, is also elected on a broader basis, inasmuch as it not only includes the trade, but the professional gardening element. This appears to be a reversion in principle to that on which the first Council of the Society was elected nearly eighty years ago, only that Council included three *bonâ fide* gardeners—namely, Mr. W. Townsend Aiton, gardener to the King at Kew; Mr. Thomas Hoy, gardener to the Duke of Northumberland at Sion; and Mr. William Smith, gardener to Lord Liverpool at Coombe, Surrey. There was no representative nurseryman on the first Council, but a Covent Garden herbalist in the person of Mr. James Dickson: indeed there was little trade to represent then in comparison with the position now. Two nurserymen are added now, and one gardener, Mr. J. Woodbridge, will no doubt be elected. Possibly more may be added in future, and such addition, as will be seen, would be no innovation, but exactly in accordance with precedent; and gardeners are not men, as a rule, to encourage expenditure without full justification, or to sanction outlay without clearly seeing it would be profitably applied.

The safe policy to be pursued at the present juncture is a policy of economy. Spending money before it is earned, or while debts remain to be paid, is to say the least a risky procedure, and not likely to gain a large share of public approval. Let rooms and halls be secured so far as means allow; but how stands the means? Can more than £1500 be expected from Fellows in 1888? It is doubtful. Can less than £1300 suffice for Chiswick? No. Here then we have £200. The establishment expenses of last year exceeded £800. Can they be reduced? The fortnightly meetings cost £230. Can they on the same scale be done for less? Then if the whole of the South Kensington Garden expenses, or say £600, be saved, where is the money to come from for West End rooms and an exhibition hall? This question of means cannot be ignored; and if the financial position is as stated, is it prudent to give £5 a time for a hall that will be unsuitable for tender plants over half the year, and which will depress by its emptiness? Let the amount of gate money taken at South Kensington last year be ascertained and place it against the cost of the "Shows," and on this determine the "hall" question, for there is no certainty that the attendance would be greater in Westminster than at Kensington. The fortnightly "Shows" either weaken the Society or strengthen it. Let the facts on that point be ascertained before experimenting in the same direction. The meetings of the Committees with the plants and produce submitted to them are distinct from those Shows and of vital importance, and a room less than half a hundred feet long would suffice for them. It may be too late for alluding to the matter, but whether that be so or not, it is a question, if facts are faced boldly, whether the most prudent course to adopt would not be to make Chiswick the head quarters of the Society this year for husbanding the resources and formulating plans of reorganisation. There would be no loss of status in that, while the meetings as such need not entirely lapse, and the partial rest gained would be followed by more certain and complete reinvigoration.

It is with the newly constituted Council that the decision rests on the line of action that shall be taken in what is perhaps the greatest crisis in the Society's career. The responsibility is a serious one, and a false step may have momentous consequences. Very grave deliberation is called for, and anything of the nature of impulsive movement should be held in check. A strictly horticultural policy can alone bring sympathy and support. The severance from South Kensington will result in a loss of local Fellows, and new supporters are wanted in their stead. Nothing can concentrate the attention of horticulturists on the Society so well, or nearly so well, as the maintenance of the gardens at Chiswick, and to cut the gardens adrift, of which there is danger, will be to cut off its head. The elements of danger lurk in a question of sentiment. If the produce raised at Chiswick cannot be sold the expenses cannot be

met, and as it is considered derogatory to sell, the gardens must go. Those who argue in that way forget the very nature of the Society and its essential objects. It is not a botanic society, but was established as the patron and exponent of practical horticulture; and this is now conducted on a commercial basis. If the selling of garden produce were humiliating it would not prevail amongst persons of the most delicate feelings and highest sense of honour.

The Chiswick Garden was established for a distinctly practical purpose—namely, for conducting experiments for acquiring sound information and disseminating it for the use of others. This cannot be done to meet present and future requirements without the subjects in hand are thoroughly tested, and they cannot be so tested except on commercial principles. Nothing can be more honourable than work of the nature indicated with the high object in view, and the more that can be realised in its conduct the more creditable to its conductors. More than ever now is it requisite to determine the profit and the loss of crops under differing circumstances; and the need will grow with the inevitable changes of the future. Let such work be prosecuted, and not only varieties tested, but the effects of chemical manures, and Chiswick may become a real school, which because of its usefulness will win the respect of the community.

Has not the Royal Agricultural Society its experimental farm, and is not the produce sold? In what other way could proof be afforded of the usefulness of its work? And what more honourable engagement than the acquirement of knowledge for the purpose of distributing it for the benefit of the commonweal? Her Majesty the Queen and the Prince of Wales avowedly act on these principles in respect to farm stock; how, then, can it be derogatory to any Society to proceed on the same lines? Common sense rises in rebellion against such sentimental notions, and it is earnestly hoped that common sense will prevail in the conduct of the Royal Horticultural Society and a great and useful future may be in store for it; but if its resources are devoted to semi-scientific objects, and for the gratification of specialists, and no tangible results can be presented to the world, the Society must degenerate into a nonentity, and it will fall a victim to that pride that goeth before destruction. As it has lived so long, and struggled through so many difficulties, it deserves a better fate; and it should be, ought to be, and might be, a pioneer in the work of profitable garden culture that it is so desirable to promote in the British Isles.

ANNUAL MEETING.

THE annual meeting of this Society was held on Tuesday afternoon in the East Crush Room of the Royal Albert Hall, Sir Trevor Lawrence, Bart., M.P., presiding, and the following members of the Council were present: Dr. Robert Hogg, William Lee (Secretary), E. G. Loder, G. F. Wilson, together with the retiring members, Major F. Mason, William Haughton, and Colonel Trevor Clarke. About sixty Fellows were also present.

After the reading of the minutes a number of new Fellows were elected.

The Rev. W. WILKS said it was well known to everybody that a certain amount of blame had been cast on the Council for the action they took in resigning in a body and then proposing the re-election of the greater body of themselves. It appeared to him that instead of any blame they ought to receive the most cordial thanks, for by their resignation they enabled the Society to elect a new Council *en bloc* if they thought fit, or to infuse as much new blood into it as they chose; and by many of them offering themselves for re-election, they showed plainly that there was ample life in the Society to enable it to continue for many years to come. They had, in fact, utterly declined to act like the proverbial rats deserting a sinking ship. He thought therefore that it would only be a graceful act if they re-elected those members of the Council who were willing to continue their services. He therefore moved that "This meeting begs to thank the Council for the opportunity which by their proffered resignations they have given to the Fellows of electing an entirely new Council, but respectfully declines to accept the resignation of the following members—Sir Trevor Lawrence, Dr. Robert Hogg, Professor M. Foster, Mr. W. T. Dyer, Mr. William Lee, Colonel Beddome, Mr. Sydney Courtauld, Mr. E. G. Loder, Baron Henry Schröder, and Mr. George F. Wilson."

Mr. H. G. VEITCH seconded the motion, which was unanimously passed.

The CHAIRMAN then announced that the election of the officers and Council would next be proceeded with, and ballot papers were, in accordance with the usual custom, handed round to those present. Sir Trevor Lawrence remarked that, with regard to the nomination of Baron Schröder for the post of Treasurer, the Council were very anxious that the Baron should act in that capacity, and did their very best to induce him to accept the post. Baron Schröder, however, was unfortunately obliged, out of paramount considerations of health and work, to decline, and he might inform them that he had received a letter from the Baron in which he expressed his extreme regret at being unable to attend the meeting that day, inasmuch as he was confined to his bed with an attack of bronchitis. He also regretted to say that Professor Foster was likewise prevented from being present in consequence of a bad cold. Col. Beddome, who was one of the nominees for the post of Treasurer, and who would have made an excellent officer, had also declined to serve, and the Council had unanimously nominated Mr. Morris for that position. A good many of the Fellows in the Royal Horticultural Society did not, perhaps, know who Mr. Morris was. He might, however, for the information of those who were not acquainted with his career, state that Mr. Morris, after a distinguished course at the University, had been engaged in horticultural matters in the Colonies for many years, and had occupied many important positions in connection with them. He (Sir Trevor) was informed that the gardens under Mr. Morris's control had always been well managed, not only from a horticultural but also from a business point of view, and the Council would be fortunate if they succeeded in obtaining the services of that gentleman. (Hear, hear).

Major LENDY and Mr. WYNNE then formally withdrew their opposition respectively, to the nominations of Mr. Morris and Mr. Dyer as members of the Council.

The CHAIRMAN, who rose amidst cheers, said it was now his duty to make a few remarks with regard to the present position of the Society, and he must say that, in his opinion, the Society occupied a more hopeful position now than it did a year ago. That arose mainly, in his opinion, from the fact that they were now no longer trammelled by a connection with South Kensington. (Cheers.) He had no desire to recall disagreeable memories, and he might here say, with reference to the gentlemen who thought it their duty to send in their resignations as members of the Council—Colonel R. Trevor Clarke, Major F. Mason, and Mr. W. Haughton—that he thought the thanks of the Council and of the Society were due to them for the services they had rendered during many years. They did not altogether agree as to what was the wisest to do for the future of the Society, but these gentlemen loyally accepted the position when they found they were in a minority, and with a view to rendering the future consultations of the Council more satisfactory they withdrew. They took that step, of course, after they ascertained that their views no longer commanded the general acceptance of the Council. Colonel Trevor Clarke was well known in the horticultural world, and, apart from other considerations, his resignation in that respect was a loss to the Society. (Hear, hear.) The absence of the other two gentlemen would also be felt; and he might especially say with regard to Mr. Haughton, that the Society would have liked to continue his services if possible. (Hear, hear.) He (Sir Trevor Lawrence) had not the least doubt that the vast majority of the members of the Council were now at all events of one opinion; and that majority were agreed that the connection of this Society with South Kensington had been prejudicial to the interests of the Society. There had, amidst the gloom, been transient gleams of sunshine, but they had not taken advantage of those transient gleams of sunshine in a financial sense to put money by for a rainy day. On the contrary, these glimpses of sunshine had done rather more harm than good, as they had had the effect of leading the Society into a rather extravagant course. If it had not been for the lamented death of the Prince Consort, the circumstances of the Society probably would have been far different. They would have had the enormous advantage to be derived from his prudent and wise advice and great influence, and if he had lived the story of their connection with South Kensington would doubtless have been a totally different one. As they knew, about this time last year negotiations were going on with the Albert Hall Corporation. Those negotiations never came to anything, and he was never sanguine that they would. He must confess that he never believed it was likely that their negotiations with the Royal Commissioners of the 1851 Exhibition would ever lead to a result satisfactory to the Society. Reference was made in the report read at the previous annual general meeting to the desirability of getting a site for the Society on the property of the Royal Commissioners. A site was offered to them by the Royal Commissioners, not in a good position, it was true, though if it had been adequate in size it might, perhaps, have been adopted by the Society. But the offer was encumbered with this perfectly impossible condition, that it was not to confer on the Society any right, either moral or legal, to the use of the gardens and conservatory. They would thus have found themselves hampered with the incubus of a building of considerable costliness, and the use of which would have been annihilated if they had not had at the same time the use of the gardens and conservatory. Then there was an offer to let the gardens to them at a rental of £1000 a year. That in the present financial condition of the Society was impossible. To have paid the rates and taxes as well as to have incurred the cost of the maintenance of the gardens would have been an enormous additional burden, and whatever the financial position of the Society might be now, it would have been infinitely worse if they had entered into any such agreement as that suggested by the Royal Commissioners. Thus it was that the negotiations that had been going on year after year,

and the offers made by the Royal Commissioners, had practically failed, and it had long been obvious that the ceasing of the connection with South Kensington was only a matter of time. The time had now arrived for a complete and definite severance. In thus going away they would leave a great deal behind them. He was sorry to say the Society had spent on the grounds where they were now located £78,557 18s. 4d., or, in round figures, £80,000. On leaving the grounds they would not receive consideration even to the extent of one halfpenny; and whether or not the Society was acting wisely in bringing its connection with South Kensington and the Royal Commissioners to an end, there remained this fact that it left this enormous sum of money behind, and he was afraid he might also say it left some small portion of its credit and renown behind with it. (Hear, hear.) It was their business to look the state of affairs in the face, and see if they could not—by setting the Society on a new basis, and finding it a proper home—re-establish its character and position. They had received very great assistance from horticulturists in all parts of the country, and he believed that when the proposals that to-day would be laid before the Society became known that assistance would be largely increased. As to the charter, they had consulted their solicitors, and they advised them that once possessed of a charter it was exceedingly difficult for a Society to get rid of it, and a costly and troublesome proceeding to get it amended, and consequently that if possible it was desirable to go on with the present charter. No doubt a great deal of the charter was absolutely obsolete, and when they departed from South Kensington would refer to a state of affairs that had entirely ceased to exist. But he thought, in face of the advice they had received, they had better run on with the present charter as long as possible. With regard to the bye-laws, a considerable portion of them were also obsolete. With reference to the Council, he should like to mention that they had placed their resignations in the hands of the Fellows, with the view of leaving the Society at perfect liberty to make whatever selection they thought proper of a new Council. It had been suggested in one quarter that as they had proceeded to re-nominate a certain number of their body, their resignations were scarcely sincere; but a little reflection and study of the bye-laws would show that this was not so. There was not one of them who would not most willingly resign his place to make way for anybody else, if it could be shown to be of the slightest advantage to the Society. (Cheers.) Some comment had been made on the fact that they had on the Council two gentlemen connected with the national establishment at Kew. It was feared that the rest of the Council would not be able to hold their own against them. Now, if the Council could not hold its own against two of its members—whether they came from Kew or anywhere else—they would be unfit for their position. But the fact was that they had acted in the most perfect harmony with them, and the fact of the Council having among them the head of the greatest botanical and horticultural institution in the world was of the greatest advantage. With regard to the outside Committee, the Council had met with the greatest possible assistance from them. Out of the seven gentlemen proposed by that Committee for election to the Council, the Council had adopted four. Two of the gentlemen whose resignations the Fellows had declined to accept would find it necessary, they said, to retire, and would make way for two others of the seven proposed by the outside Committee. The result would be that out of the fifteen new Council eight would be old members and seven would be new. The Council had received many assurances that the persons interested in horticulture had no intention of deserting the Society. (Cheers.) It had unfortunately been in difficulties in regard to financial matters, and it would be absolutely necessary for the Council to be provided with sufficient funds to carry on the work of the Society, as they could not incur liabilities if they saw no prospect of being able to deal with them. But when matters were placed on a new footing he believed the amount of support required, which was not very large, would be accorded. (Cheers.)

MR. GEO. DEAL, Secretary, read the report of the special Committee appointed at a special general meeting held on December 13th. It described the suggestions made to the Council to fill the anticipated vacancies in the Council and the agreement arrived at, and recommended that the two extraordinary vacancies anticipated after the election of this day should be filled by the election of Messrs. T. B. Haywood and J. Woodbridge.

The principal points in the Report of the Special Committee of the Fellows of the Royal Horticultural Society, presented to the Annual Meeting, and read by Mr. G. Deal, were as follows:—

After careful consideration of the requirements of the Society, and after an inspection of numerous premises by means of a Sub-Committee, your Committee submits that the undermentioned premises seem to meet the present requirements of the case better than any other, and therefore strongly recommend that they should be forthwith secured.

Offices.—The Committee is of opinion that the first floor of No. 111, Victoria Street, is well suited for the London head-quarters and offices of the Society, and for the housing of the Lindley Library in case the Trustees consent to its being placed there. [The Trustees of the Library are not absolutely bound by their deed to place the library on the Society's premises, after its removal from South Kensington, though there is little doubt that they would do so.]

The premises occupy a good position, almost midway between the Victoria Stations and St. James's Park Station on the District (Underground) Railway, and within a few minutes' walk of either. The ground floor of the house is occupied by the "Metropolitan Drinking Fountain Association," and the upper floors are let out in sets of

chambers. The first floor consists of two rooms and the usual conveniences. The smaller of the rooms is 16 feet 2 inches long by 8 feet 6 inches wide, and could be used as a clerk's room. The larger of the rooms is a spacious and convenient apartment, 42 feet 6 inches long by 22 feet 9 inches wide. It has a coved ceiling and is very lofty, being 18 feet high, so that it is well adapted for the purposes of Library, Reading, and Council Room, and for business purposes generally.

A plan of the premises and a sketch of the larger room have been prepared, which will explain the extent of the accommodation much better than mere words can do. These premises are offered at a rental of £120 per annum, free from rates and taxes.

Arrangements for Shows and Meetings.—Your Committee having in view, at this particular time, only the metropolitan requirements of the Society, further submits that the Drill Hall of the London Scottish Rifle Volunteers is well suited for holding large exhibitions, smaller meetings, and for the assemblage of the several Committees. It is situated in James Street, Victoria Street, within two minutes' walk of St. James's Park Stations on the District (Underground) Railway, close to the Army and Navy Stores, and within two or three minutes' walk of No. 111, Victoria Street, the premises already recommended for the offices of the Society. The Hall is 135 feet long by 72 feet wide, is lofty, has a fairly good light, and is generally suitable for the purposes indicated. It has a back entrance which can be made use of for carrying in and removing exhibits, and a good carriage entrance adapted for the arrival and departure of visitors. There is a room available in the basement for the storage of the necessary tables and tressels. Your Committee has instituted inquiries and opened negotiations with the Committee of the London Scottish Rifle Volunteers, and now begs to recommend that the Society should confirm the offer made by the Committee to pay a rental of £100 per annum, from March 25th next, in order to secure the use of the Hall for twenty meetings during the year; the rent to include the cost of storage room in the basement for the Society's tables and tressels, and, if possible, to secure the use, on show days, of the Luncheon Room and probably of the Committee Room for a few hours in the morning occasionally. Propositions to hold Exhibitions, &c., at Chiswick and in other localities in London and in the Provinces, will form the subjects of future deliberation.

New Bye-Laws and General Policy.—The Committee has under consideration the construction of new bye-laws intended to facilitate the carrying out of as complete a horticultural policy as possible—one in which all aspects and departments shall be considered, to the undue preponderance of none, but to the general advantage of all. A more adequate representation of horticultural representatives and of diverse interests in the Council is aimed at as well as the creation of an enlarged constituency, especially in the provinces, by means of reduced rates of subscription, adequate privileges, and representation on the governing body being secured to the subscribers of whatever grade.

It is hoped that by the institution of such a policy the Society may become the central horticultural Society of the empire, with branches and representatives in every district of the country, and with Committees and sub Committees to meet the wants of specialists and those interested in particular departments.

Secretary and Manager.—The Committee urge the paramount importance of appointing a well-qualified paid Secretary at as early a date as possible, the services of such an officer being, in its opinion, indispensable for the adequate discharge of the work involved in the reorganisation of the Society.

Lastly, as these and other schemes for the future development of the Society must of necessity occupy some considerable time before they can be put into working order, your Committee suggests that it should this day be re-appointed with full powers, and that it should continue to co-operate for the current horticultural year in the same satisfactory spirit as heretofore with the Council in all matters relating to the welfare of the Society.

Signed on behalf of the Committee,
MAXWELL T. MASTERS, *Chairman.*
GEO. DEAL, *Secretary.*

February 14th, 1888.

DR. MASTERS, the Chairman of the Committee who presented the above report, expressed satisfaction at the harmony and co-operation which had existed between it and the Council, and added that the new policy which was indicated was substantially the same as that initiated by Prof. Forster and Mr. Dyer, and already approved by the Fellows. One great fault of their Society had been that they had looked upon horticulture as the plaything of the rich, or as a mere money-grubbing machine for the few pecuniarily interested in it. But horticulture had far higher aims than this. It had involved in it the interests of the country at large. The agriculture of the future would be to a large extent horticulture—(hear, hear)—and the Society had got to teach agriculturists how to make a living. (Hear, hear). It seemed also to him that the Society had not sufficiently considered the interests of the practical gardeners of the kingdom, many of whom, perhaps, could not afford to pay the subscription, and whom it might be well to admit at a lower subscription—(hear, hear)—and so endeavour to promote their education and welfare, and raise them in the social scale. It might be said this was a very fine scheme, but they did not expect to carry it out all at once. Gradual evolution and not sudden revolution would ultimately land them where they hoped to be. Personally he did not think they would be able to get on long without a new charter, but much might in the meantime be done by altering their bye-laws.

The report of the Committee was received and adopted, and the Committee was re-appointed.

Mr. J. Douglas and Mr. H. Turner having been appointed the scrutineers and a ballot taken, it was reported that the old members of Council already named by the Rev. W. Wilks, and also Mr. D. Morris, Mr. A. H. Smee, Mr. George Paul, Mr. Harry Veitch, and the Rev. W. Wilks himself had been elected by forty-four votes against six. The following being returned as officers:—President, Sir Trevor Lawrence, Bart., M.P.; Treasurer, David Morris, M.A., F.L.S.; Secretary, William Lee; Auditors, John Lee, Wm. Richards, H. Turner.

A resolution empowering the Council to rent the London Scottish Volunteers' Drill Hall at £100 a year, and the Victoria Street Offices at £120 was then passed.

A vote of thanks was passed to Mr. Laing, builder, for assistance rendered by him to the Committee in finding and securing these premises.

A hearty vote of thanks was then passed to Mr. Houghton, Captain Bax, Major Mason, and Colonel Trevor Clarke.

It was next resolved that the following be a new bye-law:—"The President may call a special general meeting of the Society if he consider it necessary, any bye-law to the contrary notwithstanding, subject to not less than a week's notice being given."

Colonel R. TREVOR CLARKE, rising to acknowledge the vote of thanks in which he had been included, said he had joined the Society when he was young; he had grown old amongst them; he loved and honoured the Society, and hoped to die in its service. (Cheers.)

The Council's report and balance-sheet for the year were formally adopted, and a vote of thanks to the Chairman terminated the proceedings.

REPORT OF THE COUNCIL FOR THE YEAR 1887.

I.—FINANCE.

THE statement of receipts and payments for the past year and the balance-sheet, together with the auditors' report, will be found below.

It will be seen that the Council have done all in their power to exercise economy in every direction. The labour bill at Chiswick has been reduced to its lowest limits. No money prizes have been offered, and paid advertisements have been suspended as far as practicable. An urgent circular was issued, and all outstanding subscriptions, except about £120, have been collected.

The Council desire to convey the thanks of the Society to the auditors, Messrs. John Lee, W. Richards, and H. Turner, for their continued gratuitous services in auditing the accounts.

II.—ARRANGEMENTS FOR THE FUTURE.

Throughout the year the question of the future of the Society has engaged the earnest attention of the Council.

At the last annual general meeting, held on the 8th of February, 1887, a resolution was passed to the effect "That a Committee of five Fellows, not members of the Council, be appointed to co-operate with the Council in considering the future of the Society's affairs, and to report thereon at their earliest convenience," and at a special meeting of the Council held on the 22nd of February power was given to the Committee to add to their number.

The Committee, whose names will be found in Appendix I, held their first meeting a few days after the annual general meeting, and drew up the five resolutions embodied in their letter to the Council, which, together with the answer of the Council, will be found in Appendix III.

The Committee subsequently conferred with the Council on several occasions as to the future of the Society, but, owing to unexpected difficulties, no definite plan of action could be settled.

When the Royal Commission of the Colonial and Indian Exhibition gave up their tenancy of the grounds at South Kensington the Society was practically without any home in London; but, pending other arrangements, the Council obtained the sanction of the 1851 Commissioners to use the conservatory for their shows and meetings, and their old offices and room for the Lindley library, on the understanding that the Society should "pay all rates and taxes, and make good all damage caused by their occupation, and should undertake the care of the plants, &c., in the conservatory and adjacent gardens."

In deference to the wishes of some members of the Council and of some of the Fellows who were anxious that the Society should, at all hazards, remain at South Kensington, a memorial to the Queen was drawn up and forwarded to Sir Henry Ponsonby, whose reply on behalf of Her Majesty is given, together with the memorial in Appendix IV.

After the receipt of this reply the Commissioners of 1851 were asked to grant a site on their estate at South Kensington, but the site which they proposed was far too small, had a bad approach, and was encumbered with the stipulation that whatever buildings the Society might erect on the land should not confer any right, either legal or moral, to the occupancy of the conservatory and Gardens. The offer was accordingly rejected as wholly inadequate to the requirements of the Society.

The Commissioners were then asked if they could grant a better site and a lease of the Gardens and conservatory. Their reply was that "as they were negotiating with the Royal Albert Hall Corporation they were not then in a position to make a further offer."

A large number of sites in various parts of London were subsequently inspected, but all which were likely to meet the Society's requirements were found to be too expensive.

A special general meeting of the Society was held on June 28th, when the President reviewed the various sites and proposals which the Council had had under consideration, and stated that the uncertainty which attended the future of the Society was having a prejudicial effect on its interests. At this meeting resolutions were carried to the effect—

"(1.) That this meeting requests the Council to take such steps for the maintenance and housing of the Society as may appear to them best calculated to maintain the character and utility of the Society and the interests of Horticulture committed to its charge.

"(2.) That steps be taken immediately to secure accommodation for the Society at the end of the year, either permanent or temporary, in some central situation or not far from the city."

After further search for accommodation, a building in James Street, Buckingham Palace Road, belonging to the Queen's Westminster Volunteers, was brought to the notice of the Council, and after being inspected by many members of the Council and by the Committee of Fellows, it was deemed suitable to the requirements of the Society. Negotiations were entered into, and there appeared to be every prospect of a satisfactory result, when, on October 11th, the morning of the day on which the Council met with the view of sanctioning the arrangement, an intimation was received that the officers of the Queen's Westminster Volunteers had determined not to let any portion of their building.

At a meeting held on the 8th of November, the Council discussed an informal offer from the 1851 Commissioners to let the gardens and conservatory to the Society at a guaranteed rental of £1000. They felt that, on financial grounds, it was impossible for them to accept the offer, as the cost of maintenance, with rates, taxes, &c., would amount to at least another £1000, making an expenditure of £2000 a year for South Kensington alone, leaving office charges and the cost of the Chiswick Gardens unprovided for. It was further decided that no advantage could accrue to the Society from the continuance of negotiations which, as experience showed, could end only in delay and disappointment.

The Council therefore decided to issue forthwith an appeal on behalf of the Society, to the horticultural public of the United Kingdom, which will be found in Appendix V. This appeal fully expresses the views of a large majority of the Council, after a careful review of the future prospects of the Society. In consequence of this decision of the Council, Colonel R. Trevor Clarke and Major F. Mason resigned their seats, and Mr. William Haughton gave notice that he should resign at the end of the year.

A list of donations and subscriptions received up to January 31st, 1888, in response to the appeal, will be found in Appendix VI.

On the 13th December a special general meeting of the Fellows was held, when the policy to be pursued in the future was discussed at length. A very large majority of those assembled concurred in the decision of the Council not to enter into further negotiations with the Royal Commissioners of the Exhibition of 1851, which could not result in any satisfactory arrangement, but to concentrate the efforts of the Society on its Chiswick Gardens and on the advancement of horticulture; to adopt, in short, a purely horticultural policy.

At this meeting, the following resolution, proposed by Dr. Masters, and seconded by Mr. A. H. Pearson, was carried—viz.,

"That this meeting approves of the proposals in paragraphs 6 and 8 of the circular of the Council, and authorises them to take steps to carry them out.

"This meeting requests the Council to consider the desirability of obtaining a supplemental charter, and meanwhile requests them to vary the bye-laws in such a way as will ensure the Fellows having full control over the election of the Officers and Council at the annual general meeting.

This meeting proposes the nomination of the following gentlemen, to form a Committee to carry out the above resolutions."

III.—SHOWS, TRIALS, &c.

In addition to the ordinary fortnightly meetings, the following Shows were held under the auspices of the Society:—

April 26th.—National Auricula and Primula Society's Show.

July 5th.—National Rose Society's Show.

July 26th.—National Carnation and Picotee Society's Show.

Aug. 23rd.—National Co-operative Flower Show.

It had been arranged to hold a Chrysanthemum Show and Conference on the 8th and 9th of November, but this was abandoned, as the days fixed clashed with the Show of the National Chrysanthemum Society.

Arrangements were made, through the courtesy of Mr. Thiselton Dyer, for holding some *Narcissus* trials at the Royal Gardens, Kew, in consequence of the *Narcissus* Committee having requested that the trials might be carried out there instead of at Chiswick, on account of the greater facilities existing at Kew for noting the results.

IV.—DISTRIBUTION OF PLANTS AND SEEDS.

In the last annual report it was stated that it had been decided to make special arrangements for the distribution of such plants and seeds of a rare and valuable character, as might be from time to time presented to the Society for that purpose.

Periodical lists of the plants and seeds available for distribution (in addition to the ordinary plants and seeds grown at Chiswick) have accordingly been prepared when a sufficient quantity had been collected: and notices have been inserted in the gardening papers, informing Fellows that these lists could be obtained on application to the Secretary.

V.—AWARDS.

The Scientific, Fruit, and Floral Committees have carried on their labours at South Kensington as usual during the year, and to them the thanks of the Society are due. A great variety of interesting new plants and flowers have been submitted for adjudication. The number of first-class certificates awarded has been 191.

Thanks are due to Mr. H. M. Pollett for printing free of charge and presenting to the Society 500 copies of the awards of the Fruit and Floral Committees from February 12th, 1884, to May 24th, 1887.

The Society in the past year gave thirty-five bronze Banksian medals to provincial societies and flower shows. That these medals are highly esteemed is evidenced by the letters received, which prove that much emulation is caused among the exhibitors by the desire to obtain them. This healthy competition, the Council feel, cannot fail to raise the standard of provincial horticulture.

The thanks of the exhibitors at the Society's Shows are due to Messrs. Sutton & Sons, Messrs. Carter & Co., Mr. H. Deverill, Messrs. Webb and Sons, Messrs. Wood & Son, Mr. Roupell, and Mr. C. Fidler for their donations of special prizes.

VI.—PUBLICATIONS.

The Society has published during the year Vol. VIII. of the Journal entitled "The Frost Report," on the effects of the severe frosts during the winters of 1879-80, 1880-81, edited by the Rev. George Henslow, M.A., the Hon. Sec. to the Scientific Committee; and Vol. IX., entitled "Pears," being the report of the Committee of the National Pear Conference held in the Society's Gardens at Chiswick, October, 1885, prepared by Mr. A. F. Barron, the Superintendent of the Society's Gardens, and Secretary to the Fruit and Floral Committees. Copies of these publications may still be had by the Fellows, free, on application to the Secretary.

VII.—IMPERIAL INSTITUTE.

In June the attention of the Organising Committee of the Imperial Institute was called by the Council to the fact that apparently no provisions had been made for the representation of horticulture in the scheme of the Institute as set forth in the *Times* of May 30th, 1887. The only reply received was to the effect that the letter would be laid before the Committee at their next meeting.

VIII.—COUNCIL AND FELLOWS.

At a meeting of the Council on March 22nd, Mr. A. B. Mitford, C.B., vacated his seat in consequence of other engagements, and Mr. George Maw was elected to fill the vacancy.

Reference has already been made to the resignations of Colonel Clarke, Major Mason, and Mr. Haughton.

During the year thirty-three Life Fellows and thirty-one Annual Fellows died, 195 Fellows retired from the Society, and twenty-four new Fellows were elected, showing a decrease of 235 Fellows since the last Annual Meeting.

IX.—ADDRESS TO THE QUEEN.

A loyal and dutiful Address was presented to Her Most Gracious Majesty the Queen, Patron of the Society, on the occasion of Her Majesty completing the fiftieth year of her reign. A copy of this Address will be found in Appendix VIII.

January 10th, 1888.

[The appendices referred to have been published in our columns except that referring to the list of donations and subscriptions, which

now appears. The report of the Council to the Fellows and the appeal to horticulturists appeared in this Journal on page 513, last volume.]

COMMITTEE MEETINGS.

Rarely have so many varied attractions been provided in the conservatory at the February meeting, and it seemed that the Fellows and friends of the Society were desirous of showing an undiminished interest in these meetings now they are drawing to a close at South Kensington. The Apples alone constituted an exhibition for this season of the year, Orchids, Primulas, Daffodils, and miscellaneous hardy flowers, with the brilliant Chelsea Rhododendrons, forming the chief floral attractions. There was a large attendance of the members of all the Committees.

FRUIT COMMITTEE.—T. Francis Rivers, Esq., in the chair, and Messrs. Wm. Paul, J. Wright, Harrison Weir, J. Smith, T. J. Saltmarsh, Sidney Ford, J. Woodbridge, C. Ross, J. Roberts, J. Cheal, C. Howe, G. W. Cummins, W. Denning, W. Marshall, H. J. Veitch, John Lee, P. Crowley, and J. Willard. The display of Apples was very extensive, upwards of 400 dishes being staged, and though the hot summer had not been conducive to large size, it had apparently been the reverse of inimical to the keeping properties of the fruit. Messrs. G. Bunyard & Sons, The Old Nurseries, Maidstone, placed on the table a dish of the Royal Jubilee Apple, which had been before the Committee on a previous occasion. It is a fine-looking Apple of the character of Golden Noble and Waltham Abbey Seedling, and presumably because it was not considered superior to those good varieties no award was made. Mr. James Davis, The Gardens, Bodenham, Leominster, sent a dish of a seedling Apple of good size, but as only three fruits were submitted the Committee could not take cognizance of the variety. Mr. S. Ford, Leonardslee, sent a small dessert Apple resembling Golden Drop, which was passed. Mr. Blair sent from Trentham Gardens handsome specimens of Calville Blanche Apples grown in pots and gathered on February 10th. A cultural commendation was unanimously awarded. Four dishes of seedling Apples were placed on the table from Mr. Sidney Ford, Leonardslee, but as the best in appearance was "gone" in the centre and the others not of high quality they were passed. Mr. J. Smith, Mentmore Gardens, sent specimens of Cockle's Pippin and Blenheim Pippin grown on the Crab and Paradise stocks—the trees of the former sixteen years old, of the latter four years. The fruit from the latter were twice the size of the others. A vote of thanks was awarded. The Apple that was sent by Mr. A. Dean to the last meeting was determined to be Grange's Pearmain, a heavy well-coloured Apple. Mr. Dean sent dishes of Keddleston Pippin and Sam Young; also two dishes of Onions Tennis Ball and Danesfield (vote of thanks). Mr. Burnett, Deepdene sent bunches of Lady Downe's Grapes from the West's St. Peter's and Black Hamburg stocks, the former being thinner in skin and sweeter than the latter, which was, however, good, and superior in appearance and would keep better. Mrs. Pince on the Royal Muscadine stock was good in size and quality, but not more so than on its own roots. A cordial vote of thanks was awarded for the interesting contribution.

The collections of fruit reached nearly the whole length of the conservatory, and the display was a remarkable one for the time of year. Mr. S. Ford staged twenty-five dishes of Apples and four of Pears, the former wonderfully well coloured, but not as a rule large, and all admirably kept. Three bunches of Lady Downe's Grapes were sent that had been cut twelve weeks, and were in good condition. A similar collection as regards numbers was sent by Mr. C. Ross, Welford Park, Newbury, but the fruits larger in size, and handsome. Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, sent seventy-four dishes of Apples, the majority small, but the whole well kept, though the low-lying position of the garden is not favourable to high colouring. Messrs. J. Cheal & Sons, Crawley, sent the same number of dishes—a good representative collection of large and small varieties, very well coloured. Messrs. G. Bunyard & Co. staged upwards of 100 dishes, most of them very fine, and the fruit richly coloured. Messrs. T. Rivers and Son contributed nearly 100 dishes of Apples, including some varieties as yet but little known, and the whole wonderfully well kept. Messrs. Rivers' collection of Oranges, Lemons, and Shaddocks attracted much attention from the size and clearly coloured fruit, the Maltese Blood Oranges cut being delicious in quality.

Silver medals were granted to Messrs. Rivers and Bunyard, and bronze medals to the other exhibitors referred to, the honours in each case being well merited.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., in the chair, and Messrs. H. Bennett, J. Fraser, W. Bates, E. Hill, A. J. Lendy, T. Baines, J. Walker, W. Goldring, G. Paul, G. Duffield, C. T. Druery, R. Dean, W. Holmes, B. Wynne, J. Dominy, C. Pilcher, H. M. Pollett, and J. O'Brien.

The amateurs' exhibits were principally plants and flowers of Orchids, amongst them being a choice group from Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking (Orchid grower, Mr. Biekerstaffe), comprising the following, in addition to the two for which certificates were awarded—namely, *Odontoglossum crispum pardalinum*, and *Dendrobium chryso-discus*; *Pleurothallis Roezli*, a remarkably distinct species, quite the giant of its genus in the size of the flowers, which are claret red and fleshy; *Odontoglossum crispum punctatissimum*, a peculiar variety with neat flowers, white dotted with brown and purple; *Masdevallia gargantua*, green and dull red large flowers, and unpleasant odour; *M. leontoglossa*, another large flowered species, mottled like some of the *Staplias*, and possessing a peculiar odour which has been compared to that of an old wine cask; *Odontoglossum maculatum*, with three racemes of four and six flowers each, a very fine variety; *Cattleya Percivaliana*, a beautiful variety with seven highly coloured flowers; the bright orange *Laelia harpophylla*; *Dendrobium amethystoglossum*, with narrow pointed white sepals and petals, the lip scoop-like and purple; and the bright *Masdevallia Fraseri*. Baron Schröder, The Dell, Egham (gardener, Mr. Ballantine) sent a wonderfully fine panicle of the brown spotted *Odontoglossum crispum Stevensi*, which had over fifty large flowers, and the cultural commendation awarded was well deserved. From the same garden came several choice varieties of *Laelia anceps*, including the beautiful *Dawsoni*; and *Odontoglossum crispum xanthotis*, with large white flowers, the lip yellow in the centre and a few yellow spots on the petals (vote of thanks). A. H. Smee, Esq., The Grange, Wallington, Surrey (gardener,

Mr. G. W. Cummins) showed a small collection of Orchids, comprising two forms of *Odontoglossum* (Erstedti majus, one having all the flowers singly, the other in pairs. The curious yellow flowered European terrestrial Orchid, *Ophrys lutea*, was represented, together with *Dendrobium glumaceum*, the diminutive *Masdevallia eulex*, *Sophronis violacea*, the charming little *Angræcum hyaloides*, and others. C. M. Major, Esq., Cromwell House, Croydon (gardener, Mr. W. Wright) sent a raceme of *Dendrobium Hilli*, together with a photograph of the plant noted in this Journal last week. From the Royal Gardens, Kew, plants were sent of *Lilium Thomsonianum*, the old *Bletia verecunda*, *Cœlogyne lentiginosa*, a diminutive Orchid, *Holothrix (Tryphia) secunda*, a flower head of the handsome *Brownea grandiceps*, and the peculiar dark purplish flowered *Corydalis Ledebouriana*. G. F. Wilson, Esq., F.R.S., Weybridge, exhibited dried specimens of a Japanese Grass, which was de ided to be *Eulalia japonica*, very graceful for vases.

The nurserymen's contributions were of a more varied character and added materially to the extent of the Show. Messrs. J. Veitch & Sons, Chelsea, sent from their beautiful stores flowers and plants of the useful greenhouse *Rhododendrons*, and two novelties were certificated. Noticeable amongst other more attractive forms was R. multicolor, which has small creamy white bell-shaped flowers, quite distinct from the other in shape, and it is being employed in the production of a different type with more shallow and open rather than long and tubular corollas after the *jasminiflorum* character. With them was the curious relative of the *Fritillarias*, *Korolkowia discolor*, which has glaucous Tulip-like leaves and greenish flowers. Several hybrid *Dendrobiums* were shown, including the fragrant delicately tinted *D. eusmum* from *D. endocharis* and *D. nobile*, also *D. eusmum leucopterum* from the same parents, but in which the sepals and petals are pure white, the lip having a crimson centre (vote of thanks). *D. splendidissimum* (from *D. aureum* and *D. nobile*) was represented by a small plant, and three distinct forms of *Odontoglossum triumphans* were included in the group. Messrs. Sander and Co., St. Albans, exhibited the handsome *Lycaste Skinneri Imperator* (certificated) and two plants of *L. Skinneri alba*, with wonderfully pure massive flowers. A variety of *Odontoglossum maculatum* named *anceps* was noteworthy for the size and deep colouring of the flowers.

A silver Banksian medal was awarded to Mr. J. James, Farnham Royal, Slough, for a group of *Cinerarias*, comprising some grand varieties both in the size, shape, and colours of the blooms. A collection of *Primulas* was included with these. A silver Banksian medal was also awarded to Mr. T. S. Ware, Tottenham, for a beautiful collection of the earlier *Daffodils*, comprising many choice varieties in the different sections, to which we shall have occasion to refer in another issue. Messrs. Barr & Son, King Street, Covent Garden, were awarded a bronze medal for a similar collection, but not quite so extensive. Messrs. Paul & Son, Cheshunt, had a group of hardy flowers; and Messrs. Cannell & Sons, Swanley, some excellent *Primulas*, *Swanley Giant*, *White Perfection*, and *Braid's Seedling* (certificated) being the principal varieties. Plants of *Cineraria cruenta* and the improved form were also sent.

Mr. Ross, Pendell Court Gardens, Bletchingley, showed specimens of *Dombeya (Astrapea) Wallichii*, which has cordate leaves over a foot in diameter, and dense bunch-like clusters of salmon-red flowers, the useful winter flowering *Franciseas*, and the graceful pale yellow *Acacia verticillata*.

CERTIFICATED PLANTS.—*Rhododendron Ruby* (J. Veitch & Sons).—One of the *jasminiflorum-javanicum* hybrids, with neat flowers of moderate size and rather more bell-shaped than most of the others, but remarkable for its rich dark shining scarlet colour, quite unique even amongst the fine shades already obtained.

Rhododendron Imogen (J. Veitch & Sons).—A cross between R. Teysmanni and R. Taylori, one of the earlier productions in this section, and still a valued variety. The one certificated on this occasion had unusually large flowers, of excellent form, the lobes of the corolla broad and rounded, the colour a clear delicate creamy white, contrasting admirably with the brighter tinted forms.

Ardisia mammillata (J. Veitch & Sons).—A stove plant with elliptical leaves 4 or 5 inches long by 2 or 3 inches broad, the bright green surface covered with small rounded projections and dense whitish hairs. The fruits are small, globular, and bright red, and are produced in clusters in the axils of the leaves.

Dendrobium nobile var. Cooksoni (Sir T. Lawrence, Bart., M.P., and H. M. Pollett, Esq.).—An interesting Orchid of the *D. nobile* type, the sepals pale, tinted with purple at the tips, the petals broad and somewhat resembling the lip in appearance, the lower half of each being a rich purplish crimson shade, the tips nearly white, the lip is of good shape with a central blotch of similar colour to that in the petals.

Odontoglossum crispum pardalinum (Sir T. Lawrence, Bart., M.P.).—The chief characteristics of this variety are found in the bold spots and bars upon the sepals and petals, as the flower itself is of moderate size and the divisions are narrow compared with other recognised good varieties of *O. crispum*. The markings are of a reddish brown shade, which are brought into strong relief on a pure white ground.

Dendrobium chryso-discus (Sir T. Lawrence, Bart., M.P.).—A hybrid raised in the Burford Lodge collection some time ago between *D. Findleyanum* and *D. Ainsworthi*. The *Ainsworthi* parentage predominates in the characters, the lip being much like that in shape but very different in colouring. The greater portion is white, with a dense bronzy red and yellowish blotch at the base. The sepals and petals are bluish tinted, the whole appearance of the flower being delicate.

Lycaste Skinneri Imperator (F. Sander & Co.).—A handsome variety with flowers of good size, 5 and 6 inches from tip to tip of the sepals,

which are of a light blush tint; the petals broad, of an intensely deep velvety crimson shade on the inner surface, which is not so noticeable before they are fully expanded. The lip is also large, rosy crimson, mottled with white.

Iris Histrion (Paul & Son, Cheshunt).—A charming little early flowering *Iris*, that in the beauty of the marking on the falls is equal to some of the choicest Orchids. The general colour is purplish blue, but the falls are of a brighter shade, mottled with yellow and white. The flowers are also very fragrant and being of dwarf habit it is well adapted for culture in pots.

Primula sinensis Braid's Seedling (H. Cannell & Sons).—This *Primula* also has the name *auriculæflora*, which is not a very inappropriate one. The flowers are of great size and excellent form, deep crimson, with a ring of a darker, almost a bronzy, shade round the eye, which gives it a very distinctive appearance.

Tree Carnation Phyllis (C. Turner).—A strong and free flowering variety with well-formed flowers, white, streaked with bright red round the margin, and very fragrant. A useful variety for winter flowering and cutting purposes.

Pteris cretica nobilis (H. B. May, Edmonton).—Crested Ferns are now so numerous that novelties of real merit are rarely added; the one here noted seems to differ chiefly from other forms of *P. cretica* in the fronds being erect, and the creting is dense, not so finely cut as occasionally seen. The shade of green is also a peculiarly fresh and pleasing one.

EVENTS OF THE WEEK.—Beyond the usual auction sales at Covent Garden and Cheapside there are few horticultural events down for the current week. The Royal and the Linnæan Societies hold meetings on Thursday at 4.30 P.M. and 8 P.M. respectively. The chief subject before the latter Society will be a paper by Mr. H. N. Ridley on "Self-fertilisation and Cleistogamy in Orchids."

— **ROYAL HORTICULTURAL SOCIETY.**—At the annual general meeting of the Society, held Feb. 14th, at South Kensington, Sir Trevor Lawrence, Bart, M.P., in the chair, the following candidates were duly elected Fellows of the Society:—J. E. Bonny, Esq., George A. Candler, Esq., James Gibson Dees, Esq., Rt. Hon. Polydore De Keyser, Alfred Eastly, Esq., Edward Ellis, Esq., Walter Furze, Esq., John Philipps Charles Graves, Esq., Mrs. John P. C. Graves, Augustus Elder, Esq., Fredk. J. S. Horsman, Esq., R. W. Ker, Esq., William P. Norbury, Esq., Col. C. H. Page, Mr. John Peed, John Raddenberry, Esq., Mrs. Courtenay F. Terry, John Woodbridge.

— **THE WEATHER.**—A correspondent writes:—The weather in Perthshire was mild but dull for the first three days of this week, thereafter grew colder. Some snow has fallen. On the nights of the 10th, 11th, and 12th, respectively, 10°, 14°, and 7° of frost occurred, with bright sunny days." In London slight frosts have prevailed, and about an inch of snow fell on Monday night last.

— **VEITCH MEMORIAL PRIZES FOR 1888.**—We learn that the Trustees have made the following grants of medals and prizes for the present year:—Shropshire Horticultural Society, one medal, with £5 in money for a collection of vegetables; Glasgow and West of Scotland, one medal with £5 for Roses, and one medal with £5 for Grapes; Crystal Palace, one medal with £5 for a collection of fruit; Hull and East Riding Chrysanthemum Society, one medal with £5; Bath Floral, one medal with £5.

— **NATIONAL AURICULA AND PRIMULA SOCIETY (Southern Section), NATIONAL CARNATION AND PICOTEE SOCIETY (Southern Section).**—A Committee meeting of the above Societies was held at the rooms of the Horticultural Club, on Tuesday February 7th. It was decided to hold both Exhibitions under the auspices of the Royal Horticultural Society. The Auricula and Primula Exhibition on Tuesday 24th April the Carnation and Picotee on Tuesday July 24th. The schedules were revised and ordered to be printed.

— ON Monday last, the 13th inst., at 7 P.M., the NATIONAL CHRYSANTHEMUM SOCIETY held a meeting at Anderton's Hotel, Fleet Street, to receive the reports of the Sub-Committees appointed to consider the desirability of holding a provincial Show, and the production

of a new official catalogue. Owing to the great demands on our space this week we must defer the publication of these interesting reports until next issue; but it may be said that both were unanimously adopted, and it was resolved that the cordial invitation of the Sheffield and West Riding Chrysanthemum Society to hold the first provincial Show in that town be accepted for the present year. The election of new members, the Floral and Schedule Committees, with some alterations in the rules, also occupied the attention of the meeting.

— THE GARDENERS' ORPHAN FUND.—Mr. A. F. Barron writes —“I should feel obliged if you would kindly notice in your next issue for the information of the Hon. Local Secretaries who may be pleased to attend, that the meetings of the Executive Committees have been fixed to be held on the last Fridays in each month (excepting March 30th, which, being Good Friday, the meeting will be on the 23rd), at the “Caledonian Hotel,” Adelphi, six o'clock P.M. Nomination forms for the first election of six children to the benefits of the fund on July 13th, are now ready, and may be obtained on application to me.”

— THE VICTORIA LILY OF THE VALLEY.—All who have seen this fine variety as it has been exhibited by Messrs. Hawkins and Bennett, or growing in their grounds at Twickenham, will admit its great merit—its vigorous growth and strong spikes of fine bulbs. It is not often that “market men,” when they have superior stocks of whatever they may grow to pass from their hands very readily, but as will have been seen this distinct variety of Lily of the Valley is now being distributed. We have had examples similar to it from a gardener in the north, but they may not be identical, and at any rate the Victoria is a clear advance on the typical species.

— ON Sunday last, the 12th inst., a widely known pteridologist and writer, Mr. JOHN SMITH, formerly Curator of the Royal Gardens, Kew, died suddenly at his residence in Kew, aged ninety years. Mr. Smith retired from official duties in connection with the Royal Gardens on May 16th, 1864, having then been employed there in several capacities for forty-four years, but for the greater portion as Curator. He applied himself strongly to increasing the collections of plants, which advanced considerably under his care, especially the Ferns, which he made a special study, and several works, including the “*Historia Filicum*,” were published by him dealing with these plants. In his time, too, the Museums of Economic Botany were established and were placed under the charge of his son, Mr. Alexander Smith. Partly from the materials accumulated by the latter, Mr. John Smith produced after his son's death the work “*Domestic Botany*,” which has recently been re-issued as a “*Dictionary of Economic Plants*.” Failing sight was the cause of Mr. Smith's resignation, but his long service obtained him a substantial pension, and since his retirement he has, with the assistance of an amanuensis, produced several works, notably one issued a short time since for private circulation, giving the history of the Kew collections during his period of office.

— WE are informed that the highest award and only prize medal given for AGRICULTURAL GRASSES at the recent Newcastle Exhibition has been received by Messrs. Sutton and Sons of Reading.

— CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On February 29th, Mr. Sidney Summers, foreman in the R.H.S. Gardens, Chiswick, will read a paper on “*Fruit Culture for Profit*,” and on March 7th, Mr. F. T. Daniel will read one on “*Some American Fruits and Vegetables*.” As Mr. Daniel has travelled in the United States a very interesting paper may be expected.

— MR. WILLIAM BRYANT informs us that “The second Exhibition of the RUGBY CHRYSANTHEMUM SOCIETY is fixed for November 21st and 22nd next, and instead of being confined to a limited radius for exhibitors, most of the classes are thrown open, with a special prize for cut blooms.”

— THE WEATHER IN NOTTS.—The following summary of meteorological observations at Hodsock Priory, Workson, Notts, for January, 1883, has been sent to us by Mr. Joseph Mallender:—Mean temperature of month, 37°0'. Maximum on the 9th, 59°4'; minimum on the 30th, 19°8'. Maximum in the sun on the 9th, 89°6'; minimum on the grass on the 30th, 18°6'. Mean temperature of the air at 9 A.M., 36°4'; that of the soil at 1 foot deep, 37°0'. Number of nights below 32°, in shade, eighteen; on grass, nineteen. Total duration of sunshine in month, thirty-six hours, or 11 per cent. of possible duration; sixteen sunless

days. Total rainfall, 0·77 inch. Maximum fall in twenty-four hours on 31st, 0·34 inch. Rain fell on fifteen days. Average velocity of wind ten miles per hour. Velocity exceeded 400 miles on three days, and fell short of 100 miles on five days. Approximate averages for January:—Mean temperature 37°5'; rainfall, 1·71 inch; sunshine, thirty-five hours (seven years). A dry month of about average temperature and sunshine.

— MR. R. OWEN, Maidenhead, sends us flowers of his PRIMULA SINENSIS VARIETIES, remarkable alike for their size, form, and colours. One grand white variety has flowers 2½ inches in diameter of great substance, some also are beautifully fimbriated. The colours range from pure white to blush rose, mauve, deep red, crimson, carmine, and purple, some also being streaked and spotted. The strain is undoubtedly excellent.

— THE annual meeting of the members of the UNITED HORTICULTURAL PROVIDENT AND BENEFIT SOCIETY was held on Monday evening last. We have only space at present to say that the Society is in a flourishing state, and its character was brought out by the payment of £49 10s. 6½d. to the widow of the late Mr. W. Heale, being the accumulation of his deposits, or his share of the moneys that had not been disbursed in sick payments. Mr. Richard Dean presided over the meeting of this excellent Institution.

— A CORRESPONDENT informs us that Mr. William Jennings, for many years foreman of the herbaceous plant collection at the Pine Apple Nursery, Edgware Road, died on the 6th inst., at Edgbaston, Birmingham, at the age of sixty-five. Mr. Jennings was well known in the metropolis, and possessed a wide knowledge of hardy plants.

ARTIFICIAL MANURES FOR POT PLANTS.

I HAVE often thought that the value of artificial manures for applying to plants in pots is not sufficiently appreciated by gardeners generally, considering the highly satisfactory results that can be obtained by the judicious use of the various kinds now in the market, and the clean and easy manner in which they can be applied. Liquid manure made from cow or sheep's dung, or that obtained from the drainings of stables, is also excellent; but it is not always an easy matter to have a regular supply, and in conservatories and plant houses its use is often objectionable. I do not, however, wish it to be understood that I write disparagingly of the value of liquid manure, but I simply wish by comparison to point out the advantages of artificial manures, some of which are as follows:—They are cleaner in their method of application, as nearly all are used by sprinkling a small quantity over the surface soil before watering. They are also more convenient to use, because the plants that require a little assistance when they have become root-bound can have the necessary quantity given to each pot, and the watering be carried on without interruption that takes place when a mixed collection has to be watered. When using liquid manure it is then necessary to go over the plants twice, first to water those that require stimulating, and the second time to water those that should have clear water. The action of artificial manures is also very quick on all kinds of vegetation, bringing sickly looking plants into health again and starting stunted ones into vigorous growth. We have found that equal quantities of Peruvian guano and Clay's fertiliser mixed together (and used at the rate of a teaspoonful to a 10-inch pot) make an excellent stimulant for Palms, strong growing Ferns, Richardias, Azaleas, Fuchsias, Begonias, and Primulas, and in fact nearly all plants. Its effect on those named is quite magical by imparting to their fronds or leaves that deep glossy green colour which is a sure indication of health and luxuriance, and if used at regular intervals it will keep them in good health as long as other conditions are favourable.

A mistake often made in feeding plants is to give them one or two applications and then leave them till they get into a weak and exhausted condition for want of continued nourishment. Soft-wooded plants, when once they have become established in their pots, should be continually fed till their flowers are about half expanded, a sprinkling of artificial manure about once a fortnight and liquid manure twice a week. Palms, Azaleas, and Camellias should be encouraged to make free growth by the application of liquid at each watering during the growing season, and at other times when there is little or no growth going on, once in two or three weeks. All plants grown for decorative purposes are particularly useful when of large size in proportion to the pots in which they are grown, and therefore require the feeding system to be carried out in a regular manner, gradually lessening the quantity of rich

food for a few weeks previous to their being used for embellishing rooms, so that the plants will not experience the check they certainly would do were it suddenly withheld.

Any plants that have become sickly looking can often, by the aid of a few doses of nitrate of soda, be quickly brought to a perfect state of health again; but being very powerful in its action this must be used in small quantities, a piece about the size of a marble is large enough for a 12-inch pot. This fertiliser has also the effect of forcing plants on much more quickly than other manures, and is therefore valuable for assisting those that are naturally of slow growth. I have not yet traced its effect on many kinds of Heaths, but with *Erica hyemalis* and the numerous varieties of *Epacris*, a few doses of nitrate of soda given when the plants are making their growth produce good results, the growth being made very quickly and possessing a fine healthy appearance. I also find that during the summer months, when soft water cannot be obtained for them, a little dissolved in the water used at the rate of a teaspoonful to 2 gallons of water will keep the plants in capital health; whereas if hard water is used without the addition of soda or some other substitute the young growths assume a brownish tint which is not in the least desirable. There can be no doubt that all kinds of plants are greatly benefited by having frequent changes in the food supplied to them. A little close observation will soon convince anyone on that point. I have often noticed that when the use of one kind of manure is continued for several weeks the plants receiving it do not respond to its stimulating influences so readily as when it was first given. When such is the case give a few waterings with clear water and then apply some other kind of manure, and health and vigour will be continued.

Perhaps no plants pay better for judicious feeding than *Roses* in pots, as it is not often convenient to have them in very large pots; but with liberal top-dressings and feeding they can be kept healthy and strong in the same sized pots for years. When the shoots have grown a couple of inches they should have liquid manure at each alternate watering for a week, then a sprinkling of guano and Clay's fertiliser mixed as above mentioned, to be followed by two or three supplies of clear water. Soot water is made by placing some soot in a bag and soaking it for a few hours in a tub, always taking care not to use it strong enough to leave a sediment on the surface soil of the pots. If this course of feeding is carried out regularly in accordance with the above instructions, and other conditions are favourable, successful results will assuredly follow, and will also be the means of producing plants of the sizes most useful in much smaller pots than they are generally met with.—H. DUNKIN.

HOLLYHOCKS.

OBSERVING an article by "F. M." in the *Journal* recently respecting our *Hollyhocks*, and in response to the editorial request I beg to submit a short account of my experience with the disease. Late in the autumn of 1885 I observed a few spots of the fungus on the leaves of some of our *Hollyhock* plants. This was the first time of attack. I removed the foliage thus affected and took little further notice of it, as it seemed to make no progress of any moment during that season, but to my great consternation the whole collection was attacked early the following spring. I tried various insecticides, but without effect. We propagated our usual quantity of spring-grafted plants, which went on fairly well, considering the circumstances, for a short time; in fact they were fine young plants (with the exception of a few spots of disease) hardened to the temperature of a cold greenhouse. This was about the last week in March or the first week in April. The fungus then began to spread with great rapidity over every leaf, and appeared to successfully frustrate every effort to grow that the plants could make, and my exhibition prospects for that season were spoiled. I kept them in a cold frame by themselves (they were established in small pots) and planted all the old stools out in the garden, as they, too, were diseased.

About the middle of May I commenced operations with the young plants by cutting them all down to the surface of the soil in the pots, leaving two eyes on each plant, and stood them altogether outside in a corner, covering them 2 or 3 inches deep with light soil, and there they remained till they grew through the soil, the shoots coming quite clean and healthy in about three weeks. Those plants have never again been affected with disease, but during that period the old plants in the garden were being destroyed by the fungus, and towards the middle of August the disease was rampant, killing many leaves and a few of the plants. The blooms were very poor that season compared with what they had generally been, as they were checked when about half-developed through the loss of the foliage. I set to work in the autumn, about the first week in September, and cut every plant in the garden down to within a few inches of the ground, burnt every stem and vestige of leaf, thoroughly washed the stakes and stored them away, and buried

every stool in fine soil. In a few weeks the plants began to show themselves, and were clean and healthy. As they appeared we lifted the plants late in October, stored them in a cold frame, and have never seen any disease since. I now possess healthy plants that would gratify the most enthusiastic admirer of this noble autumn flower.

This system is not altogether new, for my valued friend, Mr. Jos. Oliver of Elington Park, recommended the same practice some years ago. He is a great lover of *Hollyhocks*, and a great hater of *Hollyhock* disease. I may here state that Mr. Oliver is a grower, also a raiser of *Hollyhocks* of no mean calibre. He has two seedlings of the highest merit—viz., Robert Ryle and Agnes Ryle, the former a light red of large size and very full and well-shaped; the latter a large deep golden yellow quite distinct. Mr. Oliver was good enough to let me have these a few years ago to grow privately, and I think very highly of them.

Having often been asked if the *Hollyhock* is in as good a form now as it was twenty or thirty years ago, I most emphatically say "Yes," if you look for them in the right direction. During the above-named period, my uncle, Mr. Thomas Fenwick, and my brother, Mr. T. Finlay, were growers and exhibitors of the foremost rank, and they will tell anyone that *Hercules* was always one of the very best *Hollyhocks* grown, if you get the true variety. The late Lord Hawke was a formidable antagonist, but he never had his flowers nearly so large as those of the north country growers, but always clean and neatly finished. I have one of Lord Hawke's varieties now—viz., Ruby Queen, a splendid flower, always finishing well. Moreover, I possess the true *Hercules*, Bullion, Majestic, and Conquest, all of which were grown twenty years ago, and were even amongst the very best, but some of my seedlings from those varieties are quite equal to, and, in some instances, better than their parents. The variety, Mrs. Maynard, which is a cross between *Hercules* and Bullion, is quite equal to the parents in quality, and quite distinct. Then, again, we have Grace Darling, which is, in my opinion, the best *Hollyhock* in cultivation, also Favourite, a clear silvery lilac, almost unapproached in size, and certainly so in colour, and Queen of the Yellows. A clergyman of no mean floral interest, whilst looking through our collection before we cut for the Newcastle Show last year, minutely inspected and admired all the varieties. Queen of the Yellows, in the best form I ever saw her, was one of the last the rev. gentleman came to. He stood silently for a few moments, and then exclaimed, "Ah! I must lift my hat to this gem, for this is the Queen of the Yellows, and truly the queen of all the *Hollyhocks*."—GEORGE FINLAY, *East Layton Hall, Darlington*.

CROPS THAT PAY.

SOUTH and north borders were formed, not by building costly walls, but by erecting boards 6 feet high. Posts were inserted 12 feet apart, and well tarred before they were placed into the ground. To these were nailed 2 by 3-inch deals, one a foot from the base, and the other the same distance from the top. Boards, a foot wide and 6 feet high, were nailed to these, the base resting on a single row of bricks to keep them off the soil, and the whole was well tarred. This is a cheap method certainly of providing warm borders and invaluable positions for *Tomatoes* and many other fruits. Whatever may be urged in favour of walls, plants in general would not grow better near them, or with greater rapidity attached to them, than they will near black boards. These absorb a greater quantity of heat than brick walls, and the heat radiated warms the air to such an extent that it is favourable to the growth of early crops and the rapid maturation of fruit. The borders, back and front, are 10 and 12 feet wide, between them are squares or flats of ground 25 to 30 yards in width. The boards are sufficiently high to protect *Potatoes* from early frosts when they come with a north wind. The first one or two in the row may be sometimes caught, but they are not certain of escaping when frost comes with the wind in any other quarter.

What are grown on these borders that pay? and to what purpose are the boards employed other than to provide shelter? are only natural questions to ask. At intervals of a few years the borders back and front are double dug, and when subjected to this process, which is done directly the autumn crop is removed, the lowest spit only is enriched with manure. The surface is manured when the crop is planted, or directly before. When the ground is frequently trenched the lower spit can be turned on the surface without the slightest fear of evil consequences. The surface spit that is turned to the base is naturally fertile, and on the top of this is placed the remains of *Mushroom* beds. Material from which we do not fear much will be washed away. The surface is dressed with nearly fresh manure. When the borders are planted with *Potatoes* the manure is not placed into the drills, as frequently practised, but

spread on the surface and forked well in. The same practice is followed when the borders are planted with Cos Lettuces and Kidney Beans between them. The earliest Cabbage Lettuces are produced by planting two or three rows at the foot of the boards, as well as in the manner described. In this position they grow rapidly, and are cleared from the ground just before the Cos Lettuces are ready, therefore pay well for the trouble and ground they occupy. The Cos Lettuces planted on the open quarters form a capital succession to those on the warm borders. These seldom realise less than 8d. per dozen, and are often fetched from the ground at that price. From this ground another valuable crop can be taken, for they are all cleared from the ground by the end of June. But we rarely occupy the ground fully with Lettuces, taking them principally between other crops, except on the north borders, and these are planted from sowings made after the middle of April to the end of May. When we plant the principal portion of the ground on the open flats in every alternate row of Lettuces we miss planting every other plant. This allows of Brussels Sprouts or Veitch's Autumn Giant Cauliflowers being planted when they are ready, and then occupy the whole of the ground when the Lettuce is cleared away.

But I must return to the south borders, and may here say that the variety of Kidney Bean grown is Osborn's Foreign, and we think most highly of one called Emerald Gem—a new one; the pods are beautifully green, better in this respect than Osborn's, but it is a few days later. For the main crop Canadian Wonder alone is grown. It is a most prolific Bean if the ground is well and deeply worked and liberally manured; 2 feet from row to row is too close to plant it; to give it a chance of developing itself the rows should be 6 inches, or even 1 foot further apart. They will pay well for the room; nothing is gained by crowding them. Let it be understood that double rows are planted in the case of both varieties, the former 4 inches from bean to bean, which are angled, and the latter 6 inches apart. By placing them at the proper distance when they are sown, which may take a little longer, but thinning afterwards is dispensed with. Boys are better than men for putting in the seed; they soon become experts; offer them a small prize of 2s. or so for the boy that plants them most quickly and best. Half the resources of the Kidney Bean are never developed, especially in private gardens, where they are only demanded now and again. If they are only attended to they will continue growing and fruiting for a remarkable length of time. We gather twice a week, and if a bean has been missed and shows signs of being too old it is not left on the plants for seed, but pulled off and thrown away. They should be picked close every time, then they will continue growing and yield tender beans, but once allow them to devote their energies to the production of seed, growth is quickly brought to a standstill, and tender produce that can only be appreciated will be out of the question. I know nothing amongst vegetables more objectionable than tough Beans; they are far worse than old Peas, but if this simple method is followed useful highly prized produce will result.

The early Potatoes planted in rows 2 feet apart, and about 8 inches from set to set. The sets are well sprit and are planted moderately deep, then earthed up. They are planted on the ridge fashion. I have no faith in the lazy method of laying them on the surface and covering them over with a few inches of soil. Those that plant on these principles have them through the ground first, and may after be heard to boast, "Our Potatoes are up." But do they dig first? that is the main object we must keep in view. I know arguments in favour of shallow planting may be adduced, and the objections to the principle are too strong to tempt me to follow the plan. My object in planting moderately deep and liberally covering them with earth is not to have them up, but to keep them under the ground as long as possible. They are safe there, they are not when their tender tops are through the ground. Directly they show signs of coming through, more soil is scraped over them until this is impossible, then they take their chance. When once they are through the ridges are hoed well down to stop small weeds that may start, and then earth them up again. They are not touched again until they are dug. It is surprising after the last operation how they grow, and people that see them can scarcely realise that they have only had the protection that the ground affords. They are not so very late in the market, for all from the south borders averaged 1½d. a pound, after the expense of taking them to the market had been deducted. The variety formerly grown was the old Ashleaf, which by accident we lost; since then we have grown a variety called Kidney Dwarf Top, and if it is not the old Ashleaf it is a very near relation. The haulm is no larger, and the tubers, which scarcely seem so long, are all clustered close together.

What I have to say about other Potatoes will be deferred for the present, but if Waleheren, Eclipse, or Autumn Giant Cauliflowers have not been planted between these early Potatoes, the

ground is filled directly they are dug with small Cabbage, such as Heartwell Early Marrow, Little Pixie, Ellam's Early, or Coleworts, generally the last, because they are hardiest, and often sell well if other vegetables are scarce; but if there is anything that can be had larger, there is no market for these small but delicious little Cabbages. They are valuable crops and pay well in some localities; but in my neighbourhood they look with disdain on anything much less than Robinson's Champion Drumhead. When this was discovered I decided to leave most of the Cabbage growing to somebody else, and generally take Cauliflowers as the second crop, or if they are not planted and showery weather follows the lifting of the Potatoes, the border is planted with Cos Lettuces, or Turnips are sown. This year, although very dry at planting time, Lettuces proved a remunerative crop, but this is a matter that in each individual case must be decided by the locality and the requirements of the market.

All my difficulties were not overcome by the erection of boards for the provision of north and south borders. No, they had only just begun, and I quickly saw before me another outlay, as no provision had been made for raising the plants, and to this a few words must be devoted another time.—MARKETER.

CYPRIPEDIUM FAIRRIEANUM.

A PLANT of this beautiful but rare Orchid was shown at South Kensington last year by Mr. F. G. Tautz, Studley House, Hammer-smith, and from this the drawing was prepared represented in the engraving (fig. 18). It is now over thirty years since this *Cypripedium* was introduced from Assam, and it first flowered in Mr. A. Fairrie's collection at Aigburth, Liverpool, in whose honour it was subsequently named. Owing to the plant being of slower growth than many other members of the same family, it still remains scarce, and is valued accordingly. In habit it is dwarf, with small light green leaves, but the flowers are very conspicuous and distinct, both in shape and colour. The dorsal sepal is white, with a greenish tint, heavily and regularly veined with purplish crimson; the petals are curiously deflexed, with the points upturning, also greenish-white with crimson-purple veins and a ciliated margin; the lip is neat in form, greenish, with a few faint reddish veins. It will be remembered that *C. Fairrieianum* is one of the parents of the choice hybrid *C. vexillarium*, which was raised in Messrs. Veitch & Sons' establishment by Mr. Dominy some years ago.—L. C.

DENDROBIUM HILLI.

YOUR correspondent "G." is in error when he states that this species is dedicated to Mr. C. G. Hill of Nottingham. It is figured in the "Bot. Mag." (t. 5261), and is there stated to have been received at Kew from Mr. Walter Hill, Superintendent of the Botanic Garden at Moreton Bay, and Sir W. Jackson Hooker says, "we gladly dedicate it to him." It is a distinct and very pretty species, and may also be seen in flower at St. Albans in the nurseries of Messrs. F. Sander & Co.—J. D.

In my note last week I was in error in supposing the above to be named in honour of C. G. Hill, Esq.

It is beautifully illustrated in Bateman's "Second Century of Orchidaceous Plants," plate 195. The accompanying note may be useful at the present time, as there appears to be some confusion between this and *D. speciosum*. "In his notice of this plant (1861) Sir William Hooker wrote as follows:—'Many years ago Mr. J. Smith assures me living samples of this fine *Dendrobium* were sent from Moreton Bay to the Royal Gardens of Kew, with an opinion expressed that it might possibly be the *D. undulatum* of Brown's 'Prodromus,' p. 332. I do not find that they ever flowered, but one thing is certain, that I possess in my herbarium a specimen of the true *D. undulatum* of Mr. Brown with the correct name in Mr. Cunningham's handwriting, and another specimen from Albany Island from A. C. Gregory, and also from Port Curtis, gathered by Mr. McGillivray during the voyage of the 'Rattlesnake' (1847). It is a very different species from that now under consideration. The *D. undulatum* has, as its name would imply, singularly undulated petals and sepals of very lurid colours and sharp segments to the lobes of the lip, and it is also a native of Java. Dr. Lindley has shown that his *D. discolor*, from the latter country, figured in

'Bot. Reg.' for 1841, table 52, is identical with Mr. Brown's *D. undulatum*."

"The present plant must then be considered a new species, and

once recognised as distinct in consequence of the greater length of the pseudo-bulbs or stems and of the leaves. The dense drooping racemes of *D. Hilli* and the longer and more tapering sepals,

FIG. 13—CYPRIPEDIUM FAIRRIEANUM.

as our living specimens were derived from the very zealous botanist and superintendent of the botanic garden at Moreton Bay, Mr. Walter Hill, Sir William dedicated it to him. Even without the flowers this plant, standing by the side of *D. speciosum*, may be at

together with the long narrow linear petals, are additional points of distinction. It requires, as might be expected, more heat than *D. speciosum*, but must have, like that species, a decided season of rest in a dry house."—G.

CYRTOCHILUM MACULATUM.

THIS old species is also in flower at St. Albans. It first flowered in the gardens of the Royal Horticultural Society, from specimens sent home by Mr. Hartweg, who found it near Vera Cruz. The flowers have narrow sepals and petals, densely blotched reddish maroon; the lip white and yellow. It is a vigorous-growing plant, and the spikes of flowers have an excellent effect, and if it is winter or early spring flowering, will be very useful to arrange amongst other plants producing more gaudy coloured flowers. It has been referred to *Oncidium*, and is in cultivation under the name of *Oncidium maculatum*.

EPIDENDRUM ENDRESI.

A lovely little Orchid, now in flower with Messrs. Sander & Co. The whole plant might be packed into an ordinary snuff box, and its lovely amethyst flowers, in colour like those of *Saccolabium coeleste*, are borne on stems about 2 inches high. It was growing in the warmest house, and with it in charming contrast were numerous examples of a recent introduction of the firm, *Angraecum Sanderianum*. It was recently exhibited at South Kensington, where it received a first-class certificate of merit. It was described in this Journal recently; but I can add from experience that it is very vigorous in growth, and flowers most freely, quite small plants producing strong spikes of its glistening white flowers: they sparkle in the sunlight. The lovely tiny *A. hyaloides* was, as usual, flowering itself to death. Amongst them—it is quite a gem in its way—another recent species, *A. Scottianum*, was flowering quite freely. This is now much more plentiful, and moderate in price.—J. D.

SIZE v. QUALITY—FRUIT AT NEWCASTLE.

WHEN I referred to Mr. Thomson's article I had in mind Black Hamburgh Grapes, which I had seen as large and as black as could be found hanging in the vineries at Drumlanrig, as well as other fruits, also large, including Pines as big as 24-sized pots, therefore I thought the opportunity a favourable one for asking if your correspondent could find fault with and recommend such fine examples of culture to be consigned to the rubbish heap; and as his opinions would have weight, I also thought it advisable to learn whether he considered Tomatoes ripe and fit for table, dessert fruit; but as no answer is given on that subject, I have no alternative but to act on the advice in hand, and when I exhibit again at Newcastle I shall include Tomatoes in my collection, and if they are not recognised "the fat will be in the fire."

If "Old Hand" could claim the same title for his head he could have seen that my Pears at the above Show were all distinct varieties, and I think it would have been a most easy task for the most casual observer to have distinguished the difference between any of the dishes staged by me, as the following list of names will show:—1, Williams's Bon Chrétien; 2, Doyenné d'Hiver; 3, Doyenné d'Été; 4, Louise Bonne of Jersey; 5, Citron des Carmes; 6, Jargonelle; 7, Windsor; 8, Early Crawford. In addition to these we had the following also ripe at the end of August;—Lammas, Beurré Giffard, Huntingdon, and Green Chisels—so in my case it was quite unnecessary to resort to any attempt at fraud, as my friend insinuates. "Old Hand" is doubtless aware of the fact that there are few better collections of Pears than we possess, and in favourable seasons the sizes he boasts of are by no means exceptional, especially for Beurré Diels. In common with many other gardeners I am kept pretty well informed of markets values, and I can get double the price for Bon Chrétien that I can for Beurré Diel, although the latter attains twice the size of the former. But what has market value to do with the matter? Would it not be as reasonable to exhibit a horse in a class for pigs, and claim the prize because the horse was of infinitely more value? The comparison is quite as justifiable. I took the precaution to inquire of the Secretary whether the rules would be adhered to. That gentleman replied in the affirmative that "all fruit must be ripe and fit for table;" and it is quite evident that I am the only exhibitor who staged fifty dishes of ripe fruit, as stipulated, for the Jubilee Prize. I anticipate the usual compliments to be forthcoming, that my exhibits received the awards they were worthy of. This is all I have to say at present.—J. H. GOODACRE.

STRATAGEM PEA.

IN reference to Mr. G. Garner's remarks in last week's issue anent the failure of Stratagem Peas with him, I beg leave to offer the following remarks if you consider them worth inserting. I have grown Stratagem Peas a few years here in trenches with liberal quantities of manure with the results as described by Mr. Garner, with the addition of brown spots on the pods, the produce being diminutive and of inferior flavour. I tried them in different ways without the desired result till I chanced to sow some Peas in a bed that had been well manured the previous spring for growing show Onions, without any further preparation than clearing off weeds. Nicks were made 3 inches deep, and the Peas sown 3 inches apart, 6 inches between the rows, the soil filled in and made as firm as before. The result was all that could be desired—stems as thick as Raspberry canes, 3½ feet high, with forty pods to a plant, 15 to 18 inches across the foliage, with tendrils like Cucumber

plants, and from eight to ten large peas in each pod of exquisite flavour. I think if Mr. G. Garner tries the firm ground he will be satisfied with the result, of course giving them every attention with water and liquid manure.—JOHN SWAN.

THWAITE HOUSE, COTTINGHAM.

PICTURESQUELY situated at the foot of the Yorkshire wolds, and within easy driving distance of the busy seaport town of Hull, stands the delightful country residence of Sir Albert K. Rollit, M.P. On entering the grounds the visitor is at once surprised at the vast extent of lawn and pleasure grounds, which for beauty and extent cannot be surpassed in the East Riding. When passing to the drive from the eastern side of the mansion two splendid plants of *Phormium tenax* are seen, which are strikingly effective in the position they occupy on a strip of lawn on each side of the road. The house is clothed with plants, such as Ivy, Clematis Jackmanni, Tea Roses, and *Pyrus japonica* and *Maulei* in fruit. On reaching the northern side a splendid view of the extensive grounds is obtained, and the fine Palms, *Dracænas*, *Phormiums*, *Agaves*, and standard Bays dotted about, with water in the background, impart to the whole place a tropical appearance not easily forgotten, and causes one to think whether the style of ornamentation is not more effective than the stereotyped bedding so generally seen.

Immediately in front of the house is the flower garden, the beds arranged round a large fountain, in the base of which are growing *Nymphæas*, *Herpestis reflexa*, and other aquatics, and many fine golden orfe, golden tench, and other rare fish. In the bedding arrangements Crystal Palace Gem, Robert Fish, Flower of Spring, McMahan, and West Brighton Gem *Pelargoniums* were largely used. *Tropæolum Vesuvius*, *Coleus Verschaffelti*, *Lobelias*, and *Alternantheras* have also been used with good effect. Raised circular beds of *Pelargonium* Henry Jacoby were effective. Forming a half circle to those beds on the opposite side from the house, are immense *Agaves*, splendid specimens brought from the Riviera. Another large hed filled with succulents and edged with varieties of *Mesembryanthemums* contains many gems of this interesting class of plants, including a good specimen of *Agave ferox*. Of course a summer view is here described.

The lake, some five acres in extent, is fed by powerful springs and a small stream which enters on the western side of the grounds and passes through them, the water clear as crystal, and is abundantly stocked with fish, including the American brook trout (*Salmo fontinalis*), the great lake trout (*Salmo ferox*), the land-locked salmon (*Salmo lacustris*), the white fish (*Coregonus albus*), golden orfe, tench, &c. Feeding is done on an extensive scale, pisciculture being a pursuit with Sir Albert, who is Vice-President of the National Fish Culture Association at South Kensington and Delaford Park. Many species of waterfowl of the rare kinds also find a happy home here, and breed upon the islands.

Wending our way over rustic bridges we find *Rhododendrons* and *Ghent Azaleas* in enormous quantities, in fine variety and surprisingly vigorous; *Liliums* of various kinds planted amongst them give a grand effect, whilst the Heather, red and white, with which many of the shrubberies are edged, luxuriates in a manner seldom seen off its native moor. *Bilberries* and *Cranberries* are also seen in fine clumps. Large beds of *Roses* in various parts of the grounds in all the finest varieties and all edged with *Gloire de Dijon*. These are tied down to a wire 10 inches from the ground. In that way they are easily protected from the frost, and by keeping the growths tied down they produce enormous quantities of blooms.

Leaving much that is attractive outside, we find many plants in the houses especially interesting. *Orchids*, *Palms*; also *Ferns*, *Peaches*, *Oranges*, *Vines*, and greenhouse plants all have houses devoted to their culture, whilst numbers of pits and frames are required for the production of plants for decorative purposes. The Palm stove contains many fine specimens, which have already made their mark in the exhibition tent. *Cocos Weddelliana*, 7 feet across, with about thirty leaves; *Kentia canterburyana*, 7 feet high, with twelve fine leaves; a splendid *Lantana borbonica* 12 feet across, with eighteen fine leaves; *Areca Verschaffelti*, *Thrinax elegans*, and many others all in the finest possible condition. Mention must also be made of a splendid specimen of the rare and beautiful *Cocos neo-caledonica*, with 5½ feet stem, carrying a splendid head, and some fine *Crotons* beautifully coloured, fine *Ixoras*, *Anthuriums*, *Stephanotis*, and *Rondeletias*, all fine specimens. These with an exceptional collection of economic plants and large *Bananas*, *Ipomæas*, *Clerodendrons*, and *Combretum purpureum* on the rafters furnish the house.

The greenhouse contains fine specimen *Heaths* in grand condition; also large *Trec Ferns*, *Camellias*, *Azaleas*, and a good collection of hard-wooded plants generally, hybrid *Rhododendrons*, and a splendid specimen *Dasylyrion aerotrichum*. *Lapagerias*, *Taesonias*, and other climbers occupy the roof. The fernery, a winding structure 60 feet in height, is entered from the greenhouse, and presents a pretty sight, the back wall covered with *Ficus repens* and *Caladium*, and *Begonias* freely interspersed among the *Ferns* in rockwork. On the front stage are healthy *Gleichenias*, *Dicksonias*, &c. In the centre is a tank, in which we note aquatics and fish again thriving together, *Aponogeton distachyon*, *Limnocharis Humboldtii*, and others, with golden orfe, tench, and other fish.

The Orchid house contains *Cattleyas*, *Lælias*, *Cypripediums*, *Oncidiums*, *Phalenopsis*, &c., with *Nepenthes* well "pitched," whilst on the roof *Dipladenias* bloom profusely, splendid flowers of *hybrida*, *amabilis* and *Regina* being counted by the dozen. Another division is

occupied with Allamandas; Hendersoni, nobilis, Schotti, chelsoni, and grandiflora are all grown. Eucharis, Dendrobiums, and small Palms occupy the stages. The orangery is filled with specimens in tubs (the largest 9 feet by 7 feet), and include the Maltese Blood, Jaffa, Brazilian, Otaheite, and Tangeine, the flowers and fruits from those being highly appreciated. There are also fine Lemons and Citrons. The Peach trees and Vines are in fine condition, all recently planted and carrying splendid crops. The fruit garden is well stocked with pyramid Pears and Apples, Ribston Pippin and Cox's Orange being the favourite varieties. Quinces, Medlars, Mulberries, and Blackberries are also grown, and the kitchen garden has the stamp of good management throughout.

Much more might be written about this interesting garden, but enough has been said to show its owner is a generous patron of horticulture. The gardens are under the management of Mr. A. Greaves, who is to be congratulated on the condition of everything under his charge.—VISITOR.

MOSS ROSES.

In every garden, large or small, Moss Roses should be accorded a position. However beautiful other Roses may be, none surpasses or are more admired than the blooms of these charming Roses. Although there are numbers of varieties, there are not more than four that are really worth growing, except perhaps as objects in the shrubbery and other borders. The two best are the Old Moss and White Bath. These two are true Moss Roses. None of the others can be compared with them for the quantity or beauty of the moss that surrounds their buds. The Crested Moss is most peculiar, and should be included by all who grow Moss Roses.

For climbing up a pillar or for covering a fence, Baron de Wassenaer is decidedly the most suitable. It flowers freely when grown on this principle, and the blooms, which are produced in clusters, are fairly well mossed. Gloire des Mousseuses forces better than any other variety. Although Moss Roses are not well adapted for very early forcing, this one flowers freely, and may be had in presentable condition after the middle of March, and it is even more beautiful than when allowed to flower naturally outside.

Lanei is conspicuous for its colour, and being a good grower is well adapted for shrubbery borders. The buds are not well mossed, besides the moss surrounding them is too dark and too short to present such a charming appearance as either of those first named. This has also another great defect, for it appears to be a general favourite with aphides. The buds are very gummy, and are the first to be attacked. This objectionable feature is not decreased afterwards.

Blanche Moreau came out with the highest credentials, but those who grow it by the side of White Bath will find that it cannot be compared with that excellent variety. It is, however, worth a place in the shrubbery border, for it is one of the strongest growers. It quickly forms a large and imposing bush; it flowers freely if the wood is well ripened and not pruned too severely. Although a strong grower it is almost certain to be severely attacked by mildew. It has always been one of the first in our moderately light soil, while the Old Moss and White Bath have not been attacked.

All the varieties named do very well worked on the Briar, except the two old ones, which do not appear to grow freely. With us at least they do best on their own roots. Both are weak growers, but in rich fertile soil they push up moderately strong shoots from the base. I have grown nearly every variety, and find all do well when planted the same as other Roses, except the two I have recommended as the best, which appear to do best when they are practically laid in or planted in a sloping direction, being careful not to bury the roots deeply. By this method they appear to throw up best from the base. Celini has proved the poorest grower of all, for it failed with us both on its own roots and worked.

In pruning Moss Roses we have found it to be the best policy to prune rather severely. All the weakest shoots should be cut back to one eye, while strong ones for pegging down should be cut back to within 1 foot or 15 inches. We prefer to plant closer together than would be the case if the shoots were left nearly their whole length when pegged down. Baron de Wassenaer, although it flowers freely when but slightly pruned, has a tendency to become bare towards the base unless the shoots are trained as much as possible in a horizontal position after pruning. This induces the back eyes to break freely, which not only insures more buds, but the growths starting from the base upon which the flowers will be produced the following season.—B. P.

SOUVENIR DE LA MALMAISON.

In most gardens this grand old Bourbon Rose is generally seen and treated as a dwarf, being pruned closely back every year. I think it is not generally known that it is a splendid Rose for training to a pillar or against a wall. Even for this purpose it is not necessary that it should have a sunny or warm aspect, for it will grow and flower

amazingly even on a north wall. Until that severe winter of a few years ago, when the thermometer fell below zero, we had a plant that had reached a height of 14 feet against a wall with a north-eastern aspect; and although this would not be regarded a favourable position it was sadly overshadowed by Hollies. In spite of this, however, it flowers profusely twice yearly, in early summer and again in autumn, in fact long after slight frosts have set in. In some seasons I have gathered very creditable Roses from this tree in December. Although I had about a hundred of this variety on the Briar and upon their own roots, this old plant always produced the largest blooms.

Although the Bourbons are looked upon as rather tender Roses, and are recommended generally to be planted in light rich soil, it has struck me that it may be the better treatment that renders them less hardy than they would otherwise be. Light rich soil unquestionably encourages a soft succulent growth that cannot endure severe weather. The old tree to which I have referred must have braved many a winter, and probably this was largely due to the good soil in which it was growing. It was planted in a narrow border about 10 inches wider with a number of other varieties, and to my knowledge had no manure applied to its roots for over ten years. From this border it could ramble into a gravel walk, and beyond this there are no attractions that would induce the roots to travel. No doubt the wood made was firm, although the aspect was not favourable for ripening it well, and the firmness of the wood may be the secret of the fine flowers it used to produce.—R. G. W.

SHORTENING SEEDLING BRIAR ROOTS.

A CORRESPONDENT in a recent issue seemed to be in favour of planting the seedling Briar without cutting or shortening the tap roots. In his case evidently the tap root is no drawback. But really it is so. If this correspondent wishes to get the same effect which would be produced by leaving the roots of the Briars long he has only to plant ordinary-grown plants about 18 inches deep. He may try this for one season; after that I think he will discover that what Canon, or rather Dean, Hole says in his "Book on Roses" is correct. What the Dean says is, "Plant as near the surface as possible; deep planting means disease, debility, and death" I say ditto to that. The soil I cultivate, where I have grown Roses for some years, is a barren rock on which long cultivation has accumulated about 6 inches of soil. During the dry burning season we had in 1887 my Roses, planted near the surface, while they no doubt suffered a great deal, in my opinion did much better than if they had been planted, or rather buried, deeper.—D. GILMOUR, JUN.

BUDDING ROSES ON SEEDLING BRIAR.

A CORRESPONDENT "R." (page 86), asks for information on this subject. I have read somewhere directions for cooking a hare, which begin "First catch your hare." I am afraid my friend is somewhat in the position of the cook who has not yet caught the hare. If the seed were dried—that is, not sown immediately it was gathered—it will most probably not germinate for eighteen months, by which time "R." will hate the sight of the box in which he has sown the seed. I do not need, I think, under the circumstances, to go on to give directions as to the budding of the Briars which are yet to grow, there will be time enough for that this time next year. The best plan "R." can follow is to sow the seed outside in a bed, and when the Briars grow and are strong enough they may be budded where they grow, or transplanted at any time of the year when Roses are moved. No doubt the richer the land where the Briars are sown the stronger will be the growth.—D. GILMOUR, JUN.

OLD AND NEW LAWNS.

THE value of lawns for use and ornament depends chiefly on the keeping, though some, through natural advantages of situation, give no trouble as compared with others less favourably located. Our climate and soil are peculiarly favourable to grasses, so that there is no excuse for a bad lawn in any position in these islands. Daisies, Plantains, and other weeds are a great disfigurement, and equally objectionable are the coarser grasses. Moss in many may be seen very much more abundant than grass, and lichen is not absent in some cases. There is no satisfaction in an uneven, weedy, patchy, mossy lawn. There are lawns that only looked well once—i.e., a brief period after formation. Probably the soil had no particular preparation, draining was not considered, no care was taken to provide a regular depth of soil for laying turf or sowing seeds, and the location whence the turf was taken was not considered. Some lawns get into a bad state through neglect; the soil is good, the drainage all that is desired, yet the lawn is poor and thin of the coveted herbage to make a close, firm, yet elastic turf. Poverty is the cause of so many lawns being as they are; what they want is cultivation, the frequent cutting and clearing off is impoverishment. Some soils will bear the removal without showing distress for a long time; indeed, some lawns, from the particular quality of the soil, will improve for many years, but the majority are not in that condition.

UNEVEN LAWNS.—These are such as have inequalities from the subsidence of the soil over drains, filling up hollows, taking out trees, or alterations, &c., and which are not so pronounced as to necessitate taking up the whole of the turf, leveling and relaying. Such slight unevenness as a sunk drain, an inequality occasioned by the removal of a tree, when rectified, converts an otherwise unserviceable lawn into one suitable for tennis. Paring the turf, filling with soil similar in quality to that forming the lawn, and firmly so as not to settle, relaying and

beating will do wonders; but work of this kind needs to be done expeditiously, and at a time when it will give the turf a chance, as when it is done late, or after the grass begins to grow, there is danger of its not being equal with the rest, or watering must be resorted to. Do not employ rich soil: it will cause the grass to grow rankly, and mar the appearance, both before and after cutting, for a long time.

MOSSY AND PATCHY LAWNS.—If there be much moss, scratch it off, or as much as possible, with an iron rake. Treat the places bare of grass similarly. Those that have the grass worn off should be pointed or lightened with a fork, applying a dressing of quicklime and wood ashes in equal parts, at the rate of half a bushel per rod. Failing those, apply a pound each nitrate of soda and muriate of potash. This should be done by March, or better, by the middle of February, and in a fortnight follow with a dressing of well decayed manure, that will work in. Leaf soil, or the rubbish heap material reduced to soil or passed through a $\frac{3}{4}$ -inch sieve, will do. Five bushels per rod (six hundred per acre, about twenty tons) is a maximum quantity. Spread it evenly, rake with a hay rake every week, but not in very wet or dry weather. Early in April, with a prospect of rain, sow seed on the bare places with lawn grass seeds thickly, using discretion about the whole being seeded, and seek to make the whole even. Rake lightly, and roll it well down. Some may say they have no manure, but they can use 2 lbs. superphosphate, and a peck of soot per rod just before sowing the seeds, and rake it well in. If the early mowings are with the scythe it will be an advantage; any way, it should not be cut quite so close in early summer as an established lawn in good or even fair condition. In sowing the seed on very bare places use half a pound per rod, and correspondingly less, according to the quantity of grass.

GENERAL LAWNS.—The first attempt at improvement must be in the direction of cleanliness. It is useless expecting the lawn to give a crop of thick set velvety turf if the finer grasses have to contend with Daisies, Plantains, Dandelions, Docks, coarse grasses, &c. Enough soil should be used over the lawn after grubbing up the weeds to make good all inequalities of surface, dressing with the back of a rake. If there be any moss, employ lime and wood ashes as before advised, but in less proportion of lime by half; or if nitrate of soda and muriate of potash be used take half the quantity of the former, and follow with a dressing of short manure or compost, or soot and superphosphate, treating as before advised, also as regards seeding where the grass is thin. Whenever the turf is not quite satisfactory prompt measures should be instituted. An application of manurial matter may be given occasionally, short manure or rich compost every second or third year, or wood ashes and soot applied in February or as soon after as the weather permits, equal quantities at the rate of a peck per rod, which will keep down moss and encourage a sufficient quantity of grass, or if not another dressing of soot may be applied later, and always during moist weather. A good rain will make all right as regards appearance and cleanliness. It may be mentioned that nothing does a lawn so much good as scratching it with an iron rake, and spreading the wormcasts, that being far better than making the surface impervious to air and rain by continual rolling in weather during which there is no prospect of grass growing.

There is benefit in other manures—sulphate of ammonia, for instance, 1 lb. per rod, and double the quantity of salt. Gypsum may also be mentioned, but it has the liability of encouraging too much Clover, which is objectionable on tennis grounds from keeping the turf wet in the autumn too long in the day, otherwise it is very useful on general lawns, and may be used at the rate of a ton per acre. For lasting and to encourage the finer grasses bonemeal at the rate of 20 bushels per acre is unrivalled, and I may conclude by stating that guano and the advertised manures so far as I have tried them are excellent, all of which should be applied in early spring in moist weather.—G. ABBEY.

BEGONIA ODORATA.

This variety of Begonia is well suited for growing into neat little plants in small pots for winter flowering. The fragrance from its pure white flowers, which are borne in large trusses, is very agreeable. The details of culture are simple—indeed, anyone possessing a warm house during the winter and suitable convenience during the summer months can grow this Begonia to perfection by following the method of culture here described.

Towards the end of the present or early next month take short stout cuttings about 4 inches long, insert them in sandy soil singly in small pots, or about four in a 3-inch pot. Plunge the pots in a gentle bottom heat in the propagating house or under a handlight in the Cucumber or Melon house, where the temperature does not fall below 65°. When well rooted transfer the plants into pots one size larger, using soil two parts loam, one part peat, a dash of bone meal, and some sand. Place the plants on a shelf close to the glass, where the growth will be of a stocky short-jointed nature. When the plants are 6 inches high top them by pinching the point from each to induce side branches and suckers from the bottom, which make the strongest growth. When the pots are again filled with roots transfer into larger pots, 48 or 32 sizes being very useful where the plants are required for vases in the decoration of rooms. Keep the plants on the shelf close to the glass during the summer, where the temperature does not fall below that indicated. Supply

water to the roots freely, so that the foliage is retained in a healthy green state, alternating the supply with weak liquid manure when the pots are filled with roots. No more pinching will be needed, as from the first topping from three to six branches will be produced; the numbers of each will guide the cultivator as to the size of pots required. One stake to each plant, fixed in the centre, to which each branch may be loosely looped, or one stake to each stem may be used at will. The stems are rather short and firm in themselves, but a slight support may be of service to prevent accident. Moderate shade during the hottest part of the day during the summer months will assist in preserving healthy foliage. Towards the middle of September the shade may be dispensed with altogether, as after that date what sun there is will aid in ripening the growths, and the plants will flower more freely. Directly after Christmas the plants will commence flowering, and will continue for two or three months, the plants reaching the height of from 1 foot 6 inches to 2 feet 6 inches.—E. MOLYNEUX.

[With this communication came flowers of the Begonia named, which amply testified to the correctness of our correspondent's remarks concerning its merits.]

PRIMULAS AT PERRY HILL.

MESSRS. J. CARTER & Co., High Holborn, have a most extensive display of Primulas in their Perry Hill nurseries at the present time, representing all the carefully proved old and new varieties sent out by this firm. Two span-roofed houses, each 100 feet in length, are devoted to the plants grown for seed, and there are upwards of 5000 plants flowering now that later on will yield a most valuable stock of seed, of which some pounds are required annually. The usefulness of *Primula sinensis* and its numerous varieties has been amply demonstrated in recent years, but few are aware of the continuous careful experiments needed to improve the "strains," or to keep good varieties true. Every day when the plants are in flower they are examined critically, and self or cross-fertilisation is assisted by a most tedious process. Primulas grown for seed-bearing, too, need some special knowledge of their peculiarities, as it is easy to have the plants so vigorous with coarse foliage that very few, or only imperfect seeds, will be produced. Sturdy, dwarf, yet well-developed plants are required, with bold substantial pure or highly coloured flowers, and these Messrs. Carter & Co. have evidently secured in their present season's stock.

Some of the principal varieties may be briefly noted, but all are good, and though novelties are eagerly sought nothing of an inferior character can be tolerated now. First on the list comes Holborn Blue, which has now been in cultivation six or seven years, and distinct as was the colour when first seen, it has been steadily improved since, a marked advance having been made in one selection this year. This is several shades darker than the original, one with well formed single flowers and round leaves. Near to this is Double Crimson, a fine acquisition of a rich dark crimson shade, the flowers having a little tuft of petals in the centre. Next to this is a grand single white with dark coloured Fern leaves, the flowers are of great substance and quite pure. Holborn Vermilion, a brilliantly coloured single variety, of compact habit, with dark stems. Holborn White Improved is a useful single variety with massive flowers in fine trusses, well above the plain green leaves, but there is also a selection from it with Fern leaves. This is a free and good constitutioned *Primula* for decorative purposes. Prince of Wales has double salmon-tinted flowers borne in large trusses, the leaf round, and the habit dwarf. Holborn Ruby is one of the graceful Fern-leaf type, with flowers of a soft pleasing colour. Holborn Fawn is very distinct, the flowers neat, tinted rosy fawn, with a lace-like white edge. Holborn Carmine is a strong growing variety, with round leaves and large bright flowers. Holborn Elaine is a Fern-leaf variety, with dark stems and handsome flowers. Holborn Magenta is an intensely deep crimson magenta single *Primula*, the flowers of great size in good trusses. It contrasts well with the white varieties. Holborn Salmon has delicately tinted flowers, and is of compact sturdy habit. Snowflake is a charming double white variety, faintly flush tinted, very free and admirable for cutting. Holborn Gold Leaf is a curiosity, with yellow foliage and pale pink flowers, very delicate. Holborn Pearl is one of the Fern-leaf type, with dark stems and delicately tinted flowers of fine shape and substance. Holborn Venus is distinct and pretty, the flowers of moderate size but good shape, dotted and streaked with pink on a white ground.

To produce these plants the seed is sown in June and July, so as to have a succession. The seedlings are first pricked out in boxes, then potted singly in "thumbs," and finally transferred into 48's, in which they flower. A compost which gives much satisfaction is formed of four barrowloads of yellow loam, two of old manure, and one of leaf mould with river sand. Owing to the artificial fertilisation resorted to the flowers do not remain long upon the plants after they are sufficiently expanded, but there is a succession which will maintain a display for some time yet.—X.

STOVE PLANTS.

THE Acanthaceous genus *Dipteracanthus* includes a number of beautiful plants, natives of tropical South America, and useful for the decoration of stoves and warm conservatories in winter.

DIPTERACANTHUS.—The flowers produced from one-year-old plants are always the finest. If cuttings are struck in the spring they may be grown into plants sufficiently large for most purposes. The soil should consist of about equal parts of good leaf mould, peat, loam, and sand. They enjoy an abundant supply of water, and the temperature of an ordinary moist stove. Insect pests must be kept away by the frequent application of the syringe.

D. HERBSTI.—This species, though somewhat doubtfully referred to the present genus, is perhaps one of the very finest Acanthaceous plants for winter decoration. If proper attention is given to stopping the shoots during the growing season a handsome plant will have been

with an obtuse base upwards of 2 inches in length, deep green above, paler below. Flowers large, about the same length as the leaves, mostly solitary from the axils of the upper ones; tube long, and enlarging upwards; limb large and spreading, five-lobed; colour rich scarlet.

D. SPECTABILIS (fig. 19).—In this plant the leaves are ovate acuminate, slightly hairy, some 2 inches long, and deep green. Flowers produced from the axils of the leaves on the upper branches, mostly in pairs, large and spreading, of rich deep blue.

D. CAULESCENS.—Certainly less beautiful than either of the preceding, but the profusion with which its purplish-lilac flowers are produced through the very depth of winter amply compensates for its somewhat

FIG. 19.—DIPTERACANTHUS SPECTABILIS.

formed by the end of September, about which time its flowers first begin to open, and continue to do so for some three months. It is a half-shrubby plant, producing opposite lanceolate leaves about 6 inches in length and about 2 inches in breadth, upper side deep green, with a grey band traversing the entire length of midrib on each side, the lower surface dull purple. Flowers produced in clusters of about five from the axils of the upper leaves; tube of corolla very slender and nearly 3 inches long, the upper portion much enlarged and pale rosy purple in colour, limb white, spreading, five-lobed, each lobe having a central notch or division.

D. AFFINIS.—Here we have another very fine plant, but still it must be confessed it has proved with us much less prolific than the preceding species. Neither is it naturally so purely a winter flowerer; this, however, can be overcome by continually stopping the young growths up to about the end of August. Leaves opposite, ovate acuminate at the apex,

less decided colour. Naturally this species is of a rather straggling habit, and will therefore require a little extra attention in the matter of stopping side shoots, &c. Leaves opposite, nearly 2 inches in length, somewhat oblong acuminate, full green above, paler below, slightly tinged with dull purple. Flowers in pairs; base of tube white, upper part large and spreading, limb five-lobed, lobes slightly crisp, purplish-lilac, more or less streaked with lines of a deeper hue.

EMPLOYERS AND THEIR GARDENERS.

As regards exhibiting, and whether the employer or the employed should be named as taking the prizes, your pages have contained some remarks from both sides. It is a large subject, far larger than it seems at first sight. My son has a horse of his own; riding up the town one of my friends overheard two lads talking. One says to the other, "That be his own boss, but he do keep it in Mr. Snooks' stable." (Snooks is the *nom de plume* of my man). If I address a label or letter to myself

I address it plainly, adding neither Mr. nor Esq. "Phantom" seems very anxious about the "Mr.," but I have heard servants talk of "Mr. Rose over at Johnson's," Mr. Rose being the gardener and Johnson the principal person in the town. I have in days gone by often seen my name without prefix or addition in a prize list, and been very glad so to see it too.

I can fully understand that a gardener may, under certain conditions, feel that he has a right to call the plants, say Chrysanthemums, his own. I can understand a gentleman saying to his gardener, "Make the best of the houses, fill them with any flowers you please at your own expense, find the manure, &c., &c. In return, supply me in the house, exhibit if you please at your own expense, and of course take the prize money." This gardener has a claim to call these plants and the blooms shown his own. I am presuming that the gardener takes a real interest in his work. But supposing plants, manures, show expenses, paid by the employer, what claim can the gardener have to be considered the owner? And if the employer's name be left out whom do the public suppose to be the owner?

Again, I can understand a nobleman saying, "I give you such a salary, have what you think best in the houses. I expect whatever fruit I require to be forthcoming, and if you have not got it you must provide it." Such a gardener might possibly have the right to give away fruit as he pleased, seeing he would have to provide it if not there; but in the absence of permission he has no right to give away anything that is not his own.

I do not see that "Phantom's" rather strained comments on the Duke of Ramsgate or the Marquis of Willerford exhibiting help the matter, though it is quite possible that their lordships might, if fond of gardening, do some of the things for which "Phantom" in a rather curious way gives them credit. The brains that grow the flowers have by their contract with the master, whether lord or otherwise, given themselves up to the master for that purpose, and should, as it seems to me, be proud to see the owner's name attached to silver cup or first prize. Everyone who knows anything about it gives the gardener the credit. I should not in the slightest degree mind attaching my usual *nom de plume*, well known to your readers for many years, but as I have been obliged to speak of myself somewhat egotistically let me subscribe myself plain—JOHN HOBGOBLIN.

[Nothing is more annoying to gardeners as a rule, and we know of no exception, than to see the owners of the produce staged ignored on prize cards at exhibitions. The fault of omitting owners' names, and it is a fault, rests with the show authorities; nor are gardeners responsible for reports in the press.]

EARLY FLOWERS.

ALREADY the gentle drooping Snowdrop is showing its buds of white. Here and there odd flowers of the Primrose and its near of kin, the Polyanthus, are seen. The true old Christmas Roses are flowering, and Hepaticas will soon be open. We have sheets of Christmas Roses—that's the way to let them show us their beauty, not in single clumps, but in long borders, or in masses solely of themselves. Then will come sweet Violets in plenty, and there are none so sweet or so early as the old common sort, and next to that I think the Czar for usefulness. Along with these, sheltered at the foot of walls, the Neapolitan, De Brazza, and Marie Louise yield a few fine blooms, the latter the earliest and sweetest. Hepaticas and Snowdrops, yellow Crocuses and white Arabis, the satin-flowered white and purple Sisyrinchiums, various of the Helleborus tribe, and clumps of the little Daffodil, Forget-me-nots, and Aubrietias, masses of Winter Aconites with tender shoots of many flowers.

This month also, if we are wise, we shall have in greenhouse and sitting-room plants of Primroses and Polyanthuses lifted from outside and allowed to open their flowers under a little kindly shelter. Just at the time we write we lift many clumps of various Daffodils, the early Squill, Lily of the Valley, Solomon's Seal, Dielytras, Glory of the Snow, and other spring flowers. They are placed in pots under glass, and during the early and latter days of the month nothing gives greater pleasure than these. Crocuses potted in autumn and kept growing cool are in the beginning of February not only pretty, but very beautiful, and of much value. Of other hardy flowers not so common, but happily becoming better known every day, we ought to have some Azaleas, both mollis and the Ghent varieties. They merely require potting, and when summer weather comes may be turned out of doors again. Treated in the same way we may have the beautiful Spiraea palmata, good Rhododendrons, and that very sweet shrub Choisy ternata, and, indeed, were we less fond of running after merely the more "fashionable" flowers we might have very much more interesting and quite as attractive gardens. I am going to say nothing about Cinerarias, Hyacinths, Chinese Primulas, Azaleas, &c. They are in everybody's gardens, but I do think, now that many of the best Orchids are so cheap, as witness Dendrobium Wardianum, Odontoglossum Rossii, and others, that we ought to see more of these in everyday gardens. Anybody with a vinery can grow the former. A cold frame and greenhouse will suit the

latter. Others which are easily had in flower during this month are Dendrobium Pierardi, a very pretty sort, and the old D. nobile. Then we have that lovely flower Cœlogyne cristata, also of the easiest culture. Lycaste Skinneri, Lælia anceps, which, if grown cool, flowers at this time. The whole of these Orchids succeed with the exception of Lycaste Skinneri, which I have not so tried, fastened to and rooted on pieces of Fern stems.

Yet another February flower I should like to say a word for—Clematis indivisa. If there is any place where this can ramble unchecked during this month it will be a perfect veil of white starry blossoms with just the faintest bit of pink diffused from its anthers. These notes are only meant to indicate some of the good things, all easily grown, all most beautiful, appropriate to those who may have the means of procuring anything grander, and who may yet wish, and rightly wish, for something to beautify their gardens, their lawns, their rooms, and their greenhouse.—B.

THE WILTS HORTICULTURAL SOCIETY.

THE annual meeting of the Wilts Horticultural Society was held in the Council Chamber, Salisbury, on the afternoon of the 8th inst., the ex-Mayor (Mr. Fred. Griffin) presiding. The Hon. Secretary (Mr. Walter H. Williams) read the report of the Society's financial position during the past year, which was considered by the subscribers and Committee as satisfactory. The Earl of Radnor was re-elected as President of the Society, and Lord Heytesbury, Sir Michael Hicks Beach, Bart., W. H. Gramshaw, Esq., Hurdcott House; H. Stevens, Esq., and — Alexander, Esq., were elected as Vice-Presidents for the present year.—Mr. D. H. Williams was, on the proposition of Captain Marryat and seconded by the Chairman, re-elected Hon. Secretary. Subsequently a hearty vote of thanks, proposed by the Chairman, was accorded to Mr. Williams for the valuable services which he rendered to the Society during the past as in previous years. The annual dinner was held in the evening in the banqueting hall of the Council Chamber, when over a hundred gentlemen and gardeners were present, presided over by the Mayor (E. Waters, Esq.) and ex-Mayor of Salisbury, supported by the Rev. C. N. Wyld, Rev. E. Hassan, Alderman Brown, the Town Clerk, &c. The usual patriotic toasts having been duly honoured, the Mayor gave the toast of the evening "The Wilts Horticultural Society and the Hon. Secretary." He referred in flattering language to the business-like manner in which Mr. Williams managed the affairs of the Society. The Honorary Secretary responded in a suitable and practical speech. The ex-Mayor—submitting the toast of the President of the Wilts Horticultural Society, the Earl of Radnor—remarked that it was fortunate that gentlemen who had the means should take such an interest as his Lordship did in the culture of fruits, flowers, &c. Mr. Ward, whose name was coupled with the toast, responded. The toast of the exhibitors, proposed by C. Moody, Esq., J.P., was suitably responded to by C. W. Gater, Esq., and Mr. John Horsefield, gardener to Lord Heytesbury, Heytesbury, who suggested that for about six months in every year, say from October to March, the Society should have monthly meetings, at which papers on horticulture could be read, followed by a discussion. The toast of "The Judges," proposed by Captain Marryat, was acknowledged by Messrs. Ward and C. Warden (Clarendon Park). Before the meeting was brought to a close it was suggested by Mr. Garland that in the event of Mr. Horsefield's suggestion being carried out, that Mr. Ward be asked to read a paper on Vine culture. This Mr. Ward promised to do when the time came.

ANCIENT SOCIETY OF YORK FLORISTS.

MR. T. E. ABBEY presided at the annual meeting of the members of the above Society at the "White Swan Inn," Goodramgate, recently.

The annual report, read by Mr. J. Lazenby, the Secretary, stated that the very satisfactory position the Society had attained at the close of 1886 as regarded its business matters was still maintained at the end of last year, 1887. The subscriptions for the past twelve months from members had reached £106, or an increase equivalent to thirty new members. The various shows, held as usual in the Guildhall, had in the past season been accorded a very much increased attendance of visitors, and it could not be doubted that great good must have resulted from an horticultural point of view. The number of competitors had also increased, although in a pecuniary sense exhibitors had not benefited to any great extent, as the increased vote brought out upwards of forty competitors, amongst whom 1420 prizes were awarded. The Chrysanthemum Show again resulted in a great success, for financially the receipts at the door showed an increase each day over the preceding years. The gross receipts were upwards of £200. The special prizes offered by the ex-Lord Mayor (Sir Joseph Terry), the ex-City Sheriff (Mr. Alderman Wright), the Stewards, and Messrs. Backhouse & Son, Mr. Deverell, Mr. Morton, and Messrs. Wood & Son, constituted a feature of considerable attraction, and some recognition was due to those gentlemen for the interest so practically manifested by them in the success of the Exhibition. The general condition of the Society was most encouraging, and several recommendations for the shows of this year from the present Committee would be brought before the annual meeting, and from past experience were considered essential towards promoting the usefulness and success of the Society in the future.

The financial statement showed that there was a balance in hand at

the beginning of last year of £106 4s. 3½d. The annual subscriptions and donations amounted to £106; receipts of the three days of the Chrysanthemum Show, £179 11s. 4d. and including some other items of income the total was £415 18s. 2d. The expenditure, including award of prizes, printing, advertising, music, judges' allowance, Secretary's salary, &c., amounted to £266 17s. 1d., leaving a balance available of £149 1s. 1d., being the largest sum the Society had ever had at disposal at the close of any season. On the motion of Mr. G. Cowper, seconded by Mr. W. Robinson, the report and balance sheet were adopted.

The officers were elected as follows:—President, His Grace the Archbishop of York; senior Vice-President, the Lord Mayor (Mr. Ald. J. Sykes Rymer); Vice-Presidents, the City Sheriff (Mr. S. Border), and Mr. G. Cowper; Stewards, Mr. G. Lamb, and Mr. T. Horsley; junior Steward, Mr. W. C. Milburn; Treasurer, Mr. J. Fielden. Mr. T. Coulson moved and Mr. Folkard seconded that Mr. J. Pilmoor be appointed Secretary. Mr. J. Lazenby having intimated that he had not resigned, Mr. J. E. Wilkinson proposed the re-election of that gentleman. Mr. Hardesty seconded the proposition. In the course of the discussion which followed, it was shown that Mr. Lazenby, since his appointment as Secretary nine years ago, had satisfactorily attended to his duties, and that whereas in the early portion of the Society's career they had only a membership of thirty or forty, with scarcely any cash in hand, there were now upwards of 400 members, and a balance of £149 in hand. Mr. Lazenby held that he had always faithfully performed his duties, and said that if re-elected he should continue to do his best for the welfare of the Society. Mr. Pilmoor's name was then withdrawn, and Mr. Lazenby was unanimously appointed Secretary.

The following gentlemen were chosen as the Committee:—Messrs. Folkard, Key, Moore, Pilmoor, Rodwell, Robinson, Simpson, Smith, Fieldhouse, Douglas, Hudson, and Richardson. Mr. Manton and Mr. G. Pilmoor were elected Auditors. An alteration in Rule 8 was made; the annual meeting to be held on the second Tuesday in January, instead of the first Tuesday in February.

Votes of thanks were passed to the donors of special prizes and to the officers of the Society, and the meeting made a grant of £100 for the Chrysanthemum Show of 1888, and £40 for the series of periodical exhibitions held in the Guildhall.

GROWING DAFFODILS IN POTS.

LIKE the Rev. Mr. Englehart I agree with your correspondent, Mr. J. A. Calthorpe, that Daffodils are not nearly so much grown in pots as they should be for blooming during January and February. They should be forced to have them sooner than January, and, except the Tenby Daffodil and in a less degree N. Princeps, they force badly. Besides with a profusion of Chrysanthemums in December they are not required then, neither are they required after mid-February, except in special cases for house or conservatory decoration, as in the south of England and Ireland they commence flowering then in the open air. I have numbers of them either expanded or preparing to do so. If pot culture of Daffodils is to be extended, I would suggest that it should be with the sweet-scented ones. I do not mean a mere perceptible scent, but such as is obtained from N. Tazetta Grand Monarque or N. Tazetta Her Majesty. The true varieties of these can only be had from respectable firms. Perhaps Mr. Burbidge might tell us more of fragrant Narcissi for pot culture.

The size of the pots cannot be fixed for general purposes, as Mr. Calthorpe seems to convey, for the pot that will suit N. Bulboodium, say to flower and grow in, would hardly hold the bulb of the "large Welshman," N. B. Sir Watkin, Horsefield, Emperor, or Empress. Many of the Tazetta section are equally as large. There is this supposition to explain this reference to "3 or 4-inch pots." Either the bulbs were lifted out of the ground for the mere flowering one season, or they were principally small varieties like N. nanus or N. minor, or say N. poeticus. I never give those named of the Bicolor section less than an 8-inch pot, as I take care of them for the following season. Many are difficult to procure true to name, and large flowering bulbs of some exceed 1 lb. per dozen, and if for no other reason should have fair play.

I fully agree with the Rev. Mr. Englehart, after many years' experience, that light has nothing to do with the failure of the bulbs to flower. Undue forcing may help to produce it, where the embryo flower inside is only partially developed; but a main cause in my experience is where the Dutch growers send out "offsets" or side bulbs that should have had an additional year to mature florally. This they always do when the demand is considerable, as, for instance, for N. Leda, after the Daffodil Conference.—W. J. MURPHY, *Clonmel*.

YOUR correspondent, "J. H. E.," page 112, seems to think that I attribute the fact of my Daffodils going blind to a wrong cause; but to confirm what I previously stated I may say that I took six pots out of the ashes the same as the others, these were placed into a warm pit, and pot shaded. Strange as it may appear, only four flowers appeared on the eighteen bulbs, while of those in a cold frame and shaded 90 per cent. have flowered. As to the bulbs not having room to develop, I send you two double flowers taken from a 4-inch pot with three bulbs in it, so that you may see they are of good substance, and the colour can scarcely be equalled in any other flowers. Standing between the winter flowering Pelargoniums they give the whole house a charming appearance.—JOHN A. CALTHORPE, *Summerville, Dunmore East, Waterford*.

[The flowers sent were of good size and bright in colour.]

SHOWING—OWNERS' CLAIMS.

I HAVE felt very much flattered by the attentions of Mr. Raillem. When I ventured to indulge in a little quiet humour the other week I did not think I should attract such serious attention from Mr. Raillem, and I hope he will forgive me. I feel that I deserve a rebuke for such levity, but I will try not to do it again, and I hope "Wraith" will not be so provokingly mirthsome.—PHANTOM.

RIPENED WOOD.

FEW incurved varieties came up to the usual standard of perfection last season. This must be very disappointing to the advocates of thoroughly ripened wood as necessary to the production of blooms of the finest quality. Long ago in these pages I repudiated this theory, but at that time the prevailing testimony was against me. The past summer has been all that could be desired for the thorough maturation of the wood of these plants, and if the result had been blooms of exceptional quality throughout, we must have accepted the theory as a correct one. It may be said the spring was a late and cold one, but this will scarcely hold good, for it is only a poor pretext upon which the ripened wood theory can be maintained. We have had springs as late and cold, if not worse, and summers and autumns that have been sadly deplored, and yet the incurved blooms of Chrysanthemums have been superior to what they have been this year. On the whole the plants had not such a hard struggle early in the season as they had the previous year, and yet the blooms generally were then better than they were last autumn. While a certain amount of firmness in the wood is unquestionably necessary for the plants to produce good flowers that possess brightness, depth, and solidity, it can be over-ripened and thus prove detrimental to the size of the flowers generally. If I have observed rightly, those plants that have produced the best flowers this year have been particularly strong, taking them all through, and therefore less likely to be over-matured. The consequence is that these growers have shown better blooms than the majority of other competitors. This year I have seen no better blooms than those from Wyncote and Impney. The plants at the former were strong, kept their foliage to the base, and presented a less ripened appearance than we should have expected to find. Those that showed unmistakably their ripened condition by the foliage did not produce blooms good enough for showing. Three that I especially noticed were Refulgence, Nil Desperandum, and Prince Alfred. I think only one bloom of the former was staged, none of the second, and the latter, with the exception of one bloom, was inferior to those staged by Mr. Mease in past years. I have not seen the Impney plants, but from what I have heard they are exceptionally strong—just the plants I should say in a season like the past for producing good blooms. Stands that have been shown from plants that were less strong and evidently more ripened have been smaller in size, taking them throughout, but even, and possessing greater solidity than those staged from the two gardens I have referred to. A little perplexing, perhaps, was the condition of the plants from which Mr. J. P. Leadbetter cut the blooms he staged at Hull in the open class. It was generally said that the stems of the plants were no thicker than a lead pencil. This was confirmed by the plants in his first prize group of Chrysanthemums arranged for effect. The plants were conspicuous for their weakness in comparison to what we are in the habit of seeing, and yet many of the blooms were of sufficient quality to have been shown in a cut state.

The southern growers are noted for their blooms being brighter in colour and possessing greater solidity than those grown in the north. The latter may be due to a more thoroughly ripened condition of the wood, while the former is due principally to a lighter atmosphere. They do not, as a rule, however, grow them so large or develop the same width in the florets. There is unquestionably a reason for this, and it is worth discussion. I think this may be traced to thoroughly ripened wood. The drier atmosphere of the south may, even against the cultivators' will, bring about this condition. It cannot be disputed that a plant thrives best at a certain temperature, and it may be that the south is too hot and dry at times for these plants, and therefore the growth is practically brought to a standstill. The wood may be too thoroughly matured for the plant to produce good blooms, for the cells must become filled with matter that cannot be dissolved, and the plants do not take up by their roots the nutriment requisite for the proper development of the blooms. The flower may for a time after the roots cease actively draw supplies from the upper leaves and portion of the stem. Under such conditions width of floret and large blooms cannot be expected. The wood may and should be matured, but not too much so to prevent activity at the roots and the various processes in the leaf and stem carrying out their proper functions until the blooms are fully developed.

Those who wish to attain success must not place too much trust in the ripened condition of the wood, for they may, and will, assuredly be deceived. The object to be attained is hard fine wood, but not so ripe as to bring the plant to a standstill. The roots must be kept thoroughly active to the last, and the broad florets and large blooms produced about

Liverpool is mainly due to top-dressing and keeping the roots in full activity, so that they can take up what nourishment the cultivator feels disposed to give them. Healthy foliage down to the base and active roots insure large flowers with depth and breadth of floret. Last season was just a little too warm, and ripened the wood too much even about Liverpool. When the blooms were developing at Wyncote the roots were like hundreds of small tiny worms in the top-dressing. Plants that are too ripe never root into these top-dressings, even if they are applied, and if such plants are turned out when the flowers are half-developed, it will be found that they have practically ceased to work.

Over-feeding, or stimulants too strong in their latter stages, will bring about similar conditions as takes place when the wood is too ripe. The roots are poisoned and brought to a standstill; supplies are cut off, and the flowers only develop under difficulties. I have seen the hopes and prospects of more than one grower blighted by this cause just in the last stages. Under-feeding is safer than over-feeding, but if the roots can be kept in full swing, and feeding carefully and judiciously practised to the last, fine flowers are almost certain to be the result, provided the plants are strong enough and the buds have been taken at the right time.—W. B.

THE CHRYSANTHEMUM.

[THE following essay has been adjudged the best in the competition for the prize given by Mr. E. Kay, Holbeck Moor Pottery, Leeds, open to under gardeners residing in the West Riding of York. It was sent in by Mr. Geo. Anderson, The Gardens, Ferniehurst, Shipley, and was read by him at a recent meeting of the Leeds Paxton Society.]

After some introductory remarks respecting the history of the Chrysanthemum the culture is thus described:—

PROPAGATION.

The usual method of propagating is by cuttings; those intended for large-flowered specimens should be struck in December under handlights near the glass in a house with a temperature of from 40° to 50°. Some growers prefer to strike in heat in February and March; this is not advisable for two or three reasons. The early suckers become drawn and weakly before they are wanted for cuttings, and the time for the proper development of the plant is considerably shortened, and although growth is slow at the turn of the year, the advantage of having stocky plants in 3-inch pots against cuttings to be rooted in February is obvious. Not that striking at the latter date is to be condemned, as many varieties that are tardy in throwing up suckers in the autumn may then be struck and make plants producing flowers to be by no means despised. Another reason for early rooting is to have the old plants cleared off in good time.

Striking Cuttings.—At whatever time they are struck select from the base of the plant cuttings about 3 inches long, a medium between the weakly and the thick sappy ones being the best. Avoid stem cuttings, as they are liable to set flower buds early in the summer to the exclusion of shoots, and thus have blooms of very inferior quality many weeks before they are required. Side shoots of scarce varieties may, however, be struck in May and June with the object of making plants to propagate from the following season.

Suckers.—Rooted suckers may be taken with every prospect of doing as well as cuttings, the only objection to them being in the case of scarce varieties, for it is obvious that when cut off at the surface it may break below and produce more cuttings, which possibility is precluded when lifted with a root. It is preferable to strike the cuttings singly in thumb pots, the best soil for the purpose being equal parts loam and leaf mould with a free use of silver sand; sprinkle a little of the latter on the surface after filling the pot, and make the soil firm round them.

Treatment of the Cuttings.—After insertion the cuttings should be watered with a fine rose and placed on a bed of ashes under handlights as above described, and kept close until roots are formed, with the exception of an hour or so in the morning to evaporate excessive moisture and give what water is required. When two or more cuttings are struck in the same pot—3 or 4-inch sizes are the best for this purpose—re-pot them before the roots are entangled, thus reducing the check they receive, and keep them in the same conditions as when striking until they have hold of the fresh soil, when air may be admitted more freely until they have all the light and air possible, subject, of course, to modification according to the weather. The best structure for the purpose is a low house provided with hot-water pipes, as they are less liable to be affected by damp and mildew than when in a frame, not to mention the better facilities afforded for protection from frost.

Damp and Mildew.—Damp and mildew are the greatest enemies of the Chrysanthemum at this period, and as the former is the precursor of the latter, keeping the plants airy and carefully attending to their watering will tend to check it. Should mildew appear, the affected parts should immediately be dusted with flowers of sulphur.

POTTING.

When the pots are well filled with roots it must be decided in what size they are to bloom, and be repotted accordingly before they are root-bound. Plants to be potted finally into 9-inch pots should first be placed into 3½-inch, next into 5 or 6-inch, and from that into 9-inch pots. Plants to be grown in 10-inch pots must have a size larger than those mentioned at each potting. The soil for this potting should consist of two parts fibry loam to one of leaf mould and one of spent Mushroom bed

with a liberal addition of sharp sand and charcoal, the latter especially if the soil is heavy. Use clean pots well drained, and pot firmly, afterwards returning them to their former or a similar situation until the roots reach the sides of the pots, when they may be removed to a cold frame standing on ashes close to the glass. Keep them close for a few days, after which admit air freely to keep the plants stocky. Immediately after potting and also after removal be specially careful not to overwater them.

First Break.—While the plants are in the pots named they will make their first break about the end of May, caused by the formation of a flower bud at the apex of the stem, which induces side shoots to break out at the nodes. The bud should be removed and the shoots reduced to the required number, the latter to be decided by the purposes for which the plants are intended; if for flowers of the largest size three stems will be ample and the three topmost buds must be left, if for flowers of secondary size six or eight may be left.

Final Potting.—By the first or second week in June, if all has gone well with the plants, they will be ready for their final potting, which should be done before they are rootbound, and done properly, or the chances of success are decidedly minimised. One essential is good soil, but it is equally important to have a soil capable of taking in a quantity of food in addition to what it contains, also to be capable of passing the water quickly through it. The best mixture for the purpose is loam, with the addition of a portion of spent Mushroom bed, a little leaf mould, crushed bones, or horn shavings, coarse silver sand, charcoal, and wood ashes, but no hard-and-fast rule can be laid down for the quantity and proportion of each ingredient to be used. What the cultivator must aim at is to have a good bodied mixture rather light than otherwise; not too wet, or it will run together and retain water too long, and not too dry or the plants cannot be potted properly. Use clean pots with 2 or 3 inches of drainage surfaced with moss or rough leaves and pot firmly. Too much importance cannot be attached to firm potting, for if potted loosely they are likely to develop large leaves on soft sappy stems from which it is impossible to get good substantial flowers. Pot sufficiently deep to cover the surface of the ball, and stand them on a cool base in their summer quarters.

(To be continued.)

HARDY FRUIT GARDEN.

BIRDS AND FRUIT BUDS.—Already the bullfinches have commenced destroying the fruit buds, Plums and Damsons being the first to suffer. Gooseberries, Pears, Apricots, Peaches, and Apples all will be visited in their turn unless something is done to stop the birds. There is a good promise of bloom on all kinds of fruits, but in many districts so unusually numerous are the bullfinches that these bold marauders may soon spoil it all, and that, too, without perhaps being noticed. The surest and quickest way of clearing a neighbourhood of these beautiful pests is to trap them. Double trap cages with a live hen bird of the same species in a lower division and a little Turnip or bird seed in the top will attract and catch all the male birds and most of the hens in the district, two or three being sometimes caught in the same day. They are also very fond of the seed on Weeping Ash trees, as many as fifteen birds having been seen on a tree at one time. The gun has altered this somewhat, and what the trap misses will also be shot, at least whenever this can be done without injury to fruit trees. A reckless use of the gun in a fruit garden must be guarded against, the shots proving most injurious to the trees. Sentiment ought not to stand in the way in this matter of destroying garden pests, as it simply means either death to the bullfinches, netting over the trees, or little or no fruit.

PRUNING APRICOT TREES.—A few warm days will bring these rapidly forward, and if not already pruned and nailed, this work ought to be completed. Where they are fruited principally on the spurs formed to summer stopping the laterals, not much pruning beyond reducing the length of these spurs is needed. Supposing the young growths stand out about 4 inches from the stems they should be cleanly shortened to a length of 2 inches, or otherwise unsightly old spurs will be gradually created. When spurs thus become unduly long these lose much of the benefit to be derived from a warm wall, and do not produce such luscious fruit as do those better situated. It is not advisable to clear off these long spurs wholesale, or one season's crop may be lost. Be content rather to thin them out, or gradually get rid of them. If cleanly sawn or cut off near their starting point next season may see a cluster of young growth around these short stumps, and which may be converted into good fruiting spurs. If preferred the long spurs may be gradually shortened, each time to a good back growth.

FRUIT FORCING.

PEACHES AND NECTARINES.—Earliest Forced House.—The trees must be syringed every morning and afternoon in order to keep red spider in check. If, however, the weather be dull the syringing must be practised early in the afternoon, so that the trees may become fairly

dry before night, or if that does not take place the afternoon syringing must be dispensed with, damping the paths and borders instead, as keeping the trees dripping with water through the night causes weak growth and thin foliage. See that the outside border is well protected from the cold, and water the inside border with liquid manure, which will much assist the fruit in swelling, especially in the case of weakly trees long subjected to repeated forcing. Vigorous trees will not require any stimulants, excessive vigour being unfavourable to the fruit safely passing the stoning process. When the fruit is the size of small marbles thinning may be commenced, but remove a few fruits only at a time, first removing those that are badly placed. Disbudding must be followed up, taking care to leave a growth at the base of each bearing shoot, and another at its extremity, or at least level with the fruit. The shoots retained for attracting the sap to and supporting the fruit should be stopped at the second or third leaf, but the basal shoots must be trained to take the place of those now bearing fruit. Shoots upon extensions must be left at 12 to 15 inches distance apart to form the bearing shoots of the future. It is a great mistake to crowd the trees with growths for which there is not space to allow of its full exposure to light and air, therefore avoid overcrowding, seeking to maintain an equal balance of growth throughout the trees and its solidification by judicious ventilation.

Second Early House.—Continue fertilising the flowers gently, distributing the pollen by shaking the trellis or drawing over each flower a camel's hair brush or other means of distributing the pollen. Lose no opportunity of admitting air, avoiding, however, cold currents, and leave a little ventilation constantly at the apex. The night temperature may be continued at 50°, 5° less on cold nights, 55° by day artificially, and 60° to 65° from sun heat, not allowing a rise above 65° without a free circulation of air.

Houses Started Early in February.—The trees started early in the month are swelling their flower buds rapidly. Syringing must cease when they show colour. Maintain, however, a good moisture by damping paths and borders two or three times a day as the weather may dictate, avoiding a close, stagnant atmosphere. If the flowers are very numerous, thin them by rubbing the hand downwards on the under side of the shoots, which will strengthen the remainder, enabling them to set better. Examine the trees closely, and if there be any aphides fumigate with tobacco, so as to destroy them before the flowers expand. Continue the temperature at 40° to 45° at night, and 50° by day, above which ventilate freely. When the flowers expand raise the temperature to 50° at night, 55° by day, and 60° to 65° from sun heat with free ventilation. On cold nights the temperature may fall to 45°, or even less; also 50° by day, allowing a little ventilation constantly at the top of the house.

MELONS.—The weather lately has not been favourable to the growth of the young plants. In a Melon house, a ridge the whole length of the bed, about 2 feet wide at the base, with the top flattened so as to give a depth of 10 to 12 inches, is preferable to hillocks, the soil being made rather firm, and when warm the plants may be turned out, firming the soil well, and raising it to within half an inch of the seed leaves. The plants may be placed 2 to 2½ feet apart, the leading or primary shoots being taken up without stopping until fully two-thirds the distance they are intended to travel is reached, then pinch out the point of each. When three or four lateral joints are made the points should be taken out. Some varieties will show fruit freely on the first laterals, and as early Melons are a consideration, let them remain, taking out the point at a joint above them. To allow all the laterals to remain would very much overcrowd the foliage, therefore rub off every alternate one whilst they are quite young. After stopping the first laterals, the succeeding growths will show fruit at the second or third joint. The growths should be trained thinly and regularly, so that every part of the surface is evenly clothed with foliage and fruit. The plants will require but little water as yet, nevertheless maintain the soil in a moist state, avoiding anything approaching to saturation. Sprinkle every available surface in the morning of bright days, and again at closing time or early in the afternoon. Ventilate carefully, avoiding currents of cold air. Some hexagon netting or scrim canvas placed over the ventilators will break the force of cutting winds. Maintain the night temperature at 70°, falling to 65° in the morning, 5° less in severe weather being better than seeking to maintain the higher temperature by sharp firing; 75° by day, rising to 80° or 85° from sun heat; bottom heat kept steady at 80°.

In pits and frames with the shoots trained over the surface of the beds, the plants, being stopped at the second leaf, will produce two shoots, and these in turn being stopped will result in four shoots, two being taken to the front and two to the back of the frame. Besides these a number of shoots will appear near the collar of the plant; these should be rubbed off whilst quite young, and do not encourage any lateral nearer the stem than 6 inches. This will keep the collar clear. Stop the principal shoots when within a foot of the sides of the pit or frame, and thus throw vigour into the laterals, which will show fruit at the second or third joint, stopping them at one joint beyond the fruit. Cover the lights with double mats at night, and see that linings are regularly attended to, renewing the old linings as required. Prepare material for making up fresh beds. About a fortnight before it is desired to make up the bed the dung and leaves should be thoroughly incorporated. In a few days it will be seen whether there is sufficient moisture to produce decomposition, fermentation being the result; if not turn the whole, sprinkling with water, so as to moisten the mass, and

when in good heat turn again outside to inside and *vice versa*, two or three turnings being required at intervals of about four days. The bottom heat of fermenting beds should be 85° to 90°.

Shift later sown plants into large pots, or add soil as the plants advance, stopping those for frames at the second leaf, not stopping those for trellises, but placing a small stick to each for support.

CUCUMBERS.—Examine the plants in bearing once or twice a week, removing bad leaves and exhausted growths, thinning the shoots, stopping, and removing old and deformed fruits. Thin the shoots if necessary, overcrowding and overcrowding being highly prejudicial. In securing the young shoots to the trellis do not tie them too tightly, but allow room for development. Plants that have been in bearing for some time should have the surface soil removed and have previously warmed fresh soil added. Turfy loam with a fourth of well decayed manure will answer; we, however, prefer for Cucumbers and Melons turfy loam without an admixture of manure, seeking vigour by rich surface dressings or liquid manure. The bottom heat should not be allowed to fall below 75° or exceed 90°, 80° being suitable, the night temperature 65° to 70°, 5° less in severe weather, 70° to 75° by day, rising to 85° from sun, closing early in the afternoon, damping the pathways on bright mornings and at closing time.

For young plants hillocks or ridges should be formed as described for Melons. Afford the same temperature as advised for older plants. If the sun be powerful and the plants show indications of flagging shade them for a few days. Attend to dung-heated frames with linings as required, protecting at night as advised for Melons. Do not apply more water than to keep the plants gently growing. Where red spider has appeared on the winter fruiting plants coat the pipes with sulphur and lime in equal parts, heating the pipes to as near boiling point as possible for a couple of hours on a calm evening, taking care that the temperature of the house is not more than 80° to 85°, and then allow the pipes and house to cool down to their regular temperature. The foliage should be thoroughly dry. The same process may be repeated the following evening, and is generally effectual, the mixture being applied whilst the pipes are hot.

STRAWBERRIES IN POTS.—A fair set characterises the first plants. Remove all badly set or deformed fruits, leaving from four to half a dozen of the most promising fruits to each plant, and aid their swelling by liquid manure. The temperature should be 60° to 65°, advancing to 75° by day with moderate ventilation. Avoid drying currents of air, as they injuriously affect the swelling of the fruit. Examine the plants twice each day, giving water only to those needing it, and in sufficient quantity to show at the drainage. See that succession plants are kept free from aphides, fumigating if necessary before the flowers open. British Queen and other late sorts may now be started, introducing, however, proportionate quantities of Sir Harry, Sir Joseph Paxton, President, James Veitch, &c., to maintain the succession.

PLANT HOUSES.

Azaleas.—As these plants cease flowering remove all the seed pods and wash the plants if any trace of thrips can be found upon them. A good solution for this purpose is tobacco water reduced to the colour of stout; in each gallon of this dissolve 1 oz. of soft soap and a piece of common washing soda about the size of a Cob Nut. This solution will not only destroy living insects, but their eggs as well. Place them afterwards where they can enjoy gentle heat and moisture until they have made their growth. The conditions of a Peach house or vinery at work, where the night temperature does not exceed 55°, will suit them well. Directly their roots commence activity those that need repotting may be attended to, while the remainder may have a little artificial manure applied to the surface of the soil. In repotting be careful not to disturb the roots further than is necessary in the removal of the old drainage. The soil, consisting of good peat and sand, must be pressed in the pots firmly. Syringe the plants and pots freely afterwards, but no water at the roots will be needed for some days if the soil was in a satisfactory state of moisture when they were potted.

Camellias.—Plants that have flowered should be pushed into growth at once if they are required to flower as early as possible next autumn. Undue forcing at that period of the year is certain to end in failure. No matter how carefully forcing operations are conducted the buds will invariably fall. The necessary forcing can be done now by inducing the plants to make an early growth, so that they will unfold their flowers almost naturally, or with the least possible difference in temperature at the time they are required. If the plants are infested with scale-syringe them liberally with petroleum and water, using 3 ozs. of the oil in each four gallons of water. If no signs of new growths are visible upon the plants 4 ozs. may be safely used. Place the plants afterwards in a temperature of 50° to 55°, with a rise from sun heat during the day. The house should be kept closed, and the plants heavily syringed during the day. If they need repotting do so at once, using a compost of good fibry loam, one-seventh of horse manure, and a liberal quantity of coarse sand; a little charcoal and half-inch bones may also be added if the plants are large. About a 10-inch potful of the former and an 8-inch potful of the latter will be ample to each barrowful of soil. If top-dressing only is needed use equal portions of loam and manure.

Greenhouse Rhododendrons.—R. Gibsoni, Princess Alice, Princess Royal, and others, will bear gentle forcing if their flowers are appreciated moderately early in the season. Strong heat is most injurious to these plants, and if applied in the hope of inducing them to open their flowers, they will, in the majority of cases, fail to do so. They must not

be subjected to a higher temperature than 50°. Avoid placing them on a dry stage, and syringe them freely while in the forcing house.

THE BEE-KEEPER.

BEES WEARING OUT AT THE HEATHER.

"A. L. B. K.," page 94, places this matter in quite a different light from what I understood him to mean. I have never seen the number of dead bees inside the hives at the Heather as he describes, nor anything similar. The only case in which I have seen a quantity of dead bees in a hive—that had neither been starved nor suffocated—was one winter, in one of Abbott's copyable hives; frames across the entrance, sides double walled, front single walled. In this hive I found a full seam of dead bees, and the queen—an imported Cyprian—between the front comb and the hive wall. The hive stood exposed, and I concluded these bees had been chilled to death, as there was plenty of food, and the seams between the other frames were well filled with healthy bees. Probably the same cause may have had to do with the death of those mentioned by our friend.

ODOURLESS FOUL BROOD.

I am very much obliged to "A. L. B. K." for the information he gives, in which he proves my system of curing this disease is practically like the one he has taught and practised long ago, though I think my mode is much less trouble. However, it seems very strange the "authorities" have never practised or recommended it; others have stamped the disease out. Down here in Hallamshire, when one is praising himself, his ways, systems, &c., as being the only true and correct way, and deriding those of others, we simply describe him as "a man who likes to hear himself talk." Do not the various teachers of apiculture resemble the showmen in a fair, each one doing his best to make the greatest noise?

After all I have said and written on the subject, the editor of the *Bee-keepers' Record* says it is the true foul brood, though Mr. Cheshire was positive in 1885 that it was not. He also says my system of curing it "is the well-known starving process," though, be it noted, the bees have their full liberty and are fed, if no honey is to be had; "that it is a costly process," though it is the cheapest of any, and does not involve the expenditure of a penny either for physic or appliances; and as to its throwing back the stock to the position of a weak swarm, the value of this contention may be judged when I repeat that I have twice cured a diseased stock in one summer, and yet had a splendid stock to go into winter quarters, while the best stock last spring in this district was one that was built up from a teacupful of bees in August, with no help beyond feeding. These were Punie bees, that with their queen were diseased in the spring. I have previously stated these facts, so there is no excuse for ignoring them. As a matter of fact, a handful of bees in a clean hive have 100 chances to one against a bucketful in a hive of diseased bees.

In the same journal I have referred to, the editor of the *American Bee Journal* is quoted on the subject as follows:—"If the larva is elastic and ropy it is a sure indication of foul brood. This is a sure test, but the odour is not to be relied upon."

Now the disease I have had so many years' experience with is neither "ropy" nor "elastic" in its early stages; when the larva is three parts dried then, if a pin-head is struck into it, it resembles ripe honey as much as anything—viz., it can be drawn out into a string, perhaps half an inch long before breaking.

Now what I recognise it by is first a sunken cap—sealed brood cells are convex. If I see a sunken cap amongst the brood I take a pin by the point and remove the cap. Very often I find only sealed honey, and sometimes a white grub, in which case all is right. If the enclosed larva is the colour of coffee and milk, not coffee alone, as generally stated, it is diseased; this colour is a sure test, and one that may be relied on. In this stage there is no "clasticity" whatever. At this point, if I could not find any pierced cells, I should wash out the diseased larva with undiluted carbolic acid either with a feather or camel's-hair pencil, for as there cannot be any ripe spores to be given off the disease may be localised and thus stamped out. I give this advice to be followed out at this stage, as I have thus stopped the disease in several hives.

If a cell cap is sunken, and it also has a little hole in it, I try it with a pin-head as before. Often it is a healthy larva nearly sealed over, or a honey cell; but if it is of coffee and milk colour it is diseased; the colour in this stage is deeper than the first, but in no stage does it resemble pure coffee unmixed with milk. If such cells are found you may depend upon it that spores are flying off, and no doctoring will pay for trying to preserve the combs. I believe many apiarists have the disease in their hives without knowing it, and therefore I wish to impress this simple means of recognising it. Healthy brood is milk white, the disease then through all its stages just looks as if more and more coffee had been added. Brood chilled to death is either white or black, nor is a full shaped bee diseased. Many dealers and queen breeders boast that they never had foul brood, never saw it, &c., and advise those who want bees or queens never to buy from anyone who has had it. Now, my advice is "Do not put faith in them." No one is safe from foul brood; queens and bees may be diseased long before they are suspected. A

man who has had it in his apiary, is quite clear of it, and makes it a point to stamp it out in his neighbourhood, is far safer to buy from. Such a man is always on the look-out, and he will never overlook a sunken cap in the brood nest.—A HALLAMSHIRE BEE-KEEPER.

TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Improving Lawn (G. A. B.).—The pressure is so great that your letter cannot be fully answered till next week, nor can some others that arrived only a day before going to press.

Early Tomatoes—Roses (R.).—Probably Sutton's Earliest of All Tomato would suit you as well as any for outdoor culture. It is very productive, and the fruit is as good in quality as the variety you name. Probably you could not plant two Roses better likely to answer your purpose than Maréchal Niel and Gloire de Dijon, and they succeed quite well with the roots in good soil outside, and the stems brought inside the house after the manner of Vines; but the outside portions should be protected from frost by haybands. They also grow well planted in good soil in the house and adequately supplied with water. The shading of the soil in the house would not be injurious.

Plants with Blue Flowers (J. James).—Plants of various shades of blue for the greenhouse are *Agapanthus umbellatus*, *Burtonia violacea*, *Crowea saligna major*, *Diosma capitata*, *Hovea Celsi*, *H. pungens major*, *Kennedyia bimaiculata variegata*, *K. inophylla floribunda*, *Pleroma elegans*, *Plumbago capensis*, and *Witsenia corymbosa*. For outdoors—*Verbena venosa*, **Verbena Blue Boy*, *Anemone apennina*, *Aubrietia purpurea*, *Campanula carpatia*, *Gentiana acaulis*, *Hepatica double blue*, *Myosotis arvensis*, *M. palustris*, *Scilla sibirica*, **Ageratum Imperial Dwarf*, *Delphinium Barlowi*, *D. Belladonna*, *D. Hendersoni*, *D. formosum*, **Heliotropium of sorts*, **Veronica Blue Gem*, and *Centaurea Cyanus major* and *minor*, which are annuals. The blue varieties are very useful for cut flowers. All the others are hardy perennials, except those marked with an asterisk, which require the protection of a greenhouse in winter.

Camellias from Cuttings (Brooks).—The best time to put in cuttings of Camellias is when the wood is nearly ripe, which it will be by the end of June or early in July. Take cuttings of the current year's growth 4 or 5 inches long, cut the bottom off smoothly just below a bud, trim off the lowest two leaves, and leave the same number on the cuttings. They may be inserted in 6-inch pots, which should be clean, and have a rock large enough to cover the hole at the bottom; on it place an inch of crocks of smaller size, and another inch of very small ones, and then a very thin layer of moss. The pot should be filled to the rim with two parts sandy loam and one part sandy peat, adding a half part of silver sand. The soil should be made very firm, but use the hand only for pressing. Insert the cuttings about an inch apart round the sides of the pot, and to the extent of half their length, and set the pots on ashes in a cold frame. Keep the cuttings just moist, nearly close, and shade from bright sun. By the middle or end of September they will be rooted, and should be potted off singly and placed in the cold frame; there keep them close, and they will soon become established. Afterwards they should have air freely, and be removed to a greenhouse or pit where they will be safe from frost. This is the mode usually adopted for propagating the single varieties for stocks, and will answer for the others; but experience has shown that the double sorts do not grow nor flower so well on their own roots as when grafted.

Chrysanthemums after Flowering (Ed. D.).—The old shoots should be cut down to the ground, and the young shoots which come out of the soil at the base of the old plants should be taken off, either with or without a small portion of root, when 3 or 4 inches long, and should be potted singly in 3-inch pots, placing them half their depth in the soil. The latter should consist of two parts turfy loam and one part leaf soil or well-rotted manure with a sixth of sharp sand. If the shoots have roots they may be plunged in ashes in a cold frame; but if they have none they may be kept in a house with a temperature of from

45° to 50°, and when rooted be removed to the cold frame. Give them air whenever the weather is mild, and protect the lights with mats when necessary. In April, when the roots are showing at the sides of the pots, shift into 5-inch pots, and early in May, or at the end of April if mild, the plants may be placed out of doors on ashes in an open situation sheltered from winds. Shift into the blooming pots by the middle of June, using the same compost as before, with the addition of a quart of half-inch bones to every peck of compost, and we should drain the pots with calcined oyster shells. Eight-inch pots will answer for the Pompons and the less promising of the large flowering kinds, but good plants of the latter may have 10-inch pots. Stop the plants when they are 6 inches high, and when they have made other shoots stop these in their turn at 5 inches. When they have again shoots an inch or two long peg down the shoots, taking care not to break them, and stop again at the fourth leaf, continuing the stopping up to the beginning of July, but not later. Tie out the shoots so as to form a well-shaped plant. Keep them well supplied with water, and when the flower buds appear water with liquid manure. Remove the plants to a cool, light, airy house in October, and merely keep them from frost.

Heat and Plants (E. Mason).—Plants, like animals, can bear a higher temperature in dry air than they can in air charged with vapour. Animals are scalded in the latter if the temperature is very elevated, and plants die under similar circumstances, as if boiled. M.M. Edwards and Colin found Kidney Beans sustained no injury, when the air was dry, at a temperature of 170°; but they died in a few minutes if the air was moist. Other plants under similar circumstances would perish probably at a much lower temperature; and the fact affords a warning to the gardener to have the atmosphere in his stoves very dry whenever he wishes to elevate their temperature for the destruction of insects or other purposes. Certain plants flourish in hot-water springs, of which the temperature varies between the scalding heats of from 150° to 180° of Fahrenheit's thermometer; and others have been found growing freely on the edges of volcanoes, in an atmosphere heated above the boiling point of water. Indeed, it is quite certain that most plants will better bear, for a short time, an elevated temperature, which, if long continued would destroy them, than they can a low temperature. Thus a temperature much above the freezing point of water, to orchidaceous and other tropical plants, is generally fatal if endured by them for only a few minutes; whereas a considerable elevation above a salutary temperature is rarely injurious to plants. But this is not universally the case; for the elegant *Primula marginata* is so impatient of heat, that, although just about to bloom, it never opens a bud if brought into a room in which there is a fire. The temperature should always be regulated, in our hothouses, with a due regard to the light. At night it should be so low as to put the circulation of the sap into a comparative state of rest; and in dull days the temperature should be full 10° lower than in those of bright sunshine.

Weather Signs (E. James).—There are so many "signs" and fancies on this subject that it is impossible to collect and publish the whole of them, as you appear to desire. No doubt the subject is of interest to cultivators, but it is possible to have too much of a good, or bad, thing, just as it may be regarded by different persons who entertain divergent views on the matter. A few of the more marked signs of weather, considered useful alike to farmer and gardener, are the following:—1, Weather clear or cloudy—a rosy sky at sunset presages fine weather; a red sky in the morning bad weather, or much wind (perhaps rain); a grey sky in the morning, fine weather; a high dawn, wind; a low dawn, fair weather. 2, Soft-looking or delicate clouds foretell fine weather, with moderate or light breezes; hard-edged, oily-looking clouds, wind. A dark, gloomy, blue sky is windy; but a light bright blue sky indicates fine weather. Generally, the softer clouds look the less wind (but, perhaps, more rain) may be expected; and the harder, more "greasy," rolled, tufted, or ragged, the stronger the coming wind will prove. Also, a bright yellow sky at sunset presages wind; a pale yellow, wet; and thus by the prevalence of red, yellow, or grey tints, the coming weather may be foretold very nearly—indeed, if aided by instruments, almost exactly. 3, Small, inky-looking clouds foretell rain; light seed-clouds driving across heavy masses show wind and rain; but, if alone, may indicate wind only. 4, High upper clouds crossing the sun, moon, or stars, in a direction different from that of the lower clouds, or the wind then felt below, foretell a change of wind. 5, After fine clear weather, the first signs in the sky of a coming change are unusually light streaks, curls, wisps, or mottled patches of white distant cloud, which increase, and are followed by an overcasting of murky vapour that grows into cloudiness. This appearance, more or less oily, or watery, as wind or rain will prevail, is an infallible sign. 6, Usually, the higher and more distant such clouds seem to be, the more gradual but general the coming change of weather will prove. 7, Light, delicate, quiet tints or colours, with soft undefined forms of clouds, indicate and accompany fine weather; but gaudy or unusual hues, with hard definitely outlined clouds foretell rain, and probably strong wind. 8, Misty clouds forming, or hanging on heights, show wind and rain coming—if they remain, increase, or descend. If they rise or disperse the weather will improve or become fine. 9, Remarkable clearness of atmosphere near the horizon, distant objects, such as hills, usually visible, or raised (by refraction), and what is called "a good hearing day," may be mentioned among the signs of wet, if not wind, to be expected. 10, More than usual twinkling of the stars, indistinctness or apparent multiplication of the moon's horns, haloes, "wind dogs," and the rainbow, are more or less significant of increasing wind, if not approaching rain, with or without wind.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, (*J. M.*)—It is impossible to name with certainty a leafless spray, but if you will send us a flowering spray, if one is produced, at the right time, or failing that a leaf-bearing branch, we think we shall be able to give the name of the tree.

COVENT GARDEN MARKET.—FEBRUARY 15TH.

Good samples of Grapes are now coming short, and prices have improved all round. Apples in demand. Business better.

PERMANENT PASTURE.

ONE of the subjects for discussion in which we took part at a recent meeting of our local Farmers' Club was permanent pasture,

and while the members present were unanimous in saying that there ought to be a larger proportion of pasture upon farms in the great corn-growing districts, they were evidently not at all clear as to how this was to be effected. The chief hindrance to laying down land to pasture is the very common but erroneous hypothesis that it requires a lifetime to form really sound productive pasture, and as usual, we find that in this, ignorance and obstinacy go together.

Now we know plenty of old, very old pasture that is in sorry plight, and from which the annual bulk of produce is so low that it cannot be profitable. But our knowledge of this lamentable fact cannot be regarded as singular. Let anyone with ordinary powers of observation look at such meadows as are to be seen in a journey of a hundred miles by railway in this season of the year, and what will they see? Why, precisely what comes under our notice repeatedly, and that is fully two-thirds of them are brown, bare of food even for sheep, and so foul with weeds as to present a ragged untidy aspect of poverty and negligence. Neither cattle nor sheep will consume many of the perennial weeds with which such foul pastures are infested, and they consequently remain in winter a visible sign of bad practice. We use the term advisedly, for surely it cannot be owing to ignorance that such robbers of the soil are suffered to become established and to spread in it?

We have taken some pains to explain how land intended for permanent pasture must be prepared for the seed by drainage, if necessary, by a thorough clearance from it of couch grass and other perennial weeds, and by sufficient ploughing and stirring to insure a deep tilth and fine seed bed. We have gone farther, and shown how, with careful folding by well-fed lambs in the first season, and by ewes and lambs in the second season, a really well-knit pasture may be had at a minimum cost in two years, and we have been met in discussion by the shallow argument, "Yes; you may be able to establish good pasture in two years, but the question is, How are you to keep it good?" The answer to this is obvious—*i.e.*, By an equally careful process of cultivation year by year. This is the point we wish to enforce, that pasture requires careful cultivation equally with all other farm crops, and we may add that experience shows such cultivation to be profitable. It is high time that all easy-going practice in agriculture were ended. We hold that no full crop can be taken from the land without a certain per-centage of exhaustion of its fertility; and in order to obtain an equally full crop next season such loss must first of all be made good. Now, we have heard excellent practical farmers declare that they have little faith in chemists or nicety of analysis, but surely common sense must tell them that in order to obtain a full crop from the soil it must contain a full store of plant food. We must not rest content with half crops, but we must ascertain how much per acre by weight or measure it is possible to obtain of each sort of grain, foliage, or roots, and that maximum quantity must be our common standard subsequently, and we ought not to rest content with anything short of it. How obvious is the absurdity of the application of manure for one farm crop, and then following with another crop without manure simply because the first crop has not exhausted all the manurial constituents imparted to the soil by such manure! The second crop may be, and frequently is, one of medium excellence, but we certainly ought not to be satisfied with a medium crop when it is possible to obtain a maximum one. But we may be told that to apply manure annually is so expensive. We reply that results invariably justify the expense in a given number of years, for to take the result of an extremely good or bad season would be misleading, and we must compare the common result of four or five seasons.

Our remarks now on the treatment of permanent pasture may be regarded as especially to the purpose now, for this is the best time of all the year for the application of manure, and we strongly recommend our readers to do what is possible at once to eradicate Ononis, Gorse, Nettles, Rushes, Thistles, Brambles, and Broom

from pasture, to mow down any long Sedges or other rough herbage, and by the end of the month to apply per acre a quarter of a cwt. nitrate of potash, 1 cwt. nitrate of soda, 1½ cwt. mineral superphosphate, and a quarter of a cwt. steamed bone flour. Take care to procure each sort of manure separately from a reliable source, and have the mixture made at the farm three or four days before using it. By keeping down weeds by an annual dressing of this manure or sheep-folding, and by draining when necessary, pasture may be brought into a high state of fertility, which may be fully sustained under such treatment. The outlay of £1 per acre or a shilling or two more for manure will not only insure a full crop of hay, but an abundant aftermath with favourable weather, and the pasture will also present a green flourishing appearance during winter in pleasant contrast to the brown stunted guise of neglected pasture.

WORK ON THE HOME FARM.

All our calculations and arrangements for our spring supply of chemicals are complete, and the order for a supply to be sent to each of our farms has been given. The total quantity by weight is about 52 tons, and the cost, inclusive of carriage by rail, is about £400. In comparison with special mixtures on the market this quantity represents a much greater weight, because the whole of the manures are genuine and the fertilising power of all of them is high. In addition to this supply of chemical manures, we have folded sheep upon a large area of land, and we have also used a considerable quantity of farmyard manure taken in valuation upon the two additional farms which came upon our hands last Michaelmas—about a thousand cartloads in all, so that we have done all we could to store the land with fertility. In our manure book is shown the calculations of quantities for every crop at each farm, with totals and cost, so that we can always refer to it, and also have the necessary details taken from it for the guidance of our bailiffs. The manure has been ordered early in order to have it at hand both for pasture, winter and spring corn, and it will be applied so far as is possible by means of drills rather than by hand, for however careful men may be, hand-sowing can never equal or even approach the accuracy of machinery.

Spring corn sowing will be pushed on with as soon as the soil is ready, the land, seed, and manure being all in readiness. We hope to obtain as high a yield of Wheat by careful cultivation on our best farms as we did last season. If we are again able to get 56 bushels per acre we know that even under present low prices we shall obtain a handsome margin of profit, but we could not do so if we were content to attempt Wheat growing without thoroughly sound all-round practice. Take for example the Wheat averages of last year, and we find that in Russia the average yield per acre was as low as 12 bushels, in France 17 bushels, and in Great Britain 32 bushels, or 5 bushels more than the average of 1886. Well, now, have we not reason—apart from egotism—for saying that the only way to meet and overcome the foreign importation of Wheat is so to cultivate the land as to produce more of it? Certainly we know that we have, for by high cultivation we are able to bring farmed out land into such a state of fertility as to render its produce really profitable even at present low prices.

REMARKS.

- 5th.—Calm and generally dull, but with a little sunshine at mid-day.
6th.—Cloudy all day.
7th.—Generally bright, but clouded over once or twice, with spots of rain.
8th.—Rain early; a cloudy day, with one or two intervals of sunshine.
9th.—Rain in the small hours; a fine and generally bright day.
10th.—Cloudy morning; spots of rain in the afternoon.
11th.—Dull morning, with spots of rain; frequent rain in afternoon and evening.

A warm and pleasant week, for although rain fell on four days the amounts were small, and the greater part fell at night. Temperature 6° above the average, and more than 10° above that of the preceding week.—G. J. SYMONS.

IS CHISWICK TO GO?

ONE of the most important decisions ever arrived at as affecting the interests of the Royal Horticultural Society was registered after the last general meeting. This was done under the impulse imparted by the special Committee. The Committee, which has exercised power and relieved itself of responsibility, recommended measures involving an expenditure of £700 at a time when the Society is in debt to the extent of upwards of £1000, and when the estimated income for the year is £2000, and the estimated expenditure only a trifle below, and will probably exceed £3000. The Committee relieved itself of responsibility by inducing the meeting to "adopt" their report, and the Council was "empowered," which virtually means in that case compelled, to carry out their recommendations. The Council in turn was thus relieved of a large share of responsibility, and so matters became loose all round.

The motives of the Committee, it may be conceded, were of the best. The desire of its members, which include some members of the Council, was to strengthen the Society and find a base on which it could rest firmly for future working. It is to be presumed that the exact financial position of the Society was fully appreciated by every member of the directing body; but was this equally appreciated by the Fellows of the Society who constituted the meeting that "adopted" the Committee's report? It is questionable if half of them comprehended it, for the matter was not placed before the meeting, or at least not so clearly as it will be placed before the public now. This can be done the more freely since it is impossible to suspect the conductors of this Journal of being animated by any other feelings than those of deep sympathy with the Society and earnest wishes for its stability and prosperity.

When the report of the Committee was adopted by the meeting forcing the Council to commit the Society to a definite line of action involving an expenditure that will probably be little short of £1000, the Society was actually in debt to the amount of £1152. But it may seem that against that there is the special list of promised donations and subscriptions, the former amounting in round figures to £1210 and the latter to £208. But let it be understood that the first of these contributions must be left entirely out of the estimates. It was never intended for the general revenue of the Society, and will never be paid into it. It was promised for a specified purpose—namely, as the nucleus of a fund for providing a permanent home for the Society. It can neither be applied to the maintenance of Chiswick, nor to the payment of the rent of the new rooms and hall that are essentially of a temporary character. Were all the members of the Committee cognisant of that, and was the fact present to their minds when they recommended their report incurring liabilities without the means for meeting them? That is a fair and reasonable question, also a somewhat serious one to those members who do not happen to be able to answer it in the affirmative. There then arises the further question—Did the Fellows who adopted the report fully and clearly understand that the money in question could not be devoted to the ordinary purposes of the Society? It is practically certain they did not, and, if that is so, the resolution was passed in ignorance of a circumstance having an important bearing on the whole matter. And on whom did the duty devolve of making the point clear but on the Committee that formulated

the report, and induced the meeting, having faith in its wisdom and safety, to adopt it? Well will it be if the decision arrived at so hastily does not result in obstacles not easy to remove from the path that it is hoped may lead to prosperity. Only extraordinary zeal, vigilance, and prudence can now place the Society in a satisfactory state; and it is with the object of stimulating effort on those lines that attention is called to the real state of affairs, as revealed by the published report and advertisement.

FINANCIAL ESTIMATE.			
Income.		Liabilities.	
	£		£
By Subscriptions...	1500	Chiswick	1300
Sale of Chiswick produce.....	500	Establishment Expenses (see Report)	845
	2000	Assistant Secretary's Salary	200
		Exhibitions	234
		Offices	120
		Hall	100
		Committees	127
Balance against Income ...	2078	Debt	1152
	£4078		£4078

That is a sufficiently serious statement. Let it be examined, and the best or the worst made of it, and the necessity for strenuous action on the part of all who are responsible for the position will be apparent. The responsibility rests virtually on the Committee, though technically it was removed from them and incurred by the Fellows in their adoption of the report; also by the Council, inasmuch as they did not reject it when forced on them. Having accepted the liability imposed, they must meet it in the best way they can. The moment for dignified retirement has passed, and they must work under the Committee they have accepted, and which, as a body, is so well satisfied with the work achieved, that the members of it recommended their continuance in office another year, with "power to add to their number" to an unlimited extent. This power, too, is being exercised, and it is noticeable that the two opposition candidates to their own nominees for the Council are now added; it is hoped they will enjoy the solatium and no longer criticise adversely. There seems a probability that the Society will, ere long, have no free critics, which would be, perhaps, the worst thing that could befall it.

But how could the position have been improved? The answer is, by adopting a recuperative instead of an adventurous policy for a year. If the Committees sat at Chiswick for a season, what was really new and good would have found its way to them by a quarter of an hour's further train run from South Kensington and a three minutes' walk—a much shorter walk than before. Then the £234 for shows would have been saved, that have not brought the Society as many shillings; about £200 out of the £250 for rooms and hall could have been saved, and for the time, say £200 for a paid secretary, utilising the services of Mr. Dick and Mr. Barron to the fullest extent, and it is probable they would have done more for the Society than a stranger can in the year. Moreover, however competent a new official may be, he cannot work effectively without further expenditure, and where is the money to come from?

The President, in his speech at the meeting, dwelt on the Society not having taken advantage of gleams of sunshine, and putting money by for a rainy day, but, on the contrary, the fitful gleams had done rather more harm than good in leading to extravagance. The meeting on the 14th was of a sunshiny nature, and spirits were high and hearts gay. History then repeated itself, and speculation to the extent of between £600 and £700 was indulged in. Most sincerely do we hope it will prove a wise investment, and heartily glad shall we be if our grave doubts on the matter prove groundless.

It is for all those responsible for the policy adopted to prove it right—to determine that it shall succeed. It is a question of reputations, or of the Society perishing; and it is more than ever

certain if its garden is not made a producer of revenue to the greatest extent possible, that Chiswick must go sooner or later. Can there be a desire for this? Nothing but the success of the new venture can prevent the famous old garden being starved into inanition. Chiswick, with all its traditions, its present fine, if not unequalled, collection of fruits, and resources for future usefulness at a time when, if utilised, they would be of national benefit—Must it perish? and the Royal Horticultural Society be thereby deprived of the honour of teaching the way, as suggested by Dr. Masters in a pregnant sentence at the meeting, of showing how the land in England, now depreciating in value, can be profitably cultivated? That can be shown undoubtedly, if scope be afforded and means provided for conducting cultural experiments on a commercial basis to their final issue; and what is more, no other garden in the kingdom could carry out the work, most important and most honourable, so well. There is no doubt the Committee desire to see Chiswick flourish, and the only way in which means can be afforded is by making the expenditure remunerative, gaining a continuous stream of supporters, and turning the productive power of the garden to substantial account.

I WAS glad to read your leading article (page 121) on the R.H.S. Do anything rather than let Chiswick go. Everybody trades nowadays, and if labour is honourable trade is also honourable. Sell to anybody if Chiswick can be preserved. The loss of Chiswick, as I take it, will be the end of the Society. I sometimes think that in gardening, as in many other arts and sciences, the better the trade returns the better the science. Horticulture must get rid of its dilettanteism, and, like the proverbial tub, stand on its own bottom. Take Veitch's nursery as an example, managed more scientifically, and doing better scientific work than half the so-called experimental and botanical gardens in Europe, and moreover paying its way. In a word a scientific success is, or ought to be, a practical or pecuniary success as well, and in the cases above quoted it really is so. My aphorism is, I feel sure, correct—viz., that our future farming will be gardening in the fields. A focus of power on smaller areas, glass protected or otherwise, must supplant the rude or rough-and-ready culture now scotched and often strangled by foreign competition. The struggle of the future will not be with brute force, but in organisation and brain power of the finest and best.—F. W. B.

EUCHARIS CULTURE.

I SHOULD like to say a few words about Eucharis culture. When I took charge of these gardens about eight years ago the Eucharises were in a very bad condition—indeed, I found about a dozen 8-inch pots filled with bulbs with scarcely any leaves, and these were only a few inches long—spotted, wrinkled, broken, and unhealthy. The soil was very wet and sour, with plenty of little mites all round and in the bulbs that I thought were this dreadful Eucharis mite, but a few experiments proved to my satisfaction that they were not, but only a small white mite living on the decaying matter on and near the bulbs.

Like "M. D." we washed, sorted, and placed all the healthiest-looking bulbs in pots to suit the different sizes, in about the same compost as recommended by Mr. Pettigrew, and placed them in their old position—an open, wooden, tressle-work stage near the glass in a span-roof house, where the temperature very often stands about 50°, and in very hard weather as low as 45°. After potting they had no water for a long time. The place being cool they did not start to grow until well on in the summer, but with plenty of sun heat and keeping the atmosphere as moist as possible they started at first slowly, but they gradually gained strength, and when well started we began to supply water very carefully, simply giving enough to moisten the soil. The same treatment was followed all that year, never syringing the plants, but keeping the stage and outside of the pots syringed as often as we could to supply the moisture about them that we know they like. These plants have grown and been potted as they required it, always giving them the same kind of soil, and only varying the treatment when in full growth. By giving more water and occasional supplies of liquid manure we encouraged them to make a good growth, and gradually decreased the supply as they seemed to stop growing, or until

they were well ripened. Now we have a dozen plants from 3 feet to 4 feet 6 inches across, with plenty of the leaves, our best plant in a 15-inch pot measuring 3 feet in diameter. They flower regularly three and four times a year; the last time, during October and November, we gathered 350 blooms, and once before we gathered over 600 in one month, and all under the dry system that Mr. Pettigrew condemns. No doubt with a large house, the plants plunged, and with plenty of heat, light, and air, they will stand more water and do well, but if we were to water ours as Mr. Pettigrew recommends we should certainly kill them. My advice to all that have or try to grow Eucharises with only a limited supply of heat is keep them moderately dry, only giving them enough to keep the leaves fresh and prevent much limpness during the cold part of the year, and just enough when growing to encourage them to finish or ripen it well. I am of the same opinion as "M. D.," that it is far better to err in giving too little than too much water.

Perhaps Mr. Pettigrew will kindly tell us what heat suits Eucharises best, or rather what temperature his plants are grown in, and whether they are plunged or not, and if plunged the heat of the bed, and of what it is composed. I am inclined to think from the quantity of water they receive that they are not plunged, but in a dry position near the glass or over hot pipes.—A. HAGGART.

APRICOTS AND PLUMS.

I FIND these fruits do well under the same general treatment, the latter when grown on a wall being a most important dessert fruit, and well repaying any extra attention that may be bestowed upon the trees. No sorts I have had experience with are superior to the old Green Gage, Jefferson, and Coe's Golden Drop.

As to the best Apricots, I suppose we cannot pass the Moorpark so far as flavour is concerned, but its very slow habit of growth and incurable disease makes us hesitate to grow it as much as the high quality of its fruit would otherwise induce us to do. Shipley I find to be a very good substitute; the flavour is excellent, the fruit of good size, and the tree fills up wall space rapidly. For preserving and kitchen purposes the Royal is a good strong-growing, free-bearing, healthy variety, and very reliable. In order to keep a supply of healthy young trees I have been in the habit of buying in a few every second year, placing them about on any open portion of those walls having a southern exposure. I invariably select trees one year from the bud, and procure them from the nursery as early in the season as possible.

Apricots as a rule differ from Plums in the maiden stage, inasmuch as the former have made a shorter sturdier growth, often with a few young shoots springing up the lower portion of the stem. Plums, if they have broken into side shoots, generally do so towards the upper portion of the season's growth. Consequently at this stage the method of pruning is somewhat different, Plums requiring to be cut back to within a foot of the stock, or if weakly somewhat closer. Apricots, on the other hand, may simply have a portion of the top cut off, at the same time thinning the side shoots, so as to have only sufficient to lay in not too closely. If a neat-fashioned tree is wanted, then the growth must be cut back in the same way as recommended for Plums. The beginning of February is a good time to prune. The after treatment of the shoots in both cases is the same. Superfluous buds should be rubbed off, and only those required to form the base of the tree allowed to grow. I do not find it necessary to pinch strong growths in order to make the different parts of the tree balance, for if allowed to grow freely these strong shoots will throw out plenty of smaller side growths, which must be thinned and laid in as needed. All the pruning the trees need should be done while the trees are in foliage, and by September it is quite possible to see what is required to be cut out or shortened. The treatment of after years consists in merely allowing a sufficient number of shoots to grow, so that the wall may be rapidly covered without in any way overcrowding them. Allow at least 6 inches between the growths. The young trees must be transplanted the second year into their permanent quarters, and may safely be lifted in October, or even earlier if the soil is in good condition.

The method of pruning I find does best here is that which makes a supply of healthy fruit-bearing spurs, and these not crowded. For years we have had to thin both Plums and Apricots to a very great extent, the spurs, as a rule, being clustered with fruit, and as not more than two fruits are allowed to remain to the spur, and often only one, the amount of thinning which has to be undertaken is no slight labour; but it pays, as the fruit is so much better both as to size and quality, and the next year's crop is not prejudiced by overtaxing the trees to forward that of the current year. Of Plums we have some very aged trees, but these do not pay so well as younger stocks, which if not bearing more freely at least produce finer fruits.

Disbudding I consider to be a point of great importance. Of course I understand that this and thinning the fruits are recognised points in the cultivation of these fruits, but I do not think either process is carried so far as is profitable. To leave a number of young budding growths, which by-and-by crowd those which are to remain, to pinch them back, and finally to have to remove them altogether, after allowing them to interfere with the foliage and growths, is not economy. Far better is it to thin freely both fruit and growths early in the season.

The time to prune is doubtless as soon as the fruit is removed. Pruning under this system is a very simple process, but there are always a few spurs which outgrow their bounds, some of them needing removal altogether, others merely cutting back. The work at nailing time, which is most expeditiously overcome in early spring and on warm days, is reduced very considerably by this autumn pruning. As to nailing, those who have not adopted the spring practice can form no conception of the rapidity with which it is overtaken at this season. There are no cold feet to be warmed, no numbed fingers to be restored to a state of semi-torpority. Recalling my own experience, I failed sometimes to be aware of the possession of fingers at all until a smart knock with a hammer demonstrated the fact. When mornings are chilly the time is best employed in digging or any other similar work until the air gets warmed, leaving the nailing altogether on cold days. I have said nothing about making borders, for the simple reason that it is often unnecessary, most often I should say. The soil in which young trees are planted may be any good loam, not turf, unless plenty of water can be given. But the most remarkable root-producing, and at the same time fruit-producing, material I have tried is common garden refuse. Our Apricots have so completely taken possession of the borders dressed with the above material—properly prepared, of course—that it is impossible to get anything on the borders for roots. Last autumn we had simply to add a further coating of this material, and no doubt by the end of another season they will be ready for more.

It only remains to say a few words as to the gathering of the fruits. The best practice I find is to examine the trees at intervals, depending on the heat or coolness of the weather, and remove all that are ripe or nearly approaching ripeness. Laid on the shelves of a cool fruit room they keep for a few days, and as a rule improve in flavour. Coe's Golden Drop Plum if gathered in a fit state and kept dry keeps a very long time. In seasons when it does not ripen well, the advantage of placing the fruits in a warm house will be noted, as they ripen very well under such treatment. The old Green Gage should be allowed to become dead ripe if possible before gathering. Moorpark Apricot is also best allowed to hang as long as possible on the tree, but if the weather is not of a ripening nature it is safer to remove as above recommended. Jefferson Plum, it may be noted, is grown alike for cooking and preserving purposes.—B.

GARDENERS' DIARIES.

THESE few remarks on the above subject are especially addressed to under gardeners. A well kept diary of garden operations is nevertheless very useful to head gardeners also; but every young gardener, without exception, should keep one.

I know of no system so calculated to impart a thorough knowledge of gardening and all pertaining thereto as a systematic and well kept diary of operations. They are now so cheap as to be within the reach of all, and a shilling or two per year invested in them will amply repay the purchaser. To those employed in very large gardens I would say, Rather keep two than one, so that one can be used for the inside work, and the other for the kitchen garden.

Most young men will have ample means for obtaining particulars as to all indoor work, either from personal observation (which is always advisable) or from the foremen of each department; and if he will take a walk round the kitchen garden each evening after tea he will be able to see what has been done during the day in that department. I think also head gardeners would assist with any information asked for in connection with the outside work. All seeds sown and crops planted should be written with red ink, leaving a space opposite for remarks "as to what time such crops reach maturity, also for particulars as to quality and fruitfulness." This with other items as to preparation of ground to be written with black ink. Finishing each day with the state of the weather and temperature.

The diary of indoor work should be much on the same principle—viz., all important matters, such as starting vineries, Peach houses, and forcing of all kinds, sowing seeds and potting to be in red ink, leaving as previously advised a space opposite for remarks, and the temperatures of each department. Notice should also be

made of the composts the different plants are grown in, also results; in fact, any little matters noticed as worth recording should be added; and I venture to say any young man who is at all observant and interested in his work may collect a large amount of valuable information, which he will find most useful when the cares and responsibility of managing a garden devolve upon himself; and the very fact of looking into things and carefully noticing them (which he will be obliged to do if he keeps a diary as it should be kept) will tend towards gaining a thorough knowledge of the work more than any other mode of teaching.—J. H. L.

SPARMANNIA AFRICANA.

THIS Sparmannia is a most useful winter flowering greenhouse plant, either in a large or a small state. Well developed trusses of flowers arranged singly in specimen glasses with some Maidenhair or other Fern fronds are very pleasing. Bushy dwarf plants in 48 or 32-sized pots can be had, and are useful alike for the house or conservatory decoration. Short stout side shoots about 3 inches long may be taken early in March and rooted in a gentle bottom heat, repotted into a larger size as required, pinching the points of the shoots when 4 inches high, and again when the succeeding branches have advanced that length. The soil best suited for its culture is a mixture of loam and peat, two of the former to one of the latter, some partly decayed horse manure, and some sand, potting the plants firmly to induce a stocky growth. Take the young plants from the bottom heat where the cuttings were struck, and gradually harden them until they can be placed in a cool greenhouse, where they may remain during the summer and autumn. During the months of December and January a few degrees warmer will much assist the development of their flowers. At all seasons, particularly during the hot summer days, a plentiful supply of water to the roots is necessary to keep the foliage a deep green colour, otherwise a delicate colour is quickly discerned if the plants are allowed to remain dry at the roots for any length. Deep green foliage enhances the appearance of the plants so much that especial pains should be taken to procure it.—E. MOLYNEUX.

HOW TO GROW MELONS.

I HAVE received a letter from a young gardener asking me to tell him how to grow Melons, and it struck me that the information might also prove useful to readers of the Journal. So I append it.

Assuming that you have ordinary garden frames and that you understand how to make a hotbed, sow the seeds singly in small pots three parts filled with light loamy soil, covering lightly with some of the same mould, and plunge in the hotbed, covering the pots with glass. This, however, should be removed as soon as the young plants appear, and when they have made 2 inches of growth top-dress with soil which had been previously in the frame for twenty-four hours to become slightly warmed, taking care not to damage the stems of the plants, as they are very easily injured by the slightest pressure of the hand at this stage of their growth. When the plants have made three rough leaves plant them on a ridge along the centre of the bed about 15 inches wide and 9 inches deep, the surface of the edge being 9 inches from the glass. Set two plants at 9 inches apart on the ridge in each light, being careful not to bury the stems any deeper in the ridge than they were in the pots, and make the soil firm about the roots. Then give a little lukewarm water through a rose to settle the soil, and shade the plants from sun for a few days until the roots have taken to the soil, when it may be discontinued. As the roots push through the sides of the ridge add a couple of inches thick of soil, and continue to make such additions until the space between the ridge and frame is filled.

When the plants have made fresh growth pinch out the points to cause them to branch. Three of the shoots resulting from this stopping should be trained thinly over the surface of the bed, and when these have made about 15 inches of growth they also must be stopped, which will result in fruit-bearing laterals being produced, in their turn to be stopped at one joint beyond the fruit. Keep all other shoots that may afterwards appear pinched out. When the fruit blossoms open fertilise them, until sufficient fruits for a crop are secured. Four fruits will be enough for each plant to ripen, and these should be about the same size, and distributed pretty regularly over the individual plants. When the plants are in flower, and again when the fruit is approaching maturity, water should not be distributed over the leaves or bed, and air must be admitted more freely than hitherto until the fruit is set. Then close the frame early enough in the afternoon to raise the temperature to 85° or 90° with sun heat, damping the foliage at the same time. Very little water need be given at the roots after the

latter have pushed well into the bed of fermenting manure beneath.

Provide a night temperature of 65° to 70°. This may be secured by making up the linings every fortnight, removing the spent materials, and supplying hot dung and leaves, covering the glass with mats and fern. Admit a little air in the morning when the thermometer reaches 75°, increasing the amount given when a temperature of 80° is indicated, adding thereto when the glass registers 85°. If the above details are carried out in an intelligent manner there need be no doubt about success in the first attempt to grow Melons. If two or three frames are to be devoted to them sow seed at intervals.—H. W. WARD.

LÆLIA SUPERBIENS.

HEREWITH I send you a note on *Lælia superbiens*, an Orchid which does not bloom freely in an intermediate house, although it grows very freely, throws out splendid air roots, and makes fine pseudo-bulbs. Several plants have been grown in an intermediate house for some years, one only of which bloomed. Not being satisfied with plants of two dozen pseudo-bulbs without flowers, I decided to place them in a higher temperature, drier atmosphere, with more light, last summer, and the result is several fine spikes of bloom 5 feet long. The plants were returned to the intermediate house in the end of the summer, and continue there. One young plant has been grown in a stove for several years, has increased the size of pseudo-bulbs annually, and has now flowered for the first time.

This plant does not flower until the pseudo-bulbs are of large size, and it should be grown in high temperature, somewhat dry at the end of summer to consolidate the growth. The flower spikes are several months developing, but is a noble plant in bloom.—G. H.

AN UNCOMMON ORCHID DISPLAY.

IN one of the Orchid houses at Waddon House, Croydon, Mr. Philip Crowley has had during the past week or two a display of flowers quite unique in the method of arrangement adopted and exceptionally beautiful. The house is a small span-roof structure with side stages and a path down the centre, and is devoted chiefly to *Cœlogynes*, *Dendrobiums*, and a few other Orchids. Upon one of the side stages are about a dozen grand specimens of *Cœlogyne cristata*, from 2 to 3 feet in diameter, and bearing some hundreds of flowers, three to seven in a raceme. The variety is a very good one, the sepals and petals massive, broad, and pure white, with a fine orange tint in the lip, a smaller but healthy plant of the delicate *C. cristata Lemoniana* being also included amongst them. The *Cœlogynes* alone are worth going a long way to see, but their beauty is considerably heightened by a number of plants of *Ada aurantiaca* arranged alternately with them, and which, judging by the numerous spikes, large flowers, and unusually deep orange colour, thoroughly appreciate the treatment they receive. Suspended from the roof in small 60-size pots are a dozen or more plants of *Sericographis Ghiesbreghtiana*, and the long slender sprays of rosy crimson tubular flowers drooping gracefully over the pure *Cœlogynes* produce a delightful effect. It is one of the most pleasing and tasteful examples of grouping that I have seen, and the gardener, Mr. W. King, must be congratulated both on the healthy condition of the plants and the manner in which they are associated.

CYPRIPEDIUM VAN HOUTTEI.

Hybrid *Cypripediums* are now in the acme of their popularity, and the demand for rarities or novelties is very great. Several amateurs, both in England and on the Continent, have formed valuable collections of these plants, and amongst them M. Jules Hye-Leysen of Ghent is noted for the representatives of choice species, hybrids or varieties included, in his houses. Three years ago I had the pleasure of inspecting his plants in company with Mr. Manning (Messrs. J. Veitch & Sons' courteous manager), and I was equally surprised at the numbers of scarce forms and their vigorous health. It was evident that both their collection and culture had been carefully studied with the enthusiasm amateurs usually display in horticultural matters. I now learn that M. Jules Hye has recently flowered a remarkable novelty, which when exhibited at the last meeting of Belgian Horticulturists was awarded a certificate

"*par acclamation.*" M. L. Masereel of Ghent when in London last week brought over a flower of this *Cypridium* which I had the good fortune to see, and to that gentleman I am indebted for the following particulars. It was obtained by M. Jules Hye from M. Jules de Cock, who had it from M. Louis Van Houtte amongst plants of C. Dauthieri, which it resembles in habit and foliage. There is a probability that it reached Belgium originally from England, and some think is one of the Veitchian productions. The first price paid was a very moderate one, but now it is valued at over 100 guineas. The flower is a bold one, well formed, and quite distinct in colouring; the dorsal sepal is nearly circular, broad, and of a fine purple tint margined with white; the lip is also freely proportioned, and the petals are purplish at the base, but the chief beauty of the plant is in the dorsal sepal. Some have thought that it is a hybrid between C. Dauthieri and C. niveum, but it is only conjecture.—L. CASTLE.

WHAT IS AN HERBACEOUS PLANT?

WHILE taking a general view of horticulture in the past year, your correspondent, "D., Deal," in his reference to herbaceous and alpine plants at page 39, touches upon the important and, using his own words, "thorny questions," first, "What is to be considered an herbaceous plant?" and, secondly, "Do bulbs come under that designation?" Without attempting to decide, I may be permitted to offer an opinion respecting them, trusting others may be induced to do likewise. First, then, What is an herbaceous plant? and the answer, in the broadest sense, is, Any plant which produces annual flowering stems from a perennial root, no matter whether that plant is a native of the hottest or coldest parts of the world, or indigenous to our own little isle. I merely mention this fact with a view to removing the erroneous notion from the minds of not a few that the term herbaceous is only applied to hardy plants. This, no doubt, has been brought about by constant use, as there is a much greater number of strictly herbaceous plants among hardy plants than in other groups. There are some who regard those plants which die to the ground annually as strictly herbaceous, these persons placing this construction upon the meaning of the word herbaceous—viz., "a plant which dies down and springs up again"—the dictionary rendering being this, "having a soft stem that dies to the root annually." My ideas may be more clearly defined by my supplying a few examples under the different heads.

Taking, then, the broadest view—viz., any plant producing annual flowering stems from a perennial root, we have a very wide field, embracing the whole array of hardy perennials, with bulbs included if not entirely, to a very great extent. But if we would take the second view, which runs thus—plants which die down and spring up again, the number of plants figuring under this head would be more limited. Among the foremost to be admitted would be *Pæonies* of the *sinensis* group, *Phloxes* of the *decussata* section; *Delphiniums*, *Campanulas* of the *latifolia*, *Carpathian*, *pumila* and *turbinata* sections; *Michaelmas Daisies*, *Spiræas*, such as *digitata*, *palmata*, *Ulmaria*, *Aruncus*, *venusta*, and so forth; *Sunflowers*, *Thalictrums*, *Rudbeckia purpurea*, *Trollius*, many *Anemones*, while the law that admits all these cannot shut out *Narcissi*, *Lilies*, *Alstromerias*, *Seillas*, *Orchises*, *Cypripediums*, *English* and *Spanish Iris*, and *Erythroniums*, any more than it can a *Funkia* or a *St. Bruno's Lily*. The question is undergoing a severe strain if in accepting the latter rendering we exclude, for example, such plants as *Rudbeckia Newmani*, *Campanula persicifolia alba* pl., *Leucanthemum maximum*, *Spiræa filipendula* fl. pl., *Stenactis speciosa*, *Chelone barbata*, *Enothera fruticosa*, *Achillea millefolia rosea*, *Tritomas*, *Pyrethrums* (which in some cases lose all old leaves), *Lychnis Viscaria splendens* pl., and the typical *Iris germanica*, all of which do not die down entirely, but retain in a greater or less degree tufts of evergreen leaves. Going even farther, a friend of mine, well posted up in hardy plants, considered that *Violas* should be regarded as herbaceous during an argument upon the subject last year, and based his argument on the fact that the rootstock was perennial, and that the plant annually produced flowers. I did not agree with him, and for this reason, that by doing so we must of necessity admit *Gentiana verna*, *G. acaulis*, *G. bavaria*, and *G. alpina*, and by the same rule even *Aubrietias*, *Drabas*, *Iberises*, *Armerias*, and in short all alpinas, but this was never intended to apply in such a form, since plants of diminutive growth are always considered as alpinas; still there are instances where some few taller plants creep into the alpine ranks on account of the altitude at which they are usually found in their native habitats, and upon the same grounds may some bulbous plants—e.g., *Chionodoxa*, be regarded as alpine.

Referring to the second question—"Do bulbs come under that designation?"—I should unhesitatingly reply, Yes the majority of them; indeed, I should only exclude from the ranks of true herbaceous plants those whose bulbs flower but once and die—that is, bulbs which are annually formed, and which after flowering perish. For an example of this take the *Gladiolus*; the corms or bulbs of these flower and perish annually, new ones being formed to perform the same function in their turn. Your correspondent appears to regard *Lilium auratum* out of place as a hardy herbaceous plant, yet I cannot see where else he would place it, and I imagine no plant can be nearer the mark than a *Lilium*, which flowers annually from a perennial root. It may be urged that *Lilium* form new scales inside the old ones annually; still this only causes an enlargement of the bulb, providing greater strength with

better spikes of bloom. In some other species this takes an elongated course, eventually forming a rhizome. In each instance the bulbs do not perish, but annually increase in size. This is the case with plants not bulbous, the rootstock or crowns composing them annually increase in number and in strength. I certainly think that the admission of bulbous plants would be within the meaning of the term herbaecous; at any rate, before such plants as Antirrhinums, hybrid Pentstemons, German Wallflowers, and Stocks, which frequently do service for hardy herbaecous flowers, and are awarded prizes too. I have frequently seen this in provincial shows, and can only suggest as a remedy that the framers of schedules omit the word herbaecous, and in its stead use the words "hardy border plants," or "hardy border perennials," with a brief explanation of the plants intended to figure in this particular class. Hard-and-fast lines are, however, by no means advisable, still the matter should be made as clear as possible for the guidance of exhibitors and judges alike. Disqualification upon this score should only be resorted to when the merits in other respects are equal.—J. H. E.

IMPRESSIONS AND OBSERVATIONS.

I AM asked if after reading the articles that have appeared on Potatoes, especially that of Mr. W. J. Murphy on page 39, I think the Potato disease is stamped out, or if it is conquered by the improved varieties. There have been disease-free years before 1887, and the murrain followed, and it will probably appear again when the conditions are favourable for the growth of the destructive fungus in the tissues of the plants.

A YEAR or two of immunity from the Potato murrain counts for little, since the existence of resting spores of the fungus (*Peronospora*) has been demonstrated by Mr. W. G. Smith, and I suspect no one knows how long they "rest." With a continuance of wet weather and a warm moist atmosphere for several weeks, the disease may be expected to recur, as in past times, and it is wise to expect it. It is well also to remember that in years when it was most virulent those varieties of upright growth with woody stems and thick-textured leaves were the least injured. It will be the same again when the disease appears; and those of prostrate habit, arresting evaporation from the sodden soil, and with flimsy leaves, will be the first to succumb.

WHEN fungus spores are present and fall on the leaves, the spores grow, and the mycelial threads penetrate the plant, and its destruction follows. It is possible that the cuticle of the leaves may be so stout as to have material resisting power, and I believe this is so. Even red spider first attacks the young soft leaves of Vine laterals, and mildew certainly does, making little or no impression on matured leaves, even though a vinery may be full of spores. The enemy also takes possession of the fruit in its early stage, seldom when advanced and the cuticle hardened. When mildew attacks Roses it makes the least impression on the matured leaves, the spores must fall on them, as on the young and more tender, else more vulnerable, and these are devoured by the enemy. Why, then, should not the stout leaves of Potatoes have the same mildew-resisting power? I am convinced they have, as the result of experiments, and everybody knows, or ought to know, that the leaves cannot be perfect in the absence of full exposure to light and air, and this they cannot have when the stems fall over, one overlapping the other, till what ought to be the best leaves are spoiled, only the younger and inferior remaining—precisely those that are most open to the inroads of the fungus when the spores are prevalent.

I HAVE known two seasons to elapse without seeing or hearing of anyone else seeing a diseased Potato in a great Potato-growing district; yet subsequently the murrain has appeared and become virulent. We must not be lulled in a feeling of false security because of one or two dry summers, and consequently clean Potato crops; but the same care should be exercised in the selection of varieties, and seed tubers with all their vitality intact, and in the preparation of the soil for inducing the best possible growth, as if an unfavourable season were expected; and especially as this is equally sound policy, let the weather be ever so good for the crops. Subjects cannot be exhaustively treated in these scratch notes, and now the theme must be left to others who may have something to say thereon, and I shall not in the least object to my upright-woody-stem-and-stout-foilage theory being opposed as of disease-resisting tendency, because I think it cannot be overturned without teaching me something that may be even more serviceable to others. By the way, is there not a mistake in 1843 being the "famine and total blight year"? 1845 was the year of the terrible outbreak of the Potato scourge. That is well within my recollection, though it is possible it may have visited Ireland a year or two sooner. Let Irish cultivators trust to nothing but their intelligence and persevering labour in the production of this, to them, vital crop, and they have a good guide and friend, as I know from more than one source, in Mr. W. J. Murphy.

"WHAT do you think about Mr. Goodaere's great sensation?" asks a correspondent who estimates himself as "A Humble Grower." That was in reference to the bunch of Gros Colman Grapes represented on page 67. It is the best bunch of Grapes I have seen figured, but not the best I have seen in the flesh. Mr. Goodaere has grown and shown both larger bunches and berries; so has Mr. Wm. Thomson at Clovenfords, and I believe I have seen Drumlanrig berries quite equal to the

Elvaston "Sensation;" still there is no mistaking its high merit, and Mr. Goodaere deserves a mark of high commendation for the excellence of his work.

THERE is a hint in the notes of the cultivator worth bringing out a little more prominently relative to the importance of early thinning. It is not all persons who dare "commence thinning almost before the flowers expand," and there are instances where it would not be safe to do so, but it is certain that thousands of bunches of Grapes are left too long unthinned to the prejudice of the crops. Let anyone try, as I have tried, an experiment with a few bunches of Grapes, thinning one side at the first moment it is safe to do so, leaving the berries on the other side to press against each other before thinning, and the danger of needless delay in the work will be apparent before the season is half over.

It is painful to me to see Grapes crushing against each other before the scissors are applied. "No time," says the six o'clock man. It is true other work may press and command attention between these magic hours; but then I have never seen a hard-and-fast six o'clock man excel in the culture of Grapes, and not as a rule in many other things. I have thinned Grapes from four o'clock in the morning till six, and from six at night till nine, times out of number. "Paid for overtime" does someone suggest? No, pay was not even thought about, good Grapes on the Vines being the coveted reward. Overtime pay is not allowed in many gardens. Shall, then, the Grapes spoil? No young man devoted to his calling would allow that if in his power to prevent it, but would rather rejoice in the opportunity of becoming an expert in the important work, that is so often slovenly done, of thinning them; but at the same time, when a little encouragement can be given it has a stimulating effect. I remember winning a prize for thinning Grapes before I was thirteen years old—the first and most cherished of my few gardening honours. Ten bunches each were to be thinned by three workers before 6 A.M., and though the prize was only a shilling the striving to excel was as great amongst all as if it had been a pound. I wonder if the hint will be taken by anyone interested in the gentle employment in question.

THOSE cogitations appear to lead to a few further observations on the "under gardener question," that has evidently been of interest to many readers. On the whole it must be admitted that the young writers of the several letters have acquitted themselves well. Though it is evident that some of them consider that much work is done for nothing, yet the general idea is that a kind word or act of recognition for honest effort and nightly labour is valued more highly than a small amount of money that might be given for the extra services rendered. Ladies and gentlemen of the highest rank frequently, if not commonly, thank their servants for many acts that are essentially duties, and grace is not lost in the giving on the one hand, while the recipients are made happier by the marks of approval thus considerably bestowed. Every servant worthy of the name who is thus kindly treated will strive to the utmost to increase the value of his services, head and under gardeners being no exception to the rule. Both in tone and style the letters referred to are creditable productions. Let the writers of them work with a will, cultivating the art of agreeable demeanour and expression, and the future of gardening will be safe in their keeping.

By the way, I am not able to entirely agree with an observation of Mr. Goodaere to the effect that learning and laziness go hand in hand, and if that is what he means by his remark on page 112 I will cite himself against the accuracy of the dictum advanced. He may disclaim being a "learned" man; but even so, is he prepared to admit that if he were more ignorant he would be more industrious? I do not believe he would, and the best educated gardeners of my acquaintance have worked as hard with their hands as with their heads in making themselves what they are; and those who strive the most assiduously in both manual and mental exercise usually attain to the best positions in the gardening world when these are open to applicants in fair competition.

JUST as my pen was flowing smoothly and about to glide into another paragraph on a subject in mind, another letter comes. With a "bother the letters" it is torn open, and I soon see it is a case of "Goodaere again." It is not to the big Grape question, nor even to the brobdignagian Melon, that my attention is directed; but to the 16 oz. Royal George Peaches, mentioned on page 82. And what, kind readers, do you think I am requested to do? I am actually asked if I cannot "give him a wipe?" If my appellant will look in the dictionary I think he will find a variety of interpretations attached to the word "wipe," and if he will further suggest which of those he would prefer me to adopt the matter shall be considered. In the meantime I have not yet had the pleasure of seeing a Royal George Peach either 15 ozs. or 16 ozs. in weight, and if Mr. Goodaere or anyone else can send me one during the season I shall be glad to wipe my mouth with it, only stipulating there must be no mistake in the variety; and if Elruge Nectarines weighing 10 ozs. or 12 ozs. are also plentiful, perhaps one or two might be spared at the same time. If they should happen to be heavier they will not be objected to, but I do not expect to receive many. Now then, ye great growers, press on to the goal—Royal George Peaches 16 ozs. and Elruge Nectarines 12 ozs. in weight, and those who accomplish the feat, and afford me ocular demonstra-

tion of the fact, shall, so far as I can help in the matter, be enrolled in the list of worthies of 1888.

I HAVE been specially requested to turn my attention to the master-and-gardener-and-exhibiting question, but before doing so I am constrained to indulge in a few observations on my own account. I have a lurking suspicion that your plain-spoken correspondent, "Experientia docet," has at some time or other seen some of my letters; anyway he hits me rather hard. I will plead guilty to being one of the worst of writers to the Journal, and hereby acknowledge my obligations to the compositors who "set up" my copy so well. How they pick out the letters passes my comprehension. But they manage not only to do that but to correct the spelling and grammar; or at least somebody does, when there happen to be mistakes. I mention this as encouraging to would-be writers who hesitate in sending letters for publication because they are not perfect in all points. If they wait for perfection they will wait for a lifetime. Perfection is a Divine attribute. It may be approached but not attained; and there is only one way of approaching it—namely by practice, perseverance, and the elimination of faults. In the matter of writing editors do the eliminating. Sometimes they have been good enough to eliminate more than half of what I have written. In that way they become educators; and I could tell a story or two about pupils having profited by that form of teaching to an extent that would surprise the multitude. I have to be content with a humble position, but that is my own fault, and I ought to have made myself a better writer. By the way, in reference to your correspondent's signature, "Experientia docet," he may perhaps be amused to hear that it has been rendered into both English as "experience does it"—a practical translation, he will admit, though not literally exact.

THE exhibiting question must stand over, as I have found by experience that the longer my contributions are the longer they have to wait, and the shorter they are the sooner they appear, and I begin to fear, if I do not stop, my string of observations may be again crowded out altogether.—SPECTATOR.

EVENTS OF THE WEEK.—On Thursday, the 23rd inst., the Royal Society has a meeting at 4.30 P.M. The Quekett Club meets on Friday at 8 P.M.; the Royal Botanic Society on Saturday at 3.45 P.M.; the Royal Geographical Society on Monday at 8.30 P.M.; and the Society of Arts on Wednesday, the 27th inst., at 8 P.M. The usual auction sales will be held at King Street and Cheapside.

— THE ROYAL HORTICULTURAL SOCIETY.—At a meeting of the Council of this Society, held last Tuesday, the resignations of Mr. William Lee and Mr. Sidney Courtauld were accepted, and the Council appointed Mr. T. B. Haywood and Mr. J. Woodbridge as their successors. The Rev. W. Wilks was chosen Secretary of the Society in place of Mr. Lee, resigned.

— WE regret to learn that MR. A. H. SMEE was taken suddenly ill last Thursday morning, having ruptured some deep-seated muscles in his back, causing very acute pain. He has been confined to his bed since. Just as we are going to press we are glad to hear he is now progressing favourably.

— AT the last meeting of the ROYAL HORTICULTURAL SOCIETY'S FRUIT COMMITTEE at South Kensington a silver Banksian medal was awarded to Messrs. T. Rivers & Son for the fine collection of Oranges, referred to in our report on page 126.

— THE schedule of the SCOTTISH PRIMULA AND AURICULA SOCIETY is just to hand, and from it we learn that the Dowager Duchess of Athol has become the Patroness of the Society, with Robert Cathcart, Esq., Piteairlie, Fifeshire, as President. The second Show will be held in the Calton Convening Rooms, Waterloo Place, Edinburgh, on May 9th this year, when prizes and certificates will be offered in twenty-two classes. As the result of last year's Show the Society has a favourable balance of £8.

— THE WEATHER.—Mr. W. K. Woodcock writes from Sheffield, 'We are having very cold weather here now, wind E.N.E. Snow falling every day, and frost each night. The first real winter we have

experienced this season." From Scotland "B. D." writes—"The week ending the 20th inst. has been wintry throughout. An average of about 7° of frost has been experienced nightly, except on one night 14°. The Scotsman contains a report of 4° below zero (!) on the grass on the night of the 14th at Aviemore, Strathspey. Only once have we had half that intensity during the winter in South Perthshire. Snow, varying from 2 inches to over a foot in depth, fell generally over the country on the night of the 16th, and still lies, though somewhat lessened by the bright sunshine." In the south and other parts of England much snow has fallen, but around the metropolis it soon melted, though the wind for several days has been exceedingly cold.

— WRITING—from Old Warden Park, Mr. G. R. Allis remarks—"From the 13th to the 19th inst. the WEATHER has been of a very stormy and winterly character. Snow has been falling more or less since the 13th inst., followed by 6° and 7° of frost on most nights, with a keen north-easterly wind. The ground is covered with snow from 6 inches to 8 inches deep, a good deal having melted as it fell. We have had about 12 inches altogether. Gardening and farming operations are at a standstill, consequently many labourers are thrown out of work; but the water produced by the snow will be beneficial to the land, as the springs are low and water scarce—so much so that some farmers have to cart water long distances for stock and household purposes; but this short supply will be accounted for when I mention that the rainfall for 1887 was only 16.76 inches—very much below the average rainfall; but in referring to the rainfall of 1884 I find it was even less, as then we only registered 16.74 inches."

— PACKING FRUIT.—"W. H." writes:—"On reading your correspondent, 'R. W.'s,' criticisms upon Mr. Pettigrew's mode of packing mixed fruits, I could not find anything in what he had written to be of the least benefit to the readers of the Journal. It is to be regretted that he did not give some advice on the subject, which is of so much importance, and I think when anyone writes to condemn another's method he ought in justice to give his own."

— WE are informed that MR. B. W. CLEAVE, NEWCOMBE HOUSE, CREDITON, who it may be remembered was the owner of the fine plants so successfully exhibited of late years by Mr. George Lock, died on February 3rd, and was buried amid every token of respect on February 8th. The deceased gentleman took great interest in his plants and flowers, and was extremely popular among all classes of society in the district.

— THE ordinary fortnightly meeting of the WALKLEY (SHEFFIELD) AMATEUR FLORAL AND HORTICULTURAL SOCIETY held on Friday evening last proved more than ordinarily interesting. Mr. T. B. Hague (President of the Society) occupied the chair, and there was a large attendance of members. Mr. J. Shipman, a former Secretary of the Society, read a very instructive paper upon the "Florist's Tulip." By far the greatest interest of the meeting, however, was centred in the exhibits placed upon the tables, which were numerous and generally meritorious, but especially so in the case of those from Mr. W. Corp, manager to Mr. Duncan Gilmour, junr., Rose Grower, Sandygate, which comprised about fifty cut blooms of Tea Roses, beautifully fresh flowers artistically arranged with their own foliage and Maidenhair Fern fronds. The most conspicuous varieties were Catherine Mermet and its beautiful white sport, The Bride, several very fine blooms of each; also Sunset, Rubens, Marie Van Houtte, Madame Caroline Kuster, and Niphotos. Of the latter a grand flower more than 3 inches in depth and very full was shown, also a large box of cut blooms of Rhododendron Lady Alice Fitzwilliam, each flower being about 4 inches in diameter, very stout in texture, and of the purest white (these, as exhibited in a large Rose box, with a groundwork of dark green moss and relieved with fronds of Adiantum cuneatum, were highly effective), and a number of pots of the old double white Primula, well grown, and densely flowered. Several new members were enrolled, and a very enjoyable evening was spent.

— HORTICULTURAL CLUB.—There was a large attendance of members at the annual dinner of this Club on Tuesday the 14th inst., when the chair was occupied by Mr. John Lee, and amongst those present were Dr. Hogg, Rev. W. Wilks, Messrs. J. D. T. Llewelyn, Crowley, Harry J. Veitch, W. Bull, H. Turner, H. J. Pearson, Chas. Pearson, H. Herbst, J. S. Cussens, C. T. Druery, George Deal, T. Francis Rivers, Geo. Bunyard, George Paul, A. F. Barron, and George

Nicholson. When the usual loyal toasts had been given by the Chairman, he proposed "Success to the Horticultural Club," and mentioned that it had been able, during the past year, to offer a place of meeting, not only to the National Rose Society, but to the Nursery and Seed Trade Protection Society, the National Dahlia Society, the National Carnation and Picotee Society, and the National Auricula Society, and had thus shown its value to the horticultural world in general. The Secretary, in responding, announced that the Committee had that day voted a donation to the Gardeners' Orphanage Fund, as they had done some years ago to the Gardeners' Benevolent Institution. The toast of the "Royal Horticultural Society" was responded to by Mr. Harry Veitch; the "Horticultural Press" by Dr. Hogg; and the "Visitors" by Mr. Barron and Mr. Nicholson. Some magnificent bunches of Gros Colman Grape were kindly sent by Mr. Thomson of Clovenfords, and some beautifully coloured Apples by Messrs. Rivers and Geo. Bunyard, the former also contributing a dish of fine samples of Knight's Monarch Pear. A very pleasant and agreeable evening was spent, and hearty wishes expressed for the prosperity of the Club.

— GARDENING APPOINTMENT.—Mr. Robert Titterington, late foreman at Dallam Tower gardens, Westmoreland, has been appointed head gardener to H. T. Welsh, Esq., Leek Hall, Kirkby Lonsdale, Westmoreland, in place of the much-respected Mr. F. B. Brookes, deceased.

— WE learn that MR. T. W. HELLIWELL, 5, WESTMINSTER CHAMBERS, LONDON, S.W., has been awarded the gold medal from the Jubilee of Railways Exhibition at Paris, 1887, for his patent system of glazing.

— MR. H. SWIFT, Balrath Burry, Kells, Co. Meath, sends us some fine flowers of *FREESIA REFRACTA ALBA*, five and six to a scape and extremely fragrant. Our correspondent remarks that "They have been grown on the shelf in a cool house near the glass, only keeping the frost out. I have thirty pots of them and they are much admired."

— GARDEN LITERATURE AND ART.—"From the very earliest times," writes Mr. F. W. Burbidge in "Harper's Magazine," we find gardening illumined and directed by the pen. Bacon's celebrated essay 'On Gardens' will recur to those interested, and George Herbert, the divine, quaintly tells us that 'of gardening and building no man knoweth the cost'—a shrewd observation which is likely to find an echo in the experience of many who have ventured on either pursuit. I have purposely avoided many allusions to ancient or what are properly called classical authors, but I cannot resist pointing out the fact that some of our most successful writers of to-day, and of those whose works are read in these pages, are literally and truly gardeners. Who has not lingered over 'Christowell,' by R. D. Blackmore, who Virgil-like, devotes much of his time to his fruit trees at Twickenham? And have we not noted the true instinct of fruit and flower culture in 'Nature's Serial Story' and in the 'Home Acre,' by Mr. E. P. Roe, or laughed at Charles Dudley Warner's 'My Summer in a Garden?' Even the artists share the fate of the writers, and become bond-servants to Flora. I have never seen Mr. W. H. Gibson's garden, but I am quite sure he has a good one, for it is only true and practical gardeners who can draw leaves and petals as he and Mr. Alfred Parsons do draw them. Everyone fond of flowers and gardens should read Alphonse Karr's 'Tour Round My Garden,' also 'Days and Hours in a Garden,' by Mrs. Boyle (E.V.B.); and every work written by the late Mrs. J. H. Ewing is alive with sympathy for garden blossoms, as is also a little volume entitled 'The Six of Spades,' a book about the garden and the gardener, by the Rev. Reynolds Hole, the genial pastor and rosarian, who formulated the aphorism that 'he who would grow beautiful Roses in his garden must first of all have beautiful Roses in his heart.' Charles Kingsley had a charming little garden near the Pine trees at Eversley, and both he and his brother, Henry Kingsley, the novelist, always wrote feelingly on floriculture. There is scarcely a single work of John Ruskin's that does not enlighten us as to the exquisite fitness and grace of vegetation, and in his 'Proserpina; or, a Study of Wayside Flowers,' there are minute studies and much subtle reasoning as to their anatomy and nomenclature."

— WE referred briefly to the annual meeting of the UNITED HORTICULTURAL PROVIDENT AND BENEFIT SOCIETY LAST WEEK. Notwithstanding its unwieldy name this institution has done, is doing, will do much good to those gardeners who belong to it, or to their

representatives. The Society is strong and gaining in strength yearly, and so it will continue to do with a steady accretion of new members. The sum invested in consols is now £4000. Though the claims of the benefit fund have been heavy, amounting to upwards of £60, the fund has increased in round figures from £2482 to £2879 during the year. There have been no claims on the benevolent fund, which has risen from £1092 to £1183. The management fund shows a balance of £19 over expenditure, but the outlay is quite insufficient for keeping the advantages of the Society before the public. This fund is inadequate for the important work of extension; the benevolent fund in exc. ss of requirements; and if half the contributions of honorary members could be turned to the management fund and more business enterprise displayed the Society might become a great national institution. It would have remained almost stationary but for the efforts of outside friends, yet, if we are correctly informed, even press invitations were not issued for the meeting. In answer to inquiries we give the address of the Secretary—Mr. W. Collins, 5, Martinhoe Terrace, Martindale Road, Balham, London, S.W.

— MR. W. J. MURPHY, Clonmel, in referring to remarks which have appeared concerning CARTER'S STRATAGEM PEA, observes that he has found it "one of the best Peas ever issued. If grown in firm ground, even though tolerably rich, it will not exceed 3 feet high; and if for exhibition, where size is imperative, thinning both side stems and extra fruiting flowers is desirable. Surely Mr. Swan (page 132) does not mean to say he can grow the splendid specimens he describes, 'with forty pods to a plant, and from eight to ten peas in each, having his plants in rows only 6 inches between the rows?' This pea is an immense favourite with birds and vermin, so when wanted early I would recommend Mr. Garner to try starting in shallow zinc trays and then lift into the future drills. Fresh manure should be avoided."

— THE monthly meeting of BELGIAN HORTICULTURISTS was held in Ghent on the 16th inst., when the following were present:—Messrs. V. Cuvelier, Boelens, Ch. Spae, Edm. Story, Jules Hye, Emile de Coeck, and A. Wallern, M. Laurent Mascreele presiding, and M. Gustave Van Eckhaute was Secretary. Certificates were awarded to M. Ad. D'Haene for *Oncidium splendidum*, to M. Ed. Pynaert for *Cypripedium Dauthieri marmoratum*, to M. J. Hye-Leysen for *Cattleya Trianae* varieties, *Odontoglossum coronarium*, and *Cypripedium Van Houttei* (see page 146), to MM. Vervaeck et Cie. for three varieties of *Cattleya Trianae*. Honourable mention was also accorded to M. Ad. D'Haene for *Cattleya Trianae* varieties, to M. Jules Hye-Leysen for *Cypripedium Spicerianum magnificum*, *Lycaste Skinneri alba*, and *Cypripedium Argus*; also to MM. Vervaeck & Cie. for *Cypripedium vernixium* and *Odontoglossum Wilckeanum*. A cultural commendation was awarded to M. Jules Hye-Leysen for *Cypripedium Boxalli*, and a wish was expressed that Mr. James Bray would show his plant of *Cattleya Trianae alba* at the next meeting.

— RELATIVE to the report of the LIVERPOOL HORTICULTURAL ASSOCIATION, supplied by "A Committeeman," and published on page 112, Mr. W. Bardney writes:—"When condensed reports are issued from official sources we naturally expect them to be correct. It is clear that 'A Committeeman' was in too great a hurry to amend the previous report (page 4); it would have been better if before doing so he had obtained the facts necessary to render his addition an accurate one. If he asks the Secretary (Mr. Bridge) for a copy of the resolution I proposed and handed to the Chairman, he will then be in a position to detect the error into which he has fallen, and thus make the necessary correction."

— A NOBLE CAMELLIA.—A correspondent writes—"A magnificent plant of the old *Camellia japonica alba plena*, probably the largest in the kingdom, is thriving under the care of Mr. Toft at Eddisburg, West Derby, Liverpool, the residence of J. Latham, Esq. It is one of those imported by Burton & Higginson from China, and bought and planted in its present position by Edward Porter, Esq., then Mayor of Liverpool. The circumference of its main stem is 2 feet 7 inches, and the diameter and height of the tree is not less than 20 feet; indeed, had the house (already enlarged) been made larger the dimensions of the tree would also be greater. I noticed in a contemporary some time ago a correspondent recording the return in one year from a very large *Camellia* as £20. I am informed that the above plant has yielded in one year more than treble this amount."

— "H. C." sends us flowers of some uncommonly fine CINERARIAS, evidently of a good strain and well grown. The flowers are rich and varied in colour, some being of great size, nearly 3 inches in diameter, the florets over an inch broad. Our correspondent states that "out of 100 plants grown from seed supplied by Messrs. Sutton & Sons not one is of indifferent quality."

— THE LIVERPOOL CHRYSANTHEMUM SHOW is to be held on November 21st and 22nd, and Lindfield (Sussex) on November 15th and 16th.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 14TH.

SCIENTIFIC COMMITTEE.—Present: Mr. F. Pascoe, in the chair; Messrs. Murray, Wilson, O'Brien, Ridley, Michael, Smee, Bennett, Smith, Boulger, Morris, Dr. Lowe, and Rev. G. Henslow, Hon. Secretary.

Oreohids.—Mr. O'Brien remarked on a so-called *Masdevallia eulex*, but which is really *Pleurothallis Barberiana*, bearing minute delicate flowers. A *Dendrobium Kingianum*, var. *albidum*, was also exhibited. The inflorescence bore eighteen flowers. The original specimen, figured in the "Botanical Magazine," 1845, No. 61, bears pink flowers, and in the description two only are said to have then been the average number. It is refigured in 1850 in the "Botanical Magazine," No. 4527.

Ponthieva, *Drawing of*.—Mr. Ridley showed a drawing of this genus by Lehmann, from Ecuador, which was figured and described in the *Gardeners' Chronicle*.

Wallflower, Monstrous.—Mr. Henslow reported upon the specimens exhibited by Mr. Lynch at the last meeting, known as "Miss Hope's." They were not gynantherous, but a form of "double" flowers. The calyx was normal, but contained more or less than ten petals, that is to say, the usual four, and six others representing the stamens. Instead of a pistil, the axis was prolonged, and terminated with a double flower, having a normal calyx, but a corolla of an indefinite mass of petals. This case, therefore, resembled the double form of *Helianthemum vulgare*, only in that flower the calyx and corolla are repeated three or four times.

Æcidium pseudo-columnare (J. Kühn).—At the last meeting of the Scientific Committee some specimens of the Silver Fir were exhibited which showed the injury done to the extreme tips of their branches by an *Æcidium*. Having in my herbarium some specimens of the fungus in question which Mr. Munro had sent me some years ago, I submitted them to Professor Julius Kühn, with the request that he would examine them and report whether they were the true *Æcidium columnare* of Albertini and Schweinitz, which has its teliospores of *Vaccinium Vitis-idaea* as *Calyptospora Gœppertiana*, or whether they were the recently described *Æcidium pseudo-columnare* into whose life cycle the *Calyptospora* does not enter. Professor Kühn in reply says, that they belong to his *Æcidium pseudo-columnare*, a fungus which has not previously been recorded as British.—*Charles B. Plowright*.

Honey from Eucalyptus globulus.—A specimen had been sent from Adelaide, South Australia, to Mr. T. Christy, as possessing similar properties to those of the tree itself; being, for example, antiseptic in its nature. It is found to be very efficacious in cases of lung disease. The honey can only be procured every other year, as the tree flowers biennially. One peculiarity is that, though liquid on arrival, it rapidly crystallises in this climate. It has a very peculiar flavour and scent.

"Jambul," Eugenia Jambolana.—Mr. T. Christy sent a growing plant as well as seeds of this important drug. Its peculiarity resides in the power of its seeds to arrest the conversion of starch into sugar; hence its value in diabetes. The seed appears to contain about 31.4 per cent. of oil and 4.32 per cent. of ash; also yellow-green resin and a crystalline principle are present. Experiments with starch and malt extract, with and without jambul, showed that while 22.4 grains were converted into sugar where no jambul was present, only 9.8 grains were changed with 15 grains of the seed; and 6.3 grains of starch became sugar with 25 grains of jambul. It is now used very extensively in America and Germany, and has begun to be employed in England apparently with very beneficial results. From a preliminary analysis, the seed does not appear to contain any starch, and therefore the question arises whether the particular ferment which emulsifies oils in seeds may not generally have a sort of anti-diastatic action. Further details will be found in No. 10 of *Med. Com. Pl. and Drugs*, by Mr. Christy.

Oranges, Cultivation of, in England.—Mr. T. Christy contributed the following remarks upon Orange growing:—"In discussing the question of Orange growing in this country with Dr. Amadeus he tells me how much has been done by grafting in Porto Rieo. He recommends the graft to be made on the strong stems, and the plants do so much better when not grafted too young. With regard to the transport of the fruit, he believes that the sixteen days' sea journey will be fatal to the quality and flavour of the thin-skinned Oranges, so that it would be better to send some cases of plants of the best varieties for growth in houses here. Since the receipt of the large shipment from Bahia many growers have bought stock of the Orange trees, with the view of so doing, and some correspondents have already contributed some very interesting information, showing how well the culture is understood (see communications from Mr. Jas. Douglas and 'M. F.' *Gardeners' Chronicle*, vol. iii., January 14, 1888, pp. 46, 47), and it only remains for the commercial question to be threshed out. One grower informed me that he got so much juice in his fruit that it burst in ripening; so this

fact sets at rest the question of hard 'woody fruits' only being produced in this country. Mr. H. Dixon, of Cherkley Court, Leatherhead, has two Orange trees, each bearing more than 200 fruits; and from his *Pomeloes* he says that he is able to make a delicious preserve. With regard to foreign fruit, a captain in the Mediterranean trade tells me that from his experience in collecting Oranges from most parts of the world where they are grown, he believes the palm for delicately flavoured varieties must be awarded to those from Malta. This he attributes to the great care bestowed in their cultivation. When attending the display of fruit at the Agricultural Show in Paris every year, I have been struck with the fine exhibitions of these fruits, together with Citrons and Limes from Algeria; and I was informed that the French Government obtained thence the best varieties for their botanical gardens, and that the trees were in full bearing."

A fine series of home-grown Oranges, Lemons, Citrons, and kindred fruits was exhibited by Mr. Rivers, who has cultivated them for the last twenty years. Mr. Michael corroborated the difficulty of importing Oranges from Bahia—one of the best Orange-growing districts.

Rhododendron Hybrids.—A series was exhibited by Mr. Veitch at the exhibition as follows:—*R. Imogene*, between *R. Teysmanni*, male (pure yellow), with *R. Taylori* (red), itself a hybrid. It retained the foliage of the male, the blossoms being pale lemon-coloured, tinged with red in the filaments and anthers alone. The red tint was thus almost entirely eliminated. *R. Ruby*.—This is a cross between *R. jasminiflorum*, *R. carminatum* (crimson, female), with *R. multicolor*, var. *Curtisi* (male)—this being a crimson variety of the normally lemon-coloured *R. multicolor*—both parents being red, the offspring was ruby-coloured. Two effects gained were a dwarfier habit and a freer blooming. *R.* (unnamed).—A hybrid between *R. Monarch* (salmon-coloured, female), and *R. malayanum* (pale crimson, male). The influence of the male overpowers the female, as there is no salmon colour in the hybrid, though it has the habit of the male with an increase in the number of flowers. *R.* (white, unnamed).—A cross between *R. Princess Beatrice* (rosy-pink), and *R. multicolor* (lemon). In this case the union of two colours caused the total disappearance of both, the result being a pure white.

IRIS SUSIANA.

It is not everybody who can grow this "Guinea Hen" Iris, imported 300 years ago from Susa, one of the towns in Persia, although it is now very cheap, and may be bought by the dozen or the hundred at a low rate. I knew a lady very fond of flowers who knew little or nothing of Iris, but she read in a gardening paper that they were as fine as tropical Orchids, and that anybody could grow them anywhere. So she went to a bulb shop and told the man behind the counter that she wanted the best Iris he had. The bulb man recommended her English, Spanish, and German galore, but said he, drawing a few nubby brown roots out of a bag, "This is a very rare and beautiful thing, I can strongly recommend this." It was included, and home went the lady full of hopes for the future. "John," who is groom and poultry keeper, swineherd, and gardener in chief, was summoned, and he, good man, being always busy, dug holes anywhere among the bushes, and in went the Iris. Holes and earth were all they had, and away he went to his pigs and Cabbages.

An anxious eye was cast on the roots by their owner from time to time, and one morning the lady saw something like a speckled chicken fluttering among the leaves, and on looking closer she found a flower—the Iris *Susiana* was in bloom. Imagine her delight, you who have struggled with this Iris as earnestly as Charles Dudley Warner struggled with the "pussley" weed in his garden. But the lady was not delighted; she loved Pansies and Roses, or any flowers with a sweet smell and a bit of colour about them, but this ugly spotted thing fluttering in the sunny breeze she did not like at all. "The dirty, ragged-looking thing," said she, "why talk about Orchids; this 'lovely Susan,' as the man called it, is the colour of a well-worn hearth brush, and smells like bad Mushrooms." "There's more of the sooty brute," said she, as another flower or two caught her eye among the bushes. Then she called "John" from the stables and showed the flowers to him, and spoke her mind. "Yes'm," said John, "the—the thing certainly is a bit sooty-lookin', and they do smell of Toadstools surely." But then a lucky thought jumped into her mind, and she wrenched off leaves and flowers together and drove into town to see the seedsman. "Why did you sell me this dirty stinking thing?" she said; "looks like an Orchid, doesn't it?" she gasped in her anger. "Madam," said the shopman, "you surprise me. We have sold a great many of this *Susiana*, but we never saw it in flower before. Believe me, your excellent culture has worked wonders! Pardon me," he said, as she was about to ask if his senses had left him, "Pardon me! I'll call the proprietor."

The shopman came round her and gazed at the flowers, and just as she was doubting their sanity, the proprietor appeared—florid, white-haired, dignified, and bland. "My foreman informs me, Madame," said he, with a bow, "that your gardener has succeeded in blooming the rare and beautiful Iris *Susiana*, and that you have been so kind as to bring us the flowers. They are most handsome!" he ejaculated, as he saw a sort of lax and helpless look in her face. "Most handsome!" ejaculated the shopman in a chorus. "And I hope," said the big man, "you will do us the honour to allow your beautiful flowers to be placed in water and exhibited in our window; for, believe me, such handsome blossoms have never been produced before." Not quite convinced as to the "most handsome," she resigned the flowers, and for days they were the talk and wonder of the town. People blocked the pathway in front of the window, and even a policeman went over to see "what was up," and

stayed to admire. A paragraph appeared in the papers, and a good many people wrote (to the lady) asking for roots of her wonderful Iris. When the English and Spanish Iris bloomed she felt delighted; and she still wonders why these really lovely kinds go unregarded in comparison with the admiration lavished on the "smutty looking Susan," as John called it—which was so much admired in the town.—F. W. BURBIDGE.

MARECHAL NIEL ROSE.

IN reading an article on the forcing of the above variety in the Journal by your correspondent, "N.," page 107, I was somewhat surprised at the following remarks—"Keep the temperature of the house from 50° to 55°, as if forced out in strong heat the flower stems come weak and the flowers colourless. Give no ventilation in the early stages of growth, in fact not before April, as the cold air checks their progress and produces that dreaded pest, mildew." Your correspondent may be experienced in the cultivation of Roses, and keeping the ventilators closed until April may be one of the secrets of his success and a preventive of mildew, but I must admit that it is quite an innovation to my mind, and so far contrary to my experience, and I should require the above recommendation endorsed by some well-known rosarian before I ventured to adopt it.

I beg to ask "N." what aspect he would recommend for a forcing house for *Maréchal Niel* Roses, so that the temperature could be kept below 55° to the end of March with the ventilators closed.

I had occasion very recently to visit the gardens of J. C. Reid, Esq., Lady Wood Villas, Roundhay, one of the prettiest suburbs of Leeds, and had the pleasure of inspecting the largest *Maréchal Niel* Rose tree that has ever come under my notice. From a conversation I had with Mr. Beaumont, the gardener, I ascertained that the tree was planted some ten or twelve years ago in a span-roofed greenhouse, 28 feet by 12, in the natural soil of the garden. It is budded on a Briar stock 4 feet high, the stem now in the thickest part measuring 12 inches in circumference; it is trained to the roof, which it nearly covers. The house is heated by one 4-inch pipe round to exclude the frost in winter when the house is stored with bedding and other plants. It has evidently grown remarkably strong when young and been allowed its own way; in fact, from its appearance I should say it has grown almost wild, but flowering so profusely the last few years has reduced its robustness. It produced last year over 2000 blooms. It makes sturdy growths from 12 to 18 inches long, and flowers from almost every joint. It is at present in perfect health, and the young growths are 3 or 4 inches long with buds at nearly every point. Air is admitted freely, the gardener informs me, for the purpose of preventing that dreaded pest mildew, and when I read the article by "N." I became puzzled on the question between the two Rose-growers, and no wonder, one recommending giving all the air possible for the prevention of mildew, and the other keeping the ventilators closed, in fact, until April as a preventive. I forgot to mention that no attempt is made to force the remarkable specimen above alluded to—that may possibly constitute the difference. I should be glad to have the opinion of some of your eminent Rose-growers through the columns of the Journal on this perplexing difficulty.—L. T.

ROSE GRACE DARLING.

ON reading the "Rosarian's Year Book" for 1888, page 36, I found in a chapter on decorative Roses, by Mr. T. W. Girdlestone, the following concerning *Grace Darling*:—"The exquisite *Grace Darling* (which must regretfully be admitted to be a Hybrid Tea—that is to say, for exhibition purposes a Hybrid Perpetual)." I believe Mr. Girdlestone is a member of the General Committee of the N.R.S. On reading page 34 of the National Rose Society's schedule for 1887 I read thus:—"A tentative list of a few Roses which the Committee suggests should be ultimately added to the Society's catalogue of exhibition Roses." Then comes a list of H.P. Roses, and then "Teas and Noisettes, *Grace Darling*, &c." I believe *Grace Darling* was raised by Mr. Bennett, but I do not know its parentage. I am very anxious to know for my own sake and that of other rosarians whether it is a fact that *Grace Darling* is to be exhibited as a Hybrid Perpetual or as a Tea Rose. I have asked this question, thinking some young rosarians may be as ignorant as myself.—HENRY V. MACHIN.

NEW FRENCH ROSES.

(Continued from page 108.)

IN continuation of my remarks upon the new French Roses, we next come to the Hybrid Perpetuals.

SCHWARTZ, VEUVE.

AUGUSTE PERRIN.—Bright cherry red, shaded amaranth.

MORPHÉE.—Flowers globular, bright velvety crimson, shaded bluish purple.

PERNET, PÈRE.

ALBERT LA BLOTAIS.—Flowers globular, nearly full bright red, passing to crimson.

FRANÇOIS DAVID.—Bright red shaded with crimson and violet.

MONSIEUR CHEVALIER.—Flowers nearly full cherry red, tinted lilac.

EUGÈNE VERDIER.

DUK D'ANDRIFFET PASQUIER.—Purplish carmine red, with brighter centre.

DUCHESSE DE GALLIERA.—Flowers globular, of a very fresh bright carmine red.

L'ANI LOURY.—Scarlet crimson shaded with purple and cream; rich velvety texture.

SCIPION COCHET.—Flowers of moderate size, velvety maroon, shaded with brilliant scarlet crimson.

C. VERDIER, FILS.

JAMES BOUGAULT.—A sport from Auguste Mie with white flowers.

MONSIEUR JOURDAN.—Flowers brilliant crimson red; plant very vigorous.

LEVÊQUE.

DIRECTEUR TYSSERAND.—Bright carmine red.

MADAME HEINE-FURTADO.—Flowers globular, bright rose, shaded lilac.

MARQUIS D'ALIGRE.—Vermilion shaded with brown and deep scarlet.

REINE ISABELLE II.—Flowers imbricated, soft and tender, flesh colour.

SOPHIE STERN.—Flowers globular, bright carmine rose red.

GESHWIND.

CEULE SCHARSACH.—Flesh white, passing to white.

NABONNAND.

BARDOU JOB.—Flowers semi-double, velvety scarlet, shaded black, semi-double; a seedling from Gloire de Rosamène.

ROI FRANÇOIS D'ASSIZE D'ESPAGNE.—Imbricated, very deep scarlet shaded with purple.

MOREAU-ROBERT.

CHARLOTTE WALTER.—Flowers cupped; bright shaded rose colour.

KATKOFF.—Flowers imbricated; bright cherry carmine.

LIABAUD.

MADAME ALPHONSE SEUX.—Delicate rose colour, sometimes brighter.

MADAME RICHAUX.—Tender satiny rose.

MONSIEUR NIGARET.—Brilliant amaranth red with purple centre; very vigorous.

PIERRE LIABAUD.—Velvety purple.

SOUPERT ET NOTTING.

CONSEILLER STOCKER, T.—Moderate size; imbricated petals satiny rose; very free flowering.

PRINCE CHARLES D'AREMBERG.—Large petalled satiny rose flower.

MARGOTTIN, PÈRE.

GLOIRE DE MARGOTTIN.—Flowers of moderate size, nearly full; very bright cherry rose.

GONOD.

LOUIS DONADINE.—Dark velvety maroon, shaded crimson; blooms freely in autumn.

SUSANNE CHAVAGNON.—Bright rose-coloured flowers with thick petals; seedling from Baroness Rothschild.

DUBREUIL.

LOUIS LILLE.—Cupped, bright red; between Baroness Rothschild and Firebrand.

BERNAIX.

MADAME CÉSAR BERNAIX.—Medium size; flowers bright china rose.

SOUVENIR DE MADAME FAURE.—Crimson, shaded with rich deep velvety purple.

VIGNERON.

MADAME DE TERROUENNE.—Flowers globular; carnation red a seedling from Jules Margottin.

There are a number of other Roses, Hybrid Teas, Polyantha, Bourbon, &c., but we have been year after year supplied with plenty of these, and with little good results, so I leave them on one side. There is one Rose for which we shall look with interest—a product of *Rosa rugosa*—Madame C. Bruant, raised by Bruant from *rugosa* fertilised with *Sombreuil*—it may indicate a new break. In looking through the list that I have given, there does not seem much to excite our curiosity. It is remarkable how many of the Teas are high-coloured—suggesting perhaps that they are not altogether pure—and, indeed, with the exception of the two sent out by Lacharme and Guillot fils, there does not seem to be anything tempting. Amongst Hybrid Perpetuals nothing strikes me as being novel or out of the ordinary run—but it is all a lottery; descriptions avail but little, raisers' names more; and it is most probable that amongst those sent out by the Widow Schwartz, Liabaud, C. Verdier, and Margottin we shall find the gems we are seeking for, but I shall be very much surprised if we do not find, after all, that the gems are nearer home, and that in such flowers as Earl of Dufferin, and Sir Rowland Hill, we shall find flowers that exceed in beauty and novelty those of our French friends.—D., *Deal*.

ROYAL METEOROLOGICAL SOCIETY.

THE monthly meeting of this Society was held on Wednesday evening, the 15th instant, at the Institution of Civil Engineers, 25, Great George Street, Westminster, Dr. W. Marcet, F.R.S., President, in the chair.

Mr. T. S. Ainge, Mr. J. C. Bell, F.R.G.S., Mr. C. A. Markham, Surgeon-Major S. Smith, Mr. J. T. Tibbles, and Dr. J. Walther were elected Fellows of the Society.

The following papers were read:—

1, "Electrical and Meteorological Observations on the Peak of Teneriffe," by the Hon. Ralph Abercromby, F.R.Met.Soc. The author made a trip to the Island of Teneriffe in October, 1887, for the purpose of making some electrical and meteorological observations, and now gives some of the results which he obtained, which may be summarised as follows:—The electrical condition of the Peak of Teneriffe was found to be the same as in every other part of the world. The potential was moderately positive from 100 to 150 volts at 5 feet 5 inches from the ground, even at considerable altitudes; but the tension rose to 549 volts on the summit of the peak, 12,200 feet; and to 247 volts on the top of the rock of Gayga, 7100 feet. A large number of halos were seen associated with local showers and cloud masses. The necessary ice-dust appeared to be formed by rising currents. The shadow of the peak was seen projected against the sky at sunset. The idea of a south-west current flowing directly over the north-east trade was found to be erroneous. There was always a regular vertical succession of air currents in intermediate directions at different levels from the surface upwards, so that the air was always circulating on a complicated screw system.

2, "Rainfall of South Africa, 1842-86," by Mr. W. B. Tripp, M.Inst.C.E., F.R.Met.Soc. The author gives the rainfall statistics from all those stations situated in South Africa which possess records of ten complete years and upwards. He remarks upon the chronological succession of wet and dry years, and the consecutive years above and below the mean; and also describes the seasonal distribution of monthly maxima, and the extent over which monthly rains prevail. He concludes by comparing the curves of rainfall with those of sunspot energy.

3, "Some Methods of Cloud Measurements," by Mr. Nils Ekholm. As exact cloud measurements afford almost the only easily available means of determining motions in the upper regions of the atmosphere, the author describes some methods which seem to him likely to give the best results. He also details the plans adopted at the Swedish Polar Station, Cap Thorsden, in Spitzbergen, and at the Upsala Observatory, for determining the direction and angular velocity of the clouds, and for making direct measurements of the height and absolute motions of the clouds.

THE BULB MITE.

OUR good Journal is so full of the best advice upon all subjects pertaining to horticulture, that it is only upon a chance occasion that one like myself, with something less than an ordinary complement of talent, can venture to pen a few observations. For the present, however, my thoughts are fixed upon the *Eucharis* mite, so called, but whether or not it has any legitimate right to its title I have yet to learn. I prefer to call it the bulb mite, as it is certainly found among nearly all bulbous plants, more particularly *Liliums*, *Pancretiums*, *Amaryllises*, *Vallotas*, *Hyacinths*, &c.

Very much indeed has been written respecting the mite for several years past, with the result that the cry is more general than ever, "What can we do to get rid of it?" This was the subject of a lively discussion held by the members of the Preston and Fulwood Horticultural Society on Saturday evening, February 4th; and the latest remedy I have heard, and possibly the only one open to us, is to get rid of it in the best way we can, and the sooner done the better. Good advice no doubt, but the most serviceable information is still wanting to carry out the above remedy. At the meeting referred to we had ample evidence of the existence of the mite, and no sane man would or could doubt it. The pest was exhibited by thousands upon *Eucharises* both in pots and out of pots, also upon *Pancretiums*; and although much useful infor-

mation was brought as to the best means of destroying it, I must confess we had to close the discussion feeling that the mite has the best of it.

I purpose asking one or two questions which I hope will receive the careful thought and consideration this important subject deserves, for very recently I have learned that many gardeners are almost at their wit's end through their fruitless endeavours to rid their plants of the mite. Some have thought their bulbs cured, when twelve months later they are affected as bad as before.

First, Does the mite come in the compost in which the bulbs are potted? or is it the result of some check given to the plants, either by resting them in too low temperatures, or a few doses of cold water at the roots?

Secondly, Is it possible that by a judicious system of culture we may not only arrest but entirely stamp out the mite?

These are the points upon which I would like the opinion of some of my more enlightened brethren, and I venture to think that some good may result from a few plain inquiries. I will willingly give my thoughts upon the above question in a future note provided the subject is taken up in the right spirit.—OBSERVER.

WINTER NOTES AT SYON HOUSE GARDENS.

THOUSANDS of persons who during the summer months travel up and down the Thames between Kew and Richmond are familiar with the plain substantial quadrangular building on the Middlesex side near Isleworth known as Syon House, one of the most famed of the Duke of Northumberland's residences in the south of England. The gigantic figure of a lion which stands out boldly on the top of the mansion is pointed to as an almost historical object that so long surmounted Northumberland House at Charing Cross, the verdant lawns and dense shrubberies are admired, and there the general interest terminates. For horticulturists, however, Syon House, its gardens and pleasure grounds, possess many attractions, and though May or June would be preferably chosen for a visit, yet it is surprising how much can be found that is worth noting even on a bleak and snowy day in February.

It often happens that establishments near at hand receive less frequent notices than those at a distance, and Syon is an example of what might be almost termed a species of neglect. The work there is carried out in such an unpretentious manner that it is only occasionally when some wanderer penetrates the mysterious wilds of Brentford, that we hear anything of the ducal garden, although in historical interest and for good all-round practice it is second to none in the metropolitan district. No attempt can now be made to relate its history, but for the benefit of some far away readers it may be as well to state a few facts connected with it. First, then, it may be said that when our energetic monarch, Henry VIII., demolished the monasteries, there was one such institution upon the ground now occupied by Syon which shared the same fate. After the estate had been bestowed upon several persons in succession, including one of the Dukes of Northumberland, it reverted to the Crown, and in Queen Mary's reign was partially restored to its former use. Early in the seventeenth century, however, it was conferred by James I. upon the ninth Earl of Northumberland, and in this family it has now remained ever since. At different times extensive improvements have been effected in the estate, which comprises over 200 acres, about sixty being laid out as gardens and pleasure grounds, but its horticultural interest commenced soon after the middle of the eighteenth century, at the time it was in the possession of Sir Hugh Smithson. The grounds are said to have been laid out and planted from designs furnished by "Capability" Brown, most of the larger specimens dating from that period, though considerable additions have been made since amongst the shrubs and choicer trees. Very rich indeed is the collection of trees and shrubs, and to some of these a few notes may be devoted.

THE PLEASURE GROUNDS.

Though the grounds are naturally level, rising in a gentle slope from the river, yet the most has been made of them by judicious planting and varying the surface as much as possible. The shrubbery walks furnish some delightful shady retreats in the summer; and after spending half an hour or so in traversing these an idea would be formed that the grounds are much more extensive than is really the case. Some beautiful vistas of the river and the Royal gardens, with the great Palm house on the opposite side, are also obtained, the effect being heightened by clumps planted at irregular intervals near the banks, which seen at a distance seem to connect the Middlesex and Surrey shores, especially when the tide is low. Emerging on the open expanse in front of the mansion a beautiful prospect is afforded in the direction of Richmond, with the high ground towards the terrace, from which rises the elegant spire of St. Matthias' Church in the background, the Kew shrubberies, the old Deer Park, and the Thames in the foreground. When the trees are clothed in all the freshness of early summer foliage and glistening under an unclouded sun this is a delightful

spot to linger in, but a keen north-east wind whistling round our ears does not tempt to the indulgence of imagination in February. So hurrying on we note on the way the grand old Cedar of Lebanon, which was so successfully rescued a few years ago. This magnificent tree, which must be counted amongst the finest proportioned specimens in England, was disturbed in a storm and partially overturned, the roots being dragged up for a long distance and the branches on the opposite side touching the ground. By means of various mechanical contrivances it was, however, restored to its former position, and the lower branches are now supported near the stem by stout iron columns resting on concrete, so that there is little fear of a similar accident again befalling it. The roots were carefully relaid, and the tree does not appear in the least the worse for its partial collapse. On the banks of the lake, which by the way is a well designed piece of water, are specimens of another remarkable tree, the deciduous Cypress, *Taxodium distichum*, some of which are nearly 100 feet high, or approaching closely to

of its light graceful branches. When in leaf this is a beautiful tree, and it forms one of the numerous attractions to tree lovers. Liquidambar are occasionally seen in gardens, but rarely of good size, and it is surprising that such handsome trees as these are in autumn, when their leaves are unequalled in rich tints of crimson, gold, and green, that they are not more frequently planted: at Syon are some good specimens 30, 40, and 50 feet high. Hosts of other trees might be mentioned, but an historical Mulberry must not be passed, for it is reputed to be one of the oldest in England, having been planted at the time these gardens were occupied by the Monastery already referred to. In the shrubberies are numberless fine Hollies 12 to 20 feet high, *Ilex opaca*, the distinct *Ilex diplyrena*, and the Highclere Holly being capitally represented. Huge bushes of Box, Laurels, and scores of rare shrubs are also seen, together with several exceptionally fine examples of the Snowdrop Tree, *Halesia tetraptera*, which frequently bear a profusion of pure white bell-like flowers. Of one rare shrub, *Stuartia virginica*, there is a

FIG. 20.—*TAXODIUM DISTICHUM* AT SYON HOUSE.

their full dimensions. Where it succeeds this is a graceful Conifer, the peculiar bright green foliage contrasting very markedly with the darker tint of evergreen trees, and though it looks bare in winter it is useful for planting in damp situations where few other Conifers thrive, and has a most refreshing appearance in the spring and summer. One peculiarity in this tree is admirably shown by a large specimen at Syon—namely, the production of “knees” from the roots extending to 60 feet from the stem. These protuberances, which exactly resemble the roots in structure, are mostly only a few inches above the soil, but in some cases they are said to rise 2 feet above the surface, and have been employed as bee hives in the Southern States of North America. It is somewhat curious that from these “knees” tap roots descend straight into the soil, as if shoots were to be produced, though this does not occur. In the engraving (fig. 20), kindly lent by Messrs. J. Veitch & Sons from their valuable “Manual of the Coniferæ,” the peculiar “knee” characteristic of the Syon *Taxodium* is accurately represented.

A short distance from the conservatory is a fine example of the Cretan Maple, *Acer creticum*, about 40 feet high, with a wide spread

fine bush that is generally regarded as rather tender, but which succeeds well there. It is a North American plant included in the Tea family, and its large handsome white flowers are somewhat suggestive of a single Camellia. It was first introduced to this country in 1742, and in “Andrews’ Botanists’ Repository” (t. 397), an excellent figure was given of the plant which had then just flowered. Another beautiful shrub, *S. pentagyna*, is similar in characters to *S. virginica*, both preferring moist situations. A handsome well-proportioned pair of the deciduous spring flowering Magnolia, *M. conspicua*, stand in the flower garden in front of the conservatory, one each side of a central walk, and every year these are covered with flowers, forming two extremely beautiful objects.

THE CONSERVATORY.

The conservatory is an imposing but rather heavy structure, and like the mansion is built of Bath stone. It is 380 feet long, of crescent form, with two wings and a central dome 60 feet high. In front is the flower garden of semicircular shape, with numerous simple beds and marginal rows of standard Roses. The wings and

connecting divisions of the conservatory are filled with Ferns, Palms, and miscellaneous decorative plants, the central octagon containing the principal plants of interest. One of the most remarkable of these is *Bambusa arundinacea* planted out in a large bed, and so vigorously has it grown that it now forms quite a tropical forest, twenty huge stems 6 to 9 inches in diameter rising to the roof and almost filling the dome with their leaves and branchlets. A gigantic specimen of *Cereus hexagonus* is also secured to one of the columns, and has several stems nearly 60 feet high. An old trunk of the Date Palm, *Phoenix dactylifera*, having reached the roof has been beheaded, and though now bearing no leaves it is retained as a curiosity. At the base of the stem is a large conical mass of roots or fibres, and several feet above this is another globular mass of a similar character, imparting a strange appearance to the stem. The Guava, *Monstera deliciosa*, and other tropical fruit-bearing plants are grown in the same house with a fine specimen of the Caffer Bread, *Encephalartos Caffra*, *Brosimum macrocarpum*, and *Sterculia nobilis*. In one of the wings there is an old and large Loquat, *Eriobotrya japonica*, which has occasionally flowered, but cannot be induced to perfect its fruit.

One occupant of the house, which is rarely seen in gardens, is *Cunonia capensis* (fig. 21, page 157), though it is one of the most beautiful flowering trees that can be grown in a conservatory, greenhouse, or similar structure. Probably one reason why it is scarce is that the propagation has been found rather difficult, yet the tree is of free growth, and attractive even when not flowering, and would well repay for any attention bestowed upon it. The specimen at Syon is believed to be unrivalled in this country, and when bearing some dozens of its long close racemes of white flowers the effect produced is really magnificent. I was fortunate enough to call upon Mr. Woodbridge some time ago when the tree was in its best condition, and though it did not occupy the most favourable position, being partly hidden by other trees and shrubs in front, it was yet surprisingly beautiful. The specimen is about 15 feet high in a large pot, and bears pinnate glossy green leaves, with racemes in some cases nearly a foot in length. The species is, as its specific name implies, a native of the Cape of Good Hope; it has been in cultivation for over sixty years, and the genus constitutes the type of a natural order allied to the Saxifragaceae. The following extract from Burchell's Travels in Africa may be of interest:—"This is a handsome tree, with fine shining green foliage, contrasted by numerous, dense, elongated bunches of small milk-white flowers, and twigs of a red colour, having the habit rather of a tropical than of a Cape plant. Its colonial name is Rood Elze (Red Alder), although the tree has not, in any point of view, the least resemblance to the Alder of Europe; but the waggon-makers say there is some similarity in their wood. I am inclined, however, to believe that the name was given rather in consequence of their growing in similar situations."

THE KITCHEN GARDEN AND HOUSES.

The kitchen garden is some distance from the conservatory, being situated nearer the Brentford Road, and adjoining a public footpath leading from there to Isleworth. Between three and four acres are enclosed within high walls, and outside these about another acre has been recently taken under cultivation, the whole being closely cropped with the best vegetables. The walls are clothed with fruit trees, fine collections of Cherries, Peaches, and Pears being included, all admirably trained. The surface of the walls was for some years covered with cement, but the trees were so unsatisfactory that it has been removed, the walls re-faced or re-pointed, and the trees have since succeeded as well as could be desired. Morello Cherries are grown in large quantities, and after the Pear Conference at Chiswick a collection of the best varieties there observed was added, and these are now grown as single upright cordons on one of the walls. Bush and other Apple and Pear trees are also planted in the lower portion of the kitchen garden near the walks, and yield useful supplies of fruit.

The principal glass houses are in one range extending across the centre of garden from west to east, and nearly 400 feet in total length, but all the houses are not connected. Most of these formed part of the first great range constructed in this garden in 1826 under the superintendence of the gardener, Mr. Forrest. They have a metallic framework, and were originally heated with flues, though of course that method has long since been superseded by hot-water pipes. It is said that the houses were completed and planted within eight months, and Loudon states that in the second year ripe Grapes were cut in the early vinery on April 19th, "when they were worth in London a guinea and a half per pound," ripe Peaches being gathered in May weighing 7 to 9 ozs. each. The houses were built for Pine pits and forcing purposes generally, but Pine culture has now been discontinued for many years, and they are used as vineries, Peach, Fig, and Rose houses. The first of three divisions at the west end of the range is an old vinery, the

Vines (Black Hamburg) having been planted in 1851, and several times cut down or lifted; they still produce strong canes from the base, and have hitherto fruited well, but cannot be relied upon, and will be superseded another season by young Vines. The second division is also a vinery, which has been renewed, and the front raised so as to allow of ventilation there. Roses occupy the third section, the trees being planted outside in a good border, and the stems taken in through the walls just like Vines. Madame Berard, William Allen Richardson, Niphetos, Gloire de Dijon, and Cheshunt Hybrid are the favourite varieties, and of the last-named there is an uncommonly large specimen that has been lifted and replanted with considerable advantage, the tree being now in fine condition and showing flowers freely. In an early Peach house the blooms are setting well, especially on a very old Elruge Nectarine, and the back wall is covered with Camellias trained to a trellis. This is found to be a convenient arrangement, as the plants make an early growth and come into flower about Christmas time when Camellias are valuable. A late Peach house in another portion of the range contains some well-trained, healthy, fruitful trees, and there Roses are trained to the back wall, giving a succession to the house already mentioned. Royal George Peaches, with Elruge and Lord Napier Nectarines, are mainly relied upon under glass, while of Figs, to which a house is devoted, abundant crops are obtained from young and old trees of Brown Turkey planted out in borders. Several other varieties complete this range, and then comes a series of lean-to pits employed for forcing Beans, plants, and temporary Vines. The latter are managed in a very simple manner. They are planted in a central bed and trained to the roof, both up and down, leaving clear spaces over the front and back shelves, and after one good season's growth they are fruited freely for one or two years. An adjoining pit is worked alternately with this, so that as the Vines are cut out in one those in the other are fruited, and this is found to answer better than growing Vines in pots. Amongst the miscellaneous plants forced in these pits the old Sprekalia, or *Amaryllis formosissima*, is very notable. Three to four bulbs are grown in a 32-sized pot, and at the present time are producing their rich scarlet flowers freely.

At the back of this range are the potting sheds, Mushroom house, bothy, and various offices, all conveniently arranged. In the Mushroom house the shelves are formed with iron plate fronts and T-iron supports, upon which tiles are placed to hold the beds, the lower space covered with wooden shutters on hinges being devoted to Seakale and Rhubarb forcing, with any salading that needs blanching. The bothy is a convenient one, a bath room and lavatory heated with hot water being attached; and not only is the personal comfort of the young men considered, but provision is also made for their educational improvement, as a schoolmaster attends several evenings a week during the winter to give courses of plain instruction on useful subjects. Too seldom do employers recognise the benefits they can confer upon those in their service by such consideration and assistance, and the advantages they gain themselves by the greater interest manifested in the work of the establishment.

HYMENOCALLIS MACROSTEPHANA.

In the northern portion of the kitchen garden within the walls are numbers of useful houses, forcing pits, and frames devoted to Cinerarias, Primulas, and miscellaneous plants for decorative purposes. Amongst Orchids there are some large specimens of *Ceologyne cristata*, *Cymbidium Lowianum*, *Cypripediums*, *Aerides*, and excellent pans of *Pleiones*. *Anthurium Schertzerianum* is represented by numbers of healthy plants, but a most remarkable feature is afforded by a house full of *Hymenocallis macrostephana* for which Syon is celebrated. It is about nine years since this plant was brought prominently into notice, but even now it is unknown in many gardens where it would be greatly valued when its qualities were known. The origin of the plant is unknown, but it is believed to have been first sent to this country from a continental nursery as *Panacratium fragrans*, and Mr. Baker has hinted that it is possibly a garden hybrid between *Hymenocallis caribæa* and *Ismene calathina*. In 1879 specimens were sent to Kew by Sir Philip Egerton, who stated that his gardener, Mr. William Muir, had recognised its distinctness from *Panacratium fragrans* two years before, and by Mr. Woodbridge; it was also exhibited by the latter at South Kensington, being first awarded a botanical certificate and subsequently a first-class certificate. The plant was fully described under the name given above, and an excellent coloured plate was published in the "Botanical Magazine" for July of the same year (t. 6436). The flowers are much like a *Panacratium*, but with a broad funnel-shaped corona 3 inches across, and, like the long linear segments, is pure white. They are produced in umbels of six to twelve, the majority of these open now averaging eight or ten each, and the fragrance is peculiarly sweet and distinct. Another advantage respecting the plant is that though it naturally flowers in February, yet it can be

had in flower at almost any season of the year; in fact, there is a constant succession if bulbs in different stages are potted together. This *Hymenocallis* is treated exactly the same as *Eucharis*, and both grows and flowers freely; it is also readily increased, as the offsets are produced in numbers.

Convenient pits are employed for forcing Strawberries, of which about 3000 are required annually of the varieties Keens' Seedling, President, and Sir Joseph Paxton, which afford a succession in the order named. The pots are half-plunged in beds of leaves quite near the glass, and the plants are looking extremely promising. The chief other houses are on the south side of the north wall, lofty curvilinear structures employed as vinery and Banana houses. *Musa Cavendishi* is grown in the latter, planted out in beds of rich soil liberally supplied with water and heat. Vanilla is also extensively grown and abundance of fruit is obtained, at the present time there are several large bunches of the long pods ripening. The Vanilla is planted in narrow shallow troughs near the top of the back walls and at the side of the houses, the growth being very vigorous and well matured.

It only remains to add that Syon garden has been under the charge of Mr. Woodbridge for seventeen years, during which time his strict attention to his employer's interests and his kindness of manner have gained him many friends. He has this week been appointed a member of the Council of the Royal Horticultural Society, and by a strange coincidence a former gardener at Syon House—Mr. Hoy—was elected a member of the Council formed when the Horticultural Society received its first charter of incorporation.—LEWIS CASTLE.

FRUIT AT THE NEWCASTLE SHOW.

MR. GOODACRE places himself in an unenviable position when he publicly attempts to throw ridicule upon the exhibits of his successful rivals. The authenticity of his statements are challenged, as has been the case in his allegation of "Warner's King Apples" and "Green Citrons" forming part of the collection of fruit that won the Jubilee prize. He now finds it convenient to ignore the subject altogether, not even attempting to substantiate one of his charges. I can only judge of the Pears grown at Elvaston by those exhibited at Newcastle, and if they are to be taken as a fair sample of his productions then the less said about them the better. Your representative at the Show must have correctly described these when he stated Mr. Goodacre "was not exhibiting in his usual style." He appears to find some comfort in saying, "I am the only exhibitor who staged fifty dishes of ripe fruit, as stipulated, for the Jubilee prize." Rather strong language this, but notwithstanding, I venture to challenge him to name a single dish in either of the collections awarded the first and second prizes that was further from being ripe and fit for use than was the dish of green Louise Bonne of Jersey Pears in his own lot. With your permission I beg to submit this question to the decision of the two gentlemen who officiated as Judges upon the above named three collections, and let honour go to whom honour is due.

Beyond all question the Tomato is a fruit; whether Dr. Hogg includes or excludes it from his "Fruit Manual" will in nowise alter the fact, any more than it would do in the case of Melons or Oranges being considered fruits. There are more ways of eating Apples than eating them from the tree; so likewise with Tomatoes, the precise form in which we partake of them being simply a matter of taste.—AN OLD HAND.

SELF-IMPROVEMENT.

IN the *Journal of Horticulture* of February 9th "Experientia docet," in his "Plain Words to Some Gardeners," has broached a subject of the very gravest importance to all who hope to attain success in life, and especially to those to whom it is addressed—viz., some professional gardeners.

This illiteracy of head gardeners is more prevalent than is generally supposed, and when it affects themselves only it is bad enough, but when it proves detrimental to those employed under them it is much worse. Of this fact I am painfully aware, for unfortunately it has been my lot to serve under no less than three head gardeners who could not write a decent letter of recommendation, and this in establishments where eight or ten men were employed. Now, as all gardeners know, this is absolutely necessary when a young man applies to any of the nurseries for assistance in obtaining a change of situation, for invariably the usual form is received to be filled up and returned with a letter of recommendation from the head gardener. The inability of the head gardener to comply with this request, however good his intentions may be towards the young man, places that individual in a difficult position.

In view of these facts it is much to be deplored that gardeners, and especially young gardeners, should be so blind to their own interest, and so careless of their future welfare, as to neglect the many opportunities which are afforded at the present time for self-improvement. At no time in the history of this country, and probably in the history of the world, was the necessity of education so important and the means of obtaining it so accessible as now. No time also in the career of a gardener is so propitious for self-education as the years of his apprenticeship and bothy life—years which all qualified gardeners must pass

through on their way to preferment. Yet it is painful to relate that in instances innumerable those years, the best a gardener will ever have, when his opportunities are greatest and his cares and responsibilities least, are generally wasted in the pursuit of the most thoughtless and unmanly frivolities, if nothing worse.

During my career as a gardener it has been my lot to live in several bothies and to have an intimate knowledge of many more; and I do not recollect one instance where a young man systematically devoted the whole or part of his evenings to self-improvement. In some cases, it is true, I have come across those who have made spasmodic efforts to learn French, Latin, and even Greek, but their ambition to become linguists was generally extinguished before the expiration of many days. My knowledge of their attainments has led me to the conclusion that the time spent in this way would have been better employed in the endeavour to acquire a decent acquaintance with their mother tongue. I have also in my travels met with young men in bothies who, finding the time hang heavy on their hands during the long winter evenings, have expressed a desire to take up some kind of study, and I have been asked to suggest a subject. In complying with a request of this kind I once recommended the course of "Lessons in English" in Cassell's "Popular Educator," knowing it to be a subject of great importance; and I even went so far as to offer the loan of my volumes for the purpose. This suggestion was, however, scornfully scouted, the person in question declaring indignantly that he "learned all that at school." This, however, was more than doubtful, for many were the half hours I had had with him when at breakfast he has insisted on reading to me paragraphs of news from the morning paper. His pronunciation was not pure, and manifestly he did not always understand the meanings of the words he tortured.

Occasionally I have found young men in bothies who have studied in a dilettante fashion such useless things as phrenology, physiognomy, and the like; but, strange as it may seem, I have never yet met one who studied in any way whatever the science of botany. This is to be deplored, for there is, I presume, no science, the pursuit of which is more healthy, more fascinating, and more eminently useful to a gardener than this. It is intimately associated with his everyday work, and its value to him cannot be over-estimated.

Before I close this article I would like to mention one means of self-improvement, of which I have taken advantage, and of which I recommend all young men to take advantage, if they wish to seriously engage in the task of self-education. It is shorthand—and when I say shorthand, I mean Mr. Pitman's phonography. I commenced the study of this system of shorthand eight or nine years ago, and in a short time obtained a certificate of proficiency from Mr. Pitman. I have used it almost daily ever since, and to it alone I owe the ability, such as it is, to write this article, and numerous paragraphs of news which I contribute weekly to a certain paper in my capacity of local correspondent. It has been to me the "open sesame" of the storehouse of knowledge, in that the study of it has created in me habits of patient application, without which nothing can be achieved. It has also strengthened my memory, and led me unconsciously into the subjects of spelling, grammar, and composition, subjects with which I had previously but a very slight acquaintance. I would therefore advise all young gardeners to learn phonography. It is easily acquired by persons of ordinary capacity, and though no one not a phonographer can estimate the pleasure to be derived from the ability to trace fluently the beautiful characters, they may be able to see the practical use to which it may be put in keeping a commonplace book or diary, instead of the ordinary tedious system of writing.—G. B.

"EXPERIENTIA DOCET" has reopened the question of gardeners' defective education. The British gardener is in a state of evolution; he is in a great measure what his environment has made him, and as a matter of course the impress of his surroundings will leave its mark upon him in the future as in the past. So far as defective composition and blundering spelling are concerned the march of education will provide a remedy, but it will not solve the problem which faces us when we take the question in all its bearings, from the gardener of the duke down to the single-handed gardener. This problem is, Can we combine the high standard to which a gardener may attain in a profession which gives scope to the highest intellectual capacity with the social status of a mere servant in the light of which a great portion of employers view their gardeners? It will at once be seen what a serious obstacle confronts us if all gardeners are to be educated to a high standard. It goes without saying that when employers can get a more intelligent class of gardeners for the same amount of remuneration they will of course take advantage of the opportunity, and neither gardener nor employer be the worse for it. But let us look at things as they are at present. We shall find that, generally speaking, as we descend in the scale of establishments, there is not in the same proportion a corresponding deterioration in the capacities of the men who preside over them. If employers engage the ignorant and incompetent when there is abundant good men to choose from, it is more the fault of the system under which gardeners have been engaged than the lack of really good men. If ignorant men get pitchforked into good places the superior men, for the want of influence, are often driven to accept situations considerably below their capacities and merits, hoping that by their industry and talents to work themselves into a decent position by improving the places under their charge and getting credit for so doing. Some few succeed, but how many fail because neither sympathy nor

confidence is accorded to them by their employers, the garden being looked upon as a convenient sort of shop to supply the family with fruit and flowers, &c., at the cheapest rate, and otherwise being looked upon as an expensive necessity, being as it were part and parcel of the establishment, and must have the semblance of being kept. Under these conditions the gardener's position becomes irksome, to which may be added the whole catalogue of petty annoyances incidental to such a position, one of the worst being, that whilst the gardener is looked upon as a sort of useful labourer, the inhabitants of flunkeydom and the stables are pampered in everything, and by reason of better pay and its equivalents, they are tacitly allowed to assert themselves as the gardener's superiors. If by the sheer force of character he avoids falling to their level, he places himself between two stools; he will have considerable difficulty to repel invasions of his legitimate rights in the garden proper, to which, if he submits, he loses his self-respect, and if he does not submit he will eventually become the victim of their intrigues. This sort of thing is the "gall and vinegar" which makes the bonds of servitude so bitter, and which a high standard of education of itself would rather intensify than mitigate. It is no use blinking the fact, our position is that of a servant purely and simply, a little lower than the position of the artisan. How is it that other classes of the community combine to make their influence felt? I have no desire to raise the bugbear of trade's unionism with its pernicious doctrine of strife and strikes, which under no conditions could be applied to gardening and gardeners, I would rather trust to the united voice appealing to the newer doctrine of "Right prevailing over Might," which is now bringing about the general improvement and amelioration of mankind. That the force of public opinion is now becoming the arbiter, not only of differences between employer and employé, but it is also, in a large measure, the ruler of events both social and political, inclines us to the opinion that if gardeners were organised to give effect to their aspirations, it could be made the engine to lift them on to a higher social level. It is an axiom that "Knowledge is power;" so also would unity multiply that power in the proportion that as a man standing alone, no matter how eminent he may be, he represents but a unit; where if he call upon others to join him, he multiplies his own individuality, and by the force of his knowledge lifts up the others to his own level. It is this sort of levelling upwards which we require. That there is abundance of good material in the aggregate for the beginning of this movement there can be no doubt. To the ignorant and lazy I would give fair warning, to which, if they paid no heed, I would trust to the law of the survival of the fittest to push them out of existence.

The question now arises, By what means can this revolution be brought about? I answer, By organising a National Horticultural Society embracing the whole of the United Kingdom, something on the lines of the "Yorkshire Association of Horticulturists," of course, with higher aims and further reaching in effect. An example might be taken from the Foresters and other friendly societies, with individual societies wherever practicable, with districts parcelled out so that a *bonâ fide* representative body to discuss matters of special interest for the general good. In addition to practical essays and discussions thereon, and the further extension of the library movement to the fullest extent, by the combination of districts, botanical and other teachers might be engaged. Every district at least should be the headquarters of a Natural History Museum, giving prominence to such subjects as entomological specimens injurious to garden and farm crops, and models of pomological specimens.

If gardeners would really bestir themselves, taking into confidence their employers, and show them that the movement was for their mutual interests, both sympathy and substantial help might be accorded. Once they are convinced of its genuineness a greater degree of confidence would be established between them, which would make them more accessible in all cases of difficulty; and many a misfortune could be explained where for want of this confidence it would probably be magnified into a fault. A better state of things would eventually be the result. The gardener with a good library at his service, opportunities for joining in discussions, giving more confidence and a better address, a knowledge of physiological botany, and able at all times to give an intelligent reason for effects by tracing them to their true causes in matters relating to the garden, with the whole fraternity of gardeners at his back, would no doubt rise above his fellows in the same establishment, and he would thus be better able to hold his own. So, as you may see, Mr. Editor, the only difference between "Experientia docet" and myself is a difference of methods, his being isolation and self-schooling, mine combination, unity, and general advancement.—GAMO.

"EXPERIENTIA DOCET" has not spared the rod in his castigation of illiterate gardeners, and I shall be much surprised if he does not have some bad writing and spelling to wade through in the next few days. But has he not made a mistake in supposing that all men are endowed with the same natural gifts? I have no doubt he has penned his remarks from actual experience, but one can hardly understand men in good positions as gardeners making such public displays of their ignorance as pointed out. I know some good gardeners and unassuming men who have told me it is a laborious business for them to sit down and write a letter, but neither of these men would think of publicly exhibiting their inabilities, and I think they do their gardening work with enthusiasm and regard the other part as quite a secondary affair. Still, they are good servants for all that. Has not your correspondent started this controversy rather late in the day? The men he has brought

to the pillory, I take it, had but a poor education. I quite agree that they might have gone to some evening classes, as I did until I was twenty-five years old; but the rising generation of gardeners ought to be good scholars, seeing that the Board School officers look after even the poorest lad's education. Even then there will be some illiterate men, who will still get good situations, while others who have tried hard to fit themselves for good places will have to stand aside. I know this is the experience of some good men, and also of one who left school at the age of ten, when copy-books were 10d. each.—D. T.

I WAS much pleased with the leading article on page 99. It contains capital advice for us all, and should be the means of making some of us try and improve ourselves. There are few young men that have the same opportunities for improving themselves that young gardeners have. If a young fellow has an average amount of ability, and continues to be a dunce all his life with so many opportunities within his reach, it is his own fault. It is quite true—as stated in the article in question—that there are many gardeners holding good places that cannot write an intelligent letter to their employers or to anybody else. It is a pity when such is the case, as such men lower the standard of gardeners; and gardeners, as a rule, are in my opinion the most intelligent class of people on the face of the earth.—P. C.

CHRYSANTHEMUM W. G. DROVER.

MESSRS. W. & G. DROVER, Fareham, Hants, send us two large blooms of the Japanese variety which was awarded a first-class certificate at the January Show of the National Chrysanthemum Society. This seems to be naturally a late-flowering variety, and is much better now than it was in November. The florets are 3 to 4 inches long and half an inch broad, incurving, white, streaked with purple.

CHRYSANTHEMUM SHOWS.

WE have received notices of the following fixtures for the Shows of 1888:—

National Chrysanthemum Society, September 12th and 13th; November 7th and 8th; and January 9th and 10th, 1889.
 Kingston-on-Thames, November 6th and 7th.
 Portsmouth, November 7th, 8th, and 9th.
 Brighton, November 13th and 14th.
 Putney, November 13th and 14th.
 Winchester, November 13th and 14th.
 Lindfield (Sussex), November 15th and 16th.
 Sheffield and West Riding, November 16th and 17th.
 Birmingham, November 21st and 22nd.
 Liverpool, November 21st and 22nd.
 Hull, November 22nd and 23rd.
 Pontefract, November 23rd.

NATIONAL CHRYSANTHEMUM SOCIETY.

AS stated last week, an important meeting of this Society was held at Anderton's Hotel, Fleet Street, on February 13th, but we could only give a brief reference to the business then transacted. There was a large attendance of the members of the General Committee, including the representatives of several affiliated provincial shows, R. Ballantine, Esq., presiding.

The principal matters for consideration at the meeting were the Provincial Show and Catalogue schemes, which have been previously alluded to. The Hon. Secretary, Mr. William Holmes, read the following report with regard to the

PROVINCIAL SHOW.—Pursuant to the resolution passed at the annual general meeting, "That the whole question of a provincial show be referred to a Sub-Committee, to consist of Messrs. Bevan, Wynne, Castle, Dean, Gordon, and Rundell, with the officers, to consider and report to the General Committee," the Sub-Committee now report that they met on Friday, February 3rd. The whole of the correspondence that had transpired was first read, and then the question as to the desirability of this Society holding a provincial show was debated in all its bearings, with the result that your Committee unanimously arrived at the opinion that it is most desirable in every way that the National should hold provincial shows, providing the Society can be secured against heavy or substantial loss in so doing.

It was further agreed that several Societies in the North should be communicated with, with a view of ascertaining their opinions as to the desirability of holding provincial shows, and also their willingness to co-operate in the matter. Amongst the towns so selected were York, Sheffield, Leicester, Newcastle, Manchester, and Darlington.

The following basis of terms was then agreed upon to enable the Secretary to institute negotiations with any society that might be

desirous of inviting the National to hold a provincial Show in conjunction with their own—viz.

medals and cash, not less than one-third more than the sum guaranteed by the local Society.

FIG. 21.—CUNONIA CAPENSIS. (See page 154.)

1.—That the local Society should guarantee the National a stipulated sum towards the Prize Fund for the provincial show.
 2.—That the National should undertake to offer a sum for prizes in

3.—That an equal number of judges should be appointed by each Society, the judges themselves selecting a referee.
 4.—That the local Society undertake all the expenses usually attend-

ing a good Chrysanthemum Show, and also the general arrangements, with the exception of those on the show day itself, which shall be carried out conjointly.

5.—The local Society to take all gate and ticket money, and the National to receive one-third of the actual profits, if any, resulting from the Show.

6.—All members of the N. C. Society to be entitled to compete or visit the Show free of charge.

7.—The Show to be styled, "The Provincial Show of the National Chrysanthemum Society, held in conjunction with the exhibition of the local Society."

An adjourned meeting of those present on February 3rd was held on February 13th to consider the further information and replies from the northern Societies. The replies from the several northern societies were read and considered, with the result that your Committee unanimously recommend that the provincial show for 1888 be held at Sheffield upon the basis of terms already suggested, and the invitation of the Sheffield and West Riding Society as set forth in Mr. Woodcock's letter of February 8th.

The adoption of this report having been formally proposed and seconded, Mr. Holmes read several letters received from the Hon. Secretary of the Sheffield and West Riding Chrysanthemum Society, which indicated what an enthusiastic interest was being aroused in support of the scheme, and it was unanimously resolved that the report be adopted and referred to the Sub-Committee previously appointed to carry out the details.

THE NATIONAL SOCIETY'S CATALOGUE.—Mr. Holmes also read the annexed report respecting the proposed new Catalogue, which was at once adopted.

A Sub-Committee of Messrs. Castle, Gordon, Dean, Harman Payne, and Wynne was appointed at the annual general meeting, January 31st, to consider and report to the General Committee as to the best method of preparing and publishing a new Catalogue. The Sub-Committee met on Friday, February 3rd, the whole of its members being present, also Mr. Ballantine and W. Holmes as officers of the Society, and report as follows:—The Sub-Committee have fully considered and discussed the question of a new Catalogue in all its bearings, and now recommend

A.—That the contents of Catalogue shall include

- 1.—A preface and statement of the procedure adopted in the preparation of the work, giving also the names of all those who have officially assisted in its compilation.
- 2.—A condensed history of the Chrysanthemum, to occupy about two pages only.
- 3.—Selected and full descriptive lists of the best varieties of Chrysanthemums for exhibition purposes in the following sections—viz., Incurved, Japanese, Japanese Reflexed, Reflexed, Large Anemone, Japanese Anemone, Pompons, Pompon Anemone, each section to be preceded by a typical illustration and brief description of its general characteristics.
- 4.—A complete alphabetical list of Chrysanthemums, with synonyms in italics, also indicating section to which each belongs; and, further, an abridged description of all those varieties not included in the selected lists.

B.—That the following procedure be adopted in preparing the work.

- 1.—That a Catalogue Committee of thirty be appointed, to consist of amateurs and gardeners only, each to be of acknowledged Chrysanthemum repute, but not necessarily members of the Society.
- 2.—That a copy of the present Catalogue be sent to all these members, with the request that each would make a supplementary list of any varieties that have come under their notice and are not included in present Catalogue, and also to indicate, both in the Catalogue and supplementary list, those varieties they consider worthy of culture for exhibition purposes, marking those suitable for specimen blooms with an X, and those for specimen plants with an O.
- 3.—That a Revision Committee of three be appointed, with power to call in such further aid as they may require, to receive the returns from the Catalogue Committee, tabulate and revise them, and prepare for the press.

C.—That advertisements be accepted on the following terms—30s a page; 18s. half page, and selected positions by agreement.

D.—That tenders be invited for printing the work, and that it be published at 1s. per copy.

E.—That the Catalogue Committee be constituted as follows—viz., Messrs. Molyneux, Gordon, Payne, Orchard, Woodcock, Herrin, Shoemsmith, Woodgate, Garnett, Cox, Lyne, Gibson, Parker, Dyer, Beckett, Sanderson, Wright, Flight, Jukes, Martin, Sullivan, Mease, C. J. Salter, Ridout, Udale, A. Salter, Castle, Kendall, Mardlin, King. The Revision Committee to be empowered to fill any vacancies that may occur.

F.—That Messrs. Castle, Gordon, and Harman Payne constitute the Revision Committee, with the latter as Secretary. This Committee to be empowered to engage such paid clerical assistance as they may require.

FLORAL COMMITTEE.—The miscellaneous business included the election of the Floral Committee, the following fifteen being elected out of eighteen nominated—viz., Messrs. Stevens, Dean, Mardlin, Owen, Bevan, Gordon, Gibson, Cannell, Gilbey, Addison, Swift, Wright, Kendall, Castle, and Boyce.

DATES OF SHOWS AND MEETINGS.—The following dates were agreed upon for the metropolitan shows:—September 12th and 13th; November 7th and 8th, 1888, and January 9th and 10th, 1889. The Floral Committee will meet on September 12th, October 10th and 24th, November 7th and 21st, December 5th and January 9th.

Some alterations were made in the rules, and a bye-law was carried to the effect that members desirous of withdrawing from the Society must signify their intention before September 1st. It was also resolved that no affiliated Society should be allowed to have more than ten medals except by special arrangement. Several new members were elected, and the Tiverton, St. Neots, Hinckley, and Faversham Societies were affiliated. The consideration of the schedules and appointment of Judges was referred to a Sub-Committee, and the proceedings terminated with the usual votes of thanks to the Chairman and Secretary.

AURICULA PAGE'S CHAMPION.

THE replies in the Journal to my inquiry about Auricula Page's Champion, as well as more than one private communication, convince me that I have the true variety. Descriptions, too, in old books of various dates all confirm the opinion, among these the following from the "Midland Florist" for 1847:—"Fine tube and paste; ground colour rather broad, a brownish crimson; the green vivid and fine; pips round and flat; the pip frequently cracks through the paste. Champion in its best style is worthy of its name. The plant is of small habit, but a fine trusser." Champion is an older flower than I thought, as Sweet's plate and description appeared, if I remember rightly, in 1827.

Some other varieties make with me less satisfactory plants than this. Countess of Wilton, for instance, I can make but little of from its persistently sending out small offsets. Talisman, too, and Conservative require watching from the same tendency. George Levick and Lancashire Hero are comparatively weak growers. The last I am told is to be found vigorous in England; I have never seen it so in Scotland.

Your correspondent, who obligingly answered my note, inquires as to the existence of Page's Duchess of Oldenburg and Lord Hill. Of the latter I can learn nothing, but the former is to be found in the north. I had it myself some years ago and gave it away. I may add that one friend has been lately looking without success for Heady's Conductor; another wonders whether Pearson's Badajos and Liberty are still to be met with, and I have failed to get hold of Stretch's Alexander. The last I have seen in only one catalogue, and that some years ago.—W. KILGOUR, *Blair Drummond*.

UNDER GARDENERS.

IF an under gardener ventures to put forth in the columns of any gardening periodical a complaint of the treatment he has received, or is receiving, he is taken to task by under as well as head gardeners. My opinion of some of the letters from under gardeners taking down their less fortunate brethren is very poor, and I trust they may never have occasion to complain of the harsh treatment many suffer; and it is very rarely that a head gardener says a word in favour of subordinates.

I had the pleasure of serving as foreman for eight years under three of our best English gardeners, and two years under one of our worst. Would your readers believe that this man, if I may call him such, had fourteen foremen under him in six years, and journeymen out of number? Were they all bad? I stuck to my post and won golden opinions of all except this man. I might write columns of the treatment we experienced, also of the means we tried to win his good will, but all to no purpose. If his eye should catch this, I trust he has reformed. Might I say here that Mr. W. Bardney's name was often mentioned by the journeymen under me for the kind way he often stood up for under gardeners.

How often do we see a thoroughly honest and experienced foreman sacrificed to ill-will, and sometimes jealousy. In my opinion no gardeners should be allowed to condemn a man unheard by the employer of both.—A HEAD GARDENER.

FRUIT FORCING.

VINES.—*Early Vines in Pots*.—Early Vines must not sustain any check through dryness. Top-dress with rich turfy loam and decayed manure in about equal parts, placing rims of zinc or lead 3 or 4 inches deep round the tops of the pots, or, if the pots are plunged to the rim in fermenting material, strips of turf about that thickness should be laid so as to form the necessary dish. In order to encourage the swelling of the berries keep the laterals below the bunches somewhat closely stopped, allowing more liberty to those above them, but avoid overcrowding the trellis with foliage that cannot have full exposure to light. With the Grapes approaching the stoning process careful treatment is necessary. Ventilate early in the day, affording a little air at 70°.

increasing it with the heat to 85° with sun, closing at 80°, and if an advance follow to 85° or 90° all the better. Avoid cold draughts, they are more prolific of decay than anything else. If red spider appear paint the return pipes with sulphur. Afford liquid manure a few degrees warmer than the house in which they are growing, applying it also to the turf placed around the sides of the pots, as also the plunging material where the roots are allowed to find their way from the bottom of the pots, there being nothing like plenty of feeders to secure well-filled berries.

Early Forced Planted-out Vines.—Those started early in December must have the berries thinned, and no time should be lost in doing so as soon as it can be seen which are properly fertilised by their taking the lead. Endeavour to obtain compact bunches, tying up the shoulders in preference to taking out a quantity of berries. Remove superfluous bunches unflinchingly, seeking a full crop of well furnished bunches, properly swelled, and perfect in colour and finish, which are much more creditable than an enormous crop of red berries, as is sometimes seen. Allow the laterals to extend beyond the fruit as far as is consistent with the exposure of the foliage to light and air, tying and stopping as required. Afford a thorough supply of tepid liquid manure to the inside border at intervals as required to maintain the soil in a thorough moist state, and mulch with 2 or 3 inches thickness of short manure and as fresh as is safe, for, although a moderate amount of ammonia is beneficial, when too powerful it is productive of serious injury. The night temperature should range from 60° to 65° at night, 70° to 75° by day, with 10° to 15° advance from sun heat, commencing to ventilate from 70°, closing between 80° and 85°, damping all available surfaces well at the time. Do not syringe the foliage, as, however clear and soft the water may be, there is danger of sediment—a deposit on the berries; and though it may escape observation until the Grapes begin to finish, it is certain to then appear as a serious blemish. The outside border must be well protected against the chilling effect of snow and cold rains.

Vines Started at the New Year.—Dishud the Vines now the best shows of fruit can be determined, and it is not wise to be in too great a hurry about this work, nor in tying the shoots to the trellis, which must be done carefully, so as not to detach the shoot at its base nor cause it to snap by bringing it down too sharply at the point. Remember also that the object of dishudding is to give the growths full exposure to light, it being better to err on the side of too little rather than too much, or overcrowding the foliage. Stopping too should not be done too hurriedly. Allow at least two and if possible three or four joints beyond the bunch, and stop all laterals below the bunch at the first joint, or they may be rubbed off except from the two lowermost leaves. The laterals from these should be pinched at the first joint, but those level with and above the fruit may be allowed to extend as space admits. When in flower afford a night temperature of 65° to 70°, with 10° to 15° rise from sun heat, closing at 80°. Vine flowers set best when the atmospheric moisture is not excessive. An over-moist or a dry atmosphere must be equally avoided. Muscats require a somewhat higher temperature and drier atmosphere than Black Hamburgs when setting, artificial impregnation being practised with all sby-setting varieties, particularly Muscats, which are often deficient of pollen, or if plentiful a better set is secured by fertilising every bunch carefully with Black Hamburgh pollen than when their own is employed.

Late Vines.—A long season of growth is required by late Vines, as to insure the Grapes keeping well they should be fully ripe by the middle or end of September. To effect this start the Vines at the end of February or the beginning of March. Let the inside border be well supplied with water at a temperature of 85° to 90°, and if there are fermenting materials at command a bed may be made upon the border, which will lessen the necessity for fire heat and induce a regular break. The rods should be sprinkled two or three times a day, maintaining a night temperature of 50° to 55°, and 65° in the daytime, by which means the Vines will start freely and there will be every chance of the Grapes becoming thoroughly ripe by September, even such varieties as Gros Colman, the most noble late Grape, and Gros Guillaume, which require a month or six weeks more time to ripen thoroughly than Lady Downe's and others. As a general rule all houses of late Grapes must be started not later than the end of next month, hence they should be prepared as soon as possible, washing the woodwork, dressing the Vines, removing the loose surface soil from the border, and supplying with fresh, to which has been added a sprinkling of crushed bones. We may mention that we have seen great benefits derived from applications of artificial manures, having tried most of those advertised and have found all good, indeed they are preferable in some instances to stable or farm-yard manure, as they have not the tendency to leave a deposit of soapy matter behind. The outside border should be protected against chill from falls of snow or heavy rains and frost. A moderate covering only will be necessary.

Late Houses of Black Hamburgs.—Keep these houses cool and dry not allowing the border to become dust dry and crack, but a moderate amount of moisture only will be necessary to preserve the roots in sound condition. The only precaution necessary is to ventilate fully at and above 50°, and when that becomes the mean of the external air, or a little before, the Vines will break naturally, which usually takes place during April; the only assistance required is to maintain an artificial temperature of 50° to 55° at night and on dull days. The Vines will set their crops by the early part of June, and swell them with sun heat, artificial heat only being required after the Grapes begin to colour, as they are much improved in quality through ripening in a higher

temperature, indeed the Grapes must be thoroughly ripened or they will not keep well.

Vines from Eyes.—Eyes inserted as advised have rooted, and if in small pots they may be shifted into a larger size as soon as the roots reach the sides, standing the pots on shelves over hot-water pipes in preference to plunging them in bottom heat; or if the eyes were inserted in pots or pans, several together, they may be placed in small pots singly, plunged in bottom heat to insure speedy root-action, and when the roots reach the sides transfer them to 6-inch pots. Syringe well amongst them, and stop those intended for fruiting at the first joint of the laterals, but those intended for planting out this season, whether grown in pots or turves, may be allowed to retain all the growth made.

PINES.—Plants Starting into Fruit.—Those which were selected about the beginning of last December, and started by an advanced temperature and moisture, will now be showing fruit; and as it is advisable to enhance the ripening of the fruit of these plants as much as possible, the temperature about them may be maintained at 65° to 70° at night, and 75° to 80° in the daytime under favourable circumstances, ventilating at 80°, allowing an advance to 85°, and close at about that figure, utilising the sun heat as much as possible. With the fruit advancing the plants will require more water at the roots, examining the whole stock once a week, as with increased light and heat the need for water will correspondingly increase. Recently started plants to succeed those already named should have a night temperature of 65°, and 70° by day artificially, which will be sufficient for them for some time longer.

Starting Suckers.—Suckers will have to be started about the commencement of March to provide plants to give a succession of fruit from next December onwards; therefore attend to the preparation of soil for potting, and a fermenting bed in some close structure to generate and maintain a bottom heat of 85° to 90° near the surface, and with means of maintaining a temperature of 55° to 65° by fire heat with regularity.

TOMATOES.—Our early supplies are grown in pots. The first are from cuttings struck in autumn and kept in small pots near to the glass in a Cucurber house until January, then we drain 10-inch pots well, place a few rough pieces of turf over the crocks, and turn out the plants, using rough turf with about a fourth of well decayed manure. There is a considerable space left in the pots after the plants are put in, which is utilised afterwards for additions of compost as the plants advance and the roots protrude. They are supplied with liquid manure after they become established. The plants are stood at the sides of a low span-roofed house kept at 60° to 65° at night, and 70° to 75° by day, and are trained to the trellis fixed about 9 inches from the glass. The plants show fruit when only a few inches above the rim of the pots, and at about every second joint right away, they being trained as single cordons, kept to one stem by pinching, or rather rubbing off all growths except the lead. In that way they go on to the extent of about 6 feet, when all growths are removed as they show, and the foliage is kept comparatively thin by shortening the leaves after the fruit corresponding to them are swelling. The first, or cutting plants, have now fruit set and swelling. To follow these we have plants from seed sown at the new year. They, too, have been transferred to the fruiting pots. These will keep up a supply until the planted out plants come in, which are from seed sown at the beginning of February, and which in strong plants showing fruit will be fit to plant out early in April. They, of course, are grown in heat and close to the glass. The varieties are Acme, Excelsior, and Hackwood Park.

KITCHEN GARDEN.

THE WEATHER AND WORK.—Of late we have had much snow and frost. With the exception of wheeling on manure outdoor operations in the vegetable garden have been at a standstill. We always prefer to wait for good weather rather than dig, plant, or sow when the soil is not in a favourable condition; but where there is any indication of a late spring and a scarcity of produce every effort should be made to push crops forward under glass or with protection.

SEEDLING VEGETABLES.—The seed of Cauliflower, Lettuce, and Brussels Sprouts sown some weeks ago in boxes under glass has now produced plants several inches in height, and timely attention must be given to thinning and transplanting, or they may be spoiled. As a rule they come very thickly in the seed boxes, and by the time they are a few inches high they are so crowded as to injure each other and produce very long spindly stems. This is bad for them at the beginning, as when they start with a weak stem they are very apt to retain it, and flower prematurely or partially fail. It is quite different, however, if given more room as soon as they can be handled, and if they are dibbled 2 or 3 inches apart into boxes or frames they will soon become sturdy plants. They require moderately rich soil to root in, and must not be kept too far from the glass or given too much heat, as this would produce the same bad results as allowing them to remain crowded in their seed quarters. There may be a desire to have large plants in a short time, but tall forced plants are never so satisfactory when planted out in the open as sturdy ones. We place them in heat for a time after being transplanted, and then transfer them in cold frames, protecting them in severe weather when necessary. We raise many hundreds of young vegetable plants in this way every spring, and always find them exceedingly useful for first crops.

EARLY CELERY.—There is no advantage in sowing Celery too early. The bulk of it is not required until October and onwards, and these plants may be raised in April, but it is always well to have a few early rows, and provision should be made for them now. Our first plants are

visible, and as soon as they appear they will be kept well in the light and always watered. They do not grow so fast as Cauliflowers, but they dislike being away from the light, and overcrowding must also be avoided in their case. In transplanting them for the first time use only a compost of fine loam and manure, and do not plant more than will be really wanted. It is an excellent plan to decide how many plants are required in all such cases as this, because space is valuable under glass in the spring months, and surplus plants should not be tolerated.

SWEET BASIL.—This is a valuable herb, but it is not quite hardy. It must be raised in heat and grown under protection. If a little seed is sown in a 6-inch pot and treated like Celery the leaves and twigs will be ready for use in April.

PARSLEY.—The time is at hand when Parsley is apt to be scarcer than at any time during the year. The winter does not kill it, but it seems to dwindle in the cold spring months, and many of the plants are now very bare. If a sprinkling of soot, guano, or a little short manure is spread round the plants and the surface stirred they will be greatly benefited. At the same time, it must not be forgotten that all Parsley plants of last year will run to flower as soon as the fine weather comes, and fresh plants must be raised annually. A row or a small bed may be sown the first time the ground is in good order, and the plants from this will be ready for picking by May.

SEED POTATOES.—Planting early Potatoes will soon demand attention. It is a great advantage to have the seed tubers in good order at planting time. If the shoots are quite dormant it will take them a long time to begin growing. On the other hand, if the growths are too long and spindly they will be severely checked in coming in contact with the cold soil, and this is very injurious to the well-being of the crop, but if the shoots are of medium length, very robust, and healthy they will produce capital stems and a fine crop. To have them in the latter condition spread all early Potato tubers out in a single layer now in a place fully exposed to the light but away from frost. They may or may not be covered with a little soil. We have quantities of ours packed in shallow trays and placed in a Peach house, and they are sprouting beautifully. Where it is intended to cut large tubers into several sets do not leave this undone until planting time, but cut them at once and allow them to heal before being planted. By giving attention to these points no blanks will occur.

KIDNEY BEANS.—Keep those coming into flower in a dry atmosphere, but give them plenty of water at the roots. Syringe them well after they are out of flower. Gather all the pods before the beans form in them, and sow more seed once a fortnight, as they will grow fast now and prove highly acceptable.

PLANT HOUSES.

Primulas.—Seed of single and double Chinese varieties should be sown at once where the plants are required in full bloom by the end of October. Sow the seed on the surface of fine soil composed of loam and leaf mould in equal proportions with a good dash of sand added. Pass the whole through a fine sieve and make the surface as level as possible. Do not cover the seeds, but water gently with a fine-rose can. Plunge the pots or pans to prevent the soil drying, and cover the surface with a square of glass with damp moss laid on the surface, and place in a temperature of 60°. As soon as the seeds germinate remove the moss and gradually expose the seedlings to light and air.

Primula obconica.—From seeds sown now some excellent plants in 6-inch pots will be produced for flowering next autumn and winter. Sow the seed in the same way as advised for the Chinese Primulas, but when the seedlings are once up slightly cooler treatment will be found advantageous.

Tuberous Begonias.—The seed of both single and double varieties may be sown at once on the surface of even finer soil than that advised for Primulas. It is a good plan to scatter a little sand on the surface of the soil before the seed is sown; too much is an evil rather than otherwise. Be also careful in watering not to wash the seed in deeply. They are best started by covering the pots in the manner described for Primulas and then plunging the pots under handglasses, so that they can be protected from drying influences. Directly the seed has germinated air and light must be carefully admitted, or the seedlings will damp off. Be careful also that they never become dry, or they will disappear rapidly.

Rhodanthes.—For all ordinary purposes the seed may be sown thinly in 5 and 6-inch pots filled with a compost of good fibry loam, one-third leaf soil, and one-seventh of manure with a little sand added. Cover the seed with fine soil. If the pots are stood in a temperature of 55° to 60° the seed soon germinates. When large enough thin the plants, leaving them about 1 inch apart. Place them close to the glass, and gradually barden to cool treatment, or they will draw up weakly. Dwarf plants are produced by sowing the seed in pans and boxes and then transplanting them into the pots directly they are large enough. In doing so the seed leaves should be just above the surface of the soil.

Nicotiana affinis.—The seed of this easily grown, but useful decorative plant, must be sown thinly on the surface of a pan and placed in heat. When the seedlings are large enough prick them off singly into other pans or boxes 2 inches apart, and from this position they can be placed into 5-inch pots. If large plants are needed they can be afterwards transferred into pots 2 inches larger. From seed sown now plants may be had in flower by the end of June.

Statice Suworowi.—Although useful in beds and borders outside this is charming for decorative purposes when grown in 5-inch pots. The seed should be sown thinly in pans, and when the plants are large enough transfer them into 2-inch pots, and from these into the size in which they are to flower. In their early stages they do well in an intermediate temperature, but by the time they are in their largest pots they should be grown perfectly cool. Be careful not to allow them to become root-bound in the small pots before transferring them into the larger ones.

THE BEE-KEEPER.

PRACTICAL BEE-KEEPING.—No. 29.

AN extractor wisely used is no doubt of very considerable advantage in an apiary. In the past, however, this means of increasing the honey harvest has been, and is in certain instances even yet, grievously misused with the worst results. There are certain rules which ought in every case and under all circumstances to be observed, and if due care in their observance is taken an increased yield of honey of equally good quality will be the result, and the bee-keeper will accordingly derive an advantage in more ways than one by using an extractor in this common-sense practical manner. These rules are

- 1, No honey to be extracted except from sealed cells.
- 2, No honey to be extracted from combs containing brood and eggs.

The advantage of allowing honey to ripen before taking it from the cells is of manifest importance. Schemes and contrivances for artificially maturing unripe honey have been invented, and they may to some extent answer the purpose for which they are called into existence; but it is perhaps more to the point to inquire whether there is any real necessity to take honey in quantity from unsealed cells. In case of disease, and possibly in late autumn, some small quantities of honey which remain in unsealed cells may need extracting; but it is not against the practice of extracting these small quantities that we protest, because it may in some instances be absolutely necessary to do so, but against the practice of wholesale extracting in the honey season proper with a view to enabling the bees to more rapidly store the incoming harvest. The argument used by those who advocate the continual emptyings of the combs by means of the extractor is, that by doing so the cells are set free and ready for refilling in much less time than they would have been had the bee-keeper waited until the honey was ripe and the bees had sealed over the cells. This may be true to some small extent, but it only holds good when there is but a small stock of ready built combs available; for it has already been pointed out—not once, but upon many occasions during the last twenty years—that if the filled or partially filled combs are removed, and a set of empty combs is placed beneath them, the partially or wholly filled combs will ripen, or be completely filled and then ripen as the case may be, with almost the same certainty as if they had been allowed to remain in their original position. The bees will at once commence to fill the cells which are empty, and the fresh space thus afforded being continually increased, the top tiers of combs filled with honey will be gradually ripened, and may be removed at the convenience of the bee-master. Now, this is surely a great advantage. In the one case it is necessary for the bee-keeper, however busy he may be—and June and July are very busy months with most people in country districts—to be continually extracting from and replacing the emptied combs; while, on the other hand, no other manipulation is necessary except that of lifting the set or sets of filled or partly filled boxes and placing beneath it a set of empty combs. All the tiers may be allowed to remain until the harvest is over, they will then contain fully ripened honey and nearly every cell will be sealed. Such boxes will contain very few bees, and may be taken with a minimum of trouble.

By this method the bee-keeper secures the same quantity of

honey of a vastly superior quality, and at a much greater convenience to himself. It saves the addition of a ripening machine to the already numerous appliances of the apiary, and has in fact no single drawback. Those who have experienced the toil and labour consequent upon frequent extracting in June and July will appreciate the comfort of having one busy time instead of continual—almost daily—trouble in the apiary. It is, of course, necessary to have on hand a stock of empty combs; but if these cannot be obtained full sheets of foundation may generally be used with advantage. In every case where it is possible to secure them it is in my experience preferable to have at least three sets of super combs to every stock which it is intended to work for extracted honey. Combs which have to be passed through the extractor must be well and firmly built; the more even they are, and the less time and trouble will be expended in uncapping and throwing out the honey. Each comb should be built well within the frame and fastened firmly to the bottom bar.

The American wired foundation is very good for use in frames which have to pass through the extractor soon after being built. If such foundation is placed firmly in the frames and kept in position neat level combs will result. The frames must be carefully spaced, otherwise bulged and hollow combs will be constructed, and the bee-keeper who has to deal with either of these freaks—if they may be so called—of comb-building will have good reason to remember in future that it is easy to uncap a level comb, but most difficult to perform the same operation on a comb which, like a Derbyshire landscape, is varied with numerous intervening hills and dales. If, however, a bee-keeper has the misfortune to possess such combs he should before replacing them in the hive cut away all inequalities, and if the comb is not in the centre of the frame, place the frame of comb on a board, such as has been before described for use when fixing foundation, and press the comb into position, retaining it in its place if necessary by a few ties of tape or thin string—preferably the former. After a few days the ties may be removed, and if the combs are properly spaced equal and good combs will then be produced.—FELIX.

(To be continued.)

DIRECT INTRODUCTION OF QUEENS.

THERE have been, as most know, two systems submitted to the public to accomplish the above—viz., the "Hallamshire law," one of Nature's undeviating truths, and Pond's system, generally called in this country "Simmins' Direct System." This latter, as explained by Mr. Pond, depends solely in giving the queen in such a way that she is not alarmed, and so does not excite the suspicion of her future subjects.

To introduce a queen by this theory the old queen was removed in the daytime, and after dark when the bees were quiet the strange queen was given them alone. I have never doubted the success of this plan, as I had long practised uniting bees in accordance with the same theory, which I had arrived at from the following observations. When a strange bee with dishonest intentions tried to enter a hive it always hesitated about it, and if it did this it was at once set upon by a live bee. This was kept up till dark, after which no guard was kept outside; thus I concluded that at night bees would readily unite, as at this time they would treat each other as friends. Since then I have done all my uniting after dark, and never use scent, syrup, or anything. I have not always been successful, but by remembering the circumstances connected with these I have been enabled to trace the cause of failure to, at the time, unknown causes.

This Pond's system of introducing queens to stocks in normal condition the evening of the same day the other was removed seemed much better than my law, as I insist the bees must have been queenless forty-eight hours, nor must they have had the means of rearing a queen during this time; and as it was much praised—though singular to state most, if not all the reported successes, were with stocks that had been both queenless and broodless forty-eight hours at least—I determined to thoroughly test the matter last summer, and I now publish the result for the information and guide of all during the coming season. The plan or system has recently been described in the Journal by "Felix," therefore I need not repeat it.

On the third or fourth day I invariably found queen cells, on the seventh or eighth day I found them sealed. If the queen was heavy with eggs, or in full laying when first given, she would always present the appearance of a non-laying queen, proving conclusively that the bees had not accepted her as the new mother. After the cells are sealed she was generally allowed to destroy the nymphs, and in about eleven or twelve days after her introduction she would begin to lay again. This

was the rule, the exceptions were that the queen cells were protected right forwards. In one I tore down the nymph was fully matured and marched about in my hand, though the queen I had given was quite safe, but in many cases the queen introduced disappeared about the eighth day. Thus the system seems peculiarly one for queen dealers.

I had much better success in removing the old queen by lamplight at night, and giving the new queen at the same time, without any preparation whatever, but even in this case queen cells were always started. The person under whose name it is announced in this country (S. Simmins) admits in the *British Bee Journal* for June 23rd, page 267, that the bees show signs of queenlessness and build queen cells, which in a preceding paragraph he denies are sealed. I am quite satisfied they are all first sealed before the new queen is allowed to destroy them; therefore, considering such enormous loss in egg laying—ten or twelve days—I claim that my law puts all known systems in the shade. First, because it is absolutely safe, never a failure; second, there is only a first loss of two days, or if the queen is not in laying order, then two days more. I have also discovered how virgin queens may be introduced equally as certain, but this I must reserve for another letter.

In "Felix's" letter on the subject he declined to enter into any controversy on the matter, or give credit to any person to whom one might feel indebted for its benefits.

Now, as a matter of fact, we all like to know who benefited us with the great discoveries and inventions which adds to our everyday comforts, and we like to honour them. But "Felix" is not consistent. He first said he would honour no man, then subsequently he honours Mr. Simmins instead of Mr. J. E. Pond, jun., of the U.S., who first published it in the *British Bee Journal* long before Simmins took it up, and this was long after he had published it in America.—A HALLAMSHIRE BEE-KEEPER.

NOTES ON BEES.

SINCE February the 4th, the first day the bees carried pollen from the Snowdrops, the weather has been wintry, with much snow. Our bees have not suffered from the snow, owing to their airing themselves so well during the previous mild weather. Nearly every one of our stocks has more bees now than in October. The bees never require stimulants to cause them to breed, and our great care with them is to have them well supplied with all that is necessary for the internal economy of the hive, having the crowns well covered with dried grass above a quilt of some sort. There is no fear of brood being chilled in such well-covered hives, and a properly made ventilating floor, in cold weather.

Since the 9th of January, the first day the bees carried peameal, they have carried in about 5 lbs., and much water, a sure indication that breeding is going on well. In a previous article I described my float feeders, being the only method that float feeders can be used without killing bees, whether it be with sugar or water. One thing I neglected to mention—viz., when the upper side of the float is smooth and damp many bees are caught when they turn their back towards it, and die in a short time. To prevent this I buoy up the float with pieces of cork, and stretch a piece of calico on top of float; this contrivance is as effective as it is simple.—LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

J. E. Dixon, Gainsborough.—*Catalogue of Vegetable and Flower Seeds.*

TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Sowing and Planting Asparagus (K. J. II.).—We forwarded your letter to Mr. Abbey, and have received his reply, but too late for

insertion in the present issue ; nothing, however, can be lost by the little delay.

Exhibiting Tuberos Begonias (G. C).—We consider it improper for flowers of Tuberos Begonias, or any other flowers, to be brought in a box and tied on plants in an exhibition tent for the purpose of winning prizes. The practice ought not to be allowed by show authorities, and if such additions to the plants were brought to the notice of judges they would be justified in disqualifying the collection.

Musa Sucker (W. J).—You may with safety to the parent plant remove the sucker 3 feet high, and instead of its injuring the old plant it will contribute to its vigour. In taking off the sucker be careful not to injure the roots of the old plant, but take away as much soil as you can, so as to remove the sucker with some roots, and without breaking it ; forcibly and sharply pulled, it will snap off at the surface like a Carrot.

Insects on Agathæa Leaf (H. P).—The objects on the leaf are the cast-off skins, "rust," as it is called, and dead bodies of a very small mite of the Phytoptus group. This is probably allied to the species which occur on the Alder and Birch. It would be impossible to determine the exact species without the inspection of a number of fresh specimens, as they are difficult to name. However, this species and others of the tribe are in no wise hurtful to the life of the plants or trees they frequent, except in very rare instances, but they are sometimes numerous enough to disfigure.

Hyacinth Roots Defective (H. C).—The roots are insufficient in quantity, also weak, and some of them discoloured, but not decayed. We are unable to account for the paucity of roots. Are you satisfied the soil was not too dry when used ? If it was suitable in composition and moisture, roots ought to have issued more plentifully from the bulb. The discoloration may be due to a too free use of the artificial manure, and that is possibly the case. If you had applied less of that and more water, we think a very good spike would have developed. The soil was too dry in the centre when we examined it ; and we suspect the flowers will yet expand, and form a very good spike.

Gardenias (H. P).—With no data to guide us as to cultural details we are unable to indicate the cause of your plants failing—"going off," as you say—somewhat suddenly. If the sprays are fairly representative your plants are in an enfeebled state, the stems being thin, and the leaves lacking substance. Is not the root action defective ? We advise you to procure cuttings from a vigorous stock and raise young plants in the meantime, giving the best support you can to the plants that are evidently the reverse of satisfactory. Not knowing the treatment to which they are subjected we cannot give a more precise reply.

Transplanted Vine (J. S).—The Vine transplanted from the back wall to a position in front, replacing another kind, will no doubt succeed, as it had a quantity of fibrous roots, which we presume were carefully preserved and spread out in the new position, fresh compost being worked in amongst them, the Vine in fact being properly planted. The vinery not being started for some time yet will be an advantage rather than otherwise ; all that is necessary is to keep the soil moist, but if moist now no water will be necessary until the buds start, when we advise a good supply of tepid water, mulching the surface as far as the roots extend with short manure a couple of inches thick, which should also be kept moist. Beyond syringing a little more frequently than for established Vines, and keeping the ventilators rather closer if that can be done near the transplanted Vine, no special treatment will be necessary.

Vine for Greenhouse (J. E).—A Vine would succeed provided you maintain an ordinary greenhouse temperature—viz., 40° to 45° at night, and 45° to 50° in the daytime by artificial means. A Black Hamburgh would be the most suitable variety. The stage as you propose making it would answer, but we should not use the spent tan or sand, being content with the shingle. Of the plants you name, Amarylises, Gloxinias, and Coleus would not succeed with the others. We should advise you confining yourself to greenhouse plants. If you have the Vine you will not need the climbers, as those you name—viz., Mandevilla suaveolens and Lapageria rosea, would require all your available roof space. Mina lobata is a half-hardy annual. Others that you may raise from seed are—Rhodochiton volubile, Lophospermum scandens, Maurandya Barclayana and var. alba, M. purpurea grandiflora, Tacsonia ignea, T. Van Volxemi, Tropæolum Lobbianum Napoleon III. We do not notice in your list of plants the very desirable Zonal, double, and show, as well as fancy Pelargoniums, which are indispensable. The wires for the trellis are best fixed horizontally about 6 inches apart.

Daffodils in Pots (J. W).—No wonder you are charmed with Daffodils grown in pots, the wonder is that everybody does not grow them. The plants should be kept in a light airy position after flowering, duly supplied with water and occasional supplies of liquid manure, assigning them a position in a cool house or cold frame, where they will have plenty of light, taking care to harden them off previously if they have been grown in heat or forced, and in April they may be placed in a sheltered position outdoors, plunging the pots to the rim in ashes, where they may remain till the growth is matured, giving water as required until the foliage dies down. They should be repotted before growth commences, or in July or August, plunging in ashes. The soil being moist they will not require any water, as the rain will be sufficient to keep the soil moist. It is advisable to cover the pots about 4 inches deep. Care must be taken to remove them from the ashes

when the growths are an inch or so above the pots, placing them in a cool frame, and shading from sun until the growth is quite green, when they should have all the light possible. From the frame they may be transplanted to the greenhouse or forcing house as required.

Raising Lilliums from Seed (T. M).—If you had sown the seed as soon as it was gathered in a mixture of sandy loam and peat kept uniformly moist in a box in the greenhouse, or covered with cocoa-nut fibre refuse in a frame, then placed the box in a warm frame in spring, you would have gained time. Sow now on soil previously well watered cover closely with squares of glass to prevent the moisture evaporating, also shade the glass from the sun. The chief point is to maintain constant and uniform moisture in the soil, as if it gets dry now and then, even for a short time, germination, which is slow, will be materially retarded if not prevented. You give no idea of your cultural conveniences, therefore we are unable to give information precisely applicable to your case. Some of the seed may germinate in the summer, especially in a moist warm frame, but the whole of it may not do so till next spring. You had better therefore not disturb the soil till then, and the plants that appear this season may be left to grow in the box. A cool frame will be suitable for seedlings in summer, or the box may be stood in a shaded place outdoors, such as behind a wall, in hot weather, the soil being liable to get too dry in the full sun.

Top-dressing an Uneven Lawn (G. A. B).—If you cover the grass 2 to 4 inches deep with soil you will ruin the lawn not only for the present season, but for ever. It would in effect destroy the finer and better description of grass, only the coarser kinds and weeds being able to grow through so thick a covering ; besides, you may not have calculated what covering the ground 2 to 4 inches deep with soil means. An inch is equal to 15 cubic yards of soil per acre, or twenty to twenty-five cartloads of compost in a fit state to apply as a surface dressing. Two inches depth of soil is equivalent to thirty, 3 inches to 45, and 4 inches to 60 cubic yards, or respectively twenty, forty, sixty, and eighty cartloads of compost per acre. The first of those quantities, or twenty cartloads per acre of good compost, is a sufficiently heavy dressing, even when the ground is uneven. It is not advisable to mix grass seeds with the compost. It should be put on with as little further delay as is practicable, spreading evenly, and when in good working order raking it over with a rake having long teeth. A rake similar to a hay-rake would do, only having iron instead of wooden teeth. This will fill up the inequalities. Repeat the raking early in April, and immediately afterwards sow Grass seeds over it, rake lightly after sowing, and roll it well at the same time.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (R. H. C.)—Passe Crasanne. (J. S. Preston).—Your Pears are correctly named.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (R. P.)—The plant, we think, is Dendrobium nobile var. cœrulescens, but the flower is, as you say, very diminutive. We have seen large flowers of this variety very little inferior in colour to D. nobile nobilium. (A. M.)—All the flowers you have sent represent varieties, not species, of plants, and can only be named by comparison with others accurately named and flowering in a large collection. As may be observed above, only species of plants are named in these columns. (G.)—1, Acaëa armata ; 2, Chorozema cordatum. (J. M.)—Yes, it resembles Aucuba japonica longifolia, or angustifolia, as it is also named. Try Chrysanthemums Cérés and Mrs. C. Carey ; they will probably suit you.

with low prices, tends to show that the year was an exceptionally bad one, and farmers have suffered accordingly.

It must not, however, be forgotten that rent has been greatly reduced, and where, under a really good system of management, the land has been well cultivated, and a high standard of cleanliness and fertility maintained, excellent and abundant crops have continued to yield a sufficient margin of profit. Such results, are perhaps, more common than is generally supposed; at any rate, out of a numerous tenantry only one gave us notice of his intention to quit his farm next Michaelmas. Nor can we wonder at this, when we recall the fact that rents have been lowered by one-third to one-half what they were a few years ago. If only the general practice of farmers were at all as sound and thorough as it ought to be, crop averages would be higher, and the depression much lighter than it is.

In some critiques of the returns of 1887 we are told that under a drought a light crop of hay and roots is a foregone conclusion. Now we by no means agree with this, because we know under high culture both hay and roots were a good crop. We repeat what we have so often said, that if only pasture is well managed we may always reckon upon a full hay crop, but the aftermath will certainly suffer from drought. Of root crops, too, we had really heavy crops of Mangolds, and where Swedes were sown in April or early in May, as is done in Norfolk, they were a heavy full crop. Then, too, in Potato culture there is frequently much poor practice, the ordinary average crop being sadly inferior to that which may be had by thorough cultivation of the soil and the use of pure chemical manures. We have proved this in our own practice for many years, and though we do not recommend Potatoes as a desirable crop for farmers generally, yet when local conditions favour the practice by all means let it be of the highest, for that only is profitable. That practice in Potato culture is low is an absolute certainty, for an ordinary average of 4 tons per acre means this if it means anything; nor can any plea justify such poor results when it is possible to do so much better.

The publication of these agricultural returns is important as a record of the outcome of last year's crops, but it is by no means to be taken as evidence of what farmers can do with the land even in a year of drought. We hold that nine-tenths of the land is not well cultivated and until this fault is set right, and we have the best possible combination of practice with science in the management of farms throughout Great Britain and Ireland, such returns ought not to be received as evidence of what the land will produce. If every farmer had to submit his practice along with its results to a State department for publication we should then have tangible evidence of the prevalence of ignorance among those who essay to do what they can to provide a home supply of corn and meat. That such ignorance does prevail there can be no doubt; why else do we still find so many men clinging to a four-course shift, to the muck cart, to fattening poor imported Irish cattle? In this, as in so many other things, ignorance and prejudice go hand in hand; improvement and change from the practice of our forefathers finds acceptance but slowly at the hands of farmers generally, and the stern teaching of adversity is not turned to account as it ought to be.

WORK ON THE HOME FARM.

The lambing continues in a very satisfactory manner, the lambs generally being strong and healthy, and the condition of the ewes, too, being excellent. With few exceptions they have an ample supply of milk, but there always will be a few delicate animals in every flock however carefully they may be selected, and the lambs of such ewes must be fed with milk fresh from the cow till they are old enough to consume other food. Our dietary for the ewes continues to be Barley straw chaff mixed with Oats, Mangolds, and grass, and they have a few lumps of rock salt to lick. We shall make no change in feeding the ewes till Turnip folding begins, but the lambs will have some bran as soon as they are able to eat it. We shall give them other food when they can take it, and every effort will be made to bring them on for sale as early in the season as possible. In the home flock we have a remarkable number of twins, but in the flock at an off-hand farm there are very few twins. We attribute this difference to the fact of our having had a

LESSONS BY THE WAY.

THE returns collected from 14,000 parishes in Great Britain, and from each police district in Ireland, have enabled the Agricultural Department to form estimates which have now been issued, and of which we have received a copy. These estimates go to show that the year 1887 was one of the worst ever experienced by British farmers. In proof of this we may give some of the averages which have been worked out, as a starting point for inquiry into the reason of such a lamentable state of things.

	1887.	1886.	Ordinary
	Bushels.	Bushels.	average.
Wheat	31.97	26.89	28.07
Barley	31.12	32.32	34.13
Oats	34.25	38.46	39.04
Beans	22.47	27.09	30.35
Peas	24.43	27.31	28.46
	Tons.	Tons.	Tons.
Potatoes	5.26	4.31	4.41
Turnips	9.89	14.75	14.41
Mangolds	14.61	20.13	19.05
Hay	1.27	1.54	1.50
	Cwt.	Cwt.	Cwt.
Hops	7.18	11.07	7.84

These figures go to show that only Wheat and Potatoes afforded a yield above the average, all the other crops being below it in the following proportions:—Barley, 3 bushels an acre; Oats, 4½ bushels; Beans almost 8 bushels; Peas, 4 bushels; Turnips, 4½ tons; Mangold, 4½ tons; hay, 4½ cwt.; Hops, about two-thirds cwt. We give these figures for what they are worth, and as proving the case in a general sort of way, knowing as we do well that the crops on some farms were far above the average, and also upon other farms crops were much below it. A low average, combined

better change of tups for the home flock, and we shall apply the lesson by having an extra one or two for each flock another season. As a rule we have had about one to every sixty ewes, but we know that in some flocks there are two to every hundred, and it is probably a good plan. The price of really well-bred tups has fallen so considerably that we can very well afford to have a superabundance rather than not enough.

Foot-rot in a flock always becomes more troublesome during the lambing than at other times, from the fact that pregnant ewes cannot be dressed for this disease, because of the risk of injury to them. Let those flockmasters whose sheep are free from the taint of this infectious disease take due care to keep them from contact with a diseased flock, for once it is in a flock there is no permanent cure for it, and it tells sadly upon the general health of the sheep. We have reason to regard it as being equally infectious as scab, which can be cured, but foot-rot always returns in an infected flock whenever conditions are favourable to its development. Lambs soon catch it, and suffer accordingly, not perhaps from any very severe pain in the feet, but they fall off in condition, and show clearly how seriously the complaint tells upon them.

FARM SEED CATALOGUES.—We have received copies from Messrs. James Carter & Co., 237, High Holborn, and Messrs. E. Webb & Sons,

once or twice before sowing, and repeatedly afterwards till the seed is well covered. Take care subsequently not to let any of the young pasture develop seed, and apply annually in February a dressing of the chemical manures mentioned on page 142 in our last article on permanent pasture. One word of caution as to coarse Grasses. Rough Cocksfoot and Rye Grass may both be so termed, yet both afford heavy crops of most nutritious herbage, and are to be valued accordingly. Do not pin your faith upon the finer and more delicate Grasses, for they will not answer your purpose.

Grass Manure—Field Fencing (W. R. R.).—You will find the formula for Grass manure in our last article on permanent pasture on page 142. Your plan of making a field fence of strained wire with old railway sleepers for posts is objectionable, because old sleepers soon perish, and then down comes the fence. We know no cheaper field fencing than that used by the railway companies. We have at different times used much of this at a cost of 2s. 8d. per length for materials, and 8½d. per length for labour. Each length consists of an oak post mortised with four holes, an oak stay and four larch rails 10 feet long; the ends of the rails slip past each other in the mortise holes, which makes each length 9 feet long when the fence is erected. The fence is supplied all ready for putting together at the price we quote, and it is put up by farm labourers, but we must own that it was only by close personal supervision we were able to get through the work at the low price

FIG. 22.—FIELD FENCING.

Wordsley, Stourbridge, of their new catalogues of farm seeds. They are copiously illustrated, and worthy of perusal by cultivators of farm crops.

OUR LETTER BOX.

British Bee-keepers' Association (Bee).—The above is the only Association of the nature suggested, and many county associations are connected with it. Particulars such as you require can be obtained from Mr. J. Huckle, King's Langley, Herts.

Chemical Manures (D).—Professor Jamieson's manure recommendation circular, being prepared solely for the benefit of members of the different associations, is not offered for sale. You must remember that the calculation of the cost per acre of manures is based upon wholesale rates for quantities of not less than a ton of each sort of manure, and for lesser quantities the price would be necessarily higher. You cannot do better than obtain your supply from a reliable source in your own neighbourhood. The manure we recommend per acre for Potatoes without farmyard manure is 1½ cwt. muriate of potash, 2½ cwt. nitrate of soda, 4 cwt. steamed bone flour, 2 cwt. ground coprolite, 2 cwt. common salt.

Unprofitable Pasture (Constant Reader).—Your acre of land "under coarse useless grass," may be ploughed deeply so as to quite bury the old sod, and sown in March with a crop of Oats and Grass seed. As you evidently require a strong growth of nutritious herbage for horses and cows the following mixture may be used:—Crested Dog-tail, 4 lbs., Rough Cocksfoot, 8 lbs., Perennial Rye Grass, 10 lbs., Tall Fescue, 4 lbs., Timothy, 4 lbs., Foxtail, 4 lbs., Meadow Fescue, 2 lbs., Yarrow, 1 lb., White Clover, 1 lb., Perennial Red Clover, 1 lb., Cow Grass, 1 lb., Alsike Clover, 1 lb., which gives a total of 41 lbs. of seed—an ample quantity for an acre of land. By ploughing deeply now you will turn up enough soil to enable you to cover the seed without bringing the old sods to the surface. Use a light harrow, passing it over the land

mentioned. This field fencing was figured in the Journal a few years ago, but as the number is out of print the engraving is reproduced for the guidance of yourself and others who may desire to erect field fencing of this nature.

REMARKS.

12th.—Fine and generally bright.
 13th.—Fine till 9 A.M., then enough snow to whiten the ground; dull day, and more snow in evening and night.
 14th.—Snow early, fine day with occasional sunshine.
 15th.—A variable day; frequently cloudy, but with a fair amount of sunshine and occasional slight snow showers.
 16th.—Dull, with a little snow in morning; fair afternoon.
 17th.—Cloudy and cold.
 18th.—Sleet shower from 8.30 to 9.30 A.M., then fine, with occasional glimpses of sun and snow and again a flake or two of snow. Snow and sleet in evening.
 A dull and snowy week, with uniform and rather low temperature.—G. J. SYMONS.

RECLAIMING SAND BANKS.

SINCE "Tourist's" "Memories of Margam" appeared in these pages I have received letters from readers of the Journal in England, Scotland, Ireland, and Wales, who have lost much land by the encroachment of sea sand, and as they all ask for full particulars of the reclaiming of the Margam sands I think the information will be most useful if given as an article. One gentleman residing in the neighbourhood of Liverpool gives details of enormous expense in hauling away the ever-encroaching sands from the buildings and gardens in his district, and the moving sand is undoubtedly most destructive to property. Although some may think that the land bordering the shore is only a very small part of the country's surface, it is surprising how large a space is covered with sand, and what trouble it gives about seaside residences. Still I can assure one and all, no matter where they live, or how shifting and extensive their sand hills may be, that if they go properly to work, they may not only fix the sand, but clothe its surface with a pleasing vegetation. In endeavouring to do this many costly experiments were tried by Mr. Talbot before success was reached. The field for operations was a grand one. Our sands border, and are fully exposed to the wide end of the Bristol Channel. They are upwards of 3000 acres in extent, and are deposited along the shore in mounds and vales. In some parts they extend landward for half a mile or more, in others they are narrow, and when sterile the surface is hardly ever still, and the sand moves in clouds with the direction of the wind. Occasionally it is only moved from one bank to another; it is rarely blown out to sea, and the prevailing direction is landwards. I have known ten acres of good land to be completely covered and lost in one winter here, and anyone can readily imagine what a repetition of this would lead to in a generation. I can safely say it would induce anyone to do their utmost to prevent it.

One of our first experiments was to haul large quantities of brushwood down and place this in ridges along the land side of the sand. This stayed its progress for a little while, but only for a little, as the sand soon covered the brushwood and moved on as before. Seeds of all kinds were tried. Bushels of Dock, Thistle, Nettle, &c., were collected in autumn and sown in spring, but the almost constant moving of the sands with the wind either covered the seed too deeply, or wafted it away, as the seedling plants never became visible. Twenty bushels of Broom seed were sown with the same result, and this confirmed the futility of seed-sowing. About this time one point of sand had encroached so far as to reach the main line of the Great Western Railway. Indeed one night the sand drift was nearly stopping the traffic, and this brought an engineer to give his advice as to its treatment, and this gentleman's proposition met with my opposition. His plan was to build a high wall and retain the sand behind it, but from observation I felt sure this would be of no lasting good. I knew the sand would collect behind the barrier until it reached the top, and move onwards as before, but in a much more dangerous form. A very high ridge or a great accumulation of sand is a most dangerous deposit, as it can neither be planted nor removed with convenience. Two hundred acres of pure sand were close behind the point merging on the railway. I had my own way in the end in planting it. That is five years ago. It now resembles a luxuriant field, and not a wheelbarrow load of sand has reached the line since.

I have been told of a case like this where old sleepers were erected as a 6-foot fence to keep the sand off the railroad. Shortly afterwards it was level with the top, when a similar fence was placed upon the first. This, too, was covered on the inside, when a third was erected, only to share the same fate, and when the fence and banks were 16 feet high it was discovered that this plan would not answer, and this is why I again say, do not attempt to fence out sand. Neither would I remove it from one place to another, as so long as it is capable of being blown about it will always prove a nuisance, no matter where it may be, and my advice is to plant in all cases. This is what has succeeded here, but it was only tried on a small scale as an experiment with the others at first.

There is a Rush-like Grass with arched leaves 2 feet long named *Ammophila arundinacea*, indigenous to sea sand banks, and it is with this only that we have succeeded. It grows here and there in close tufts on the sands, and these tufts furnish a supply of plants for clothing the bare places. The roots of them spread for yards around and penetrate to a depth of 10 feet and 12 feet. They are dug up with a spade, but rooting so deeply they are not cleared out of the sand, but simply cut off about 1 foot below the surface; and although many roots are secured to the Grass at this depth, those left below soon produce fresh and luxuriant growth and clothe the surface again in less than twelve months. The extent of our sands naturally covered with this Grass would not exceed 100 acres, but from this we have dug up and secured as much as has planted 2000 acres. It was not all taken in one year. We have been planting from 200 acres to 300 acres annually for the last seven or eight years, and the plants cut over and replanted this year would grow again from the bottom roots and furnish another crop the second year. At first we only tried the *Ammophila* on a small scale. The plants were dug up and divided into little pieces that we could hold conveniently in the hand. These were dibbled into the sand at a distance of from 2½ feet to 3 feet each way, and twelve months after planting they were tufts about 1 foot in diameter. This led to more extensive planting, until 2000 acres have been done, and the result has been a perfect success.

It was a serious matter to have 2000 acres of sterile sand to clothe with vegetation. Some asserted it ought to be a government undertaking, others said it would never be accomplished, but perseverance surmounted it all. From four to six men have been employed at it from early in October till April since planting began. Planting is done systematically. One or two men make the holes in the sand, another one or two dig up the plants and carry them to where they are wanted, and a couple of boys insert them. The holes are made with a dibble about 3½ feet in length. It has a cross head for the hands, and about 14 inches from the point there is a projecting piece of iron on which to put the foot to press it in when necessary. The point is shod with iron, and it is large enough to make a hole 3 inches in diameter. It is inserted every time up to the projecting iron. The holes are thus 1 foot deep and the plants are pushed down to this depth. The boys place them in and fix the sand to them with the heel of their boot. It is important that they be planted at least 1 foot deep, because immediately after planting the sand may be blown from them to a depth of 6 inches or more. This has happened many times, but being inserted deeply they still retain their hold. We have also had the sand blown on them, but it is astonishing how the growth scrambles through, and less harm is done by covering than uncovering. A colliery manager in South Wales who was troubled with the sand blowing on and blocking their railroad to the pit was induced to adopt our plan two or three years ago. He asked me how "far they should be planted apart." My reply was from 2½ feet to 3 feet. He had a rod made to measure from plant to plant, and soon found measuring so expensive and tedious as to be inclined to give planting up; but it is quite unnecessary, and I prefer pushing on by guesswork.

Now comes the question, "What of the expense?" This is very

moderate indeed, and I have computed that the whole of our expense of planting will average 6s. 6d. per acre. The plants become effective as soon as put in, and in the second or third year after planting they meet everywhere in a close mat. This forms an excellent cover for game, particularly hares, and I may remark that the *Ammophila* has a peculiar habit of succeeding best where the sand is deepest, driest, and most exposed. It does not grow so well in a damp place, and the drier and hotter the summer the more luxuriant does it become. It rather objects to impure sand, and where our ridges of brushwood have decayed the *Ammophila* is not so healthy as on other parts. Finally I would say no one need have any hesitation in spending their money in planting sands in the manner above indicated. They may rest assured it will not be thrown away.—J. MUIR, *Margam Park, Port Talbot, South Wales.*

IS CHISWICK TO GO?

UNDER this heading there appears in your last issue an article which to my mind fails to attain the object the writer had in view—viz., the welfare of the Royal Horticultural Society. The gist of the statement appears to be that the Committee has committed the Council to an "adventurous policy" as opposed to a "recuperative" one, and that the Fellows at the general meeting endorsed this policy without knowing what they were about. Now, there is an old adage that "one story is good until another is told," and I should feel obliged if you would allow me to submit a different version, and in doing so I shall endeavour to confine myself solely to the work done by the Committee. The Committee had only been a few weeks in existence when the annual meeting occurred, necessitating a report to be made dealing actually only with matters of pressing urgency, but prospectively to other subjects which must of necessity occupy the attention of the Committee almost immediately. As to the statement regarding Chiswick, wherein you gather from the annual report of the Council that the yearly expenditure is £1300, and that the sale of "garden produce" is in round figures £500, thus leaving a deficit of £800 a year. Doubtless this is so, but the Committee has not up to this time had any opportunity of dealing with Chiswick even in the least degree. This is one of those things to consider for which they are called into existence to help the Council. In a word, the work of the Committee is to co-operate with the Council and to realise as far as possible the idea sketched by your correspondent "F. W. B.," page 144. Although it cannot be expected that they will ever render Chiswick entirely self-supporting, much less a profitable undertaking. Indeed, the profit of such a garden is to be looked for in the results of its experiments and in the advantages it offers to the Fellows in return for their subscriptions rather than in a formal balance-sheet. So much for Chiswick and the Committee.

Now a word as to the expenditure of £700, which it is stated that the Committee has recommended. In reply to this I can only say that the only expenditure which the Committee has recommended on account of new offices is £120 a year for three years, and the hire of the Drill Hall for Shows for one year £100—total, £220. Now, seeing that the Society is driven from Kensington, where its annual expenditure, without supply of plants, &c., was over £600 a year; and, further, that a new home was immediately imperative, and that the same has been obtained for £220 a year. I submit that a saving of £380 is effected, because it must always be borne in mind that until further reductions and economies are effected all other outgoings upon the present scale of expenditure remain.

Whether the Council should have migrated in the direction of Chiswick or the City can, I think, admit of but one reply. If they had gone to Chiswick doubtless the £220 a year would have been saved, but only, I believe, at the expense of losing a still larger number of subscribers, coupled with the absence of the general public at their fortnightly Shows; whereas by putting themselves more in touch with the public on these occasions the public will mark their appreciation of the facilities offered by better patronising the Shows brought closer to their doors. As a matter of fact an echo has already been heard from the City which bears out the hopes of the Committee in respect to this.

As this is the extent to which the definite operations of the Committee have as yet extended, I do not feel it incumbent on me just now to say more except that until the lower rates of subscription are established and the country districts are mapped out, local Secretaries appointed, and the generally comprehensive machinery which the Committee has in view be set going, the new Council and the Committee must, to do good work, heartily co-operate in the future, as they have done in the past, looking forward with

confidence to the cordial support of all classes of horticulturists, at least in all matters of principle.—GEO. DEAL, *Hon. Sec. to the Fellows' Committee.*

[We readily insert this excellent letter, but notwithstanding the admitted ability and great business capacity of Mr. Deal we are bound to observe that he leaves the real position of the Society as represented in our article on page 143 untouched. Nothing confessedly can be added to its estimated income, and nothing is really subtracted from its estimated liabilities. It is true Mr. Deal only admits an expenditure of £220 as recommended by Dr. Masters' Committee, but the further estimated expenditure of £234 is directly involved for exhibitions, the only purpose for which the hall was taken; and, further, it is clearly stated in the report that the Committee strongly recommended the appointment of a paid Secretary, and one is advertised for at a salary of £200. Add this and the estimated cost of Shows (£234) to the £220 admitted, and we have £654. This is our justification for saying that speculation to the extent of "between £600 and £700" was indulged in.

It is necessary to say a word relative to the lapsed expenditure of £600 at South Kensington, because we find an impression obtains in some quarters that this sum was included in the £850 for establishment expenses on page 143. Not one penny of it was included, nor can the lapsed amount be taken into consideration in any way in respect to the future of the Royal Horticultural Society, and it is with the future we have to deal. We fear the alleged "saving" of the lapsed £600 has had an influence that it cannot legitimately bear; it is a mere shadow of the past, not a substance affecting the present position. We expected, too, when writing last week that a misapprehension existed as to the applicability of the special fund promised of £1210; we have since learned from more than one source that such was the fact, and that the true position of the Society was not present to the minds of the Fellows when the report of the Committee recommending the speculative policy was adopted.

But, it may be asked, and with a great semblance of plausibility, Why did the Council accept the report? When it is remembered that the Committee is composed in part of the members of the Council, and that the majority must rule, opposition under the circumstances would have amounted to mere obstructiveness. The truth is, the decision was arrived at under the impulse of the meeting; and the Council was not, nor can it be, an independent and responsible body when some of its members belong to an outside Committee, and thus act in a dual capacity.

Dr. Masters' Committee, on which so much depends, was excellent in inception but erroneous in principle, inasmuch as by its mixed nature its responsibility is incommensurate with its power for doing good on the one hand or making mistakes on the other. Its members are unreservedly credited with the best of intentions towards the Society which they practically govern, but not one of them can be more earnestly desirous than we are for its prosperity, and we are convinced the best policy is to preserve Chiswick, and that this can only be done by frankly making its actual position known to the horticultural world. This has been the line pursued by this Journal on critical occasions in past times, and it cannot consistently be abandoned now.

And now having discharged what we believe to be our duty, we shall with not less cordiality than hitherto do all in our power to advance the true interests of the Society, and we trust that the policy to be pursued may be such as will enable us to give it our best support with the object of securing for it a marked success.

We have now to add that the Society will be relieved of one item in the estimated expenditure, inasmuch as the Assistant Secretary's salary will for the present be provided from private sources.]

CROPS THAT PAY.

RAISING Tomatoes for planting outside did not prove such a difficult or costly task as I first imagined. A hotbed was made in February, a quantity of manure being carted into a heap, and a rough frame made by nailing boards together with four lights, as rough as the frame for covering them. On the surface of the manure ordinary garden soil was spread, and leaf soil to the depth of 3 inches. When the soil was thoroughly warm the seed was sown on the surface, and covered by scattering a little fine soil over it. The seed soon germinated, and the plants were thinned where they had come up too thickly. The result was sturdy plants, ready for placing out at the end of May. Lifting did not check them much. After being shaded and syringed for a few days they commenced growing rapidly, and set a wonderful crop of fruit from near the base to the top of the boards, as the season was a fine one. The plants were 15 inches apart, all side laterals were removed, the foliage well cut-in once a week, for it is a mistake to allow them to

grow strongly and then remove large quantities of shoots at one time. As the fruit advances in size it should be gradually exposed, and directly it begins colouring cut away all the foliage surrounding them. Some of the lowest fruits on the plants realised 6d. a pound, the remainder 4d., and we obtained the same for all that we ripened in a warm room. Fully developed fruits will ripen, and the colour will be fairly good, but those that are not fully grown are not marketable. The erection of the boards made this portion of ground "pay well," even if we had left the borders vacant.

All who grow Tomatoes outside know that a large weight of fruit never approaches maturity. The outdoor crop is largely dependent upon the season. In some seasons nearly the whole ripens, in others not more than half the crop. Last year they were a great success. Prolific varieties with moderately sized fruits generally perfect the greater portion of their crop. I regarded that which did not ripen as waste, and could see clearly that to realise to the fullest extent the produce that the plants were capable of yielding some means must be devised by which the remainder of the crop could be developed and ripened. I sought advice, with the result that I made half-a-dozen lights 3 feet wide to place over a portion. But the experiment was not a success, for cold nights stopped the growth of the plants and fruit; they finally died with a large quantity of unripened fruit upon them.

Ready for the following autumn a glass house was erected, with a flow and return hot-water pipe in it. It was a rude structure, but will grow Tomatoes as well as the best and most costly one that could be erected. The house is practically all roof. It was constructed after this fashion—posts were placed 12 feet apart, which stood above the ground 18 inches; two 9-inch boards were nailed to these, which formed the sides; the wall plate (if such it can be called), 2 by 3 inches, was nailed to the posts, the ridge or centre piece was 2 by 4 inches, the bars were 10 feet, these were shaped to fit the ridge and wall plate; when one was made to fit it was not a very difficult matter to manage the rest. The centre was fixed into position, and the bars nailed at the base and the top. The bars were grooved so that we could slip the squares up from the base one after the other, and the glazing was a simple process—no putty, no tacks, only one nail at the base to prevent their slipping down. We found it necessary to place supports here and there down the centre, and afterwards screwed light angle irons all the length of the sides, midway up the bars. It was a cheap house certainly, but one that answered our purpose admirably when we made slight alterations in providing ventilation. This was provided by pulling one of the boards off on each side, and hanging them to form shutters. Many a man hampers himself by borrowing money, if he has not enough of his own, to build costly houses for raising market produce. This is a mistake into which many fall after being trained in private gardens. My advice is, use good 21-oz. glass (large squares, say a foot by 18 inches), good boilers, and pipes; the glass will do for another house when the wood is decayed, or if the glass is sold it is worth nearly as much as when it was new. The road to success is to erect houses suitable for the purpose for which they are required, but at the least possible expense, so that the capital invested can be recovered rapidly.

We had the house, but discovered that we could not lift the Tomatoes from the boards to insure any degree of success. Lack of foresight ended in this matter being next to a total failure, for we succeeded in ripening very few more fruits than was the case when we had no house. The next season the plants for the boards were placed in small boxes, 1 foot square and 9 inches deep. As soon as the Lettuces were removed from the foot of the boards the boxes were plunged, well watered, and liberally mulched with old Mushroom bed refuse. If they are well mulched very little labour in watering is entailed. This proved the right principle, and instead of nailing the plants to the boards each was provided with a cane 7 feet long, and fastened to the top of the boards. By this means we could lift the plants indoors before they were starved by cold nights, and succeeded in ripening the whole crop. From these plants we finished cutting the last week in November. After the glut of outside fruit is over the price naturally rises, and we realised for that portion of the crop that would otherwise have been wasted 5d. and 6d. a pound respectively. Persons intending to grow Tomatoes against walls or boards will do well to place the plants, not in boxes, for they decay too quickly, but in 10-inch pots, and plunge them, burying the rim with at least half an inch of soil, and then mulch them. The plants can then be lifted inside, and perfect the whole instead of half the crop. They will root over the sides of the pots, but these roots can be cut away without the slightest injury to the plants, provided they are lifted with the manure remaining on the surface, which will be full of roots. Sow for the main outdoor crop at once. How to have a profitable crop a month later will be recorded subsequently.—MARKETER.

RICHARDIAS.

FEW plants have a more noble effect than these when properly grown, and few plants are more useful, whether for decorating the conservatory or house use; for the latter purpose it is scarcely surpassed by any other plant, because it lasts so long in a fresh state. There is a difference of opinion amongst some growers as to the best way of treating the plants. Some advise and probably succeed in growing them well by planting them out after flowering, while others cling to the system of always keeping them in pots. I have tried both methods, but much prefer to keep them in their pots; they flower earlier, more freely, and I think make much better foliage. I have been complimented on the showy character of my plants, which commenced flowering the week before Christmas, and most of them are now at their best, carrying from five to nine spathes on each plant, with others showing. They are in pots of the size called "eights," and the plants are fully developed in every way.

I will state how they have been treated, for the benefit of those who like to try the plan. When I came here, twelve months ago, they were in flower in the same pots as now. After they had flowered they were shifted from the conservatory to a cool house, remaining there until well on to the middle of May, when they were turned outdoors under a wall close together, with a few leaves between and around the pots, but otherwise exposed to the summer sun. For a time they were occasionally watered thoroughly, afterwards no water was given. At the end of the summer the crowns showed signs of moving; the drainage was examined, and sufficient water was given to prevent the soil becoming dry. When the time came to take them under cover the top soil was removed, fresh being supplied, and made as firm as possible, but no potting was done, simply removing what young side plants there were. As they showed flower the soil was top-dressed with cow manure quite twelve months old, but with about a handful of soot to a gallon of soil, well mixed. I need hardly say that the plant likes moisture, and from that time to the present they have never been allowed to be dry, and watering every day seems to do them good; no liquid manure has been given. I could scarcely have managed them with less trouble, but I could not have plants more satisfactory. The above plan I have practised for years, and we do not pot them but once in two or three.—THOMAS RECORD.

A MIXED CONDIMENT.

WAYS AND MEANS.—Some of the very best and most successful of gardeners I know have succeeded in spite of the most discouraging difficulties. The old saw, "Nothing succeeds like success," is only half true, and my own opinion is that nothing leads more certainly to success than one or two failures. I am not now speaking of the men who sit down and say, "it will never do," or "it is no use trying, we have no convenience for that sort of thing," but of men with a firm lower jaw and something harder than gristle in the small of the back. As I have said, some of our most successful gardeners have succeeded, and are still succeeding, by the exertion of their abilities on adverse circumstances—they turn their curses into blessings, and smilingly make "a desert place to blossom as the Rose." A gardener of the right stamp will make a rubbish heap beautiful, and the great point is that he will do so willingly. After all, those who are employers simply keep gardeners to undertake the troubles, anxieties, and difficulties of their gardens off their own shoulders, and the best of gardeners are those who give their employers least trouble about conveniences or ways and means. When I remember some of the drudgery I went through as a garden boy, and read of the rude appliances by which our predecessors, the Abercrombies and Speechleys and McNeils, grew their splendid productions, I sometimes think modern gardeners too exacting, and that like the "real princess" of the nursery tale, they will complain of the Rose leaves that get folded beneath them.

COLOURED LIGHT IN GARDENING.—In the long run, looking at Dame Nature, "the dear old Nurse," from an all-round point of view, no doubt mixed or white light is best for plant houses and fruit houses generally. But for particular purposes, or at particular seasons, coloured light may eventually be found of advantage. Long ago the American papers were full of accounts of General Pleasanton's vinery and its roof of purple-tinted glass. Now I have come across the following in an American paper:—"Professor Sachs, the great German botanist, has discovered that the ultra violet and invisible rays of the solar spectrum especially promote the development of flowers, the growth of which is exceedingly feeble when the rays are suppressed, although that of the other parts of the plant is very luxuriant." When practical men went to see General Pleasanton's Grapes, they found a large crop—a larger and better one than the General could produce under white

glass, but the quality of the fruit was not what our Merediths, Thomsons, Wildsmiths, Colemans, and Castles can obtain, so the idea fell to the ground. But if the most celebrated of physiologists and histologists—Sachs—is right, there was something in General Pleasanton's idea after all.

Speaking of light, I remember the late Dr. W. Siemens asserted that the electric light had the same effects on vegetation as solar light, and he attempted to prove its efficiency for forcing purposes. Now I hear of the ghastly destruction of Palms, Tree Ferns, and other choice decorative vegetation in the electric-lighted conservatories in Russia and also in Paris. Nature is jealous, and time brings in his "whirligig of revenges" after all.

MOVING FORWARD.—Now that some of us are pushing on the movement in favour of English plant names, as additions useable in co-operation with the Latin names, it is pleasant to find that our German cousins are also agitating in favour of their own tongue instead of Latin as used for prescriptions. "A Berlin contemporary informs its readers that the famous surgeon, Dr. Esmarch, is the leader of an attack upon 'Apothecaries' Latin,' and he is supported in this campaign, on behalf of common sense in medicine, by several of the most eminent physicians and medical professors in Germany. He asks why a foreign tongue should still be employed by physicians in writing their prescriptions when a general expulsion of foreign terms and phrases and the substitution of their German equivalents has become the order of the day. A pharmaceutical lexicon is being prepared for the use of doctors and chemists, so as to assist them in prescribing and making up prescriptions in the tongue understood by the people."

BERRY-BEARING PERNETTYS.—"The Pernettya is a very pretty small-leaved hardy evergreen shrub, with small white Heath-like flowers in early summer, followed by the bright berries, which give the plant a very ornamental appearance during the autumn and winter, and which were often retained till succeeded by the flowers the following season. It is now some thirty years since the first seedlings were raised by Mr. L. T. Davis in the Ogles Grove nursery at Hillsborough, Co. Down, from Pernettya angustifolia, the hardiest and best free-fruited variety of Pernettya mucronata then in cultivation, which produced several distinct sorts, varying considerably in foliage, habit, and colour of the berries. From the most promising of these another lot of seedlings was grown, and so on from subsequent raisings, till a collection has now been produced of very great merit, for variety, hardiness, and free-fruited character. The varieties of Pernettya mucronata will succeed in any good light soil, but prefer an open situation, if not exposed too much to cold east or north winds. Their berries are quite harmless, and although not palatable, may be eaten with impunity."

The above is Mr. Davis's own account of these charming little shrubs, and the following is a selection of the best kinds:—*P. mucronata alba*, profuse white berries, tinged flesh on the sunny side; *P. m. atro-coccinea* (small-leaved), bright crimson berries; *P. m. carnea nana*, dwarf, flesh pink; *P. m. lilacina macrocarpa*, large puce-coloured fruits; *P. m. macrocarpa*, large crimson berries; *P. m. sanguinea*, crimson red, approaching scarlet. Mixed seedlings are very pretty.

COLOUR EFFECTS.—The author of the paragraph quoted below from the "Popular Science Monthly" says "in what way animals are affected by colour is not very well understood," but supposing that man is a red-coated animal, and that he goes into a meadow containing a "gentleman cow," I believe it is etiquette for one of them to retire. This one animal does in deference to the other. It is the man who retires. Flying is not difficult sometimes! "There are some other curious things in regard to the way in which the human mind is affected by colours as well as the human sight. We are all familiar with what is termed colour-blindness and the unexpected results that sometimes attend it; but colour-sound is something which has received much less investigation. How much or in what way animals are affected by colours is not very well understood; but the subject has been investigated enough to know that they are influenced by them, and the future will probably bring out some surprising results to the one who shall thoroughly cultivate this comparatively unexplored field of research." It is a well known and most remarkable fact that some blind persons have the nerve centres at their finger tips so exquisitely sensitive that they can actually and infallibly recognise various colours by the sense of touch. Blacklock, a celebrated Scottish poet of his day, possessed this ability in a marked degree, and tradition tells of a noted silk buyer who was the very reverse of colour-blind, although what is usually termed sightless or blind. A visitor the other day was looking at *Lælia anceps*, and startled me by saying it was of a lovely blue colour! He could see all colours except red, so that to him purple flowers appeared as blue ones.

FLOWER FRAGRANCE.—Nothing in a garden of beautiful flowers

is so subtly delicate, so deliciously satisfying to cultured people, as the fragrance of leaves and blossoms. Fragrance is an open book that everybody reads a little, but it is mainly written in faint hieroglyphics that nobody can understand. Scent and flavour are not reproduceable in words or in pictures. You must in the main go to Nature for them direct, always if you want them of the best. I believe coal tar and rotten cheese and cowdung and other nasty unmentionable things do in the hands of the chemist mimic the flower odours pretty well, just as vanilla is made from Pine tree sawdust, and indigo from I know not what. Science is baffled so far by sweet smells. "It has been shown that the odoriferous molecule of Musk is infinitesimally small. No power has yet been conceived to enable the human eye to see one of the atoms of the Musk, yet the organs of smell have the sensitiveness to detect one. Their smallness cannot even be imagined, and the same grain of Musk undergoes absolutely no diminution in weight. A simple drop of the oil of Thyme ground down with a piece of sugar and a little alcohol will communicate its odour to 25 gallons of water. Haller kept for forty years paper perfumed with 1 grain of ambergris. After this time the odour was as strong as ever. Bordenave has evaluated a molecule of camphor, sensible to the smell, to 2,262,584,000th of a grain. Boyle has observed that one drachm of assafoetida exposed to the open air had lost in six days the eighth part of a grain, from which Keill concludes that in one minute it had lost 1.69-220th of a grain." This is most interesting, and I need scarcely ask why we find musk in rats and in oxen, as well as in our own familiar "Musk plants?" Everybody knows the story of the old woman's test for "a real princess." She was to sleep on the uppermost of fifteen feather beds, and the beldame had placed a Rose petal once folded between the two lowermost beds. "There!" said she, "if she is a real princess of our line she will not sleep a wink, and in the morning will complain of the ruckled up style of our bed-making." We want a delicate sensitiveness of this kind to appreciate perfume, especially such subtleties as the odour of "the Strawberry leaves a-dying," or the bursting of the L'me, Cherry, and Chestnut buds in spring. In a word we must have a smeller-garten and cultivate our noses. As it is the manufacturing chemist can make us swallow anything he likes under old familiar names. Beetroot spirit is gin, rum, sherry, whiskey, or brandy, just as he likes, and all done by a few added drops of colouring, scent, and flavouring from a bottle. Artificial eggs and Nutmegs, and Singapore Pine Apple made from Turnips from Sweden, are mere trifles to him.

BEDDING OUT.—I believe it is now considered heresy and schism to breathe the once sacred name of bedding out, but that good old custom as rightly used is not quite banished as yet from our gardens, nor will it be for all time to come. Bedding out is "not for an age but for all time." We need not go to Heckfield Place to see Mr. Wildsmith's beautiful flower beds; the best place to see bedding out is in the now many good gardens in which hardy plants, herbaceous and alpine, are the vogue. You must tread softly in such places, and there is a particular language or shibboleth, only current in the parterres of the good people to whom it has become a fetich, of the most satisfactory kind. It is a change of names rather than a change of systems, and what in Lobelia and seaside Cineraria once was "a bed" is now called "an arrangement" by the votaries of hardy flowers. But it is a perfectly harmless folly; it is like playing at soldiers or at whist with a dummy—very amusing and instructive as far as it goes. Formerly in the spring days we used to have orderly beds of Crocus, Squills and Iris, or dwarf Daffodils, easily cultivated and easily protected; but now these bulbs are grouped, massed, or arranged on the grass, the arrangement in nine cases out of ten being a vexation to all concerned. The bulb dealers do not object to it for planting bulbs by the cartload on the grass and in groups under trees, and under fresh carpets is very good for trade. To quote the poet, they—

* * * "——— die
As your Hours do, and dry
Away
Like to the summer's rain,
Or, as the pearls of morning's dew,
Ne'er to be found again."

HOW TO RAISE FINE FLOWERS.—There are two ready ways of doing this—good cultivation and judicious cross-fertilisation, or cross-breeding as it is sometimes called. Good cultivation in the open air—*i.e.*, for hardy flowers, consists in deep digging and ample supplies of well-rotted manure or of fresh cowdung to the soil. On some soils lime is an advantage, and on all soils soot is one of the most stimulating of manures if dug into the soil so as to become thoroughly incorporated.

Indoors and in pots good fibrous loam, leaf mould, and dried cow manure forms a compost in which nearly all quick-growing or softwooded plants do well. It should be made very firm around the roots at the last potting, and the best way of applying manure

to pot plants is in the shape of manure water—*i.e.*, manure in a liquid state. Standen's or Clay's Fertiliser are very strengthening to Pelargoniums, Fuchsias, Chrysanthemums, and other quick-growing things, but Gloxinias, Begonias, and all bulbous plants are ruined by it, and these should only receive good water in which cow manure has been dissolved. Liquid manure is best made by putting the manure and soot into a canvas bag, and then sinking it to the bottom of a tub or tank, so that a clear filtered and not too strong an infusion is obtained. Weak and often—*i.e.*, every alternate watering—is the best way of applying liquid manure, and this only when the soil is full of roots.

IMPROVING FINE FLOWERS.—When an amateur has acquired the knack of growing his favourite flowers to perfection, he may add to his pleasure by still further improving and varying them by cross-fertilisation. Most flowers have a green-headed pin in the centre communicating with the seed vessel, and this is the style, the green tip being the stigma, to which the pollen of other flowers may be applied with a wet camel-hair pencil or brush. The pollen, or fertilising dust, is contained in the anthers or yellow-headed filaments which stand around the central point of the flower. To cross-fertilise flowers successfully one may grow the seed-bearing plants at home, and get the pollen from flowers grown by flower-loving friends elsewhere, or it may be obtained from one's own flowers, but never from the seed-bearing plant. Pollen should be obtained from the best habited varieties, and seed should be saved from the varieties that are large and richly coloured, and in both cases from well-grown plants. In this way, by careful and constant cross-fertilisation and good culture, every amateur may soon possess valuable races or strains of the flowers he likes best. The point is to decide on improving what you can already grow to perfection, Primroses, Auriculas, Narcissus, or what not, and then begin to cross-breed only the finest varieties.

COAL TAR AND CEMENT.—Let us begin with the tar. I often wonder this is not more generally used by gardeners and amateurs and cottagers who have either wood or ironwork around them deserving of preservation from rot or rusty decay. It is as cheap as dirt, cheaper in the end than dirt and neglect prove to be. Wherever wooden labels or stakes, posts, &c., are used, the part intended to go into the earth should be first charred, then dipped in coal tar, then dusted over with finely sifted coal ashes, and they will last three times as long as those not so treated. But this is not all, for it has been stated in the paper above cited—"The coating of brick and wooden structures with coal tar, as a rough and ready means of preserving them from the action of damp, has been common from the earliest days of gas industry. It has also been usual in chemical works to protect the stones used in the construction of acid tanks, &c., by a preliminary soaking in heated tar. But the great improvement in strength and impermeability to moisture which results from the simple operation of boiling bricks and stones in gas tar is certainly not so generally known as it should be. Professor Lunge, in the new edition of his work, 'Coal Tar and Ammonia,' draws attention to the subject, and indicates several useful applications. He points out that drain and roofing tiles, which are quite porous and brittle as they leave the kiln, may be rendered absolutely watertight and much stronger by immersion in a bath of hot tar. Building stones are greatly improved by similar treatment; and for many purposes the dead black colour which results is an advantage rather than an objection. The tar should be deprived of water and its most volatile oils; and to produce good results the bath must be maintained at a temperature of at least 100° C. The articles to be treated should be thoroughly dried and allowed to remain in the tar for some time."

CEMENT.—Useful as is coal tar, cement is almost of more importance to all good gardeners. You can do anything with cement if you will only try. Even rotten parts of the woodwork of hot-houses filled and drawn with cement last almost as long as new repairs by a carpenter. Common wooden stages can be lined with cement, and so made watertight and damp-proof. Edgings, piers or supports, steps, concrete slabs, and all sorts of rockwork can be most effectively produced in cement. Bare walls covered with common gas coke stuck on and coloured with cement form pretty ferneries. Concrete piers or supports are readily made with clean mashed gravel or stones, or coke and cement. You can model anything in this plastic material, and the only tools are thin firm moulding boards, a trowel, and a big paint brush to soften off and smooth surfaces or to form water worn boulders, &c., *ad infinitum*. A handy man in a garden can do wonders with these cheap and simple materials.—DOCTOR'S BOY.

NOTES ON PEACH TREES.

NOTHING is more disheartening than to have a fine promise of blossom, and then as soon as the trees are started to see the buds fall in showers. Early-forced Peach trees are notorious for such

behaviour, some varieties more than others, and although much has been written detailing the real or fancied causes, it is unfortunately far from uncommon, hence any information likely to throw any light on the subject must be of service to many readers of the Journal. We are frequently told to keep our Peach borders moist through the winter, or when the trees are at rest. It is very good advice, but not always sufficient to prevent the buds falling, as I have many times proved; indeed I can go further, and say that, provided the wood be thoroughly ripe, a Peach border may become very dry and not a bud be lost.

Not long ago I had to take charge of some Peach trees which, partly from their position and partly from neglect, had become so dry that it was impossible to moisten the soil more than an inch below the surface. One reason for this was, they were planted on a level with the front sash of a lean-to house, so that what little water had been given quickly ran off to the level of the floor, which was 2 feet 6 inches below them. There had been no fruit for some years past; the buds fell every spring. The trees made very little wood, but that, which was small and wiry, was every autumn well set with fruit buds, notwithstanding that red spider had devoured the foliage by the middle of September. We tied the trees to the roof, undermined them, and wheeled the soil to the garden, which after a winter's rain, was found as dry as dust 3 inches below the surface. After putting the drainage right the trees were lowered to the level of the floor, the space was filled with fresh loam, well watered, and the surface mulched with littery manure. Not a bud fell the following spring, and we secured a good crop of fruit.

I have mentioned this, not to recommend border drought, but to show that Peach borders may become very dry without the trees losing their buds, and that dryness at the roots is not always the cause of buds falling. There is no doubt, however, that if means had not been taken to supply moisture before the trees started the buds would have fallen in showers, as they had done in previous years; hence the lesson is, always thoroughly soak the borders before starting Peach trees.

Immaturity of the wood is generally the cause of buds falling, so that any information likely to help us to secure thoroughly ripened shoots is valuable. According to my experience the very worst form of house for early forcing is a span-roof with fixed sashes, and the best is a lean-to with a south aspect and portable lights. I have always found Peach wood ripen best when the lights can be taken off after the fruit has been gathered, and especially so with early forced trees. As long as there are leaves the trees must be kept syringed in houses with fixed lights, in order to keep red spider in check, and that of necessity creates a condition in the house more favourable to the growth than to the ripening of Peach shoots. If some experienced correspondents would discuss this subject further they would be doing valuable work.—J. H. W.

ASPARAGUS CULTURE.

MR. G. ABBEY, in his very excellent articles on Asparagus in last year's Journal, August to October, advises sowing or planting on ridges 3 feet apart; and in the commencement of his paper in the Journal for September 1st, page 191, last volume, he says, "Let the height of the ridges be as before stated," but I find he has omitted giving the height of the ridges. As I am thinking of sowing a good piece this spring I should esteem it a favour if Mr. Abbey will rectify the omission in your next issue.—K. J. A.

I AM obliged to "K. J. A." for directing attention to my having omitted to state the height of the ridges at the respective distance apart of the rows and plants. In the Journal of Sept. 1st, 1887, page 191, it is stated, "For the 18-inch rows plant on the flat," which precedes the quotation of your correspondent—*viz.*, "For the other distances let the height of the ridges be as before stated." Now planting on the flat in the manner stated is the key to the ridge. There is clearly no ridge made before planting, but one is made by doing this in the way indicated—*viz.*, "Stretch a line at the required distance" (*i.e.*, 18 inches in planting on the flat), "or along the centre of each ridge, and make a sloping cut on both sides the lines at an angle of about 45° where the plants are required" &c. "The plants are placed astride the ridge, &c., to insure having all the crowns level with the surface." So far, therefore, there is no ridge, but the covering with an inch of fine soil, and over the crowns with a still further 2 inches raises a ridge of about 3 inches. For sowing where the plants are to remain the ridges should be 3 inches high for rows 18 inches apart; 6 inches high for rows 3 feet apart; 8 inches high for rows 4 feet apart; and 9 inches high for rows 4½ feet apart. In planting, the height of the ridges would be, for rows 18 inches apart flat, the planting forming the ridge about 3 inches high; for 3 feet rows, 3 inches; for 4 feet rows, 5 inches; and 4 feet 6 inch rows, 6 inches. Covering with soil at planting will raise the rows directly over the plants 3 inches, and taking out the soil from the space between the rows for covering the roots and crowns will correspondingly increase the height of the ridges, it being further increased by the operation being performed from the spaces between the rows—*i.e.*, the

ground is sunk by treading in the spaces, whilst where the plants or rows are it is not; therefore the ridges are more pronounced in practice than they would appear to be from the heights given.

I would take the opportunity afforded of stating that another season has proved the advantage of growing Asparagus on the ridge-and-increased-distance system. It is the only way to grow heads of the size and quality enabling the grower to compete successfully with imported produce. Its cultivation on the lines indicated, with the utilisation of material within the reach of all, would result in as fine Asparagus being grown in England, particularly in the sandy semi-alluvial soils of Beds and Hunts, or the light fen soil of Lincolnshire, as in any part of the world, size, nutritive quality, and freshness being the tests of merit.—G. ABBEY.

EVENTS OF THE WEEK.—To-day (Thursday) the Royal Society meets at 4.30, and the Linnean Society at 8 P.M. On Monday, March 5th, the General Committee of the National Chrysanthemum Society will hold a meeting at Anderton's Hotel, Fleet Street; and on Wednesday, March 7th, the Society of Arts has a meeting.

— **PROFESSOR I. BAILLIE BALFOUR OF OXFORD** has been elected to the Chair of Botany in the University of Edinburgh, vacant by the death of Dr. A. Dickson. Mr. Balfour is a son of Dr. J. Hutton Balfour, who filled the same chair for so many years prior to Mr. Dickson.

— **IN** the South of England the weather has been extremely cold and dull with keen north-easterly winds, and last week snow fell on several days, accumulating in some districts to a considerable depth. On Friday last week in several gardens around the metropolis a temperature of 16° was recorded.

— **THE WEATHER.**—"B. D.," writing from Scotland, says—"The week ending the 27th inst. has been the coldest of the season. There has been no intense frost, from 1° to 4° nightly, and last night the thermometer stood at 33°; but a piercing N.E. wind has prevailed, and snow showers has been occurring over the country. In some places roads are still blocked, and in the south-eastern counties drifts of 6 feet are reported. The low grounds in South Perthshire are all but clear, and there is but little on the lower hills around."

— **THE WEATHER IN FRANCE.**—Mr. Peter Barr writes to us from Bayonne, in the south of France:—"I am here in the midst of a winter that would be no disgrace to Scotland, and such, as I understand, has not been experienced at this time for fifty years."

— **BRUSSELS INTERNATIONAL EXHIBITION, 1888.**—On February 22nd a meeting of British exhibitors was held at the Mansion House, London, the Right Hon. Polydore de Keyser, Lord Mayor, presiding. A letter was read from M. le Comte d'Oultremont, Commissaire General of the Belgian Government, recommending that an official Commissioner should be appointed to facilitate the transactions between English Exhibitors and the Belgian Commissioner. After a short discussion it was resolved that Mr. S. Lee Bapty should be officially appointed as representative of the exhibitors in the British Empire section. It was stated that the Exhibition is expected to be a very comprehensive and successful one.

— **PARIS EXHIBITION, 1889.**—On the same day a meeting was held in the rooms of the British Chamber of Commerce, Eastcheap, to consider what steps should be taken with regard to British exhibits at Paris next year. After considerable discussion, in the course of which several expressed themselves as opposed to taking part in the Exhibition, a motion was carried to the effect that "the meeting considered it desirable the British Empire should be adequately represented at the Paris Exhibition of 1889."

— **THE GARDENERS' ORPHAN FUND.**—The ordinary monthly meeting of the General Committee of this Fund was held on Friday night last. Present: Mr. G. Deal (Chairman), and Messrs. Barron Wynne, Woodbridge, Nicholson, Wright, Laing, Roupell, Dean, Richards, Goldring, Head, Bates; also Mr. G. W. Cummins, a provincial Secretary.

The eminent Belgian horticulturist, Mr. Pynaert, attended the meeting, and was cordially welcomed by the Chairman. Since the last meeting amounts of £46 11s. 6d. in donations and £18 16s. in annual subscriptions were added to the Fund, including £5 from the Horticultural Club. The total sum promised to the date of the meeting is 1449 14s. 4d., of which £1168 2s. 6d. has been received. The Secretary (Mr. A. F. Barron, Chiswick) will be glad to receive contributions with the view of preparing for the first election of orphans, some of which are nominated. On the advice of the sub-Committee appointed to consider the matter it was decided to have a popular dinner in connection with the first election on July 13th, and it is hoped a large number of provincial secretaries and their friends will be able to attend on the occasion. Their co-operation is much valued, and their presence will be highly appreciated. Mr. J. Lyne was unanimously appointed Secretary for the Wimbledon district. Gardeners who are willing to help in districts where local secretaries are not appointed are invited to communicate with Mr. Barron. The subject of money boxes for placing in suitable positions was considered, but more samples were thought necessary before arriving at a decision. The question of collecting cards will also receive careful attention. The sub-Committee was re-appointed to formulate arrangements for the annual meeting. At the close of the proceedings Mr. Pynaert expressed the pleasure he had derived in being present at the deliberations, and trusted that an object so good, which had no parallel in Belgium, would be well supported in Great Britain.

— A CORRESPONDENT sends us some CINERARIA BLOOMS to "let us see that he does not lag behind other bumptious growers." We may suggest that the word "bumptious" appears to be somewhat misapplied if it refers to persons who have sent us much better Cineraria blooms than those before us, the florets of which in all the large examples do not overlap. A laced Primula accompanying them is very attractive.

— REFERRING to the reductions in the schedule of the LIVERPOOL HORTICULTURAL ASSOCIATION "A Committeeman" writes:—"Respecting my report of the annual meeting, I must remind Mr. Bardney (see page 149) that it was not written in a 'hurry,' as he suggests, to which the date of its publication will testify, but was the outcome of a few notes taken at the meeting. I distinctly heard a member inquire of Mr. Bardney the amount he would deduct from the summer schedule, to which he replied £105. This is how the mistake originated, as I now learn this is the total amount proposed to be deducted from the three schedules. The resolution handed to the Chairman reads thus:—"That the prize money offered by the Committee for the three Shows to be held this year (1888) be reduced by £105—namely, £17 on the spring Show, £50 from the schedule of the summer Show, and £35 from the autumn Show." A total by the way of £102 only." [We doubt if further communications on this subject would be of general public interest.]

GARDENERS' EDUCATION.

I HAVE been thinking over what "Experientia docet" had to say in a recent number on the educational deficiencies of gardeners. Whilst there can be no gainsaying the facts which he places before the readers of the Journal—my own experience coinciding with his—I do not think gardeners are as a class so bad as we may find in many other trades. I receive many well written communications from gardeners, and those instances which are of a nature which would fail to satisfy the inspector of an elementary school are almost entirely lapses and mistakes in little things, which I suppose every imperfectly educated man is at times liable to fall into. They are as nothing when compared with notes I occasionally receive from other head servants, and whose relations to their masters and mistresses are closer than those of gardeners. Accounts and estimates from local tradesmen are also composed in a style far inferior to what I should expect from a gardener. Only last summer I received an estimate so bungled that I was ashamed to present it at headquarters, and had to point out to the person estimating the necessity of expressing himself at least with clearness. These facts do not, of course, make the case of gardeners a whit better, and if it will in any way conduce to the improvement of the rising men who have not yet taken so much pains to improve their English as they might do, I shall be very glad to place the following remarks at their service.

By way of introduction, it may be noted that board school education is, of itself, insufficient. These schools turn out good penmen, but that is the only part of their code of instruction to which the expression "good" will apply. It therefore becomes incumbent on men whose education has been derived from that source to see to it that the other necessary elements of a fair education are made good. Your correspondent is hard on men who will not take the trouble to learn to spell the name of a plant correctly, and who fail to pick up knowledge that is lying directly under their eyes. But it is just this question of seeing

things that makes all the difference between the man who is continually adding to his stock of knowledge and to his attainments, and his neighbour who with the same advantages never gets a step further forward. Speaking from personal experience, I can safely say that I taught myself more after I began work than ever I was taught at school. But even personal teaching is not sufficient. Thanks to the strict editorial supervision which obtains in the conducting of the Journal, I found that it was possible to make mistakes. I was not too proud to ask the help of a better educated man than myself, who kindly taught me more in the course of a few lessons than I had taught myself in many years. The plan was a very simple one. An essay was written out, and we went over it together, the result being that I found it possible to express my thoughts more briefly, more clearly, in more simple language, and, above all, without these slight mistakes arising from the wrong use of little words which is so prevalent. A very great help to writing correctly is found in a correct mode of expression in speaking. I occasionally have letters from persons in a high social position, which, correct enough in spelling, are badly written and of the poorest composition. The only reason I know for the latter fault is to be found in the bad English spoken by the upper classes.

There is, however, a point to which "Experientia docet" did not allude to, and which is of as much importance as spelling—I refer to the pronunciation of plant names. If the name of a plant is badly spelled it will have at least a phonetic approach to what it ought to be, but in the case of pronouncing it, it is sometimes impossible to conclude as to what is meant. This applies in a degree to specific and generic names, but more particularly to the names of varieties; and here, again, not so much to English cognomens as to those of imported introductions. When it is considered that the majority of Roses, Gladiolus, Chrysanthemums, double Zonal and double Ivy Leaf Pelargoniums, double Begonias, besides the names of many other flowers in smaller proportion, are French, and pronounced by the employers of gardeners as the French do, how ridiculous must the attempts of gardeners be to name these to their employers! French itself is worth while acquiring so far as to be able to read it, for every year brings gardeners into a closer relation with French growers, and it is of much advantage to be able to consult their catalogues, and to obtain some knowledge of their garden literature; but a knowledge of the language does not enable us to speak it, and the only wise method is to simply ask those who can speak it to tell us the names. That is an incomparably better way than to stumble on as so many do.

What I would therefore advise young men to do while their minds are still in a receptive condition, and while they have leisure, is to make a free use of the pen, take notes of work done, names of plants, and descriptions of the same, write essays, and ask the opinion of a well-educated man—not a schoolmaster—as to faults. Teach yourself to draw by compass and freehand, learn Latin, and above all French, and in doing these and in carrying out other pursuits which you will be sure to engage in, you will have taught yourselves to employ your eyes to some effect with honour to yourselves and credit to your calling.

I have no hope for the older men to whom "Experientia docet" directs his remarks. They are unaware of their failings, and therefore incapable of applying his strictures to their own cases.—A NORTH BRITON.

EARLY FLOWERS.

MR. W. B. HARTLAND of Cork sends me *N. poeticus præcox*, the most timely purple-ringed Daffodil of the "old masters"—viz., Lobel, Dodoens, Gerard, and Parkinson. It is Italian, and flowers very early in a cool sunny greenhouse; and along with it came *N. poeticus angustifolius*, of the "Bot. Mag.," which I take to be "the timely purple ring" of the aforesaid old writers.

The big Irish yellow Daffodil, called "Ard Righ," or "Yellow King" is now fine in pots indoors, along with *N. variiformis* (pale sulphur), *N. pallidus præcox* (pale sulphur), *N. princeps* (pale lemon perianth, chrome trumpet), *N. mosehatus* (true), from the Val d'Arras, and the whitest and smallest of all the "Swan's Neck," or "Bent Head" Daffodils. *N. (Corbularia) monophyllus*, the white African "Hooped Petticoat," or "Crimoline Daffodil" is now fine in pots in cold frame along with *N. cyclamineus*, *N. minimus*, *N. "Saragossa maximus,"* a very dwarf and floriferous Daffodil imported from Italy (Saragossa) by Mr. Ware. *N. minutiflorus*, the smallest of all the Narcissi, is blooming here as the gift of Mr. A. W. Tait of Oporto, an ardent and successful collector of Spanish and Portuguese species of Narcissi. This bonnie little gem is much smaller than *N. juncifolius*, with which, as a sub-species, Mr. Baker quite rightly unites it in his latest arrangement of these flowers. Outside on the open borders odd blooms of *N. cyclamineus*, *N. minor*, *N. minimus*, *N. pallidus præcox*, and *N. minor*, are in bloom. *N. nanus* is in bud, but much later than usual this season, as also is the giant *N. maximus*. The earliest double Daffodil now showing coloured buds is *N. "Silver and Gold,"* the *N. albus aureus* of Messrs. Baarnaart & Son. It is similar to *N. Talamonius plenus*, but has white perianth segments interspersed among the deep yellow segments, into which the trumpet part of the flower is divided. Mr. Barr suggested to me long ago that this is "Gerard's Double," or the true double English form of *N. pseudo-Narcissus* enlarged and developed by cultivation. In other words it is simply the cultivated "phase" of the little double yellow *N. pseudo-Narcissus* of Devonshire and the Isle of Wight. I have grown the latter for years, and as they are now large and bi-coloured I believe Mr. Barr is right.

Snowdrops have been very fine. *Galanthus Imperati*, *G. nivalis*, *G. nivalis minor*, *G. nivalis fl. pl.*, *G. n. bracteatus*, *G. Elwesi*, *G. E. major*, *G. Melvillei*, *G. M. serotinus*, *G. plicatus*, *G. plicatus major*, *G. plicatus elegans*, are all now in bloom. Our earliest Snowdrop this year flowered early in October. It is supposed to be different to the type of *G. oetobriensis*, and came direct from Mount Hymettus in Greece, along with the fine Greek *Anemone fulgens*, the true dark blue *A. blanda*, and a form of *Scilla bifolia*, which blooms six weeks earlier than the type—viz., in December and January.

A pale turquoise blue Grape Hyacinth is now in full flower here. Can anyone suggest a name for it? It is by far the earliest form of *Muscari*, and was sent from South Europe a year or two ago by some kind friend I know not. The fine large twin-blossomed *Leucojum vernum* and *carpathicum* is now in flower, and is the best of all the forms of *L. vernum*. It has a very large Narcissus-like bulb, while the bulb of the typical *L. vernum* is Snowdrop-like, and the smaller solitary flowers are green, not yellow, dotted at their apices. Both forms are figured in the great "Hortus Eystettensis (A.D. 1613)" so that they have long been known in gardens. Blue Squills (*Scilla sibirica* and *S. bifolia*) are just peeping, and the "Lenten Roses," as the various forms of *Helleborus orientalis*, *H. olympicus*, *H. atro-rubens*, *H. purpurascens*, *H. colchicus*, and *H. guttatus*, together with the spotted Berlin seedlings, are

Fig. 23.- *Narcissus obvallaris*.

at their best. I never saw bulbs, hardy plants, and fruit trees so sturdily vigorous, well-budded, and promising.—F. W. BURBIDGE.

[The illustration (fig. 23) represents a flower of the favourite early Daffodil, *Narcissus obvallaris*, which was excellently shown by Mr. T. S. Ware, Tottenham, at South Kensington early in February. It is one of the *N. pseudo-Narcissus* major type, but is of medium size with well-formed bright gold corona and lighter perianth divisions.]

ARTIFICIAL MANURES FOR PLANTS.

THAT artificial manures are of the utmost utility to plant growers there is no disputing; but in regard to their various qualities, composition, and action there is a wide field for discussion. Your correspondent Mr. H. Dunkin (on page 128), while admitting the convenience of such plant food, seems to be somewhat puzzled as to their erratic behaviour when he says, "Where one kind of manure is continued for some weeks the plants do not respond to its stimulating influence so readily as when it was first given; when such is the case give a few waterings with clear water, and then apply some other kind of manure." Your correspondent unfortunately leaves us in the dark as to the loss of appetite on the part of the plant, unless he presumes that members of the vegetable kingdom are similar to those of the animal kingdom, inasmuch as a sameness of food causes distaste, but such I hold is not altogether the case. Where such occurrences are observed I should be inclined to doubt the quality of the manure. I do not profess a deep knowledge of chemistry, but as far as my observations go I am led to believe many of the artificial, manufactured, or patent manures—which ever we like to call them—are overcharged with ammonia-yielding substances, which is not a manure in the strict sense of the word—merely a stimulant that, unless backed up by something more substantial, is apt to leave the plant in a very debilitated state after its influence is expended.

What may be the object of mixing Peruvian guano with Clay's Fertiliser? Is it simply on account of economy, or to add to the efficacy

of the latter? As a user of Clay's Fertiliser for many years I do not consider it requires any improving. Nitrate of soda I am not much inclined to use for pot plants, but for kitchen garden crops, especially on light sandy soils, it may be used with considerable advantage; but, there again, I would not advocate its use alone, either sprinkling it on farmyard manure, or if that is not possible, using a good proportion of some cheap form of potash, kainit preferably. Some market growers have such a prejudice against nitrate of soda that I know for a fact, if anyone was to offer to make them a present of a quantity, and apply it free, they would not have it; as they have experienced the exhausting influence it has when used alone on the soil, and also the peculiar action it has on heavy land, producing an effect similar to salt in rendering it close and of a soapy texture. But if I was unable to get a good supply of farmyard manure I should not object to using a little nitrate of soda, but should take the all-important precaution of mixing some kainit with it, and, if possible, adding some bonemeal, or if the soil was of a sandy nature I should give this mixture the preference to farmyard manure for some crops. The kainit furnishing the potash would, in conjunction with the ammonia yielding nitrate of soda, produce as near a simple plant food as it is possible to make cheaply for general purposes.

In the same way in regard to plants in pots, if the manure applied in the first instance is a properly proportioned combination of the elements needed for the plant's support, no diminution of the plant's vigour will ensue even after a protracted application; but, on the other hand, if the so-called manure fails to have effect after a few applications, change of food would certainly be a step to remedy the evil, but what I should call a haphazard one—the next sort of manure applied may possibly contain the element the previous one was deficient of. I sometimes think there is an analogy between plant and animal life—between the way we should treat a plant and the way we should treat ourselves. For instance, feed a plant on strong ammoniacal manures, and the result will be gross unfruitful growth. Treat the animal to a course of sugar, Potatoes, and other starch-yielding materials: result, fat and loose tissue will increase while bone and muscle will decrease. But give to the plant according to its individual needs, ammonia, potash, lime, &c., in proper proportion, and, other things being equal, good permanent results will follow.—M. COOMBE, *Ashton Court, Bristol.*

EUCCHARIS CULTURE.

CIRCUMSTANCES which I could not avoid prevented my replying earlier to Mr. Pettigrew's strictures on my note concerning the culture of *Eucharis amazonica*. The course of treatment which I recommend has produced results of a most satisfactory nature, or I would not have sent it to the Editors for publication. Mr. Pettigrew seems to think there need be no difference in the treatment of plants in good health and those in a sickly condition—a surprising assumption from such an experienced gardener, for it is well known that plants in robust health will endure treatment which would soon kill their weakly associates. Whatever my critic may affirm to the contrary the sight of sickly *Eucharises* is far more common than desirable in many gardens, and it was with the hope that it might assist those in charge of such that I penned my note. If Mr. Pettigrew will look over my note again he will see that I do not recommend the plants to be dust dry at any time after they are once subjected to my treatment, but only to prepare them for it. I will add nothing to what I have previously written with regard to watering. Mr. Haggart's practical article in last week's *Journal* has referred to that subject in a manner which must be sufficiently convincing to all.

I may have something to say about the "mite" question in a future issue, and will only suggest that had Mr. Pettigrew adopted the treatment which I recommended with his affected plants, instead of consigning them to the fire, he might by this time have had a useful stock.—M. D.

IN complying with Mr. Haggart's request respecting the temperature in which the *Eucharises* are grown here, perhaps it will be necessary to give the dimensions of the house, and the general arrangement and appliances for heat and ventilation. The house is span-roofed, with a door in the centre of each end, and a walk round the sides. It is 60 feet long, 21 feet wide, and 16 feet high, with a slate table in the centre 50 feet long and 9 feet wide, supported on iron framework 2 feet 6 inches above the level of the floor. There are also slate shelves 2 feet wide round the sides of the house on the same level, and supported by iron framework similar to the table. The house is heated by means of six rows of 4-inch hot-water pipes on each side, placed under the side shelves, and the tables and shelves are covered to the depth of 4 inches with sand and pea-gravel to maintain moisture. The house is ventilated both top and sides by means of simultaneous opening ventilating gear.

The pots of *Eucharis* in question are placed on the top of large inverted flowerpots in the centre of the table, 18 inches above the surface to keep the outside leaves from lying on it, which they would if the pots were placed on the table. The house is in good repair, and there is no difficulty whatever in keeping the temperature at 70° in ordinary weather without making the pipes very hot, but in winter when the weather is severe the temperature is allowed to drop to 60°, and to rise to 80° and 90° in hot weather during the summer with plenty of air on. The plants, as I have stated in the *Journal* before, receive the same treatment as regards heat and moisture all the year round. They are never subjected to a lower temperature than 70° (except in severe weather), nor dried off and rested, with the idea that this treat-

ment will ripen the bulbs. The temperature recommended by "M.D." in his easy method of restoring languishing plants to vigorous health was (if I mistake not) ordinary stove heat. Now if anyone was to ask me what was meant by ordinary "stove heat," I certainly would say a minimum of 70°. Mr. Haggart informs us that the *Eucharis* can be restored to vigorous health in a much lower temperature than this. The sickly bulbs he took charge of some eight years since, "with scarcely any leaves, and these were only a few inches long, spotted, wrinkled, broken, and unhealthy," were restored to health in a temperature which often stood at 50°, and in very hard weather as low as 45°. I presume (indeed he says so) it is because he has not sufficient heat power to keep it higher, or he probably would not allow the temperature "very often" to fall so low.

Mr. Haggart's general treatment of the *Eucharis* consists in giving the plants no water for a long time after potting—not until they are well started—and simply enough then to moisten the soil, and in keeping the atmosphere as moist as possible by syringing the stage and the pots, but singularly he never syringes the plants. The plants are potted as they require it, and receive more water, and occasionally supplies of liquid manure to encourage them to make growth. The supply of water is gradually discontinued when they seem to stop growing until they are well ripened.

Under the above treatment (which he terms "the dry system" that Mr. Pettigrew condemns) the bulbs, with the few short, spotted, wrinkled, broken, unhealthy leaves, have filled large pots with plenty of leaves, which now flower regularly three and four times a year, a dozen pots producing no less than 600 blooms in a month. Mr. Haggart is to be congratulated on his successful treatment of the plants in question, but it is a wonder to me how the bulbs can flower so regularly three and four times a year, when they are often standing in such low temperatures as those described. I am not surprised at the number of flowers that twelve large pots of healthy *Eucharises* will produce, but it is the cold treatment and the regularity with which they flower three and four times a year that surprises me.

I have gathered as many as 600 blooms in a week from six of the largest plants here, but they are treated on a much more liberal system, receiving plenty of heat and moisture at all seasons.—A. PETTIGREW, *Cardiff.*

ROSE SHOWS IN 1888.

- June 30th.—Eltham and Reigate.
- July 3rd.—Bagshot, Canterbury, Diss, and Hereford.
- " 4th.—Croydon.
- " 5th.—Bath, Farningham, Hitchin, and Norwich.
- " 6th.—Sutton.
- " 7th.—Crystal Palace (National Rose Society).
- " 10th.—Ipswich.
- " 11th.—Tunbridge Wells.
- " 12th.—Winchester.
- " 17th.—Leek and Ulverstone.
- " 18th.—Birkenhead.
- " 19th.—Helensburgh.
- " 20th.—Darlington (National Rose Society).

The above list contains all the Rose Show fixtures that have as yet reached me. In future lists I shall be pleased to insert the dates of any other Rose Shows that I may receive, also those of any Horticultural Exhibitions where Roses are made a special feature of the Show.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

THE WHITE BANKSIAN ROSE.

How seldom we find this beautiful and thornless Rose favoured with a position under glass. The only reason I can advance for this is that I think its good qualities are not sufficiently well known. Its small and deliciously scented flowers are produced in clusters varying in number from three to nine or ten, and most useful little bunches they are for so many purposes, such as arranging with other flowers in vases, bouquets, or buttonholes. The plants are also of easy culture, and being of vigorous growth quickly cover a large space, are seldom troubled with insects of any kind, and if treated rightly will flower as certainly and as freely as the Rose that is sometimes spoken of as the only one without a thorn—viz., the Primrose. At Preston Hall in Kent, a fine old plant covers the roof of a corridor that forms a connection between the fruit houses. It is said that this tree has been planted twenty years, and judging from the thickness of the stem it seems quite probable, and from its trailing branches I have cut many a basketful of flowers. It is planted in a narrow border, but I have no doubt its roots must have found their way some distance from the original border. I have seen trees growing in pots, but they do not appear to be so happy under such conditions, probably owing to the roots being too much restricted. Banksian Roses will not bear hard forcing, but are admirably adapted for planting in cool Peach houses when the room can be spared, or in any structure

kept at a greenhouse temperature. During the growing season they should be freely syringed till the flowers begin to open, which in a cool house they will generally do about the beginning of March. When the flowering period is over the greater part of the wood that flowered should be cut clean away, together with any strong shoots not wanted for extension, and the medium sized growing shoots left to ramble freely during the summer months. In August these should be examined again, and thinned wherever they appear too much crowded, so as to leave room for light and air to circulate amongst them and thoroughly ripen the wood. The points of the shoots will not require shortening, except in a few cases where there is no room for extension. The shoots should then be lightly fastened to the trellis or wall here and there, just to keep them within bounds, but must never be tied in closely, as it is altogether against their rambling nature. During the autumn months they should have abundance of air, and if properly attended to at the roots and brought on gradually at the beginning of the year, they will flower from the axil of almost every leaf, and will, I am sure, give general satisfaction to lovers of white and fragrant blossoms.—H. DUNKIN.

THE ROSE GARDEN.

PLANTING Roses should be pushed on to completion as quickly as possible, weather permitting. They thrive best in a stiff loamy soil, therefore where the latter is light it will be necessary to mix some clay and manure with it before planting. Do not bury the stems of the trees deeper than they were before. Press the soil firmly about the roots with the feet, and, if standards, secure them to stiff sticks. Afterwards lay on a few inches thick of short dung as a surface-dressing, which will not only prevent frost penetrating the soil, but it will also maintain the latter in a more equable condition about the roots than would otherwise be the case. Moreover, the good resulting from a mulching of this kind during the summer, especially if it should be a hot one, cannot well be over-estimated. For beds I prefer Roses on their own roots. These may be planted about 4 feet apart every way, and be pegged down about the end of March, the suckers which spring from the base of the plants during the summer being similarly treated in July for autumn flowering. The following forty-eight varieties may be depended on for exhibition and other purposes—viz., Duke of Edinburgh, François Michelon, Marguerite de St. Amand, La France, Marie Baumann, Rosieriste Jacobs, Reynolds Hole, Louis Van Houtte, Marie Van Houtte, Victor Verdier, Merveille de Lyon, Madame Willermoz, John Bright, Edouard Morren, A. K. Williams, Beauty of Waltham, Souvenir d'un Ami, Magna Charta, Baron de Bonstettin, Duke of Wellington, Madame Lacharme, Lord Macaulay, Paul Néron, Madame Emilie Fontaine, Archduchesse Elizabeth d'Autriche, Sénateur Vaisse, Comtesse d'Oxford, Auguste Rigotard, Antoine Dueher, Xavier Olibo, Madame Nachury, Madame Gabrielle Luizet, Marquise de Castellane, Niphotos, Charles Lefebvre, Duke of Teck, Etienne Levet, Alba Rosea, Fisher Holmes, Barthelemy Joubert, Ferdinand de Lesseps, Madame Eugénie Verdier, La Rosière, Camille Bernardin, Sultan of Zanzibar, Catherine Mermet, E. Y. Teas, Edouard André, and Madame Thérèse Levet.—H. W. WARD.

ROSE GRACE DARLING.

IN reference to Mr. Machin's inquiry on page 151, Grace Darling was last year classed in the National Rose Society's report as a Tea Rose, because the Society always accepts the raiser's classification until it is found to be incorrect. Now that this exquisite Rose, charming, and in every way desirable as it is, has conclusively shown itself to be a Hybrid Tea, it will, no doubt, have to be exhibited in future as such. The point, however, will be authoritatively settled this season on the publication of the Supplement to the National Rose Society's Catalogue of Selected Roses.—T. W. GIRDLESTONE.

MARECHAL NIEL.

"L. T." (page 151) finds fault with the instructions given by "N." (page 107) and is surprised to find that he advises no air being given. He wishes "N.'s" remarks to be endorsed by some other rosarian. I do not know if he will consider me competent for this or not, but I fully endorse "N.'s" instructions. Sudden bursts of sunshine do far less harm by raising the temperature than the most careful gardener will do if he opens the ventilators. It would be very warm indeed before I would open the ventilators of a house of forced Roses.

To bring forward the case of a plant in Mr. J. C. Reid's gardens, which is not forced, is a very curious proof of "N." being wrong in his advice for forcing Roses. Air being admitted may prevent mildew, but I doubt it. By the way, if Mr. Reid's gardener is not above taking advice, let me suggest that half the flower buds on his Maréchal Niel be removed, or it will probably go after a good many others, and it will be too late then to inquire the reason of its so doing.—D. GILMOUR, JUN.

I, LIKE your correspondent "L. T.," was a little surprised on reading the article by "N." on the subject of ventilation. I have here under my charge a span-roofed house with the ends standing east and west. On the north side is planted two Maréchal Niel Roses on their own roots, and they now cover the whole of that side of the house. The plants are only three years old and have made capital growth. I prune well back after flowering. Some of the growths are 12 feet in length. The night temperature in winter is just what we can get according to the weather, and ventilation is given on all favourable occasions when the thermometer rises to 55°. If that dreaded pest mildew does appear I find no difficulty in keeping it in check by using the mixture so often described

in the Journal—viz., softsoap, sulphur, and a little petroleum, which I find not only a remedy, but, better still, a preventive. Common sense must be used in ventilating Rose houses as well as any others where plants are grown under unnatural conditions.—W. W., East Yorks.

SEASONABLE HINTS ON FLORISTS' FLOWERS.

AURICULAS.—As we have now, we may hope, passed through the gloomiest portion of our winter and we see things once more beginning to move, I think on the whole it has been a good winter for florists' flowers, save that period of severe fog which prevailed throughout England, and against which it was needful to take precautions, as damping off was very prevalent. I do not think that there was an excess of autumn flowering; indeed, the season was not provocative of that, but in my opinion there is no remedy for it. There are certain varieties which will invariably do it and others never or seldom, the time of potting makes no difference. Auriculas have been also slow to move, and are only just beginning to develop themselves. I have discarded what used to be a troublesome business at this season—viz., top-dressing, and have contented myself simply with stirring the surface of the soil, and, if necessary, filling in a little, but this is hardly needful, as I am sure it is better to have the soil under the level of the pot than high up in it, as in watering you are pretty sure that some will run over. They may be still left in their frames facing south, but especial care will be needful to cover up on frosty nights, as when the blossom is advancing is the worst time for them, not that it kills the flower stem, but makes the flowers themselves crumpled, destroying that flatness which is one of the chief characteristics of a good flower.

CARNATIONS AND PICOTEES.—I have never seen my small collection in better health than this year. Many of my plants last season failed to give me stock, but of those that did the layers were good, not too strong, or what John Ball calls "gouty." There has not been the slightest sign of spot or of the Carnation grub, and I do not think I have had to remove a dozen dead leaves, the plants having that bluish green tint so indicative of good health. The heap of compost for potting them has been for some time under a glass roof, but open at all sides so as to allow it to have the influence of the frost. This must be turned over several times yet before being used, and a careful look out kept for worms and insects of all kinds, especially the yellow wireworm, which in a day will destroy our finest plants. As they will now be pushing into growth more water may be given, but it is far better to err on the side of dryness than over-moisture. Air should be given to them night and day, and as in the case of Auriculas in case of frost the frames should be covered with matting or some other warm material. It will be well now to see what pots are required, and if any are wanted to get them in and have them all well cleaned and ready for use. The broken pots for drainage should also be clean, as nothing can be too sweet or clean for the production of good flowers and healthy plants. Where the compost has not been already prepared it should be got ready now—two parts good turfy loam, one part leaf mould, and one part old manure, with some road grit or charcoal to keep it open. The hop growers about here make their own charcoal for drying the hops, and I find that the refuse of this, the smaller pieces, with the sand used for banking up the fire, makes a capital ingredient for this and many other plants.

CHRYSANTHEMUMS.—I forbear making any notes on these, as so much advice is given to growers in the pages of the Journal. Now will be the time to add to stock, but really the multitude of new varieties makes it very perplexing as to what to choose. This I must leave to other hands.

GLADIOLUS.—Although next month will be the time for planting the corms, yet it will be necessary to make preparation for it this month. Collections should be looked over, and where any deficiencies are detected now is the time to supply them, as the corms were well ripened last autumn. I find that they are keeping well, and plump. Some few, such as Shakespeare and Horace Vernet, are beginning to move, but, as a rule, they are in a quiet state. It will be easy, where the beds are marked out and measured, to calculate how many corms are required. It must be recollected that if the corms are of good size they may be cut into two, and thus the stock doubled. Some writers have expressed a prejudice against doing this, but I can bear witness to the fact that some of my best blooms and corms were the produce of cut corms. I have even successfully cut one into three.

PANSIES IN POTS.—I have, February 11th, just completed potting my small stock, as I think this is the only satisfactory way of growing them. You may, of course, grow them in beds, but then you have to reckon with the severity of the weather, drenching rains, severe frost, &c., and if the winter be a hard one your Pansy bed will present rather a dilapidated appearance by this time, unless you are in a favourable locality, and then when your plants begin to grow and to show bloom look out for slugs, ravenous after their long fasting, and ready to devour foliage, blooms, or anything that comes in their way. Moreover, to one a septuagenarian, it is an immense advantage not to have to stoop over them to examine their beauty. They are now in a cold frame, the light of which is tilted to admit plenty of air. There they will remain until they are removed next month.

ROSES.—Here, again, such copious directions are continually given about the culture of Roses that it is hardly necessary to say much about them, but it may be well to assure growers that if they find vacancies in their beds they may, with a fair prospect of success, plant now, especially if they can procure them from a nursery near at hand. Some of the best blooms of Tea Roses that I remember seeing were

shown from plants what had been planted out in May. In some forward districts pruning will take place now, but in general it is better to defer that operation until March. The mulching had better still be left on the buds, for although much frost is not to be expected, yet it is better to err on the safe side.

RANUNCULUS.—The 12th of February was generally considered the orthodox day to plant Persian Ranunculus. I managed to get mine in yesterday, the 10th, and to-day it has been very wet. In planting them it is necessary to be very careful as to the depth at which they are put, 1½ inch being the exact depth that suits them. It is better to plant firmly, for there is the less chance of worms displacing them, which is one of the great annoyances in their culture.

There are other florists' flowers, such as the Dahlia and the Hollyhock, which I have not mentioned because I do not myself grow them, and I like simply to notice those I do grow, and I would also add that I grow not for exhibition, but for my own pleasure; although I am very strongly of opinion that as it is with the Rose so it is with other flowers, that if the exhibitor's culture be followed, and his choice of kinds adhered to, there will be far more satisfaction than by adopting a lower standard of cultivation.—D., Deal.

COELOGYNE CRISTATA.

Mr. W. GRIX, The Gardens, Gledhow Hall, Leeds, sends us a flower of *Cœlogyne cristata* with three perfectly formed lips, and no other indication of deformity. There are the normal three sepals, two petals, and one column, and the three lips are not distorted in the slightest degree. Cases of this kind are usually accompanied by other deformity, or are caused by the fusion of two or more flowers, but there is no trace of the latter in the present example. It is simply a curiosity and detracts from rather than adds to its beauty.

TWO NEW ORCHIDS.

Mr. FRED HORSMAN of Colchester recently flowered a most distinct variety of *Lælia anceps*, which has been named *Measuresiana* in honour of Mr. R. H. Measures, Streatham. The flower is of great size and good colour, but the most remarkable character is seen in the lip, which is of unusual breadth, very open and richly marked. The other is a new *Lycaste* that has been named *Tautzi*. It may be briefly described as follows:—Pseudo-bulbs 6 to 8 inches long, deeply furrowed; flowers about 5 inches in length, sepals and petals recurved. In colour the sepals are crimson brown, the petals primrose, and the lip pure white. The throat of the flower is dotted with small crimson spots like *Phalænopsis amabilis*.

CORYANTHES MACRANTHA.

Mr. J. McGRATH, Blackmoor, West Derby, Liverpool, sends a flower of this extraordinary Orchid, respecting which I have previously published the following note.

"In this and others of the genus the lip is formed like a 'bucket,' one portion of which secretes a fluid that falls into the lip and remains there until evaporated, or it sometimes fills the 'bucket' and overflows by a spout. *C. macrantha* has projections upon the lip, which tempt bees to gnaw them; and Dr. Cruger has observed that "the bees may be seen in great numbers, disputing with each other for a place on the edge of the hypochil. Partly by this contest, partly perhaps intoxicated by the matter they are indulging in, they tumble into the 'bucket' half full of fluid; they then crawl along in the water towards the anterior side of the 'bucket,' where there is a passage for them between the opening of this and the column. If one is early on the look out, as these bees are early risers, one can see in every flower how fecundation is performed. The humble bee in forcing its way out of its involuntary bath has to exert itself considerably, as the mouth of the epichil and the face of the column fit together exactly, and are very stiff and elastic. The first bee, then, which is immersed will have the gland of the pollen mass glued to its back. It passes out with this, and perhaps enters the same or another flower, when the pollen masses are placed directly upon the stigma in coming out as before."

Mr. C. Darwin, in his "Fertilisation of Orchids," has fully described the peculiarities of structure in *Coryanthes*, *Gongora*, *Acropera*, *Stanhopea*, and allied genera.

DENDROBIUM SPLENDIDISSIMUM GRANDIFLORUM.

THIS magnificent hybrid, one of Messrs. Veitch & Sons' Chelsea

productions, attracted a large share of attention at the City sale rooms last Tuesday, when a plant with two leads and ten grand flowers were sold for 55 guineas. The flowers were 4½ inches in diameter each, with broad open lip deeply coloured, the sepals and petals being also richly tinted. It is from the same species as *D. splendidissimum*, but finer varieties were selected as the parents, and the difference is very perceptible when the original hybrid and the other are seen together as in Messrs. Veitch's houses. Both are good, but *grandiflorum* has a much bolder and more effective flower.

COELOGYNE CRISTATA ALBA.

Mr. R. H. MEASURES, The Woodlands, Streatham, has probably the finest specimen white *Cœlogyne* in flower at the present time that could be found in private or other collections. It has thirty-two racemes, or a total of 170 flowers, large, massive, and pure white. It is a grand example of this beautiful Orchid, and is highly prized by its possessor.—L. C.

ORCHIDS AT ST. ALBANS.

IF any person entertains a doubt respecting the commercial importance of Orchids at the present time, a visit to Messrs. F. Sander and Co.'s nursery at St. Albans would effectually dispel the illusion. Few indeed, except those actually engaged in the business, have an adequate idea of the vast development of Orchid trade within recent years. The amount of capital now invested in these plants by amateurs and nurserymen is enormous, Orchid admirers are rapidly increasing in numbers, and quite a little army of persons is employed in one way or other in collecting, growing, and distributing them. The business has advanced far beyond the period of a fantastic craze, for the horticultural value of Orchids is now widely recognised; the distinction, beauty, durability and fragrance of their flowers have obtained for them a place not only in the collections of wealthy and aristocratic amateurs but in those of amateurs of all grades, and even in those of strictly commercial people, who supply the great markets with choice flowers. It has been repeatedly proved that many of the difficulties supposed to attend Orchid culture are purely imaginary, and in consequence hundreds have taken them in hand who would have been otherwise deterred from doing so.

These and many other thoughts are suggested by an inspection of the St. Alban's nursery, and the following notes may convey some idea of what was seen there in a couple of hours. The new nursery (for the original establishment is situated in the centre of the town) is a short distance from the Midland station to the right of the line in going from London. It comprises a great block of glass houses from 100 to 350 feet long, and with corridors connecting the ends of the houses 300 feet in length. The houses are span-roofed, running from north to south, the corridor on the south side also connecting with the printing rooms, warehouses, potting and packing departments, which will be referred to presently, while the corridor on the north side has been considerably widened, and is being converted into a *Cattleya* house. The block is thus nearly triangular in form, the apex of the triangle being formed of the offices and Mr. F. Sander's residence. The entrance hall at once gives an idea of the character of the establishment; it is spacious, simple, yet extremely tasteful, designed in Elizabethan style, and wainscotted in plain carved oak and cedar. It is separated by glass partitions and doors from an ornamental rockery, and this in turn on both sides leads to the two corridors, so that a complete tour of the houses can be made without once passing into the open air. The rockery itself is very interesting, being an improvement upon the design represented at the Indian and Colonial Exhibition of 1886. Real Tufa has been employed in a picturesque manner as bold jutting rocks, with miniature fountains and waterfalls to heighten the effect. Numerous Orchids have been tried, to test which succeed best planted out in this way, and an especial feature has been made of *Cypripedium caudatum*, which it is anticipated will afford a remarkable effect when in flower. *Lælia elegans* also thrives well, seeming thoroughly at home; *Lælia anceps*, various *Cattleyas*, *Sobralias*, and *Cœlogyne*s are freely employed, and of the beautiful *Arpophyllum spicatum* there is a fine specimen. Some little difficulty has been experienced in finding Orchids suitable for training to the roof, but *Vanda teres* is being tried, and appears likely to succeed, as it will have a light sunny position such as it most enjoys. We could scarcely imagine what the effect might be in a few years' time with the roof covered with the growths and charming flowers of this Orchid. Orchid rockeries could be introduced in many houses, and with a few Ferns or other plants to furnish them a most agreeable feature would be afforded. Few other flowering plants can, however, be satisfactorily employed with the Orchids, or a discordant effect results.

It would be impossible to describe within moderate limits the contents of the numerous houses entered from the corridor, but a few words may be given respecting the structures themselves before noting some of their principal occupants. It should be first said that they are devoted exclusively to Orchids, so that in their construction, heating, &c., especial provision has been made for the requirements of the cool, intermediate, or warm house species. All the larger houses have side stages and paths with a raised central stage near the glass, and a path under the ridge, where a good view is obtained of the closely packed banks of plants, in several cases 200 to 300 feet long. The stages are of open wooden trellis, beneath them being large beds of leaves, which afford a constant humidity, the beneficial effect of which is shown by the

sturdy healthy condition of the plants throughout. But much time or labour cannot be devoted to damping, and it is consequently accomplished in the following simple but effective manner. Beneath the stages at the sides of the walks run inch iron water pipes perforated at near intervals and furnished with taps so that it can be turned on in sections, and the surfaces of leaf beds, paths, walls, &c., are thus moistened as frequently and as thoroughly as required. Most of the houses have an incline to the south, and to insure the water remaining in the paths the tiles or iron bricks are partially hollowed in the centre, but not sufficiently to interfere with walking. Another mode is to have depressions at the sides of the paths next to the walls with divisions about a foot apart, which also serve to retain the water deposited on them. Extensive tanks are provided for rain water, which is almost exclusively used for supplying to the plants, and shading is

in all respects been carefully constructed. The roof is of the ridge and furrow style, and the shading material is to be run from ridge to ridge, thus leaving space for the free admission of air. The centre stage rests on arched brick divisions, with a stage at one side and small rockeries between the houses on the other. Over the paths are wires for the suspension of baskets or blocks, and when the house is filled it will have a fine appearance, as it is very light, the iron supports and ornamental corner pieces being of chocolate colour.

The contents of this house are varied, but include large stocks of popular and useful Orchids. *Odontoglossums*, for instance, have a large proportion of the space devoted to them, *O. crispum* (Alexandria) alone filling several long houses, while *O. Pescatorei* fills a house exceeding 200 feet in length. These are mostly in pots, but some are planted out in side beds and soon become established. They include innumerable

FIG. 24.—ANGRÆCUM SANDERIANUM.

provided by light tiffany on rollers, or a light cloudy mixture such as has been repeatedly described. As a convenient means of catching slugs small shallow saucers are filled with fresh bran and placed along the walls or stages, and these being closely examined every evening after dusk numbers of would-be depredators are caught and destroyed.

The space beneath the stages in the larger houses is utilised in another and very important way, thousands of imported plants being suspended there until they "plump" or show signs of vitality by commencing root growth. It is their first stage after removal from the cases in which they arrive, and as soon as they are found to have recovered sufficiently they are placed in pots or baskets, but mostly the former, and this is a work of some magnitude where so many thousands have to be dealt with every month. Excessive heat is avoided, but a liberal supply of piping is allowed, and several miles are required to provide the requisite temperatures for so large a block of houses, Weeks' tubular being the boiler employed. In the corridor Cattleya house alone over a mile of pipes has been found necessary, and this house has

fine varieties, as fresh treasures are being constantly discovered. *O. vexillarium* is also largely represented by vigorous plants of different sizes, and no difficulty seems to be experienced there in the culture of this Orchid. There is a good stock of the remarkably distinct and beautiful *O. Harryanum*, *O. navium majus*, and scores of the valuable hybrids or intermediate varieties are arranged in one of the houses. *Cattleyas* and *Lælias* are seen in thousands, of all sizes and in all stages, from small pieces in 60 or 48-size pots to huge masses, like one example of *Cattleya Bowringiana* 4 feet long by 3 feet wide, and comprising 300 pseudo-bulbs and sixty new leads. *Cattleya Trianae* and its varieties are admirably represented, and contribute largely to the floral display at the present time. All the best of the other *Cattleyas* are also included, while of *Lælias*, *L. anceps* is in strong force both of the richly coloured and the white varieties. The handsome *Lælia elegans* and its numerous varieties have considerable space devoted to them, some of the plants being of great size. *Cœlogynes*, such as *C. cristata* *Lemoniana*, the *Chatsworth* variety, and *maxima*, are flowering together, and the superior characters

of the latter are seen at a glance, the flowers of great size and well meriting the name bestowed upon it. Dendrobiums, Oncidiums, and many other large genera are represented in a similarly extensive manner, but in what may be termed the miscellaneous collection, the plants in flower at the present time of *Angræcum Sanderianum* (fig. 24) are most conspicuous. The plant is one of the introductions of Messrs. Sander & Co. from the Comoro Islands, and was recently certificated at South Kensington, when our illustration was prepared from the plant shown. The flowers are pure white, and are borne in long slender graceful drooping racemes, which have had as many as twenty-five to thirty flowers each. It is well adapted for basket culture, and though usually grown in a warm house it has been quite satisfactory in a temperature as low as 55°. It may be classed amongst the really useful Orchids, as it is easily grown and most profuse in flowers.

As already mentioned adjoining the south corridor are the warehouses, &c., which are in three floors. The upper is occupied with printing room and offices in connection with the production of that fine illustrated work on Orchids, the "Reichenbachia," issued by this firm. The potting and unpacking departments occupy other floors, and the ground floor is devoted to the work of packing and transport. Piles of huge cases are seen that are being rapidly opened and their contents examined, for it can be imagined that with sixteen collectors at work in as many different regions the supply of imported plants is an extensive one, indeed it is surprising how they can all find purchasers. Profits must be large occasionally, but heavy losses have also to be met, for undue delay in transport in a tropical climate often means the loss of thousands of valuable plants collected at great expense.

Only a few words can be accorded to the old nursery in the town, though it deserves a full notice. Fourteen compact span-roof houses with a corridor at the end are devoted to *Cypripediums* of all the choicest species, hybrids, and varieties obtainable, with *Phalenopsis*, *Vandas*, *Cattleyas*, *Pescatoreas*, and innumerable others, while experiments in crossing and seed-raising are there being carried out on a large scale.

It only remains to add that the presiding genius of this great establishment is Mr. F. Sander, who possesses a remarkable share of intelligent enterprise and energy, and he is assisted by a thoroughly practical manager in Mr. J. Godseff.

HEATING AND VENTILATING NEW BUILDINGS AT ETON.

The Governors of Eton College have found it necessary to augment the accommodation of the College by the erection of extensive additions, comprising a new chapel, museum, and numerous class rooms. These works are now being carried out from the designs and under the direction of A. W. Blomfield, Esq., M.A. In the present day much greater attention is paid to the warming and ventilating of such buildings than was formerly the case, and the necessary arrangements for effecting these purposes are to be carried out by Messrs. J. Weeks & Co., of Chelsea, to whom Mr. Blomfield has entrusted this branch of the work. The cost of the new buildings is about £40,000. The system to be adopted is that of admitting fresh warm air into each room by passing it through Weeks' hydrocaloric warming and ventilating coils, which have of late years been much used in all sorts of public and private buildings and by Her Majesty's Government, and the action of which is consequently pretty generally understood. They admit, day and night, a constant current of fresh warm air into the building, either moist or dry at pleasure, no cold air whatever being admitted in severe weather.

The arrangements for carrying off the vitiated air are on a somewhat comprehensive scale, and constitute a new departure in ventilation. The warm respired air, from the upper part of each room, will be drawn through ventilators specially constructed to prevent down draught, into large horizontal air ducts placed against the ceiling of the various passages. These ducts will be the full width of the passages, and will be formed by means of a false ceiling, with a space of about 2 feet between it and the floor above. This is a novel and effective means of getting over the difficulty, which appears to have been long felt in providing space for ventilating shafts, and that without at all injuring the passages, the height of which, as a rule, is very much out of proportion to the width. These horizontal air ducts will meet at a large vertical air shaft, which will pass out through the roof and be surmounted with a special cowl in the form of an ornamental turret. By means of a simple and efficient gas apparatus placed in this vertical shaft, it will be made a powerful exhaustor, and will confirm and strengthen the upward tendency already possessed by the vitiated air, will draw in a steady and constant current from the rooms and pass it out above the roof of the building without the possibility of return.

The advantage of this arrangement will be felt both summer and winter. In the summer a constant stream of fresh cool air will be drawn through the rooms, and in the winter a constant stream of fresh warm air, and that without opening either windows or doors. The whole atmosphere of the building can thus be changed two or more times, if necessary, each hour.

THE WINTER ACONITE, *ERANTHIS HYEMALIS*.

A SHRUBBERY border here affords a striking illustration at the present time of the value of this plant for shady positions under large trees or any shady woodland walk where its roots would not be disturbed. I am told the roots were planted about twenty-five years ago in several small

patches; they now cover a space of ground 60 feet by 30 feet with their rich yellow flowers, and continue spreading in all directions, large quantities of seedlings appearing every year. With us they are the first of the spring flowers, as they appear about a fortnight before the Snowdrops are in flower, and are consequently much appreciated. We find them very useful for decorating the mansion if the roots are carefully lifted and tied in moss. After two or three days in the house they may be replanted and will flower again the next season. They are also very pretty for dinner table decoration, &c., when gathered, and many other purposes.—W. H. DIVERS, *Ketton Hall, Stamford*.

THE MEANS OF PROTECTION POSSESSED BY PLANTS.—Mr. F. M. Campbell, F.Z.S., F.L.S., &c., President of the Hertfordshire Natural History Society, recently delivered the Presidential address on the above subject at the annual meeting of that Society held at the Free Library, Watford. The different means of protection touched on were as follows: Protection by means of concealment, protection by means of objectionable flavour; protection by means of objectionable flavours and colour; protection by means of appliances; protection by means of mimicry; protection of seeds and spores. In his introductory remarks Mr. Campbell stated that just as weak nations require special guarantees for their independence so do weak organisms require special protective modifications, and instances of this occurring in plants are common. In regard to concealment of plants, one of the most interesting cases of "hiding" was seen in the hardy *Cyclamens*, where, after the flower falls off in January the capsules become wholly or partially buried, and the safety of the seeds, which do not ripen till June, is secured. As to protection by means of objectionable flavour several well known plants were mentioned, including *Rhododendrons*, *Ferns*, *Mosses*, *Aeonite*, *Hemlock*, *Hellebore*, &c., and it was also stated that the flowers or petals of plants were in general more acrid than their leaves, hence they are much seldom eaten by insects. Among many instances of protection by means of appliances were mentioned the *Holly* and *Thistles*, and in connection with the latter Mr. Campbell remarked that their armament was very necessary, as they were when crushed excellent food for horses and cattle. Speaking of protection by means of mimicry Mr. Campbell explained that what was meant by the expression was that one plant was so much like another that an observer could not distinguish between the two without critical examination; for instance the *Dead Nettle* being exceedingly like the common *Stinging Nettle*, which is avoided by many animals. Light seeds were protected by being carried away by the wind, Nuts were either made inconspicuous or armed with a spiny covering. The gay coloured fruits were an invitation to a repast, and contain pips which passed through the animals eating their pulpous covering with an unimpaired or possibly augmented vitality. In conclusion he said that whatever clearness of intellectual vision mankind might obtain in the future, they would be better able than ourselves to realise that they have but read a few syllables from the title page of the *Book of Nature*.

CHRYSANTHEMUM SHOWS.

WE have received notices of the following fixtures for the Shows of 1888:—

National Chrysanthemum Society, Metropolitan Shows, September 12th and 13th; November 7th and 8th; and January 9th and 10th, 1889.

Provincial Show at Sheffield, November 16th and 17th.

Kingston-on-Thames, November 6th and 7th.

Portsmouth, November 7th, 8th, and 9th.

Teddington, November 8th and 9th.

Southend, November 13th.

Brighton, November 13th and 14th.

Putney, November 13th and 14th.

Winchester, November 13th and 14th.

Reading, November 15th.

Pembroke, November 15th.

Lindfield (Sussex), November 15th and 16th.

Sheffield and West Riding, November 16th and 17th.

Liverpool, November 20th and 21st.

Birmingham, November 21st and 22nd.

Hull, November 22nd and 23rd.

Pontefract, November 23rd.

A NOVEL CLASS

MR. W. HOLMES of Hackney has proposed that the National Chrysanthemum Society adopt a novel class at the next Westminster Exhibition. The general plan is as follows—"That a challenge trophy and £10 in money be offered for the best collection of forty-eight blooms, twenty-four incurved and twenty-four Japanese, contributed by any Chrysanthemum or horticultural society on the following conditions—First, The entry to be made in the name of the Society. Second, An

entry fee of 10s. 6d. will be charged to societies not affiliated with the National. No entry fee to be charged to affiliated societies. Third, Each society competing must be prepared to guarantee that the blooms staged are cut from the collections of its members only. Fourth, That the forty-eight blooms may be the production of one or more growers at the option of the society competing. Fifth, No limit as to number of entries from each society, but no society will receive more than one prize. Sixth, The cash will be paid to the Treasurer of the society winning the award, to be equitably divided between the contributors." The idea has been freely discussed and criticised, several difficulties having been pointed out, but the preponderance of opinion up to the present is in favour of the scheme.

CHRYSANTHEMUM PRINCESS OF TECK.

WE are told "there is nothing new under the sun," and in all probability the subject which I wish to draw attention to, although it is new to me and Mr. Crossling, and to all those whom I have spoken to about it, it is perhaps well known to some of the readers of the Journal.

When visiting Mr. Crossling's Penarth Nursery the other day I was very much surprised to find a lot of well-grown plants of the above variety in one of the houses, flowering as profusely as Chrysanthemums do in November. The plants were dwarf and well furnished with branches, which were covered with healthy leaves to the rims of the pots, and the flowers seemed fresher (though not quite so large) and whiter than they do in the autumn. The idea of prolonging the Chrysanthemum season to February and March was new to me, and while admiring the healthy state of the plants, I felt anxious to know when they were propagated, and the treatment they had received to produce an abundance of flower at this season, and asked Mr. Crossling. He informed me that the cuttings were inserted some fifteen months since, that the plants in question flowered at the usual time last autumn, and were cut down after flowering at Christmas and placed in a cold frame for protection, as he wished to increase the stock. Shortly after being placed in the frame they began to grow and show signs of flowering, when they were removed to a warm greenhouse. The plants were not shaken out of their pots and repotted in fresh soil, nor the points of the shoots stopped at any time, but they were liberally supplied with liquid manure to encourage them in making a sturdy growth.

Mr. Crossling finds it a great acquisition to flower at this season when white flowers are scarce, and thinks he will have a succession of flowers of Princess of Teck till the end of March.—A. PETTIGREW, Cardiff.

THE CHRYSANTHEMUM.

(Continued from page 138.)

SUMMER TREATMENT.

IF they can be placed singly in rows so much the better, but in any case set them so far apart that a person can pass about amongst them with ease without injury to the foliage, and also to facilitate the free circulation of air and exposure to the sun with a view to having the wood well ripened, which is most important for the production of good blooms. If the soil is moist when the plants are potted no water will be required for a day or two, after which they should have a good soaking. Great care must be exercised in giving water at this period, for too much causes them to become unhealthy, which retards them the whole season. During hot weather a gentle syringing two or three times a day, followed by a good dash with the hose pipe in the evening, is beneficial. In cold sunless weather this should be discontinued, or mildew will be encouraged. A light syringing occasionally with lime and soot water will assist in developing a dark healthy foliage. In addition to these items attend carefully to watering and staking as required, keep the stems free from side shoots and the base from suckers, to concentrate the strength in the main stems, at the apex of which will appear in due time a flower bud known as the "crown bud," in some varieties early in August, and in most cases before the month is out. In some varieties which require a longer period than the majority to develop, it is advisable to take the crown bud early in August, but in most cases, and especially in an early season, the crown bud should be rubbed off and the shoots reduced to one, which will in a short time produce the terminal bud, surrounded by a number of lesser buds, which may be rubbed off, taking the centre one for the bloom.

An explanation of the term "taking the bud" may not be out of place here. It does not signify that the bud is taken off, but that the accompanying side shoots or buds are removed, leaving the bud which is "taken" for the production of the bloom. Generally speaking the best time to take the buds for this class is the last three weeks in August, commencing with the Japanese, which take the longest period to develop their buds; this gives them time to ripen well before being housed. When taking the buds remove the superfluous shoots or buds with the thumb nail as soon as they can be handled without damaging the bud.

BUSH PLANTS.

Cuttings for bush plants should be struck in January and treated in the same manner as the others, potting as required until the plants are about 4 inches high, when they should be topped, and in the case of stronger plants again, after breaking into growth, when the shoots are from 4 to 6 inches high; at the next break thin the shoots to the required number. About the month of August, after the plants make

their natural break, select what shoots are wanted and remove the rest. The number to leave must be regulated by the demand, whether for quantity or quality, and handsome specimens of these may be turned out by judicious training. When the buds appear in September, if the plants are required for decoration no disbudding is needed, but if larger flowers are desired they should be disbudded to the centre one on each shoot and all side shoots rubbed off. The plants throughout the season must be treated similarly to the others with regard to staking, watering, and tying. A very good method of producing a quantity of bloom with little trouble is to plant them out in good positions in the spring when all danger of frost is past. All the attention they require is an occasional watering and mulching in dry weather; tie loosely to a single stake in the centre. These should be lifted when the buds are setting about the end of October or early in November according to locality. Pot firmly and stand them under a north wall for a week or more, during which time they must be thoroughly soaked at the roots and syringed two or three times a day. If properly treated in this manner they suffer little and produce abundant blooms, which may be thinned or not according to circumstances.

CUTTING DOWN CHRYSANTHEMUMS.

Cutting down Chrysanthemums has a tendency to keep them dwarf and cause them to start uniformly. Plants for this operation should be treated as previously advised for large-flowering varieties, but instead of topping train with a single stem. They should be cut down about the third week in May, a fortnight or three weeks before their final potting. Do not cut too deeply into the hard wood, or they will not break so freely. After breaking select the required number of shoots and treat as previously advised. The tops may be struck and flowered in 6 or 7-inch pots with a single stem.

Pompons.—Pompons are generally grown as bushes for decoration; they should be struck at the same time and treated in a similar manner to bushes of the large-flowering varieties; 8-inch pots for the majority of these will be large enough for the final potting.

Single Varieties.—The same remarks apply to single varieties, which are also singularly well adapted to the production of small plants by striking the points of the shoots about the end of August and placing them singly into 4-inch pots. Other classes may be similarly treated in this respect, but these are most suitable for the purpose.

Summer-flowering Varieties.—Since the introduction of summer-flowering varieties the season has been greatly prolonged. They are most useful for herbaceous beds and borders, and are not valuable as pot plants except in a late wet season, when they may with advantage be lifted and potted for the better development of their flowers. Strike cuttings in February, top once or twice, and plant out in May.

Autumn-flowering Varieties.—Following closely upon the last-named are the early autumn varieties, which are always appreciated, blooming as they do when flowers are otherwise scarce. They may either be planted out and lifted when the buds are set or grown in pots; in the latter case treat as recommended for bushes in pots.

CHRYSANTHEMUM ENEMIES.

Insects, &c.—Green fly is the most persistent pest of the Chrysanthemum. Indoors either in spring or autumn this may be cured by fumigation or dipping the shoots affected into soft soap and water; but during the summer dusting with tobacco powder and smart syringings occasionally will effect a cure. The same remarks apply to black fly and thrips. A leaf-mining maggot often appears during summer; its whereabouts can easily be detected by the peculiar markings it causes on the leaves, which must be squeezed or cut out and destroyed. Another small maggot often infests the apex of the shoots about August; this must be persistently picked off. Earwigs have the credit of damaging the flower buds and young shoots; it is doubtful if this is the case, but as they do damage to the open flowers they are better trapped, which may be effected by placing inverted pots with a little hay inside on the tops of the stakes.

Mildew.—Mildew, which appears especially in damp weather, is the most troublesome pest to contend with. The best remedy where practicable is dusting with flowers of sulphur; failing this, mix the sulphur in the proportion of two handfuls to 4 gallons of water, and apply with the syringe, giving an occasional washing with the hose pipe in favourable weather.

MISCELLANEOUS DETAILS.

Feeding.—Feeding should commence when the pots are fairly well filled with roots; it must not be overdone, or the result will be gross growth at the expense of the blooms. Many and various are the manures recommended, but I prefer commencing with soot water, to be followed by guano or cow manure as the plants gain strength. Sulphate of ammonia, an excellent stimulant, requires to be very carefully used. In an ordinary way 2 ozs. to 4 gallons of water is sufficient, but as different examples vary so much in strength, it should be tested on a few plants before applying it generally. After the first week or two of feeding the stronger growing varieties must have some stimulant every time they are watered, commencing the application in a weak state, and increasing the strength until the maximum is reached; this should be continued until the flowers are three parts developed. For weaker growing sorts the same remarks apply, but the stimulant must be given weaker and not so often.

Top-dressing.—Top-dressing should be done when the roots appear on the surface; a soil similar to that recommended for the final potting, firmly rammed, is as good as can be used.

Housing.—The proper time to house the plants can only be learned by experience of the different varieties and the locality. Some varieties require a much longer time to develop than others, and should be housed earlier to be in full bloom at the same time; but this with other peculiarities of various kinds can only be learned by experience, and notes should be taken all through the season for guidance in the future. Generally speaking the first week in October is the best time for housing, but any showing colour before that time can be removed under cover at once, or they will damp as the flowers expand. Frequently, as was the case this season, a slight frost, with a prospect of more to follow, makes it advisable to house immediately. Indoors they should have all the light and air possible, with a little fire heat in dull damp weather.

Staging.—Large-flowered Chrysanthemums are seen to the best advantage arranged so as to form a sloping bank from back to front. Bushes appear best when mixed with the usual occupants of the conservatory, especially dark foliaged plants, such as Camellias, &c. Standards and trained specimens may stand isolated where they can be seen well from all sides. Cut down those that have flowered, and keep them in a cool house as near the glass as possible, with the object of rendering the suckers stocky until propagating time, when the same routine as before will be followed, with such alterations as each individual may consider necessary according to the success or otherwise which has attended his previous efforts.

**INCURVED AND JAPANESE CHRYSANTHEMUMS
AT THE NATIONAL SOCIETY'S EXHIBITIONS.**

No one examining the accompanying tables can fail, I think, to be struck by the very conservative character of the incurved Chrysanthemums as compared with the Japanese, among which changes little short of radical are year by year taking place. For instance, in the case of the first forty varieties of the former the average date comes out as

1867, while the mean date for the same number of Japanese is only 1879. In other words, while the average age of the best incurved is twenty years, that of the Japanese is only eight years. Again, since my analysis came out last year there has been only one addition made to the list of the incurved, and this a sport coming in at the very end of it, and which, therefore, in no way disturbs the relative positions of the older varieties. Whereas the following new kinds find places for the first time in the list of Japanese—*La Triomphante*, *Ralph Brocklebank*, *Madame J. Laing*, *Monsieur Freeman*, *Mr. H. Cannell*, *Mr. C. Orchard*, *Gloriosum*, *Mdlle. P. Dutour*, and *Mr. Matthew*, several of which take quite prominent positions, thereby lowering the status of many of their elder brethren.

The November Show of the National Society was last year not quite so rich in incurved blooms as in 1886, a fact which was no doubt in a great measure accounted for by the trying nature of the summer and early autumn. On the other hand, the Japanese appeared in even greater force than before. The total number of flowers staged in each section at the three shows has been as follows—

1885	Incurved	839	Japanese	835
1886	"	1080	"	1026
1887	"	964	"	1221
		2883	3082	

The relative positions of the different varieties in the two tables are regulated by the average number of times they were shown at the three last November Exhibitions of the Society. In the case of those sent out in 1884 it has, however, been considered advisable to take only their last two years' average; while for the still newer sorts, those of 1885 and 1886, the number of times they were shown at the 1887 Exhibition has alone been considered in placing them.

INCURVED VARIETIES.

Position in Present Analysis.	Average Number of Times Shown in the Three Years.	Number of Times Shown in 1887.	Name.	Date of Introduction.	Raiser's or Introduceer's Name.	Colour.
1	53.0	55	Empress of India	1859	Laing	Pure white.
2	45.0	53	Queen of England	1849	Salter	Blush.
3	44.3	40	Golden Empress of India	1875	Loader	Pale yellow.
3	44.3	54	Jeanne d'Arc.....	1881	Laeroix	Blush, tipped rosy purple.
5	41.7	49	Lord Alcester	1882	Fremantle	Pale primrose.
6	40.7	38	John Salter	1866	Salter	Cinnamon, orange centre.
7	37.3	40	Lord Wolseley	1882	Orchard	Bronzy red.
8	36.0	39	Mr. Bunn	1879	Bunn	Bright golden yellow.
9	33.3	33	Prince Alfred	1864	Davis	Rosy carmine.
10	32.3	26	Nil Desperandum.....	1862	Smith	Dark orange red.
10	32.3	29	Princess of Wales	1864	Davis	Blush, tinted rose.
12	26.3	35	Lady Hardinge.....	1861	Clark	Silvery rose.
13	25.3	25	Alfred Salter.....	1856	Salter	Lilac pink.
14	24.0	23	Jardin des Plantes.....	1860	Salter	Rich golden yellow.
15	21.7	26	Mrs. W. Shipman	1877	Shipman.....	Fawn colour.
16	20.7	16	Prince of Wales	1865	Davis	Purple.
17	20.3	23	Barbara	1872	Salter	Bright orange amber.
17	20.3	17	Mrs. Heale	1866	Heale	White, tinted rose.
19	20.0	16	Princess of Teck	1868	Pethers	White, tinted pink.
20	19.0	16	Hero of Stoke Newington	1871	Forsyth	Rosy pink.
21	18.7	17	Refulgens	1871	Salter	Bright purple maroon.
22	18.0	12	Cherub	1862	Smith	Orange, tinted rose.
23	15.0	16	Golden George Glenny	1876	Dixon	Bright rich yellow.
23	15.0	19	White Venus.....	1872	Shrimpton.....	Pearl white.
25	14.7	22	Beverley.....	1863	Smith	Cream white.
26	13.7	17	Golden Queen of England.....	1859	Salter	Canary yellow.
27	12.7	16	Princess Beatrice.....	1868	Wyness	Rosy pink.
28	12.3	8	Mr. George Glenny	1870	Waters	Bright primrose yellow.
29	12.0	8	Venus	1865	Salter	Lilac, tinted peach.
30	11.0	10	Emily Dale	1872	Dale	Pale straw colour.
31	10.7	10	Mr. Brunlees	1865	Smith	Indian red, tipped gold.
31	10.7	6	Mrs. George Rundle.....	1867	Rundle	Pure white.
33	10.3	16	Empress Eugénie.....	1866	Pethers	Rosy lilac.
33	10.3	8	Golden Eagle.....	1863	Davis	Dark orange.
35	9.3	9	Eve	1865	Smith	Creamy white.
36	9.0	5	Lady Slade	1864	Smith	Lilac pink.
37	8.3	13	Mabel Ward	1881	Martin	Buff yellow.
38	8.0	9	Baron Beust	1868	Pethers	Chestnut red, tipped yellow.
39	6.0	8	Novelty	1860	Clark	Blush.
40	5.0	3	Antonelli	1862	Smith	Salmon orange.
40	5.0	5	Mrs. Norman Davis	1887	Mizen	Golden yellow.

Empress of India still heads the list of the incurved, but the position of this flower, although apparently well assured, has in reality within the last two years been seriously threatened by Jeanne d'Are. Indeed, but for the marked inferiority of its form in 1885 Jeanne d'Are would even now occupy the premier place. The following varieties—Queen of England, Jeanne d'Are, Lord Alcester, Mr. Bunn, Lady Hardinge, Mrs. W. Shipman, Beverley, Empress Eugénie, and Mabel Ward—were last year all staged more frequently than at either of the two preceding exhibitions. On the other hand, Nil Desperandum, Prince of Wales, Mrs. Heale, Princess of Teek, Cherub, Hero of Stoke Newington, Mr. G. Glenny, Mrs. G. Rundle, and Golden Eagle were not shown in as many stands as in the previous year. All the newer varieties (those sent out since 1878) except Lord Wolseley, which was not quite so frequently shown as in 1886, have improved their positions; and Mrs. Norman Davis, although of such very recent introduction, already finds a place on the list.

Madame C. Audiguier, with a total of 149 blooms at the three exhibitions, still stands well above all other varieties in the Japanese

section. Among the more established kinds, Mdlle. Laeroix, Fair Maid of Guernsey, Thunberg, Val d'Andorre, Japonais, Meg Merrilies, M. Tarin, Baronne de Prailly, and last, but by no means least, Belle Paule, were all surprisingly well shown. The flower last named was staged altogether only six times in 1886, but at last year's exhibition no less than twenty-six times, or as frequently as Comte de Germiny. On the contrary side must be mentioned Peter the Great, Triomphe du Nord, and Fanny Boucharlat, which were but very indifferently represented.

Turning now to the newer varieties, and beginning with those which made their first appearance in 1884, M. J. Laing was shown more than twice as many times last year as at the previous exhibition, and consequently has done well, but neither Fernand Féral nor Madame de Sévin, both so full of promise in 1886, have made any advance upon the positions they then obtained. Of the 1885 varieties we must first mention L'Adorable, which has already risen to the tenth place on the list, also well placed at No. 19 stands La Triomphante. Next comes Madame J. Laing at No. 26, followed at No. 29 by M. Freeman, while Gloriosa brings up the rear at No. 49. Considering how recently they have come

JAPANESE VARIETIES.

Position in Present Analysis.	Average Number of Times Shown in the Three Years.	Number of Times Shown in 1887.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	49.7	54	Madame C. Audiguier	1879	Marroueh	Deep mauve.
2	41.0	50	Mdlle. Laeroix	1880	Laeroix	Sulphur white.
3	36.7	37	Jeanne Délaux	1882	Délaux	Dark velvety brown.
4	36.0	43	Fair Maid of Guernsey	1872	Downton	Pure white.
5	28.7	40	Val d'Andorre	1880	Marroueh	Chestnut, shaded orange.
6	27.7	31	Elaine.....	1871	Downton	Pure white.
7	27.0	26	Comte de Germiny	1881	Veiteh.....	Nankeen, striped crimson brown.
8	26.7	34	Thunberg	1881	Veiteh.....	Pale golden yellow.
9	24.3	30	Criterion	1868	Salter	Amber.
10	24.0	24	L'Adorable.....	1885	Délaux	Canary yellow, shaded violet.
11	23.0	23	Soliel Levant.....	1874	Tr. Audiguier ?	Pale yellow.
12	22.7	23	Madame B. Rendatler	1877	Délaux	Orange, shaded to yellow.
12	22.7	22	Monsieur Astorg	1883	Délaux	White rose, violet centre.
14	22.0	22	Maiden's Blush	1886	Stevens	Creamy white, tinted blush.
15	21.7	14	Peter the Great.....	1876	Carey	Lemon yellow.
16	20.7	22	Triomphe de la Rue des Châlets	1876	Pertuzès	Salmon red.
17	18.7	19	Marguerite Marroueh	1878	Marroueh	Crimson, edged gold.
18	18.0	23	Japonais.....	1878	Délaux	Bronze yellow.
19	17.0	17	La Triomphante	1885	De Reydellet.....	White, tinted rose.
20	17.0	25	Meg Merrilies	1870	Salter	Sulphur white.
21	16.0	18	Boule d'Or.....	1882	Bernard	Yellow, tipped bronze.
22	15.0	16	Hiver Fleuri	1879	Délaux	Cream white, tinted rose.
22	15.0	21	Monsieur Tarin.....	1883	Délaux	Silvery violet rose.
22	15.0	15	Ralph Broeklebank	1886	Winkworth	Yellow.
25	14.7	24	Monsieur J. Laing	1884	Délaux	Crimson brown and gold.
26	14.0	15	Alba Plena	—	—	Delicate creamy white.
26	14.0	14	Madame J. Laing	1885	Délaux	White and rose.
28	13.7	21	Baronne de Prailly	1868	Salter	Rose blush.
29	13.0	26	Belle Paule	1881	Marroueh	White, edged rose.
29	13.0	14	Monsieur Ardène	1878	Laeroix	Rose lilac.
29	13.0	13	Monsieur Freeman	1885	Délaux	Rosy and violet.
29	13.0	13	Mr. H. Cannell	1886	Cannell	Deep yellow.
33	12.7	7	Triomphe du Nord	1857	—	Crimson maroon.
34	12.0	12	Mr. C. Orchard.....	1886	Cannell	Carmine and yellow.
35	11.7	12	Flamme de Puneh	1883	Délaux	Orange, shaded red.
36	11.3	15	Fernand Féral	1884	Délaux	Rosy mauve.
37	10.7	12	Monsieur Brunet	1879	Laeroix	Violet mauve.
38	10.3	12	Madame de Sévin.....	1884	Délaux	Rosy purple.
39	9.7	10	Monsieur Délaux	1877	Délaux	Crimson, with yellow centre.
40	9.3	5	Fanny Boucharlat	1879	Délaux	White, with pink tinge.
41	8.3	9	Balmoreau	1878	Délaux	Rose purple.
41	8.3	9	Dr. Macary	1878	Délaux	Rose, tinted white.
43	8.0	2	Agréments de la Nature.....	1881	Délaux	Golden yellow, shaded brown.
43	8.0	8	Duchess of Albany	1882	Jaekson	Orange buff.
43	8.0	9	Grandiflora	1862	Fortune	Bright yellow.
43	8.0	5	Striata	1862	Fortune	White, striped plum colour.
47	7.7	5	Comtesse de Beauregard.....	1868	Salter	Light rose.
48	7.3	9	Golden Dragon.....	1867	Salter	Bright yellow.
49	7.0	7	Gloriosa	1885	Waterer	Bright yellow.
49	7.0	6	Monsieur H. Jacotot	1883	Délaux	Crimson, tipped gold.
51	6.7	3	Sarnia.....	1876	Carey	White, shaded violet rose.
51	6.7	4	Souree d'Or	1882	Délaux	Orange, shaded gold.
53	6.0	3	Bouquet Fait.....	1879	Délaux	Bright rose pink.
53	6.0	6	Mdlle. P. Dutour.....	1886	Délaux	White, shaded rose.
53	6.0	6	Mr. Matthew.....	1886	Cannell	Terra cotta.

out some of the 1886 flowers take remarkably high positions. For instance, at No. 14 we find Maiden's Blush, and at No. 22—or only three steps lower than the veteran Meg Merrilies from which it originated—Ralph Brocklebank. At No. 29 comes Mr. H. Cannell, and at No. 34 Mr. C. Orehard, while Mdle. P. Dutour and Mr. Matthew each at No. 53 just manage to obtain a place.

REFLEXED, LARGE ANEMONE, LARGE HYBRID ANEMONE, POMPON ANEMONE, AND POMPON VARIETIES.

In the following short lists the principal varieties in each of the above sections will be found arranged according to the number of times they were staged at the Society's last year's November Exhibition.

Reflexed.—Cullingfordii, Peach Christine, King of Crimson, Golden Christine, Cloth of Gold, Pink Christine, Chevalier Domage, Phidias, White Christine, Felicity, Dr. Sharpe, Mdle. Madeleine Tezier.

Large Anemone.—Emperor, Gluck, Lady Margaret, Acquisition, Georges Sand, Louis Bonamy, Fleur de Marie, La Marguerite, Laing's Anemone, Madame Goderau.

Large Hybrid Anemone.—Fabian de Médiana, Madame Berthe Pigny, Sœur Dorothee Souillé, Minnie Chaté, Mdle. Cabrol, Jeanne Marty, Marguerite Villageoise, Madame Ghys, Ratapoi, Souvenir de Lardenne.

Pompon Anemone.—Mr. Astie, Antonius, Marguerite de Coi, Miss Nightingale, Madame Chalonge, Marie Stuart, Perle, Astrea, Madame Montels, Regulus.

Pompon.—Mdle. Marthe, Golden Mdle. Marthe, Prince of Orange, Miss Wheeler, Black Douglas, Mdle. Elise Dordan, Marabout, President, Rosinante, La Pureté, Pygmalion.

My thanks are due to Mr. C. Harman Payne for supplying the dates and raisers' names of those varieties which appear now for the first time in the list of Japanese varieties, also to the Rev. H. A. Berners and Mr. J. Burrell for the assistance they kindly gave me in taking down the names at the show.—E. M., *Berkhamsted.*

HARDY FRUIT GARDEN.

PRUNING PEACH TREES.—The good old plan of unnauling or otherwise loosening the young growths of Peach and Nectarine trees in the autumn assists to ripen them thoroughly, and as they are thus clear of the wall it also materially retards flowering. As the buds are now far advanced towards opening, the time has arrived for pruning and re-nauling or retying the trees. If when the trees were loosened much of the old fruiting wood was cut away very little more pruning is now needed. There being always the risk of the loss of much bloom from late frosts and cold easterly winds, it is unwise to be too free with the knife, a better plan being to lay in as much fruiting wood as possible without injuriously crowding it. Nor is it advisable to shorten the young growths, especially at this late date. Unpruned shoots break more evenly and strongly, and all subsequent growth or the formation of the tree may be regulated by disbudding and stopping. Cut any shoots not wanted clear away and as much of the old wood as can be spared. Also practise foreshortening, especially in the case of large old trees. When large straggling branches are shortened to well placed younger wood the latter is naturally much benefited thereby, and foreshortening, as this is termed, is also necessary to induce the formation of young wood near the base or centre of the tree. It is there such is most wanted, not at the extreme ends of the trees.

DRESSING AND TRAINING THE TREES.—Insect pests, including scale, red spider, and aphid, as well as mildew are frequently troublesome on Peach and Nectarine trees, and if not already done now is the time to attempt a timely clearance. Various remedies are to be had from all seedsmen and horticultural sundriesmen, the well-tried Gishurst Compound being still as popular as any. Anything in the shape of a wash and applied through a syringe is usually most effective, as this, in addition to thoroughly wetting the whole of the wood, penetrates into all the crevices of the walls and also destroys the aphides and other pests that lodge in the ground. Not many of these will survive a thorough wetting with water heated to a temperature of about 120°, to every gallon of which is added 2 ozs. or one wineglass of petroleum. The latter will be kept from floating on the surface if every second syringe-full is forcibly returned to the can. When training the trees first arrange and fasten all the old wood or framework and then fill in with the bearing wood. If nails and shreds are necessarily used see that none of the former come into contact with the wood, or damaged bark followed by gumming will inevitably result to the great injury of the tree. It is a good plan to tie young growths where possible over the naked main stems, this protecting these from fierce sunshine and cold winds, also economising space.

PRUNING AND TRAINING YOUNG FRUIT TREES.—If maiden trees of either Apricots, Peaches, Nectarines, Plums, Cherries, Pears, or Apples are planted with the idea of forming these into fan-shaped trees they ought now to be cut down to within 6 inches of the point of union between the stock and scion. Four shoots may eventually be

laid in from these, and sometimes it is possible to obtain six medium-sized well ripened growths in one season. Any thus treated last year to have all the branches shortened to a length of about 12 inches, and from these enough fresh shoots will be obtained to lay the foundation of a good tree. Apricots, Peaches, and Nectarines succeed admirably when grown with one central or main stem only, this being trained obliquely and the fruiting wood laid in right and left. Maidens are the best to start with in this instance, these being shortened back to a length of 18 inches. During the summer two or three pairs of side branches and one leader ought to be formed on them. When fan-shaped trees of any of the above mentioned fruits are planted these are usually furnished with eight or more branches. No leader should be permitted on these, as they are almost certain to take a strong lead and eventually overgrow the rest of the tree. If there is an odd or central branch on newly received trees cut it back at once, and thereby secure a pair if these are needed to furnish space. All the branches if sound and well ripened to be laid in to their full length and neatly fastened to the wall, or in much the same style as they were previously trained. To cut them hard back is simply suicidal, much valuable time being wasted before the branches again attain a similar length. Timely disbudding and stopping are all that are necessary to insure the formation of sufficient young wood to complete the furnishing of the tree. Should, unfortunately, any of the branches be damaged or be found unripe cut these back to sound or well-ripened wood.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—The fruit will soon have completed the first swelling, and will enter upon the stoning process. If the thinning has been carefully attended to there will be little more than the necessary quantity—namely, one fruit to every square foot of trellis covered by the trees. More Nectarines are usually left, which accounts for their being under-sized as compared with Peaches. If there is more fruit than specified above remove the smallest. There is no danger of the fruit falling during stoning provided the wood was thoroughly ripened last season, and the trees are not unnecessarily taxed by too many fruit. During the stoning process keep the temperature as equable as possible, as a sudden check by draughts of cold air in the daytime, and too high a temperature in the night, may prove disastrous. The night temperature may range from 60° to 65°, but 5° less will be safer in severe weather, and in the daytime 70° to 75° with sun heat, and about 65° by artificial means when the atmosphere outside is cold and the sky overcast. See that the growing shoots are secured to the trellis as they advance, keeping those retained to attract the sap past the fruit stopped at the second or third joint. Red spider must be kept in check by syringing with water at the same temperature as the house, or if thrips and brown aphides appear fumigate carefully when the foliage is quite dry. For destroying the insects named nothing is safer and better than a solution of softsoap at the rate of 2 ozs. to the gallon of tepid water. Be not deceived by the syringing—*i.e.*, making the surface of the border look wet, whilst the soil beneath may be too dry, but give good supplies, and if the trees are at all weak apply liquid manure.

Second Early Forced House.—Disbud gradually, removing the strongest and ill-placed shoots, and have all the leading shoots tied down, taking care not to overcrowd them. Thin the fruit by degrees, it having set very thickly will require extra attention, removing those on the under side of the trellis or otherwise badly placed, but leave those that are well exposed to light and air until they indicate by free swelling the necessity for further reduction, then remove the smallest. Syringe the trees early during fine days, and ventilate early in favourable weather. The temperature may range from 55° to 60° at night and 60° to 65° by day, ventilating at the latter temperature, and closing the house when the heat is decreasing, allowing an advance of 5° to 10° from sun heat.

Houses Started Early in February.—The trees are now in flower or well advanced. As we have many more flowers than will be needed, all those on the under side of the shoots have been removed by drawing a gloved hand the reverse way of the growths, and even yet there are three-fourths more than will be required of fruit for the crop, therefore we have thinned them still further where most crowded, especially on the weaker shoots. Maintain the night temperature at 50° to 55° and 55° by day with a little ventilation, as a close atmosphere is fatal to a good set. Ventilate freely above 55°, and allow an advance to 65° with sun heat. Fertilise the blossoms in the early part of fine days either by shaking the trellis or dusting the flowers with a camel-hair brush when the pollen of the individual flower is ripe. Syringing must cease whilst the trees are in flower, but the floor should be sprinkled morning and afternoon, avoiding cold currents of air.

Houses to Afford Ripe Fruit in Late July and August.—These should be closed, syringing two or three times a day until the buds show colour, when it must cease. The inside borders must be brought into a thoroughly moist state by repeated waterings if necessary, and with the borders properly drained liquid manure may be given to weakly trees and those having a superabundance of flower buds. There are too many buds by at least five-sixths. Our trees have the principal triple buds all fruit buds, and as we find nothing weakens the trees so much as heavy cropping, we shall ease them of at least half the blossom buds as soon as they can be rubbed off. To farther help them we have mulched the surface of the inside border with 2 to 3 inches thickness of rather short fresh manure, which colours the water in watering, and will help the active feeders, for all on the Plum stock—*viz.*, Apricots, Peaches, and

Nectarines, as well as Plums, push active feeders or adventitious roots in advance of the growth, hence the recuperative power of lifted trees, and to which much of the advantages of lifting is due. Maintain a temperature of 50° by day and 40° to 45° at night, advancing to 65° with sun and full ventilation.

Late Houses.—The weather we have lately experienced has usefully retarded the flowering. If the lights are off there need not be any hurry in replacing them before the middle of March, as that will be early enough to have the trees in full flower by the middle of April, and then they have the benefit of the sun heat. Many late houses are unheated, which is a great mistake, as the flowers even in April are not safe from severe spring frosts, and the fruit does not ripen if the late summer be cold and unless. A gentle heat during the flowering period does much towards a good set, and in autumn artificial heat ripens the fruit and wood, plumping the buds wonderfully. Houses with fixed lights should be ventilated freely, and take care to keep the borders in a moist state.

Unheated Houses or Wall Cases.—Where these are employed the chief consideration is to retard the flowering. Ours have the roof lights still off, and will so remain till the middle of March, the bloom buds not taking any harm until they are somewhat advanced and are beginning to show colour, after which it is not safe. Anything required in the way of pruning, securing to the trellis, &c., should be completed. Those that have not had the roof lights removed may need supplies of water, so as to bring the soil into a thoroughly moist state, and may have the surface mulched 2 or 3 inches thick with rather short somewhat fresh manure. Ventilate freely to retard the flowering to as late a period as possible.

Where wall cases are employed for Apricots, let the lights remain off until the flower buds begin to show white, and, after they are placed on, ventilate freely, as nothing is so fatal to Apricot blossom as a close, moist atmosphere. Plum cases may have the lights placed on by the middle of March, similar remarks applying to Cherries, also Pears.

CHERRY HOUSE.—Unremitting attention must be given to the ventilation. A free circulation of air passes through the house whenever the temperature exceeds 50°, the amount of air to be regulated by the conditions of the external atmosphere. Employ fire heat only to prevent the temperature falling below 50° in the day, and to maintain a night temperature of 40° to 45°. Attend to fertilising the flowers. Watch closely for the appearance of aphides, but it will not answer to fumigate whilst the trees are in blossom, nor will it be necessary provided they were perfectly clean previous to the flowers expanding. It may, however, be had recourse to as soon as the fruit is set. Grubs infest the Cherry under glass; one kind of grub rolls itself up in the leaves, and can be eradicated by squeezing, but the other is the greater pest, and will be found encaused on the under side of the leaves, giving them the appearance of being scalded. From the leaves it makes its way to the Cherries, perforating and destroying them. The only means of riddance is to examine the trees occasionally and destroy the grubs.

CUCUMBERS.—With increased light and solar heat evaporation is correspondingly increased, necessitating a greater supply of atmospheric moisture. The evaporation troughs must be kept filled with liquid manure, damping the house so as to maintain a genial atmosphere, and syringing the plants lightly during bright afternoons. A night temperature of 65° is sufficient, allowing 5° advance when the external air is mild, 60° being the minimum in the morning when the weather is severe. Liquid manure may be applied once or twice a week. Do not allow the fruits to hang too long, or they may weaken the plants; besides, they keep fresh for several days with their stalks inserted in saucers of water. Thin the fruits well, especially on plants just coming into bearing, stopping the shoots one joint beyond the fruit, removing superfluous growths and bad leaves as they appear, as well as staminate blossoms.

The weather continues unfavourable for early forcing in pits and frames heated with fermenting materials, the temperature being difficult to maintain to a point calculated to maintain steady progressive growth, a close atmosphere resulting in a superabundance of moisture, not unfrequently causing the loss of the plants. When the moisture cannot be expelled by admitting air much may be done by sprinkling lime or soot round the plants, those substances having a strong affinity for moisture. Continue to prepare material for making fresh beds for linings, and sow seed as successional plants are required.

MELONS.—We have little to add to our remarks in the last calendar except that the weather being so unfavourable the plants shifted into 5-inch pots may not yet be planted out, and if so they should be planted before they become root-bound. Pot later sown plants when they show the second leaves, employing warm moist soil. The plants from the seed sown early in February will soon be ready for planting out. Make up the bed for them, and make also a successional sowing. Those who are growing Melons in dung-heated frames should make a successional sowing every fortnight or three weeks until May, making fresh beds at similar intervals to receive the plants, so as to maintain an uninterrupted supply of fruit. Maintain a night temperature of 65° to 70°, 5° less if the weather be cold. 70° to 75° by day, admitting a little air at 75°, allowing the temperature to rise to 85° with increased ventilation, closing at 80° or 85°, sprinkling at the time every available surface; and if the temperature rise to 85° or 90° so much the better. Keep the bottom heat at from 75° to 80°.

FIGS.—Earliest Forced Trees in Pots.—Plunged in bottom heat, water will be required abundantly, applying it at the same temperature as the bed, or 70° to 75°, and alternating with liquid manure. Maintain the temperature at 60° to 65° at night, admitting a little air at 70°, but

not so as to lower the temperature, closing at 75°, and if the temperature rise to 80° all the better. Thin the fruit as soon as the best placed and most promising can be decided upon for the crop. The thinning should be done some time before the last swelling commences.

Early-forced Planted-out Trees.—Those started at the new year are making good growth, and should have the points of the shoots which issue from round the base of the terminals pinched at the fifth or sixth leaf. Attend to tying the young shoots to the trellis as they advance, thinning where they are too crowded. Keep the night temperature at 55° to 60°. When it reaches 65° by artificial means in the day admit a little air, increasing the ventilation with the temperature, and reducing it in like manner, closing at 70°, syringing twice a day, and maintaining a genial atmosphere.

PLANT HOUSES.

Zonal Pelargoniums.—To succeed those rooted in autumn for spring flowering cuttings should be inserted at once. Select these from plants that ceased flowering about Christmas and have since been stored in cool houses. Cuttings of this description root with greater certainty early in the season than those from plants that have been grown in heat. The cuttings will root freely if inserted singly in small pots and placed on a shelf in a temperature of 60°. Keep the soil about the cuttings in an intermediate state for moisture; if they become too wet at this season of the year they are liable to damp off. Old plants that have been kept dry for some weeks may be pruned and placed in a temperature of 50° until they commence growth. If the atmosphere is moderately moist a light syringing on fine days will be needed until they show signs of growth, when the soil about the roots may have water. Prepare other plants for cutting back by keeping them dry to harden them. All young stock in active growth will require more water at their roots than they have had up to the present time. The earliest will be showing their flower trusses, and will come forward rapidly from this date. Pinch the shoots of later plants of both single and double varieties that are not required to flower before May. The latter required to supply trusses for cutting throughout the London season may be placed into 7-inch pots after they have broken again into growth. Pot firmly in good loam and one-seventh of manure with a little sand added to insure firm, sturdy growth.

French and Finny Pelargoniums.—For decoration it is a mistake to place these in too large pots, for by so doing growth is encouraged at the expense of flowers. All in small pots that are ready should be transferred into 5-inch pots, a very suitable size to flower them in. Use the soil advised for Zonals, and press it firmly into the pots. Arrange the plants close to the glass, water carefully, and admit air on favourable occasions to insure a firm, sturdy growth. When the pots are full of roots feed liberally with artificial manure applied to the surface of the soil. The flower stems of the earliest plants will be advancing rapidly; and they should not be hurried too much in this stage. Tie out the shoots with neat stakes so as to expose the inner foliage to the light. Cuttings should also be rooted for late flowering. These can be taken from old stock plants reserved for the purpose, which can then be thrown out, or any shoots from the earliest that do not show signs of flowering. The cuttings will strike under the same conditions as Zonals.

Heliotropes.—To succeed the earliest now showing flower place others into 5-inch pots and grow them in a temperature of 55° to 60°. Under these conditions the plants will grow rapidly and soon flower, provided they have been well cared for and are in good condition. Half the stock may have the shoots pinched once or even twice according to the time they are required to flower. Insert cuttings where these flowers are appreciated until they come into flower outside.

Petunias.—The latest of the young plants that were wintered in 2 and 3-inch pots may be transferred into the 5-inch size. Place them close to the glass and encourage growth, insert cuttings for succession, and sow seed of any selected varieties. The seed should be sown on the surface of fine soil in pots or pans, gently watered and covered with a square of glass, until the seed germinates, which it will quickly do in a temperature of 60°.

Carnations.—The old Crimson Clove, Gloire de Nancy, Souvenir de la Malmaison, and others that are appreciated for cutting and decoration indoors should be potted at once from the 3-inch pots in which they are now in into 6-inch pots. Grow them close to the glass in any cool light structure where frost can be excluded. Avoid placing them in a close or confined atmosphere, which would soon draw them up weakly and ruin them.

THE BEE-KEEPER.

PRACTICAL BEE-KEEPING.—No. 30.

THE practice of extracting honey from cells in juxtaposition to those which contain eggs and larvæ in different conditions in various stages of progress cannot be too strongly condemned. It is urged by some that if the revolutions of the extractor are reduced to a certain number, and that that pace is not exceeded, no harm will be done to the brood, and that the honey will not be contaminated by

the juices which one might expect to see thrown out. If the brood nest is glutted with honey it is in nearly all cases due to the negligence of the bee-keeper. If sufficient room is continually given above the brood nest to employ the bees, and empty cells are always ready to hold any probable harvest of honey, the bees will not store any large quantity below, but will carry it up and store it in the position in which instinct apparently leads them to store it. Most amateur bee-keepers, and not a few who profess to have great practical experience, are far too eager to keep down the speed of the extractor, and consequently brood is destroyed and thrown out, and the quality of the honey is deteriorated. If the bee-keeper has the great misfortune to have a glutted brood nest, he must take such measures as will no doubt suggest themselves to his mind to remedy the evil; but in no case should such combs be allowed to enter the extractor unless the bee-keeper is willing to sacrifice some brood, and unless the honey so extracted is intended either for his own personal consumption or for use in the apiary.

Bee-keepers are often puzzled to know what description of extractor is most suitable for ordinary purposes. Price is of course a consideration, but when purchasing an appliance which may be expected to last for years, too great a stress should not be laid upon this point. Happily for the man who has not much cash to spare, the cheap extractors are quite equal to if not the superior of the more complicated machines with gearing, cogwheels, and other contrivances which in theory no doubt are a great assistance, but in practice very often do more harm than good. Geared extractors, which give so many revolutions of the cans to each turn of the handle, are responsible for more smashed and damaged combs than all other kinds put together. The simpler the better, then, must be the guide of a bee-keeper in purchasing an extractor. The can below the "cages" must hold some 40 lbs. of honey at least. The "cages" must be strong, and the wire netting against which the combs lie when the honey is being ejected from the cells should be strengthened by bars of strong wire, or even thin iron or steel, running transversely across them. This is a most important point. The ordinary cage is not sufficiently strong to bear the pressure, and the netting often gives away at the corners, thus bringing the machine to a full stop, breaking the combs, and disappointing the person who is working, and who naturally desires to get along with all possible speed. When this wire netting thus breaks out it occasions very considerable delay and damage, and the point is therefore worthy of attention. Extractors have been made from time to time, and some are advertised at the present time, to take more than two frames at once. I never had one in my possession and never saw one working, but it seems to be the prevalent opinion that no extractor of a really serviceable type has yet been made which is capable of taking more than two frames at once. By paying attention to these points most bee-keepers will be safely able to buy a suitable extractor.

The four points to which attention should be paid by the inexperienced bee-keeper, especially in purchasing an extractor, are:—

- 1, Simplicity.
- 2, Capacity to hold 40 lbs. of honey at least.
- 3, A two-comb size.
- 4, Other things being equal, the cheapest.

It is very easy to uncap a good level comb, but it has already been observed that it is a most difficult matter to unseal an irregular, badly built, series of cells. Such combs should either at once be put straight, or, if this is impossible, destroyed. Two knives are necessary in order to uncap combs with facility. One should be placed in hot water while the other is being used. Thus the knife not actually in the hand of the operator is cleansed repeatedly of any honey and wax adhering to it by the heat, which also enables the operator to pass the knife rapidly beneath the cappings, and to remove them in sheets. The "Bingham" knives are very good for the purpose, but any strong sharp knife may be

pressed into service. The cappings should be allowed to roll down the comb in front of the knife, so that the whole surface covering is removed without more than necessary trouble. If the cappings are not removed as a whole, or if the pieces fall on to the exposed surface of the honey behind the knife, it is most difficult to clear them away, and yet if they are allowed to remain they prevent the honey coming freely from the cells. The whole side of a comb can be cleared without breaking the roll of cappings if the operator is skilful and knows how to go about his work.

Enough has now been written upon this subject to enable those who wish to do so to extract from their full combs. Experience alone can teach them some of the devices which they will learn by degrees to adopt in order to facilitate their work; but in concluding we may advise every bee-keeper to turn the cage very slowly at first, gradually increasing the pace until the honey is freely thrown from the cells; if a rapid pace is adopted to begin with, a smash is nearly always the result. "Slow and sure" is a good old proverb, and one which should always be borne in mind by the bee-keeper. It would be tedious, and altogether unnecessary, to mention any particular make of extractor, but if the machine is purchased from a firm of good standing, reliance may generally be placed upon the workmanship, and there is but a small possibility of dissatisfaction owing to inherent defects in the appliance itself.—
FELIX.

DEPOSING AND INTRODUCING QUEENS BY THE DIRECT METHOD.

DEPOSING a queen or queens and the safe introduction of another are, perhaps, two of the most important matters connected with bee-keeping, and on which profitable bee-keeping so much depends. The necessity of having young queens at the head of all stocks throughout the season, and at different periods, is very great. The teaching that "queens were at their best when three years old," advanced in contemporaries up till a very recent date, led to great loss of many who depended entirely upon what was written for their instruction. That queens sometimes live to a great age I have had ample proof; still we must not hope that such long-lived queens can be profitable, and except in the case of a valuable pure-bred one, for the purpose of breeding queens from, all queens should be deposed during the month of July, and a young fertilised one take her place. Catching the aged queen by the ordinary methods employed is sometimes by no means an easy task, and very often a complete failure, which so upsets the young operator as to cause him to give it up in disgust, and leave the bees to their own dealing in such matters, which often ends in having either a drone breeder or a hive queenless.

By the proper use of carbolic acid, manipulation is an easy, if not a pleasant matter, compared with older methods. The use of carbolic acid, known to me many years since, was held in abeyance for a long time, owing to the adverse reception it had from judges and exhibitors alike at our societies' show some ten or twelve years ago. I was laughed at by many southern magnates. After I made the use of carbolic acid in manipulations public, many attempted to claim the idea, and at one exhibition I caught one person in the act of appropriation, which I might have passed over had he been judicious enough not to have contradicted me when helping to explain the process.

The latest manipulation in catching a queen by the aid of carbolic acid will, I trust, help novices as well as practical bee-keepers to catch any queen expeditiously and without being stung. The hive in question is one that at the end of July at the Heather lost its old queen, which I had allowed to remain in the hive, as I was indisposed at the time. Owing to the extreme cold shortly after, my bees were brought home, and from the determination to rob I could not with safety manipulate outside, nor owing to the great number of bees in the hive, could I manipulate satisfactorily within doors. The queen I had in reservation for it was running a risk of being lost owing to the daily loss of her (at first) few attendants. On the 26th January the temperature had fallen from 47° night temperature and 54° day, to 33° Fahr. during the day, with every likelihood of being still lower, as it did occur on the morning of the 29th, the thermometer then registering 15°, the lowest temperature during the whole season. On the 26th, in addition to the low temperature, there was a keen north wind. There was no time nor encouragement for further delay. I accordingly set to work dismantling the hive of all coverings, and I may here add, that although no bees have been bred in this hive since the begin-

ning of August, they having worked up till the 21st September, they still occupy three breeding boxes of the ordinary Stewarton type. This is nearly three times longer than the proverbial six weeks bee life, and I expect some of them will be alive at the end of another six months.

To catch a queen from such a hive, and in such weather, would be to many an impossibility. After removing all the coverings the remaining undrawn slides were pulled out after I had smeared the top bars with the acid to prevent bees rising, and then the carbonised sheets were slipped down between the combs. I used no smoke, but it would have been better had I done so, as it quickens the bees and causes them to retreat more rapidly before the paper. Less than a minute emptied the topmost division, when I lifted it off, then I placed the remaining two upon an empty hive, and put the empty division upon the stand which the flying bees took to, but not so readily as if the covering could have been placed on intact. Bee-keepers should be careful never to alter the appearance or site of a hive after October. In as short a time as with the first the second division was cleared of bees, which was instantly placed beneath the first one taken off, that by this time was quite full of bees. Owing to the sheets of paper being deeper than one box very few bees remained in the third or under box, which were easily shaken from it and restored to its original place, and the hive to its original appearance. The bees being now about equally divided between the service and original hive, a few shakes in the former sent out many to the latter until a mere handful of bees and the queen remained in it. A slight look amongst the bees for a few seconds betrayed the presence of her majesty, and the finger and thumb acted as executioner.

During the operation, although cold and windy, the sun shone brightly, which was so far favourable. A number of bees failed to enter the hive when it was bare, but these lay chilled close to it, and were easily gathered, placed upon the top of the hive, and covered with another; every bee revived, and not more than fifty became victims to the operation. If queen-excluder zinc was a perfect queen excluder (but it is not) I would use it in some cases, so that the queen could be easily caught. A more unfavourable fair day could not have been selected, yet the manipulation was a perfect success, and during a warm day in summer it was in addition to that a pleasure.—A LANARKSHIRE BEE-KEEPER.

(To be continued.)

TRADE CATALOGUES RECEIVED.

James Dickson & Sons, 108, Eastgate Street, Chester.—*Select Farm Seeds, 1888.*

Samuel Shepperson, Prospect House, Belper.—*List of Florists' Flowers.*

Oakshott & Millard, Reading.—*Farm Annual, 1888.*

T. S. Ware, Hale Farm Nursery, Tottenham.—*Catalogues of Choice Hardy Perennials, Chrysanthemums, Hardy Florists' Flowers, Pæonies, Hardy Ferns, and Climbing Plants.*

Hogg & Wood, Coldstream and Duns, N.B.—*Price List of Agricultural Seeds.*

Waite, Nash & Co., 79, Southwark Street, London, S.E.—*Wholesale Catalogue of Agricultural Seeds, &c., 1888.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Lobelia Wave of Blue (*Elm*).—Write to Messrs. Cannell & Sons, Swanley. Most of the named varieties of bedding Lobelias are only kept true by cuttings.

Bouvardia (*Southlands*).—The sport will require at least a season's trial before it will be certain whether it is fixed or not. Take the shoot

bearing the larger flowers and insert it as a cutting, cut it as low down as possible, and you will probably be able to obtain a root or two with it. There are several varieties in cultivation quite as good and some better, but probably you will be desirous of testing it out of curiosity.

Waterproof Labels (*Birdie*).—We are not able to answer your question, but think if you send a sample to advertisers of garden requisites, they will be able to supply you with what you require.

Glazed Flower Pots (*J. E.*).—We are unable to say where they are to be obtained, as we do not remember having seen them advertised. There have been several inquiries for them of late.

Grapes with Muscat Flavour (*Idem*).—Free setters of the true Muscats are scarce, but Grapes likely to meet your requirements are Madresfield Court Black Muscat and Mrs. Pearson; if the latter has not a Muscat it has a rich Frontignan flavour. Both are good Grapes, and will keep some time. They require heat.

Royal Horticultural Society (*Inquirer*).—The meetings and shows are advertised a week previous to the dates. The next meeting, on March 13th, will, we presume, be held in the conservatory at South Kensington.

Early Potatoes for Market (*A Beginner*).—The old Ashleaf and Veitch's Improved Ashleaf are suitable; the first-named is the earliest, but the second is a heavier cropper, and should be planted on a larger scale. Myatt's Prolific is the heaviest cropper of all, but is about ten days later than Veitch's, but a good crop is remunerative. Beauty of Hebron follows, and is largely grown by some farmers. M.P. is a very suitable round variety for market early in the season.

Violas (*T. L., Canterbury*).—Seed of the varieties you name is not offered by anyone, and if it were we suspect the seedlings resulting would show considerable variation from the parentage. The varieties can only be had in the form of plants raised from cuttings, and the sooner Violas are planted when the ground and weather are favourable in April the better. Planting with ordinary "bedding plants" after the middle of May is much too late for insuring free growth and prolonged flowering.

Propagating Begonias (*J. D.*).—We scarcely know what you mean by "Begonia silver leaf." Most of the silvery-leaved Begonias have very large leaves, and form thick flesh root-stems or rhizomes, not tubers. Such may be increased by dividing those root-stems, also by rooting the leaves after the manner of Gloxinias. The true Tuberous Begonias are propagated by dividing the tubers, also by topping the growths and striking the cuttings thus obtained in brisk heat in the spring, these forming tubers during the season of growth.

Violets Degenerating (*M. T. O.*).—Your Violets have reverted to the normal form by exhaustion. If you take strong runners and grow them in rich soil in an open position, mulching during the summer to keep the roots moist, you will produce stronger plants that may eventually afford large double flowers as before; but it would be better to procure fresh plants from a vigorous stock. Early in April is a good time for planting, and a number of young plants from the best runners should be established every year.

Judging Begonias (*Exhibitor*).—If a judge saw a flower accidentally broken off a plant in staging at a show, or had satisfactory evidence of such accident, and the flower was placed where it grew, he would probably not disqualify the exhibitor, as he (the judge) would be satisfied that no fraud was intended or perpetrated under the circumstances; but that is altogether different from the case mentioned last week of loose flowers being brought to a show in a box and tied on the plants; and, for obvious reasons, that ought never to be allowed in the case of any plants placed in competition for prizes.

Cucumbers without Bottom Heat (*Subscriber*).—The finest crop of Cucumbers we have seen was grown without bottom heat in a house that had been used for wintering bedding plants. It will answer very well to put in the rough prunings as you propose, and then the turfy loam. With the two rows of 4-inch pipes for top heat you could safely put out the Cucumber plants the first week in May; these if strong would afford fruit early in June and onwards away through the summer. Cardiff Castle is good for market, not being too large, of excellent form, heavy, and a greenish colour. Telegraph is a little larger. Those two we recommend as reliable for any purpose.

Cleaning Stone Pillars (*R. S. T.*).—You will find nothing better than muriatic acid for cleansing your stone pillars. The acid should be diluted with water, but if the green has become thoroughly established on the stone you had better use the acid almost pure at first, which will destroy the whole of the green, and the pillars in a few minutes can be washed white. If the pillars are not very badly affected equal parts of the acid and water will clean them thoroughly; but this entirely depends upon the stone, whether of a hard or soft material. If hard the acid must be used stronger than is necessary when the stone is of a soft nature. The diluted acid can be applied with an old scrubbing brush, but care must be taken that it does not get upon your clothes, or it will burn and destroy them. Chloride of lime mixed with water will also clean stone, but when it is of a hard nature it is not so effectual, besides leaving an unpleasant smell for days afterwards, which is not the case with muriatic acid.

Inarching Vines (*D.*).—There is no quicker and more certain way than uniting the young growth of a Vine in a pot to a growing lateral on an established Vine. As soon as the growths are firm enough to have a slice cut off each the work may be done, taking care that they are about of equal thickness, and that a good fit is made of the parts

placed in contact. Bind them together with a soft ligature, surrounding with moss and keeping it damp. The union will be effected in about a fortnight. The growth of the stock should then be suppressed—that is, the sub-laterals pinched off as they appear, and the extension of the scion, or attached growth, encouraged to make a strong cane.

Browallia elata (*T. H.*).—The seedlings should be potted either singly or three in a pot when they are large enough to handle. The latter make fine masses for conservatory or greenhouse decoration. After potting they should be kept on a shelf near the glass in a house with a gentle heat, and syringed every morning and evening to prevent attacks of insect pests. They should be stopped when a few inches high, repeating when they have grown a few inches, so as to keep them dwarf and bushy, it being necessary to stop them about three times to have well furnished plants. Supply liquid manure, not too strong, after the flower buds appear. They require plenty of light so as to insure thoroughly solidified growth and a floriferous habit.

Glazing Greenhouse (*J. E.*).—The plan of embedding the squares in putty, securing the glass with copper sprigs, and well painting the sashbars, the paint overlapping the glass the width of the rebate on which it rests, answers admirably, but it is not necessary to leave a space of one-sixteenth of an inch between the laps, the least possible space sufficing there, as the yielding nature of glass in good-sized squares renders it practically safe against breakage by the expansion of water in freezing. A smooth and ample bed of putty is essential, and the glass pressed firmly down into it, the portion squeezed out by the pressure being trimmed off quite smoothly on the under side of the bars. If there are any parts in which putty is not squeezed out below the glass the work will not be well done.

Tomato Disease (*Subscriber*).—Tomatoes are more liable to disease grown outdoors than when grown under glass. Excessive moisture, high feeding, and a close moist atmosphere are the chief points to be guarded against in the avoidance of disease. You may safely plant the Tomatoes out the first week in May in an unheated house; indeed, we have a house of similar length, and we plant out at the end of April, the plants being raised in February, grown on in gentle heat and near the glass, to have them sturdy, shifting them into 5 or 6-inch pots when the 3-inch pots in which they are first placed are filled with roots. There is no fear of your failing with proper attention in having an abundant crop. The varieties you have are of the very best. Ventilating gear can be had of most horticultural builders. Write to the Thames Bank Iron Company, Blackfriars, London, stating your requirements.

Clanthus Dampieri Culture (*T. H.*).—As you have sown the seed you will perhaps find a difficulty in establishing any plants. No matter how carefully they are handled, in preventing injury to the roots in potting, the slight disturbance causes the death of the plants. It is best to sow the seeds singly in 5-inch pots, in which the plants should remain until they are transferred to those in which they are intended to flower. Turfy loam torn up with the hand, pressed firmly in the pots, adding a fourth of leaf soil and a sixth of charcoal in lumps from a pea to a hazel nut, form a suitable mixture. Good drainage is essential. Watering requires to be done very carefully, and never over the plants, they being kept rather high in the centre of the pots. We have grown this plant very successfully in rough fibrous but sandy peat. It requires warm greenhouse treatment and plenty of light. It does very well outdoors after the middle of June, but is best treated as a biennial, sowing one year and flowering the next.

Additional Piping in Conservatory (*W. H.*).—It will hardly answer to "tap" the pipes at the farthest end—*i.e.*, on two pipes only, as that would cause the heat to rise most rapidly in those, the other two being comparatively cool through the sluggishness of the circulation, and there would be little, if any, gain in the heating power. We suggest that you continue the whole of the pipes, both the flows and returns, along the back, and being above the floor they would radiate more heat than the whole of those in the "trench." The pipes should not be tamped, but brought above the floor line with an elbow, and another above, so as to get the pipes at the proper level, and then taken to the end with a slight rise, having an air pipe or tap at the highest part. This would give you a much better circulation, and consequently very much more satisfaction in heating. We presume the piping in the conservatory would not be above that in the other houses, therefore not interfering with the feeding of the boiler from the supply cistern.

Destroying Brown Scale on Ferns and Stove Plants (*R. S. V. P.*).—There are many insecticides that will effect the purpose with due care in following the instructions accompanying them, without any injury to the plants. Many gardeners, however, use petroleum, soft-soap, and soda, dissolving 2 ozs. soft-soap and $\frac{1}{4}$ oz. soda in a gallon of hot water, and to this adding a tablespoonful of the best crystal petroleum, mixing well by brisk stirring. It should be applied with a brush or sponge, preferably the former, for moving the scale, the shell being only the covering of vast numbers of young insects, and to reach these the shield must be displaced. With care in keeping the solution mixed in its application, preventing much of it reaching the roots, and not using it over young tender parts, it will not injure the plants, especially if shaded till they are dry, whilst it destroys scale. Its success, like other insecticides, depends largely on persistent use, thorough cleanliness being a chief factor in successful culture.

Zonal Pelargoniums Unhealthy (*E. S., Herts.*).—The shoots and foliage are infested by what is termed "spot," due to a fungus, and being

internal it is not remediable. It can, however, be avoided by judicious treatment. It usually arises from the plants being grown in too rich soil, the rooting space being large in comparison to that of the size of the plants and too moist, the disease being still further aggravated by keeping the structure too moist and close, with the plants too far from the glass, and the temperature too low for their healthy growth. There will probably not be any further spread of the mischief if you lessen the supply of water, not giving any until the soil becomes nearly dry, yet before the foliage flags, admitting air freely on all favourable occasions, especially in the early part of the day, so as to dispel the moisture before the sun acts powerfully on the foliage. A drier condition of the atmosphere will by those means be insured, and the plants being kept in a light position and not crowded may be expected to improve as the season advances.

Contributions (*J. H.*).—Your article will be inserted subject to a little revision that it needs. We do not expect gardeners as a rule to write with strict accuracy, and if they have something to say that may be useful to others and say it in plain well chosen language, their notes are willingly revised. It is surprising how well many hard-working gardeners express themselves, not a few of these having learned the agreeable art through the editorial supervision to which their communications have been subjected. If you have kept a copy of your note you will see in what way it has been altered, and perhaps improved. If you write again, please let the lines be at the least half an inch apart. Many fairly written articles cannot be revised through the writing being crushed together, as if paper were a costly product, and your note had a narrow escape from the waste paper basket through your attempting to crowd as many lines on a sheet as ought to have been distributed over two or three. Abandon the crowding system, which is neither good for plants nor descriptions of their cultivation, and your next article will 'come out' better than the first.

Stove Flowering Plants (*Constant Reader*).—The Clerodendron to flower at the time you name should be started into growth about the third week in April, if grown under stove treatment the whole of the time. If brought forward in an intermediate temperature it might be started at the beginning of the month. It can easily be retarded. But in an ordinary stove temperature it will be in full bloom about ten weeks after starting it into growth. The Bougainvillea may be started a month earlier, but this depends very much whether the plant is old or young. If the former, and likely only to make short sturdy growths and flower on these, it need not be started before the Clerodendron, but if young and strong growths are made it will take at least twelve weeks from the time of starting. The Bougainvillea is much brighter in colour if its flowers are allowed to develop under cool conditions. Grow it in the stove until the flowers show, then gradually harden the plant and place it in a cool house until the flowers are freely developed. This will take twelve weeks.

Neglected Fig Tree (*A Subscriber*).—The proper way to proceed is to cut out a portion of the old bare wood and so admit of space for training in the younger parts. Avoid overcrowding, allowing sufficient space for the development of the foliage, so that all of it will be fully exposed to light and air, for unless the wood is thoroughly solidified as made it is useless expecting a crop of Figs. The training should be such as to keep the trees furnished with young wood evenly and throughout the space. As you mention Vines we presume the Figs are under them, in which case we fear your chances of growing Figs satisfactorily are extremely small, as they cannot have too much light. The trees having young shoots from the base 2 to 3 feet long shows they are not in a condition favourable to fruiting, the roots probably having too large a rooting area. Figs require to have the roots restricted to a comparatively narrow border of calcareous and gritty soil, the feeding being effected at the surface by mulching and watering with liquid manure. Stout, short jointed, thoroughly solidified wood is essential; fruit will then follow, not otherwise. If you wish for more plants you may layer the young shoots into pots, preferably with a little of the two-year-old wood. Notching or ringing is not necessary, but it will facilitate the rooting. It may be performed now. Figs are best grown with a single stem, no suckers being allowed from the soil. Not being informed as to the time of starting the house, we are unable to assist you in the matter of temperature, but you may find something that will be useful to you in that respect by a perusal of our Work for the Week column, in which Figs are treated of from time to time.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*George Channing*).—1, Not known; 2, Golden Knob; 3, Winter Pearmain; 4, Borsdörffer. (*E. F.*).—The Apple is Dumelow's Seedling.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*J. McGrath*).—*Coryanthes macrantha*, a very interesting Orchid. See page 174. (*W. J. R.*).—*Ceologyne cristata alba*. (*J. L.*).—1, *Peristrophe angustifolia variegata*; 2, *Tillandsia Lindenii*. (*J. B. S.*).—

1, Anemone fulgens; 2, Chionodoxa sardensis; 3, Narcissus obvallaris (see page 171). (J. W.).—The Fern is Polystyrium aculcatum. The Dendrobium must be a good specimen, and has evidently been well grown.

COVENT GARDEN MARKET.—FEBRUARY 29TH.

Business steady with prices unaltered.

VEGETABLES.

Table listing vegetable prices: Artichoker, Asparagus, Beans, Beet, Broccoli, Brussels Sprouts, Cabbage, Capsicums, Carrots, Cauliflowers, Celery, Coleworts, Cucumbers, Endive, Herbs, Leeks, Lettuce, Mushrooms, Mustard and Cress, Onions, Parsley, Parsnips, Potatoes, Rhubarb, Salsafy, Scorzonera, Seakale, Shallots, Spinach, Tomatoes, Turnips.

FRUIT.

Table listing fruit prices: Apples, Pears, Pine Apples, St. Michael Pines, Strawberries.

PLANTS IN POTS.

Table listing potted plants: Aralia Sieboldi, Arbor vitæ, Azalea, Cineraria, Cyclamen, Dielytra, Dracæna terminalis, Epiphyllum, Erica, Enonymus, Evergreens, Ferns, Ficus elastica, Foliage Plants, Fuchsia, Genista, Hyacinths, Hydrangea, Lilies, Lilium lancifolium, Marguerite Daisy, Myrtles, Narcissus, Palms, Pelargoniums, Poinsettia, Solanum, Spiræa japonica, Tulips.

CUT FLOWERS.

Table listing cut flowers: Abutilons, Anemone (Fulgens), Anemones (French), Aram Lilies, Azalea, Bouvardias, Camellias, Carnations, Chrysanthemums, Cyclamen, Daffodils, Gardenias, Hyacinths, Lapageria, Lilium longiflorum, Marguerites, Lilies (White, Orange), Lily of the Valley, Mignonette, Narcissus (white, various), Pelargoniums (scarlet, double), Primroses, Roses (red, indoor, tea, yellow), Snowdrops, Spiræa, Stephanotis, Tropæolum, Tuberoses, Tulips, Violets, White Lilac.

of the Journal as something tangible, that would add weight to our writings.

Well, now, we should have no difficulty in doing this, for our farm accounts are well kept, but we certainly do not intend doing so in compliance with such a suggestion. We may indeed publish some balance-sheets in due course, if we think the doing so will be likely to induce better practice on the part of any of our readers, but if we are expected to do so in proof of our veracity we must simply decline compliance. Even our candid friends will do us the credit to own that our writings possess the characteristic of frankness; we may also claim for them the much more important merit of truthfulness. We tell of our doings week after week in as plain and simple a manner as possible, and we certainly do expect our statements to be accepted in perfect good faith. If our readers do not so accept them, is it likely that any statement of accounts would induce them to do so? We think not, for we know full well what a plausible appearance figures may be made to assume to serve some dishonest purpose or to enforce some lame argument, and we have more than once done what we could to expose unfair statements of accounts. Let it not be supposed that we deprecate criticism, rather do we court it, so that it be fair and to the point. Our work is beset with too many difficulties, and we have been brought too much into contact with the stern realities of agricultural depression to shirk any responsibility.

Having thus briefly given our reasons for non-compliance, at any rate at present, with the wishes of our correspondent, we will now proceed to give a few extracts from our accounts in evidence of the difficulties which beset our work in practical farming, and to show him that we have to pay our way. It may be well to explain that when we took charge of our farms in the spring of 1885 they were cropped upon a four-course shift, which means that about one-fourth of each farm was in fallow. With the exception of a flock of ewes at the home farm, and a few starveling pigs, the whole of the live stock except the horses, and all the hay and corn had been sold, so that we had nothing wherewith to realise money out of the farms but the wool and the lambs till after harvest. We had a balance of £1000 to draw upon for current expenses, and we are glad to say that after a severe struggle that sum has practically been repaid, and the farms are now self-supporting. But we dare not say there is an end of our difficulties, for two more farms came upon our hands last Michaelmas, and we have reason to expect another one next Michaelmas. It is no light matter to take up such farms, for without exception they are in wretched plight, the soil being foul, poverty stricken, and badly cultivated, so that a considerable part of the profits derived from the improved farms are absorbed in bringing others into order as they fall in. Take for example a heavy land farm of 335 acres, part of which has clay so near the surface that all spring corn is practically a failure in such a drought as we had last year. Considerable sums of money have been absorbed by it in our work of draining, clay burning, manuring, and laying part of it down to permanent pasture, for nearly the whole of it was under the plough. When our accounts were balanced at the end of 1885 there was a debt against this farm of £418 8s. 3d. At the end of 1886 the debt had grown to £787 7s. 7d. owing to low prices for farm produce and our persistent efforts to improve the land. At the end of last year we were able to append a foot note to the effect that "This farm has paid all outgoing, and £67 5s. 2d. of the debt which was upon it at the beginning of the year, notwithstanding the practical failure of 50 acres of spring corn owing to drought."

Well, now, if all our farms had turned out as badly as this one, we should have become bankrupt long ago; but that was our worst case. Let us turn now to our best one. This is a mixed soil farm of 320 acres, of which we found some 80 under grass, but there was no flock, no pigs, and some of the land was very foul. Even this farm had a balance against it at the end of 1885 of £216 3s. 9d., but we had managed to get together some store pigs and sows, and

RESULTS.

"From all the ills which Heaven sends, Save me, Oh save me! from too candid friends."

FORCIBLY was this old couplet brought to mind by the receipt of a letter from one of our readers, wherein, after certain complimentary expressions, came a suggestion that he and other "friends" would like us to prepare a balance-sheet of one of our farms, have it audited by some disinterested person, and submit it to the readers

a certain number of ewe hoggets. As much chemical manure as we could afford was used in the spring of 1886, with such good effect that at the end of that year this farm had a balance to the good of £376 1s. 3d. This balance was carried on, and at the end of last year it had increased to £909 1s. 1d. Of course we expect to be asked about the valuation of farm stock, and we may answer that it would amount to about £100 less at the end of last year than it did at Christmas, 1886, because the corn was sold up more closely. We might go on and quote results from the other farms in hand, but it will suffice for our purpose to state generally that each farm has improved strictly in proportion to the nature of the soil, for our treatment of every farm has been equally fair.

It will, we hope, be understood that all tithes, rates, and taxes have been paid—at first out of our bank balance, and subsequently out of the money realised by the sale of farm produce—but we were unable to pay anything like a rent till the end of last year. It has indeed been an arduous undertaking, for in addition to soil difficulties we found others in faulty implements, and in some instances a want of them and of carriages that had to be supplied. No doubt our readers must sometimes think us over-persistent in our advocacy of the use of chemical manures, in conjunction with thorough cultivation in every other respect, but we have proved fully that without such manures and such thorough-going practice upon our part we must have failed in an undertaking, which under the circumstances may be said to have had something of rashness about it.

WORK ON THE HOME FARM.

Since writing our last note the land has been under snow, and glad are we to have winter corn well sheltered in such a manner. Winter Beans are especially liable to suffer from frost now; last year we lost a heavy per-centage of the plant, and we had, what we dislike so much, half crops on more than one field. Threshing Barley for seed, carting timber and gravel, has been our chief work during the past week since the carting of chemical manures was finished. We have been round to the whole of our farms to inspect the manure before it was mixed, and in every instance it is entirely satisfactory. The selection, purchase, and mixing of these manures involves much time and work, but undoubtedly it is labour well bestowed, for we get pure manures mixed in correct proportions for the different crops, and we effect a great saving upon the special mixtures of manure merchants, which we have so much reason to avoid. Compare the cost. Our manures when mixed average a bare fraction over £4 per ton, while a price list of special mixtures recently sent to us, offers Wheat manure at £8, Barley manure £11, and what is termed corn manure at £8. We might with advantage continue the comparison as to the quantity recommended per acre by the dealers and that which we advise.

Several farrows of pigs have come during this cold weather, but serious losses have been avoided by keeping sows and pigs closely shut up in warm quarters. These pigs should prove more profitable than those which we have sold recently, for even pigs have fallen off in price of late. Small porkers answer best, and we really do not see how we can better turn large fat hogs to account than turning them into bacon and lard. Certainly if returns of the importations of these articles of commerce are to be trusted there ought to be a fair margin of profit upon them. We have just purchased some capital young sows, a cross-breed between a Suffolk sow and Berkshire boar. They are compact handsome animals, admirably adapted for breeding good chubby porkers of the sort so much in favour in the London markets. Pure-bred Berkshires answer well for such a purpose, only they do not yield so abundantly as a cross-bred animal. Cross-breeding in this, as in most other cases, proving to be more profitable than pure in-and-in breeding.

HOGG AND WOOD'S SEED REPORT FOR 1888.

In submitting our annual report on the probable supplies of farm seeds for 1888 we have great pleasure in saying that there is the prospect of all sorts being abundant and low in price, with, perhaps, the one exception of Italian Rye Grass seed. Of Clovers, Rye Grasses, and Permanent pasture seeds we have already secured good supplies of excellent quality, and these have been selected after having been tested by us to grow well, so that every confidence may be placed in them.

ENGLISH AND WELSH RED, AND COWGRASS, OR PERENNIAL RED CLOVER.—A fair yield is reported, at prices similar to the moderate rates current in 1887. The Hardy Welsh Red is in good supply, and we have secured some choice clean seed of the true sort.

FOREIGN RED CLOVER.—There has been a large crop on the continent of Europe, and an average crop in America. The seed is well matured, and prices moderate.

WHITE CLOVER.—In England and abroad the yield is large, and prices lower than for some years past. Fine, clean, bold seed of English growth commands good prices.

ALSYKE CLOVER.—A large crop in most of the producing countries is reported, and rates are low. There are some strong, clean English seeds at very moderate prices.

TREFOIL OR YELLOW CLOVER.—The crop in England has been a medium one, and on the Continent the yield is reported small. Prices moderate.

PERENNIAL AND ITALIAN RYE GRASS.—Of Perennial the crop is smaller than for some years past, and the quality is remarkably fine. Prices similar to those of 1887. Anything under 22 lbs. per bushel is very foul, and we recommend the heavier weights as best value. The Italian has proved a short crop, but the crop is exceptionally fine. Prices are higher than those current last year.

TIMOTHY, COCKSFOOT, AND OTHER NATURAL GRASSES are in fair supply, and, with one or two exceptions, at prices similar to those of the past season. Cocksfoot, Timothy, and Meadow Fescue are in increased demand for two and three years' pasture, along with the usual mixture.

TARES, LARGE SCOTCH AND FOREIGN.—There is an abundant crop of excellent quality, and rates are lower than in 1887.

TURNIPS AND MANGOLDS.—The last crop was a fair one of nearly all sorts; but the yellow varieties are in short supply, and rates will be somewhat higher than last season's.

LAW'S MANURES.—These are again reduced in price, whilst the quality and condition are up to the usual high standard of excellence.—HOGG & WOOD, Coldstream.

OUR LETTER BOX.

Potash in Manures (K. J. A.).—Sulphate of potash will not answer so well as muriate of potash in the mixtures of chemical manures, simply because it contains less potash. In pure sulphate of potash the per-centage of potassium is 44.8; in pure muriate the percentage is 52.3. The comparative value of the two can be estimated in the ratio 52.3 to 44.8, or for general purposes it may be stated that muriate contains nearly one-fifth more potassium than the sulphate, if each sample shows the same degree of purity. It must not be forgotten, however, that the per-centage of purity varies. The literal meaning of the term sulphate, a salt of sulphuric acid; and of muriate, a salt of muriatic acid; a chloride might be taken as affording some indication of relative value, since it was proved to demonstration that all soil contains sufficient sulphur for plant requirements. Gladly do we answer such questions, affording as they do proof of thoroughness and an intelligent interest in a matter of such vital importance to all tillers of the soil.

Field Fencing (W. R. R.).—The fencing we figured answers well both for cattle and sheep, and is very durable, a considerable length of it which we put up seventeen years ago being still intact. As you now state you have a supply of railway sleepers at hand which you can turn to account as supports for strained wire, by all means use them, as such a contrivance may answer your purpose, but if the old sleepers are of soft pine wood their duration as fence posts even when tarred will be brief. The description, price, and figure of fencing we gave should prove useful to you even if wanted only for comparison. It so happens that our experience of fencing is a wide one embracing most kinds of wood and iron, and the teaching of such experience is that a mere makeshift may prove a costly affair in the end. We may add that it was because we have experienced the vexation of having a very similar fence of strained wire tumble down from the speedy decay of the supports that we offered a word of caution. If you do use the sleepers we recommend you to have a stout iron straining post at each angle; they are to be had at your post town very cheap, as we know some were purchased there a few months ago.

REMARKS.

19th.—A little sunshine, but generally cloudy, with frequent slight showers of snow and sleet.
 20th.—Dull, with frequent slight snow till 10 A.M., then fine and bright till 3.30 P.M.; cloudy afterwards, and N.E. gale at night.
 21st.—Fine and generally bright morning, cloudy afternoon; high wind from N.E.
 22nd.—Cloudy and cold.
 23rd.—Sleet from 8.30 to 9.30 A.M., whitening the ground; dull cold day.
 24th.—Snow from 8 to 8.30 A.M., fine morning with a good deal of sunshine; cloudy with a little snow for an hour or two at midday, then bright again.
 25th.—Snow till 10 A.M., covering the ground to the depth of an inch, then generally fine and frequently bright.
 A very cold week—the coldest this year. Mean temperature 51°, and frequent but slight falls of snow.—G. J. SYMONS.

BOUVDIAS.

FROM time to time the origin and progress of the most popular classes of plants have been traced in these pages, but little of this character has been devoted to the Bouvardias, though they have been treated very fully from a cultural point of view. The development of the valuable qualities of these plants has taken place within such recent times that many can remember when they were comparatively unknown, or the varieties so few that they received very little attention. Forty years ago the genus was represented in some gardens by a single species, and for long after that few additions were made; in fact it is only within the past twenty years that they have assumed a place of importance in collections of plants. Now their value is widely known, not only for culture in pots as decorative plants, but also for affording bountiful supplies of flowers, the double white variety especially having become a great favourite with bouquetists. In the United States of North America also Bouvardias are extremely popular, and the florists, who seem to be able to command such substantial sums for their productions, often secure during the winter months at least four times the prices obtained here, both for flowers and plants. On the Continent, particularly in France, considerable attention has been paid to the improvement of the varieties within the last two or three years, and several novelties have already found their way to this country that are likely to be followed by many others.

In glancing through the history of cultivated Bouvardias we must go back to the closing decade of the eighteenth century, when what are now generally termed "softwooded" plants were by no means numerous in British gardens. About 1791 a Mexican plant was introduced to Madrid which was described by several botanists both as an *Ixora* and a *Houstonia*. Three years later Sir Joseph Banks, to whom we are indebted for so many good things, introduced the same plant to this country, and further examination enabled the authorities to determine that it was sufficiently distinct from the genera named to merit recognition as a representative of a new genus. Accordingly the elegant title *Bouvardia* was conferred upon it in honour of Dr. Charles Bouvard of Paris, and the specific name *triphylla* in reference to the arrangement of the leaves in threes, completed the designation of the first cultivated member of this now large and important family. Its bright red tubular flowers borne in clusters at the tips of the branchlets soon obtained it many admirers, and as it was found to be easily increased by root and stem cuttings, it extended rapidly when the nurserymen took it in hand. At one time not very long since few gardens would be found without the old *B. triphylla* in some of its houses, but now it is seldom seen, except where curiosities are treasured, for though it is by no means wanting in floral attractions, it is far surpassed by the more recent productions of the same family. It is rather strange that although several varieties were obtained early in this century, one of which (*pubescens*) was afterwards separated as a new species (*B. Jacquini*) by some writers, yet neither the type nor the varieties have contributed to the present race of Bouvardias either in sports or seedlings, and this is more strange because subsequent introductions have been so extremely variable. One fact must, however, be mentioned in connection with *B. triphylla*—namely, that it is the only member of the genus for which any medicinal value has been claimed, though included in the strongly

characterised *Cinchona* family. In 1874 Professor Maisch brought before the Philadelphia College of Pharmacy a reputed remedy for hydrophobia named Trompatilla, which was prepared in Mexico from the stems of *B. triphylla*; but though some notice was taken of it at the time little has been heard of it since, and probably, like many of our old herbalists' preparations, its properties were more imaginary than real.

Several other species were introduced from Mexico and South America in the first half of the present century, and with two of them we are especially concerned in referring to the history of modern Bouvardias. These are *B. longiflora*, introduced from Mexico in 1827, and *B. leiantha*, from Guatemala, which flowered at Mr. Salter's Hammersmith Nursery in 1850, and was probably introduced a few years previously. The first named has long and handsome pure white flowers, and the second has much smaller reddish crimson flowers, a bright and rather pleasing shade. Commencing with these Mr. Parsons of Brighton, in 1855, obtained a cross, *B. longiflora* being the seed parent, and from the seedlings raised, four—namely, Hogarth, Laura, Rosalinda, and Oriana—were sent out a year or two afterwards. The production of the variety Hogarth, which has rich red flowers, was an important step, and in it and its descendants we have some of the most useful plants of the present time. It has produced quite a family of sports very distinct in characters and extremely interesting, as showing the variability of some plants when once their characters have been disturbed, without subsequent cross-fertilisation. Several years elapsed after the four already mentioned appeared in gardens before anything farther was done, but in 1869 a beautiful scarlet sport from Hogarth, under the name of *B. elegans*, was imported from America, and was soon after utilised in crossing with others.

A second remarkable sport was also produced from Hogarth in America—namely, *Vrelandi* or *Davisoni*, with white or faintly tinted flowers, arrived here in 1871, and owing to its good habit and floriferousness has become a general favourite. A delicately coloured sport from *Vrelandi*, named Maiden's Blush, was sent out by an English nurseryman in 1874, and is still prized in many collections, but the most important of all was the double white *Alfred Neuner*, a sport from *Vrelandi*, that was obtained in America in 1880, and certificated at New York of that year. Early next year Messrs. J. Carter & Co. presented it to the British horticulturists, and it rapidly extended both in trade and private collections, Mr. W. Bull obtaining a first-class certificate for it from the Royal Horticultural Society on August 9th, 1881. This has become one of the best for bouquets and buttonholes, as the flowers stand much longer than the single varieties, and are usually very symmetrical in form. A double rose-coloured sport from *Alfred Neuner* was secured in the United States in 1882, but a similar sport seems to have been obtained by several persons; amongst others Mr. David Allen, gardener at Oakley, Boston, fixed one which was named after his employer, Miss Mary Pratt. Another was also noticed at Louisville, and one of these appeared shortly afterwards as *President Garfield*. This has not at present proved so useful as the double white, as it is more variable and does not preserve its characters so well.

Reverting to *B. elegans*, one of the earlier Hogarth sports, a few of the crosses between this and others may be noted. A fine white-flowered species, *B. jasminiflora*, was introduced from South America in 1869, and proved a decided acquisition. The first cross was effected between *B. elegans* and *B. jasminiflora*, and the results in 1872 were *longiflora flammea*, for which Messrs. Henderson were awarded a certificate by the Royal Horticultural Society on May 1st; *Bridal Wreath* and *alba odorata*, followed in the succeeding year by *eandidissima*, *umbellata alba*, and *umbellata carnea*, all of which we believe originated in Messrs. Henderson's Wellington nursery. A yellow-flowered species, introduced by M. Louis Van Houtte in 1846, was also crossed with *B. elegans*, and in 1874 *bicolor* was sent out as a distinct variety, that now, however, is rarely seen. A sport

from *B. elegans*, which received the name of Priory Beauty, has rosy mauve flowers, and it was certificated at Wimbledon in 1881 when exhibited by Mr. Law. It has since become a favourite in numerous collections. One other variety of the Hogarth family has yet to be noted—namely, Queen of Roses, that resulted from a cross between *B. Hogarth* and *B. longiflora*, which came into public notice in 1869, and has been greatly appreciated ever since for its pleasing rose tint and fragrance.

Crosses between other species or varieties have not been very numerous, but some have been made that have added materially to our collections. The principal was a cross between *B. jasminiflora* and *B. Humboldti*, which yielded in 1871 *B. Humboldti corymbiflora* with large white trusses of flowers, and *B. jasminiflora longipetala*, besides several others that were not named. From *B. jasminiflora* crossed with *B. flava* in 1875 the yellowish but not beautiful *B. jasminiflorum flavescens* was raised by M. V. Lemoine, but a really good yellow variety has yet to be secured.

It is rather remarkable that only four Bouvardias have been certificated by the Royal Horticultural Society—namely, *B. longiflora flammea* and Alfred Neuner, already noted, with Dazzler, shown by Mr. Balchin of Brighton, November 16th, 1880, and President Cleveland exhibited by Messrs. Veitch & Sons, December 13th, 1887. The last named is of American origin, and one of the brightest scarlet-coloured Bouvardias in cultivation; it is probably one of the *B. elegans* or Hogarth family, but whether a seedling or a sport does not appear. In the last year or two several double scarlet varieties have been introduced, mostly from France, where M. Lemoine has given them some attention. Sang Lorraine, Triomphe de Nancy, and V. Lemoine are the best of these, and they have been well grown by Messrs. Cannell & Sons at Swanley.—L. C.

IS CHISWICK TO GO?

UNDER this heading we published articles that have received a large share of attention not only from persons identified with the reorganisation of the Royal Horticultural Society, but from others who are interested in its welfare. Taking our stand on the broad ground that as the strength of nations and the solvency of individuals depend on sound finance, corporate bodies cannot, of necessity, form an exception to the rule; therefore we were anxious that the actual financial position of the Society should be clearly understood by all its supporters, and especially by the members of the Council-moving Committee who have taken its destiny into their keeping.

We have had the most conclusive proof of the necessity for presenting the resources of the Society in their true light; and in only one particular has it been possible to question the accuracy of the estimate that was presented in these columns a fortnight ago. A friendly contemporary, while it has described the finances as "deplorable," very properly suggests the unadvisability of representing them as worse than they are. We have yet to learn that the estimated income for the year is too low, and the liabilities too high. Accepting the correction that has been tendered in respect to the Assistant Secretary's salary, and reducing the total by £175, there is a further liability that was not indicated—namely, the cost of transfer and furnishing and fitting up the new rooms. This is a necessary outlay and cannot under the circumstances be insignificant. Doubtless the salary was included in the financial statement, but at the same time it is well known the amount was not paid out of the Society's exchequer, but by good and generous friends.

We wish it were otherwise, but cannot arrive at any other conclusion than that the disbursements for the year will exceed the income by £2000. It is most important that that contingency be recognised, and also that no expenses be incurred except what are clearly foreseen will be remunerative. We know that an estimate was arrived at showing an income of £3800, instead of £2000, by simply regarding the lapsed £600 of South Kensington expenses as an asset, and including the £1200 promised for the special fund; but that position is not sustainable, and therein was the danger, obscured, but not the less existent, of Chiswick having first to be neglected, then abandoned, in which case we are not alone in the belief that the Royal Horticultural Society would melt away.

It is pleasant to learn that Chiswick is not only to be preserved but to have its resources developed on the lines we have suggested as soon as attention can be directed to it, and when means are forthcoming; or in other words the famous old garden has not to go, but only to wait. It is in our opinion the neglect of Chiswick

that has more than anything else alienated the sympathies of provincial horticulturists and gardeners from the Society; and we have a strong conviction that if sound and thorough work was done there and the results published that a greater accession of supporters would be forthcoming than could be obtained in any other way. We do not ignore the question of "City rooms," nor underestimate their importance; but, on the contrary, should regard them as a valuable adjunct to Chiswick and subservient to it, not Chiswick subservient to them, as for some time to come they cannot be otherwise than of a temporary nature. They are obtained, and a hall too, that will answer well its purpose during the summer months for exhibitions. We very earnestly hope these will answer the purpose too.

The policy of the Committee appears to be a policy of showing. The programme will have to be framed with great care, as no doubt it will be, and carried out on different lines than heretofore, to command support. It must be conceded that the shows of the past have been a source of weakness rather than of strength to the Society. Every so-called "exhibition" in connection with the meetings during the past year has entailed loss, and not brought gain, either in the form of an increase of Fellows or in receipts from visitors. Even when all the prize money was provided by seedsmen the Society has lost considerably by the venture. Take the display of vegetables in October, admittedly one of the finest shows of the kind ever seen, yet what was the result? Scarcely any visitors, and the Society in the cost of preparations, including labour, clerical and otherwise, was a loser to the amount of at least 200 per cent., and probably as much more by the joint arrangement. Is not that the road to ruin?

The lessons of the past cannot be forgotten, nor can methods that have failed be safely followed. A departure from old courses seems to be imperative. No doubt a well-thought-out scheme will be promulgated, and everything done that can be done to make it successful. We will join in any prudent course that can be devised in the interests of the Society, and should regret exceedingly to have to record the failure of the endeavours that are being strenuously made to strengthen it and enable it to do its legitimate work. To speak paradoxically, on the non-responsible Committee rests the responsibility, and nothing but success can justify its existence. The difficulties to be encountered are great, but this only means that the greater will be the honour due to those who overcome them.

FRUIT IN NEW ZEALAND.

AN error appears to have crept into the fifth edition of the "Fruit Manual." I feel sure the author will only need to be made acquainted with the fact to rectify the same at the first opportunity. On page 181 it is stated "Prince Bismarck Apple was raised in Canterbury Province, N. Z." It was raised near Ballarat, Australia, and the first six plants were sent to a friend of mine, Mr. Bull, nurseryman, Gisborne, Poverty Bay, New Zealand, who told me the full history, but I have forgotten the raiser's name. I am well acquainted with the two McIndoe Brothers in Auckland, one of whom sent plants to their brother in England after it was disseminated locally from most of the New Zealand nurseries. There is another, and many think a better, Apple, named "Ballarat Seedling," by the same raiser. We have a New Zealand raised variety named "Lord Wolseley" that is equal to Winter Majetin in its Aphis lanigera-resisting power. It is a most handsome variety and a long keeper. I shall have great pleasure in sending you some dormant buds per post if you would care to have them. Carefully cut off shallow and budded without removing any of the eye underneath the bud, they push at once if put on some good free stocks. I get scions from England, France, and America this way and we are very successful with them. We grow Apples to a very large size in this North Island of New Zealand. Warner's King has been grown to 28½ ozs., 27 ozs., and 24 ozs. by different growers. Many of the varieties of Pears are very superior here in flavour compared to the midland counties of England, but sometimes we get a second crop of flowers and fruit. I have eaten Williams' Bon Chrétien second crop equal in flavour to the first, though not in size. I have seen Passe Colmar with three crops of fruit at one time, though this is rare. Plums also crop well in this country. I forward our catalogue that you may see the varieties of fruit we grow.—JOSEPH MAYO, *Drury, Auckland, N.Z.*

GLADIOLUS NOTES.

LAST year I reverted to a very old method of starting the corms before planting them in the open. So well was I satisfied with the results that I have already placed a few hundreds in boxes to start slowly in a cool house. The reason for so starting the plants

into growth may not be apparent to the less experienced grower without some explanation. The explanation is this. Our summers are too short for many varieties to properly mature their flower spikes, and even in the case of some which do this the corm which is to continue the plant's existence and to flower the succeeding year is not sufficiently developed before winter. For many years I lifted plants and allowed them to finish growth under glass, but this practice is not so commendable as that of extending the length of the season of growth from what may be called the "bud" end of the plant. The rationale of this system is very much the same as that of sprouting Potatoes before planting, and indeed in many respects the Gladiolus appreciates the same treatment as the Potato. I am sprouting my Gladiolus like the Potatoes, being alongside them. A little leaf soil (sifted) is placed in the bottom of cutting boxes, and the corms are laid somewhat closely together on the top of the soil, a covering of moss helping to start the growths in an even manner. I have cut the corms for the past few years, and though not a necessary proceeding it enables us to produce a given number of spikes from one corm with absolute precision. A friend who followed this practice complained of the number which failed to grow, but I have not the slightest doubt that there had been a failure on the part of the grower, just as it so often happens that Kidney Potatoes are never seen after they are put in the ground when dormant. If corms with imperfectly started buds are cut and placed into cold soil it is no wonder that they fail to grow. It must be borne in mind that in some seasons on account of a want of heat the corms do not ripen sufficiently for the full development of more than one bud.

It must be remembered that a Gladiolus is, after all, simply a corm, and in trying to increase it by cutting we are limited by the condition of its rootstock, for if in endeavouring to make every prominent bud into a detached plant we cut outside the circle of latent roots we cannot make that bud grow into a plant. Many of the corms that have lately passed through my hands have shown four and five good buds, but in no case have I been able to cut up into a greater number than three pieces, because of the impossibility of securing roots along with a greater number of buds. Lemoine's hybrids require exactly the same treatment, and the same care in cutting the corms. Last season several spikes were so late as to be spoiled by cold and wet. This year I hope by starting them to have them much earlier. Moreover, this year I asked M. Lemoine to select me only those which he knew to be early, so that I hope to be on the safe side. The earlier varieties of the Gandavensis section do not require to be started, and of course those who are far enough south will hesitate to adopt a system which in their case may not be necessary at all.

A few years ago I began to plant much shallower than growers recommend. My reason for doing so was to secure more heat to the corms in autumn in order to their more thorough maturation. I confess I tried this plan with some hesitation, but the results have so far justified this innovation. Last autumn some of the stronger growers—such as Mabel, Léandre, Teresita, Titania, &c.—ran up to from 6 to 7 feet, and in one case as many as seventy-eight flowers were produced on one growth. Moreover, many of the corms measure 9 to 10 inches in circumference, and a few from 10 to 11, while dozens of them will throw three and four growths from one corm, so that in our case there cannot be much wrong with this system.

Another cultural point worth directing the attention of large growers to is the distance the corms should be planted apart. When clumps of one variety are planted, say of nine to a dozen together, the corms need not be farther than from 2 to 3 inches apart. When planted in lines or beds four single growths can be put into each foot run, and they will succeed just as well at this distance apart as when allowed more room. In order to get freely to the plants a distance of 18 inches between the rows is not too much to allow.

The soil should be thoroughly broken into small particles to a depth of from 18 inches to 2 feet. Last year I added a 9-inch dressing of prepared garden refuse to the Gladiolus quarter. I shall add quite as much this year, as it seems to suit them so well. Superphosphate of lime employed as a surface dressing three or four times in the course of the season, and watered-in, is of much advantage. A good guano is equally beneficial but more expensive, though in many cases it may be more easily obtained than the other.—B.

NOTES ON GRAPES.

SIZE AND QUALITY.

UNDER the above heading there appeared in the Journal for the 26th of January last an ably written article from the pen of Mr.

David Thomson. I agree that those gardeners who grow for market are bound to produce what is most in demand, whether it be coarse or otherwise, therefore my remarks shall be confined to garden produce which is cultivated specially for home consumption. With regard to size and quality in hothouse fruits, Mr. Thomson will, I doubt not, admit that both may be obtained together in the best kinds and varieties of fruits. I take it that anyone knowing anything about Grapes would look upon the production of well-proportioned and finely finished bunches from 3 lbs. to 7 lbs. each as bearing evidence of high cultural skill, and my experience leads me to say that nineteen out of every twenty guests would prefer the 7 lb. bunch to the 3 lb. bunch being seen on the dinner table. Size in this case would not necessarily be secured at the expense of quality pointed out by a correspondent at page 82. However, I do not advocate growing all large bunches of Grapes. On the contrary, I should say from one to three dozen such bunches for special occasions would be ample, as there can be no doubt in the minds of Grape-growers about bunches of every variety of Grape, ranging from 1½ lb. to 3 lbs. each, being the most useful, and at the same time the most economical size bunch to grow.

VARIETIES OF GRAPES.

With regard to varieties I daresay all practical Grape-growers for home consumption would, if they were confined to two varieties, grow Black Hamburgh and Muscat of Alexandria in preference to any others. At the same time I fail to see that anything is lost by including a rod each of other varieties in the second and third Hamburgh houses. But Black Hamburgh, Muscat of Alexandria, Madresfield Court, Buckland Sweetwater (which is a grand Grape when well done), and Foster's Seedling, cannot be had all the year through, hence it is that the thicker-skinned and less highly flavoured varieties are cultivated to continue the supply of Grapes during the winter and early spring months. With regard to late or long-keeping Grapes, I look upon the old and much-abused Syrian (which is nearly identical with Trebbiano), and Mrs. Pearson, as being two good keeping white varieties, the berries of both being juicy and very refreshing when well ripened. Of blacks, we depend mostly upon Lady Downe's, Mrs. Pince's Black Muscat, and Gros Guillaume. The latter is a much-abused Grape by those who have never succeeded in growing it as it should be, and also by those who have not even attempted to grow it, but who, nevertheless, condemn it upon hearsay gossip. Here the Gros Guillaume is much valued as a late Grape. The Vines are not given any more space to grow in than that accorded to other varieties.

PRUNING FOR LARGE BUNCHES.

Like the Syrian, Gros Guillaume has this advantage over all other late Grapes—namely, that either a greater number of medium-sized bunches, or a less number of abnormally large ones, according to the desire of the cultivator, may be taken off the Vine. A crop may also be had of both large and small bunches by pruning at the beginning of the year two or more shoots back to a plump bud, irrespective of its distance on the previous year's wood from the main stem, and cutting all the other shoots hard back to one eye from their bases. As an instance of this system of pruning Vines, I may be allowed to state that this year I cut two bunches of Gros Guillaume weighing 10 lbs. and 12 lbs. respectively, and five bunches ranging from 2½ lbs. to 4 lbs. each off the same Vine. I never reduce the shoulders of any of the bunches of this Grape at thinning time as was suggested recently by Mr. William Iggulden, who, I believe, grows the Grape creditably at Marston. I have had small bunches of Gros Guillaume keep plump up to the end of March, the berries being juicy and full of flavour. Gros Guillaume requires a long season to ripen it well. It does very well here in the Muscat house, which is started the middle of January, and also in two other houses of mixed late Grapes which are started a month later.

OTHER LATE GRAPES.

Alnwick Seedling and Gros Maroc I value very highly. The flavour of the latter is greatly improved by being grafted on the Black Hamburgh stock, by which union the flavour of all late varieties of Grapes would be improved. Gros Colman, as Mr. Thomson pointed out, is a noble-looking Grape when well grown, the berries being of great size, fleshy, and of pleasant flavour if not eaten till January or February. However, as showing how Gros Colman is appreciated here, I may mention that during the week ending February 25th I have, by way of a change from medium-sized Gros Guillaume and Mrs. Pince, been sending to the Castle for dessert Mrs. Pince and Gros Colman, with the result that the former is eaten and the Gros Colman left untouched. The bunches are suspended from a figure, one on either side, stood on the centre of the dinner table, and that the bunch of Gros Colman placed thereon a week since is still plump and fresh. The supply of Mrs. Pince is renewed once and sometimes twice a day, the bunches

ranging from 2 lbs. to 4 lbs. each. I admit it is hardly fair to thus test any late Grape with Mrs. Pince.

TESTING THE QUALITY OF GRAPES.

Where several long-keeping varieties of Grapes are grown for home consumption it is a good plan, in order to ascertain which of the several varieties (Mrs. Pince excluded) find most favour, to place two together on the table of persons who have been accustomed to the flavour of Grapes from their infancy, and who, therefore, may be considered competent judges of the quality of the Grapes set before them. Lady Downe's should be the standard variety, as being the generally acknowledged best late Grape in cultivation; therefore, the contest might be opened by sending to table Lady Downe's and Gros Maroc three or four days following, renewing supplies of the variety finding most favour daily during that period. Assuming Lady Downe's to be that variety, Gros Guillaume might take the place of Gros Maroc, and so on until all the varieties had been tested by the standard thus set up. On the other hand, should preference in the first instance be given to the Gros Maroc, Lady Downe's would be succeeded by Gros Guillaume or some other variety at the end of the specified time. In this way a pretty correct decision of the relative qualities of late Grapes by competent and impartial judges might be arrived at. In reference to societies which only provide one class for black Grapes at shows held in August, as is the case at Southampton, good judges would, I have no doubt, give the prizes to moderately good and fairly well finished bunches of Black Hamburg in preference to good examples of Alicante, Gros Colman, Gros Maroc, or Lady Downe's. They would also give the prize to good examples of any of the last-named four varieties in preference to "red" Hamburgs, which only afford evidence of bad cultivation.

BOTTLED GRAPES.

I quite agree with what Mr. Thomson says with regard to the effect which the system of cutting and bottling late Grapes has on their flavour—namely, that the latter is considerably impaired by reason of the water which the Grapes imbibe from the bottles. There is no doubt about Grapes keeping better and being of better flavour by being allowed to hang on the rods till February in properly constructed houses, and in which no plants requiring or giving off moisture are wintered. This would be better for the Grapes; but would not the fact of the bunches being left so long on the Vines permanently and injuriously affect them, seeing that they would have no interval of rest between cutting the Grapes and starting the Vines, as I maintain all late Vines should be started by the middle of February? Moreover, the Vines, borders, and interior of the vineries need attention in the meantime. No. Where a supply of Grapes is required all the year through, as is the case here, and in many other places besides, the bottling system must be had recourse to notwithstanding the extent to which Grapes lose flavour in consequence thereof.—H. W. WARD.

SIX GOOD CAULIFLOWERS.

ENCOURAGED by many private letters I have received confirming my recommendation of "Six Good Peas," I have selected Cauliflower for my third article; and although probably one or two varieties may be sufficient for amateurs, large garden owners are obliged to have the earliest and latest varieties, as well as others that will give a succession throughout the whole season. Cauliflowers are not so numerous as some other vegetables, yet there are about a dozen and a half affording ample room for selection. The Cauliflower season may be said to begin in May and end in November, and the earliest of all is

VEITCH'S EXTRA EARLY FORCING.—This is a most desirable variety. If sown in a little heat in February, transplanted in March, and planted out in April, it will head in May, and a Cauliflower that gains maturity in a little more than three months after sowing merits the name of "early." It is very compact in growth, may be planted 18 inches apart each way, and the heads produced, from 3 to 4 inches in diameter, are as white as snow, and exceedingly delicate in flavour. It heads a fortnight before any other variety I have seen. We have ceased to sow Cauliflowers in the autumn, as this variety, when sown about the present time, will head before any autumn-sown plants, and while many of these become very leggy, or "bolt," the spring-sown ones invariably grow compact and do well generally.

VEITCH'S PEARL.—A fine second early variety. It grows taller, more bushy, and produces larger heads than the preceding, but in these respects it might be described as of medium development, and it is a useful Cauliflower. The heads are exceedingly firm, very compact, and pure white. It is a splendid Cauliflower for the table, and if sent to market in June and early in July it would be sure to meet with a ready sale, and at the top price.

WEBB'S KINVER MONARCH.—A new Cauliflower, and as a main summer crop sort it is in my opinion unique. Like all well selected vegetables it does not produce a quantity of superfluous leaves, but grows most compactly and develops fine heads with certainty. We sometimes see Cauliflowers exhibited at shows in June, but it is towards the end of July and throughout August that they are shown in the greatest profusion, and as an exhibition sort at such times the Kinver Monarch is difficult to surpass. If sown in the open ground in March it will head freely in July, and a succession can be had for a long time.

SUTTON'S KING OF CAULIFLOWERS.—A well known variety, and especially for late autumn use, its merits being included amongst a good half-dozen everywhere. It is a strong healthy grower, and although it does not head so quickly as some of the preceding it comes in well in good time, and anyone going through a quarter of it a little while after the first were cut would be delighted with the many fine heads they would find. The heads are well protected by leaves, and this is why I like it so much for autumn use.

CARTER'S MONT BLANC.—This has the merit of being distinct. The plants are strikingly compact in habit, and the heads are large. It is a summer sort, and those who grow half a dozen varieties of Cauliflower and do not include this may rest assured that they are without one good one at least. Some Cauliflowers only succeed in certain soils, but I have noticed that this one does well in all, and its good constitution and robust style of growth indicates it as a variety that will prove remunerative.

VEITCH'S AUTUMN GIANT.—It speaks well for the class of Cauliflower Messrs. Veitch deal in when three out of my good half-dozen are of their introduction, but they all merit note, and this one as much, or perhaps more, than any of them. It is as well known as any Cauliflower in existence. I have nothing new to say of it, but I could not help including it amongst the six, and it would have had a place in a less number. It is not, however, an early Cauliflower, and it can hardly be called a summer variety, as it must be sown early to head in August, but for September, October, and November it outdistances all rivals.—J. MUIR.

PEACH TREES CASTING THEIR BUDS.

THE vexed question of Peach trees casting their buds is ever reappearing amongst us, and although various opinions are from time to time advanced as to the cause of the evil, no effectual means of preventing it have been found, as it is still very prevalent. It is generally attributed to dryness of the borders and unripe wood, but anyone who has had Peach trees under his charge in different localities will have found bud-casting take place even when the borders have received ample supplies of water at all seasons, and also when the nature of the wood as to ripeness has left nothing to be desired.

Taking unripe wood first, "J. H. W." (page 169) says "unripe wood is generally the cause of buds falling." Now, this is exactly the reverse of my experience and observations, for whatever other evils are due to unripe wood, and they are many, I have never found it conducive to buds falling. The wood of outside trees is often in an unripe state at the commencement of winter, and yet, as everyone is aware, with these the evil very rarely if ever occurs. Again, it is much less frequent in late houses than in early ones. The latest Peach house here is in a very unfavourable position for the trees ripening their wood, being shaded by a high plantation most of the afternoon, consequently the wood is weaker and greener in colour than is the case in the other houses, but the trees never cast their buds; whilst in the early house, where the wood is stout, hard, and red coloured, some of the buds fall every year, although not enough to cause anxiety, yet the evil is present. Judging from these facts, unripe wood would not appear to be the cause.

Dryness of the borders no doubt contributes greatly to increase the disposition of trees to cast their buds; but, on the other hand, strict attention to watering will not always prove a sure preventive. I have had charge of Peach houses from which all the roof lights have been removed directly after the last fruits were gathered, and have only been replaced in time to prepare the house for forcing, yet, notwithstanding the most cautious and gentle forcing, they would cast their buds in showers; and often I have entertained the gravest fears that enough would not remain to furnish a crop of fruit. What, then, could have been the cause of the evil in this instance? It was neither unripe wood nor dryness at the roots for these trees I am confident never suffered in that respect.

The origin of the evil, I am of opinion, is to be found in forcing—not alone the early forcing of the trees into growth, but the forcing to rest at a time of the year when, under natural conditions, they would be full of life and vigour. The Peach appears to require the warm sunshine and cool nights of autumn to mature

and perfect its buds for another season, and when forced to perform these functions under the burning heat of the summer sun the work is, as it were, overdone—in a word, a large proportion of the buds never are perfected, and soon die, although they remain attached to the trees until the rising sap pushes them off. I do not believe we can insure complete immunity from bud-falling in early houses which are forced every year, but by carrying out a judicious system of cultivation it may be reduced to harmless limits. One of the best means to adopt as a preventive is frequent lifting and relaying the roots, wholly or in part supplying them with fresh soil, and keeping them near to the surface of the border. Over-cropping should not be indulged in, and insects allowed no quarter. There is no excuse for allowing the foliage to be devoured by red spider, for the syringe if properly used is a most effectual check to this pest. Lastly, give plenty of water at the roots and over the foliage of the trees. Make sure the borders are thoroughly soaked, and give the foliage an evening bath daily.—A. BARKER, *Hindlip*.

RECORDS OF EXPERIENCE.

WINTER ACONITE (ERANthis HYEMALIS).

THOUGH growing anywhere and anyhow, it is only in open spaces in shrubland or woodland arrangements that the wealth of bright yellow flowers and deeply cut leafage of this plant are seen to advantage. It seems to like a cool soil—a good loam over clay, not disturbing it, but give it a chance to spread. It is the first flower of consequence to the bee-keeper, as it affords the first gathering of pollen and nectar, especially to the black bees.

HELLEBORES.

Of other flowers *Helleborus niger altifolius* (maximus) has been grand with flowers 4 to 5 inches across, one to three on a stalk, rose tinted outside and in bud, leaves large, green, their stalks mottled with purple. We have it on a narrow outside south-west border of a conservatory along with *H. atrorubens*, which bears numerous reddish-purple flowers. *H. niger* is poor beside *H. niger angustifolius* (Scotch variety), which has its flowers tinged with rose externally, white inside, and yet the most floriferous and finest of the Christmas Roses, the plant being dwarf and compact. There is a variety—viz., *H. niger angustifolius* (Manchester variety) with large pure white flowers, freely produced, and very fine. Hellebores like a cool soil, good loam over clay, and a protective and enriching mulch of leaf soil or partially decayed manure. They are all the better for shelter, flowering best when covered with handlights or frames. Their chief requirement is to be left alone—i.e., plant properly, and let them grow into masses, when they charm everybody.

CHIMONANTHUS FRAGRANS.

Chimonanthus fragrans is a bush with us about 6 feet high, and rather more through at the base. It is at the south-west end of a vinery, and has been flowering since the end of January, and will probably last, as it did last year, until April. The early flowers are borne on the short stubby shoots in the interior of the bush, the late ones proceeding from the stronger growths of last year. It needs to have a warm situation, either in front of a wall or building with a south to west aspect, or trained against walls or buildings with the aspect cited. In the north a wall is absolutely necessary. Close pruning is essential, so as to have the principal branches well furnished with young wood, as the flowers are produced on the previous year's growth in the axils of the leaves of the preceding year. Pruning should be done after flowering, cutting in close to the main branches all young shoots except the leading ones, which may be cut back half their length, more or less, so as to induce side shoots for furnishing the bushes against walls. Our bush merely has the oldest of the old wood thinned out, and any straggling or overgrown shoots shortened. The result is a good crop of wood, bearing flowers freely the following season. Where sweet scented flowers are in request in winter they are much appreciated. A few sprays with brighter flowers in vases afford the charm of delicious aromatic fragrance. It is generally considered to thrive best in deep rich sandy soil; but I have not succeeded with it in such unless the soil was firm as for fruit trees, so as to induce sturdy, short-jointed, well ripened, floriferous wood. Our plant is in strong loam over clay, and a mulching of partially decayed leaves or spent hotbed in autumn is sufficient enrichment.

VIOLETS.

Violets in frames dispute with *Chimonanthus fragrans* the claim to acceptance as general favourites in winter. There is none to equal (and I have grown nearly, if not quite, all *Viola odorata* vars.) the Neapolitan varieties. Marie Louise, deep mauve, red streak, and white eye; De Parme, light mauve, with white eye;

and Count Brazzi's White Neapolitan. Count Brazzi does not claim any credit for the last variety beyond making it known. That I had personally from him. I find these varieties have the best constitutions, give larger and finer blooms than any others, as well as more of them over a longer period, and with most scent. There is another characteristic in that they never vary, are always reliable, and yet there is an advance in Marie Louise (the true Marie Louise is light mauve or lavender, with a white eye, without any red streak) towards two flowers on a stem, which is more pronounced each year, though I have not as yet had two fully developed flowers on a stem. De Parme, on the other hand, is just the same as it was received from Florence in 1870. What I wish culturally to state is that Violets are most floriferous, have most substance, and most scent when grown in strong loam than in light. There is a sturdier more solidified growth, plumper crowns, and more flowers.

CELERY.

Celery last year had a trying time. It seems strange we should dig ditches to grow it in and yet omit to provide the water. In the fen districts the finest Celery in the world is grown; the black vegetable soil and the water enable the plants to luxuriate under a broiling sun in the dog days, whilst that in gardens relied upon for the reservations of moisture in the manure, which in the quantity used never made the crop pay, except it be as preparatory of the ground for other crops, particularly Onions. I find there is more virtue in drenchings of liquid manure, say three or four during the hot weather in the early stages, than in great thicknesses of soapy manure. The slopes of the house and laundry run alongside of the Celery trenches cause less stench than results from overflows in ditches, besides causing the Celery to shoot ahead. Another thing in making Celery trenches is digging-out the good soil—a capital thing, no doubt, to grow Lettuces on the ridges—leaving very little beyond the manure and the stubborn unameliorated soil for the Celery to grow in. Surely Celery likes good soil. There is no need to plant on the flat, but a moderate excavation, or if one is made enough good soil as well as manurial matter should be placed in the trenches to insure a full growth. The better plan would be to have the ground trenched; it sounds more like cultivating a ditch plant, and then the Celery would have a chance to root according to its own "sweet will." The best Celery I have seen and had was on deeply cultivated ground. It cannot be practised on all soils, as some are a mass of stubborn material beyond a few inches of ameliorated surface. In such it is a good plan to prepare the trenches some time before they are wanted, not less than 2 feet wide, removing some of the bad material and loosening that at the bottom. I prefer the waste of the potting bench, vegetable refuse, including weeds not of a rooted character, such as Couch, Bindweed, Plantain, Dandelion, &c., which have been sprinkled with a little salt, and charred or burnt clippings and prunings of hedges and trees and shrubs, altogether—the rooted weeds even burned on the fire of trimmings, &c.—incorporated and put in the trenches 4 to 6 inches thick, mixed with that depth of the soil. Then a similar thickness of fresh short manure is given, leaf soil, and good surface soil well mixed. Nothing further is needed but to wait for planting time, forking over the trenches every fortnight. Make the trenches as soon as time and ground admit after the seed is sown for the respective crops. There is another point—viz., I have dug the trenches with wall-like sides, also with a good slope. There is no comparison of the two. The slope shoots the water of any passing shower into the trench, also the liquid given; the Celery grows with a much sturdier base, and it is bulk as measured by stoutness rather than weight, resulting of length that is wanted. The Celery is useless unless solid and crisp, with a sweet nutty flavour; to obtain it rich sweet and firm material is necessary, along with plenty of light, so that the growth may be sturdy from first to last. Of white, Sandringham is good alike as an early or late variety. I had last year for the first time Veitch's Early Rose. It is a very good sort, and not given to bolt. Those two I recommend as early. For main crop I do not think more is to be desired than is found in Wright's Giant White and Major Clarke's Red. Ivery's Nonsuch Pink and Sulham Prize Pink, the one large and the other medium size, are excellent. For late use I have found Standard Bearer (red) and Sandringham first-rate: indeed, if I was restricted to two varieties, those would be honoured for their good and reliable qualities.—UTILITARIAN.

RECLAIMING SANDBANKS.

MR. MUIR'S excellent article on the above recalls to my memory a practice which has been adopted for many years (about fifty) on the coast of Sussex. Stretching from three to four miles from Rye Harbour are extensive banks of the finest sand, which are securely held together and form miniature hills by a Rush-like Grass provincially called "Bind-wheat." On inquiry at my only visit a few years since I was informed

that it was originally brought from Holland, where it is largely used for fixing the sand, but that it was a native of Italy and introduced by a local farmer whose interest lay in the extensive sheep runs across the marshes from Rye and Camber to Lydd and Romney. Its generic name I was at that time unable to ascertain. Neither can I find now in the "Cottage Gardeners' Dictionary" the name given by Mr. Muir, so that I am unable to fix it as the same Rush-like Grass used by him. Whatever the plant may be that is so plentifully growing near Rye, it is of inestimable benefit in collecting and preventing acres of land being buried and rendered useless in stormy periods. Perhaps some of your numerous readers can throw more light on the subject.—J. W. MOORMAN.

EVENTS OF THE WEEK.—The Royal Society has a meeting at 4.30 P.M. on Thursday, the 8th inst., the Quekett Microscopical Club at 8 P.M. on Friday, the 9th, and the Royal Botanic Society on Saturday, the 10th inst., at 3.45 P.M. The Fruit and Floral Committees of the Royal Horticultural Society will meet on Tuesday, March 13th, in the Conservatory at South Kensington.

— **ROYAL HORTICULTURAL SOCIETY.**—A meeting of the Council was held on Tuesday, the 28th ult., at which power was given to the President, Sir Trevor Lawrence, Bart., M.P., to sign the agreement for the occupation of the Society's new premises, at 111, Victoria Street, S.W., for offices, &c.; and the Drill Hall of the London Scottish R.V., in James Street, Westminster, for exhibitions and shows; the Society to enter into possession on March 25th. Both premises are conveniently situated midway between Victoria and St. James's Park Stations on the Underground Railway. The Council also drew up and adopted a scheme for the admission of Fellows paying £1 ls. subscription, and determined to admit as Associates *bonâ fide* gardeners or employés at any nursery, market garden, or seed establishment, at a subscription of 10s. 6d. a year. The following Committees were appointed:—*Finance*: Baron Schröder, Messrs. T. B. Haywood, E. G. Loder, H. J. Veitch, with the President, Secretary (Rev. W. Wilks), and Treasurer (Mr. D. Morris). *Chiswick Gardens*: Colonel Beddome, Dr. Hogg, Mr. George Paul, Mr. Woodbridge, with the President, Secretary, and Treasurer. *For Revising the Bye Laws*: Messrs. T. B. Haywood, A. H. Smee, G. F. Wilson, with the President, Secretary, and Treasurer, coupled with a request that Messrs. Deal, Pearson, and Marshall, members of the Fellows' Committee, would be kind enough to confer with them. The Trustees of the Lindley Library had an interview with the Council, and it was determined to remove their library to the Society's new rooms, at 111, Victoria Street, Westminster.

— THE above ought to have appeared in our last week's issue, but was not received till after we had gone to press.

— A MEETING of the Council was held at South Kensington on Tuesday, March 6th, when the agreement as to the lease of the premises, 111, Victoria Street, Westminster, was finally settled, and a Sub-Committee was requested to see the details of furnishing, &c., promptly carried out, as the Exhibition on March 13th will be the last held at South Kensington. Reports were received and adopted from the Finance and the Chiswick Committees, whereby it is hoped that both increased economy and increased efficiency may be introduced into the Society's work. It was resolved to ask the advice of the Fellows' Committee on the following subjects—viz., 1, The appointments of Local Secretaries; 2, The best mode of affiliation between local Societies and the Royal Horticultural Society; 3, The advisability of petitioning the Government to include horticulture with agriculture under the new Government Board. The next meeting of the Council was fixed for March 13th.

— **THE WEATHER.**—Writing from Brading, Isle of Wight, Mr. C. Orchard says—"What bitter weather we have been having! Here in this favoured place the winds and frosts combined are playing sad havoc with the Myrtles, Euonymus, Laurustinus, &c., that grow to a large size, and which are only injured in exceptional seasons. The condition of the spring flowers and shrubs, are in striking contrast to what

they were a month ago. This is the coldest February here since 1854, just thirty-four years ago, but no doubt it will make it all the better for the fruit and other crops in the end."

— "B. D.," writes from Scotland:—"The week ending 5th March has been similar to the preceding one, a cold N.E. wind prevailing throughout, except on two afternoons, when the wind changed to the W. for a few hours. The nights, with two exceptions, have been frosty, ranging from 2° to 9° on the night of the 1st inst., and 11° last night. The days have been sunny throughout. Farmers are getting far forward in the sowing of the Bean crop in Carse lands."

— IN the southern counties, but especially in the metropolitan district, a very agreeable change has been experienced within the past few days. The temperature has risen considerably, with bright sunny days, that are most welcome after the long continuance of severe weather.

— MR. R. GILBERT sends us from Burghley SAMPLES OF MUSHROOMS, such as he has been gathering from outdoor beds during the late unusually cold weather, also from an inside bed. The former were much the finer, and remarkable for their substance and freshness. One of these was 9 inches in diameter, upwards of an inch thick, and weighed $\frac{3}{4}$ lb., and when cooked was tender, juicy, and delicious. We award to the grower this, our vote of thanks and cultural commendation.

— CEMENT FOR A GARDEN VASE.—"A. P." would be glad to know if anyone can recommend him a strong cement suitable for mending a garden vase.

— GARDENING APPOINTMENTS.—Mr. Wm. Jordan, who for the past seven and half years has held the post of head gardener to J. H. Nix, Esq., Tilgate, Crawley, Sussex, has been appointed steward over the Tilgate estates, and Mr. D. Jones, his foreman, succeeds him as head gardener.

— AMARYLLISES—"W. J." writes:—"Can any of your readers say what is the largest number of flower spikes an Amaryllis bulb will produce? I have a variety named Amazon showing nine spikes, and many more with three spikes. The largest bulb is 15 inches in circumference. Is this unusual?"

— ROTHERHAM GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The usual monthly meeting of this Society was held in the Society's rooms, St. George's Hall, Rotherham, on Thursday evening, March 1st, Mr. W. Eskholme, Vice-President, occupied the chair, and about thirty members were present. A paper was read by Mr. W. K. Woodcock of Sheffield upon the history and cultivation of the Lapageria, after which many questions were asked upon cultural points by members, and replied to by the essayist. A vote of thanks to Mr. Woodcock was proposed by Mr. Butterill, seconded by Mr. Oswald, supported by Mr. Cooke, and carried unanimously. Several very pretty exhibits of miscellaneous cut flowers were upon the tables.

— THE second issue of Mr. Lewis Castle's "CHRYSANTHEMUM ANNUAL" is before us, and we suspect no long time will elapse before it is possessed by most growers of the autumn favourite to which its fifty-three pages are devoted. The work opens with a concise chapter on Chrysanthemum topics by the Editor, in which among other things he estimates the number of Chrysanthemum growers in this country as exceeding 100,000. Mr. J. Wright follows with an essay on showing and judging, but whether he attaches too much importance to his shillings and pence system of recording the merits of blooms is for others to determine. He shows that a stand of twenty-four blooms exhibited by Mr. E. Coombs was worth 96s. 3d., and its competitor, Mr. M. Sullivan, 96s. Mr. George Gordon discourses on challenge trophies, as he is entitled, having, as he points out, assisted in awarding more prizes to them than anyone else has, and £7000 in money (not all his own). Mr. C. Orchard contributes an excellent account of new Chrysanthemums of 1887; Mr. N. Davis gives a select list of exhibition Japanese varieties, indicating the heights of the plants and time for taking the buds of each, in columns—an innovation that many persons will be glad to see. Mr. E. Molyncux follows on "Taking the Buds," and does his best to make the subject plain. Mr. C. Gibson writes on "Preparing for Shows," and tells his readers that exhibitors do not like being bothered with visitors the day before the event. Then follows a history of the

National Chrysanthemum Society, and Mr. H. Cannell tells of the first Chrysanthemum Show and how he befriended the Japanese—good Mr. Cannell! Mr. W. Bardney writes on Chrysanthemums in the North, Mr. J. Udale on them in the Midlands, Mr. W. Iggulden noting them in the Western Counties, all acquitting themselves well, as might be expected. Four pages are devoted to prize blooms at some of the leading shows, and six to certificated varieties—the most complete list that has been compiled. The work is adorned by the portraits of those “good men and true,” Mr. Edward Sanderson and Mr. William Holmes, and its price is 1s., post free 1s. 2d., from this office.

— IT will be in the recollection of many readers that on the lamented death of MR. ALEXANDER HONEYMAN (“Single-handed”), an appeal was made on behalf of his widow and children. The contributors to the fund will be pleased to hear that the amount raised has been of substantial benefit, as will be seen from the following letter, received by Mr. J. Wright. Mrs. Honeyman, who was placed in a small stationery business at Grangemouth, writes:—“You will be glad to hear that we have succeeded beyond our expectations, as papers are always in demand. I can never forget that we owe it all to what was done for us through the Journal. All the children are well, and every one at school, the eldest in the sixth standard, the youngest in the first. I will not trespass longer, but again wish to thank all for their great kindness to us in the day of our extreme distress.”

— MR. JOSEPH MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, for February, 1888:—Mean temperature of month, 35·8°. Maximum on the 8th, 52·3; minimum on 26th, 19·5°. Maximum in the sun on the 23rd, 111·3°; minimum on the grass on 26th, 2·9°. Mean temperature of the air at 9 A.M., 35·2. Mean temperature of soil 1 foot deep, 36·3. Nights below 32°, in shade twenty, on grass twenty-four. Total duration of sunshine in month, sixty-one hours, or 22 per cent. of possible duration. We had nine sunless days. Total rainfall, 1·29 inch. Maximum fall in twenty-four hours on the 14th, 0·40 inch. Rain fell on fifteen days. Approximate averages for February:—Mean temperature, 40·2°. Rainfall, 1·63 inch. Sunshine (seven years) fifty-eight hours. Colder than any of the previous twelve years except 1886. Nearly all the downfall came as snow, which attained a depth of about 4 inches in the open, but drifted in places. It wasted a good deal in the dry winds. The proportion of winds between N.W. and N.E. is very large.

SUB-TROPICAL PLANTS AND THEIR USES.

WHERE opportunities exist for the favourable cultivation of sub-tropical plants during the summer and autumn a most agreeable aspect is imparted to gardens. A position well sheltered from south-westerly winds should be chosen, as much disfigurement may be caused to the leaves of many plants by strong gales of wind during the early part of September, and just at a time when the plants are expected to be in full beauty. If possible, the position should also be secure from north-east winds in the spring when the plants are first placed in the beds, as a serious check is sometimes given from which they take a long time to recover. A position sheltered from these winds, yet open to the south to receive the sun freely, is best suited to the requirements of sub-tropical plants. A few notes on the best varieties, method of growth, and a few styles of arrangements may be of service to intending planters, although the latter is a matter to be decided according to local circumstances and individual taste.

ACACIA LOPHANTHA.—This plant, distinguished by its elegant leaves, grows in one season from 2 to 3 feet high with one straight stem and numerous side branches. Towards the end of the present month sow the seeds singly in small pots of sandy peat soil, plunge the pots in a gentle bottom heat until the seedlings appear above the soil, then transfer them into larger pots. Grow the plants close to the glass and gradually harden them before planting out. As “dot” plants in carpet bedding this *Acacia* answers well, or planted in a mass in a bed, carpeting the soil beneath them with *Perilla nankinensis* in a small state, which must be kept pinched and dwarf. They may also be used with good effect in mixed beds of various sub-tropical plants, as the plants can be kept in shape if necessary by pinching out the points of the shoots.

ABUTILON THOMPSONIANUM VARIEGATUM.—When grown with a single straight stem this is a capital “dot” plant. It is also good in a mass at such a distance apart that the leaves nearly touch. A carpet of *Agatheæ cœlestis* (Blue Marguerite) beneath makes a

suitable groundwork. When good soil is used the plants make vigorous growth, and the golden marble-like markings of the leaves come out boldly. Short cuttings inserted several in a pot during September in a gentle bottom heat make good plants if potted separately during February and grown in a cool house. Tops from stock plants may be inserted at the present time and quickly root. In any form the plants should not have the points of the shoots taken out, but be grown with one single straight stem. All lateral growths must be removed during the summer or pinched to one eye as best suits the position the plants occupy.

CANNAS.—These are well adapted for the sub-tropical garden. They vary so much, both in height and colour, that they may be used in many positions with good effect. There are many varieties, some having dark coppery leaves, while others are green, and many also bear handsome flowers. To obtain a good effect they are best planted in a mass. Their preparation in the spring is simple. The roots may be wintered in the Mushroom house or cellar, keeping them moderately dry, and about the middle of March divide the roots if large. Place them in boxes or in pots, using any moderately good soil, arranging the roots in a cool house where growth will be steady, and not in any way drawn up weakly. From the boxes the plants are easily transferred to the beds without a check. While in pots the roots are liable to become matted around the sides. *C. zebрина*, *Annei aurantiaca*, *Warscewiczii*, and *gigantea major* are good varieties.

CENTAUREA GYMNOCARPA.—The narrow silvery foliage of this *Centaurea* well suits for planting beneath the dark-leaved Castor Oil plants, or as edgings to beds with similar coloured leaves. The easiest way to secure a stock of plants is by sowing the seed in a gentle hotbed at the end of the present month or early in the next. Pot the plants as soon as ready, growing them on in a temperature of not less than 60° as near the glass as possible to prevent their drawing up weakly, hardening them off thoroughly previous to planting out.

CHAMÆPEUCE DIACANTHA AND CASABONÆ (Fish-bone Thistles).—The former has white foliage with long spines, the latter green foliage, shorter, and small brown spines. For “dot” plants either is adapted when arranged with suitable colours—as, for instance, the white variety planted amongst *Herniaria* or red *Alternantheras*, and the green sort with any white or yellow bedder of dwarf habit. Either makes a good edging to many kinds of foliage beds. Sufficient space should be allowed between the plants to allow a proper development of the leaves. Planted alternately both varieties have a good effect. By treating them in the same way as advised for the *Centaurea* capital plants are easily obtained.

GREVILLEA ROBUSTA.—An excellent plant, having Fern-like foliage, capitally suited for the flower garden, either as a “dot” plant or associating with others. Perhaps the former manner of planting this *Grevillea* is most suitable to its evenly balanced foliage when employed for bedding purposes. Seedling plants at the end of the first year will be from 1 to 2 feet high, and may be lifted from the beds early in October. Potted and wintered in a cool house without the loss of their leaves such plants are useful for other purposes in the next season. The seeds should be sown early in the year in a brisk bottom heat, as they take a long time to germinate. Pot the plants as soon as they are large enough, adding some peat to sandy soil, and grow them in a Melon house or vinery where a brisk heat is maintained until they reach a good size, afterwards harden them gradually.

HUMEA ELEGANS.—Where these succeed they are generally much appreciated; their long drooping spikes of graceful flowers, plume-like, are handsome. Planted singly they are the most attractive. In many places directly the plants are placed in the beds they die in a most unaccountable manner, which is very disappointing. Sow the seed in sandy soil in a cold frame in June, shading from bright sun, potting them as required until 7-inch or even larger pots are used. A position in the cool greenhouse during the winter suits them best.

PERILLA NANKINENSIS.—This and other varieties are useful where a little dark bronze colour is required. The plants can be kept dwarf, or they can be had 2 feet high, and for planting in mixed beds very useful. It is not wise to grow the plants too large before planting, as the bottom leaves are liable to fall if a check is given them either by cold or dryness at the roots. The middle of March will be early enough to sow the seed, placing the pots in a moist warm atmosphere, pricking the seedlings into boxes as soon as large enough; by this means a sturdy dwarf habit is maintained.

RICINUS AFRICANUS AND GIBSONI.—Two of the best Castor Oil plants; the latter, with dark foliage, usually grows from 3 to 6 feet high, according to the treatment it receives. It is the most commonly used, adapting itself to a variety of purposes, such as singly or mixing with other foliage or flowering subjects, such as dotting here

and there among scarlet Pelargoniums. The green variety is much more robust. I have seen plants grow 8 feet high in one season, which had a noble effect, the immense green leaves and red stems contrasting well with the surroundings. Early in March sow the seeds singly in small pots, as from these the plants are more easily transferred to larger ones without check than when several are in a pot.

CANNABIS GIGANTEA.—The Giant Hemp is not often seen except in favourable positions, such as near water in low situations, where it grows to a height of 12 feet in a season. The leaves are deeply serrated and of a pleasing green tint. The plants should only be small when planted out, as they run up quickly, and if very tall growth is not wished, early in April is soon enough to sow the seed.

SOLANUMS MARGINATUM, ROBUSTUM, AND PYRACANTHUM.—Useful plants for the sub-tropical garden. The former grows vigorously, but may be kept to a height of 2 to 3 feet by pinching the points of each shoot. A row next to *Ricinus Gibsoni* has a good effect. *S. robustum* has much larger green leaves and requires more space, but is effective. The last named makes an excellent "dot" plant surrounded by low-growing plants. Its narrow drooping leaves, with long brown spines, are very graceful in appearance. Sow the seeds early in March in a brisk bottom heat.

WIGANDIAS.—These possess noble foliage, and where space can be given them a fine effect may be had. Sow seed at once, in a similar manner to that required by the *Solanums*.

CASUARINA SUMATRANA.—A plant with drooping feathery foliage, useful for the summer garden either in small or tall plants. Planted singly it shows to advantage. A stock of plants may be raised by means of seed sown in February or by cuttings inserted in April in a cool house.

DRACENA INDIVISA.—Either in a small or large state this is most useful for the summer garden. Planted singly in a carpet of red *Alternanthera*, *Antennaria*, or any other low-growing plant, it is very elegant.

EULALIA JAPONICA VARIEGATA.—One of the best "dot" plants we have. A stock is easily obtained by dividing an old stool in the spring, starting them in a gentle heat, after which a cool temperature suits them best.

FICUS ELASTICA.—This should be planted in a mass to be effective. If a purple or blue *Viola* be used to carpet the bed between the plants a good effect is obtained. Where an old stock plant exists, cuttings from 6 inches to 1 foot in length strike readily if placed singly in pots filled with sandy soil and plunged in a brisk bottom heat. A stake should be placed to each cutting to prevent their becoming loose in the soil occasioned by their weight.

FERRULA COMMUNIS.—With its flat Fennel-like leaves this is very effective when the plants are of medium size, especially near the margin of a bed or on the edge of a pond. Seeds sown early in March in a gentle hotbed quickly yield plants that soon reach a suitable size for planting.

MELIANTHUS MAJOR.—Notable for its glaucous green foliage, planted singly and restricted to a single stem is a very showy plant, but is not often seen. Seed can be sown in the spring, or suckers can be taken from the base of an old plant with roots attached, and these quickly grow into a useful size.

PHORMIUM TENAX VARIEGATUM AND P. COLENSOL.—The *Phormiums* are perfectly hardy in the south of England, are easily increased by division of the roots, and are well adapted for planting in a mixed bed as they are to stand, singly either on the grass, or in the centre of a bed containing low-growing plants.

AGAVE AMERICANA VARIEGATA.—This is often used in the summer for the sub-tropical garden, carpet beds, or the rock garden. Anywhere placed singly it is effective. Offsets which spring from the base of plants quickly grow into a serviceable size. If the pots are simply plunged during the summer where needed they are much more easily housed in the autumn in a cool greenhouse.

ZEA JAPONICA VARIEGATA.—Much valued for its silvery-like foliage, which is heavily striped with green. Seeds sown singly in small pots in a gentle heat about the middle of March quickly germinate, and the plants grow to a good size if transferred to larger pots, using rather poor soil.

EUCALYPTUS GLOBULUS is much liked by some persons for the fragrance of its leaves and for its blue colour. Seeds sown now in a brisk bottom heat soon yield useful plants if not allowed to become drawn weakly by overcrowding. In a mass by itself or mixed with other plants, allowing room for a free development of its branches, it is a capital plant for sub-tropical gardens.

FUNKIA SIEBOLDI makes a capital edging to other taller-growing plants of a dark or deep green colour. It is perfectly hardy anywhere. Division of the roots is a ready way to increase the stock.—E. MOLYNEUX.

ROSE SHOWS IN 1883.

June	30th.	—Eltham and Reigate.
July	3rd.	—Bagshot, Canterbury, Diss, and Hereford.
"	4th.	—Croydon.
"	5th.	—Bath, Farningham, Hitchin, and Norwich.
"	6th.	—Sutton.
"	7th.	—Crystal Palace (National Rose Society).
"	10th.	—Ipswich.
"	11th.	—Tunbridge Wells.
"	12th.	—Winchester.
"	17th.	—Leek and Ulverstone.
"	18th.	—Birkenhead.
"	19th.	—Helensburgh.
"	20th.	—Darlington (National Rose Society).

The above list contains all the Rose Show fixtures that have as yet reached me. In future lists I shall be pleased to insert the dates of any other Rose Shows that I may receive, also those of any Horticultural Exhibitions where Roses are made a special feature of the Show.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

WE are informed that the Committee of the Broekham Rose Association have accepted provisionally an invitation from Mrs. Gough Nichols to hold their Show for the fourth time at Holmwood Park near Dorking, on Thursday, June 28th, 1883.

MDLLE. FRANCISCA KRUGER.

A COLOURED plate of this Tea appears in the February number of the *Journal des Roses*, with some remarks by M. Pierre Du Plouy. Although not altogether a new Rose, it is not the less sought after, he says, by rosarians. Its vigour, colouring, and agreeable perfume render this beautiful variety much appreciated in the neighbourhood of Paris, as well as in the countries of the north. Sown in 1873 in a mixed lot of seeds, it was sent out by the raiser, M. P. Nahonnand, in 1879. It forms a vigorous bush, with handsome green foliage, and possesses a very strong constitution. The flowers are large, very full, well formed, of a pretty flesh-white, coppery, shaded yellow and rose. Grown out of doors for cut flowers it is not perhaps a Rose of the first order of merit, but excellent results are secured by placing it under a frame or in a greenhouse. He particularly recommends it as a garden Rose for growing on walls and columns, where it blooms abundantly.

THE DESCRIPTION AND CLASSIFICATION OF ROSES.

THE *Maison de Campagne* publishes the following letter from a correspondent on the classification of Roses:—"Although it may be difficult to restrain the liberty of the raisers of Roses, it would be possible to diminish the number of so-called 'novelties.' It would also be practicable to simplify the catalogues where the same variety figures under different names—where the same Rose is described amongst the Teas, then amongst the Noisettes, &c. It is very desirable that a less fanciful classification should be adopted than exists at present. Another step that might be taken with advantage would be to regulate the designations and choice of terms for describing the different varieties in order to give an approximate idea of them. At present it is very difficult to recognise them, even the colours being badly defined and applied. A flower may be described in a catalogue as salmon rose, when in reality it approaches more nearly to earmine. Purple, again, is often given in place of crimson, while some varieties of various shades are described in a manner quite opposed to the reality. What is wanted is a defined gradation of colours and tints. The taste for Roses is so widespread at the present time that it would not be idle to attempt to devise some means for the better classification of Roses, and, judging by myself, amateurs will readily combine with the specialist to this end."

A STRIPED NIPHETOS.

A STRIPED *Niphetos* is announced from America by Mr. Wilson says a French journal. The stripes are described as green and white, and much prettier than those of the "American Banner."

MARÉCHAL NIEL ROSE.

"N." page 107, may be congratulated on having his instructions on the non-ventilation of forced *Maréchal Niel* Roses fully endorsed by such an experienced rosarian as Mr. D. Gilmour, jun., page 173, but I am inclined to the belief that there is something more to contend with than sudden bursts of sunshine before the end of March. Keeping the ventilators closed until April may be the best method to adopt and prevent mildew, but I doubt it. I did not bring the case forward of the plant in Mr. J. C. Reid's gardens as a proof that "N.'s" instructions were wrong, but to show that *Maréchal Niel* Roses could be successfully grown without "N.'s" restrictions as regards ventilation, and for the purpose of eliciting information from those more experienced in the cultivation and management of *Maréchal Niel* Roses than myself.—L. T.

THERE is much difference between a Rose that is forced into bloom

and one that is allowed to come forward naturally in a cool house. The foliage of those that are developed under warm genial conditions is naturally tender, and consequently easily checked by the admission of cold air. The young foliage of plants that develop under cool airy conditions may to all appearance be equally tender and delicate, but such is not the case, for they withstand the cold air around them without experiencing a check. Early in the season, say during the months of February, March, and I might say the greater part of April, if not the whole of that month in the majority of seasons, it is impossible to admit air in a sufficiently warmed condition to be advantageous to forced Roses. The sun may at times appear warm and raise the temperature of the house considerably while the air is piercingly cold—too cold, in fact, for the rosarian to admit it to his plants if he is anxious not to subject them to an attack of mildew. Nothing will cause mildew sooner than the admission of cold air, and it is often impossible to protect the young foliage from draughts even with closed ventilators. If "L. T." had been engaged in the production of Roses on a large scale early in the year, and had to remove his plants after placing them in 5-inch pots to make room for others coming on into rather draughty pits, he would find that matting up the frames, not only at night, but during the day in cold weather, was a necessity if he wished to keep the plants free from mildew.

I have condemned in these pages the admission of air to Roses early in the season, and have done so from practical experience. The temperature recommended was intended to be from fire heat, and during cold, severe weather I prefer to see the house 50°, rather 55°. On mild occasions gentle heat is kept in the pipes, whatever the temperature be. By day, when the weather is mild and the season has advanced fairly, no fire heat is used; in cold weather the highest figures given are not exceeded.

"L. T." asks what position would I recommend for a forcing house for *Maréchal Niel*. That entirely depends whether the structure is a lean-to or a span-roof; if the former, a southern aspect; if the latter, the ends running north and south. The admission of air freely to the tree in Mr. Reid's garden does not insure it against mildew, or why are we ever troubled with it on the plants outside? Under cool treatment *Maréchal Niel*, if healthy and in luxuriant condition, is not much subject to mildew. Under the same conditions the old *Gloire de Dijon* and many others are more liable to be attacked, while when forced the *Maréchal* is one of the very first to fall a prey to its ravages. From "W. W.'s *East Yorks*," letter it is clear that his plant under the ventilating system is not proof against mildew. But neither his plant or the example produced by "L. T." can be said to be forced; by the treatment the plants receive they come forward naturally. I was pleased to see that such an able rosarian as Mr. D. Gilmour, jun., endorses my instructions, and I can freely confirm the advice he tenders to Mr. Reid's gardener, for my plants have suffered from the cause he advises him to guard against. If this variety carried less flowers, especially in its early stages, I believe that it would be constitutionally stronger, and last in health for a much longer period.—N.

"W. W., *East Yorks*" (page 173), in his article on *Maréchal Niel*, says:—"If that dreaded pest mildew does appear, I find no difficulty in keeping it in check by using the mixture so often described in the *Journal*—viz., softsoap, sulphur, and petroleum." I should feel very much obliged to "W. W." if he would kindly give the proportions of each to the gallon of water.—A. B., *Ayrshire*.

ROSE CUTTINGS.

ANY that have been inserted in the open ground after the style of Gooseberry and Currant cuttings must be examined directly the frost has disappeared. The majority of them will be found upheaved 2 inches or more out of the ground, and unless they are pressed back into the bottoms of the holes originally formed and the soil made firm about them very few indeed will strike root. A mulching of either strawy manure, ashes, or leaf soil to a certain extent prevents this upheaval by frosts, but even where they are thus treated it is advisable to look them over and fix any that require it. Properly attended, 90 per cent. should strike root and make good plants this season. It is too late to insert more cuttings in the open ground; but if a number of strong cleanly cut pieces of ripened wood about 12 inches in length, with or without heels, have the lower half of the buds removed and are at once firmly dibbled into a border at the foot of a north wall, many will strike root. In this instance it is advisable to mix plenty of leaf soil and grit with the ordinary soil, the cuttings being buried in this to about one-half of their depth. Rub out the first buds that break, the object being to retard top growth till the cuttings are calloused. If the former takes place first the cuttings will fail to strike.

STRIKING CUTTINGS OF TEA ROSES

When strong well-ripened growths of these can be obtained it is possible to root them in the open ground, or similarly to the Hybrid Perpetuals. Those having a number of plants growing against sheltered walls may adopt an equally sure method of striking cuttings. Select short medium-sized shoots, taking these off with a heel or a thin portion of old wood attached, and shorten the tops to about three good joints, leaving the leaves on these. Dibble each singly in the centre of a 3-inch pot filled with loamy soil and surfaced over with sharp sand, taking care to fix the cutting firmly. Water them in, plunge closely in a gentle hotbed, and cover closely with handlights or bottomless boxes covered

with large squares of glass. If kept perfectly close and shaded from bright sunshine they will strike root in about three weeks. When well rooted gradually expose to full light. They ought not to be long kept in these small pots, nor be prematurely hardened. First shift them into 6-inch pots, and when growing strongly they may either be hardened off and planted out, or be transferred into larger pots for flowering under glass.

PLANTING ROSES.

Directly the ground is again in a fit state for planting, any Roses laid in by the heels should be planted out. Others may be transplanted, but in every case extra pains ought to be taken, or failure will most probably be the result. The soil should be made as congenial as possible to the roots, this to induce an early formation of fibre. In addition to digging in plenty of manure deeply, add a liberal dressing of either leaf soil, old Mushroom-bed manure, burnt garden refuse, or any material that when well mixed with the surface soil will keep it in an open condition. Little or no fibre will be formed in heavy lumpy soil, and this is also the first to feel the effects of drought. Tea Roses being usually supplied well-rooted in pots may be planted out a little later, or after there is less likelihood of severe frost being experienced.

PRUNING CLIMBING ROSES.

Tea and Noisette Roses growing against sunny walls are the first to flower, and what pruning needed ought to be completed at once. Healthy vigorous plants to have the wood lightly thinned out, the leading branches shortened to about half their length and laid in, all lateral growth and spray being freely cut back. Plants that are weakly will be improved if cut rather hard back, as the stronger the growth the more flowers the Teas produce. *Maréchal Niel* flowers principally on strong well-ripened young growths, every joint producing a bloom. Preserve these, therefore, to nearly their full length, and cut out as much old growth as possible, this inducing the formation of more strong growths for next season. Hybrid Teas including the serviceable Cheshunt Hybrid also to be well-cut back, leading growths being shortened and laid in where space has to be filled. Banksian Roses produce trusses of flower from both spray and medium-sized well-ripened growths. Thinning out and shortening back is necessary, very rank growths being cleanly removed unless wanted for filling vacant spaces.—W. I.

ROBY HALL, LIVERPOOL.

THE old established seat of Wm. Pilkington, Esq., J.P., D.L., surrounded by villas and small mansions of modern style, "which add grandeur by contrast to the more venerable mansion," is also a home for horticulture in its many branches, and a place where gardening in its less popular days was carried to a successful issue, and held up as an example to the Liverpudlians, which by the way they were not slow to follow, for in no part of the kingdom do we find a higher or more general taste for gardening than in the neighbourhood of Liverpool. Orchids, foliage and flowering plants, Chrysanthemums, herbaceous plants, as well as fruit, all have their champions here, as testified at our leading exhibitions.

The flower garden in former seasons has been devoted to the usual bedding out, but the beds are now undergoing the process of remaking and remodelling for the reception of herbaceous plants, and with a judicious selection of these, such as Mr. Jones can well be trusted to make, we prophesy a great transformation such as will fully compensate for the labour. A centre bed has been prepared as a loose rockery for some of the smaller but not less deserving plants, and cannot fail to be highly pleasing when established.

The conservatory is attached to the mansion and is always gay with bloom. During our last visit just before Christmas the house was full of Chrysanthemums. "What fine blooms!" was our exclamation on entering, "and so late in the season too!" They were really fit for exhibition, especially the incurved varieties. The problem seems to be how to produce good bloom late in the season, for Christmas and towards spring. Here in some Peach houses was a large quantity of well-budded plants calculated to maintain a supply into the new year. Stove plants, such as Crotons, Dracenas, &c., are grown for house decoration only. They are clean, healthy, well-furnished plants for this purpose, pictures of robust health; and Gardenias planted out at the back of one of the stoves are well calculated to afford a capital return of bloom. Orchids are sparingly represented. *Dendrobium nobile*, however, is here in quantity, well cared for, and evidently prepared to compensate for its liberal treatment by abundance of bloom when needed. Greenhouse plants for cut bloom and decorative purposes consist of Primulas, Cinerarias, &c. Specially useful, however, are the several varieties of Ivy-leaved Pelargoniums, of which quantities are grown, and *Primula Sieboldi*. One of the features at Roby Hall is the Fern *Lygodium scandens*, thriving like a weed; and hardily grown as we find it in the vineries on back walls, it is most valuable for table decoration, for trailing on mantel-boards and mirrors. Being free from the brown semi-decayed appearance it frequently has when grown in too much heat, and so unique in habit and also standing well in a cut state, it is certainly worthy of the space afforded it.

The fruit houses we find as well cared for as other departments. Cleanliness is the order of the day. The Vines are heavily cropped annually, so that we do not find Grapes up to exhibition style, though quite in form for table. Alnwick Seedling finds favour, and deservedly so, the wonder being that so few grow what is one of the most desirable

Grapes in cultivation. In long ranges of well furnished Peach houses large crops are annually produced, and the appearance for the coming season is all that can be desired. In some frames we find a capital stock of Vicomtesse Herieart de Thury Strawberries for forcing. This variety seems to be the popular favourite for forcing everywhere, its constitution, as well as its productiveness and flavour, rendering it most valuable. The forcing house was well filled with Azaleas and bulbs to meet the large demand for cut flowers, and the Cucumber house was not allowed to rest after its summer work. A brace of Cucumbers cut from here, and awarded a certificate by the Liverpool Horticultural Association, were models. A constant supply of Mushrooms is maintained in a house devoted to their culture, the supply bed at the time of our visit being literally covered. The good results obtained in all departments bear testimony to the general knowledge and skill of Mr. Jones, who very generously attributes much of his success to his foreman, now awaiting an appointment as head gardener.—S.

LACHENALIAS.

THESE beautiful greenhouse bulbous plants are not grown so much as they deserve to be. They cannot be too strongly recommended for winter and early spring flowering in pots or baskets. They are easy of culture, and will grow in almost any position, flowering at a time when flowers of their colour are scarce in the conservatory. To those who have a desire to try them, and are not acquainted with their culture, a few simple hints may be useful. Procure the bulbs not later than the middle of September, placing six to eight in 5-inch pots in a compost of half loam, the remaining half equal parts of leaf soil and well decomposed cow manure, with a dash of sand. These pots may be placed in a cold frame till the bulbs start growing, then transfer them to a greenhouse, or any other place where frost is excluded. These plants then require very little attention until the flower spikes appear, as insects scarcely ever attack them. About Christmas, or when the flowers are growing freely, a little weak liquid manure once a week will benefit them. If wanted early they can then be placed in a temperature of 50°, when they will be in flower in about six weeks. They continue attractive for six to eight weeks, and their beautiful erect yellow spikes have a charming effect when arranged with other flowers. They increase freely, each bulb producing four to six others, which flower the following year. The two best varieties I am acquainted with are Nelsoni and pendula.—T. H.

ORCHIDS AT MOUNT VIEW, SHEFFIELD.

THE proprietor of the above-named place, D. Ward, Esq., has long been well known locally as an ardent lover and supporter of horticulture in general, and of late years his attention appears to have been more especially devoted to Orchids, of which he has from time to time made extensive purchases, so that now he is the possessor of a very extensive and valuable collection of plants, which appear to be in the most robust health and vigour, reflecting high credit upon the head gardener, Mr. Page. In a rapid run through the numerous houses a few days since some notes were taken, which are appended.

A house is specially devoted to Phalænopses, and nearly all the known varieties are represented. Especially noticeable was a remarkably fine variety of *P. amabilis* with flowers fully 4 inches in diameter. The flowers of many have suffered much from recent dense fogs, which have caused the buds to fall unexpanded. Most of the larger plants are grown on teak wood cylinders 9 to 12 inches in diameter and 18 inches deep. These cylinders were recommended in the Journal a few weeks since for Phalænopsis culture, and are evidently well adapted for the purpose, the large stout roots running freely over the whole outside surface. The leaves also produced last season were very large. Growing in the Phalænopsis house are about thirty plants of *Odontoglossum Roezli*, which are very vigorous, and appear quite at home; also twelve plants of *Cypripedium Lawrencianum*, one in a large pan 3 feet across, and all with very large and highly coloured foliage.

In the *Cattleya* house large specimens of *C. Trianae* are flowering freely. Several plants of *C. Percivaliana* were also flowering, with *C. amethystoglossa* and the pretty *Lælia acuminata* on a side stage filled with healthy plants of *C. Mossiæ*, *C. Mendelli*, *C. gigas*, and others. Over 260 flowers were counted. One plant of *C. Mossiæ* in an 8-inch pot has eleven strong sheaths. In the same house are strong plants of *Dendrobium Wardianum*, the growths of which

averaged 3 feet in length. *D. albo-sanguineum* was here seen with growths equalling in size good specimens of *D. nobile*. *D. luteolum* was in flower, and is very distinct and pretty, also *D. crassinode* very strong. *D. nobile* was represented by numerous large specimens, the growths averaging 2 feet long and very stout. Mr. Page, the gardener, is a believer in pruning, and certainly as practised at Mount View it appears to be a very commendable practice. He tells me he follows no hard-and-fast rule, but prunes according to the vigour of the plants. We noticed, however, that on few of the plants were any growths left, except those flowering and those made during the past season. *Cattleya citrina* is represented by large plants, which have all made vigorous growths and are showing flowers freely. *Lælia anceps* has been very fine, one specimen has carried twenty flower spikes. *Odontoglossum vexillarium* is represented by about fifty strong plants grown in a low span-roofed house with a collection of *Lycastes*, and in which a temperature of about 65° is maintained. In the *Odontoglossum* house some hundreds of fine healthy plants are to be seen of all the best varieties. Of *Odontoglossum crispum* there are some fine varieties; *O. Rossi majus* is flowering, also a large number of *Sophranitis grandiflora*. In the conservatory is a splendid display of *Cœlogyne cristata* and *Lemoniana*, a pan of the latter carrying thirty-five strong flower spikes.—W. K. W.

CALANTHES IN TANNERS' BARK.

Two years ago after potting what I required there were a few small pseudo-bulbs left, which I was about to throw away, when it so happened that at the time there was some bark from the Pine pit laying on the potting table, as it is used for mixing with composts here in place of leaf mould; and having noticed that various plants root readily into and grow vigorously after their contact with it, I thought I would put the few small ones into pots with nothing but the bark, just for an experiment. These were placed along with the others, received the same treatment as to heat and moisture, but the growths they made were so much superior to the others in comparison to the size of the pseudo-bulbs that I was astonished, and when they were shaken out of the old compost there was the same marked difference, for whilst all had made good roots those in the bark were masses of roots. I was so satisfied with the small experiment that I resolved (right or wrong) to grow them all in bark again last year. As the result all who saw them were astonished at their strength and vigour. The query was, What are they grown in? On being informed one or two of my neighbours who have no bark pits were so favourably impressed with the treatment that they asked me to let them have a little bark this spring to grow theirs in.

I have just been shaking the plants out again, and the pots were so full of roots that it was difficult to disentangle them—in fact impossible, without breaking some of them. The pseudo-bulbs of *Calanthe Veitchi* graduate in length up to 9½ inches full, with a girth of 6 inches. The flower spikes varied in length from 2 to nearly 4 feet. *Calanthe vestita* did equally well and made pseudo-bulbs much larger than I have had them before. It struck me whilst busy with them that as others would be preparing for potting for another season the result of this experiment might be interesting, and might bring out the experience of others. I have never seen nor heard of their being grown in bark before, and should be glad to hear if anyone else has. All our plants will be grown in it for the future.

I generally start them in boxes in moss placed upon the evaporating troughs in the stove, always keeping the moss moist, until they begin to show their leaves, when they are placed into 6 and 7-inch pots, three in a pot, well drained, and the material covered with moss to prevent the bark running into it. This size pot I find is better for them than larger ones. The pseudo-bulbs are placed firmly into the bark, and the bark well covered with sphagnum to keep it from being washed out when watering. Noticing the dark colour of the water which ran from the plants I thought it was a pity it should be wasted, besides staining the shelves, so I placed them in feeders, which seemed to suit them well, besides saving time in watering, as there was always a moisture about them. Beyond this I simply used the syringe freely in the growing season, and had them on a shelf as near the glass as possible with a slight shading.—J. SMITH, Leeds.

ORCHIDS AT LEEDS.

MR. WALTER CLIFFE'S Orchids at Western Flats, Wortley, Leeds, though not very numerous, are highly attractive, and remarkably well grown, and reflect the highest credit on the careful gardener, Mr. Hyam. Three small houses are devoted to their culture; No. 1, the *Odontoglossum* house, containing some 200 plants or more, principally *O. crispum* (*Alexandræ*), several of them in flower, others sending up strong spikes, amongst which

are some very good varieties, *O. Cervantesi*, *O. Rossi majus*, also in flower, *O. Roezli*, *O. Pescatorei*, *O. grande*, *O. citrosum*, *O. vexillarium*, &c. No. 2 contains a miscellaneous collection, including *Cœlogyne cristata* now in flower, one of them a splendid plant 3 feet in diameter, several good examples of *Dendrobium nobile*, *D. suavissimum*, *D. chrysotoxum*, *D. Parishii*, *D. Picardi*, and *D. Wardianum*. A fine plant of the latter, with growths 3 feet long, is suspended in a basket from the roof. Of *Cymbidium eburneum* good plants are sending up their flower spikes. *Cypripedium Stonei*, *C. Veitchii*, *Masdevallia towarensis*, *Oncidium*s, *Trichoplias*, &c., are all good. No. 3, the *Cattleya* house, was gay with some twenty good flowering plants of *C. Trianae*, amongst them being some remarkably good varieties with flowers measuring

one of the largest specimens. This is growing in a pot 17 inches in diameter, and has had 104 racemes of six to nine flowers each, or a total of about 800 flowers. Smaller plants in 24 and 32-size pots have fifty and thirty racemes each, the total number of racemes out at one time having been 700.

Mr. Walter King, the gardener, has obliged us with the following cultural hints, and his success renders his practice very interesting:—"As the following hints on the growing of *Cœlogyne*s are chiefly intended for amateurs and beginners, the instructions are as brief and simple as possible. Commencing with this lovely Orchid in the flowering stage of treatment, I would advise in the first place not to cut the old flowering spikes too close to the pseudo-bulbs, say about 1 inch, as it will be observed the new breaks come freely from

FIG. 25.—MR. PHILLIP CROWLEY'S SPECIMEN *CŒLOGYNE CRISTATA*.

7 inches across. A good specimen of *C. crispa*, this plant last year produced sixty-four blooms. *C. Mossiae*, *C. Mendelli*, *C. Dowiana*, *C. Percivaliana*, *Lælia purpurata*, *L. albida*, *L. anceps*, *L. majalis*, and others too numerous to mention in this brief note are well grown.

I cannot allow this opportunity to pass without expressing the pleasure it gives me to record the progress that has been made in this locality in the cultivation of Orchids, thanks to Mr. Lewis Castle for his exertions in the publication of a sound practical work on the subject at a price that brings it within the reach of all.—L. T.

CŒLOGYNE CRISTATA.

REFERENCE was recently made to the display of Orchids in Mr. Phillip Crowley's collection at Waddon House, Croydon, and we are now able to give an illustration, prepared from a photograph, of

the base of the old racemes. When the flowering season is over we give our plants about six weeks' rest, keeping them somewhat dry, and it does not injure them to shrivel slightly. This treatment will cause them to break freely, and more water may then be given. When the pseudo-bulbs are swelling and in active growth, I find the plants like some stimulant, and what we use here is liquid from the cow house, but it requires care. One quart of liquid mixed with two and a half gallons of water is ample and safe once a week. This applies to established plants, newly potted plants would require only clear water for the first season. We grow our plants in the *Cattleya* house in a group, as this enables us to syringe between the pots and lightly over the foliage. We ventilate freely, guarding against cold winds, and closing the house in the afternoon according to the weather, leaving a little ventilation all night. This will greatly assist in maturing the pseudo-bulbs, which is one secret of

success. When the pseudo-bulbs have finished growth give only sufficient water to keep them plump until the flower spikes show, then gradually increase the water supply, taking care not to pour it on the flower spikes, as it will cause them to go black and decay. We keep our *Cœlogynes* in the *Cattleya* house all the year round. The compost is two parts of good fibrous peat, one of charcoal, and one of sphagnum well mixed together, with plenty of drainage."

ORCHIDS AT BLENHEIM.

THE extensive glass department at Blenheim continues to increase, and notwithstanding the amount of room afforded by a score or more large Orchid houses, the plants are arranged closely together; indeed, many of the pans and baskets hanging from the various roofs are actually touching each other. One great advantage derived from having houses with different aspects and temperatures is that plants which do not succeed in one may be shifted about until the best one is found. If I remember rightly the Mexican house has been turned into the *Vanda* or East Indian house, and the *Odontoglossums* of the *crispum* section have been transferred from a large and lofty house about 70 feet long to a new one 116 feet in length with a much lower roof, with the result that the growths are much stronger, and the condition of the plants would satisfy the most sanguine. Their old abode is now occupied with *Cattleyas* and *Lælias*, and the great amount of air and direct light which was not the best for *Odontoglossums* are very beneficial to the newer occupants. *Cattleya Wageneri* is here in fine condition, one large plant in a basket has nine good sheaths. On one of the side stages are 500 *C. Bowringiana*, many flowering freely. Like most other species they vary considerably in size and depth of colour in bloom, but the best are very beautiful. It is a useful winter blooming *Cattleya*, bearing some resemblance to the well-known *C. Skinneri* in the flowers, which are borne on erect spikes averaging five or six on each, being about 2½ inches in diameter, and of a rich rosy purple with deeper coloured veins; the anterior portion of the lip is deep purple, and has a transverse maroon band, below which is a white blotch. Also in bloom are some fine forms of *Lælia pumila præstans* in shallow pans, and *Lælia albidia*. On the other side stage are numerous plants of the lovely *C. Lawrenceana* and *C. Harrisoniana*, the latter in flower. Above the path are suspended plants of the quaint looking *Cœlogyne pandurata*. *Lælia cinnabarina* is grown in 6-inch to 9-inch teak baskets, and some of them are finishing as many as nine good strong growths each. The centre stage is filled with *Lælia purpurata*, *C. Mendeli*, having eight and nine flowering sheaths on each, *C. Eldorado* and *C. Gaskelliana*, while *C. amethystoglossa* and *C. Leopoldi* are remarkable for their fine growth in this house.

The large *Cattleya* house is worth going many miles to see; it is over 100 feet long by 20 feet wide, and although the end of December is about the worst time of year to find much in the way of bloom, yet the few that are in help to make the place attractive, and the hundreds of flower sheaths already formed promise a grand display by-and-by. One of the most noticeable perhaps is a specimen of *Lælia purpurata*, 6 feet across, and carrying twenty-two flower sheaths. Immense pieces of *Cattleya Skinneri*, *C. Mossiæ*, and *C. Mendeli* are showing well, and the first of *C. Trianae* is already in bloom, together with *C. maxima* and several of *C. Dormaniana*, and among others thriving admirably are *C. aurea*, *C. Sanderiana*, *C. Schilleriana*, *Oncidium sarcodes*, *Epidendrum Stamfordianum*, and numbers of large pans of the useful *Cœlogyne cristata*. An interesting feature here is the great rockwork opposite the folding doors at each end, and the natural way in which many Orchids are growing on them. Pockets or rather well-lined openings have been left and filled with drainage and compost to suit the individual requirements of each plant.

The *Pescatoreas* and *Warszewiczellas*, which are unmanageable in the majority of Orchid collections, are growing freely: the leaves are all free from spot, and produced abundantly together, and the roots are clinging to the rough stone surface, which they appear to like much better than a quantity of potting material. *Zygopetalums* are in a similar condition. *Z. Gautieri*, with fine spikes of bloom, *Sobralia macrantha*, and *S. virginalis*, with *Cymbidiums*, are also planted out and growing vigorously. Some of the *Cattleyas* and *Lælias* like the treatment, but in my opinion they should not be put out unless intended to remain, for after the roots are attached to the stone it would be difficult to transfer them into pots without breaking the best roots.

Two houses are devoted to *Cypripediums*, one having a wide centre stage containing other Orchids besides, including a quantity of *Vanda teres* planted out and rooting freely, splendid specimens of *Cymbidiums*, *C. eburneum*, *C. Lowii*, and *C. giganteum*, and *C. Mastersi* in bloom, but these are soon to be removed, and the end they occupy will be filled with choice *Phalænopsis* from a smaller house. The side stages are planted with *Cypripediums*, crocks being laid thickly on the bottom and the roots covered with a layer of growing sphagnum; they include plants of *C. Boxalli*, *C. caudatum*, *C. ciliolare*, *C. hirsutissimum*, *C. Lowi*, *C. levigatum*, *C. Lawrenceanum*, *C. Pearcei*, *C. selligerum*, and *C. Stananum*, with *C. grande*, and *C. nitens* showing flower spikes. *Calanthe Veitchi* in bloom is dotted freely amongst them, and *Oncidium Lanecanum* enjoys the heat growing in baskets suspended from the roof.

The other house is more like a span-roofed pit, and the dwarf-growing ones are established there, such as *Cypripedium concolor* and *C. Gode-*

froyæ with a hundred healthy pieces of *C. Sanderianum* and many *C. Hookeræ*. *Maxillaria Sanderiana* is represented by a fine plant, but which has not yet flowered. *Aerides mitratum*, *Angræcum Ellisii*, *A. Sanderianum*, and *A. Scottianum* are remarkably well grown and flowered. *Cymbidium Parishii* is making seven new growths from three old ones. *Odontoglossum Roezlii* and *O. vexillarium* are rooting well in new material of peat and sphagnum. Overhead several fine varieties are in bloom of *Odontoglossum Kramerii* and *Paphinia grandis*, and *Odontoglossum Phalænopsis* deserves special mention on account of its numerous growths and clean and healthy appearance. Another house is filled with various *Odontoglossums* planted out in the peat shaken from the fibre. It is found to be a good practice to start them when a large number of imported plants are received, and as they begin to root and make new pseudo-bulbs they can be drawn from the loose soil and potted without risk of breaking their roots. In what is styled the *O. grande* house are many other species; *O. Inscayi splendens* is plentiful, and from one growing here the drawing for the *Reichenbachia* was made, *Oncidium cucullatum*, *O. Marshallianum*, *O. Rogersi*, and *O. undulatum* make their growth here; *O. Phalænopsis* is in bloom, hanging to wires from the roof, and the pretty *O. Limminghei* in a similar position is doing well. *Nanodes Medusæ* close to the glass is equally at home.

In a long house having a north aspect are the *Masdevallias*, *Trichosma suavis*, *Disa grandiflora* in large pans, several of them containing as many as thirty flowering growths each. *Odontoglossum Rossi majus*, and the pretty *Butterwort*, *Pinguicula caudata*. In the *Gardenia* house Mr. Whillans is experimenting with *Cattleya citriua*, to endeavour to make a quick and early growth, to be succeeded by a long and cooler rest. Great masses of *Dendrobium Falconeri* are still in this heat, a *D. bigibbum*, *D. Dearei*, and *D. Wardianum* have grown and are flowering well.

It is a treat to see the scores of hanging baskets laden with bloom of the pretty little yellow *Oncidium cheiroporum*; in another house with hundreds of flowers on, the useful old *Cypripedium insigne*, and in another the sweet-scented *O. ornithorhynchum*, *Sophronis coccinea*, and *S. grandiflora*, the former of a brick-red colour with shorter pseudo-bulbs and smaller blooms than the latter, which is orange scarlet, some of the blooms measuring 2½ inches across.

The *Lælia* house is also gay. There are about a hundred spikes of *L. anceps*; two large plants of the alba variety have seven strong spikes, these are much thicker than any of the other forms. *L. harpophylla* can be counted in the three figures, and a fine stock of *Odontoglossum Harryanum* occupies one corner; some have bloomed, and others are showing.

Dendrobiums at rest are in a light airy house. *D. Jamesianum* is flowering on well-ripened growths, and specimens of the same species as those in the *Gardenia* house mentioned, and others will yield plenty of flowers for cutting in their respective season. Most of these had been subjected to a sojourn in the open air last summer.

The *Vanda*, or East Indian house, contains a collection of good Orchids. *V. Sanderiana* is plentiful, growing in long boat-shaped baskets and rafts. A plant of *V. Cathcarti* has five leads, one being 8 feet long, and bore ten spikes of bloom at one time. *Vanda Hookeriana* is present in numbers. *Aerides vandarum* has eleven spikes; of *A. Lawrenceæ* there are good plants, and among others in bloom were *Angræcum sesquipedale* and *A. Leonis*.

An additional block of four houses was built last spring, each 116 feet in length, connected at each end by a wide corridor. The one on the south end is filled with *Odontoglossum citrosimum*, there being no stages in it. The whole of the plants, which are in baskets, are suspended near to the glass. The other one is used for resting *Dendrobiums*, and for *Lapagerias*, *Roses*, and *Chrysanthemums*.

The *Odontoglossum* house comes first, and I was informed that with *O. Alexandre*, *O. Pescatorei*, and *O. cirrhosum* there are no less than 8000 plants, consequently there is always something in flower. Mr. Whillans has had all these, besides many others, repotted, since he took charge of the extensive gardens at Blenheim. They were formerly grown in roots of *Polypodium vulgare*, which is very abundant about the plantations, but he found on examination that Orchid roots below the surface had perished. They appeared to do well at first, but afterwards the Fern commenced growing at the expense of the Orchid, besides introducing a number of slugs and other insects. Nothing is used now but good peat and fresh sphagnum.

The other houses are filled with *Bouvardias*, &c., which I hope to note another time. But in a mixed stove I noticed healthy plants of *Calanthe vestita gigantea* with 100 spikes. This is much later and stronger than the other deciduous *Calanthes*. *Phaius grandifolius* was also sending up many strong spikes. It may be imagined that with forty-five men under his charge Mr. Whillans is obliged to depend a great deal upon responsible foremen in each department, and that each feels that responsibility there can be no doubt; and Mr. John Coles, who has charge of the one I am writing about, is entitled to a certain amount of credit for the pains he takes in the Orchid houses, and Mr. Whillans speaks well of him. The young men's comfort is looked to, for they have a splendid bothy, in an excellent position, fitted with every convenience, with a large kitchen, dining-room, and library, which certainly requires a few more good useful volumes, but as the place has not been completed very long they may yet be forthcoming.

I have only now to add my best thanks to Mr. and Mrs. Whillans for their kindness and hospitality, and to give, as my opinion, that the right man is in the right place.—G. W. CUMMINS.

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.

NEW SERIES.—No. 7.

PERHAPS it was for the sake of contrast between their dry pursuits and the freshness of Nature that the lawyers of the olden time surrounded their London quarters with gardens, often somewhat extensive, for it does not appear that they themselves were, like the monks, particularly fond of horticulture in any branch. Yet the precincts of the Temple to this day witness that a love of plants and flowers exists in some legal minds, for we see many pots arranged in odd nooks and corners. Window sills are also turned into miniature greenhouses. One window, indeed, has been curiously adorned by its owner, who has covered the panes with dried fronds of various Ferns stuck to the glass, amongst them here and there a flattened body of a moth or butterfly. Evergreens have long been a speciality of the Temple. The poet Cowper tells of his experiences in trying to keep Myrtles alive at his chambers, and advises a friend to change the earth about October, and water regularly twice a week through the winter. But Myrtles will not thrive in London's smokier gardens. Still, it is surprising how little some evergreens, chiefly those with large leaves, seem to suffer from it, not even if the leaves during the winter are so coated with soot that their texture cannot be seen. Perhaps to some extent this carbon deposit acts as a preservative from the cold, and if well syringed off with tepid water in spring leaves no evil effects afterwards.

The Temple Gardens are not likely to be forgotten as long as English literature endures, for many are the allusions made to them by famous writers. All students of Shakespeare will remember the scene he lays in these gardens, where the rivalry between the Yorkists and Lancastrians is represented as starting from the plucking of red and white Roses by some of their partisans, who took this flower for symbols. And indeed it is probable that the gardens had during the fifteenth century a profusion of Roses, and they grew there for centuries, till the smoke-laden air forbade even the strong Perpetuals to put forth blooms. The last to struggle for existence were the old Provence Rose, the Cabbage, and Maiden's Blush. Then there came a turn for the better owing to Smoke Prevention Acts, and Mr. Broome could show in 1864 some twenty trusses of Temple Roses. The continued growth of London, however, has not been favourable for this plant. About the Temple we still find that pleasant quietude on which Charles Lamb and Miss Landon have commented—so different to the streets outside and the Embankment below. Of course the gardens are less picturesque now than when the Thames crept up to their edge, forming a little bay. But in the summer season, by the kindness of the Benchers, many poor persons are much benefited by the privilege allowed them of strolling here, and perhaps eventually the gardens may be opened to the public daily.

The Temple Gardens now existing must be about five acres in size, and they are named from the Middle and the Inner Temple. There may have been formerly a garden attached to the Outer Temple, if so, it has been built over. In the upper square or terrace of the Middle Temple Garden the memorable fountain still throws up its spray, but the jet is now of diminished height to what it was, according to tradition, in the olden time. It is under the shade of some trees, the notable ones being two well grown. Descending to the larger space below, we see no signs of the shady recesses or bowers which, in the eighteenth century, attracted meditative authors, but there is a broad lawn, edged by some Planes and young Limes, and over which are scattered flower beds of shapes somewhat singular, bare in February, but which receive plants for a summer display. Vases and boxes show some of the spring bulbs, to which the N.E. winds have been unkindly of late. As this garden had the repute of being the most retired, it was probably here that the rooks had their settlement, oft referred to. The commencement of the colony was said to have been a few birds, brought hither from Woodcote Green, Epsom. Of the one or more Catalpa trees planted in Stuart times there is no relic left, and not a Fig tree has survived to our day of those that had flourished and borne fruit. There are some venerable evergreens, but the Hollies have fared badly, and also the Rhododendrons (which very possibly used to flower years ago, when more vigorous). Aucubas, Portugal Laur ls, and Thujas, however, have strongshoots, fairly leafy. Along the borders one may notice Pinks, Irises, and Chrysanthemums, and amongst them annuals are sown with variable success. Mignonette is one of these that has for years been a favourite flower in both gardens; it may advantageously be allowed to sow itself, and from observation I do not think sparrows are such destroyers of seeds in town gardens as some suppose, but the Temple has ever been a rare haunt of these birds. Leigh Hunt declared he saw them by thousands, and in the accounts appears a disbursement, while Barrington was treasurer, of a pound for poison to thin their numbers, which was rather a severe measure.

Of the Inner Temple garden there is an old engraving dated 1671, one of the few that exist representing the gardens of our ancestors. It enables us to mark the places where trees then stood. It is likely these were chiefly Elms and Poplars. The last to survive of these venerable trees was a Sycamore, for many years carefully propped up and Ivy-clad, beneath which Johnson and Goldsmith are said to have sat in talk. About that date it was usual for the leading counsel to promenade the gardens on summer evenings, habited in their satin smalls, with stockings, ruffles, and cocked hats, and they would stoop over the borders to admire the "Sweet Williams," the "London Prides," Stocks, Larkspurs, Wallflowers, and other old favourites, which are still cultivated here, but outshone by the Chrysanthemums, which are now the speciality of the

Temple. These have been oft described in their annual display. Of course, all the choicer varieties are grown under cover, though there are some that will bloom in the open pretty freely, the best position for them being a bend of the grounds towards the east, where the gales of spring and autumn touch the plants lightly. Some shelter is afforded by evergreens, which might be more extensively planted on the Embankment side of the gardens. I perceive it is now becoming common to set Golden Feather abundantly along the borders of London gardens; it has the advantage of looking green and fresh most winters.

The enclosure of Clifford's Inn upon the north side of Fleet Street is an example of a town garden, which thousands pass near daily, unconscious of its existence. Being so enclosed by buildings, it is not favourable for the growth of trees and many plants, but it might be greatly improved, and the Public Gardens Association are endeavouring to have it thrown open to the public. The square space is sub-divided into four lesser squares, on their sides scattered Planes, Elders, and Laburnums. The ground, however, is so impoverished that the few herbaceous plants look feeble; the most vigorous growth noticeable was that of a hank of Ivy.—J. R. S. C.

CULTURE OF FREESIAS.

YOUR correspondent "J. C. A." has done well in directing attention to these charming Cape bulbs at page 65. Few semi-hardy bulbous plants are more delightfully fragrant than these. They possess a perfume peculiarly their own, and cannot be too strongly recommended as especially valuable for cultivation in all gardens where choice fragrant flowers are appreciated; and whether for personal adornment, dinner table, or vase decoration, their characteristic beauty and exquisite perfume can hardly be overrated, the more so, as already pointed out by the writer above referred to, they may be had in succession for a long period. I suppose that "J. C. A." has special use for these flowers in November by potting his bulbs as early as June, which I may remark is an extremely early date, and very much before the time that they can be procured from our largest bulb growers and importers. From November onward to Christmas too there is such a wealth of Chrysanthemum blooms, tree Carnations, Cyclamens, and such flowers that I have regarded the Freesias as of greater value when the former are on the wane. This is, however, no reason why these charming flowers should not be among their number, and my reason for calling attention to them is that those who may wish to take them in hand for the first time may not be disappointed in their endeavours to obtain them so early from the bulb merchants, who usually receive them from August to the end of the year. Not infrequently do consignments come to hand even in January, the bulbs as plump and sound as ever, and these when potted will start readily in about three weeks in a temperature of about 50°, and if grown in this continuously will flower at the end of April. With a view to protecting their frail growths I always prefer a frame for them, where they may be protected from heavy rains or destructive hailstorms. At all times overwatering should be studiously avoided. A thorough baking in full sun and without water near them is essential to their success, which may be secured by placing them on a shelf near the glass.

My experience of Freesias, however, will not allow my endorsing the statement that "a single pot will frequently treble its produce of flowering bulbs in one year," and I doubt if growers generally will be able to give so highly satisfactory an account of the rapid increase of their stock. I willingly admit they can be rapidly increased by offsets, but the statement that they frequently treble themselves in one year, and flowering bulbs too, is something I had never heard or even dreamt of. One instance alone while writing occurs to me of any plant doing so much, and this is *Gladiolus Colvillei* The Bride. Frequently this trebles its produce of flowering corms in one season, but it is purely the result of extra large corms, and good culture, fully protected from spring frosts. In this case the corm is but annual, which may to some extent account for its prolific reproduction, and I do not know of any strictly perennial bulb increasing so freely. Numbers of bulbs, as *Lachenalias*, *Erythroniums*, *Muscarias*, *Alliums*, and some *Scillas*, increase at a surprising rate, but do not make flowering bulbs for two years even with good culture. The Freesias in general appearance resemble the *Erythroniums*, the offsets being disposed similarly in both genera, and I have never yet seen a flowering bulb produced as a one year's offset upon either; on the contrary, I have had some hundreds of medium-sized Freesias which never produced an offset at all. From time to time I have had various inquiries from amateur growers of these bulbs who complain that they do not come up the second year. This is a sure sign of not being properly ripened, and to all those who have a similar experience it cannot be too strongly urged that a thorough baking in full sun, regardless of how hot or dry the soil becomes in consequence, is most essential to their success, not, however, brought about too suddenly, but gradually and thoroughly.—J. H. E.

SELF-IMPROVEMENT.

THE opinions and the discussion on this subject, now appearing in the *Journal of Horticulture*, are worthy of the attention and consideration of all who are interested in horticulture—to young gardeners they are specially applicable.

The importance of this question will hardly need an confirmation which I can give, for anyone will comprehend that a knowledge of the higher subjects relating to gardening is of immense advantage

individually, as well as to horticulture generally, for by this means many of the secrets of plant life may be discovered, increasing our knowledge, and opening fresh paths to pursue the course onward. Knowledge being the key which unlocks the "Golden Door" leading to success, the acquiring of it should be the aim of everybody. The mere rudiments of elementary education are not always sufficient for the particular profession one may be following, but they are indispensable in the first instance. If to excel and get to the front be the ambition of a young man, something higher and extra must be sought for and found.

It is an indisputable fact that the facilities possessed by the young men of the present day are in every respect greater than those the head gardeners of to-day were blest with. Nowadays a good education can be procured at a comparatively small cost.

Among the subjects which are so eminently useful botany holds a foremost place. A study of the classification and structure of plants and flowers, besides being a pleasant pursuit, is also instructive, and helps the gardener in the culture thereof, though be it understood botany is not indispensable to a gardener. The most useful language is unquestionably French. So many names of flowers, especially continental varieties, are written in French that a knowledge of this language stands one in good stead. Thus, when an employer, or it may be a visitor, desires the name and meaning of a plant, it places one in an uncomfortable position if only a literal pronunciation can be rendered, at the same time being altogether ignorant of its meaning. Phonetic shorthand, as was forcibly pointed out by one of your correspondents, is very valuable, and whoever is proficient in the "winged art" must be justly proud of the achievement, for the opportunities to use it are endless, and it saves much tedious handwriting. Latin and geometry merit mention here, the first being so extensively used in the nomenclature of plants, a strong recommendation to acquire it may be given.

Having mentioned these subjects the next question is, How are they to be learnt, and what are the facilities for acquiring them? Schools of horticulture are wanting, a deficiency which will be felt more as time rolls on; so self-reliance must be depended on, and he who perseveres will in the end attain success. Near our large towns, classes for any subject may be attended. Some young men are indifferent to, and ridicule the notion of, anything beyond the practical part of their work; some again have no ability or talent, and others who have the talent, with a desire to progress, have no facilities for doing so.

Further, it should be the resolve to start early in life to acquire these subjects, as the inclination will gradually decline as the years roll on, and even were this not the case, so little time can be spared for this purpose that it would be almost useless to commence. It is not the rule with employers, or even head gardeners, when engaging their young men to inquire how far their knowledge extends. If it was the rule, they would hestir themselves more than is the case now, so that a better standard of gardeners would be the result. As a body gardeners are on an equal with any class in the kingdom for intelligence and intellectual capacity, but there is room for improvement. Now, it is not said in these notes that the technical part of horticulture as mentioned above is indispensable to a gardener, or even necessary when commencing a career in this profession; but it is said, and will be maintained, that the advantages to be derived are many, and will tend to place horticulture in still higher position than it now holds.—F. R. S.

[We have several communications on this subject, some of which will be inserted.]

THE BULB MITE.

IN the Journal for February 23rd, page 152, "Observer" asks a general plain questions respecting the above, and the Eucharis being a general favourite in most gardens, I am not surprised its treatment is so often discussed, particularly as the plant so often fails to grow satisfactorily.

During the last few years I have carefully studied this matter, having had to deal with a stock badly infested with the mite, and the plants had been in a bad state for some time; indeed, I was strongly advised to consign them to the fire and start with a fresh stock. On closely examining the plants I was not surprised to find them infested with the mite. The pots had scarcely any drainage, and what there was had been completely choked, a heavy pasty loam having been employed without anything to assist in making it porous, it was consequently full of worms and sodden with water. I resolved to start with this stock, and in less than twelve months I was proud to have under my charge thoroughly healthy plants, about 100 in all, with plenty of foliage and flowers. I am pleased to say they have remained in a healthy condition since (nearly four years), and we are scarcely ever without flowers in winter and summer.

In commencing I shook them out clean, thoroughly washing them in warm water, and cut back most of the roots close to the bulbs. I potted them in 10, 8, and 6-inch pots, selecting the strongest bulbs for the largest pots. The soil previously prepared and warmed consisted of two parts fibrous loam, one part peat, a little thoroughly decayed manure and leaf mould, a plentiful supply of coarse silver sand, and finely broken crocks and charcoal, with a little soot thoroughly mixed. Water was withheld from the roots entirely for a month, except syringing twice a day, morning and afternoon, which we make a practice of doing all through the year. They were placed on the front stage of our Banana house, where they have remained since, never plunging them, but shading lightly in bright weather. I was soon satisfied they

would get the better of the mite. As the pots became filled with roots liquid manure was applied at every third watering, made from cow manure and soot, with a change of weak guano water occasionally, and since we have used Wood & Son's liquid manure powder, which suits them extremely well; indeed, I consider this a fine stimulant for all softwooded plants. We repot them annually, carefully removing any old soil we can without damaging the roots.

Observer asks, Does the mite come in the compost in which the bulbs are potted? I do not think it does, but I am fully persuaded it is owing to some severe check the plants receive, and not till the plants become in an unhealthy state does it make its appearance, some of the causes of which are over-potting, imperfect drainage, unsuitable soil, over-watering, using icy cold water, injudicious uses of stimulants, or subjecting them to extreme temperatures, &c. Secondly, he asks, Is it possible by a judicious system of culture to arrest and stamp it out? I do not hesitate to answer in the affirmative.

I must confess I was not a little surprised to read your correspondent, Mr. A. Pettigrew's, remarks, page 102, when he states his plants require and receive a good watering three times a day during hot weather in summer, and a heavy watering every day through the winter. Most of our plants stand directly over hot-water pipes in rather a high temperature, and we only water when dry enough to receive it, which is certainly not oftener than once a day in the hottest weather. They are examined twice a day, but only those requiring water receive it. Care is taken to thoroughly soak them.

I entirely agree with your correspondents, "M. W." and Mr. A. Haggart, that it is safer to err on the side of giving too little than too much water, particularly when plants are not in a flourishing condition.—EDWIN BECKETT, *The Gardens, Aldenham House, Elstree.*

STRATAGEM PEAS.

IN reply to Mr. Murphy (page 149) I may state that the number of pods given—viz., forty to a plant, was the aggregate crop for the season, and I am certain I have not overstated the quantity. As to the number of peas in the pods, I know that eight to ten will be produced with good cultivation. I know an amateur who has grown Stratagem Peas with plenty of pods containing twelve peas each. About $\frac{1}{2}$ lb. seed was sown in a 12 foot row, and the plants grown without any of the orthodox topping or thinning of pods. I have no doubt the distance at which I sowed the Peas might be disastrous in some soils poisoned with manure, and lacking the essential constituents necessary for building up a robust, sturdy, fruitful Pea plant, and possibly with the additional disadvantage of growing in a high walled garden without the benefit of a good breeze of wind to consolidate the growth. On the windy uplands of Kilmalcolm they do as well sown thickly as described, when supplied with the required stimulants, as they do in other places with four times the distance between them, while being free from mildew and every other ailment to which Peas are subject when grown in soil containing a gross accumulation of vegetable matter. As a preventive against ground vermin and mice I steep the peas in naphtha for twenty-four hours before sowing, and I find it also a remedy against the seed souring in the soil should very wet cold weather succeed the sowing of early Peas. Early Peas forwarded inside when planted out are cut down here in spite of all means taken to prevent it.—JOHN SWAN.

FRUIT PACKING.

YOUR correspondents, Mr. Tresder and "W. H.," referring to my criticism on Mr. Pettigrew's method of fruit packing, justly remark that it can be of no service unless my own ideas are more fully explained, which I will endeavour to do. Mr. Pettigrew advocates hay as a packing material, and spares no pains in describing his mode of using it, but unfortunately he does not say why he prefers it to paper shavings, as the latter in my opinion is preferable in all respects. What I was most struck with, however, was Mr. Pettigrew's system of Grape packing, described in page 8, as I maintain, without fear of contradiction, that nothing that touches the bloom of Grapes can protect it. Therefore, my mode of packing in order to secure the bloom on one side of the bunches is as follows. I have wooden boxes for the purpose partitioned, each space to contain two bunches, the partitions being made of various sizes, so that large and small bunches can be made equally secure in each division. I have a thick layer of paper shavings covering the same, and the partitions with wadding, thickening both materials to the sides of the box, so as to give the bed as much fall to the centre of the box as its depth and size of bunch will permit. The whole is then smoothly lined with tissue paper, and the box is ready to be taken to the vinery. The bunches as they are cut are tied at the stem with a string, and the bunch laid in the divisions, according to the size, best side up. Two holes are then bored in the side of the box, through which the string is drawn and securely tied. A sheet of paper is then stretched over the partitions to protect the Grapes from dust, the lid then being made secure. I will venture to say, whether they have to travel both by land and water, if kept right side up, one side of the bunch at the journey's end will be looking almost as perfect as when they were cut from the Vines.

I also take exception to Mr. Pettigrew's mode of Peach packing. He recommends the use of two boxes, tin and wood. The former I do not find necessary. The box I use is made of wood divided in various sizes, suitable both for Peaches and Nectarines. Mr. Pettigrew also recommends rolling the Peaches in the packing materials, and dropping

them into the divisions; but I find a better plan is to first line the divisions with paper shavings and wadding; then place each fruit on square pieces of tissue paper sufficiently large to well envelope the fruit, then draw the four corners of the paper together and by them let each fruit down in the compartments, if necessary slightly drawing them up and down, so as to get them firmly seated. The four corners of the paper should then be spread over the fruit and the wadding, of which a liberal portion should have been laid over; the partitions should be lapped over and around the fruit, and in order to make it quite firm a small piece of wadding should be gently thrust into each corner of the compartment. In unpacking the first things to be removed are the corner pieces of wadding, the four corners of the paper being again brought together; the fruit is lifted by them out of the divisions, so that not a finger mark can be seen, which is so desirable to avoid, and can in no other way that I know be so successfully accomplished. I may also remark in the dispatch of fruit, should there be two or three boxes to be sent to the same address, I invariably find the fruit in better condition when tied together in one package than if travelling singly. —R. W.

THE NEWCASTLE-ON-TYNE SHOW.

YES, "Old Hand," I can do more than substantiate my former statements, that the most glaring instances of size being preferred to quality are to be found in the North, and justify my remarks by stating the stipulated rules of the schedule and particularising the favoured exhibits at the above Exhibition, where handsome prizes were offered for fifty dishes of fruit to be ripe and fit for table, to include the following:—Six sorts of Grapes, three of Melons, three of Neectarines, and two of Peaches; four of Plums, two of Figs, three of Cherries, two of Apriots, three each of Gooseberries and Currants, and eight varieties of Pears, with the like number of Apples. Thus we find we have forty-seven dishes stipulated, leaving three dishes to the option of the exhibitors, which are required to be distinct. The numbers of fruits in each dish were also given, yet we find the first prize awarded to a collection not only deficient in the stipulated dishes, but containing at least one-third of unripe coarse fruits and some dishes that never would be fit for table, as the following particulars will show:—One dish or peck of Tomatoes, one of unripe Citrons, one of Lemons, six dishes of unripe Pears, seven dishes of unripe Apples (mostly culinary varieties), two dishes of unripe Plums, and one dish of Cycas fruits. The second prize collection was equally faulty, containing as it did two dishes or pecks of Tomatoes, one dish of green Bananas, one of unripe Citrons, six of unripe Pears, and the like number of unripe Apples (mostly culinary sorts). If "Old Hand" can get a couple of conscientious, disinterested, practical gardeners to say in plain English that the awards were justly made and in accordance with the stipulated conditions of the schedule, it would strengthen his case much more than any reference to the Judges, as they would naturally uphold their former awards. Nevertheless, it would do no harm to know who the gentlemen are that officiated as Judges. Are they some noted *chefs*? as some allusion is made by "Old Hand" to different ways of eating fruit other than from the trees. Suppose we grant him the assistance of a *chef* to make his exhibits eatable, they could not rightly be termed dessert fruit, as cooked fruits are always under the heading of sweets in a *menù* for a dinner. I have seen many skilful feats in cookery, but it would confound the cleverest *chef* to convert Cycas pods into an eatable delicacy of any sort.

With regard to Tomatoes, to say the best of them, they are certainly an injudicious innovation amongst fruit at our exhibitions, and ought not to be admitted as fruit and passed over at convenience; it is nothing less than an injustice that I am anxious to abolish. Personally, "Old Hand," I am anxious to give honour where it is due, but where is the honour in violated treaties? If anyone can lay claim to honour it is the Committee for their spirited enterprise, and I am glad they are so well rewarded.

"Old Hand" seems somewhat alarmed at my position, but I can assure him that I can still find comfort in the fact that I am the only exhibitor that staged fifty dishes of ripe fruit, and I can well afford to ignore his insinuations.—J. H. GOODACRE.

FOR several weeks past I have watched with great interest the correspondence with reference to the awarding of prizes in the Jubilee fruit competition at Newcastle-on-Tyne. The name of Mr. Goodacre is familiar enough as a successful exhibitor throughout England, but in this instance he has certainly showed very bad taste in challenging the judging at a show, on the exhibits of which he should certainly not venture to give such a decided opinion, being an absentee from the said Show, and, therefore, he must have received his information from others. Of the superiority of the premier collections over his own, no one would have been more convinced than himself had he seen them. If Mr. Melndoe, who is well known to be one of the finest fruit growers in the kingdom, and who took second prize, had in any way complained it would not have been so surprising, as the difference in merit between his and the premier collection was trifling in comparison with the difference of the first and second prize money. There was a marked difference between these two and Mr. Goodacre's collection, so marked that had these been disqualified Mr. Goodacre would even then have only been justified to receive the award he did for a prize of such value. Seeing that the Committee offered such a magnificent prize as fifty guineas for the Jubilee collection of fruit, it must have been in the highest sense gratifying to the energetic and courteous Secretary, Mr.

Gillespie, and his fellow workers, to see the unabated and general interest and attention these collections excited in the thronging crowd of visitors.—ONE OF THE JUDGES.

CHRYSANTHEMUM SHOWS.

WE have received notices of the following fixtures for the Shows of 1888:—

National Chrysanthemum Society, Metropolitan Shows, September 12th and 13th; November 7th and 8th; and January 9th and 10th, 1889. Provincial Show at Sheffield, November 16th and 17th.

Kingston-on-Thames, November 6th and 7th.

Portsmouth, November 7th, 8th, and 9th.

Teddington, November 8th and 9th.

Southend, November 13th.

Brighton, November 13th and 14th.

Putney, November 13th and 14th.

Winchester, November 13th and 14th.

Reading, November 15th.

Pembroke, November 15th.

Lindfield (Sussex), November 15th and 16th.

Sheffield and West Riding, November 16th and 17th.

Liverpool, November 20th and 21st.

Birmingham, November 21st and 22nd.

Hull, November 22nd and 23rd.

Pontefract, November 23rd.

MRS. J. WRIGHT.

THIS variety appears to be both early and late. The finest blooms we have seen were too early for the November shows; and now Mr. J. W. Flight, who has obtained the first certificate for this variety, writes from Twyford, Winchester, under date of March 2nd, "I have still a bloom of Mrs. J. Wright in one of my rooms; it was cut six weeks ago, but, being kept in a cool place, it retains its form and looks quite fresh. I believe the demand for plants has been immense, and I do not know of any other variety that produces young growths so freely."

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday, March 5th, the General Committee of the above Society met at Anderton's Hotel, Fleet Street, to receive the report of the Sub-Committee previously appointed to arrange for the shows and schedules of the present year. There was a large attendance of members, about forty being present, including the representatives of several affiliated societies, Mr. E. Sanderson presiding. The three delegates from the Sheffield and West Riding Chrysanthemum Society, Mr. W. K. Woodcock (Hon. Secretary), Mr. J. G. Newsham (Trustee), and Mr. T. B. Hague, the Sheffield Society's representative on the General Committee, were introduced to the meeting by Mr. William Holmes, and were very cordially received. They had held a conference with three members of the National Society's Sub-Committee in the afternoon with regard to the provincial show, and the final details were arranged to mutual satisfaction. Referring to this Mr. Holmes stated that the Sheffield officials had taken up the scheme so earnestly and in such a business-like manner that its success was practically ensured; a fund of £120 would be guaranteed which, with the National Society's contribution, would amount to at least £160, and there is a possibility that by local assistance it will exceed that sum. Mr. Woodcock in thanking the members for their hearty welcome, said that they had throughout the negotiations remarked the great fairness which had characterised the terms suggested by the National Society; he complimented Mr. Holmes highly upon his promptitude, energy, and tact, and observed that no efforts would be wanting on the part of their Society to render the show a thorough success. It was hoped that it would be rendered the best representative exhibition of north and south country productions that has yet been held. Mr. Newsham also responded in similar terms, fully endorsing all that Mr. Woodcock had said with regard to the interest that was already being excited in the show, and it was felt that the National Society would fully justify their title in undertaking a provincial exhibition.

After several new members had been elected, and some miscellaneous business transacted, the Committee proceeded to the examination of the schedules for the three metropolitan Shows, the dates of which have been already given. After considerable discussion the recommendations of the Sub-Committee were adopted, and the following Judges were appointed. September Show: Messrs. Dean, Gordon, Henshaw, and Drain. November Show: Messrs. Donald, Prickett, Barron, Douglas, Wright, Gordon, Molyneux, Beckett, Castle, and Head. January Show: Messrs. Dean and Gordon, with Mr. W. Holmes as referee at all the London Shows. At the provincial Show the Judges will be Messrs. Wright, Udale, Gordon, Garnett, Castle, and Dean, with a referee to be appointed by themselves. Numerous alterations were made in the classes at the metropolitan shows, several being added for amateurs, and

medals are offered as prizes in several classes, on the understanding that money can be had instead if desired.

This being the last meeting of the session, hearty votes of thanks were accorded to Mr. Sauderson and to Mr. Holmes, who responded in suitable terms.

LATE CHRYSANTHEMUM.

MR. T. WINKWORTH, Childwall, Liverpool, sends us some fresh bright blooms of Chrysanthemums, and remarks that the varieties are "two latest flowering Chrysanthemums with which I am acquainted—namely, Ceres and Golden Gem. I scarcely need say they are terminal flowers from late-struck plants."

A PEEP AT PITCAIRLIE.

PITCAIRLIE, the residence of Robert Cathcart, Esq., of Pitcairlie, and of Carbiston in Ayrshire, lies among the Ochils, midway between Auchtermuchty and Newburgh in Fife. The family is an old one, the wardship of Carbiston dating from 1368, in the reign of David II., and bears an honourable and honoured name in the service of their country. Captain Robert Cathcart, R.N., of the "Bellerophon," played a distinguished part in the Battle of the Nile, and added to his fame in his subsequent career. In these peaceful times no proprietor holds his place more worthily, or discharges in "the kingdom of Fife," and beyond it, many important duties with more acceptance than the present well-known and highly respected laird of Pitcairlie. Of much that could be said in his praise, although no one would be less likely to thank the sayer of it, most suited to the columns of the Journal is the fact that it would not be easy to find a gentleman more interested in horticulture generally, or to meet with a more enthusiastic florist.

The mansion dates from different periods, the tower being over 400 years old. All around wood grows luxuriantly and is abundant, fine old trees meeting one everywhere. Special mention may be made of the Oak and the Limes in the immediate vicinity of the house. Near the keeper's lodge is a handsomely proportioned Silver Fir of great size, which is figured in Jeffrey's book of the famous trees of Fife and Kinross. Beside the walk leading to the garden stands a grand Elm. This last several years ago lost a huge limb, which somewhat impaired its symmetry, but it is still an enormous and splendid example of its kind. But, as usual in such fine old places, one does not realise the great size of the Pitcairlie trees from the proximity of so many noble specimens.

The grounds to the west of the mansion are laid out in well-kept terraces; on the south in the flower garden brilliant in the season with the best bedding plants. The walk referred to above winds through a shrubbery to the houses and garden. A broad border is filled with thousands of Polyanthus and Primroses, especial favourites, affording when in bloom, as I had previously seen them, a sight to be remembered. The houses are numerous, and all in excellent condition. I can do little more than indicate these. There are in all five vineries. In the early and second house are grown mainly Black Hamburgs, with Madresfield Court, Buckland Sweetwater, Duke of Buccleuch, and one house is of Muscats alone. In the late house are Lady Downe's, Alicante, Gros Colman, Gros Maroc, and a large span-roofed vinery is devoted chiefly to Black Hamburgs. Inside the garden is also a large conservatory, which was filled with the usual greenhouse plants all capitally grown, many of them models, and in profuse bloom. Amid the fine display of Fuchsias, with Zonal Pelargoniums, Begonias, and other comparative novelties, were observable older flowers now not so often seen as they deserve, but which a judicious taste rightly refuses to discard. The whole effect of this house was very fine. Outside the garden are a smaller greenhouse, four Peach houses, Fig, Cucumber, and Melon and Tomato houses, with the usual frames heated and cold. The culture of Pines has been discontinued.

There is a Rose house, and here I make confession. Personally my knowledge of Vines is of the smallest, but a friend with me made up for that. We were being shown two of the vineries. Even I could see that the crop was one of uncommon excellence. The sturdy canes, the ample foliage, the bunches of fruit so numerous, so large, so uniform, told that, and I had my friend's repeated assurance that he had never seen anything to equal them. I overheard, during a minute inspection and a pretty lengthened discussion of their merits, strong expressions of surprise as to the age of some of these heavily laden Vines, and I let slip a golden opportunity of increasing my scanty Grape lore. But that Rose house did it. I had my hands full of Tea Roses, and the Grapes might then have been miles away. How these Pitcairlie Roses cling to one's memory! The house is in two divisions, and is filled with Teas of the best sort, planted out in borders and trained on trellises up the glass and on the back wall. Of course Maréchal Niel is there, with Gloire de Dijon, Niphotos, Marie Van Houtte, Rubens, Duchess of Edinburgh, Souvenir d'un Ami, and all of worth. I never saw Cheshunt Hybrid in such perfection, and one plant of Souvenir d'un Ami, covering 9 or 10 feet square of the glass as you enter, was a mass of exquisite flowers, yet for months it had been constantly drawn upon. From it I carried to the neighbouring town some beautiful blooms, and there left them—shall I say not without reluctance!—to fulfil the function of their name. In the open about 500 Hybrid Perpetuals, including always the latest of merit are grown, and grown as everything at Pitcairlie is. The collection of herbaceous plants is very extensive. Dahlias in the different sorts were numerous and good. The collection of Auriculas, stage and Alpine, is one of the most complete I know, including all the best of the old sorts, and I believe every new variety obtainable. Mr. Cath-

cart was one of the chief promoters of the Scottish Primula and Auricula Society, of which he was unanimously elected President.

I had almost omitted to mention that Pears, which did not give satisfaction in the garden, have been given up. The other sorts of fruit on the well-clad walls and throughout the garden are grown in abundance, the collection of Apples being especially choice, extensive and satisfactory. Such cases may be less rare than I imagine, but to me it was a new experience to see a heavy crop of Red Currants on a wall, and a fine break of Gooseberries still untouched at the beginning of October.

The head gardener does high credit to a name of note in his profession. His father, the late Mr. John Laing, well known as one of the most successful Grape growers and exhibitors of his time, for forty-nine years held the same position at Pitcairlie, and at his death in 1883, Andrew, who had been trained under him, was called from England where he had served for several years to fill his place. I may mention that at Wellfield, five miles to the west, Mr. Robert Laing, brother of the late gardener of Pitcairlie, has lately retired to enjoy, I hope for many years, the considerate beneficence of the family he has served so long and faithfully. He also is succeeded by his son. Such facts, creditable alike to employer and employed, need no comment. In concluding this sketch, too imperfect, but which someone better able may yet amplify, let me add that the pleasant recollection of my visit to Pitcairlie is owing not more to the excellence of everything to be seen there than to the genial courtesy and the warm hospitality of its owner.—A NORTHERN AMATEUR.

EUCHARIS CULTURE.

MY thanks are due to Mr. Pettigrew for the very lucid way in which he has, "in answer to my request," described the house, position, and heat in which the Eucharises are grown at Cardiff Castle. He says he has no difficulty whatever in keeping the temperature of this house up to 70°, except in severe weather, when it may be allowed to fall to 60°, while we have to be content with a temperature during winter of 60°, falling during severe weather below 50°. Such being the case your readers will see at a glance the advisability of our plants being kept very much drier than those under his charge; the conditions being so different, the treatment, as a matter of course, must differ also. Had we the position and heat that Mr. Pettigrew has at his command very probably our treatment would vary; but for plants growing in a temperature at least 10° colder than his are would he recommend giving them as much water as his are having three times a day during summer and a heavy watering every day during winter? Ours receive water about three times a week in summer, and during winter once a fortnight, the temperature of the water being always about 80°. Mr. Pettigrew is surprised at the regularity with which our Eucharises flower three and four times a year. Perhaps the dry treatment is the cause of their flowering so often. No doubt his plants flower with greater abundance, but not so often as ours.

The point at issue, in my opinion, is the quantity of water required to keep Eucharises in a healthy flower-producing condition under different temperatures. With a minimum of 70° they, according to Mr. Pettigrew, will require a greater quantity of water, but with a minimum under 60° we maintain it is wise treatment to keep them very much drier than recommended by Mr. Pettigrew, and I shall be very glad to hear what are his views on this point. As I am afraid there are more gardeners who have a limited supply of heat than otherwise who are expected to grow and flower Eucharises, I hope they will be careful how they read articles on Eucharis culture, and not give plenty of water unless this can be supplemented by plenty of heat.—A. HAGGART.

KITCHEN GARDEN.

A LATE SPRING.—Many are already predicting this, and the weather in February encourages this impression. It has been the most severe February experienced for many years. It is not, however, a genial February that brings forward early vegetables. Neither does March influence them much, but a good April and a fine May are most important. We therefore feel little concern as yet about the weather, and advise open-air operations to be delayed, but as much as possible should be pushed forward under protection, and if good supplies of young plants are ready for turning out when the weather becomes favourable the results will be far more satisfactory than are obtainable by early planting and sowing in unfavourable weather in the open.

PEAS FOR PLANTING OUT.—Our December-sown Peas are at a standstill. They are later than usual, and our first crop will now be secured from plants sown under protection. Many attempts are made to raise Peas in this way, but they are not all successful. A common cause of failure is sowing too early and raising them in too much heat. Peas raised under protection cannot be planted out with safety until the first week in April, and if the seed is sown in the second week in March the plants will be from 4 inches to 6 inches high in three or

four weeks at most. This is a suitable height, and if upright and sturdy they will grow away much more freely than if raised in January or February and grown under protection until a foot or more in height and spindly. Where 3-inch pots are plentiful the seed may be sown in them. Half fill the pots with rich soil, make this firm, then place ten or twelve seeds on it, and fill up with more soil. Place them in a temperature of 65°, keep them near the glass when the leaves begin to show, give water and air freely, and by April each pot will be full of roots and good robust plants to turn out and place at a distance of 10 inches or 1 foot apart. We have never any failure with our indoor-raised Peas if treated in this way, and they never receive a check at planting time in either root or branch, and this is greatly in their favour. Peas may also be raised in turves and troughs, but the pots are most convenient.

KIDNEY BEANS.—These are amongst the most valuable of all early vegetables. Their culture is easy, and wherever there is any prospect of vegetables being scarce in April or May they should be sown largely. They will now fruit in seven weeks after sowing. There is no better way of treating them than to sow the seed in small pots and transfer them into 8-inch or 9-inch pots to fruit. They will germinate in a few days in a temperature of 65° or 70°, and they will succeed in this heat always. Our earliest sown plants are now in pod, and all plants coming into bloom should have plenty of liquid manure at the roots, but do not syringe them during the time they are in flower. They are apt when gaining maturity to be affected with red spider, and if grown in ainery or Peach house then they will introduce this pest at a time it would do much harm, and it is better if the Beans can be kept away from anything that is liable to harbour the spider. Destroy all plants as soon as the pods have been secured, and fill every available corner with others, as they will be very acceptable on the table and command a high price in the markets.

FORCING SEAKALE IN THE OPEN.—In the autumn and about mid-winter it is only those who have forcing appliances that can readily secure Seakale, but now everyone who has roots may do so, as its culture in the open will be a success from this time. It may be secured in two ways—one is quicker than the other. The quicker is to place some pots over the roots as they grow in the ground and pack a quantity of hot manure round the outside to induce the crowns to push up. This they will very soon do at this season, and Seakale may be secured in three weeks from the time of covering it. Pots are very convenient, but easks and makeshifts will also serve the purpose so long as the manure is kept off the crowns and the young growths have room to develop. The other and more tedious way is to cover the crowns with finely sifted ashes to a depth of 1 foot or more and allow the growths to push up through this. The ashes do not force it in any way, but they blanch the stems beautifully, and of all ways of securing finely flavoured Seakale this is the best.

MINT.—Green Mint will soon be in demand, but it will be many weeks before it can be gathered in the open, and roots should be taken up, placed in any old shallow box, and transferred to some warm house. It will be green in a fortnight if grown in a temperature of 65°. We have sometimes secured abundance of Mint in spring by lifting a good turf of roots and laying them down on the inside border of an early ininery. If covered with a little leaf soil a Mint bed will soon be formed.

YOUNG VEGETABLES.—The Cauliflower, Leeks, Lettuce, and Celery plants are growing apace under glass. We shall have a fine supply of them to turn out when the weather warrants us in doing so. This style of rearing plants should have much attention, but on no account try to "make them large all at once." They will not keep it up when taken from the protectors, and failure will be the result. Transplant them into boxes or frames in good time, keep them near the glass, and they are sure to succeed. Where they are now in cold frames protect them from frost at night, but expose them to the light and sun during the day. Protect early Potatoes in frames securely. They are very easily injured by the slightest frost, and if once checked they will never be so good afterwards. Where Radishes in frames are very close together and a mass of leaves, thin them out carefully that all that are left may have the opportunity of bulbing. Pull the weeds from early Carrot frames, and thin the plants where necessary. We are protecting ours nightly, but the mats are off during the day, and very often a little ventilation is given from 11 A.M. to 2 P.M.

FRUIT FORCING.

VINES.—*Early Vines in Pots.*—These must sustain no check through dryness at the roots, affording liquid manure liberally, surfacing the soil with rich material, and if the roots extend beyond the pots feed them there as well. Secure a good moisture by damping available surfaces in the morning and early afternoon, also before nightfall, maintaining a night temperature of 65°, 70° to 75° by day, and 80° to 85° with sun heat. Admit a little air at 75°, allowing the temperature to rise with sun heat, and close sufficiently early to keep it at 85° or 90°. When the Grapes begin colouring still continue the atmospheric moisture and feed liberally, as the fruit swells considerably after commencing to colour, and to enhance the quality maintain the temperature named with sufficient ventilation constantly to insure a circulation of air.

Houses Started in December.—Vines started early in that month will have the fruit thinned and swelling freely. The border must not lack moisture, which should be applied at a temperature of 80° to 85°, liquid manure materially assisting in swelling the berries. It will be a material

advantage to mulch the border with some short but rather fresh manure, or a few fresh horse droppings sprinkled on the surface occasionally will afford much benefit to the foliage and the roots. Maintain a genial condition of the atmosphere by damping in the morning and at closing time or early in the afternoon. Ventilate early, but not before 70° to 75° is reached, securing with increased ventilation and sun heat a temperature of 80° to 85°, closing between those figures so as to husband the sun heat. At night 60° to 65° is suitable, and 70° to 75° by day artificially.

Vines Started in January.—The Vines are only just in flower, having been retarded by the severe weather. Secure a night temperature of 65° to 70°, 5° more for Muscats, 70° to 75° by day artificially, and 80° to 85° with sun heat. Maintain a moderately dry condition of the atmosphere, ventilating a little constantly. Fertilise all shy setting varieties carefully. Early Vines in many places have not made satisfactory progress this year, especially those with the roots in cold borders which have not been covered with fermenting materials. Some Vines started tardily, and the bunches show a tendency to blindness, some of them running to tendrils and others not advancing freely. Under such circumstances a slight increase of temperature and a reduced supply of moisture for a short time may be beneficial. Bright sunny days with sharp winds may now be expected. Avoid sudden changes of temperature, and admit air in small quantities at a time.

Vines Started Early in February.—Where breaking into growth freely these will require attention in disbudding and regulating, stopping them two to four joints beyond the bunches according to the space. Stop the laterals up to the fruit at one joint, or remove them altogether except from the two lowest leaves; those above the bunches may be allowed to make two or more joints before being pinched, but no more foliage should be encouraged than can have full exposure to light. Remove all superfluous bunches, also ill-shaped bunches of the free-setting varieties as soon as those that are the most promising for the crop can be determined. Raise the temperature to 60° at night, 65° by day from fire heat, and up to 75° to 80° with sun heat.

Vines to Afford Fruit in August and September.—Start the houses intended for the purpose named. Render inside borders thoroughly moist by the application of liquid manure or water at a temperature of 80°. It will in some degree stimulate the roots and compensate for the lack of fermenting materials to outside borders which can do little good after this. The atmosphere should be kept moist by damping the rods and every available surface two or three times a day, 50° being a sufficiently high night temperature, and 65° by day with sun.

Late Varieties.—We again urge the importance—rather necessity—of starting all the thick-skinned varieties without delay, as a longer period of growth is mostly all that is needed to produce good-sized and highly finished fruit, and such as possess good keeping qualities. Syringe the rods several times a day, maintaining a moist atmosphere by damping the borders every evening. It is advantageous to cover the inside border with fresh stable manure, the straw being shaken out, the ammonia given off having an invigorating tendency. Night temperature 50° to 55°, day 55° to 60°, and 10° to 15° more with sun, and rather free ventilation from 65°.

Vines from Eyes.—Those inserted as before advised and alluded to in our last calendar, are now well rooted and advancing, and should be shifted as soon as the roots reach the sides of the pots into 6 inch size, placing them on shelves over the hot-water pipes in preference to plunging them in bottom heat. Syringe well amongst them, and pinch the laterals at the first leaf unless they are intended for planting out this season, when the laterals may be left intact.

Cut-backs.—Vines for fruiting in pots next season will now be fit for reducing, repotting in the same size, 7 or 9-inch, from which they can, when established, be transferred to 12 or 13-inch pots. If these, or the eyes named in the preceding paragraph, have been plunged in bottom heat, they may be returned to it for a time, 75° to 80° being suitable, but otherwise bottom heat is not necessary. Keep them close and moderately moist until they are established. Train the canes near the glass, as they cannot have too much light, it being important that the growth be solidified as it is made. Turfy loam rather rough with a fifteenth part of crushed bones, form a suitable compost for Vines in pots. Clean pots, and efficient drainage of clean crocks, must always be employed in Vine culture.

FIGS.—*Planted-out Trees Started Early in the Year.*—Attention must be given to disbudding and stopping, removing all the overrowed shoots, stopping those intended to form well developed spurs for the second crop at the fifth or sixth joint, the leading shoots where there is space being allowed to extend, as they invariably afford the finest fruit. Water the borders freely with liquid manure at 80°, taking care not to apply it too strong, and mulch with rich compost, which will attract the roots to the surface. Encourage also the emission of roots from the stem by placing fibrous pieces of turf and partially decayed manure in contact with it; and by extending the material outwards a quantity of feeders will be secured, which, if supplied with warm liquid manure, will greatly assist the maturity of the fruit.

STRAWBERRIES IN POTS.—La Grosse Suerée as usual is affording the best fruits, one fruit weighing more than three of Vicomtesse Hericart de Thury, but the crop is not so good, though the weight per plant is not materially different. Perhaps there is no prettier fruit for jellies than Vicomtesse Hericart de Thury, and when the fruit is well thinned it is of fair size. All plants will now be in a position for advancement by gentle forcing, or if not they should be brought under glass without further delay. Some may be advanced by placing them

in houses where there is gentle heat, and others may be placed in cool houses where they will come on gradually. In all cases it is necessary to examine the drainage, removing any moss or other matter from the surface of the soil, and wash the pots, surfacing with horse droppings rubbed through a sieve, which prevents the soil leaving the sides of the pots and encourages action at the surface. Until the trusses are showing it is well if the temperature does not exceed 50° by artificial means, and between that and the flowering and setting 55° is safe, advancing to 65° by day with free ventilation. The Strawberry also likes plenty of light until the fruits are set, but afterwards they are apt to become dried, hence they swell best in positions where the sun's rays are not so strong at midday. After the fruit is set and swelling a temperature of 60° to 65° at night, 70° to 75° by day (with an advance from sun heat to 80°, 85°, or 90°) is necessary, affording copious supplies of water and liquid manure until the fruit shows indications of ripening, when a somewhat drier and more airy atmosphere with diminished supplies of moisture at the roots will afford large well-swelled fruit of good flavour. Thinning the fruit must be attended to as soon as the setting is completed, removing the smallest and deformed fruit; and on no account must there be insufficient water at the roots during the swelling, but during flowering the soil must be kept moist, avoiding extremes either way. The chief object in Strawberry forcing is to secure an early and unbroken supply until those in the open ground come in, and this where there is a number of houses started at intervals will admit of its being done without much trouble or change of plants, whilst in others some tact will be necessary to meet the requirements.

PLANT HOUSES.

Tree Carnations.—To obtain plants for flowering next autumn and winter cuttings should be inserted at once. To insure their striking with certainty select short-jointed, sturdy growths from plants that have been in a cool, airy structure. Cuttings from plants that have been kept in a close atmosphere are almost certain to damp. Carnations root readily if the cuttings are good. They may either be inserted singly in sandy soil in small pots, or a number may be inserted together in larger pots or pans; in either case they should be covered with bell-glasses, or placed under handlights that can be rendered airtight. In making the cuttings a clean cut only is needed at the base, none of the foliage need be removed. Give a good watering after insertion, and plunge where gentle bottom heat can be given, and the temperature of the structure is not lower than 60° at night. When numerous cuttings are inserted together, pot them singly directly they are rooted, and grow them afterwards in the same temperature for a fortnight, then gradually harden them until they will bear cool treatment. In the process of hardening be careful not to check them.

Richardia athiopisa.—Where it is necessary to increase the stock of these for another year, all the small suckers may be carefully removed from the base. If possible, remove them with a portion of root attached. This cannot always be done without turning out the plants and carefully dividing them. With care, however, many can be taken with a portion of root. These, if inserted in small pots, will soon advance in a moist atmosphere and a temperature of 50° to 55°. When well rooted they can be placed into 6-inch pots and be grown perfectly cool until the end of May, when they can be planted outside. These plants will during the season attain an enormous strength and produce spathes of large size in early autumn. Plants raised by this means will flower long before old plants that are divided and planted out about the same time.

Imantophyllums.—Where these are grown for decoration in from 5 to 8-inch pots they should be repotted annually to keep them in presentable condition. If this is not done they become crowded with roots and lift themselves out of their pots. Potting should be done as the plants cease flowering, the whole of the soil being shaken from the roots, a few of the lower leaves being removed as well as the suckers. By the removal of a portion of foliage the plants can be potted lower, which adds to their appearance. If they possess too many roots to allow of this being done, a good portion of the lower ones may be removed. These plants are free rooting, and if all the roots are removed it does not appear to injure them in the least. If placed afterwards in a warm vinery they are not long before they commence rooting freely and growing vigorously. Keep plants that are being retarded in a cool house rather dry at their roots, or else the ends of the foliage will turn yellow and spoil the appearance of the plants. Injury to the tips of the leaves is a sure indication of too much water during their season of rest. These plants do well in fibry loam, one-seventh of manure, and sand. The soil should be pressed firmly into the pots.

FLOWER GARDEN.

CLEMATISES require good attention, or they soon become matted together and unsightly. Those that flower in May, June, and July, and which comprise the Florida and Patens types, to be thinned out and lightly shortened only, the bloom being produced from last season's wood. The Jackmanni and lanuginosa types are of very different habit, the bloom being principally formed on the current year's growths. Cut these freely back, or to within three or four joints of their last starting point. Honeysuckles, including the small Japanese variety, pay for thinning out and shortening back. *Jasminum nudiflorum* to be cut closely back after flowering, and the common Jessamine at once, the former flowering on ripened wood, and the latter on the newly formed growths. *Forsythia viridissima* is of the same habit as *Jasminum nudiflorum*, only later in flowering. Cut these back after flowering; also spur back *Chimonanthus fragrans* and the *Pyrus japonica*. Wis-

tarias to be treated somewhat similarly to Pears. Spur back all long lateral growths, but do not touch the short spurs. *Passifloras* flower on the young growths, and in order to get plenty of these cut all last season's wood hard back to the main branches. Ivies ought to be kept closely trimmed in, or they soon become unsightly. The stronger growers, and especially the common Ivy, may well have all the old leaves as well as loose growths trimmed, the fresh foliage following being the most ornamental.

THE BEE-KEEPER.

NOTES ON BEES.

INTRODUCING A QUEEN.

AFTER the deposition comes the still more important part, the introduction of a successor, and we must use every precaution that no harm comes to her afterwards. In order to make this intelligible it may be advisable to reproduce a few things in connection with queen introduction since the Ligurian bee was introduced. It will still be remembered by many how many failures there were in introducing Ligurian queens during the time Mr. Woodbury was at the head of bee affairs, and how, owing to that, he advised procuring stocks instead of queens alone. In a private letter from Mr. Woodbury he said, "The only sure method of introducing queens to strange bees is to deprive them of the power of raising a successor," an opinion I held from the first, as many years before I had a lesson to my loss by allowing a bee-master to kill the old queens (of the first hive I possessed) and to introduce the young queen without ceremony. Next spring my hives were queenless, and I was bee-less. According to later experiments, which I never saw fail, had he introduced the dead queen along with the living one the latter would have been safe.

Owing to the many failures to introduce alien queens to native bees cages were invented, and some precautions were taken to insure the safety of valuable queens. Pipe covers were called into requisition, and a Mauchline bee-keeper described a cage so as to cause the bees to fraternise with the queen, and so as to liberate her in a quiet manner. The description and uses of this cage which differs in no material way from the "Raynor," appeared in this Journal some time ago. Shortly after that appeared "A Stewarton Bee-keeper" gave similar instructions, but it was not until "A Renfrewshire Bee-keeper" took active steps and presented large numbers of these cages to bee-keeping friends that their utility became known. These cages were in use long before the Raynor cage was heard of. Good as these cages are, I never quite approved of them, being selfish a little of my own invention "The Safety Cage." It is used safely upon the top of the hive, the bee-keeper having at all times bees and queen under his eye, and from their appearance and conduct towards the queen know the time to liberate when she will be well received. "Felix" at page 34 speaks highly of "Alley's" queen cage on the grounds of it having a safe retreat for the queen against angry bees. Now my safety cage possesses a safe retreat against the most infuriated bees, while it is kept at a proper temperature on the top of the hive until the time of release, and if desirable she should be removed for a time, only requires to be lifted and put in the pocket or in a warm place. But while the queen has a safe retreat the cage has a large space covered with gauze, where many bees can fraternise, and if a bit of honeycomb is taken from the hive she is to be introduced to and put in the cage it will give the queen an odour more acceptable to the bees than anything else. Several of these cages were sent to the first Crystal Palace Bee and Honey Show along with the other intended exhibits, but like them shared the same fate—"exclusion."

After the cages many plans were tried to insure safe introduction. One person deprived the bees of their queen, then the moment the commotion commenced the bees were confined, the top of the hive was laid bare, and a cloth was thrown over it.

When the bees in this state had become frantic, the queen was introduced from under a corner of the cloth. After another minute's confinement the cloth was taken away and the hive covered, and when I saw the operator in 1863, he informed me that he never had a single failure. At the same date I deposed the queen, then after thirty to forty-eight hours, if I suspected she was roughly treated, I carried the hive within doors, after confining the bees, placing a bell-glass on the top where they could ascend. On finding their doorway closed against them a few minutes sufficed to pacify the bees, the hive was restored to its stand, and in the cases so treated I never had a failure. The most effectual plan, and the only one I would recommend where a valuable queen is at stake, is to remove the queen regnant, and at the end of eight days remove about midday every queen cell, then after a few hours place the queen in a safety cage, and in most cases she may be liberated shortly after sunset, the quietest time for bees during the whole twenty-four hours, but it is safer to let her remain in the cage for at least thirty hours. When alien queens are introduced into a hive containing eggs or larvæ there is a chance that royal cells may be raised and the newly introduced queen deposed, or she may be encased and so mutilated that she will be dethroned shortly after a seemingly safe introduction. I could give numerous cases of failure after every precaution had been taken, as well as numerous successes where queens had been introduced in the most reckless manner, but I will close with the following statements and queries concerning Simmins' method of direct introduction.

At page 74 "Felix" mentions four points in Simmins' plan necessary for safe introduction, but there is only one of these, No. 2, that is new—viz., "Confinement of queen alone and without food for thirty minutes previous to introduction." Will a shorter or longer time not suffice? What are the advantages gained by keeping her alone and without food? If it is for the purpose of removing any odour about the queen I fear that will not be effected, as keeping her fasting thirty minutes will not remove the odour, which is very strong and fixed. But if, on the other hand, the thirty minutes' fasting is the key to successful introduction without the discoverer knowing the occult influence therein, we must accept the discovery as it is given without asking questions or criticising in any way. For my own part I cannot boast of its success. In one case, where a queen with directions came from Mr. Simmins, the queen was at first well received, but afterwards encased. I obeyed the instructions given by Mr. Simmins to the letter, except in examining the hive an hour after the queen was introduced instead of forty-eight hours, which if I had not done, I fear if the queen was not killed she would have been mutilated, and so doomed to destruction at a time unsuitable to bees and bee-master. Notwithstanding my failure, I trust that Mr. Simmins will be able to remove my unbelief, and if so, no one will more readily accord him the praise due as a public benefactor, which, if successful in but nine cases out of ten, he will well deserve.—
A LANARKSHIRE BEE-KEEPER.

IMPROVING BEES AND PROFITABLE BEE-KEEPING.

FROM time to time articles appear in the bee journals on this subject, setting forth the desirability of improving the races of bees, but everyone advises "judicious crossing" as the only proper way. Recently the *British Bee Journal* has had some elaborate articles on the matter, all of which indicate a hapless "groping in the dark." In this article I propose to consider the whole subject, for be it remembered all the races of bees in cultivation are really and truly wild ones, and probably bear the same relation to the coming bee that the wolf does to the sheep dog. I feel constrained to write this because I consider the present modes of rearing bees are those calculated to produce the opposite effect to what is desired. All wild animals seem pre-eminently designed by Nature to maintain their own existence. There is no question but that every animal, as well as every plant now used in the service of man, originated from wild progenitors. The beginning of all these things is so remote there is no tracing them. Certain it is the first breeders had no foreign blood to cross them with, and had to rely solely on feeding, selecting, training, and cultivating, as the only means—and a most powerful means, as all know who have well studied the subject.

Let us consider these points in connection with the improvement of bees. When they are left to themselves the old queen leads off the majority of the bees in the shape of a first swarm; the hive is depopulated, thus reducing the temperature with fewer bees to feed and attend to the young queens; therefore the successor is not improved. Some will say this is the way of Nature. Yes, but I know no instance where Nature steps in to do what she has designed man to do. Then there is nothing very "natural" about the modern frame hive and the crate of sections on the top when a swarm leaves. Let us just consider how queens are now reared by the host of breeders, all of whom claim to breed from "selected" stock, reared under the "swarming impulse." But every one of these cuts the cells out, and either hatches them in a nursery or nucleus; and I defy anyone to cut a cell out without chilling it. The natural temperature of a hive is from 96° to 98°, while outside it is rarely over 80° in the shade, oftener 60° to 65°. To chill a cell is to stop its development, often retarding the queen's hatching two days, or even more. To keep her in a nursery or nucleus is to further weaken her, bees being exactly like chickens—viz., they must be well "brooded" during the first days of their wing state. The point I am here contending for can be tested by anyone in the following way. Take a frame of new-laid eggs from some yellow queen and put it in a black stock to be developed. On the fifteenth day, or eighteen days from the eggs being laid, remove it and keep it out of the hive until it is quite cold—say for two hours with a temperature of 55°, then return it for the bees to hatch out. They will all do so, but not a yellow banded bee will be found in the hive twenty-one days hence, and few at seven days. The same results will follow if eggs from a black queen are treated the same way in a yellow-banded stock. This experiment is exactly the same as is followed by thousands of bee-keepers in manipulating their stocks, and then they wonder that their bees do not succeed better. It is also similar to the way most queens are reared—viz., the cells are cut out just at the critical moment. They are chilled before they can be grafted into another stock, hence there is a weak queen, one that is worse than worthless, as she is too often used for breeding purposes by her purchaser.

What we want in the "coming bee" is greater strength and greater vitality. If we succeed in getting these we shall find we have better honey-gatherers and much stronger stocks. We want our bees to be stronger on the wing and longer lived, also extra prolific, but not simply of extra size. We also want them as easy to manage as possible. In connection with this point the fiercer they are the better, so long as they can be easily and quickly handled without fear of attack.

For years I have closely studied this question, and by rearing queens from the egg in full stocks and never attempting to cut out the queen cells, I have reared some splendid queens in my time, which would keep 14 to 16 square feet of combs solid full of brood on both sides, yet it has been questioned lately in the *B. B. J.* if it is possible for queens to fill 10 square feet of comb with eggs. These queens when in full laying order were 2 inches long, but not very thick, and could run about as quickly as spiders. Their bees also were stronger, better honey gatherers, longer lived, resisted the winter better, and came out in the spring as strong as they were in the autumn, thus giving stocks capable of storing surplus honey from the early fruit blossoms.

These advantages were gained solely by breeding the queens well, but as it took a full month to rear and have such a queen laying, and often they did not lay for two months, such queens were very expensive. I have tried and thought of many plans by which I could get a multitude of queens from one stock. My "Hallamshire law" of direct queen introduction enabled me to calculate the time of the queen's hatching to the hour, but this did not give me the necessary "brooding" so essential to success. Then I thought of catching the old queen as she led off a first swarm, and with a few of the bees making a small swarm or nucleus, and returning the rest of the bees to await their swarming in eight or nine days in the nature of a cast. By this plan I should have several well-bred queens which, with a good proportion of the bees, could be formed into nuclei, cutting up the stock hive on purpose. The stock also could be much improved by breeding, and a number of virgin queens could also be had for distribution. This is a plan I can safely recommend to anyone who wishes to improve his stock. It is infinitely better than any "cell cutting" system, though I cannot see how a person rearing queens for sale can profitably employ it at the prices queens are now sold for. Two lots of queens from one mother would be as many as he would get in the season. Then there is watching for the swarms, and the risk of losing one, which, with other difficulties, would make the system impossible to him.

Early last spring I noticed that my stock of Punie bees showed signs of swarming, I opened it to prevent their doing so, when I noticed something peculiar. After carefully thinking the matter over I at once began experiments on a stock of Cyprians, the queen of which was an imported one. Judge of my delight at finding there was very much more to learn, that I could get hundreds of queens from one stock all reared from the egg, that the queens were first kept imprisoned and fed in their cells for two days or more, and when they hatched out they were not allowed to kill one another. Nor was this all; I could obtain a batch of such queens every week from one stock even while they had a reigning queen. I carried out the experiments during the whole season, rearing all kinds of queens, and so superior were they that after they began to lay I tossed them into the air, when they flew about as quickly as drones. This is safe to do with young queens just beginning to lay, as they recognise or remember their hive, and make for it, while

every queen reared in a nucleus, or the "cell cutting" and nursery systems, could not fly at all. This system of testing the queens I consider the most valuable of any, as all the muscles of the bee are in the thorax, to which both the legs and wings are attached, and by getting the queens weighted with eggs and noting their powers of flight we can judge very well as to what her offspring will be, and when a queen rearer is breeding hundreds of queens he can select the best to keep himself for stock. It will be seen that my theory for producing the coming bee is to breed for muscle, and I give the means of judging of it in the queen instead of waiting to see it in her offspring.

In the preceding I have not touched on cross-breeding. I would first of all improve the existing races. When we begin crossing we do not always have a blending of the two races, it is often more of one than another; often the cross shows traits belonging to neither of their first parents, termed sports. These, if good, by careful selection and breeding through several generations may be fixed, in which case we procure a new breed, but to secure all these we must have our drones quite under control. Some say we cannot do this. I think we can; at least, I have been able to do so for several years. The plan was picked up through a neighbour 200 yards off keeping Italians while I kept blacks. His young queens always mated with my black drones, while none of my queens mated with his drones. I begged a piece of drone brood from him and put it in one of my hives, and when the drones began flying my young queens mated with them, though black drones were much more numerous. This led me to study the physical geography between his apiary and mine, which has led me to form a certain theory on the matter, which I must further test before making public; this I hope to do on a pretty large scale in the coming season.

It will be seen from the preceding that we are on the eve of quite a new practice. Before long there will be men devoting their whole energies to the breeding and improvement of bees. Bee-keepers will send to them every spring for virgin queens. They could be sold, carriage paid, safe delivery and introduction guaranteed, by odd ones at 2s. 6d. each, bred and selected in the way I have described, and yield a good profit to the breeder. These the following season would be producing improved drones, perhaps long before any other drones were flying in the district; a nucleus could be made, and another virgin queen bought and given to it. When she began to lay the old queen could be dethroned, and the nucleus with the young one united to the old stock hive. Young queens rarely lay drone eggs or lead off a swarm in their first season; therefore the stock will always be strong, will never, or rarely, swarm, and will always have a young queen.

With well-bred queens at the price I have named it will pay no one to rear his own, and here it will be noted I have given a new name, "Swarming System," in which a young queen always heads the stock, and few or no drones are reared. Nearly all the other systems leave an old worn-out queen after the first season, or there is an enormous amount of manipulation, which, if valued at 6d. per hour, would leave no profit after deducting expenses; also no spare hive are required, and no bees will either have to be bought or sold in the fall.—A HALLAMSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Chadborn, Coldwell, & Co., 223, Upper Thames Street, London.—*List of Lawn Mowers.*

J. J. Jensen & Co., 109, Fenchurch Street, London.—*Pamphlet and Price List of Guanos, &c.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (W. T.).—You do not say whether you require a dictionary of botanical terms or a dictionary of plant names. If the former, Henslow's "Dictionary of Botanical Terms," published by Groombridge, price 4s., will suit you; and, if the latter, Johnson's "Cottage Gardeners' Dictionary," published at this office, price 7s. 6d., by post 8s.

(E. H. P.).—Mr. B. S. Williams' "Select Ferns and Lycopods," published at Holloway, contains the information you require.

The Bulb Mite (W. J.).—The bulbs are seriously infested with the bulb mite, but there are also several other insects which seem to be similar to those often found in decaying vegetable matter. The cure is not hopeless, as you will see by Mr. Beckett's notes in another column.

Ferns and Beetles (E. H.).—We do not know a Fern which possesses the peculiarity mentioned by you, but we have sent your letter to an experienced grower, who may furnish some information on the subject.

Destroying Ants (J. W. N.).—Numerous modes of trapping and destroying ants have been described in this Journal, and you will find several letters from correspondents on this subject on page 147, February 24th, 1887.

Piping for Greenhouse (A. B. C.).—Your statement is insufficient. You do not even say whether the house is a span-roof or lean-to. Please give its height, length, and width, indicating the glass exposure; also repeat your question, and it shall be answered.

Cineraria Blooms (H. C.).—It is not necessary to publish your letter, as the remark alluded to had no reference to yourself. We are glad to recognise superior productions, and to give the growers credit for their work, but do not covet boxes filled with ordinary varieties sent with the object of advertising some wonderful "strain." A correspondent, "W. W." has sent us some trusses, but withholds his name, and we can only say they did not arrive in good condition, the flowers being much curled and withered through lack of damp packing material for keeping them fresh in transit.

Pruning Roses (Novice).—All that you can do to preserve the centre bud or main flower on the stem is to disbud. But this will not be needed to such a large extent if you prune closely the weak growths and leave the strong ones longer, say from 18 inches to 2 feet in length. These, if laid horizontally or pegged near the surface of the ground, will give you more than three times the quantity of Roses that you are now having under a moderately close system of pruning. When quality alone is the object aimed at, it can only be attained by close pruning and disbudding freely.

Asparagus plumosus (J. C. Derry).—The most certain method of propagation is the division of the crowns. This is best effected just before growth commences. Small pieces taken off with the roots attached are not long, if placed in a warm house, before they are established and growing freely. This variety flowers and sets its fruit freely when well established and grown under the influence of light and air. We have no doubt that the berries would germinate freely, although we have never raised young plants by this method. A tenuissimus, which is not infrequently seen under the name of plumosus, may be increased by striking the upright growths.

Tomatoes, Cucumbers, and Melons under Vines (E. J.).—You cannot grow either of them satisfactorily under your Vines, which would shade them too much. Tomatoes require plenty of light and air, Melons full light, and although Cucumbers are benefited by slight shade the foliage of the Vines would prove too heavy for them to give you any satisfaction. You could ripen Tomatoes in pots under the Vines providing you had the fruit set in some other position where the plants enjoyed full sunshine with plenty of air. You could grow Adiantums and other Ferns successfully under your Vines. Richardias are referred to in another column, and a very simple and successful method of culture was described on page 167 last week; another equally simple and good awaits publication.

Protests at Shows (Exhibitor).—There is a clause in most schedules, and ought to be in all, to the effect that no protest can be entertained if not made in writing to the secretary by a stipulated time, say 2 or 3 P.M. on the day of the show, and while the judges are still in attendance to examine with the officials any class in which the awards are alleged to have been made erroneously. Judges are quite ready to do this, as it is quite immaterial to them to whom the prizes are awarded, their whole object being to do justice. It is useless and worse for exhibitors to enter objections to awards months after a show, because nothing can be altered then, but meetings are disturbed, and contentions often provoked where harmony ought to prevail. Those who act as described simply afford evidence of their own neglect of duty in not having objected to the awards at the proper time.

Various (J. G.).—The top 3 or 4 inches dug from a pasture or road side where grass grows closely and well, and stacked till the grass decays results in turfy loam, the nature of the soil governing its quality. It should neither be very sandy on the one hand, nor a stiff clay on the other. It is good when a few Buttercups and plenty of Clover grow in the pasture. Half of this or a little more, the remaining portion consisting of equal parts of leaf mould, manure so far decayed and dried that it can be rubbed through a wire sieve ¼-inch mesh, and wood ashes or crushed charcoal, with a dash of sand is a suitable mixture for Fuchsias, Pelargoniums and softwooded plants generally. Spring, when fresh growth is commencing, is a good time for potting. Decayed leaves and silt from a wet ditch are not suitable for your purpose. Leaf soil is made from leaves that decay by exposure in the open air. Those you mention are too dry. Good leaf mould can be scraped from the surface of the ground in plantations and from hedge bottoms, not from wet ditches. Cauliflowers and Cabbage plants raised now in good soil and a sheltered position would, if well grown, be ready for cutting in

August. If you sow in the frame the sash must be drawn off except in very cold and inclement weather; if kept close the plants will be weak and tender. Sow thinly. If the plants are an inch asunder when they appear they will be quite close enough, and if much closer thin them promptly, dusting the others with soot occasionally if slugs attack them.

Camellia Waratah (W. II.).—As may be seen by the notification under "Names of Plants," we only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Nine hundred and ninety-nine out of every thousand Camellias grown in gardens are varieties of the nature indicated, and if we were to undertake to name them we should be inundated with blooms, and besides, many alleged varieties are known under different names, and some of the flowers too closely resemble each other to be named with accuracy, or without actual comparison with others in a large collection. As one of the two blooms you send is so distinct, and as the owner of the plant is under the impression it is the only one in this country because his father imported it forty years ago, we have no hesitation in making an exception in this case, and give the name of the variety in order to show that it has been grown in England more than forty years, and is still grown, though plants are perhaps not so numerous as formerly. The rich red Waratah, with its broad guard petals and cushioned centre, is also known as Anemoniflora. It is a variety of *C. japonica*. There are several forms with Anemone or Hollyhock shaped flowers of different colours, but the red one is the original, hence is known as the Old Waratah. We have known this variety for more than fifty years, and find it in a nurseryman's catalogue seventy years old. We have a flower before us exactly like yours, but from a plant now flowering in a garden in the midland counties, and we know of others. The striped variety is probably caryophyllioides.

Annuals for Cutting (G. T. A.).—The following are suitable for the purpose—some for bouquets and small vases, others for larger receptacles:—*Asperula azurea setosa*, blue, 1 foot; *Calliopsis* in variety, yellow and brown, 2 feet; *Candytufts*, white, carmine, and purple, 1 foot; *Catchfly (Lobel's)*, pink, 1 foot; *Centaurea Cyanus (Cornflowers)*, blue, also in lighter colours, 1½ foot; *Centranthus macrosiphon*, red, 1 foot; *Chrysanthemums*, *carinatum* and *coronarum* varieties, yellow, white, and crimson, 1½ foot; *Collinsias*, blue and white, 1 foot; *Collomia coccinea*, red, 1 foot; dwarf *Convolvulus*s, blue and various colours, 1 foot; *Erysimum*s, orange and yellow, 1½ foot; *Eschscholtzias*, orange and yellow, 1 foot; *Godetias*, crimson, rose, and white, 1½ foot; *Gypsophilas*, white and pink, producing graceful sprays, 2 feet; *Kaulfussia amelloides*, blue, 1 foot; *Love-lies-Bleeding*, drooping crimson tails, 2 feet; *Lupinus nanus*, blue and white, 1 foot, taller varieties in different colours, 2 feet; *Larkspurs*, 1½ to 3 feet; *Malope grandiflora*, crimson, 3 feet; *Mignonette*, familiar to all; *Nigellas (Love-in-a-Mist)*, white and lilac, 1½ foot; *Prince's Feather*, crimson plumes, 3 feet; *Senecios*, crimson and purple, 1 foot; *Sweet Scabious*, biennials, though flowering freely as annuals, various, 1½ foot; *Sweet Sultan*, yellow, white, and lilac, 1½ foot; *Sweet Alyssum*, 1 foot; *Sweet Peas*, various, 4-5 feet; *Venus' Looking-glass*, blue, ½ foot; *Miniature Sunflower*, yellow, 4 feet. Cut flowers of those are suitable for room adornment, and some of them, *Mignonette* and dwarf *Convolvulus*s for instance, will be found to grow and flower in water in light rooms for a considerable time. Several half-hardy annuals afford beautiful flowers for cutting, including *Stocks*, *Asters*, *Zinnias*, *Salpiglossis*, *Phlox Drummondii*, and *Helichrysums*.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*J. U.*).—Large, Althorp Crasanne; long stalk, Old Crasanne; medium, Ne Plus Meuris; small, March Bergamot.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*Old Reader*).—The tree of which you send sprays is not the *Lucombe Oak*, but the true old *Evergreen Oak (Quercus Ilex)*, of which there are many seminal forms. The *Lucombe Oak* is the result of a cross between the *Turkey* and the *Evergreen Oak*, hence is commonly known as the *Evergreen Turkey Oak*; botanically, *Quercus Lucombeana*. The Fern appears to be *Gymnogramma tartarea (L. A. W.)*.—1, *Celsia Arcturus*; 2, *Anthericum variegatum*; 3, *Begonia manicata*; 4, *Begonia Schmidtii (F. II.)*.—1, *Adiantum assimile*; 2, *Adiantum cuneatum*; 3, *Davallia canariensis*; 4, *Selaginella caesia*; 5, *S. Martensi*; 6, *Lycaste aromatica*.

COVENT GARDEN MARKET.—MARCH 7TH.

LENT CORN.

THE month of March will be a busy one this year owing to the fact that after a winter of singular mildness, frost, snow, and bitter north-east winds have prevailed during the greater part of February, so that work on the land has been at a standstill, and all we could do was to make due preparation for sowing the spring corn when the change to milder weather does come. With such an exceptionally mild open winter we did think even the laggards would have had all the land ploughed quite a month ago, but to our surprise we saw some ploughs going upon a Barley stubble only a few days ago, and they were ploughing in 2 or 3 inches of snow. No practice could possibly be worse than this, for we know that to plough in snow is to cause the land to continue wet so long as to retard work upon it subsequently. We must own, however, if it is foul land intended for a fallow it would not matter so much, yet still the ploughing ought to have been done before. The only late ploughing for Lent corn that is justifiable is the ploughing for

Barley or Oats after the sheep folds on Swedes or White Turnips. We shall do so on a light land field where we can follow the folds closely and sow as we plough, so that not a day will be lost.

Oats have become so cheap that our area of land under spring Oats will be less than it has ever been before, for while we can purchase sound wholesome imported Oats at the rate of 154 lbs. for 7s. 6d. it certainly will not answer to have much land under this crop. But we do not intend to lay down a rule in Oat growing; rather would we say wherever it is done let it be done so well that the average yield of grain is fully 80 bushels an acre. We know full well that to attain this average the practice must be good, and not one point of cultural importance must be lacking. We know that the Oat crop of many farmers falls much below this average, yet if they only would apply manure to the land for Oats just as they do for Wheat or roots they would be well repaid for the outlay. Many years ago we saw in the same field Oats 6 inches high and 6 feet high, the latter growing upon the site of a manure heap, the former at the other end of the field upon a hard headland quite innocent of manure, and we have never forgotten the lesson. Now, we do not say that a 6-foot crop of Oats is to be the common mean, but we have proved that a crop with straw from 4 to 5 feet high, crowned with heavy panicles of clustering grain, affords a yield of grain up to our average and a heavy bulk of straw of much value when chaffed for feeding horses, cattle, and sheep; pigs, too, will consume a lot of straw both of Oats and Barley if it is given to them in small quantities daily. No doubt under certain conditions it may answer to cultivate Oats both for home consumption and for sale, but then both the sort and sample must be of the best. Take for example a sample of pure home-grown White Canadian Oats, which we had recently on offer from one of our farms; this met a ready sale at 20s. per quarter, and a crop of 10 quarters an acre would not be unprofitable even at such a price.

Barley has, under the depression, so far proved fairly profitable, but even this one bright streak in the dark horizon of our troubles is likely to be obscured by low-priced foreign importations, which malsters are turning to such profitable account that Barley merchants declare the trade is ruined. Farmers who have been so imprudent as to hold over their Barley till now find they must incur a heavy loss if they sell, and such prices as 36s. or 40s. per quarter, as were made easily by full bright samples in autumn, are now not to be had. While making mention of this fact, it will never answer to suffer it to act as a hindrance to our plans for this season; rather should it prove an incentive to greater exertion in doing all we can to insure a full crop of "Ripe and golden Barley." We intend sowing several hundreds of acres, all which will have a dressing of pure home-mixed chemical manures where sheep-folding has not been thoroughly done, for we know that we cannot have a full crop out of soil that is not well stored with fertility. We also know that while taking care to make such provision of plant food it must be done in the most economical manner. Both in ordinary practice and under careful experiments it has been proved repeatedly that heavy dressings of farmyard manure, however carefully applied to the soil, are not equal to chemical manures in promoting the development of a full crop of grain; the comparative cost is also much in favour of the pure chemicals, and yet there are men even now ready to declare that muck is the sheet-anchor of farmers. "Why," said a shrewd man of business to us recently, "for a man to declare he is losing some hundreds of pounds yearly in cattle breeding, simply that he may manufacture a certain quantity of muck for his land, is just equivalent to proclaiming himself a fool." Certainly such a man has no right to grumble about hard times, for is not he the very embodiment of obstinacy? and to go on telling him he might do better, is very much like that casting of pearls before swine against which we have a scriptural injunction.

WORK ON THE HOME FARM.

A commodious snug fold, well fed ewes, and careful attention have enabled the lambs to pass through the recent spell of cold weather with

impunity; with very few exceptions they are strong and healthy, and the elder ones have already been docked and otherwise properly treated. We prefer having this done at the age of a month, for if left much later there appears to be a proportionate increase of suffering. At from three weeks to a month from the birth lambs begin eating, and we at once give them what bran they can consume, and when the weather becomes mild again the ewes will be taken to fold upon Swedes, while the lambs will be let run forward upon White Turnips for the sake of the green tops which they consume greedily, as well as much of the root. The proper use of Turnips for ewes and lambs is a very simple matter. We let the ewes have none before lambing, but plenty afterwards, with a fair allowance of corn and chaff; we thus avoid all risk of loss by abortion, or rather, we may add, of the serious loss both of ewes and lambs which so frequently happens by carelessness or ignorance about a diet of Turnips. Often during the severe weather which was so general during the greater part of the month of February did we pass flocks folded out upon Swedes, with but scanty shelter around the lambing fold, and with the lambs standing about shivering under the scathing influence of a cold nor-easter. Weakly lambs must suffer and often die from such exposure, and dear-bought experience leads to the conclusion that there must be losses among the ewes too. We have lost three ewes, but neither case was caused by mismanagement. Last year we had a serious loss of some twenty ewes in one flock simply because Turnips were used contrary to our express orders, and we had to part with the shepherd, who was a respectable, sober, steady man, but whose overweening conceit led to the disobedience and its consequences. Upon an off-hand farm the flock has very snug quarters in a commodious old barn, opening on one hand into pasture, and on the other into a high-walled yard with a large shed. When this farm came upon our hands the barn was almost bare of thatch, and altogether sadly out of repair; the money spent in its restoration to a sound building was certainly a sound investment, the barn being filled with corn in autumn, then cleared for the lambing, and subsequently it is used for early-shorn fat hoggets. We know a gentleman who has thus turned all the old barns upon his estate to account for sheitering ewe flocks during lambing, but then he has laid most of his land down to permanent pasture, and has no other use for his barns.

FARM LITERATURE.—Messrs. James Carter & Co., 237, High Holborn, send us a copy of their Essay upon Permanent Pastures, which is now embodied in a more comprehensive shilling brochure entitled "Carter's Practical Farmer." The work consists of ninety large pages, and contains a mass of information on various subjects in which many of our readers are interested, and is worthy of perusal. The illustrated Farm Seed Catalogue of Messrs. Sutton & Sons, Reading, is an useful rather than ornamental production, and includes a concise review of the agricultural position. Messrs. Little & Ballantyne also send a good catalogue of farm seeds.

OUR LETTER BOX.

Sowing Oats and Grass Seed (W).—Drill 3 bushels per acre of Black Tartarian Oats as soon as the land is dry enough, and follow with the seeds for permanent pasture, the Grass seed to be well mixed and sown first, following at once with the Clovers, and then harrowing sufficiently to well cover the seed. Have birds kept off till growth is visible, or there will be a heavy percentage of loss of the small seed. Here is a suitable mixture for your chalky soil:—Perennial Rye Grass, 10 lbs.; Cocksfoot, 7 lbs.; Crested Dog's-tail, 5 lbs.; Meadow Fescue 2 lbs.; Cat's-tail, 3 lbs.; Hard Fescue, 4 lbs.; Sheep's Fescue, 4 lbs. Golden Oat Grass, 1 lb.; Yarrow, 2 lbs.; Perennial Red Clover, 1 lb. Alsike Clover, 1 lb.; White Dutch Clover, 1 lb.

REMARKS.

26th.—Fine bright morning, cloudy afternoon.
27th.—Dull all day.
28th.—Overcast all day except for five minutes at 1 P.M.
29th.—Dull, with occasional flakes of snow in the morning; frequently bright in afternoon, but with one or two slight snow showers.
1st.—A little snow early and till 9.30 A.M., then bright and fine throughout.
2nd.—A lovely day, though cold.
3rd.—Fine, and generally bright.
Not quite so cold as the previous week, but much colder than usual, even in January Frost every night, no rain, and very little snow.—G. J. SYMONS.

FAREWELL TO SOUTH KENSINGTON.

At last after a chequered career, in which fitful periods of sunshine have alternated with longer terms of shadow, occasionally deepening to gloom, the end of an epoch has come, and the last meetings of the Fruit, Floral, and Scientific Committees of the Royal Horticultural Society have been held at South Kensington. The Gardens were opened with an imposing ceremonial on June 5th, 1861. The members of the Fruit and Floral Committees, Her Majesty's Commissioners of 1851, the Council of the Society, and other officials to the number of about 150, with the President, the late Prince Consort, and a dozen other members of the Royal Family assembled in the Council Room and from thence marched in procession through the Gardens to the entrance to the Conservatory, where the proceedings were conducted.

Dr. Lindley, the Secretary of the Society, read an address to the President, recounting the past history of the Society and its re-establishment under such brilliant auspices. A paragraph in that address is worthy of reproduction. "Horticulture is the parent of agriculture. It determines on a small scale the value of the principles on which an extended cultivation of the soil depends. It is associated with our food, our wealth, and many of our social enjoyments. Your Council believe that this Society has already contributed largely to the establishment of the sound principles on which cultivation is founded. In the course of the last half-century the Society has unremittingly used its influence and its means to enlarge the skill of the gardener and the taste of the community. It has had the good fortune to see during that long period many ornamental plants and every race of fruits and esculents undergo great improvement; and it is not too much to assert that its labours have raised English gardeners to the highest rank." There is the true horticultural ring in those words, and for a time the affairs of the Society were conducted largely in their spirit, but not for long. Expenditure was indulged in a manner that seems extraordinary, and liabilities incurred that could not be met, until the real objects of the Society were crushed by the iron hoof of financial difficulties, which have not to this day been surmounted.

Attempts have been made time after time to strengthen the Society, but almost invariably on the wrong lines. Shows have been tried and failed, and tried again with the same results. Shows large and shows small, shows at home, in London and abroad in the provinces have been provided, and though good in themselves have drained the Society almost of its life. Now and then one of them has been a success financially, but the whole system has been a lottery in which the blanks, as is usual in such cases, have far exceeded the prizes. Exhibitors have no doubt benefited, or some of them, but the Society as a corporate body has undoubtedly been weakened; and unless the elements of strength are provided it cannot perform the functions for which it was established.

It has been said that some of the shows have been successful. Without going further back, one of the most important opened on July 21st, 1875. It was an expression of horticultural rejoicing on the overthrow of what may be termed the skating rink dynasty, for it was actually proposed to form a rink in the gardens, and preparations were made to that end. But horticulturists rose in rebellion, and Lord Bury's Council was overturned; Lord Aberdare, and an excellent chief he proved, being elected President of the Society. The show in question was, so to say, a spontaneous act of the chief nurserymen and others, and was wholly of a complimentary

character, no schedule being provided nor prizes offered. It was a splendid triumph, and though not the originator of the "arrangement for effect" groups of plants for which prizes are now systematically offered, it gave an enormous impetus to that method of exhibiting, for the show itself was an aggregation of grand miscellaneous arrangements of plants displayed with consummate taste. This was followed by a great competitive exhibition in June, 1876, and this in turn by perhaps the most unique show of flowers that has ever been arranged—the show of Covent Garden produce on May 2nd, 1877, which was attended by Her Majesty and a great throng of visitors. On May 23rd of the following year the Prince and Princess of Wales attended the chief exhibition, which was, as might be expected, a brilliant gathering; but even this sunshiny era in the Society's career did not prove of lasting benefit, and the resources of the Society were exhausted by the Preston fiasco, and again at Liverpool; so that it may be said that shows on the whole, however extensive and meritorious, and notwithstanding an occasional financial success, have been exhausters of the Society's resources, leaving it weaker after the efforts that had been designed for its support.

During the period indicated the fortnightly and monthly Committee meetings were held in the Council room, which was quite large enough for the products—new, rare, or specially meritorious—that were brought for examination. This plan continued till the series of great general Exhibitions—the Fisheries, Health, and Colonial—that appropriated nearly the whole of the gardens, in fact they were demolished, except the upper portion, including the terraces and conservatory, in which fine structure the meetings and periodical shows have been since held. For such exhibitions as have been from time to time arranged in it the building was admirably adapted, but for the ordinary fortnightly meetings it was much too large; however, it was agreeable by the surrounding Palms and plants, comfortable in being suitably heated, and there are few members of the Committees and others who do not leave the scene of their labours and deliberations with some regret. There was no alternative but to sever the connection that has so long existed, the terms imposed by Her Majesty's Commissioners as the landlords of the property for the retention of the site being quite untenable, not to say exacting, considering the vast sums that have been expended on the property by the Society. Reflections on the action of the Commissioners can, however, do no good, and the past must be left to "Time's effacing fingers," and attention concentrated on the future with the object of rendering it, as far as is possible under the circumstances, prosperous for a Society that ought to be made to flourish in this wealth-possessing and garden-loving land.

Though we have stated our preferences, and the reasons for them, for relinquishing for a time a policy savouring of speculation, and adopting instead the principle of husbanding resources, and at the same time gathering strength from and to Chiswick, a different course has been determined. This, and the reasons for it, are clearly and consisely stated in the following letter from a true horticulturist, Mr. A. H. Smee.

"If the Royal Horticultural Society is to continue to exist it is in my opinion absolutely necessary that it should have a London office easy of access in some central position.

"It is also necessary that the Society should endeavour to induce horticulturists to join, in order that funds may be procured for the maintenance of the Chiswick Garden.

"I believe it will be advisable to have a few meetings in the summer in these Gardens, in order to give persons who reside near Chiswick some inducement to join the Society.

"I think it will prove good policy to have some place nearer the City than either South Kensington or Chiswick to hold fortnightly shows. Although the Drill Hall near Victoria Street may not be everything that could be wished, nevertheless it is close to the Army and Navy Stores, which large numbers of people frequent.

"I shall be much disappointed if sufficient gate money is not taken to at least pay the rent of the Hall, provided the trade support the Society by exhibiting the plants of their establishments.

"I expect to be told that gate money at South Kensington was a failure, but it must be remembered that during the Colonial and other Exhibitions the Society did not charge for entrance.

"If, as I have known, £50 be taken as gate money in Finsbury Circus for the exhibition of a few sickly plants grown in the City, surely the Council may reasonably expect to take at least £200 during the whole year at shows at Westminster."

No one can doubt that Mr. Smee and his coadjutors have been animated with an earnest desire to place the Society on a firmer basis; and anything that we can do we shall do most willingly towards "gaining funds for the maintenance of Chiswick." Though showing in the past has, with rare exceptions, been the exact reverse of remunerative, it does not follow that the new departure in taking flowers and fruits to the multitude may not have better results. The plan has to be tried, and it shall, so far as we are concerned, have a fair trial in the earnest hope that it will fulfil the expectations of its projectors. It cannot be forgotten, however, that the most profitable Exhibition the Society has had of late years was at Chiswick, where "people will not go," but *did* go to see the Apples and left a good profit behind them. Moreover, the local shows held yearly in the gardens have been much better attended than the ordinary "meeting-shows" have at South Kensington. Westminster, however, is fresh ground, and may prove fertile, though many well-wishers of the Society who favour a forward policy are of opinion a bolder move to the business heart of the City of London would have brought more support. Be that as it may, the plan to pursue is for all well-wishers of the Society to act cordially in supporting it on the lines laid down for its future working with the object of achieving a distinct success.

VEGETABLES FOR EXHIBITION.

POTATOES AND PEAS.

As an old showman in several counties, and not entirely unsuccessful, I have been asked to give selections of varieties and methods of growing them for the purpose in question. Even cultivators who never exhibit their produce should all the same endeavour to grow it in the best possible manner, and as if the different kinds had to be staged in competition at the leading shows.

No collection of vegetables, however limited in number, may be said to be complete without a dish of Potatoes. Judges always expect to find them, and are apt to form an unfavourable opinion of any collection from which they are absent. I have also observed that rounds used to be preferred to kidneys, but of late years this has been less perceptible, many of the so-called kidneys more nearly approaching the rounds both as regards the roughness of the skins and shape. Prizes nowadays are rarely offered for large collections of Potatoes, and I am glad that such is the case, as these only tend to encourage the cultivation of too many varieties. Supposing twelve varieties can be grown, I would recommend of kidneys, Snowdrop, Sutton's Seedling, Cosmopolitan, Carter's Surprise, Cole's Favourite, and Welford Park; and rounds, Reading Russet or the improved form Carter's King of the Russets, Schoolmaster, Sutton's Satisfaction, Prime Minister, Vicar of Laleham, and Village Blacksmith. If room can be spared try also some of the many novelties now being distributed. Among these may perhaps be found some superior to any named in my selection.

Potatoes generally delight in deeply worked fresh soil, any that is "manure sick" being altogether unsuited to them. The latter may be improved by bastard trenching, and sometimes a dressing of quicklime will work wonders. The ground being in a sweet condition a fairly liberal dressing of farmyard manure may safely be given, the tubers, however, not coming in contact with it. When I have to deal with stiff clayey soil such as abounds in some parts of Kent and Sussex, as well as largely in Essex, Middlesex, and Somerset, I found it almost impossible to grow handsome tubers without special pains being taken with the soil. During the winter a large quantity of old sifted potting soil, as much leaf soil as could be spared, and plenty of ashes from the heap of burnt garden refuse were all thrown together and well mixed ready for planting time. As early in April as the ground could be ventured on without causing it to bind badly it was deeply stirred and all lumps broken, this being either done with the fork or the two-tined Canterbury hoe. The rows being next lined out a good layer of the prepared fine soil was forked in where these would run, and the drill being opened with either a half-mattock or Canterbury hoe; this is still further mixed with the soil. Contrast this with the

usual surface scratchings with lumpy soil underneath, and it will soon be seen where the advantage rests. Drills 6 inches deep are suitable, and the heavier the land the greater the need to plant on or near the surface.
